There is another kind of anticathexis, however, which seems more suited to the peculiar character of hysteria. A repressed instinctual impulse can be activated (newly cathected) from two directions: from within, through reinforcement from its internal sources of excitation, and from without, through the perception of an object that it desires. The hysterical anticathexis is mainly directed outwards, against dangerous perceptions. It takes the form of a special kind of vigilance which, by means of restrictions of the ego, causes situations to be avoided that would entail such perceptions, or, if they do occur, manages to withdraw the subject's attention from them. Some French analysts, in particular Laforgue, have recently given this action of hysteria the special name of 'scotomization'. This technique of anticathexis is still more noticeable in the phobias, whose interest is concentrated on removing the subject ever further from the possibility of the occurrence of the feared perception. The fact that anticathexis has an opposite direction in hysteria and the phobias from what it has in obsessional neurosis - though the distinction is not an absolute one - seems to be significant. It suggests that there is an intimate connection between repression and external anticathexis on the one hand and between regression and internal anticathexis (i.e. alteration in the ego through reaction-formation) on the other. The task of defence against a dangerous perception is, incidentally, common to all neuroses. Various commands and prohibitions in obsessional neurosis have the same end in view.

[1926d, 4311]

Even a purely terminological innovation ought to justify its adoption; it ought to reflect some new point of view or some extension of knowledge. The revival of the concept of defence and the restriction of that of repression takes into account a fact which has long since been known but which has received added importance owing to some new discoveries. Our first observations of repression and of the formation of symptoms were made in connection with hysteria. We found that the perceptual content of exciting experiences and the ideational content of pathogenic structures of thought were forgotten and debarred from being reproduced in memory, and we therefore concluded that the keeping away from consciousness was a main characteristic of hysterical repression. Later on, when we came to study the obsessional neuroses, we found that in that illness pathogenic occurrences are not forgotten. They remain conscious but they are 'isolated' in some way that we cannot as yet grasp, so that much the same result is obtained as in hysterical amnesia. Nevertheless the difference is great enough to justify the belief that the process by which instinctual demands are set aside in obsessional neurosis cannot be the same as in hysteria. Further investigations have shown that in obsessional neurosis a regression of the instinctual impulses to an earlier libidinal stage is brought about through the opposition of the ego, and that this regression, although it does not make repression unnecessary, clearly works in the same sense as repression. We have seen, too, that in obsessional neurosis anticathexis, which is also presumably present in hysteria, plays a specially large part in protecting the ego by effecting a reactive alteration in it. Our attention has, moreover, been drawn to a process of 'isolation' (whose technique cannot as yet be elucidated) which finds direct symptomatic manifestation, and to a procedure, that may be called magical, of 'undoing' what has been done - a procedure about whose defensive purpose there can be no doubt, but which has no longer any resemblance to the process of 'repression'. These observations provide good enough grounds for re-introducing the old concept of defence, which can cover all these processes that have the same purpose - namely, the protection of the ego against instinctual demands - and for subsuming repression under it as a special case. The importance of this nomenclature is heightened if we consider the possibility that further investigations may show that there is an intimate connection between special forms of defence and particular illnesses, as, for instance, between repression and hysteria. In addition we may look forward to the possible discovery of yet another important correlation. It may well be that before its sharp cleavage into an ego and an id, and before the formation of a super-ego, the mental apparatus makes use of different methods of defence from those which it employs after it has reached these stages of organization.

[1926d, 4316]
For we consider that what is responsible for the anxiety in hysteria and other neuroses is the process of repression. We believe it is possible to give a more complete account of this than before, if we separate what happens to the idea that has to be repressed from what happens to the quota of libido attaching to it. It is the idea which is subjected to repression and which may be distorted to the point of being unrecognizable; but its quota of affect is regularly transformed into anxiety - and this is so whatever the nature of the affect may be, whether it is aggressiveness or love. It makes no essential difference, then, for what reason a quota of libido has become unemployable: whether it is on account of the infantile weakness of the ego, as in children's phobias, or on account of somatic processes in sexual life, as in anxiety neurosis, or owing to repression, as in hysteria. Thus in reality the two mechanisms that bring about neurotic anxiety coincide. [1933a, 4690]
The character of erotogenicity can be attached to some parts of the body in a particularly marked way. There are predestined erotogenic zones, as is shown by the example of sucking. The same example, however, also shows us that any other part of the skin or mucous membrane can take over the functions of an erotogenic zone, and must therefore have some aptitude in that direction. Thus the quality of the stimulus has more to do with producing the pleasurable feeling than has the nature of the part of the body concerned. A child who is indulging in sensual sucking searches about his body and chooses some part of it to suck - a part which is afterwards preferred by him from force of habit; if he happens to hit upon one of the predestined regions (such as the nipples or genitals) no doubt it retains the preference. A precisely analogous tendency to displacement is also found in the symptomatology of hysteria. In that neurosis repression affects most of all the actual genital zones and these transmit their susceptibility to stimulation to other erotogenic zones (normally neglected in adult life), which then behave exactly like genitals. But besides this, precisely as in the case of sucking, any other part of the body can acquire the same susceptibility to stimulation as is possessed by the genitals and can become an erotogenic zone. Erotogenic and hysterogenic zones show the same characteristics.¹

If this idea of a woman with a penis becomes 'fixated' in an individual when he is a child, resisting all the influences of later life and making him as a man unable to do without a penis in his sexual object, then, although in other respects he may lead a normal sexual life, he is bound to become a homosexual, and will seek his sexual object among men who, owing to some other physical and mental characteristics, remind him of women. Real women, when he comes to know them later, remain impossible as sexual objects for him, because they lack the essential sexual attraction; indeed, in connection with another impression of his childhood life, they may even become abhorrent to him. The child, having been mainly dominated by excitations in the penis, will usually have obtained pleasure by stimulating it with his hand; he will have been detected in this by his parents or nurse and terrorized by the threat of having his penis cut off. The effect of this 'threat of castration' is proportionate to the value set upon that organ and is quite extraordinarily deep and persistent. Legends and myths testify to the upheaval in the child's emotional life and to the horror which is linked with the castration complex - a complex which is subsequently remembered by consciousness with corresponding reluctance. The woman's genitalia, when seen later on, are regarded as a mutilated organ and recall this threat, and they therefore arouse horror instead of pleasure in the homosexual. This reaction cannot be altered in any way when the homosexual comes to learn from science that his childish assumption that women had a penis too was not so far wrong after all. Anatomy has recognized the clitoris within the female pudenda as being an organ that is homologous to the penis; and the physiology of the sexual processes has been able to add that this small penis which does not grow any bigger behaves in fact during childhood like a real and genuine penis - that it becomes the seat of excitations which lead to its being touched, that its excitability gives the little girl's sexual activity a masculine character and that a wave of repression in the years of puberty is needed in order for this masculine sexuality to be discarded and the woman to emerge. Since the sexual function of many women is crippled, whether by their obstinate clinging on to this excitability of the clitoris so that they remain anaesthetic in intercourse, or by such excessive repression occurring that its operation is partly replaced by hysterical compensatory formations - all this seems to show that there is some truth in the infantile sexual theory that women, like men, possess a penis.

¹[1905d, 1504]
(e) It follows from what has been said that there remains for hysteria an intimate relation to the final phase of libidinal development, which is characterized by the primacy of the genitals and the introduction of the reproductive function. In hysterical neurosis this acquisition is subjected to repression, which does not involve regression to the pregenital stage. The gap in determining the disposition owing to our ignorance of ego development is even more obvious here than with obsessional neurosis. [1913i, 2631]
In the same connection I will give the explanation of a vision that was described to me by another hysterical patient (a woman of forty) as having happened before she fell ill. One morning she opened her eyes and saw her brother in the room, though, as she knew, he was in fact in an insane asylum. Her small son was sleeping in the bed beside her. To save the child from having a fright and falling into convulsions when he saw his uncle, she pulled the sheet over his face, whereupon the apparition vanished. This vision was a modified version of a memory from the lady's childhood; and, though it was conscious, it was intimately related to all the unconscious material in her mind. Her nurse had told her that her mother (who had died very young, when my patient was only eighteen months old) had suffered from epileptic or hysterical convulsions, which went back to a fright caused by her brother (my patient's uncle) appearing to her disguised as a ghost with a sheet over his head. Thus the vision contained the same elements as the memory: the brother's appearance, the sheet, the fright and its results. But the elements had been arranged in a different context and transferred on to other figures. The obvious motive of the vision, or of the thoughts which it replaced, was her concern lest her little boy might follow in the footsteps of his uncle, whom he greatly resembled physically. [1900a, 978]

Am I now going on to assert that in every instance in which there are periodical attacks of aphony we are to diagnose the existence of a loved person who is at times away from the patient? Nothing could be further from my intention. The determination of Dora's symptoms is far too specific for it to be possible to expect a frequent recurrence of the same accidental aetiology. But, if so, what is the value of our elucidation of the aphony in the present case? Have we not merely allowed ourselves to become the victims of a jeu d'esprit? I think not. In this connection we must recall the question which has so often been raised, whether the symptoms of hysteria are of psychical or of somatic origin, or whether, if the former is granted, they are necessarily all of them psychically determined. Like so many other questions to which we find investigators returning again and again without success, this question is not adequately framed. The alternatives stated in it do not cover the real essence of the matter. As far as I can see, every hysterical symptom involves the participation of both sides. It cannot occur without the presence of a certain degree of somatic compliance offered by some normal or pathological process in or connected with one of the bodily organs. And it cannot occur more than once - and the capacity for repeating itself is one of the characteristics of a hysterical symptom - unless it has a psychical significance, a meaning. The hysterical symptom does not carry this meaning with it, but the meaning is lent to it, soldered to it, as it were; and in every instance the meaning can be a different one, according to the nature of the suppressed thoughts which are struggling for expression. However, there are a number of factors at work which tend to make less arbitrary the relations between the unconscious thoughts and the somatic processes that are at their disposal as a means of expression, and which tend to make those relations approximate to a few typical forms. For therapeutic purposes the most important determinants are those given by the fortuitous psychical material; the clearing-up of the symptoms is achieved by looking for their psychical significance. When everything that can be got rid of by psycho-analysis has been cleared away, we are in a position to form all kinds of conjectures, which probably meet the facts, as regards the somatic basis of the symptoms - a basis which is as a rule constitutional and organic. Thus in Dora's case we shall not content ourselves with a psycho-analytic interpretation of her attacks of coughing and aphony; but we shall also indicate the organic factor which was the source of the 'somatic compliance' that enabled her to express her love for a man who was periodically absent. And if the connection between the symptomatic expression and the unconscious mental content should strike us as being in this case a clever tour de force, we shall be relieved to hear that it succeeds in creating the same impression in every other case and in every other instance. [1905e, 1378]
The removal of the symptoms of hysterical patients by psycho-analysis proceeds on the supposition that those symptoms are substitutes - transcriptions as it were - for a number of emotionally cathected mental processes, wishes and desires, which, by the operation of a special psychical procedure (repression), have been prevented from obtaining discharge in psychical activity that is admissible to consciousness. These mental processes, therefore, being held back in a state of unconsciousness, strive to obtain an expression that shall be appropriate to their emotional importance - to obtain discharge; and in the case of hysteria they find such an expression (by means of the process of 'conversion') in somatic phenomena, that is, in hysterical symptoms. By systematically turning these symptoms back (with the help of a special technique ) into emotionally cathected ideas - ideas that will now have become conscious - it is possible to obtain the most accurate knowledge of the nature and origin of these formerly unconscious psychical structures.
[1905d, 1489]

The field I have in mind is indeed very different from yours. I am referring to the therapy employed for certain 'nervous diseases' - what are known as the psychoneuroses - of which hysteria and obsessional ideas may be taken as samples. The method is called 'psycho-analysis'; it was evolved by me from the 'cathartic' method of therapy first practised by Josef Breuer in Vienna.¹ To combat your surprise, I must draw an analogy between the criminal and the hysteric. In both we are concerned with a secret, with something hidden. But in order not to be paradoxical I must at once point out the difference. In the case of the criminal it is a secret which he knows and hides from you, whereas in the case of the hysteric it is a secret which he himself does not know either, which is hidden even from himself. How is this possible? Now we know, through laborious research, that all these illnesses are the result of the patient's having succeeded in repressing certain ideas and memories that are strongly cathected with affect, together with the wishes that arise from them, in such a way that they play no part in his thinking - do not enter into his consciousness - and thus remain unknown to him. But from this repressed psychical material (these 'complexes') are generated the somatic and psychical symptoms which plague the patient in just the same way as a guilty conscience does. In this one respect, therefore, the difference between the criminal and the hysteric is fundamental.
[1906c, 1892]

These day-dreams are cathected with a large amount of interest; they are carefully cherished by the subject and usually concealed with a great deal of sensitivity, as though they were among the most intimate possessions of his personality. It is easy to recognize a person who is absorbed in day-dreaming in the street, however, by his sudden, as it were absent-minded, smile, his way of talking to himself, or by the hastening of his steps which marks the climax of the imagined situation. Every hysterical attack which I have been able to investigate up to the present has proved to be an involuntary irruption of day-dreams of this kind. For our observations no longer leave any room for doubt that such phantasies may be unconscious just as well as conscious; and as soon as the latter have become unconscious they may also become pathogenic - that is, they may express themselves in symptoms and attacks. In favourable circumstances, the subject can still capture an unconscious phantasy of this sort in consciousness. After I had drawn the attention of one of my patients to her phantasies, she told me that on one occasion she had suddenly found herself in tears in the street and that, rapidly considering what it was she was actually crying about, she had got hold of a phantasy to the following effect. In her imagination she had formed a tender attachment to a pianist who was well known in the town (though she was not personally acquainted with him); she had had a child by him (she was in fact childless); and he had then deserted her and her child and left them in poverty. It was at this point in her romance that she had burst into tears.
[1908a, 1933]
In this way, unconscious phantasies are the immediate psychical precursors of a whole number of hysterical symptoms. Hysterical symptoms are nothing other than unconscious phantasies brought into view through 'conversion'; and in so far as the symptoms are somatic ones, they are often enough taken from the circle of the same sexual sensations and motor innervations as those which had originally accompanied the phantasy when it was still conscious. In this way the giving up of the habit of masturbation is in fact undone, and the purpose of the whole pathological process, which is a restoration of the original, primary sexual satisfaction, is achieved - though never completely, it is true, but always in a sort of approximation.

(2) Hysterical symptoms are substitutes, produced by 'conversion', for the associative return of these traumatic experiences.

The two last-mentioned forms of distortion give us some idea of the intensity of the resistances which the repressed material must take into account even when it breaks through in a hysterical attack.

Investigation of the childhood history of hysterical patients shows that the hysterical attack is designed to take the place of an auto-erotic satisfaction previously practised and since given up. In a great number of cases this satisfaction (masturbation by contact or by pressure of the thighs, or, again, by movements of the tongue, and so on) recurs during the attack itself, while the subject's consciousness is deflected. Moreover, the onset of an attack that is due to an increase of libido and is in the service of the primary purpose - as a consolation - exactly repeats the conditions under which, at the earlier time, the patient had intentionally sought this auto-erotic satisfaction. The anamnesis of the patient shows the following stages: (a) auto-erotic satisfaction, without ideational content; (b) the same satisfaction, connected with a phantasy which leads to the act of satisfaction; (c) renunciation of the act, with retention of the phantasy; (d) repression of the phantasy, which then comes into effect as a hysterical attack, either in an unchanged form, or in a modified one and adapted to new environmental impressions. Furthermore, (e) the phantasy may even reinstate the act of satisfaction belonging to it which had ostensibly been given up. This is a typical cycle of infantile sexual activity: repression, failure of repression, and return of the repressed.

Speaking as a whole, hysterical attacks, like hysteria in general, revive a piece of sexual activity in women which existed during their childhood and at that time revealed an essentially masculine character. It can often be observed that girls who have shown a boyish nature and inclinations up to the years before puberty are precisely those who become hysterical from puberty onwards. In a whole number of cases the hysterical neurosis merely represents an excessive accentuation of the typical wave of repression which, by doing away with her masculine sexuality, allows the woman to emerge.²
It was observed that, while the patient was in her states of 'absence' (altered personality accompanied by confusion), she was in the habit of muttering a few words to herself which seemed as though they arose from some train of thought that was occupying her mind. The doctor, after getting a report of these words, used to put her into a kind of hypnosis and then repeat them to her so as to induce her to use them as a starting point. The patient complied with the plan, and in this way reproduced in his presence the mental creations which had been occupying her mind during the 'absences' and which had betrayed their existence by the fragmentary words which she had uttered. They were profoundly melancholy phantasies - 'day dreams' we should call them - sometimes characterized by poetic beauty, and their starting-point was as a rule the position of a girl at her father's sick-bed. When she had related a number of these phantasies, she was as if set free, and she was brought back to normal mental life. The improvement in her condition, which would last for several hours, would be succeeded next day by a further attack of 'absence'; and this in turn would be removed in the same way by getting her to put into words her freshly constructed phantasies. It was impossible to escape the conclusion that the alteration in her mental state which was expressed in the 'absences' was a result of the stimulus proceeding from these highly emotional phantasies. The patient herself, who, strange to say, could at this time only speak and understand English, christened this novel kind of treatment the 'talking cure' or used to refer to it jokingly as 'chimney sweeping'.¹

[1910a, 2202]

It was now easy to reconstruct the pathogenic process. Let us keep to a simple example, in which a particular impulsion had arisen in the subject's mind but was opposed by other powerful impulsions. We should have expected the mental conflict which now arose to take the following course. The two dynamic quantities - for our present purposes let us call them 'the instinct' and 'the resistance' - would struggle with each other for some time in the fullest light of consciousness, until the instinct was repudiated and the cathexis of energy withdrawn from its impulsion. This would have been the normal solution. In a neurosis, however (for reasons which were still unknown), the conflict found a different outcome. The ego drew back, as it were, on its first collision with the objectionable instinctual impulse; it debarrèd the impulse from access to consciousness and to direct motor discharge, but at the same time the impulse retained its full cathexis of energy. I named this process repression; it was a novelty, and nothing like it had ever before been recognized in mental life. It was obviously a primary mechanism of defence, comparable to an attempt at flight, and was only a forerunner of the later-developed normal condemning judgement. The first act of repression involved further consequences. In the first place the ego was obliged to protect itself against the constant threat of a renewed advance on the part of the repressed impulse by making a permanent expenditure of energy, an anticathexis, and it thus impoverished itself. On the other hand, the repressed impulse, which was now unconscious, was able to find means of discharge and of substitutive satisfaction by circuitous routes and thus to bring the whole purpose of the repression to nothing. In the case of conversion hysteria the circuitous route led to the somatic innervation; the repressed impulse broke its way through at some point or other and produced symptoms. The symptoms were thus results of a compromise, for although they were substitutive satisfactions they were nevertheless distorted and deflected from their aim owing to the resistance of the ego.

[1925d, 4206]
In this secondary defensive struggle the ego presents two faces with contradictory expressions. The one line of behaviour it adopts springs from the fact that its very nature obliges it to make what must be regarded as an attempt at restoration or reconciliation. The ego is an organization. It is based on the maintenance of free intercourse and of the possibility of reciprocal influence between all its parts. Its desexualized energy still shows traces of its origin in its impulsion to bind together and unify, and this necessity to synthesize grows stronger in proportion as the strength of the ego increases. It is therefore only natural that the ego should try to prevent symptoms from remaining isolated and alien by using every possible method to bind them to itself in one way or another, and to incorporate them into its organization by means of those bonds. As we know, a tendency of this kind is already operative in the very act of forming a symptom. A classical instance of this are those hysterical symptoms which have been shown to be a compromise between the need for satisfaction and the need for punishment. Such symptoms participate in the ego from the very beginning, since they fulfil a requirement of the super-ego, while on the other hand they represent positions occupied by the repressed and points at which an irruption has been made by it into the ego-organization. They are a kind of frontier-station with a mixed garrison. (Whether all primary hysterical symptoms are constructed on these lines would be worth enquiring into very carefully.) The ego now proceeds to behave as though it recognized that the symptom had come to stay and that the only thing to do was to accept the situation in good part and draw as much advantage from it as possible. It makes an adaptation to the symptom - to this piece of the internal world which is alien to it - just as it normally does to the real external world. It can always find plenty of opportunities for doing so. The presence of a symptom may entail a certain impairment of capacity, and this can be exploited to appease some demand on the part of the super-ego or to refuse some claim from the external world. In this way the symptom gradually comes to be the representative of important interests; it is found to be useful in asserting the position of the self and becomes more and more closely merged with the ego and more and more indispensable to it. It is only very rarely that the physical process of 'healing' round a foreign body follows such a course as this. There is a danger, too, of exaggerating the importance of a secondary adaptation of this kind to a symptom, and of saying that the ego has created the symptom merely in order to enjoy its advantages. It would be equally true to say that a man who had lost his leg in the war had got it shot away so that he might thenceforward live on his pension without having to do any more work.

[1926d, 4259]
(e) It follows from what has been said that there remains for hysteria an intimate relation to the final phase of libidinal development, which is characterized by the primacy of the genitals and the introduction of the reproductive function. In hysterical neurosis this acquisition is subjected to repression, which does not involve regression to the pregenital stage. The gap in determining the disposition owing to our ignorance of ego development is even more obvious here than with obsessional neurosis. [1913i, 2631]

On the other hand, it is not hard to show that another regression to an earlier level occurs in hysteria too. The sexuality of female children, is, as we know, dominated and directed by a masculine organ (the clitoris) and often behaves like the sexuality of boys. This masculine sexuality has to be got rid of by a last wave of development at puberty, and the vagina, an organ derived from the cloaca, has to be raised into the dominant erotogenic zone. Now, it is very common in hysterical neurosis for this repressed masculine sexuality to be re-activated and then for the defensive struggle on the part of the ego-syntonic instincts to be directed against it. But it seems to me too early to enter here into a discussion of the problems of the disposition to hysteria. [1913i, 2631]

We are obliged to take quite another view of the process of repression when we consider the picture of a true conversion hysteria. Here the salient point is that it is possible to bring about a total disappearance of the quota of affect. When this is so, the patient displays towards his symptoms what Charcot called 'la belle indifférence hystériques'. In other cases this suppression is not so completely successful: some distressing sensations may attach to the symptoms themselves, or it may prove impossible to prevent some release of anxiety, which in turn sets to work the mechanism of forming a phobia. The ideational content of the instuctive representative is completely withdrawn from consciousness; as a substitute - and at the same time as a symptom - we have an over-strong innervation (in typical cases, a somatic one), sometimes of a sensory, sometimes of a motor character, either as an excitation or an inhibition. The over-innervated area proves on a closer view to be a part of the repressed instuctive representative itself - a part which, as though by a process of condensation, has drawn the whole cathexis on to itself. These remarks do not of course bring to light the whole mechanism of a conversion hysteria; in especial the factor of regression, which will be considered in another connection, has also to be taken into account. In so far as repression in hysteria is made possible only by the extensive formation of substitutes, it may be judged to be entirely unsuccessful; as regards dealing with the quota of affect, however, which is the true task of repression, it generally signifies a total success. In conversion hysteria the process of repression is completed with the formation of the symptom and does not, as in anxiety hysteria, need to continue to a second phase - or rather, strictly speaking, to continue endlessly. [1915d, 2986]
Discussions like this, Gentlemen, are bound to become somewhat arid. So let us turn to clinical material in order to find applications of it that will be a little more impressive. Hysteria and obsessional neurosis are, as you know, the two chief representatives of the group of transference neuroses. Now it is true that in hysteria there is a regression of the libido to the primary incestuous sexual objects and that this occurs quite regularly; but there is as good as no regression to an earlier stage of the sexual organization. To offset this, the chief part in the mechanism of hysteria is played by repression. If I might venture to complete what we already know for certain about this neurosis by making a construction, I might explain the position thus. The unification of the component instincts under the primacy of the genitals has been accomplished; but its results come up against the resistance of the preconscious system which is linked with consciousness. Thus the genital organization holds good for the unconscious, but not in the same way for the preconscious; and this rejection on the part of the preconscious brings about a picture which has certain resemblances to the state of things before genital primacy. But it is nevertheless something quite different.

[1916-1917, 3406]

Of the two kinds of regression of the libido, that to an earlier phase of the sexual organization is by far the more striking. Since this is absent in hysteria, and since our whole view of the neuroses is still far too much under the influence of the study of hysteria, which was chronologically the first, the significance of libidinal regression also became clear to us far later than that of repression. We must be prepared to find that our views will be subjected to still further extensions and revaluations when we are able to take into consideration not only hysteria and obsessional neurosis but also the other, narcissistic neuroses.

[1916-1917, 3406]
In other cases the connection is not so simple. It consists only in what might be called a 'symbolic' relation between the precipitating cause and the pathological phenomenon - a relation such as healthy people form in dreams. For instance, a neuralgia may follow upon mental pain or vomiting upon a feeling of moral disgust. We have studied patients who used to make the most copious use of this sort of symbolization. In still other cases it is not possible to understand at first sight how they can be determined in the manner we have suggested. It is precisely the typical hysterical symptoms which fall into this class, such as hemi-anaesthesia, contraction of the field of vision, epileptiform convulsions, and so on. An explanation of our views on this group must be reserved for a fuller discussion of the subject.

[1895d, 8]

These two psychical characteristics, which I regard as generally present in hysterical paroxysms, opened the way to a number of important considerations. I will, however, put off discussing them till I have given some attention to the mechanism of the somatic symptoms.

[1895d, 82]

(5) Where it is a question of hysterias which run a chronic course, accompanied by a moderate but constant production of hysterical symptoms, we find the strongest reason for regretting our lack of a therapy which is effective causally, but we also have most ground for the appreciation of the value of the cathartic procedure as a symptomatic therapy. In such cases we have to do with the mischief produced by an aetiology that persists chronically. Everything depends on reinforcing the patient's nervous system in its capacity to resist; and we must reflect that the existence of a hysterical symptom means a weakening of the resistance of that nervous system and represents a factor predisposing to hysteria. As can be seen from the mechanism of monosymptomatic hysteria, a new hysterical symptom is most easily formed in connection with, and on the analogy of, one that is already present. The point at which a symptom has already broken through once (see p. 181) forms a weak spot at which it will break through again the next time. A psychical group that has once been split off plays the part of a 'provoking' crystal from which a crystallization which would otherwise not have occurred will start with the greatest facility. To get rid of the symptoms which are already present, to undo the psychical changes which underlie them, is to give back to patients the whole amount of their capacity for resistance, so that they can successfully withstand the effects of the noxious agency. A very great deal can be done for such patients by means of prolonged supervision and occasional 'chimney-sweeping' (p. 29).

[1895d, 234]
We have already learnt that it quite regularly happens that a single symptom corresponds to several meanings simultaneously. We may now add that it can express several meanings in succession. In the course of years a symptom can change its meaning or its chief meaning, or the leading role can pass from one meaning to another. It is as though there were a conservative trait in the character of neuroses which ensures that a symptom that has once been formed shall if possible be retained, even though the unconscious thought to which it gave expression has lost its meaning. Moreover, there is no difficulty in explaining this tendency towards the retention of a symptom upon a mechanical basis. The production of a symptom of this kind is so difficult, the translation of a purely psychical excitation into physical terms - the process which I have called 'conversion' - depends on the concurrence of so many favourable conditions, the somatic compliance necessary for conversion is so seldom forthcoming, that an impulsion towards the discharge of an unconscious excitation will so far as possible make use of any channel for discharge which may already be in existence. It appears to be far more difficult to create a fresh conversion than to form paths of association between a new thought which is in need of discharge and the old one which is no longer in need of it. The current flows along these paths from the new source of excitation to the old point of discharge - pouring into the symptom, in the words of the Gospel, like new wine into an old bottle. These remarks would make it seem that the somatic side of a hysterical symptom is the more stable of the two and the harder to replace, while the psychical side is a variable element for which a substitute can more easily be found. Yet we should not try to infer anything from this comparison as regards the relative importance of the two elements. From the point of view of mental therapeutics the mental side must always be the more significant.

The removal of the symptoms of hysterical patients by psycho-analysis proceeds on the supposition that those symptoms are substitutes - transcriptions as it were - for a number of emotionally cathcted mental processes, wishes and desires, which, by the operation of a special psychical procedure (repression), have been prevented from obtaining discharge in psychical activity that is admissible to consciousness. These mental processes, therefore, being held back in a state of unconsciousness, strive to obtain an expression that shall be appropriate to their emotional importance - to obtain discharge; and in the case of hysteria they find such an expression (by means of the process of 'conversion') in somatic phenomena, that is, in hysterical symptoms. By systematically turning these symptoms back (with the help of a special technique) into emotionally cathcted ideas - ideas that will now have become conscious - it is possible to obtain the most accurate knowledge of the nature and origin of these formerly unconscious psychical structures.

Gentlemen, - Some eight years have passed since I had the opportunity, on the invitation of your much respected chairman, Professor von Reder, of speaking here on the subject of hysteria. Shortly before that occasion I had published, in 1895, in collaboration with Dr. Josef Breuer, the Studies on Hysteria in which, on the basis of the new knowledge which we owe to his researches, an attempt was made to introduce a new method of treating the neuroses. I am glad to be able to say that the efforts we made in our Studies have met with success; the ideas expressed in them concerning the effects produced by psychical traumas owing to retention of affect, as well as the conception of hysterical symptoms as the results of an excitation transposed from the sphere of the mental to the physical - ideas for which we coined the terms 'abreaction' and 'conversion' - are to-day generally known and understood. There is, at least in German speaking countries, no presentation of hysteria to-day that does not take them to some extent into account, and we have no colleagues who do not, for a short distance at least, follow the road pointed out by us. And yet, while they were still new, these theorems and this terminology must have sounded not a little strange.
I think it is worth emphasizing the fact that, whatever modifications my views on the aetiology of the psychoneuroses have passed through, there are two positions which I have never repudiated or abandoned - the importance of sexuality and of infantilism. Apart from this, accidental influences have been replaced by constitutional factors and 'defence' in the purely psychological sense has been replaced by organic 'sexual repression'. The question may, however, be raised of where convincing evidence is to be found in favour of the alleged aetiological importance of sexual factors in the psychoneuroses, in view of the fact that the onset of these illnesses may be observed in response to the most commonplace emotions or even to somatic precipitating causes, and since I have had to abandon a specific aetiology depending on the particular form of the childhood experiences concerned. To such a question I would reply that the psycho-analytic examination of neurotics is the source from which this disputed conviction of mine is derived. If we make use of that irreplaceable method of research, we discover that the patient's symptoms constitute his sexual activity (whether wholly or in part), which arises from the sources of the normal or perverse component instincts of sexuality. Not only is a large part of the symptomatology of hysteria derived directly from expressions of sexual excitement, not only do a number of erotogenic zones attain the significance of genitals during neuroses owing to an intensification of infantile characteristics, but the most complicated symptoms are themselves revealed as representing, by means of 'conversion', phantasies which have a sexual situation as their subject-matter. Anyone who knows how to interpret the language of hysteria will recognize that the neurosis is concerned only with the patient's repressed sexuality. The sexual function must, however, be understood in its true extent, as it is laid down by disposition in infancy. Wherever some commonplace emotion must be included among the determinants of the onset of the illness, analysis invariably shows that it is the sexual component of the traumatic experience - a component that is never lacking which has produced the pathogenic result.

[1906a, 1582]

In this way, unconscious phantasies are the immediate psychical precursors of a whole number of hysterical symptoms. Hysterical symptoms are nothing other than unconscious phantasies brought into view through 'conversion'; and in so far as the symptoms are somatic ones, they are often enough taken from the circle of the same sexual sensations and motor innervations as those which had originally accompanied the phantasy when it was still conscious. In this way the giving up of the habit of masturbation is in fact undone, and the purpose of the whole pathological process, which is a restoration of the original, primary sexual satisfaction, is achieved - though never completely, it is true, but always in a sort of approximation.

[1908a, 1935]

(2) Hysterical symptoms are substitutes, produced by 'conversion', for the associative return of these traumatic experiences.

[1908a, 1936]
In the classificatory system of the neuroses no definite position has hitherto been assigned to 'phobias'. It seems certain that they should only be regarded as syndromes which may form part of various neuroses and that we need not rank them as an independent pathological process. For phobias of the kind to which little Hans's belongs, and which are in fact the most common, the name of 'anxiety-hysteria' seems to me not inappropriate; I suggested the term to Dr. W. Stekel when he was undertaking a description of neurotic anxiety states,¹ and I hope it will come into general use. It finds its justification in the similarity between the psychological structure of these phobias and that of hysteria - a similarity which is complete except upon a single point. That point, however, is a decisive one and well adapted for purposes of differentiation. For in anxiety-hysteria the libido which has been liberated from the pathogenic material by repression is not converted (that is, diverted from the mental sphere into a somatic innervation), but is set free In the clinical cases that we meet with, this 'anxiety-hysteria' may be combined with 'conversion-hysteria' in any proportion. There exist cases of pure conversion-hysteria without any trace of anxiety, just as there are cases of simple anxiety-hysteria, which exhibit feelings of anxiety and phobias, but have no admixture of conversion. The case of little Hans is one of the latter sort. [1909b, 2099]

Such is my excuse for having curtailed so drastically the history of this case and its treatment. And I can offer still more cogent reasons for having confined myself to the statement only of some disconnected results of the psycho-analytic investigation of obsessional neuroses. I must confess that I have not yet succeeded in completely penetrating the complicated texture of a severe case of obsessional neurosis, and that, if I were to reproduce the analysis, it would be impossible for me to make the structure, such as by the help of analysis we know or suspect it to be, visible to others through the mass of therapeutic work superimposed upon it. What add so greatly to the difficulty of doing this are the resistances of the patients and the forms in which they are expressed. But even apart from this it must be admitted that an obsessional neurosis is in itself not an easy thing to understand - much less so than a case of hysteria. Actually, indeed, we should have expected to find the contrary. The language of an obsessional neurosis - the means by which it expresses its secret thoughts - is, as it were, only a dialect of the language of hysteria; but it is a dialect in which we ought to be able to find our way about more easily, since it is more nearly related to the forms of expression adopted by our conscious thought than is the language of hysteria. Above all, it does not involve the leap from a mental process to a somatic innervation - hysterical conversion - which can never be fully comprehensible to us. [1909d, 2128]
In the first place, it must be emphasized that Breuer's patient, in almost all her pathogenic situations, was obliged to suppress a powerful emotion instead of allowing its discharge in the appropriate signs of emotion, words or actions. In the episode of her lady-companion's dog, she suppressed any manifestation of her very intense disgust, out of consideration for the woman's feelings; while she watched at her father's bedside she was constantly on the alert to prevent the sick man from observing her anxiety and her painful depression. When subsequently she reproduced these scenes in her doctor's presence the affect which had been inhibited at the time emerged with peculiar violence, as though it had been saved up for a long time. Indeed, the symptom which was left over from one of these scenes would reach its highest pitch of intensity at the time when its determining cause was being approached, only to vanish when that cause had been fully ventilated. On the other hand, it was found that no result was produced by the recollection of a scene in the doctor's presence if for some reason the recollection took place without any generation of affect. Thus it was what happened to these affects, which might be regarded as displaceable magnitudes, that was the decisive factor both for the onset of illness and for recovery. One was driven to assume that the illness occurred because the affects generated in the pathogenic situations had their normal outlet blocked, and that the essence of the illness lay in the fact that these 'strangulated' affects were then put to an abnormal use. In part they remained as a permanent burden upon the patient's mental life and a source of constant excitation for it; and in part they underwent a transformation into unusual somatic innervations and inhibitions, which manifested themselves as the physical symptoms of the case. For this latter process we coined the term 'hysterical conversion'. Quite apart from this, a certain portion of our mental excitation is normally directed along the paths of somatic innervation and produces what we know as an 'expression of the emotions'. Hysterical conversion exaggerates this portion of the discharge of an emotionally cathexed mental process; it represents a far more intense expression of the emotions, which has entered upon a new path. When the bed of a stream is divided into two channels, then, if the current in one of them is brought up against an obstacle, the other will at once be overfilled. As you see, we are on the point of arriving at a purely psychological theory of hysteria, with affective processes in the front rank.

[1910a, 2207]
(1) Our first reflection will tell us that it cannot be the case that this detachment of the libido occurs exclusively in paranoia; nor can it be that, where it occurs elsewhere, it has such disastrous consequences. It is quite possible that a detachment of the libido is the essential and regular mechanism of every repression. We can have no positive knowledge on that point until the other disorders that are based upon repression have been similarly examined. But it is certain that in normal mental life (and not only in periods of mourning) we are constantly detaching our libido in this way from people or from other objects without falling ill. When Faust freed himself from the world by uttering his curses, the result was not a paranoia or any other neurosis but simply a certain general frame of mind. The detachment of the libido, therefore, cannot in itself be the pathogenic factor in paranoia; there must be some special characteristic which distinguishes a paranoic detachment of the libido from other kinds. It is not difficult to suggest what that characteristic may be. What use is made of the libido after it has been set free by the process of detachment? A normal person will at once begin looking for a substitute for the lost attachment; and until that substitute has been found the liberated libido will be kept in suspension within his mind, and will there give rise to tensions and colour his mood. In hysteria the liberated libido becomes transformed into somatic innervations or into anxiety. But in paranoia the clinical evidence goes to show that the libido, after it has been withdrawn from the object, is put to a special use. It will be remembered that the majority of cases of paranoia exhibit traces of megalomania, and that megalomania can by itself constitute a paranoia. From this it may be concluded that in paranoia the liberated libido becomes attached to the ego, and is used for the aggrandizement of the ego. A return is thus made to the stage of narcissism (known to us from the development of the libido), in which a person’s only sexual object is his own ego. On the basis of this clinical evidence we can suppose that paranoics have brought along with them a fixation at the stage of narcissism, and we can assert that the length of the step back from sublimated homosexuality to narcissism is a measure of the amount of regression characteristic of paranoia.

It was conclusively proved that hysterical symptoms are residues (reminiscences) of profoundly moving experiences, which have been withdrawn from everyday consciousness, and that their form is determined (in a manner that excludes deliberate action) by details of the traumatic effects of the experiences. On this view, the therapeutic prospects lie in the possibility of getting rid of this ‘repression’, so as to allow part of the unconscious psychical material to become conscious and thus to deprive it of its pathogenic power. This view is a dynamic one, in so far as it regards psychical processes as displacements of psychical energy which can be gauged by the amount of their effect on the affective elements. This is most significant in hysteria, where the process of ‘conversion’ creates the symptoms by transforming a quantity of mental impulses into somatic innervations.

Breuer’s discoveries have so often been described that I can dispense with discussing them in detail here. These were the fundamental fact that the symptoms of hysterical patients are founded upon scenes in their past lives which have made a great impression on them but have been forgotten (traumas); the therapy founded upon this, which consisted in causing them to remember and reproduce these experiences in a state of hypnosis (catharsis); and the fragment of theory inferred from it, which was that these symptoms represented an abnormal employment of amounts of excitation which had not been disposed of (conversion). Whenever Breuer, in his theoretical contribution to the Studies on Hysteria (1895), referred to this process of conversion, he always added my name in brackets after it, as though the priority for this first attempt at theoretical evaluation belonged to me. I believe that actually this distinction relates only to the name, and that the conception came to us simultaneously and together.
I shall try here to penetrate a little further into the mechanism of paraphrenia and shall bring together those views which already seem to me to deserve consideration. The difference between paraphrenic affections and the transference neuroses appears to me to lie in the circumstance that, in the former, the libido that is liberated by frustration does not remain attached to objects in phantasy, but withdraws on to the ego. Megalomania would accordingly correspond to the psychical mastering of this latter amount of libido, and would thus be the counterpart of the introversion on to phantasies that is found in the transference neuroses; a failure of this psychical function gives rise to the hypochondria of paraphrenia and this is homologous to the anxiety of the transference neuroses. We know that this anxiety can be resolved by further psychical working over, i.e. by conversion, reaction-formation or the construction of protections (phobias). The corresponding process in paraphrenics is an attempt at restoration, to which the striking manifestations of the disease are due. Since paraphrenia frequently, if not usually, brings about only a partial detachment of the libido from objects, we can distinguish three groups of phenomena in the clinical picture: (1) those representing what remains of a normal state or of neurosis (residual phenomena); (2) those representing the morbid process (detachment of libido from its objects and, further, megalomania, hypochondria, affective disturbance and every kind of regression); (3) those representing restoration, in which the libido is once more attached to objects, after the manner of a hysteria (in dementia praecox or paraphrenia proper), or of an obsessional neurosis (in paranoia). This fresh libidinal cathexis differs from the primary one in that it starts from another level and under other conditions. The difference between the transference neuroses brought about in the case of this fresh kind of libidinal cathexis and the corresponding formations where the ego is normal should be able to afford us the deepest insight into the structure of our mental apparatus.

[1914c, 2941]

We are obliged to take quite another view of the process of repression when we consider the picture of a true conversion hysteria. Here the salient point is that it is possible to bring about a total disappearance of the quota of affect. When this is so, the patient displays towards his symptoms what Charcot called 'la belle indifférence hystériques'. In other cases this suppression is not so completely successful: some distressing sensations may attach to the symptoms themselves, or it may prove impossible to prevent some release of anxiety, which in turn sets to work the mechanism of forming a phobia. The ideational content of the instinctual representative is completely withdrawn from consciousness; as a substitute - and at the same time as a symptom - we have an over-strong innervation (in typical cases, a somatic one), sometimes of a sensory, sometimes of a motor character, either as an excitation or an inhibition. The over-innervated area proves on a closer view to be a part of the repressed instinctual representative - a part which, as though by a process of condensation, has drawn the whole cathexis on to itself. These remarks do not of course bring to light the whole mechanism of a conversion hysteria; in especial the factor of regression, which will be considered in another connection, has also to be taken into account. In so far as repression in hysteria is made possible only by the extensive formation of substitutes, it may be judged to be entirely unsuccessful; as regards dealing with the quota of affect, however, which is the true task of repression, it generally signifies a total success. In conversion hysteria the process of repression is completed with the formation of the symptom and does not, as in anxiety hysteria, need to continue to a second phase - or rather, strictly speaking, to continue endlessly.

[1915d, 2986]
A great deal of what we have found in anxiety hysteria also holds good for the other two neuroses, so that we can confine our discussion to their points of difference and to the part played by anticathexis. In conversion hysteria the instinctual cathexis of the repressed idea is changed into the innervation of the symptom. How far and in what circumstances the unconscious idea is drained empty by this discharge into innervation, so that it can relinquish its pressure upon the system Cs. - these and similar questions had better be reserved for a special investigation of hysteria. In conversion hysteria the part played by the anticathexis proceeding from the system Cs. (Pcs.) is clear and becomes manifest in the formation of the symptom. It is the anticathexis that decides upon what portion of the instinctual representative the whole cathexis of the latter is able to be concentrated. The portion thus selected to be a symptom fulfils the condition of expressing the wishful aim of the instinctual impulse no less than the defensive or punitive efforts of the system Cs.; thus it becomes hypercathected, and it is maintained from both directions like the substitutive idea in anxiety hysteria. From this circumstance we may conclude without hesitation that the amount of energy expended by the system Cs. on repression need not be so great as the cathectic energy of the symptom; for the strength of the repression is measured by the amount of anticathexis expended, whereas the symptom is supported not only by this anticathexis but also by the instinctual cathexis from the system Ucs. which is condensed in the symptom.

After the present writer had, during the early nineties, confirmed Breuer's results in a considerable number of patients, the two, Breuer and Freud, together decided on a publication, Studies on Hysteria (1895d), which contained their findings and an attempt at a theory based on them. This asserted that hysterical symptoms arose when the affect of a mental process cathected with a strong affect was forcibly prevented from being worked over consciously in the normal way and was thus diverted into a wrong path. In cases of hysteria, according to this theory, the affect passed over into an unusual somatic innervation ('conversion'), but could be given another direction and got rid of ('abreacted'), if the experience were revived under hypnosis. The authors gave this procedure the name of 'catharsis' (purging, setting free of a strangulated affect).
It was now easy to reconstruct the pathogenic process. Let us keep to a simple example, in which a particular impulsion had arisen in the subject's mind but was opposed by other powerful impulsions. We should have expected the mental conflict which now arose to take the following course. The two dynamic quantities - for our present purposes let us call them 'the instinct' and 'the resistance' - would struggle with each other for some time in the fullest light of consciousness, until the instinct was repudiated and the cathexis of energy withdrawn from its impulsion. This would have been the normal solution. In a neurosis, however (for reasons which were still unknown), the conflict found a different outcome. The ego drew back, as it were, on its first collision with the objectionable instinctual impulse; it debared the impulse from access to consciousness and to direct motor discharge, but at the same time the impulse retained its full cathexis of energy. I named this process repression; it was a novelty, and nothing like it had ever before been recognized in mental life. It was obviously a primary mechanism of defence, comparable to an attempt at flight, and was only a forerunner of the later-developed normal condemning judgement. The first act of repression involved further consequences. In the first place the ego was obliged to protect itself against the constant threat of a renewed advance on the part of the repressed impulse by making a permanent expenditure of energy, an anticathexis, and it thus impoverished itself. On the other hand, the repressed impulse, which was now unconscious, was able to find means of discharge and of substitutive satisfaction by circuitous routes and thus to bring the whole purpose of the repression to nothing. In the case of conversion hysteria the circuitous route led to the somatic innervation; the repressed impulse broke its way through at some point or other and produced symptoms. The symptoms were thus results of a compromise, for although they were substitutive satisfactions they were nevertheless distorted and deflected from their aim owing to the resistance of the ego.

[1925d, 4206]

The commonest symptoms of conversion hysteria - motor paralyses, contractures, involuntary actions or discharges, pains and hallucinations - are cathetic processes which are either permanently maintained or intermittent. But this puts fresh difficulties in the way. Not much is actually known about these symptoms. Analysis can show what the disturbed excitatory process is which the symptoms replace. It usually turns out that they themselves have a share in that process. It is as though the whole energy of the process had been concentrated in this one part of it. For instance, it will be found that the pains from which a patient suffers were present in the situation in which the repression occurred; or that his hallucination was, at that time, a perception; or that his motor paralysis is a defence against an action which should have been performed in that situation but was inhibited; or that his contracture is usually a displacement of an intended innervation of the muscles in some other part of his body; or that his convulsions are the expression of an outburst of affect which has been withdrawn from the normal control of the ego. The sensation of unpleasure which accompanies the appearance of the symptoms varies in a striking degree. In chronic symptoms which have been displaced on to motility, like paralyses and contractures, it is almost always entirely absent; the ego behaves towards the symptoms as though it had nothing to do with them. In intermittent symptoms and in those concerned with the sensory sphere, sensations of unpleasure are as a rule distinctly felt; and in symptoms of pain these may reach an extreme degree. The picture presented is so manifold that it is difficult to discover the factor which permits of all these variations and yet allows a uniform explanation of them. There is, moreover, little to be seen in conversion hysteria of the ego's struggle against the symptom after it has been formed. It is only when sensitivity to pain in some part of the body constitutes the symptom that that symptom is in a position to play a dual role. The symptom of pain will appear no less regularly whenever the part of the body concerned is touched from outside than when the pathogenic situation which it represents is associatively activated from within; and the ego will take precautions to prevent the symptom from being aroused through external perceptions. Why the formation of symptoms in conversion hysteria should be such a peculiarly obscure thing I cannot tell; but the fact affords us a good reason for quitting such an unproductive field of enquiry without delay.

[1926d, 4270]
The reaction-formations in the ego of the obsessional neurotic, which we recognize as exaggerations of normal character-formation, should be regarded, I think, as yet another mechanism of defence and placed alongside of regression and repression. They seem to be absent or very much weaker in hysteria. Looking back, we can now get an idea of what is peculiar to the defensive process in hysteria. It seems that in it the process is limited to repression alone. The ego turns away from the disagreeable instinctual impulse, leaves it to pursue its course in the unconscious, and takes no further part in its fortunes. This view cannot be absolutely correct, for we are acquainted with the case in which a hysterical symptom is at the same time a fulfilment of a penalty imposed by the super-ego; but it may describe a general characteristic of the behaviour of the ego in hysteria.

This was at a date before the investigations of Charcot and Pierre Janet into the origin of hysterical symptoms, and Breuer's discovery was thus entirely uninfluenced by them. But he did not pursue the matter any further at the time, and it was not until some ten years later that he took it up again in collaboration with Sigmund Freud. In 1895 they published a book, *Studies on Hysteria*, in which Breuer's discoveries were described and an attempt was made to explain them by the theory of 'catharsis'. According to that hypothesis, hysterical symptoms originate through the energy of a mental process being withheld from conscious influence and being diverted into bodily innervation ('conversion'). A hysterical symptom would thus be a substitute for an omitted mental act and a reminiscence of the occasion which should have given rise to that act. And, on this view, recovery would be a result of the liberation of the affect that had gone astray and of its discharge along a normal path ('abreaction'). Cathartic treatment gave excellent therapeutic results, but it was found that they were not permanent and that they were not independent of the personal relation between the patient and the physician. Freud, who later proceeded with these investigations by himself, made an alteration in their technique, by replacing hypnosis by the method of free association. He invented the term 'psycho-analysis', which in the course of time came to have two meanings: (1) a particular method of treating nervous disorders and (2) the science of unconscious mental processes, which has also been appropriately described as 'depth-psychology'.

[1926d, 4274]

[1926f, 4401]
(1) The attack becomes unintelligible through the fact that it represents several phantasies in the same material simultaneously - that is to say through condensation. The elements common to the two (or more) phantasies constitute the nucleus of the representation, as they do in dreams. The phantasies which are thus made to coincide are often of quite a different nature. They may, for instance, be a recent wish and the re-activation of an infantile impression. The same innervations are in that case made to serve both purposes, often in a most ingenious way. Hysterical patients who make a very extensive use of condensation may find a single form of attack sufficient; others express their numerous pathogenic phantasies by a multiplication of the forms of attack.
[1909a, 1982]

(2) The attack becomes obscured through the fact that the patient attempts to carry out the activities of both the figures who appear in the phantasy, that is to say, through multiple identification. Compare, for instance, the example I mentioned in my paper on 'Hysterical Phantasies and their Relation to Bisexuality' (1908a), in which the patient tore off her dress with one hand (as the man) while she pressed it to her body with the other (as the woman).
[1909a, 1982]

(3) A particularly extensive distortion is effected by an antagonistic inversion of the innervations. This is analogous to the transformation of an element into its opposite, which commonly happens in the dream-work. For instance, an embrace may be represented in the attack by drawing back the arms convulsively till the hands meet over the spinal column. It is possible that the well-known arc de cercle which occurs during attacks in major hysteria is nothing else than an energetic repudiation like this, through antagonistic innervation, of a posture of the body that is suitable for sexual intercourse.
[1909a, 1982]

(4) Scarcely less confusing and misleading is a reversal of the chronological order within the phantasy that is portrayed, which once more has its complete counterpart in a number of dreams which begin with the end of the action and end with its beginning. Supposing, for instance, that a hysterical woman has a phantasy of seduction in which she is sitting reading in a park with her skirt slightly lifted so that her foot is visible; a gentleman approaches and speaks to her; they then go somewhere and make love to one another. This phantasy is acted out in the attack by her beginning with the convulsive stage, which corresponds to the coitus, by her then getting up, going into another room, sitting down and reading and presently answering an imaginary remark addressed to her.
[1909a, 1982]

The two last-mentioned forms of distortion give us some idea of the intensity of the resistances which the repressed material must take into account even when it breaks through in a hysterical attack.
[1909a, 1982]

(3) Finally, I have to explain to you what I mean by the 'general effect' of our work, and how I come to set hopes on it. What we have here is a very remarkable therapeutic constellation, the like of which is perhaps not to be found anywhere else and which will appear strange to you too at first, until you recognize in it something you have long been familiar with. You know, of course, that the psychoneuroses are substitutive satisfactions of some instinct the presence of which one is obliged to deny to oneself and others. Their capacity to exist depends on this distortion and lack of recognition. When the riddle they present is solved and the solution is accepted by the patients these diseases cease to be able to exist. There is hardly anything like this in medicine, though in fairy tales you hear of evil spirits whose power is broken as soon as you can tell them their name - the name which they have kept secret.
[1910d, 2312]
You see, then, that the libido's escape under conditions of conflict is made possible by the presence of fixations. The regressive cathexis of these fixations leads to the circumvention of the repression and to a discharge (or satisfaction) of the libido, subject to the conditions of a compromise being observed. By the roundabout path via the unconscious and the old fixations, the libido finally succeeds in forcing its way through to real satisfaction - though to one which is extremely restricted and scarcely recognizable as such. Let me add two comments to this conclusion. First, I should like you to notice how closely here the libido and the unconscious on one side and the ego, consciousness and reality on the other are shown to be interlinked, although to begin with they did not belong together at all. And secondly, I must ask you to bear in mind that everything I have said about this and what is still to follow relates only to the formation of symptoms in the neurosis of hysteria.

[1916-1917, 3419]

It is something else besides that makes symptoms seem strange to us and incomprehensible as a means of libidinal satisfaction. They do not remind us in the very least of anything from which we are in the habit of normally expecting satisfaction. Usually they disregard objects and in so doing abandon their relation to external reality. We can see that this is a consequence of turning away from the reality principle and of returning to the pleasure principle. But it is also a return to a kind of extended auto-erotism, of the sort that offered the sexual instinct its first satisfactions. In place of a change in the external world these substitute a change in the subject's own body: they set an internal act in place of an external one, an adaptation in place of an action - once again, something that corresponds, phylogenetically, to a highly significant regression. We shall only understand this in connection with something new that we have still to learn from the analytic researches into the formation of symptoms. We must further remember that the same processes belonging to the unconscious play a part in the formation of symptoms as in the formation of dreams - namely, condensation and displacement. A symptom, like a dream, represents something as fulfilled: a satisfaction in the infantile manner. But by means of extreme condensation that satisfaction can be compressed into a single sensation or innervation, and by means of extreme displacement it can be restricted to one small detail of the entire libidinal complex. It is not to be wondered at if we, too, often have difficulty in recognizing in a symptom the libidinal satisfaction whose presence we suspect and which is invariably confirmed.

[1916-1917, 3423]
(1) The attack becomes unintelligible through the fact that it represents several phantasies in the same material simultaneously - that is to say through condensation. The elements common to the two (or more) phantasies constitute the nucleus of the representation, as they do in dreams. The phantasies which are thus made to coincide are often of quite a different nature. They may, for instance, be a recent wish and the re-activation of an infantile impression. The same innervations are in that case made to serve both purposes, often in a most ingenious way. Hysterical patients who make a very extensive use of condensation may find a single form of attack sufficient; others express their numerous pathogenic phantasies by a multiplication of the forms of attack.
[1909a, 1982]

I will illustrate the first of these theses by a few examples. Hysterical attacks have long been recognized as signs of increased emotional excitement and equated with outbreaks of affect. Charcot attempted to reduce the multiplicity of their modes of manifestation by means of descriptive formulas; Pierre Janet recognized the unconscious ideas operating behind such attacks; while psycho-analysis has shown that they are mimetic representations of scenes (whether actually experienced or only invented) with which the patient's imagination is occupied without his becoming conscious of them. The meaning of these pantomimes is concealed from the spectators by means of condensations and distortions of the acts which they represent. And this applies equally to what are described as the 'chronic' symptoms of hysterical patients. All of them are mimetic or hallucinatory representations of phantasies which unconsciously dominate the subject's emotional life and which have the meaning of fulfilments of secret and repressed wishes. The tormenting character of these symptoms is due to the internal conflict into which these patients' minds are driven by the need to combat such unconscious wishes.
[1913j, 2809]

We are obliged to take quite another view of the process of repression when we consider the picture of a true conversion hysteria. Here the salient point is that it is possible to bring about a total disappearance of the quota of affect. When this is so, the patient displays towards his symptoms what Charcot called 'la belle indifférence hystériques'. In other cases this suppression is not so completely successful: some distressing sensations may attach to the symptoms themselves, or it may prove impossible to prevent some release of anxiety, which in turn sets to work the mechanism of forming a phobia. The ideational content of the instinctual representative is completely withdrawn from consciousness; as a substitute - and at the same time as a symptom - we have an over-strong innervation (in typical cases, a somatic one), sometimes of a sensory, sometimes of a motor character, either as an excitation or an inhibition. The over-innervated area proves on a closer view to be a part of the repressed instinctual representative - a part which, as though by a process of condensation, has drawn the whole cathexis on to itself. These remarks do not of course bring to light the whole mechanism of a conversion hysteria; in especial the factor of regression, which will be considered in another connection, has also to be taken into account. In so far as repression in hysteria is made possible only by the extensive formation of substitutes, it may be judged to be entirely unsuccessful; as regards dealing with the quota of affect, however, which is the true task of repression, it generally signifies a total success. In conversion hysteria the process of repression is completed with the formation of the symptom and does not, as in anxiety hysteria, need to continue to a second phase - or rather, strictly speaking, to continue endlessly.
[1915d, 2986]
It is something else besides that makes symptoms seem strange to us and incomprehensible as a means of libidinal satisfaction. They do not remind us in the very least of anything from which we are in the habit of normally expecting satisfaction. Usually they disregard objects and in so doing abandon their relation to external reality. We can see that this is a consequence of turning away from the reality principle and of returning to the pleasure principle. But it is also a return to a kind of extended auto-erotism, of the sort that offered the sexual instinct its first satisfactions. In place of a change in the external world these substitute a change in the subject's own body: they set an internal act in place of an external one, an adaptation in place of an action - once again, something that corresponds, phylogenetically, to a highly significant regression. We shall only understand this in connection with something new that we have still to learn from the analytic researches into the formation of symptoms. We must further remember that the same processes belonging to the unconscious play a part in the formation of symptoms as in the formation of dreams - namely, condensation and displacement. A symptom, like a dream, represents something as fulfilled: a satisfaction in the infantile manner. But by means of extreme condensation that satisfaction can be compressed into a single sensation or innervation, and by means of extreme displacement it can be restricted to one small detail of the entire libidinal complex. It is not to be wondered at if we, too, often have difficulty in recognizing in a symptom the libidinal satisfaction whose presence we suspect and which is invariably confirmed.

[1916-1917, 3423]

A noteworthy relation between the symptoms of the 'actual' neuroses and of the psychoneuroses makes a further important contribution to our knowledge of the formation of symptoms in the latter. For a symptom of an 'actual' neurosis is often the nucleus and first stage of a psychoneurotic symptom. A relation of this kind can be most clearly observed between neurasthenia and the transference neurosis known as 'conversion hysteria', between anxiety neurosis and anxiety hysteria, but also between hypochondria and the forms of disorder which will be mentioned later under the name of paraphrenia (dementia praecox and paranoia). Let us take as an example a case of hysterical headache or lumbar pain. Analysis shows us that, by condensation and displacement, it has become a substitutive satisfaction for a whole number of libidinal phantasies or memories. But this pain was also at one time a real one and it was then a direct sexual-toxic symptom, the somatic expression of a libidinal excitation. We are far from asserting that all hysterical symptoms contain a nucleus of this kind. But it remains a fact that this is especially often the case and that whatever somatic influences (whether normal or pathological) are brought about by libidinal excitation are preferred for the construction of hysterical symptoms. In such cases they play the part of the grain of sand which a mollusc coats with layers of mother-of-pearl. In the same way, the passing indications of sexual excitement which accompany the sexual act are employed by the psychoneurosis as the most convenient and appropriate material for the construction of symptoms.

[1916-1917, 3441]
I once had an opportunity of making a detailed study of a young woman who passed through a variety of psychical conditions. Her illness began with a state of confusional excitement during which she displayed a quite special aversion to her mother, hitting and abusing her whenever she came near her bed, while at the same period she was docile and affectionate towards a sister who was many years her senior. This was followed by a state in which she was lucid but somewhat apathetic and suffered from badly disturbed sleep. It was during this phase that I began treating her and analysing her dreams. An immense number of these dreams were concerned, with a greater or less degree of disguise, with the death of her mother: at one time she would be attending an old woman's funeral, at another she and her sister would be sitting at table dressed in mourning. There could be no question as to the meaning of these dreams. As her condition improved still further, hysterical phobias developed. The most tormenting of these was a fear that something might have happened to her mother. She was obliged to hurry home, wherever she might be, to convince herself that her mother was still alive. This case, taken in conjunction with what I had learnt from other sources, was highly instructive: it exhibited, translated as it were into different languages, the various ways in which the psychical apparatus reacted to one and the same exciting idea. In the confusional state, in which, as I believe, the second psychical agency was overwhelmed by the normally suppressed first one, her unconscious hostility to her mother found a powerful motor expression. When the calmer condition set in, when the rebellion was suppressed and the domination of the censorship re-established, the only region left open in which her hostility could realize the wish for her mother's death was that of dreaming. When a normal state was still more firmly established, it led to the production of her exaggerated worry about her mother as a hysterical counter-reaction and defensive phenomenon. In view of this it is no longer hard to understand why hysterical girls are so often attached to their mothers with such exaggerated affection. [1900a, 738]

If we consider a number of analyses of obsessional neurotics we shall find it impossible to escape the impression that a relation between love and hatred such as we have found in our present patient is among the most frequent, the most marked, and probably, therefore, the most important characteristics of obsessional neurosis. But however tempting it may be to bring the problem of the 'choice of neurosis' into connection with instinctual life, there are reasons enough for avoiding such a course. For we must remember that in every neurosis we come upon the same suppressed instincts behind the symptoms. After all, hatred, kept suppressed in the unconscious by love, plays a great part in the pathogenesis of hysteria and paranoia. We know too little of the nature of love to be able to arrive at any definite conclusion here; and, in particular, the relation between the negative factor in love and the sadistic components of the libido remains completely obscure. What follows is therefore to be regarded as no more than a provisional explanation. We may suppose, then, that in the cases of unconscious hatred with which we are concerned the sadistic components of love have, from constitutional causes, been exceptionally strongly developed, and have consequently undergone a premature and all too thorough suppression, and that the neurotic phenomena we have observed arise on the one hand from conscious feelings of affection which have become exaggerated as a reaction, and on the other hand from sadism persisting in the unconscious in the form of hatred. [1909d, 2187]
In place of a single sick person let us put society - suffering as a whole from neuroses, though composed of sick and healthy members; and in place of individual acceptance in the one case let us put general recognition in the other. A little reflection will then show you that this substitution cannot in any way alter the outcome. The success which the treatment can have with the individual must occur equally with the community. Sick people will not be able to let their various neuroses become known - their anxious over-tenderness which is meant to conceal their hatred, their agoraphobia which tells of disappointed ambition, their obsessive actions which represent self-reproaches for evil intentions and precautions against them - if all their relatives and every stranger from whom they wish to conceal their mental processes know the general meaning of such symptoms, and if they themselves know that in the manifestations of their illness they are producing nothing that other people cannot instantly interpret. The effect, however, will not be limited to the concealment of the symptoms which, incidentally, it is often impossible to carry out; for this necessity for concealment destroys the use of being ill. Disclosure of the secret will have attacked, at its most sensitive point, the 'aetiological equation' from which neuroses arise - it will have made the gain from the illness illusory; and consequently the final outcome of the changed situation brought about by the physician's indiscretion can only be that the production of the illness will be brought to a stop.

[1910d, 2312]

The reaction-formations in the ego of the obsessional neurotic, which we recognize as exaggerations of normal character-formation, should be regarded, I think, as yet another mechanism of defence and placed alongside of regression and repression. They seem to be absent or very much weaker in hysteria. Looking back, we can now get an idea of what is peculiar to the defensive process in hysteria. It seems that in it the process is limited to repression alone. The ego turns away from the disagreeable instinctual impulse, leaves it to pursue its course in the unconscious, and takes no further part in its fortunes. This view cannot be absolutely correct, for we are acquainted with the case in which a hysterical symptom is at the same time a fulfilment of a penalty imposed by the super-ego; but it may describe a general characteristic of the behaviour of the ego in hysteria.

[1926d, 4274]
An important element in the theory of repression is the view that repression is not an event that occurs once but that it requires a permanent expenditure. If this expenditure were to cease, the repressed impulse, which is being fed all the time from its sources, would on the next occasion flow along the channels from which it had been forced away, and the repression would either fail in its purpose or would have to be repeated an indefinite number of times. Thus it is because instincts are continuous in their nature that the ego has to make its defensive action secure by a permanent expenditure. This action undertaken to protect repression is observable in analytic treatment as resistance. Resistance presupposes the existence of what I have called anticathexis. An anticathexis of this kind is clearly seen in obsessional neurosis. It appears there in the form of an alteration of the ego, as a reaction-formation in the ego, and is effected by the reinforcement of the attitude which is the opposite of the instinctual trend that has to be repressed - as, for instance, in pity, conscientiousness and cleanliness. These reaction- formations of obsessional neurosis are essentially exaggerations of the normal traits of character which develop during the latency period. The presence of an anticathexis in hysteria is much more difficult to detect, though theoretically it is equally indispensable. In hysteria, too, a certain amount of alteration of the ego through reaction-formation is unmistakable and in some circumstances becomes so marked that it forces itself on our attention as the principal symptom. The conflict due to ambivalence, for instance, is resolved in hysteria by this means. The subject's hatred of a person whom he loves is kept down by an exaggerated amount of tenderness for him and apprehensiveness about him. But the difference between reaction- formations in obsessional neurosis and in hysteria is that in the latter they do not have the universality of a character-trait but are confined to particular relationships. A hysterical woman, for instance, may be specially affectionate with her own children whom at bottom she hates; but she will not on that account be more loving in general than other women or even more affectionate to other children. The reaction-formation of hysteria clings tenaciously to a particular object and never spreads over into a general disposition of the ego, whereas what is characteristic of obsessional neurosis is precisely a spreading-over of this kind - a loosening of relations to the object and a facilitation of displacement in the choice of object.
[1926d, 4310]
Even a purely terminological innovation ought to justify its adoption; it ought to reflect some new point of view or some extension of knowledge. The revival of the concept of defence and the restriction of that of repression takes into account a fact which has long since been known but which has received added importance owing to some new discoveries. Our first observations of repression and of the formation of symptoms were made in connection with hysteria. We found that the perceptual content of exciting experiences and the ideational content of pathogenic structures of thought were forgotten and debarred from being reproduced in memory, and we therefore concluded that the keeping away from consciousness was a main characteristic of hysterical repression. Later on, when we came to study the obsessional neuroses, we found that in that illness pathogenic occurrences are not forgotten. They remain conscious but they are 'isolated' in some way that we cannot as yet grasp, so that much the same result is obtained as in hysterical amnesia. Nevertheless the difference is great enough to justify the belief that the process by which instinctual demands are set aside in obsessional neurosis cannot be the same as in hysteria. Further investigations have shown that in obsessional neurosis a regression of the instinctual impulses to an earlier libidinal stage is brought about through the opposition of the ego, and that this regression, although it does not make repression unnecessary, clearly works in the same sense as repression. We have seen, too, that in obsessional neurosis anticathexis, which is also presumably present in hysteria, plays a specially large part in protecting the ego by effecting a reactive alteration in it. Our attention has, moreover, been drawn to a process of 'isolation' (whose technique cannot as yet be elucidated) which finds direct symptomatic manifestation, and to a procedure, that may be called magical, of 'undoing' what has been done - a procedure about whose defensive purpose there can be no doubt, but which has no longer any resemblance to the process of 'repression'. These observations provide good enough grounds for re-introducing the old concept of defence, which can cover all these processes that have the same purpose - namely, the protection of the ego against instinctual demands - and for subsuming repression under it as a special case. The importance of this nomenclature is heightened if we consider the possibility that further investigations may show that there is an intimate connection between special forms of defence and particular illnesses, as, for instance, between repression and hysteria. In addition we may look forward to the possible discovery of yet another important correlation. It may well be that before its sharp cleavage into an ego and an id, and before the formation of a super-ego, the mental apparatus makes use of different methods of defence from those which it employs after it has reached these stages of organization.
(3) A particularly extensive distortion is effected by an *antagonistic inversion of the innervations*. This is analogous to the transformation of an element into its opposite, which commonly happens in the dream-work. For instance, an embrace may be represented in the attack by drawing back the arms convulsively till the hands meet over the spinal column. It is possible that the well-known *arc de cercle* which occurs during attacks in major hysteria is nothing else than an energetic repudiation like this, through antagonistic innervation, of a posture of the body that is suitable for sexual intercourse.

[1909a, 1982]
(4) Scarcely less confusing and misleading is a reversal of the chronological order within the phantasy that is portrayed, which once more has its complete counterpart in a number of dreams which begin with the end of the action and end with its beginning. Supposing, for instance, that a hysterical woman has a phantasy of seduction in which she is sitting reading in a park with her skirt slightly lifted so that her foot is visible; a gentleman approaches and speaks to her; they then go somewhere and make love to one another. This phantasy is acted out in the attack by her beginning with the convulsive stage, which corresponds to the coitus, by her then getting up, going into another room, sitting down and reading and presently answering an imaginary remark addressed to her.
[1909a, 1982]
Here is some further interpretative material. Handing him the glass reminded me of the story of the peasant at the optician's, trying glass after glass and still not being able to read. - (Peasant-catcher [Bauernfänger, 'sharper': girl-catcher [Mädchenfänger] in the preceding episode of the dream.) - The way in which the father in Zola's La terre was treated among the peasants after he had grown feeble-minded. - The tragic requital that lay in my father's soiling his bed like a child during the last days of his life; hence my appearance in the dream as a sick-nurse. - 'Here it was as though thinking and experiencing were one and the same thing.' This recalled a strongly revolutionary literary play by Oskar Panizza, in which God the Father is ignominiously treated as a paralytic old man. In his case will and deed were represented as one and the same thing, and he had to be restrained from cursing and swearing by one of his archangels, a kind of Ganymede, because his imprecations would be promptly fulfilled. - My making plans was a reproach against my father dating from a later period. And indeed the whole rebellious content of the dream, with its lèse majesté and its derision of the higher authorities, went back to rebellion against my father. A Prince is known as the father of his country; the father is the oldest, first, and for children the only authority, and from his autocratic power the other social authorities have developed in the course of the history of human civilization - except in so far as the 'matriarchy' calls for a qualification of this assertion. - The phrase 'thinking and experiencing were one and the same thing' had a reference to the explanation of hysterical symptoms, and the 'male urinal' belonged in the same connection. I need not explain to a Viennese the principle of the 'Gschnas'. It consists in constructing what appear to be rare, and precious objects out of trivial and preferably comic and worthless materials (for instance, in making armour out of saucepans, wisps of straw and dinner rolls) - a favourite pastime at bohemian parties here in Vienna. I had observed that this is precisely what hysterical subjects do: alongside what has really happened to them, they unconsciously build up frightful or perverse imaginary events which they construct out of the most innocent and everyday material of their experience. It is to these phantasies that their symptoms are in the first instance attached and not to their recollections of real events, whether serious or equally innocent. This revelation had helped me over a number of difficulties and had given me particular pleasure. What made it possible for me to refer to this by means of the dream-element of the 'male urinal' was as follows. I had been told that at the latest 'Gschnas'-night a poisoned chalice belonging to Lucrezia Borgia had been exhibited; its central and principal constituent had been a male urinal of the type used in hospitals.

¹ [Footnote added 1909:] Hysterical attacks sometimes make use of the same kind of chronological reversal in order to disguise their meaning from observers. For instance, a hysterical girl needed to represent something in the nature of a brief romance in one of her attacks - a romance of which she had had a phantasy in her unconscious after an encounter with someone on the suburban railway. She imagined how the man had been attracted by the beauty of her foot and had spoken to her while she was reading; whereupon she had gone off with him and had had a passionate love-scene. Her attack began with a representation of this love-scene by convulsive twitching of her body, accompanied by movements of her lips to represent kissing and tightening of her arms to represent embracing. She then hurried into the next room, sat down on a chair, raised her skirt so as to show her foot, pretended to be reading a book and spoke to me (that is, answered me). - [Added 1914:] Cf. in this connection what Artemidorus says: 'In interpreting the images seen in dreams one must sometimes follow them from the beginning to the end and sometimes from the end to the beginning . . .'

² [Footnote added 1909]
I do not wish to deny categorically that this fourth power in dream-construction - which we shall soon recognize as all old acquaintance, since in fact it is the only one of the four with which we are familiar in other connections - I do not wish to deny that this fourth factor has the capacity to create new contributions to dreams. It is certain, however, that, like the others, it exerts its influence principally by its preferences and selections from psychical material in the dream-thoughts that has already been formed. Now there is one case in which it is to a great extent spared the labour of, as it were, building up a façade for the dream - the case, namely, in which a formation of that kind already exists, available for use in the material of the dream-thoughts. I am in the habit of describing the element in the dream-thoughts which I have in mind as a 'phantasy.' I shall perhaps avoid misunderstanding if I mention the 'day-dream' as something analogous to it in waking life.¹ The part played in our mental life by these structures has not yet been fully recognized and elucidated by psychiatrists, though M. Benedikt has made what seems to me a very promising start in that direction. The importance of day-dreams has not escaped the unerring vision of imaginative writers; there is, for instance, a well-known account by Alphonse Daudet in Le Nabab of the day-dreams of one of the minor characters in that story. The study of the psychoneuroses leads to the surprising discovery that these phantasies or day-dreams are the immediate forerunners of hysterical symptoms, or at least of a whole number of them. Hysterical symptoms are not attached to actual memories, but to phantasies erected on the basis of the basis of memories. The frequent occurrence of conscious daytime phantasies brings these structures to our knowledge; but just as there are phantasies of this kind which are conscious, so, too, there are unconscious ones in great numbers, which have to remain unconscious on account of their content and of their origin from repressed material. Closer investigation of the characteristics of these day-time phantasies shows us how right it is that these formations should bear the same name as we give to the products of our thought during the night - the name, that is, of 'dreams.' They share a large number of their properties with night-dreams, and their investigation might, in fact, have served as the shortest and best approach to an understanding of night-dreams.

¹ [Footnote added 1909:] In my 'Fragment of an Analysis of a Case of Hysteria' (1905e), I have analysed a good specimen of a dream of this sort, made up of a number of superimposed phantasies. Incidentally, I underestimated the importance of the part played by these phantasies in the formation of dreams so long as I was principally working on my own dreams, which are usually based on discussions and conflict of thought and comparatively rarely on day-dreams. In the case of other people it is often much easier to demonstrate the complete analogy between night-dreams and day-dreams. With hysterical patients, a hysterical attack can often be replaced by a dream; and it is then easy to convince oneself that the immediate forerunner of both these psychical structures was a day-dream phantasy.

[1900a, 931]
Now that the old antithesis between conscious life and dream life has been reduced to its proper proportions by the establishment of unconscious psychical reality, a number of dream-problems with which earlier writers were deeply concerned have lost their significance. Thus some of the activities whose successful performance in dreams excited astonishment are no longer to be attributed to dreams but to unconscious thinking, which is active during the day no less than at night. If, as Scherner has said, dreams appear to engage in making symbolic representations of the body, we now know that those representations are the product of certain unconscious phantasies (deriving, probably, from sexual impulses) which find expression not only in dreams but also in hysterical phobias and other symptoms. If a dream carries on the activities of the day and completes them and even brings valuable fresh ideas to light, all we need do is to strip it of the dream disguise, which is the product of dream-work and the mark of assistance rendered by obscure forces from the depths of the mind (cf. the Devil in Tartini’s sonata dream); the intellectual achievement is due to the same mental forces which produce every similar result during the daytime. We are probably inclined greatly to over-estimate the conscious character of intellectual and artistic production as well. Accounts given us by some of the most highly productive men, such as Goethe and Helmholtz, show rather that what is essential and new in their creations came to them without premeditation and as an almost ready-made whole. There is nothing strange if in other cases, where a concentration of every intellectual faculty was needed, conscious activity also contributed its share. But it is the much-abused privilege of conscious activity, wherever it plays a part, to conceal every other activity from our eyes.

[1900a, 1038]

For example, the phantasies of hysterics concerning sexual and cruel maltreatment correspond, at times even down to details, with the complaints of persecuted paranoics. It is curious, but not unintelligible, that we meet the identical content in the form of reality in the contrivances of perverts for the satisfaction of their desires.

[1901b, 1325]
An opportunity very soon occurred for interpreting Dora's nervous cough in this way by means of an imagined sexual situation. She had once again been insisting that Frau K. only loved her father because he was 'ein vermögender Mann' ['a man of means']. Certain details of the way in which she expressed herself (which I pass over here, like most other purely technical parts of the analysis) led me to see that behind this phrase its opposite lay concealed, namely, that her father was 'ein unvermögender Mann' ['a man without means']. This could only be meant in a sexual sense - that her father, as a man, was without means, was impotent.¹ Dora confirmed this interpretation from her conscious knowledge; whereupon I pointed out the contradiction she was involved in if on the one hand she continued to insist that her father's relation with Frau K. was a common love-affair, and on the other hand maintained that her father was impotent, or in other words incapable of carrying on an affair of such a kind. Her answer showed that she had no need to admit the contradiction. She knew very well, she said, that there was more than one way of obtaining sexual gratification. (The source of this piece of knowledge, however, was once more untraceable.) I questioned her further, whether she referred to the use of organs other than the genitals for the purpose of sexual intercourse, and she replied in the affirmative. I could then go on to say that in that case she must be thinking of precisely those parts of the body which in her case were in a state of irritation, - the throat and the oral cavity. To be sure, she would not hear of going so far as this in recognizing her own thoughts; and indeed, if the occurrence of the symptom was to be made possible at all, it was essential that she should not be completely clear on the subject. But the conclusion was inevitable that with her spasmodic cough, which, as is usual, was referred for its exciting stimulus to a tickling in her throat, she pictured to herself a scene of sexual gratification per os between the two people whose love-affair occupied her mind so incessantly. A very short time after she had tacitly accepted this explanation her cough vanished - which fitted in very well with my view; but I do not wish to lay too much stress upon this development, since her cough had so often before disappeared spontaneously.

[1905e, 1384]
As regards the second kind of emotional reaction, which is not directed against me this time, but against my patient - supposing that my view of her is correct - and which regards the perverse nature of her phantasies as horrible, I should like to say emphatically that a medical man has no business to indulge in such passionate condemnation. I may also remark in passing that it seems to me superfluous for a physician who is writing upon the aberrations of the sexual instincts to seize every opportunity of inserting into the text expressions of his personal repugnance at such revolting things. We are faced by a fact; and it is to be hoped that we shall grow accustomed to it, when we have put our own tastes on one side. We must learn to speak without indignation of what we call the sexual perversions - instances in which the sexual function has extended its limits in respect either to the part of the body concerned or to the sexual object chosen. The uncertainty in regard to the boundaries of what is to be called normal sexual life, when we take different races and different epochs into account, should in itself be enough to cool the zealot's ardour. We surely ought not to forget that the perversion which is the most repellent to us, the sensual love of a man for a man, was not only tolerated by a people so far our superiors in cultivation as were the Greeks, but was actually entrusted by them with important social functions. The sexual life of each one of us extends to a slight degree - now in this direction, now in that - beyond the narrow lines imposed as the standard of normality. The perversions are neither bestial nor degenerate in the emotional sense of the word. They are a development of germs all of which are contained in the undifferentiated sexual disposition of the child, and which, by being suppressed or by being diverted to higher, asexual aims - by being 'sublimated' - are destined to provide the energy for a great number of our cultural achievements. When, therefore, any one has become a gross and manifest pervert, it would be more correct to say that he has remained one, for he exhibits a certain stage of inhibited development. All psychoneurotics are persons with strongly marked perverse tendencies, which have been repressed in the course of their development and have become unconscious. Consequently their unconscious phantasies show precisely the same content as the documentarily recorded actions of perverts - even though they have not read Krafft-Ebing's *Psychopathia Sexualis*, to which simple-minded people attribute such a large share of the responsibility for the production of perverse tendencies. Psychoneuroses are, so to speak, the negative of perversions. In neurotics their sexual constitution, under which the effects of heredity are included, operates in combination with any accidental influences in their life which may disturb the development of normal sexuality. A stream of water which meets with an obstacle in the river-bed is dammed up and flows back into old channels which had formerly seemed fated to run dry. The motive forces leading to the formation of hysterical symptoms draw their strength not only from repressed normal sexuality but also from unconscious perverse activities.¹

[1905e, 1387]
The less repellent of the so-called sexual perversions are very widely diffused among the whole population, as every one knows except medical writers upon the subject. Or, I should rather say, they know it too; only they take care to forget it at the moment when they take up their pens to write about it. So it is not to be wondered at that this hysterical girl of nearly nineteen, who had heard of the occurrence of such a method of sexual intercourse (sucking at the male organ), should have developed an unconscious phantasy of this sort and should have given it expression by an irritation in her throat and by coughing. Nor would it have been very extraordinary if she had arrived at such a phantasy even without having had any enlightenment from external sources - an occurrence which I have quite certainly observed in other patients. For in her case a noteworthy fact afforded the necessary somatic prerequisite for this independent creation of a phantasy which would coincide with the practices of perverts. She remembered very well that in her childhood she had been a thumb-sucker. Her father, too recollected breaking her of the habit after it had persisted into her fourth or fifth year. Dora herself had a clear picture of a scene from her early childhood in which she was sitting on the floor in a corner sucking her left thumb and at the same time tugging with her right hand at the lobe of her brother's ear as he sat quietly beside her. Here we have an instance of the complete form of self-gratification by sucking, as it has also been described to me by other patients, who had subsequently become anaesthetic and hysterical.

The interpretation we have just been discussing of Dora's throat symptoms may also give rise to a further remark. It may be asked how this sexual situation imagined by her can be compatible with our other explanation of the symptoms. That explanation, it will be remembered, was to the effect that the coming and going of the symptoms reflected the presence and absence of the man she was in love with, and, as regards his wife's behaviour, expressed the following thought: 'If I were his wife, I should love him in quite a different way; I should be ill (from longing, let us say) when he was away, and well (from joy) when he was home again.' To this objection I must reply that my experience in the clearing-up of hysterical symptoms has shown that it is not necessary for the various meanings of a symptom to be compatible with one another, that is, to fit together into a connected whole. It is enough that the unity should be constituted by the subject-matter which has given rise to all the various phantasies. In the present case, moreover, compatibility even of the first kind is not out of the question. One of the two meanings is related more to the cough, and the other to the aphonia and the periodicity of the disorder. A closer analysis would probably have disclosed a far greater number of mental elements in relation to the details of the illness.

² I have already indicated that the majority of hysterical symptoms, when they have attained their full pitch of development, represent an imagined situation of sexual life - such as a scene of sexual intercourse, pregnancy, childbirth, confinement, etc.

The next thing to do was to turn to account our knowledge of the existence of this phantasy: 'If it is true that you were delivered of a child nine months after the scene by the lake, and that you are going about to this very day carrying the consequences of your false step with you, then it follows that in your unconscious you must have regretted the upshot of the scene. In your unconscious thoughts, that is to say, you have made an emendation in it. The assumption that underlies your phantasy of childbirth is that on that occasion something took place,¹ that on that occasion you experienced and went through everything that you were in fact obliged to pick up later on from the encyclopaedia. So you see that your love for Herr K. did not come to an end with the scene, but that (as I maintained) it has persisted down to the present day - though it is true that you are unconscious of it.' - And Dora disputed the fact no longer.²
¹ The phantasy of defloration is thus found to have an application to Herr K., and we begin to see why this part of the dream contained material taken from the scene by the lake - the refusal, two and a half hours, the wood, the invitation to L--.
[1905e, 1439]

¹ The contents of the clearly conscious phantasies of perverts (which in favourable circumstances can be transformed into manifest behaviour), of the delusional fears of paranoics (which are projected in a hostile sense on to other people) and of the unconscious phantasies of hysterics (which psycho-analysis reveals behind their symptoms) - all of these coincide with one another even down to their details.
[1905d, 1490]

Though even to-day I do not consider these assertions incorrect, it is not to be wondered at that, in the course of ten years of continuous effort at reaching an understanding of these phenomena, I have made a considerable step forward from the views I then held, and now believe that I am in a position, on the basis of deeper experience, to correct the insufficiencies, the displacements and the misunderstandings under which my theory then laboured. At that time my material was still scanty, and it happened by chance to include a disproportionately large number of cases in which sexual seduction by an adult or by older children played the chief part in the history of the patient's childhood. I thus over-estimated the frequency of such events (though in other respects they were not open to doubt). Moreover, I was at that period unable to distinguish with certainty between falsifications made by hysterics in their memories of childhood and traces of real events. Since then I have learned to explain a number of phantasies of seduction as attempts at fending off memories of the subject's own sexual activity (infantile masturbation). When this point had been clarified, the 'traumatic' element in the sexual experiences of childhood lost its importance and what was left was the realization that infantile sexual activity (whether spontaneous or provoked) prescribes the direction that will be taken by later sexual life after maturity. The same clarification (which corrected the most important of my early mistakes) also made it necessary to modify my view of the mechanism of hysterical symptoms. They were now no longer to be regarded as direct derivatives of the repressed memories of childhood experiences; but between the symptoms and the childish impressions there were inserted the patient's phantasies (or imaginary memories), mostly produced during the years of puberty, which on the one side were built up out of and over the childhood memories and on the other side were transformed directly into the symptoms. It was only after the introduction of this element of hysterical phantasies that the texture of the neurosis and its relation to the patient's life became intelligible; a surprising analogy came to light, too, between these unconscious phantasies of hysterics and the imaginary creations of paranoics which become conscious as delusions.
[1906a, 1578]
I think it is worth emphasizing the fact that, whatever modifications my views on the aetiology of the psychoneuroses have passed through, there are two positions which I have never repudiated or abandoned - the importance of sexuality and of infantilism. Apart from this, accidental influences have been replaced by constitutional factors and ‘defence’ in the purely psychological sense has been replaced by organic ‘sexual repression’. The question may, however, be raised whether convincing evidence is to be found in favour of the alleged aetiologic importance of sexual factors in the psychoneuroses, in view of the fact that the onset of these illnesses may be observed in response to the most commonplace emotions or even to somatic precipitating causes, and since I have had to abandon a specific aetiology depending on the particular form of the childhood experiences concerned. To such a question I would reply that the psycho-analytic examination of neurotics is the source from which this disputed conviction of mine is derived. If we make use of that irreplaceable method of research, we discover that the patient’s symptoms constitute his sexual activity (whether wholly or in part), which arises from the sources of the normal or perverse component instincts of sexuality. Not only is a large part of the symptomatology of hysteria derived directly from expressions of sexual excitement, not only do a number of erotogenic zones attain the significance of genitals during neuroses owing to an intensification of infantile characteristics, but the most complicated symptoms are themselves revealed as representing, by means of ‘conversion’, phantasies which have a sexual situation as their subject-matter. Anyone who knows how to interpret the language of hysteria will recognize that the neurosis is concerned only with the patient's repressed sexuality. The sexual function must, however, be understood in its true extent, as it is laid down by disposition in infancy. Wherever some commonplace emotion must be included among the determinants of the onset of the illness, analysis invariably shows that it is the sexual component of the traumatic experience - a component that is never lacking which has produced the pathogenic result.

We are all familiar with the delusional imaginings of the paranoic, which are concerned with the greatness and the sufferings of his own self and which appear in forms that are quite typical and almost monotonous. We have also become acquainted, through numerous accounts, with the strange performances with which certain perverts stage their sexual satisfaction, whether in idea or reality. Nevertheless, it may be new to some readers to hear that quite analogous psychical structures are regularly present in all the psychoneuroses, particularly in hysteria, and that these latter - which are known as hysterical phantasies - can be seen to have important connections with the causation of the neurotic symptoms.
These day-dreams are cathected with a large amount of interest; they are carefully cherished by the subject and usually concealed with a great deal of sensitivity, as though they were among the most intimate possessions of his personality. It is easy to recognize a person who is absorbed in day-dreaming in the street, however, by his sudden, as it were absent-minded, smile, his way of talking to himself, or by the hastening of his steps which marks the climax of the imagined situation. Every hysterical attack which I have been able to investigate up to the present has proved to be an involuntary irruption of day-dreams of this kind. For our observations no longer leave any room for doubt that such phantasies may be unconscious just as well as conscious; and as soon as the latter have become unconscious they may also become pathogenic - that is, they may express themselves in symptoms and attacks. In favourable circumstances, the subject can still capture an unconscious phantasy of this sort in consciousness. After I had drawn the attention of one of my patients to her phantasies, she told me that on one occasion she had suddenly found herself in tears in the street and that, rapidly considering what it was she was actually crying about, she had got hold of a phantasy to the following effect. In her imagination she had formed a tender attachment to a pianist who was well known in the town (though she was not personally acquainted with him); she had had a child by him (she was in fact childless); and he had then deserted her and her child and left them in poverty. It was at this point in her romance that she had burst into tears.

Unconscious phantasies have either been unconscious all along and have been formed in the unconscious; or - as is more often the case - they were once conscious phantasies, day-dreams, and have since been purposely forgotten and have become unconscious through 'repression'. Their content may afterwards either have remained the same or have undergone alterations, so that the present unconscious phantasies are derivatives of the once conscious ones. Now an unconscious phantasy has a very important connection with the subject's sexual life; for it is identical with the phantasy which served to give him sexual satisfaction during a period of masturbation. At that time the masturbatory act (in the widest sense of the term) was compounded of two parts. One was the evocation of a phantasy and the other some active behaviour for obtaining self-gratification at the height of the phantasy. This compound, as we know, was itself merely soldered together.¹ Originally the action was a purely auto-erotic procedure for the purpose of obtaining pleasure from some particular part of the body, which could be described as erotogenic. Later, this action became merged with a wishful idea from the sphere of object-love and served as a partial realization of the situation in which the phantasy culminated. When, subsequently, the subject renounces this type of satisfaction, composed of masturbation and phantasy, the action is given up, while the phantasy, from being conscious, becomes unconscious. If no other mode of sexual satisfaction supervenes, the subject remains abstinent; and if he does not succeed in sublimating his libido - that is, in deflecting his sexual excitation to higher aims -, the condition is now fulfilled for his unconscious phantasy to be revived and to proliferate, and, at least as regards some part of its content, to put itself into effect, with the whole force of his need for love, in the form of a pathological symptom.

In this way, unconscious phantasies are the immediate psychical precursors of a whole number of hysterical symptoms. Hysterical symptoms are nothing other than unconscious phantasies brought into view through 'conversion': and in so far as the symptoms are somatic ones, they are often enough taken from the circle of the same sexual sensations and motor innervations as those which had originally accompanied the phantasy when it was still conscious. In this way the giving up of the habit of masturbation is in fact undone, and the purpose of the whole pathological process, which is a restoration of the original, primary sexual satisfaction, is achieved - though never completely, it is true, but always in a sort of approximation.

[1908a, 1933]

[1908a, 1934]

[1908a, 1935]
Anyone who studies hysteria, therefore, soon finds his interest turned away from its symptoms to the phantasies from which they proceed. The technique of psycho-analysis enables us in the first place to infer from the symptoms what those unconscious phantasies are and then to make them conscious to the patient. By this means it has been found that the content of the hysteric's unconscious phantasies corresponds completely to the situations in which satisfaction is consciously obtained by perverts; and if anyone is at a loss for examples of such situations he has only to recall the world-famous performances of the Roman Emperors, the wild excesses of which were, of course, determined only by the enormous and unrestrained power possessed by the authors of the phantasies. The delusions of paranoics are phantasies of the same nature, though they are phantasies which have become directly conscious. They rest on the sadomasochistic components of the sexual instinct, and they, too, may find their complete counterpart in certain unconscious phantasies of hysterical subjects. We also know of cases - cases which have their practical importance as well - in which hysterics do not give expression to their phantasies in the form of symptoms but as conscious realizations, and in that way devise and stage assaults, attacks or acts of sexual aggression.

This method of psycho-analytic investigation, which leads from the conspicuous symptoms to the hidden unconscious phantasies, tells us everything that can be known about the sexuality of psychoneurotics, including the fact which is to be the main subject-matter of this short preliminary publication.

Owing, probably, to the difficulties which the unconscious phantasies meet with in their endeavour to find expression, the relationship of the phantasies to the symptoms is not simple, but on the contrary, complicated in many ways.¹ As a rule - when, that is, the neurosis is fully developed and has persisted for some time - a particular symptom corresponds, not to a single unconscious phantasy, but to several such phantasies; and it does so not in an arbitrary manner but in accordance with a regular pattern. At the beginning of the illness these complications are, no doubt, not all fully developed.

(4) Hysterical symptoms are the realization of an unconscious phantasy which serves the fulfilment of a wish.

Among these various definitions the seventh brings out the nature of hysterical symptoms most completely as the realization of an unconscious phantasy; and the eighth recognizes the proper significance of the sexual factor. Some of the preceding formulas lead up to these two and are contained in them.
This connection between symptoms and phantasies makes it easy to arrive from a psycho-
analysis of the former at a knowledge of the components of the sexual instincts which dominate
the individual, as I have demonstrated in my Three Essays on the Theory of Sexuality. In some
cases, however, investigation by this means yields an unexpected result. It shows that there are
many symptoms where the uncovering of a sexual phantasy (or of a number of phantasies, one
of which, the most significant and the earliest, is of a sexual nature) is not enough to bring about
a resolution of the symptoms. To resolve it one has to have two sexual phantasies, of which one
has a masculine and the other a feminine character. Thus one of these phantasies springs from
a homosexual impulse. This new finding does not alter our seventh formula. It remains true that
a hysterical symptom must necessarily represent a compromise between a libidinal and a
repressing impulse; but it may also represent a union of two libidinal phantasies of an opposite
sexual character.
[1908a, 1937]

(9) Hysterical symptoms are the expression on the one hand of a masculine unconscious
sexual phantasy, and on the other hand of a feminine one.
[1908a, 1938]

I must expressly state that I cannot claim the same general validity for this formula as I have
done for the others. As far as I can see, it applies neither to all the symptoms of a given case
nor to all cases. On the contrary, it is not hard to adduce cases in which the impulses belonging
to the opposite sexes have found separate symptomatic expression, so that the symptoms of
heterosexual and those of homosexuality can be as clearly distinguished from each other as
the phantasies concealed behind them. Nevertheless, the condition of things stated in the ninth
formula is common enough, and, when it occurs, important enough to deserve special
emphasis. It seems to me to mark the highest degree of complexity to which the determination
of a hysterical symptom can attain, and one may therefore only expect to find it in a neurosis
which has persisted for a long time and within which a great deal of organization has taken
place.¹
[1908a, 1938]

The bisexual nature of hysterical symptoms, which can in any event be demonstrated in
numerous cases, is an interesting confirmation of my view that the postulated existence of an
innate bisexual disposition in man is especially clearly visible in the analysis of
psychoneurotics.² An exactly analogous state of affairs occurs in the same field when a person
who is masturbating tries in his conscious phantasies to have the feelings both of the man and
of the woman in the situation which he is picturing. Further counterparts are to be found in
certain hysterical attacks in which the patient simultaneously plays both parts in the underlying
sexual phantasy. In one case which I observed, for instance, the patient pressed her dress up
against her body with one hand (as the woman), while she tried to tear it off with the other (as
the man). This simultaneity of contradictory actions serves to a large extent to obscure the
situation, which is otherwise so plastically portrayed in the attack, and it is thus well suited to
conceal the unconscious phantasy that is at work.
[1908a, 1938]
When one carries out the psycho-analysis of a hysterical woman patient whose complaint is manifested in attacks, one soon becomes convinced that these attacks are nothing else but phantasies translated into the motor sphere, projected on to motility and portrayed in pantomime. It is true that the phantasies are unconscious; but apart from this they are of the same nature as the phantasies which can be observed directly in day-dreams or which can be elicited by interpretation from dreams at night. Often a dream takes the place of an attack, and still more often it explains it, since the same phantasy finds a different expression in a dream and in an attack. We might expect then that by observing an attack we should be able to get to know the phantasy represented in it; but this is seldom possible. As a rule, owing to the influence of the censorship, the pantomimic portrayal of the phantasy has undergone distortions which are completely analogous to the hallucinatory distortions of a dream, so that both of them have, in the first resort, become unintelligible to the subject's own consciousness as well as to the observer's comprehension. A hysterical attack, therefore, needs to be subjected to the same interpretative revision as we employ for night-dreams. But not only are the forces from which the distortion proceeds and the purpose of the distortion the same as those we have come to know through the interpretation of dreams; the technique employed in the distortion is the same too.

[1909a, 1981]

(1) The attack becomes unintelligible through the fact that it represents several phantasies in the same material simultaneously - that is to say through condensation. The elements common to the two (or more) phantasies constitute the nucleus of the representation, as they do in dreams. The phantasies which are thus made to coincide are often of quite a different nature. They may, for instance, be a recent wish and the re-activation of an infantile impression. The same innervations are in that case made to serve both purposes, often in a most ingenious way. Hysterical patients who make a very extensive use of condensation may find a single form of attack sufficient; others express their numerous pathogenic phantasies by a multiplication of the forms of attack.

[1909a, 1982]

(2) The attack becomes obscured through the fact that the patient attempts to carry out the activities of both the figures who appear in the phantasy, that is to say, through multiple identification. Compare, for instance, the example I mentioned in my paper on 'Hysterical Phantasies and their Relation to Bisexuality' (1908a), in which the patient tore off her dress with one hand (as the man) while she pressed it to her body with the other (as the woman).

[1909a, 1982]

(4) Scarcely less confusing and misleading is a reversal of the chronological order within the phantasy that is portrayed, which once more has its complete counterpart in a number of dreams which begin with the end of the action and end with its beginning. Supposing, for instance, that a hysterical woman has a phantasy of seduction in which she is sitting reading in a park with her skirt slightly lifted so that her foot is visible; a gentleman approaches and speaks to her; they then go somewhere and make love to one another. This phantasy is acted out in the attack by her beginning with the convulsive stage, which corresponds to the coitus, by her then getting up, going into another room, sitting down and reading and presently answering an imaginary remark addressed to her.

[1909a, 1982]
The onset of hysterical attacks follows laws that are easily understandable. Since the repressed complex consists of a libidinal cathexis and an ideational content (the phantasy), the attack can be evoked (1) associatively, when the content of the complex (if sufficiently cathected) is touched on by something connected with it in conscious life; (2) organically, when, for internal somatic reasons and as a result of psychical influences from outside, the libidinal cathexis rises above a certain degree; (3) in the service of the primary purpose - as an expression of a 'flight into illness', when reality becomes distressing or frightening - that is, as a consolation; (4) in the service of the secondary purposes, with which the illness allies itself, as soon as, by producing an attack, the patient can achieve an aim that is useful to him. In the last case the attack is directed at particular individuals; it can be put off till they are present, and it gives an impression of being consciously simulated.

Investigation of the childhood history of hysterical patients shows that the hysterical attack is designed to take the place of an auto-erotic satisfaction previously practised and since given up. In a great number of cases this satisfaction (masturbation by contact or by pressure of the thighs, or, again, by movements of the tongue, and so on) recurs during the attack itself, while the subject's consciousness is deflected. Moreover, the onset of an attack that is due to an increase of libido and is in the service of the primary purpose - as a consolation - exactly repeats the conditions under which, at the earlier time, the patient had intentionally sought this auto-erotic satisfaction. The anamnesis of the patient shows the following stages: (a) auto-erotic satisfaction, without ideational content; (b) the same satisfaction, connected with a phantasy which leads to the act of satisfaction; (c) renunciation of the act, with retention of the phantasy; (d) repression of the phantasy, which then comes into effect as a hysterical attack, either in an unchanged form, or in a modified one and adapted to new environmental impressions. Furthermore, (e) the phantasy may even reinstate the act of satisfaction belonging to it which had ostensibly been given up. This is a typical cycle of infantile sexual activity: repression, failure of repression, and return of the repressed.

It was observed that, while the patient was in her states of 'absence (altered personality accompanied by confusion), she was in the habit of muttering a few words to herself which seemed as though they arose from some train of thought that was occupying her mind. The doctor, after getting a report of these words, used to put her into a kind of hypnosis and then repeat them to her so as to induce her to use them as a starting point. The patient complied with the plan, and in this way reproduced in his presence the mental creations which had been occupying her mind during the 'absences' and which had betrayed their existence by the fragmentary words which she had uttered. They were profoundly melancholy phantasies - 'day dreams' we should call them - sometimes characterized by poetic beauty, and their starting-point was as a rule the position of a girl at her father's sick-bed. When she had related a number of these phantasies, she was as if set free, and she was brought back to normal mental life. The improvement in her condition, which would last for several hours, would be succeeded next day by a further attack of 'absence'; and this in turn would be removed in the same way by getting her to put into words her freshly constructed phantasies. It was impossible to escape the conclusion that the alteration in her mental state which was expressed in the 'absences' was a result of the stimulus proceeding from these highly emotional phantasies. The patient herself, who, strange to say, could at this time only speak and understand English, christened this novel kind of treatment the 'talking cure' or used to refer to it jokingly as 'chimney sweeping'.

[1909a, 1983]

[1910a, 2202]
It is in obsessional neuroses that the survival of the omnipotence of thoughts is most clearly visible and that the consequences of this primitive mode of thinking come closest to consciousness. But we must not be misled into supposing that it is a distinguishing feature of this particular neurosis, for analytic investigation reveals the same thing in the other neuroses as well. In all of them what determines the formation of symptoms is the reality not of experience but of thought. Neurotics live in a world apart, where, as I have said elsewhere, only 'neurotic currency' is legal tender; that is to say, they are only affected by what is thought with intensity and pictured with emotion, whereas agreement with external reality is a matter of no importance. What hysterics repeat in their attacks and fix by means of their symptoms are experiences which have occurred in that form only in their imagination though it is true that in the last resort those imagined experiences go back to actual events or are based upon them. To attribute the neurotic sense of guilt to real misdeeds would show an equal misunderstanding. An obsessional neurotic may be weighed down by a sense of guilt that would be appropriate in a mass-murderer, while in fact, from his childhood onwards, he has behaved to his fellow-men as the most considerate and scrupulous member of society. Nevertheless, his sense of guilt has a justification: it is founded on the intense and frequent death wishes against his fellows which are unconsciously at work in him. It has a justification if what we take into account are unconscious thoughts and not intentional deeds. Thus the omnipotence of thoughts, the overvaluation of mental processes as compared with reality, is seen to have unrestricted play in the emotional life of neurotic patients and in everything that derives from it. If one of them undergoes psychoanalytic treatment, which makes what is unconscious in him conscious, he will be unable to believe that thoughts are free and will constantly be afraid of expressing evil wishes, as though their expression would lead inevitably to their fulfilment. This behaviour, as well as the superstitions which he practises in ordinary life, reveals his resemblance to the savages who believe they can alter the external world by mere thinking.

I will illustrate the first of these theses by a few examples. Hysterical attacks have long been recognized as signs of increased emotional excitement and equated with outbursts of affect. Charcot attempted to reduce the multiplicity of their modes of manifestation by means of descriptive formulas; Pierre Janet recognized the unconscious ideas operating behind such attacks; while psycho-analysis has shown that they are mimetic representations of scenes (whether actually experienced or only invented ) with which the patient's imagination is occupied without his becoming conscious of them. The meaning of these pantomimes is concealed from the spectators by means of condensations and distortions of the acts which they represent. And this applies equally to what are described as the 'chronic' symptoms of hysterical patients. All of them are mimetic or hallucinatory representations of phantasies which unconsciously dominate the subject's emotional life and which have the meaning of fulfillments of secret and repressed wishes. The tormenting character of these symptoms is due to the internal conflict into which these patients' minds are driven by the need to combat such unconscious wishes.
One of the ways in which the ego is related to its neuroses is, however, so obvious that it was possible to take it into account from the first. It seems never to be absent; but it is most clearly recognizable in a disorder which we are even to-day far from understanding - traumatic neurosis. For you must know that the same factors always come into operation in the causation and mechanism of every possible form of neurosis; but the chief importance in the construction of the symptoms falls now upon one and now upon another of these factors. The position is like that among the members of a theatrical company. Each of them is regularly cast for his own stock role - hero, confidant, villain, and so on; but each of them will choose a different piece for his benefit performance. In the same way phantasies which turn into symptoms are nowhere more obvious than in hysteria; the anticathexes or reaction-formations of the ego dominate the picture in obsessional neurosis; what in the case of dreams we have termed 'secondary revision' stands in the forefront in paranoia in the shape of delusions, and so on.

A noteworthy relation between the symptoms of the 'actual' neuroses and of the psychoneuroses makes a further important contribution to our knowledge of the formation of symptoms in the latter. For a symptom of an 'actual' neurosis is often the nucleus and first stage of a psychoneurotic symptom. A relation of this kind can be most clearly observed between neurasthenia and the transference neurosis known as 'conversion hysteria', between anxiety neurosis and anxiety hysteria, but also between hypochondria and the forms of disorder which will be mentioned later under the name of paraphrenia (dementia praecox and paranoia). Let us take as an example a case of hysterical headache or lumbar pain. Analysis shows us that, by condensation and displacement, it has become a substitutive satisfaction for a whole number of libidinal phantasies or memories. But this pain was also at one time a real one and it was then a direct sexual-toxic symptom, the somatic expression of a libidinal excitation. We are far from asserting that all hysterical symptoms contain a nucleus of this kind. But it remains a fact that this is especially often the case and that whatever somatic influences (whether normal or pathological) are brought about by libidinal excitation are preferred for the construction of hysterical symptoms. In such cases they play the part of the grain of sand which a mollusc coats with layers of mother-of-pearl. In the same way, the passing indications of sexual excitement which accompany the sexual act are employed by the psychoneurosis as the most convenient and appropriate material for the construction of symptoms.

We have pointed out that this predominance of the life of phantasy and of the illusion born of an unfulfilled wish is the ruling factor in the psychology of neuroses. We have found that what neurotics are guided by is not ordinary objective reality but psychological reality. A hysterical symptom is based upon phantasy instead of upon the repetition of real experience, and the sense of guilt in an obsessional neurosis is based upon the fact of an evil intention which was never carried out. Indeed, just as in dreams and in hypnosis, in the mental operations of a group the function for testing the reality of things falls into the background in comparison with the strength of wishful impulses with their affective cathexis.
It seems to me that we have here an important discovery - namely, that the qualitative factor, the presence of certain neurotic formations, has less practical significance than the quantitative factor, the degree of attention or, more correctly, the amount of cathexis that these structures are able to attract to themselves. Our consideration of the first case, the jealous paranoia, led to a similar estimate of the importance of the quantitative factor, by showing that there also the abnormality essentially consisted in the hypercathexis of the interpretations of someone else's unconscious. We have long known of an analogous fact in the analysis of hysteria. The pathogenic phantasies, derivatives of repressed instinctual impulses, are for a long time tolerated alongside the normal life of the mind, and have no pathogenic effect until by a revolution in the libidinal economy they receive a hypercathexis; not till then does the conflict which leads to the formation of symptoms break out. Thus as our knowledge grows we are increasingly impelled to bring the economic point of view into the foreground. I should also like to throw out the question whether this quantitative factor that I am now dwelling on does not suffice to cover the phenomena which Bleuler and others have lately proposed to name 'switching'. One need only assume that an increase in resistance in the course taken by the psychical current in one direction results in a hypercathexis of another path and thus causes the flow to be switched into that path.

[1922b, 3905]

The normal processes in the formation of conscience must be similar to the abnormal ones described here. We have not yet succeeded in fixing the boundary line between them. It will be observed that here the largest share in the outcome is ascribed to the passive component of repressed femininity. In addition, it must be of importance as an accidental factor whether the father, who is feared in any case, is also especially violent in reality. This was true in Dostoevsky's case, and we can trace back the fact of his extraordinary sense of guilt and of his masochistic conduct of life to a specially strong feminine component. Thus the formula for Dostoevsky is as follows: a person with a specially strong innate bisexual disposition, who can defend himself with special intensity against dependence on a specially severe father. This characteristic of bisexuality comes as an addition to the components of his nature that we have already recognized. His early symptoms of death-like attacks can thus be understood as a father-identification on the part of his ego, which is permitted by his super-ego as a punishment. 'You wanted to kill your father in order to be your father yourself. Now you are your father, but a dead father' - the regular mechanism of hysterical symptoms. And further: 'Now your father is killing you.' For the ego the death symptom is a satisfaction in phantasy of the masculine wish and at the same time a masochistic satisfaction; for the super-ego it is a punitive satisfaction - that is, a sadistic satisfaction. Both of them, the ego and the super-ego, carry on the role of father.

[1928b, 4561]

To sum up, the relation between the subject and his father-object, while retaining its content, has been transformed into a relation between the ego and the super-ego - a new setting on a fresh stage. Infantile reactions from the Oedipus complex such as these may disappear if reality gives them no further nourishment. But the father's character remained the same, or rather, it deteriorated with the years, and thus Dostoevsky's hatred for his rather and his death-wish against that wicked father were maintained. Now it is a dangerous thing if reality fulfils such repressed wishes. The phantasy has become reality and all defensive measures are thereupon reinforced. Dostoevsky's attacks now assumed an epileptic character; they still undoubtedly signified an identification with his father as a punishment, but they had become terrible, like his father's frightful death itself. What further content they had absorbed, particularly what sexual content, escapes conjecture.

[1928b, 4562]
We shall be glad, then, to know the nature of the girl's libidinal relations to her mother. The answer is that they are of very many different kinds. Since they persist through all three phases of infantile sexuality, they also take on the characteristics of the different phases and express themselves by oral, sadistic-anal and phallic wishes. These wishes represent active as well as passive impulses; if we relate them to the differentiation of the sexes which is to appear later - though we should avoid doing so as far as possible - we may call them masculine and feminine. Besides this, they are completely ambivalent, both affectionate and of a hostile and aggressive nature. The latter often only come to light after being changed into anxiety ideas. It is not always easy to point to a formulation of these early sexual wishes; what is most clearly expressed is a wish to get the mother with child and the corresponding wish to bear her a child - both belonging to the phallic period and sufficiently surprising, but established beyond doubt by analytic observation. The attractiveness of these investigations lies in the surprising detailed findings which they bring us. Thus, for instance, we discover the fear of being murdered or poisoned, which may later form the core of a paranoid illness, already present in this pre-Oedipus period, in relation to the mother. Or another case: you will recall an interesting episode in the history of analytic research which caused me many distressing hours. In the period in which the main interest was directed to discovering infantile sexual traumas, almost all my women patients told me that they had been seduced by their father. I was driven to recognize in the end that these reports were untrue and so came to understand that hysterical symptoms are derived from phantasies and not from real occurrences. It was only later that I was able to recognize in this phantasy of being seduced by the father the expression of the typical Oedipus complex in women. And now we find the phantasy of seduction once more in the pre-Oedipus prehistory of girls; but the seducer is regularly the mother. Here, however, the phantasy touches the ground of reality, for it was really the mother who by her activities over the child's bodily hygiene inevitably stimulated, and perhaps even roused for the first time, pleasurable sensations in her genitals.

[1933a, 4722]

I now pass on to my second example, which raises the same problem. An unmarried woman, no longer young, had been cut off from life since puberty by an inability to walk, owing to severe pains in the legs. Her condition was obviously of a hysterical nature, and it had defied many kinds of treatment. An analysis lasting three-quarters of a year removed the trouble and restored to the patient, an excellent and worthy person, her right to a share in life. In the years following her recovery she was consistently unfortunate. There were disasters in her family, and financial losses, and, as she grew older, she saw every hope of happiness in love and marriage vanish. But the one-time invalid stood up to all this valiantly and was a support to her family in difficult times. I cannot remember whether it was twelve or fourteen years after the end of her analysis that, owing to profuse haemorrhages, she was obliged to undergo a gynaecological examination. A myoma was found, which made a complete hysterectomy advisable. From the time of this operation, the woman became ill once more. She fell in love with her surgeon, wallowed in masochistic phantasies about the fearful changes in her inside - phantasies with which she concealed her romance - and proved inaccessible to a further attempt at analysis. She remained abnormal to the end of her life. The successful analytic treatment took place so long ago that we cannot expect too much from it; it was in the earliest years of my work as an analyst. No doubt the patient's second illness may have sprung from the same source as her first one which had been successfully overcome: it may have been a different manifestation of the same repressed impulses, which the analysis had only incompletely resolved. But I am inclined to think that, were it not for the new trauma, there would have been no fresh outbreak of neurosis.

[1937c, 5020]
As regards the second kind of emotional reaction, which is not directed against me this time, but against my patient - supposing that my view of her is correct - and which regards the perverse nature of her phantasies as horrible, I should like to say emphatically that a medical man has no business to indulge in such passionate condemnation. I may also remark in passing that it seems to me superfluous for a physician who is writing upon the aberrations of the sexual instincts to seize every opportunity of inserting into the text expressions of his personal repugnance at such revolting things. We are faced by a fact; and it is to be hoped that we shall grow accustomed to it, when we have put our own tastes on one side. We must learn to speak without indignation of what we call the sexual perversions - instances in which the sexual function has extended its limits in respect either to the part of the body concerned or to the sexual object chosen. The uncertainty in regard to the boundaries of what is to be called normal sexual life, when we take different races and different epochs into account, should in itself be enough to cool the zealot's ardour. We surely ought not to forget that the perversion which is the most repellent to us, the sensual love of a man for a man, was not only tolerated by a people so far our superiors in cultivation as were the Greeks, but was actually entrusted by them with important social functions. The sexual life of each one of us extends to a slight degree - now in this direction, now in that - beyond the narrow lines imposed as the standard of normality. The perversions are neither bestial nor degenerate in the emotional sense of the word. They are a development of germs all of which are contained in the undifferentiated sexual disposition of the child, and which, by being suppressed or by being diverted to higher, asexual aims - by being 'sublimated' - are destined to provide the energy for a great number of our cultural achievements. When, therefore, any one has become a gross and manifest pervert, it would be more correct to say that he has remained one, for he exhibits a certain stage of inhibited development. All psychoneurotics are persons with strongly marked perverse tendencies, which have been repressed in the course of their development and have become unconscious. Consequently their unconscious phantasies show precisely the same content as the documentarily recorded actions of perverts - even though they have not read Krafft-Ebing's Psychopathia Sexualis, to which simple-minded people attribute such a large share of the responsibility for the production of perverse tendencies. Psychoneuroses are, so to speak, the negative of perversions. In neurotics their sexual constitution, under which the effects of heredity are included, operates in combination with any accidental influences in their life which may disturb the development of normal sexuality. A stream of water which meets with an obstacle in the river-bed is dammed up and flows back into old channels which had formerly seemed fated to run dry. The motive forces leading to the formation of hysterical symptoms draw their strength not only from repressed normal sexuality but also from unconscious perverse activities.¹

[1905e, 1387]
The less repellent of the so-called sexual perversions are very widely diffused among the whole population, as everyone knows except medical writers upon the subject. Or, I should rather say, they know it too; only they take care to forget it at the moment when they take up their pens to write about it. So it is not to be wondered at that this hysterical girl of nearly nineteen, who had heard of the occurrence of such a method of sexual intercourse (sucking at the male organ), should have developed an unconscious phantasy of this sort and should have given it expression by an irritation in her throat and by coughing. Nor would it have been very extraordinary if she had arrived at such a phantasy even without having had any enlightenment from external sources - an occurrence which I have quite certainly observed in other patients. For in her case a noteworthy fact afforded the necessary somatic prerequisite for this independent creation of a phantasy which would coincide with the practices of perverts. She remembered very well that in her childhood she had been a thumb-sucker. Her father, too recollected breaking her of the habit after it had persisted into her fourth or fifth year. Dora herself had a clear picture of a scene from her early childhood in which she was sitting on the floor in a corner sucking her left thumb and at the same time tugging with her right hand at the lobe of her brother's ear as he sat quietly beside her. Here we have an instance of the complete form of self-gratification by sucking, as it has also been described to me by other patients, who had subsequently become anaesthetic and hysterical.

¹ The contents of the clearly conscious phantasies of perverts (which in favourable circumstances can be transformed into manifest behaviour), of the delusional fears of paranoics (which are projected in a hostile sense on to other people) and of the unconscious phantasies of hysterics (which psycho-analysis reveals behind their symptoms) - all of these coincide with one another even down to their details.

We are all familiar with the delusional imaginings of the paranoic, which are concerned with the greatness and the sufferings of his own self and which appear in forms that are quite typical and almost monotonous. We have also become acquainted, through numerous accounts, with the strange performances with which certain perverts stage their sexual satisfaction, whether in idea or reality. Nevertheless, it may be new to some readers to hear that quite analogous psychical structures are regularly present in all the psychoneuroses, particularly in hysteria, and that these latter - which are known as hysterical phantasies - can be seen to have important connections with the causation of the neurotic symptoms.

Anyone who studies hysteria, therefore, soon finds his interest turned away from its symptoms to the phantasies from which they proceed. The technique of psycho-analysis enables us in the first place to infer from the symptoms what those unconscious phantasies are and then to make them conscious to the patient. By this means it has been found that the content of the hysterics unconscious phantasies corresponds completely to the situations in which satisfaction is consciously obtained by perverts; and if anyone is at a loss for examples of such situations he has only to recall the world-famous performances of the Roman Emperors, the wild excesses of which were, of course, determined only by the enormous and unrestrained power possessed by the authors of the phantasies. The delusions of paranoics are phantasies of the same nature, though they are phantasies which have become directly conscious. They rest on the sadomasochistic components of the sexual instinct, and they, too, may find their complete counterpart in certain unconscious phantasies of hysterical subjects. We also know of cases - cases which have their practical importance as well - in which hysterics do not give expression to their phantasies in the form of symptoms but as conscious realizations, and in that way devise and stage assaults, attacks or acts of sexual aggression.
Though even to-day I do not consider these assertions incorrect, it is not to be wondered at that, in the course of ten years of continuous effort at reaching an understanding of these phenomena, I have made a considerable step forward from the views I then held, and now believe that I am in a position, on the basis of deeper experience, to correct the insufficiencies, the displacements and the misunderstandings under which my theory then laboured. At that time my material was still scanty, and it happened by chance to include a disproportionately large number of cases in which sexual seduction by an adult or by older children played the chief part in the history of the patient's childhood. I thus over-estimated the frequency of such events (though in other respects they were not open to doubt). Moreover, I was at that period unable to distinguish with certainty between falsifications made by hysterics in their memories of childhood and traces of real events. Since then I have learned to explain a number of phantasies of seduction as attempts at fending off memories of the subject's own sexual activity (infantile masturbation). When this point had been clarified, the 'traumatic' element in the sexual experiences of childhood lost its importance and what was left was the realization that infantile sexual activity (whether spontaneous or provoked) prescribes the direction that will be taken by later sexual life after maturity. The same clarification (which corrected the most important of my early mistakes) also made it necessary to modify my view of the mechanism of hysterical symptoms. They were now no longer to be regarded as direct derivatives of the repressed memories of childhood experiences; but between the symptoms and the childish impressions there were inserted the patient's phantasies (or imaginary memories), mostly produced during the years of puberty, which on the one side were built up out of and over the childhood memories and on the other side were transformed directly into the symptoms. It was only after the introduction of this element of hysterical phantasies that the texture of the neurosis and its relation to the patient's life became intelligible; a surprising analogy came to light, too, between these unconscious phantasies of hysterics and the imaginary creations of paranoics which become conscious as delusions.

We are all familiar with the delusional imaginings of the paranoid, which are concerned with the greatness and the sufferings of his own self and which appear in forms that are quite typical and almost monotonous. We have also become acquainted, through numerous accounts, with the strange performances with which certain perverts stage their sexual satisfaction, whether in idea or reality. Nevertheless, it may be new to some readers to hear that quite analogous psychical structures are regularly present in all the psychoneuroses, particularly in hysteria, and that these latter - which are known as hysterical phantasies - can be seen to have important connections with the causation of the neurotic symptoms.

Anyone who studies hysteria, therefore, soon finds his interest turned away from its symptoms to the phantasies from which they proceed. The technique of psycho-analysis enables us in the first place to infer from the symptoms what those unconscious phantasies are and then to make them conscious to the patient. By this means it has been found that the content of the hysterics' unconscious phantasies corresponds completely to the situations in which satisfaction is consciously obtained by perverts; and if anyone is at a loss for examples of such situations he has only to recall the world-famous performances of the Roman Emperors, the wild excesses of which were, of course, determined only by the enormous and unrestrained power possessed by the authors of the phantasies. The delusions of paranoics are phantasies of the same nature, though they are phantasies which have become directly conscious. They rest on the sadomasochistic components of the sexual instinct, and they, too, may find their complete counterpart in certain unconscious phantasies of hysterical subjects. We also know of cases - cases which have their practical importance as well - in which hysterics do not give expression to their phantasies in the form of symptoms but as conscious realizations, and in that way devise and stage assaults, attacks or acts of sexual aggression.
Discussions like this, Gentlemen, are bound to become somewhat arid. So let us turn to clinical material in order to find applications of it that will be a little more impressive. Hysteria and obsessional neuroses are, as you know, the two chief representatives of the group of transference neuroses. Now it is true that in hysteria there is a regression of the libido to the primary incestuous sexual objects and that this occurs quite regularly; but there is as good as no regression to an earlier stage of the sexual organization. To offset this, the chief part in the mechanism of hysteria is played by repression. If I might venture to complete what we already know for certain about this neurosis by making a construction, I might explain the position thus. The unification of the component instincts under the primacy of the genitals has been accomplished; but its results come up against the resistance of the preconscious system which is linked with consciousness. Thus the genital organization holds good for the unconscious, but not in the same way for the preconscious; and this rejection on the part of the preconscious brings about a picture which has certain resemblances to the state of things before genital primacy. But it is nevertheless something quite different.

Obsessional neurosis is unquestionably the most interesting and repaying subject of analytic research. But as a problem it has not yet been mastered. It must be confessed that, if we endeavour to penetrate more deeply into its nature, we still have to rely upon doubtful assumptions and unconfirmed suppositions. Obsessional neurosis originates, no doubt, in the same situation as hysteria, namely, the necessity of fending off the libidinal demands of the Oedipus complex. Indeed, every obsessional neurosis seems to have a substratum of hysterical symptoms that have been formed at a very early stage. But it is subsequently shaped along quite different lines owing to a constitutional factor. The genital organization of the libido turns out to be feeble and insufficiently resistant, so that when the ego begins its defensive efforts the first thing it succeeds in doing is to throw back the genital organization (of the phallic phase), in whole or in part, to the earlier sadistic-anal level. This fact of regression is decisive for all that follows.

This is as far as our investigations into the formation of symptoms take us. It is hardly worth while summing them up, for the results they have yielded are scanty and incomplete and tell us scarcely anything that we do not already know. It would be fruitless to turn our attention to symptom-formation in other disorders besides phobias, conversion hysteria and obsessional neurosis, for too little is known about them. But in reviewing those three neuroses together we are brought up against a very serious problem the consideration of which can no longer be put off. All three have as their outcome the destruction of the Oedipus complex; and in all three the motive force of the ego’s opposition is, we believe, the fear of castration. Yet it is only in the phobias that this fear comes to the surface and is acknowledged. What has become of it in the other two neuroses? How has the ego spared itself this fear? The problem becomes accentuated when we recall the possibility, already referred to, that anxiety arises directly, by a kind of fermentation, from a libidinal cathexis whose processes have been disturbed. Furthermore, is it absolutely certain that fear of castration is the only motive force of repression (or defence)? If we think of neuroses in women we are bound to doubt it. For though we can with certainty establish in them the presence of a castration complex, we can hardly speak with propriety of castration anxiety where castration has already taken place.
We shall be glad, then, to know the nature of the girl's libidinal relations to her mother. The answer is that they are of very many different kinds. Since they persist through all three phases of infantile sexuality, they also take on the characteristics of the different phases and express themselves by oral, sadistic-anal and phallic wishes. These wishes represent active as well as passive impulses; if we relate them to the differentiation of the sexes which is to appear later - though we should avoid doing so as far as possible - we may call them masculine and feminine. Besides this, they are completely ambivalent, both affectionate and of a hostile and aggressive nature. The latter often only come to light after being changed into anxiety ideas. It is not always easy to point to a formulation of these early sexual wishes; what is most clearly expressed is a wish to get the mother with child and the corresponding wish to bear her a child - both belonging to the phallic period and sufficiently surprising, but established beyond doubt by analytic observation. The attractiveness of these investigations lies in the surprising detailed findings which they bring us. Thus, for instance, we discover the fear of being murdered or poisoned, which may later form the core of a paranoic illness, already present in this pre-Oedipus period, in relation to the mother. Or another case: you will recall an interesting episode in the history of analytic research which caused me many distressing hours. In the period in which the main interest was directed to discovering infantile sexual traumas, almost all my women patients told me that they had been seduced by their father. I was driven to recognize in the end that these reports were untrue and so came to understand that hysterical symptoms are derived from phantasies and not from real occurrences. It was only later that I was able to recognize in this phantasy of being seduced by the father the expression of the typical Oedipus complex in women. And now we find the phantasy of seduction once more in the pre-Oedipus prehistory of girls; but the seducer is regularly the mother. Here, however, the phantasy touches the ground of reality, for it was really the mother who by her activities over the child's bodily hygiene inevitably stimulated, and perhaps even roused for the first time, pleasurable sensations in her genitals.
[1933a, 4722]
If we consider a number of analyses of obsessional neurotics we shall find it impossible to escape the impression that a relation between love and hatred such as we have found in our present patient is among the most frequent, the most marked, and probably, therefore, the most important characteristics of obsessional neurosis. But however tempting it may be to bring the problem of the 'choice of neurosis' into connection with instinctual life, there are reasons enough for avoiding such a course. For we must remember that in every neurosis we come upon the same suppressed instincts behind the symptoms. After all, hatred, kept suppressed in the unconscious by love, plays a great part in the pathogenesis of hysteria and paranoia. We know too little of the nature of love to be able to arrive at any definite conclusion here; and, in particular, the relation between the negative factor¹ in love and the sadistic components of the libido remains completely obscure. What follows is therefore to be regarded as no more than a provisional explanation. We may suppose, then, that in the cases of unconscious hatred with which we are concerned the sadistic components of love have, from constitutional causes, been exceptionally strongly developed, and have consequently undergone a premature and all too thorough suppression, and that the neurotic phenomena we have observed arise on the one hand from conscious feelings of affection which have become exaggerated as a reaction, and on the other hand from sadism persisting in the unconscious in the form of hatred.

[1909d, 2187]
The other members of this class of wish-fulfilments - hysterical symptoms, for instance - possess one essential characteristic, however, which I cannot discover in dreams. I have learnt from the researches which I have mentioned so often in the course of this work that in order to bring about the formation of a hysterical symptom both currents of our mind must converge. A symptom is not merely the expression of a realized unconscious wish; a wish from the preconscious which is fulfilled by the same symptom must also be present. So that the symptom will have of at least two determinants, one arising from each of the systems involved in the conflict. As in the case of dreams, there are no limits to the further determinants that may be present - to the 'overdetermination' of the symptoms. The determinant which does not arise from the Ucs. is invariably, so far as I know, a train of thought reacting against the unconscious wish - a self-punishment, for instance. I can therefore make the quite general assertion that a hysterical symptom develops only where the fulfilments of two opposing wishes, arising each from a different psychical system, are able to converge in a single expression. (Compare in this connection my most recent formulations on the origin of hysterical symptoms in my paper on hysterical phantasies and their relation to bisexuality.) Examples would serve very little purpose here, since nothing but an exhaustive elucidation of the complications involved could carry conviction. I will therefore leave my assertion to stand for itself and only quote an example in order to make the point clear, and not to carry conviction. In one of my women patients, then, hysterical vomiting turned out to be on the one hand the fulfilment of an unconscious phantasy dating from her puberty - of a wish, that is, that she might be continuously pregnant and have innumerable children, with a further wish, added later, that she might have them by as many men as possible. A powerful defensive impulse had sprung up against this unbridled wish. And, since the patient might lose her figure and her good looks as a result of her vomiting, and so might cease to be attractive to anyone, the symptom was acceptable to the punitive train of thought as well; and since it was permitted by both sides it could become a reality. This was the same method of treating a wish-fulfilment as was adopted by the Parthian queen towards the Roman triumvir Crassus. Believing that he had embarked on his expedition out of love of gold, she ordered molten gold to be poured down his throat when he was dead: 'Now', she said, 'you have what you wanted.' But all that we so far know about dreams is that they express the fulfilment of a wish from the unconscious; it seems as though the dominant, preconscious system acquiesces in this after insisting upon a certain number of distortions. Nor is it possible as a general rule to find a train of thought opposed to the dream-wish and, like its counterpart, realized in the dream. Only here and there in dream-analyses do we come upon signs of reactive creations, like, for instance, my affectionate feelings for my friend R. in the dream of my uncle (cf. p. 637 ff.). But we can find the missing ingredient from the preconscious elsewhere. Whereas the wish from the Ucs. is able to find expression in the dream after undergoing distortions of every kind, the dominant system withdraws into a wish to sleep, realizes that wish by bringing about the modifications which it is able to produce in the cathexes within the psychical apparatus, and persists in that wish throughout the whole duration of sleep.¹ [1900a, 999]
Here is an instance of this. Another physician in Vienna, whose conviction of the unimportance of sexual factors in hysteria has probably been very much strengthened by such experiences as this, was consulted in the case of a fourteen-year-old girl who suffered from dangerous hysterical vomiting. He made up his mind to ask her the painful question whether by any chance she had ever had a love-affair with a man. ‘No!’ answered the child, no doubt with well-affected astonishment; and then repeated to her mother in her irreverent way: ‘Only fancy! the old stupid asked me if I was in love!’ She afterwards came to me for treatment, and proved - though not during our very first conversation, to be sure - to have been a masturbator for many years, with a considerable leucorrhoeal discharge (which had a close bearing on her vomiting). She had finally broken herself of the habit, but was tormented in her abstinence by the most acute sense of guilt, so that she looked upon every misfortune that befell her family as a divine punishment for her transgression. Besides this, she was under the influence of the romance of an unmarried aunt, whose pregnancy (a second determinant for her vomiting) was supposed to have been happily hidden from her. The girl was looked upon as a ‘mere child,’ but she turned out to be initiated into all the essentials of sexual relations.

Her alleged facial neuralgia was thus a self-punishment - remorse at having once given Herr K. a box on the ear, and at having transferred her feelings of revenge on to me. I do not know what kind of help she wanted from me, but I promised to forgive her for having deprived me of the satisfaction of affording her a far more radical cure for her troubles.

It is essentially in hysteria and in states of a hysterical type that this is found. Here the mechanism by which the sense of guilt remains unconscious is easy to discover. The hysterical ego fends off a distressing perception with which the criticisms of its super-ego threaten it, in the same way in which it is in the habit of fending off an unendurable object-cathexis - by an act of repression. It is the ego, therefore, that is responsible for the sense of guilt remaining unconscious. We know that as a rule the ego carries out repressions in the service and at the behest of its super-ego; but this is a case in which it has turned the same weapon against its harsh taskmaster. In obsessional neurosis, as we know, the phenomena of reaction-formation predominate; but here the ego succeeds only in keeping at a distance the material to which the sense of guilt refers.
In this secondary defensive struggle the ego presents two faces with contradictory expressions. The one line of behaviour it adopts springs from the fact that its very nature obliges it to make what must be regarded as an attempt at restoration or reconciliation. The ego is an organization. It is based on the maintenance of free intercourse and of the possibility of reciprocal influence between all its parts. Its desexualized energy still shows traces of its origin in its impulsion to bind together and unify, and this necessity to synthesize grows stronger in proportion as the strength of the ego increases. It is therefore only natural that the ego should try to prevent symptoms from remaining isolated and alien by using every possible method to bind them to itself in one way or another, and to incorporate them into its organization by means of those bonds. As we know, a tendency of this kind is already operative in the very act of forming a symptom. A classical instance of this are those hysterical symptoms which have been shown to be a compromise between the need for satisfaction and the need for punishment. Such symptoms participate in the ego from the very beginning, since they fulfil a requirement of the super-ego, while on the other hand they represent positions occupied by the repressed and points at which an irruption has been made by it into the ego-organization. They are a kind of frontier-station with a mixed garrison. (Whether all primary hysterical symptoms are constructed on these lines would be worth enquiring into very carefully.) The ego now proceeds to behave as though it recognized that the symptom had come to stay and that the only thing to do was to accept the situation in good part and draw as much advantage from it as possible. It makes an adaptation to the symptom - to this piece of the internal world which is alien to it - just as it normally does to the real external world. It can always find plenty of opportunities for doing so. The presence of a symptom may entail a certain impairment of capacity, and this can be exploited to appease some demand on the part of the super-ego or to refuse some claim from the external world. In this way the symptom gradually comes to be the representative of important interests; it is found to be useful in asserting the position of the self and becomes more and more closely merged with the ego and more and more indispensable to it. It is only very rarely that the physical process of 'healing' round a foreign body follows such a course as this. There is a danger, too, of exaggerating the importance of a secondary adaptation of this kind to a symptom, and of saying that the ego has created the symptom merely in order to enjoy its advantages. It would be equally true to say that a man who had lost his leg in the war had got it shot away so that he might henceforward live on his pension without having to do any more work.

[1926d, 4259]

The reaction-formations in the ego of the obsessional neurotic, which we recognize as exaggerations of normal character-formation, should be regarded, I think, as yet another mechanism of defence and placed alongside of regression and repression. They seem to be absent or very much weaker in hysteria. Looking back, we can now get an idea of what is peculiar to the defensive process in hysteria. It seems that in it the process is limited to repression alone. The ego turns away from the disagreeable instinctual impulse, leaves it to pursue its course in the unconscious, and takes no further part in its fortunes. This view cannot be absolutely correct, for we are acquainted with the case in which a hysterical symptom is at the same time a fulfilment of a penalty imposed by the super-ego; but it may describe a general characteristic of the behaviour of the ego in hysteria.

[1926d, 4274]
The normal processes in the formation of conscience must be similar to the abnormal ones described here. We have not yet succeeded in fixing the boundary line between them. It will be observed that here the largest share in the outcome is ascribed to the passive component of repressed femininity. In addition, it must be of importance as an accidental factor whether the father, who is feared in any case, is also especially violent in reality. This was true in Dostoevsky's case, and we can trace back the fact of his extraordinary sense of guilt and of his masochistic conduct of life to a specially strong feminine component. Thus the formula for Dostoevsky is as follows: a person with a specially strong innate bisexual disposition, who can defend himself with special intensity against dependence on a specially severe father. This characteristic of bisexuality comes as an addition to the components of his nature that we have already recognized. His early symptoms of death-like attacks can thus be understood as a father-identification on the part of his ego, which is permitted by his super-ego as a punishment. 'You wanted to kill your father in order to be your father yourself. Now you are your father, but a dead father' - the regular mechanism of hysterical symptoms. And further: 'Now your father is killing you.' For the ego the death symptom is a satisfaction in phantasy of the masculine wish and at the same time a masochistic satisfaction; for the super-ego it is a punitive satisfaction - that is, a sadistic satisfaction. Both of them, the ego and the super-ego, carry on the role of father.
[1928b, 4561]
Here, then, we have a true hysterical symptom. The fever may have been organically determined - perhaps by one of those very frequent attacks of influenza that are not localized in any particular part of the body. Nevertheless it was now established that the neurosis had seized upon this chance event and made use of it for an utterance of its own. Dora had therefore given herself an illness which she had read up about in the encyclopaedia, and she had punished herself for dipping into its pages. But she was forced to recognize that the punishment could not possibly apply to her reading the innocent article in question. It must have been inflicted as the result of a process of displacement, after another occasion of more guilty reading had become associated with this one; and the guilty occasion must lie concealed in her memory behind the contemporaneous innocent one.¹ It might still be possible, perhaps, to discover the nature of the subjects she had read about on that other occasion.

¹

Dora had listened to me without any of her usual contradictions. She seemed to be moved; she said good-bye to me very warmly, with the heartiest wishes for the New Year, and - came no more. Her father, who called on me two or three times afterwards, assured me that she would come back again, and said it was easy to see that she was eager for the treatment to continue. But it must be confessed that Dora's father was never entirely straightforward. He had given his support to the treatment so long as he could hope that I should 'talk' Dora out of her belief that there was something more than a friendship between him and Frau K. His interest faded when he observed that it was not my intention to bring about that result. I knew Dora would not come back again. Her breaking off so unexpectedly, just when my hopes of a successful termination of the treatment were at their highest, and her thus bringing those hopes to nothing - this was an unmistakable act of vengeance on her part. Her purpose of self-injury also profited by this action. No one who, like me, conjures up the most evil of those half-tamed demons that inhabit the human breast, and seeks to wrestle with them, can expect to come through the struggle unscathed. Might I perhaps have kept the girl under my treatment if I myself had acted a part, if I had exaggerated the importance to me of her staying on, and had shown a warm personal interest in her - a course which, even after allowing for my position as her physician, would have been tantamount to providing her with a substitute for the affection she longed for? I do not know. Since in every case a portion of the factors that are encountered under the form of resistance remains unknown, I have always avoided acting a part, and have contented myself with practising the humbler arts of psychology. In spite of every theoretical interest and of every endeavour to be of assistance as a physician, I keep the fact in mind that there must be some limits set to the extent to which psychological influence may be used, and I respect as one of these limits the patient's own will and understanding.

Her alleged facial neuralgia was thus a self-punishment - remorse at having once given Herr K. a box on the ear, and at having transferred her feelings of revenge on to me. I do not know what kind of help she wanted from me, but I promised to forgive her for having deprived me of the satisfaction of affording her a far more radical cure for her troubles.

The involuntary passing of urine is certainly not to be regarded as incompatible with the diagnosis of a hysterical attack; it is merely repeating the infantile form of a violent pollution. Moreover, biting the tongue may also be met with in undoubted cases of hysteria. It is no more inconsistent with hysteria than it is with love-making. It occurs more readily in attacks if the patient's attention had been drawn by the doctor's questions to the difficulties of making a differential diagnosis. Self-injury may occur in hysterical attacks (more frequently in the case of men) where it repeats an accident in childhood - as, for instance, the result of a romp.
There are clearly also inhibitions which serve the purpose of self-punishment. This is often the case in inhibitions of professional activities. The ego is not allowed to carry on those activities, because they would bring success and gain, and these are things which the severe super-ego has forbidden. So the ego gives them up too, in order to avoid coming into conflict with the super-ego. [1926d, 4251]

In this secondary defensive struggle the ego presents two faces with contradictory expressions. The one line of behaviour it adopts springs from the fact that its very nature obliges it to make what must be regarded as an attempt at restoration or reconciliation. The ego is an organization. It is based on the maintenance of free intercourse and of the possibility of reciprocal influence between all its parts. Its desexualized energy still shows traces of its origin in its impulsion to bind together and unify, and this necessity to synthesize grows stronger in proportion as the strength of the ego increases. It is therefore only natural that the ego should try to prevent symptoms from remaining isolated and alien by using every possible method to bind them to itself in one way or another, and to incorporate them into its organization by means of those bonds. As we know, a tendency of this kind is already operative in the very act of forming a symptom. A classical instance of this are those hysterical symptoms which have been shown to be a compromise between the need for satisfaction and the need for punishment. Such symptoms participate in the ego from the very beginning, since they fulfil a requirement of the super-ego, while on the other hand they represent positions occupied by the repressed and points at which an irruption has been made by it into the ego-organization. They are a kind of frontier-station with a mixed garrison. (Whether all primary hysterical symptoms are constructed on these lines would be worth enquiring into very carefully.) The ego now proceeds to behave as though it recognized that the symptom had come to stay and that the only thing to do was to accept the situation in good part and draw as much advantage from it as possible. It makes an adaptation to the symptom - to this piece of the internal world which is alien to it - just as it normally does to the real external world. It can always find plenty of opportunities for doing so. The presence of a symptom may entail a certain impairment of capacity, and this can be exploited to appease some demand on the part of the super-ego or to refuse some claim from the external world. In this way the symptom gradually comes to be the representative of important interests; it is found to be useful in asserting the position of the self and becomes more and more closely merged with the ego and more and more indispensable to it. It is only very rarely that the physical process of 'healing' round a foreign body follows such a course as this. There is a danger, too, of exaggerating the importance of a secondary adaptation of this kind to a symptom, and of saying that the ego has created the symptom merely in order to enjoy its advantages. It would be equally true to say that a man who had lost his leg in the war had got it shot away so that he might thenceforward live on his pension without having to do any more work. [1926d, 4259]

The reaction-formations in the ego of the obsessional neurotic, which we recognize as exaggerations of normal character-formation, should be regarded, I think, as yet another mechanism of defence and placed alongside of regression and repression. They seem to be absent or very much weaker in hysteria. Looking back, we can now get an idea of what is peculiar to the defensive process in hysteria. It seems that in it the process is limited to repression alone. The ego turns away from the disagreeable instinctual impulse, leaves it to pursue its course in the unconscious, and takes no further part in its fortunes. This view cannot be absolutely correct, for we are acquainted with the case in which a hysterical symptom is at the same time a fulfillment of a penalty imposed by the super-ego; but it may describe a general characteristic of the behaviour of the ego in hysteria. [1926d, 4274]
I am tempted to extract a first advantage from this more restricted view of the case by applying it to the process of repression. As we have learned, neurotic symptoms are, in their essence, substitutive satisfactions for unfulfilled sexual wishes. In the course of our analytic work we have discovered to our surprise that perhaps every neurosis conceals a quota of unconscious sense of guilt, which in its turn fortifies the symptoms by making use of them as a punishment. It now seems plausible to formulate the following proposition. When an instinctual trend undergoes repression, its libidinal elements are turned into symptoms, and its aggressive components into a sense of guilt. Even if this proposition is only an average approximation to the truth, it is worthy of our interest.

[1930a, 4527]

We know the meaning and intention of such deathlike attacks. They signify an identification with a dead person, either with someone who is really dead or with someone who is still alive and whom the subject wishes dead. The latter case is the more significant. The attack then has the value of a punishment. One has wished another person dead, and now one is this other person and is dead oneself. At this point psycho-analytical theory brings in the assertion that for a boy this other person is usually his father and that the attack (which is termed hysterical) is thus a self-punishment for a death-wish against a hated father.

[1928b, 4559]

The normal processes in the formation of conscience must be similar to the abnormal ones described here. We have not yet succeeded in fixing the boundary line between them. It will be observed that here the largest share in the outcome is ascribed to the passive component of repressed femininity. In addition, it must be of importance as an accidental factor whether the father, who is feared in any case, is also especially violent in reality. This was true in Dostoevsky's case, and we can trace back the fact of his extraordinary sense of guilt and of his masochistic conduct of life to a specially strong feminine component. Thus the formula for Dostoevsky is as follows: a person with a specially strong innate bisexual disposition, who can defend himself with special intensity against dependence on a specially severe father. This characteristic of bisexuality comes as an addition to the components of his nature that we have already recognized. His early symptoms of death-like attacks can thus be understood as a father-identification on the part of his ego, which is permitted by his super-ego as a punishment. 'You wanted to kill your father in order to be your father yourself. Now you are your father, but a dead father' - the regular mechanism of hysterical symptoms. And further: 'Now your father is killing you.' For the ego the death symptom is a satisfaction in phantasy of the masculine wish and at the same time a masochistic satisfaction; for the super-ego it is a punitive satisfaction - that is, a sadistic satisfaction. Both of them, the ego and the super-ego, carry on the role of father.

[1928b, 4561]

To sum up, the relation between the subject and his father-object, while retaining its content, has been transformed into a relation between the ego and the super-ego - a new setting on a fresh stage. Infantile reactions from the Oedipus complex such as these may disappear if reality gives them no further nourishment. But the father's character remained the same, or rather, it deteriorated with the years, and thus Dostoevsky's hatred for his rather and his death-wish against that wicked father were maintained. Now it is a dangerous thing if reality fulfils such repressed wishes. The phantasy has become reality and all defensive measures are thereupon reinforced. Dostoevsky's attacks now assumed an epileptic character; they still undoubtedly signified an identification with his father as a punishment, but they had become terrible, like his father's frightful death itself. What further content they had absorbed, particularly what sexual content, escapes conjecture.

[1928b, 4562]
It was during these days, too, that she made her complaints about gaps in her memory 'especially about the most important events', from which I concluded that the work I had done two years previously had been thoroughly effective and lasting. One day, she was walking with me along an avenue that led from the house to an inlet in the sea and I ventured to ask whether the path was often infested by toads. By way of reply she threw a reproachful glance at me, though unaccompanied by signs of horror; she amplified this a moment later with the words 'but the ones here are real'. During the hypnosis, which I induced in order to deal with her railway inhibition, she herself seemed dissatisfied with the answers she gave me, and she expressed a fear that in future she was likely to be less obedient under hypnosis than before. I determined to convince her of the contrary. I wrote a few words on a piece of paper, handed it to her and said:

'At lunch to-day you will pour me out a glass of red wine, just as you did yesterday. As I raise the glass to my lips you will say: "Oh, please pour me out a glass, too", and when I reach for the bottle, you will say: "No thank you, I don't think I will after all". You will then put your hand in your bag, draw out the piece of paper and find those same words written on it.' This was in the morning. A few hours later the little episode took place exactly as I had pre-arranged it, and so naturally that none of the many people present noticed anything. When she asked me for the wine she showed visible signs of an internal struggle - for she never drank wine - and after she had refused the drink with obvious relief, she put her hand into her bag and drew out the piece of paper on which appeared the last words she had spoken. She shook her head and stared at me in astonishment.

Dora was by that time in the first bloom of youth - a girl of intelligent and engaging looks. But she was a source of heavy trials for her parents. Low spirits and an alteration in her character had now become the main features of her illness. She was clearly satisfied neither with herself nor with her family; her attitude towards her father was unfriendly, and she was on very bad terms with her mother, who was bent upon drawing her into taking a share in the work of the house. She tried to avoid social intercourse, and employed herself - so far as she was allowed to by the fatigue and lack of concentration of which she complained - with attending lectures for women and with carrying on more or less serious studies. One day her parents were thrown into a state of great alarm by finding on the girl's writing-desk, or inside it, a letter in which she took leave of them because, as she said, she could no longer endure her life. Her father, indeed, being a man of some perspicacity, guessed that the girl had no serious suicidal intentions. But he was none the less very much shaken; and when one day, after a slight passage of words between him and his daughter, she had a first attack of loss of consciousness - an event which was subsequently covered by an amnesia - it was determined, in spite of her reluctance, that she should come to me for treatment.

In order to show that such a supplement to the story was possible, I questioned the patient very cautiously as to whether she knew anything of the physical signs of excitement in a man's body. Her answer, as touching the present, was 'Yes', but, as touching the time of the episode, 'I think not'. From the very beginning I took the greatest pains with this patient not to introduce her to any fresh facts in the region of sexual knowledge; and I did this, not from any conscientious motives, but because I was anxious to subject my assumptions to a rigorous test in this case. Accordingly, I did not call a thing by its name until her allusions to it had become so unambiguous that there seemed very slight risk in translating them into direct speech. Her answer was always prompt and frank: she knew about it already. But the question of where her knowledge came from was a riddle which her memories were unable to solve. She had forgotten the source of all her information on this subject.
I did not find it easy, however, to direct the patient's attention to her relations with Herr K. She declared that she had done with him. The uppermost layer of all her associations during the sessions, and everything of which she was easily conscious and of which she remembered having been conscious the day before, was always connected with her father. It was quite true that she could not forgive her father for continuing his relations with Herr K. and more particularly with Frau K. But she viewed those relations in a very different light from that in which her father wished them to appear. In her mind there was no doubt that what bound her father to this young and beautiful woman was a common love-affair. Nothing that could help to confirm this view had escaped her perception, which in this connection was pitilessly sharp; here there were no gaps to be found in her memory. Their acquaintance with the K.'s had begun before her father's serious illness; but it had not become intimate until the young woman had officially taken on the position of nurse during that illness, while Dora's mother had kept away from the sick-room. During the first summer holidays after his recovery things had happened which must have opened everyone's eyes to the true character of this 'friendship'. The two families had taken a suite of rooms in common at the hotel. One day Frau K. had announced that she could not keep the bedroom which she had up till then shared with one of her children. A few days later Dora's father had given up his bedroom, and they had both moved into new rooms - the end rooms, which were only separated by the passage, while the rooms they had given up had not offered any such security against interruption. Later on, whenever she had reproached her father about Frau K., he had been in the habit of saying that he could not understand her hostility and that, on the contrary, his children had every reason for being grateful to Frau K. Her mother, whom she had asked for an explanation of this mysterious remark, had told her that her father had been so unhappy at that time that he had made up his mind to go into the wood and kill himself, and that Frau K., suspecting as much, had gone after him and had persuaded him by her entreaties to preserve his life for the sake of his family. Of course, Dora went on, she herself did not believe this story; no doubt the two of them had been seen together in the wood, and her father had thereupon invented this fairy tale of his suicide so as to account for their rendezvous.¹

On the other hand we must assume, or we can convince ourselves by a psychological examination of other people, that the very same impressions that we have forgotten have none the less left the deepest traces on our minds and have had a determining effect upon the whole of our later development. There can, therefore, be no question of any real abolition of the impressions of childhood, but rather of an amnesia similar to that which neurotics exhibit for later events, and of which the essence consists in a simple withholding of these impressions from consciousness, viz., in their repression. But what are the forces which bring about this repression of the impressions of childhood? Whoever could solve this riddle would, I think, have explained hysterical amnesia as well.

¹ [1905e, 1371]

[1905d, 1498]
A second observation of Breuer's, again, compels us to attach great importance, among the characteristics of the pathological chain of events, to states of consciousness. Breuer's patient exhibited, alongside of her normal state, a number of mental peculiarities: conditions of 'absence', confusion, and alterations of character. In her normal state she knew nothing of the pathogenic scenes or their connection with her symptoms; she had forgotten the scenes, or at all events had severed the pathogenic link. When she was put under hypnosis, it was possible, at the expense of a considerable amount of labour, to recall the scenes to her memory; and, through this work of recollecting, the symptoms were removed. The explanation of this fact would be a most awkward business, were it not that the way is pointed by experiences and experiments in hypnotism. The study of hypnotic phenomena has accustomed us to what was at first a bewildering realization that in one and the same individual there can be several mental groupings, which can remain more or less independent of one another, which can 'know nothing' of one another and which can alternate with one another in their hold upon consciousness. Cases of this kind, too, occasionally appear spontaneously, and are then described as examples of 'double conscience'.¹ If, where a splitting of the personality such as this has occurred, consciousness remains attached regularly to one of the two states, we call it the conscious mental state and the other, which is detached from it, the unconscious one. In the familiar condition known as 'post-hypnotic suggestion', a command given under hypnosis is slavishly carried out subsequently in the normal state. This phenomenon affords an admirable example of the influences which the unconscious state can exercise over the conscious one; moreover, it provides a pattern upon which we can account for the phenomena of hysteria. Breuer adopted a hypothesis that hysterical symptoms arise in peculiar mental conditions to which he gave the name of 'hypnoid'. On this view, excitations occurring during these hypnoid states can easily become pathogenic because such states do not provide opportunities for the normal discharge of the process of excitation. There consequently arises from the process of excitation an unusual product - the symptom. This finds its way, like a foreign body, into the normal state, which in turn is in ignorance of the hypnoid pathogenic situation. Wherever there is a symptom there is also an amnesia, a gap in the memory, and filling up this gap implies the removal of the conditions which led to the production of the symptom. [1910a, 2208]

To take the place of a number of instances, I will relate a single one of my cases, in which the determinants and advantages of repression are sufficiently evident. For my present purpose I shall have once again to abridge the case history and omit some important underlying material. The patient was a girl, who had lost her beloved father after she had taken a share in nursing him - a situation analogous to that of Breuer's patient. Soon afterwards her elder sister married, and her new brother-in-law aroused in her a peculiar feeling of sympathy which was easily masked under a disguise of family affection. Not long afterwards her sister fell ill and died, in the absence of the patient and her mother. They were summoned in all haste without being given any definite information of the tragic event. When the girl reached the bedside of her dead sister, there came to her for a brief moment an idea that might be expressed in these words: 'Now he is free and can marry me.' We may assume with certainty that this idea, which betrayed to her consciousness the intense love for her brother-in-law of which she had not herself been conscious, was surrendered to repression a moment later, owing to the revolt of her feelings. The girl fell ill with severe hysterical symptoms; and while she was under my treatment it turned out that she had completely forgotten the scene by her sister's bedside and the odious egoistic impulse that had emerged in her. She remembered it during the treatment and reproduced the pathogenic moment with signs of the most violent emotion, and, as a result of the treatment, she became healthy once more. [1910a, 2213]
There is another question that I might draw your attention to, which has been dealt with too little in our discussions: that of 'unconscious' masturbation. I mean masturbation during sleep, during abnormal states, or fits. You will recall the many hysterical fits in which masturbatory acts recur in a disguised or unrecognizable way, after the subject has renounced that form of satisfaction, and the many symptoms in obsessional neurosis which seek to replace and repeat this kind of sexual activity, which has formerly been forbidden. We may also speak of a therapeutic return of masturbation. A number of you will have found on occasion, as I have, that it represents a great advance if during the treatment the patient ventures to take up masturbation once more, though he may have no intention of making a permanent stop at that infantile halting-place. In this connection I may remind you that a considerable number of precisely the most severe sufferers from neurosis have avoided all recollection of masturbation during historic times, while psycho-analysis is able to prove that that species of sexual activity had by no means been strange to them during the forgotten earliest period of their lives. [1912f, 2574]
In this way, firstly, the painful region had been extended by the addition of adjacent areas: every fresh theme which had a pathogenic effect had cathected a new region in the legs; secondly, each of the scenes which made a powerful impression on her had left a trace behind it, bringing about lasting and constantly accumulating cathexis of the various functions of the legs, a linking of these functions with her feelings of pain. But a third mechanism had unmistakably been involved in the building up of her astasia-abasia. The patient ended her description of a whole series of episodes by complaining that they had made the fact of her 'standing alone' painful to her. In another series of episodes, which comprised her unsuccessful attempts to establish a new life for her family, she was never tired of repeating that what was painful about them had been her feeling of helplessness, the feeling that she could not 'take a single step forward'. In view of this, I was forced to suppose that among the influences that went to the building up of her abasia, these reflections of hers played a part; I could not help thinking that the patient had done nothing more nor less than look for a *symbolic* expression of her painful thoughts and that she had found it in the intensification of her sufferings. The fact that somatic symptoms of hysteria can be brought about by symbolization of this kind was already asserted in our 'Preliminary Communication'. In the Discussion on the present case I shall bring forward two or three conclusive instances of this. This psychical mechanism of symbolization did not play a prominent part with Fräulein Elisabeth von R. It did not create her abasia. But everything goes to show that the abasia which was already present received considerable reinforcement in this way. Accordingly, this abasia, at the stage of development at which I came across it, was to be equated not only with a functional paralysis based on psychical associations but also with one based on symbolization.

I have already discussed in the case history the way in which the patient's astasia-abasia was built up on these pains, after a particular path had been opened up for the conversion. In that passage, however, I also expressed my view that the patient had created, or increased, her functional disorder by means of symbolization, that she had found in the astasia-abasia a somatic expression for her lack of an independent position and her inability to make any alteration in her circumstances, and that such phrases as 'not being able to take a single step forward', 'not having anything to lean upon', served as the bridge for this fresh act of conversion.

I shall try to support this view by other examples. Conversion on the basis of simultaneity, where there is also an associative link, seems to make the smallest demands on a hysterical disposition; conversion by symbolization, on the other hand, seems to call for the presence of a higher degree of hysterical modification. This could be observed in the case of Fräulein Elisabeth, but only in the later stage of her hysteria. The best examples of symbolization that I have seen occurred in Frau Cäcilie M., whose case I might describe as my most severe and instructive one. I have already explained that a detailed report of her illness is unfortunately impossible.
In these examples the mechanism of symbolization seems to be reduced to secondary importance, as is no doubt the general rule. But I have examples at my disposal which seem to prove the genesis of hysterical symptoms through symbolization alone. The following is one of the best, and relates once more to Frau Cäcilie. When a girl of fifteen, she was lying in bed, under the watchful eye of her strict grandmother. The girl suddenly gave a cry; she had felt a penetrating pain in her forehead between her eyes, which lasted for weeks. During the analysis of this pain, which was reproduced after nearly thirty years, she told me that her grandmother had given her a look so 'piercing' that it had gone right into her brain. (She had been afraid that the old woman was viewing her with suspicion.) As she told me this thought she broke into a loud laugh, and the pain once more disappeared. In this instance I can detect nothing other than the mechanism of symbolization, which has its place, in some sense, midway between autosuggestion and conversion.

My observation of Frau Cäcilie M. gave me an opportunity of making a regular collection of symbolizations of this kind. A whole set of physical sensations which would ordinarily be regarded as organically determined were in her case of psychical origin or at least possessed a psychical meaning. A particular series of experiences of hers were accompanied by a stabbing sensation in the region of the heart (meaning 'it stabbed me to the heart'). The pain that occurs in hysteria of nails being driven into the head was without any doubt to be explained in her case as a pain related to thinking. (‘Something's come into my head.’) Pains of this kind were always cleared up as soon as the problems involved were cleared up. Running parallel to the sensation of a hysterical 'aura' in the throat, when that feeling appeared after an insult, was the thought 'I shall have to swallow this'. She had a whole quantity of sensations and ideas running parallel with each other. Sometimes the sensation would call up the idea to explain it, sometimes the idea would create the sensation by means of symbolization, and not infrequently it had to be left an open question which of the two elements had been the primary one.

I have not found such an extensive use of symbolization in any other patient. It is true that Frau Cäcilie M. was a woman who possessed quite unusual gifts, particularly artistic ones, and whose highly developed sense of form was revealed in some poems of great perfection. It is my opinion, however, that when a hysteric creates a somatic expression for an emotionally coloured idea by symbolization, this depends less than one would imagine on personal or voluntary factors. In taking a verbal expression literally and in feeling the 'stab in the heart' or the 'slap in the face' after some slighting remark as a real event, the hysteric is not taking liberties with words, but is simply reviving once more the sensations to which the verbal expression owes its justification. How has it come about that we speak of someone who has been slighted as being 'stabbed to the heart' unless the slight had in fact been accompanied by a precordial sensation which could suitably be described in that phrase and unless it was identifiable by that sensation? What could be more probable than that the figure of speech 'swallowing something', which we use in talking of an insult to which no rejoinder has been made, did in fact originate from the innervatory sensations which arise in the pharynx when we refrain from speaking and prevent ourselves from reacting to the insult? All these sensations and innervations belong to the field of 'The Expression of the Emotions', which, as Darwin has taught us, consists of actions which originally had a meaning and served a purpose. These may now for the most part have become so much weakened that the expression of them in words seems to us only to be a figurative picture of them, whereas in all probability the description was once meant literally; and hysteria is right in restoring the original meaning of the words in depicting its unusually strong innervations. Indeed, it is perhaps wrong to say that hysteria creates these sensations by symbolization. It may be that it does not take linguistic usage as its model at all, but that both hysteria and linguistic usage alike draw their material from a common source.
¹ In states in which mental alteration goes deeper, we clearly also find a symbolic version in concrete images and sensations of more artificial turns of speech. Frau Cäcilie M. passed through a period during which she transformed every thought she had into a hallucination, the explanation of which often called for much ingenuity. She complained to me at that time of being troubled by a hallucination that her two doctors - Breuer and I - were hanging on two trees next each other in the garden. The hallucination disappeared after the analysis had brought out the following explanation. The evening before, Breuer had refused to give her a drug she had asked for. She had then set her hopes on me but had found me equally hard-hearted. She was furious with us over this, and in her anger she thought to herself: ‘There’s nothing to choose between the two of them; one’s the pendant [match] of the other.’

[1895d, 163]

The determination of the symptom by the psychical trauma is not so transparent in every instance. There is often only what may be described as a ‘symbolic’ relation between the determining cause and the hysterical symptom. This is especially true of pains. Thus one patient suffered from piercing pains between her eyebrows. The reason was that once when she was a child her grandmother had given her an enquiring, ‘piercing’ look. The same patient suffered for a time from violent pains in her right heel, for which there was no explanation. These pains, it turned out, were connected with an idea that occurred to the patient when she made her first appearance in society. She was overcome with fear that she might not ‘find herself on a right footing’. Symbolizations of this kind were employed by many patients for a whole number of so-called neuralgias and pains. It is as though there were an intention to express the mental state by means of a physical one: and linguistic usage affords a bridge by which this can be effected. In the case, however, of what are after all the typical symptoms of hysteria- such as hemi-anaesthesia, restriction of the visual field, epileptiform convulsions, etc. - a psychical mechanism of this sort cannot be demonstrated. On the other hand this can often be done in respect to the hysterogenic zones.

[1893a, 294]
Indeed, when we look into the matter more closely, we must recognize the fact that the dream-work is doing nothing original in making substitutions of this kind. In order to gain its ends - in this case the possibility of a representation hampered by censorship - it merely follows the paths which it finds already laid down in the unconscious; and it gives preference to those transformations of the repressed material which can also become conscious in the form of jokes or allusions and of which the phantasies of neurotic patients are so full. At this point we suddenly reach an understanding of Scherner's dream interpretations, whose essential correctness I have defended elsewhere. The imagination's pre-occupation with the subject's own body is by no means peculiar to dreams or characteristic only of them. My analyses have shown me that it is habitually present in the unconscious thoughts of neurotics, and that it is derived from sexual curiosity, which, in growing youths or girls, is directed to the genitals of the other sex, and to those of their own as well. Nor, as Scherner and Volkelt have rightly insisted, is a house the only circle of ideas employed for symbolizing the body; and this is equally true of dreams and of the unconscious phantasies of neurosis. It is true that I know patients who have retained an architectural symbolism for the body and the genitals. (Sexual interest ranges far beyond the sphere of the external genitalia.) For these patients pillars and columns represent the legs (as they do in the Song of Solomon), every gateway stands for one of the bodily orifices (a 'hole'), every water-pipe is a reminder of the urinary apparatus, and so on. But the circle of ideas centring round plant-life or the kitchen may just as readily be chosen to conceal sexual images.¹ In the former case the way has been well prepared by linguistic usage, itself the precipitate of imaginative similes reaching back to remote antiquity: e.g. the Lord's vineyard, the seed, and the maiden's garden in the Song of Solomon. The ugliest as well as the most intimate details of sexual life may be thought and dreamt of in seemingly innocent allusions to activities in the kitchen; and the symptoms of hysteria could never be interpreted if we forgot that sexual symbolism can find its best hiding-place behind what is commonplace and inconspicuous.

There is a valid sexual meaning behind the neurotic child's intolerance of blood or raw meat, or his nausea at the sight of eggs or macaroni, and behind the enormous exaggeration in neurotics of the natural human dread of snakes. Wherever neuroses make use of such disguises they are following paths along which all humanity passed in the earliest periods of civilization - paths of whose continued existence today, under the thinnest of veils, evidence is to be found in linguistic usages, superstitions and customs.

[1900a, 815]

Similarly, falling, stumbling and slipping need not always be interpreted as purely accidental miscarriages of motor actions. The double meanings that language attaches to these expressions are enough to indicate the kind of phantasies involved, which can be represented by such losses of bodily equilibrium. I can recall a number of fairly mild nervous illnesses in women and girls which set in after a fall not accompanied by any injury, and which were taken to be traumatic hysterias resulting from the shock of the fall. Even at that time I had an impression that these events were differently connected and that the fall was already a product of the neurosis and expressed the same unconscious phantasies with a sexual content, which could be assumed to be the forces operating behind the symptoms. Is not the same thing meant by a proverb which runs: 'When a girl falls she falls on her back'?

[1901b, 1254]
Ladies and Gentlemen, if I may be allowed to generalize - which is unavoidable in so condensed an account as this - I should like to formulate what we have learned so far as follows: *our hysterical patients suffer from reminiscences*. Their symptoms are residues and mnemic symbols of particular (traumatic) experiences. We may perhaps obtain a deeper understanding of this kind of symbolism if we compare them with other mnemic symbols in other fields. The monuments and memorials with which large cities are adorned are also mnemic symbols. If you take a walk through the streets of London, you will find, in front of one of the great railway termini, a richly carved Gothic column - Charing Cross. One of the old Plantagenet kings of the thirteenth century ordered the body of his beloved Queen Eleanor to be carried to Westminster; and at every stage at which the coffin rested he erected a Gothic cross. Charing Cross is the last of the monuments that commemorate the funeral cortège.¹ At another point in the same town, not far from London Bridge, you will find a towering, and more modern, column, which is simply known as 'The Monument'. It was designed as a memorial of the Great Fire, which broke out in that neighbourhood in 1666 and destroyed a large part of the city. These monuments, then, resemble hysterical symptoms in being mnemic symbols; up to that point the comparison seems justifiable. But what should we think of a Londoner who paused to-day in deep melancholy before the memorial of Queer Eleanor's funeral instead of going about his business in the hurry that modern working conditions demand or instead of feeling joy over the youthful queen of his own heart? Or again what should we think of a Londoner who shed tears before the Monument that commemorates the reduction of his beloved metropolis to ashes although it has long since risen again in far greater brilliance? Yet every single hysterical and neurotic behaves like these two unpractical Londoners. Not only do they remember painful experiences of the remote past, but they still cling to them emotionally; they cannot get free of the past and for its sake they neglect what is real and immediate. This fixation of mental life to pathogenic traumas is one of the most significant and practically important characteristics of neurosis.

[1910a, 2206]
Names and words are not nearly so frequently or so recklessly employed in obsessional neuroses as in hysteria for the purpose of establishing a connection between unconscious thoughts (whether they are impulses or phantasies) and symptoms. I happen, however, to recollect another instance in which the very same name, Richard, was similarly used by a patient whom I analysed a long time since. After a quarrel with his brother he began brooding over the best means of getting rid of his fortune, and declaring that he did not want to have anything more to do with money, and so on. His brother was called Richard, and 'richard' is the French for 'a rich man'.
[1909d, 2148]
Such is my excuse for having curtailed so drastically the history of this case and its treatment. And I can offer still more cogent reasons for having confined myself to the statement only of some disconnected results of the psycho-analytic investigation of obsessional neuroses. I must confess that I have not yet succeeded in completely penetrating the complicated texture of a severe case of obsessional neurosis, and that, if I were to reproduce the analysis, it would be impossible for me to make the structure, such as by the help of analysis we know or suspect it to be, visible to others through the mass of therapeutic work superimposed upon it. What add so greatly to the difficulty of doing this are the resistances of the patients and the forms in which they are expressed. But even apart from this it must be admitted that an obsessional neurosis is in itself not an easy thing to understand - much less so than a case of hysteria. Actually, indeed, we should have expected to find the contrary. The language of an obsessional neurosis - the means by which it expresses its secret thoughts - is, as it were, only a dialect of the language of hysteria; but it is a dialect in which we ought to be able to find our way about more easily, since it is more nearly related to the forms of expression adopted by our conscious thought than is the language of hysteria. Above all, it does not involve the leap from a mental process to a somatic innervation - hysterical conversion - which can never be fully comprehensible to us.

I shall no doubt be overstepping common linguistic usage in postulating an interest in psycho-analysis on the part of philologists, that is of experts in speech. For in what follows 'speech' must be understood not merely to mean the expression of thought in words but to include the speech of gesture and every other method, such, for instance, as writing, by which mental activity can be expressed. That being so, it may be pointed out that the interpretations made by psycho-analysis are first and foremost translations from an alien method of expression into the one which is familiar to us. When we interpret a dream we are simply translating a particular thought-content (the latent dream-thoughts) from the 'language of dreams' into our waking speech. In the course of doing so we learn the peculiarities of this dream language and it is borne in upon us that it forms part of a highly archaic system of expression. Thus, to take an instance, there is no special indication for the negative in the language of dreams. Contraries may stand for each other in the dream's content and may be represented by the same element. Or we may put it like this: concepts are still ambivalent in dream-language, and unite within themselves contrary meanings - as is the case, according to the hypotheses of philologists, in the oldest roots of historical languages.¹ Another striking feature of our dream-language is its extremely frequent use of symbols, which make us able to some extent to translate the content of dreams without reference to the associations of the individual dreamer. Our researches have not yet sufficiently elucidated the essential nature of these symbols. They are in part substitutes and analogies based upon obvious similarities; but in some of these symbols the tertium comparationis which is presumably present escapes our conscious knowledge. It is precisely this latter class of symbols which must probably originate from the earliest phases of linguistic development and conceptual construction. In dreams it is above all the sexual organs and sexual activities which are represented symbolically instead of directly. A philologist, Hans Sperber, of Uppsala, has only recently (1912) attempted to prove that words which originally represented sexual activities have, on the basis of analogies of this kind, undergone an extraordinarily far-reaching change in their meaning.

¹[1909d, 2128]
The language of dreams may be looked upon as the method by which unconscious mental activity expresses itself. But the unconscious speaks more than one dialect. According to the differing psychological conditions governing and distinguishing the various forms of neurosis, we find regular modifications in the way in which unconscious mental impulses are expressed. While the gesture-language of hysteria agrees on the whole with the picture-language of dreams and visions, etc., the thought-language of obsessional neurosis and of the paraphrenias (dementia praecox and paranoia) exhibits special idiomatic peculiarities which, in a number of instances, we have been able to understand and interrelate. For instance, what a hysteric expresses by vomiting an obsessional will express by painstaking protective measures against infection, while a paraphrenic will be led to complaints or suspicions that he is being poisoned. These are all of them different representations of the patient's wish to become pregnant which have been repressed into the unconscious, or of his defensive reaction against that wish. [1913], 2814]
The discovery of the reason for the first conversion opened a second, fruitful period of the treatment. The patient surprised me soon afterwards by announcing that she now knew why it was that the pains always radiated from that particular area of the right thigh and were at their most painful there: it was in this place that her father used to rest his leg every morning, while she renewed the bandage round it, for it was badly swollen. This must have happened a good hundred times, yet she had not noticed the connection till now. In this way she gave me the explanation that I needed of the emergence of what was an atypical hysterogenic zone. Further, her painful legs began to 'join in the conversation' during our analyses. What I have in mind is the following remarkable fact. As a rule the patient was free from pain when we started work. If, then, by a question or by pressure upon her head I called up a memory, a sensation of pain would make its first appearance, and this was usually so sharp that the patient would give a start and put her hand to the painful spot. The pain that was thus aroused would persist so long as she was under the influence of the memory; it would reach its climax when she was in the act of telling me the essential and decisive part of what she had to communicate, and with the last word of this it would disappear. I came in time to use such pains as a compass to guide me; if she stopped talking but admitted that she still had a pain, I knew that she had not told me everything, and insisted on her continuing her story till the pain had been talked away. Not until then did I arouse a fresh memory.

[1895d, 134]

Among the tasks presented by analysis is that of getting rid of symptoms which are capable of increasing in intensity or of returning: pains, symptoms (such as vomiting) which are due to stimuli, sensations or contractures. While we are working at one of these symptoms we come across the interesting and not undesired phenomenon of 'joining in the conversation'. The problematical symptom re-appears, or appears with greater intensity, as soon as we reach the region of the pathogenic organization which contains the symptom's aetiology, and thenceforward it accompanies the work with characteristic oscillations which are instructive to the physician. The intensity of the symptom (let us take for instance a desire to vomit) increases the deeper we penetrate into one of the relevant pathogenic memories; it reaches its climax shortly before the patient gives utterance to that memory; and when he has finished doing so it suddenly diminishes or even vanishes completely for a time. If, owing to resistance, the patient delays his telling for a long time, the tension of the sensation - of the desire to vomit - becomes unbearable, and if we cannot force him to speak he actually begins to vomit. In this way we obtain a plastic impression of the fact that 'vomiting' takes the place of a psychical act (in this instance, the act of utterance), exactly as the conversion theory of hysteria maintains.

[1895d, 261]
The phenomenon of hysterical symptoms joining in the conversation during the analysis involves a practical drawback, to which we ought to be able to reconcile the patient. It is quite impossible to effect an analysis of a symptom at a single stretch or to distribute the intervals in our work so that they fit in precisely with pauses in the process of dealing with the symptom. On the contrary, interruptions which are imperatively prescribed by incidental circumstances in the treatment, such as the lateness of the hour, often occur at the most inconvenient points, just as one may be approaching a decision or just as a new topic emerges. Every newspaper reader suffers from the same drawback in reading the daily instalment of his serial story, when, immediately after the heroine's decisive speech or after the shot has rung out, he comes upon the words: 'To be continued.' In our own case the topic that has been raised but not dealt with, the symptom that has become temporarily intensified and has not yet been explained, persists in the patient's mind and may perhaps be more troublesome to him than it has otherwise been. He will simply have to make the best of this; there is no other way of arranging things. There are patients who, in the course of an analysis, simply cannot get free of a topic that has once been raised and who are obsessed by it in the interval between two treatments; since by themselves they cannot take any steps towards getting rid of it, they suffer more, to begin with, than they did before the treatment. But even such patients learn in the end to wait for the doctor and to shift all the interest that they feel in getting rid of the pathogenic material on to the hours of treatment, after which they begin to feel freer in the intervals.

I then succeeded in getting her to reproduce the various scenes in which her sexual relationship with her brother (which had certainly lasted at least from her sixth to her tenth year) had culminated. During this work of reproduction, the physical sensation in her abdomen 'joined in the conversation' as it were, as is regularly observed to happen in the analysis of hysterical mnemic residues. The image of the lower part of a woman's naked abdomen (but now reduced to childish proportions and without hair on it) appeared with the sensation or stayed away, according as the scene in question had occurred in full light or in the dark. Her disgust at eating, too, found an explanation in a repulsive detail of these proceedings. After we had gone through this series of scenes, the hallucinatory sensations and images had disappeared, and (up to the present, at any rate) they have not returned.¹

We know how important doubt is to the physician who is analysing an obsessional neurosis. It is the patient's strongest weapon, the favourite expedient of his resistance. This same doubt enabled our patient to lie entrenched behind a respectful indifference and to allow the efforts of the treatment to slip past him for years together. Nothing changed, and there was no way of convincing him. At last I recognized the importance of the intestinal trouble for my purposes; it represented the small trait of hysteria which is regularly to be found at the root of an obsessional neurosis. I promised the patient a complete recovery of his intestinal activity, and by means of this promise made his incredulity manifest. I then had the satisfaction of seeing his doubt dwindle away, as in the course of the work his bowel began, like a hysterically affected organ, to 'join in the conversation', and in a few week's time recovered its normal functions after their long impairment.

¹[1896b, 400]

²[1918b, 3557]
The same dream admits of another and subtler interpretation, which in fact becomes unavoidable if we take a subsidiary detail into account. (The two interpretations are not mutually contradictory, but both cover the same ground; they are a good instance of the fact that dreams, like all other psychopathological structures, regularly have more than one meaning.) My patient, it will be remembered, at the same time as she was occupied with her dream of the renunciation of a wish, was also trying to bring about a renounced wish (for the caviare sandwich) in real life. Her friend had also given expression to a wish - to become stouter - and it would not have been surprising if my patient had dreamt that her friend's wish was unfulfilled; for my patient's own wish was that her friend's wish (to put on weight) should not be fulfilled. But instead of this she dreamt that one of her own wishes was not fulfilled. Thus the dream will acquire a new interpretation if we suppose that the person indicated in the dream was not herself but her friend, that she had put herself in her friend's place, or, as we might say, that she had 'identified' herself with her friend. I believe she had in fact done this; and the circumstance of her having brought about a renounced wish in real life was evidence of this identification.

[1900a, 644]

What is the meaning of hysterical identification? It requires a somewhat lengthy explanation. Identification is a highly important factor in the mechanism of hysterical symptoms. It enables patients to express in their symptoms not only their own experiences but those of a large number of other people; it enables them, as it were, to suffer on behalf of a whole crowd of people and to act all the parts in a play single-handed. I shall be told that this is not more than the familiar hysterical imitation, the capacity of hysterics to imitate any symptoms in other people that may have struck their attention - sympathy, as it were, intensified to the point of reproduction. This, however, does no more than show us the path along which the psychical process in hysterical imitation proceeds. The path is something different from the mental act which proceeds along it. The latter is a little more complicated than the common picture of hysterical imitation; it consists in the unconscious drawing of an inference, as an example will make clear. Supposing a physician is treating a woman patient, who is subject to a particular kind of spasm, in a hospital ward among a number of other patients. He will show no surprise if he finds one morning that this particular kind of hysterical attack has found imitators. He will merely say: 'The other patients have seen it and copied it; it's a case of psychical infection.' That is true; but the psychical infection has occurred along some such lines as these. As a rule, patients know more about one another than the doctor does about any of them; and after the doctor's visit is over they turn their attention to one another. Let us imagine that this patient had her attack on a particular day; then the others will quickly discover that it was caused by a letter from home, the revival of some unhappy love-affair, or some such thing. Their sympathy is aroused and they draw the following inference, though it fails to penetrate into consciousness: 'If a cause like this can produce an attack like this, I may have the same kind of attack since I have the same grounds for having it.' If this inference were capable of entering consciousness, it might possibly give rise to a fear of having the same kind of attack. But in fact the inference is made in a different psychical region, and consequently results in the actual realization of the dreaded symptom. Thus identification is not simple imitation but assimilation on the basis of a similar aetiological pretension; it expresses a resemblance and is derived from a common element which remains in the unconscious.

[1900a, 644]
Identification is most frequently used in hysteria to express a common sexual element. A hysterical woman identifies herself in her symptoms most readily — though not exclusively — with people with whom she has had sexual relations or with people who have had sexual relations with the same people as herself. Linguistic usage takes this into account, for two lovers are spoken of as being 'one'. In hysterical phantasies, just as in dreams, it is enough for purposes of identification that the subject should have thoughts of sexual relations without their having necessarily taken place in reality. Thus the patient whose dream I have been discussing was merely following the rules of hysterical processes of thought in expressing her jealousy of her friend (which incidentally she herself knew was unjustified) by taking her place in the dream and identifying herself with her by creating a symptom - the renounced wish. The process might be expressed verbally thus: my patient put herself in her friend's place in the dream because her friend was taking my patient's place with her husband and because she (my patient) wanted to take her friend's place in her husband's high opinion.

Her other reproach against her father was that his ill-health was only a pretext and that he exploited it for his own purposes. This reproach, too, concealed a whole section of her own secret history. One day she complained of a professedly new symptom, which consisted of piercing gastric pains. 'Whom are you copying now?' I asked her, and found I had hit the mark. The day before she had visited her cousins, the daughters of the aunt who had died. The younger one had become engaged, and this had given occasion to the elder one for falling ill with gastric pains, and she was to be sent off to Semmering. Dora thought it was all just envy on the part of the elder sister; she always got ill when she wanted something, and what she wanted now was to be away from home so as not to have to look on at her sister's happiness. But Dora's own gastric pains proclaimed the fact that she identified herself with her cousin, who, according to her, was a malingerer. Her grounds for this identification were either that she too envied the luckier girl her love, or that she saw her own story reflected in that of the elder sister, who had recently had a love-affair which had ended unhappily. But she had also learned from observing Frau K. what useful things illnesses could become. Herr K. spent part of the year in travelling. Whenever he came back, he used to find his wife in bad health, although, as Dora knew, she had been quite well only the day before. Dora realized that the presence of the husband had the effect of making his wife ill, and that she was glad to be ill so as to be able to escape the conjugal duties which she so much detested. At this point in the discussion Dora suddenly brought in an allusion to her own alternations between poor and bad health during the first years of her girlhood at B--; and I was thus driven to suspect that her states of health were to be regarded as depending upon something else, in the same way as Frau K.'s. (It is a rule of psycho-analytic technique that an internal connection which is still undisclosed will announce its presence by means of a contiguity - a temporal proximity of associations; just as in writing, if 'a' and 'b' are put side by side, it means that the syllable 'ab' is to be formed out of them.) Dora had had a very large number of attacks of coughing accompanied by loss of voice. Could it be that the presence or absence of the man she loved had had an influence upon the appearance and disappearance of the symptoms of her illness? If this were so, it must be possible to discover some coincidence or other which would betray the fact. I asked her what the average length of these attacks had been. 'From three to six weeks, perhaps.' How long had Herr K.'s absences lasted? 'Three to six weeks, too', she was obliged to admit. Her illness was therefore a demonstration of her love for K., just as his wife's was a demonstration of her dislike. It was only necessary to suppose that her behaviour had been the opposite of Frau K.'s and that she had been ill when he was absent and well when he had come back. And this really seemed to have been so, at least during the first period of the attacks. Later on it no doubt became necessary to obscure the coincidence between her attacks of illness and the absence of the man she secretly loved, lest its regularity should betray her secret. The length of the attacks would then remain as a trace of their original significance.

[1905e, 1376]
Her father, then, had fallen ill through leading a loose life, and she assumed that he had handed on his bad health to her by heredity. I was careful not to tell her that, as I have already mentioned, I too was of opinion that the offspring of luetics were very specially predisposed to severe neuropsychoses. The line of thought in which she brought this accusation against her father was continued in her unconscious material. For several days on end she identified herself with her mother by means of slight symptoms and peculiarities of manner, which gave her an opportunity for some really remarkable achievements in the direction of intolerable behaviour. She then allowed it to transpire that she was thinking of a stay she had made at Franzensbad, which she had visited with her mother - I forget in what year. Her mother was suffering from abdominal pains and from a discharge (a catarrh) which necessitated a cure at Franzensbad. It was Dora's view - and here again she was probably right - that this illness was due to her father, who had thus handed on his venereal disease to her mother. It was quite natural that in drawing this conclusion she should, like the majority of laymen, have confused gonorrhoea and syphilis, as well as what is contagious and what is hereditary. The persistence with which she held to this identification with her mother almost forced me to ask her whether she too was suffering from a venereal disease; and I then learnt that she was afflicted with a catarrh (leucorrhoea) whose beginning, she said, she could not remember.

Here, therefore (and quite in accordance with the rules), was a piece of material information coming to light in the middle of the analysis and helping to solve problems which had previously been raised. I was able to say to Dora: 'Now I know your motive for the slap in the face with which you answered Herr K.'s proposal. It was not that you were offended at his suggestions; you were actuated by jealousy and revenge. At the time when the governess was telling you her story you were still able to make use of your gift for putting on one side everything that is not agreeable to your feelings. But at the moment when Herr K. used the words "I get nothing out of my wife" - which were the same words he had used to the governess - fresh emotions were aroused in you and tipped the balance. "Does he dare", you said to yourself, "to treat me like a governess, like a servant?" Wounded pride added to jealousy and to the conscious motives of common sense - it was too much.¹ To prove to you how deeply impressed you were by the governess's story, let me draw your attention to the repeated occasions upon which you have identified yourself with her both in your dream and in your conduct. You told your parents what happened - a fact which we have hitherto been unable to account for - just as the governess wrote and told her parents. You give me a fortnight's notice, just like a governess. The letter in the dream which gave you leave to go home is the counterpart of the governess's letter from her parents forbidding her to do so.'

(2) The attack becomes obscured through the fact that the patient attempts to carry out the activities of both the figures who appear in the phantasy, that is to say, through multiple identification. Compare, for instance, the example I mentioned in my paper on 'Hysterical Phantasies and their Relation to Bisexuality' (1908a), in which the patient tore off her dress with one hand (as the man) while she pressed it to her body with the other (as the woman).

¹ [1905e, 1441]
The conclusion which our theory would require - namely, that the disposition to fall ill of melancholia (or some part of that disposition) lies in the predominance of the narcissistic type of object-choice - has unfortunately not yet been confirmed by observation. In the opening remarks of this paper, I admitted that the empirical material upon which this study is founded is insufficient for our needs. If we could assume an agreement between the results of observation and what we have inferred, we should not hesitate to include this regression from object-cathexis to the still narcissistic oral phase of the libido in our characterization of melancholia. Identifications with the object are by no means rare in the transference neuroses either; indeed, they are a well-known mechanism of symptom-formation, especially in hysteria. The difference, however, between narcissistic and hysterical identification may be seen in this: that, whereas in the former the object-cathexis is abandoned, in the latter it persists and manifests its influence, though this is usually confined to certain isolated actions and innervations. In any case, in the transference neuroses, too, identification is the expression of there being something in common, which may signify love. Narcissistic identification is the older of the two and it paves the way to an understanding of hysterical identification, which has been less thoroughly studied. [1917e, 3048]

In addition to narcissistic identification, there is a hysterical kind, which has been familiar to us very much longer. I wish it were possible to illustrate for you the differences between the two forms by a few clear specifications. There is something I can tell you about the periodic and cyclical forms of melancholia which I am sure you will be glad to hear. For in favourable circumstances - I have experienced this twice - it is possible by analytic treatment in the lucid intervals to prevent the return of the condition in the same or the opposite emotional mood. We learn from such cases that in melancholia and mania we are concerned once more with a special method of dealing with a conflict whose underlying determinants agree precisely with those of the other neuroses. You can imagine how much more there is for psycho-analysis to learn in this field of knowledge. [1916-1917, 3472]

Let us disentangle identification as it occurs in the structure of a neurotic symptom from its rather complicated connections. Supposing that a little girl (and we will keep to her for the present) develops the same painful symptom as her mother - for instance, the same tormenting cough. This may come about in various ways. The identification may come from the Oedipus complex; in that case it signifies a hostile desire on the girl's part to take her mother's place, and the symptom expresses her object-love towards her father, and brings about a realization, under the influence of a sense of guilt, of her desire to take her mother's place: 'You wanted to be your mother, and now you are - anyhow so far as your sufferings are concerned.' This is the complete mechanism of the structure of a hysterical symptom. Or, on the other hand, the symptom may be the same as that of the person who is loved; so, for instance, Dora imitated her father's cough. In that case we can only describe the state of things by saying that identification has appeared instead of object-choice, and that object-choice has regressed to identification. We have heard that identification is the earliest and original form of emotional tie; it often happens that under the conditions in which symptoms are constructed, that is, where there is repression and where the mechanisms of the unconscious are dominant, object-choice is turned back into identification - the ego assumes the characteristics of the object. It is noticeable that in these identifications the ego sometimes copies the person who is not loved and sometimes the one who is loved. It must also strike us that in both cases the identification is a partial and extremely limited one and only borrows a single trait from the person who is its object. [1921c, 3798]
There is a third particularly frequent and important case of symptom formation, in which the identification leaves entirely out of account any object-relation to the person who is being copied. Supposing, for instance, that one of the girls in a boarding school has had a letter from someone with whom she is secretly in love which arouses her jealousy, and that she reacts to it with a fit of hystericis; then some of her friends who know about it will catch the fit, as we say, by mental infection. The mechanism is that of identification based upon the possibility or desire of putting oneself in the same situation. The other girls would like to have a secret love affair too, and under the influence of a sense of guilt they also accept the suffering involved in it. It would be wrong to suppose that they take on the symptom out of sympathy. On the contrary, the sympathy only arises out of the identification, and this is proved by the fact that infection or imitation of this kind takes place in circumstances where even less pre-existing sympathy is to be assumed than usually exists between friends in a girls' school. One ego has perceived a significant analogy with another upon one point - in our example upon openness to a similar emotion; an identification is thereupon constructed on this point, and, under the influence of the pathogenic situation, is displaced on to the symptom which the one ego has produced. The identification by means of the symptom has thus become the mark of a point of coincidence between the two egos which has to be kept repressed.

We know the meaning and intention of such deathlike attacks. They signify an identification with a dead person, either with someone who is really dead or with someone who is still alive and whom the subject wishes dead. The latter case is the more significant. The attack then has the value of a punishment. One has wished another person dead, and now one is this other person and is dead oneself. At this point psycho-analytical theory brings in the assertion that for a boy this other person is usually his father and that the attack (which is termed hysterical) is thus a self-punishment for a death-wish against a hated father.

The normal processes in the formation of conscience must be similar to the abnormal ones described here. We have not yet succeeded in fixing the boundary line between them. It will be observed that here the largest share in the outcome is ascribed to the passive component of repressed femininity. In addition, it must be of importance as an accidental factor whether the father, who is feared in any case, is also especially violent in reality. This was true in Dostoevsky's case, and we can trace back the fact of his extraordinary sense of guilt and of his masochistic conduct of life to a specially strong feminine component. Thus the formula for Dostoevsky is as follows: a person with a specially strong innate bisexual disposition, who can defend himself with special intensity against dependence on a specially severe father. This characteristic of bisexuality comes as an addition to the components of his nature that we have already recognized. His early symptoms of death-like attacks can thus be understood as a father-identification on the part of his ego, which is permitted by his super-ego as a punishment. 'You wanted to kill your father in order to be your father yourself. Now you are your father, but a dead father' - the regular mechanism of hysterical symptoms. And further: 'Now your father is killing you.' For the ego the death symptom is a satisfaction in phantasy of the masculine wish and at the same time a masochistic satisfaction; for the super-ego it is a punitive satisfaction - that is, a sadistic satisfaction. Both of them, the ego and the super-ego, carry on the role of father.
To sum up, the relation between the subject and his father-object, while retaining its content, has been transformed into a relation between the ego and the super-ego - a new setting on a fresh stage. Infantile reactions from the Oedipus complex such as these may disappear if reality gives them no further nourishment. But the father's character remained the same, or rather, it deteriorated with the years, and thus Dostoevsky's hatred for his rather and his death-wish against that wicked father were maintained. Now it is a dangerous thing if reality fulfils such repressed wishes. The phantasy has become reality and all defensive measures are thereupon reinforced. Dostoevsky's attacks now assumed an epileptic character; they still undoubtedly signified an identification with his father as a punishment, but they had become terrible, like his father's frightful death itself. What further content they had absorbed, particularly what sexual content, escapes conjecture.

[1928b, 4562]
Active masturbation must be excluded from my list of the sexual noxae in early childhood which are pathogenic for hysteria. Although it is found so very often side by side with hysteria, this is due to the circumstance that masturbation itself is a much more frequent consequence of abuse or seduction than is supposed.

[1896b, 386]

¹ Here is an instance of this. Another physician in Vienna, whose conviction of the unimportance of sexual factors in hysteria has probably been very much strengthened by such experiences as this, was consulted in the case of a fourteen-year-old girl who suffered from dangerous hysterical vomiting. He made up his mind to ask her the painful question whether by any chance she had ever had a love-affair with a man. 'No!' answered the child, no doubt with well-affected astonishment; and then repeated to her mother in her irreverent way: 'Only fancy! the old stupid asked me if I was in love!' She afterwards came to me for treatment, and proved - though not during our very first conversation, to be sure - to have been a masturbator for many years, with a considerable leucorrhoeal discharge (which had a close bearing on her vomiting). She had finally broken herself of the habit, but was tormented in her abstinence by the most acute sense of guilt, so that she looked upon every misfortune that befell her family as a divine punishment for her transgression. Besides this, she was under the influence of the romance of an unmarried aunt, whose pregnancy (a second determinant for her vomiting) was supposed to have been happily hidden from her. The girl was looked upon as a 'mere child,' but she turned out to be initiated into all the essentials of sexual relations.

[1905e, 1364]

I then understood that behind the train of thought in which she brought these open accusations against her father there lay concealed as usual a self-accusation. I met her half-way by assuring her that in my view the occurrence of leucorrhoea in young girls pointed primarily to masturbation, and I considered that all the other causes which were commonly assigned to that complaint were put in the background by masturbation.¹ I added that she was now on the way to finding an answer to her own question of why it was that precisely she had fallen ill - by confessing that she had masturbated, probably in childhood. Dora denied flatly that she could remember any such thing. But a few days later she did something which I could not help regarding as a further step towards the confession. For on that day she wore at her waist - a thing she never did on any other occasion before or after - a small reticule of a shape which had just come into fashion; and, as she lay on the sofa and talked, she kept playing with it - opening it, putting a finger into it, shutting it again, and so on. I looked on for some time, and then explained to her the nature of a 'symptomatic act'.² I give the name of symptomatic acts to those acts which people perform, as we say, automatically, unconsciously, without attending to them, or as if in a moment of distraction. They are actions to which people would like to deny any significance, and which, if questioned about them, they would explain as being indifferent and accidental. Closer observation, however, will show that these actions, about which consciousness knows nothing or wishes to know nothing, in fact give expression to unconscious thoughts and impulses, and are therefore most valuable and instructive as being manifestations of the unconscious which have been able to come to the surface. There are two sorts of conscious attitudes possible towards these symptomatic acts. If we can ascribe inconspicuous motives to them we recognize their existence; but if no such pretext can be found for conscious use we usually fail altogether to notice that we have performed them. Dora found no difficulty in producing a motive: 'Why should I not wear a reticule like this, as it is now the fashion to do?' But a justification of this kind does not dismiss the possibility of the action in question having an unconscious origin. Though on the other hand the existence of such an origin and the meaning attributed to the act cannot be conclusively established. We must content ourselves with recording the fact that such a meaning fits in quite extraordinarily well with the situation as a whole and with the programme laid down by the unconscious.

[1905e, 1413]
The reproaches against her father for having made her ill, together with the self-reproach underlying them, the leucorrhoea, the playing with the reticule, the bed-wetting after her sixth year, the secret which she would not allow the doctors to tear from her - the circumstantial evidence of her having masturbated in childhood seems to me complete and without a flaw. In the present case I had begun to suspect the masturbation when she had told me of her cousin's gastric pains, and had then identified herself with her by complaining for days together of similar painful sensations. It is well known that gastric pains occur especially often in those who masturbate. According to a personal communication made to me by Wilhelm Fliess, it is precisely gastralgias of this character which can be interrupted by an application of cocaine to the 'gastric spot' discovered by him in the nose, and which can be cured by the cauterization of the same spot. In confirmation of my suspicion Dora gave me two facts from her conscious knowledge: she herself had frequently suffered from gastric pains, and she had good reasons for believing that her cousin was a masturbator. It is a very common thing for patients to recognize in other people a connection which, on account of their emotional resistances, they cannot perceive in themselves. And, indeed, Dora no longer denied my supposition, although she still remembered nothing. Even the date which she assigned to the bed-wetting, when she said that it lasted 'till a short time before the appearance of the nervous asthma', appears to me to be of clinical significance. Hysterical symptoms hardly ever appear so long as children are masturbating, but only afterwards, when a period of abstinence has set in;¹ they form a substitute for masturbatory satisfaction, the desire for which continues to persist in the unconscious until another and more normal kind of satisfaction appears - where that is still attainable. For upon whether it is still attainable or not depends the possibility of a hysteria being cured by marriage and normal sexual intercourse. But if the satisfaction afforded in marriage is again removed - as it may be owing to coitus interruptus, psychological estrangement, or other causes - then the libido flows back again into its old channel and manifests itself once more in hysterical symptoms.

¹ This is also true in principle of adults; but in their case a relative abstinence, a diminution in the amount of masturbation, is a sufficient cause, so that, if the libido is very strong, hysteria and masturbation may be simultaneously present.
I should like to be able to add some definite information as to when and under what particular influence Dora gave up masturbating; but owing to the incompleteness of the analysis I have only fragmentary material to present. We have heard that the bed-wetting lasted until shortly before she first fell ill with dyspnoea. Now the only light she was able to throw upon this first attack was that at the time of its occurrence her father was away from home for the first time since his health had improved. In this small recollection there must be a trace of an allusion to the aetiology of the dyspnoea. Dora's symptomatic acts and certain other signs gave me good reasons for supposing that the child, whose bedroom had been next door to her parents', had overheard her father in his wife's room at night and had heard him (for he was always short of breath) breathing hard while they had intercourse. Children, in such circumstances, divine something sexual in the uncanny sounds that reach their ears. Indeed, the movements expressive of sexual excitement lie within them ready to hand, as innate pieces of mechanism. I maintained years ago that the dyspnoea and palpitations that occur in hysteria and anxiety neurosis are only detached fragments of the act of copulation; and in many cases, as in Dora's, I have been able to trace back the symptom of dyspnoea or nervous asthma to the same exciting cause - to the patient's having overheard sexual intercourse taking place between adults. The sympathetic excitement which may be supposed to have occurred in Dora on such an occasion may very easily have made the child's sexuality veer round and have replaced her inclination to masturbation by an inclination to anxiety. A little while later, when her father was away and the child, devotedly in love with him, was wishing him back, she must have reproduced in the form of an attack of asthma the impression she had received. She had preserved in her memory the event which had occasioned the first onset of the symptom, and we can conjecture from it the nature of the train of thought, charged with anxiety, which had accompanied the attack. The first attack had come on after she had over-exerted herself on an expedition in the mountains, so that she had probably been really a little out of breath. To this was added the thought that her father was forbidden to climb mountains and was not allowed to over-exert himself, because he suffered from shortness of breath; then came the recollection of how much he had exerted himself with her mother that night, and the question whether it might not have done him harm; next came concern whether she might not have over-exerted herself in masturbating - an act which, like the other, led to a sexual orgasm accompanied by slight dyspnoea - and finally came concern whether she might not have over-exerted herself in masturbating - an act which, like the other, led to a sexual orgasm accompanied by slight dyspnoea - and finally came a return of the dyspnoea in an intensified form as a symptom. Part of this material I was able to obtain directly from the analysis, but the rest required supplementing. But the way in which the occurrence of masturbation in Dora's case was verified has already shown us that material belonging to a single subject can only be collected piece by piece at various times and in different connections.¹

[1905e, 1416]

There now arise a whole series of questions of the greatest importance concerning the aetiology of hysteria: is Dora's case to be regarded as aetologically typical? does it represent the only type of causation? and so on. Nevertheless, I am sure that I am taking the right course in postponing my answer to such questions until a considerable number of other cases have been similarly analysed and published. Moreover, I should have to begin by criticizing the way in which the questions are framed. Instead of answering 'Yes' or 'No' to the question whether the aetiology of this case is to be looked for in masturbation during childhood, I should first have to discuss the concept of aetiology as applied to the psychoneuroses. It would then become evident that the standpoint from which I should be able to answer the question would be very widely removed from the standpoint from which it was put. Let it suffice if we can reach the conviction that in this case the occurrence of masturbation in childhood is established, and that its occurrence cannot be an accidental element nor an immaterial one in the conformation of the clinical picture.¹

[1905e, 1417]
Unconscious phantasies have either been unconscious all along and have been formed in the unconscious; or - as is more often the case - they were once conscious phantasies, day-dreams, and have since been purposely forgotten and have become unconscious through 'repression'. Their content may afterwards either have remained the same or have undergone alterations, so that the present unconscious phantasies are derivatives of the once conscious ones. Now an unconscious phantasy has a very important connection with the subject's sexual life; for it is identical with the phantasy which served to give him sexual satisfaction during a period of masturbation. At that time the masturbatory act (in the widest sense of the term) was compounded of two parts. One was the evocation of a phantasy and the other some active behaviour for obtaining self-gratification at the height of the phantasy. This compound, as we know, was itself merely soldered together.¹ Originally the action was a purely auto-erotic procedure for the purpose of obtaining pleasure from some particular part of the body, which could be described as erotogenic. Later, this action became merged with a wishful idea from the sphere of object-love and served as a partial realization of the situation in which the phantasy culminated. When, subsequently, the subject renounces this type of satisfaction, composed of masturbation and phantasy, the action is given up, while the phantasy, from being conscious, becomes unconscious. If no other mode of sexual satisfaction supervenes, the subject remains abstinent; and if he does not succeed in sublimating his libido - that is, in deflecting his sexual excitation to higher aims -, the condition is now fulfilled for his unconscious phantasy to be revived and to proliferate, and, at least as regards some part of its content, to put itself into effect, with the whole force of his need for love, in the form of a pathological symptom.

[1908a, 1934]

In this way, unconscious phantasies are the immediate psychical precursors of a whole number of hysterical symptoms. Hysterical symptoms are nothing other than unconscious phantasies brought into view through 'conversion'; and in so far as the symptoms are somatic ones, they are often enough taken from the circle of the same sexual sensations and motor innervations as those which had originally accompanied the phantasy when it was still conscious. In this way the giving up of the habit of masturbation is in fact undone, and the purpose of the whole pathological process, which is a restoration of the original, primary sexual satisfaction, is achieved - though never completely, it is true, but always in a sort of approximation.

[1908a, 1935]

We shall not be able to dismiss a second objection so easily. If you survey a fairly long series of interpretations of symptoms, you will probably start by judging that the concept of a substitutive sexual satisfaction has been stretched to its extreme limits in them. You will not fail to emphasize the fact that these symptoms offer nothing real in the way of satisfaction, that often enough they are restricted to the revival of a sensation or the representation of a phantasy derived from a sexual complex. And you will further point out that these supposed sexual satisfactions often take on a childish and discreditable form, approximate to an act of masturbation perhaps, or recall dirty kinds of naughtiness which are forbidden even to children - habits of which they have been broken. And, going on from this, you will also express surprise that we are representing as a sexual satisfaction what would rather have to be described as the satisfaction of lusts that are cruel or horrible or would even have to be called unnatural. We shall come to no agreement, Gentlemen, on this latter point till we have made a thorough investigation of the sexual life of human beings and till, in doing so, we have decided what it is that we are justified in calling 'sexual'.

[1916-1917, 3374]
In the case of a psychical complex which has come under the influence of the censorship imposed by resistance, the affects are the constituent which is least influenced and which alone can give us a pointer as to how we should fill in the missing thoughts. This is seen even more clearly in the psychoneuroses than in dreams. Their affects are always appropriate, at least in their quality though we must allow for their intensity being increased owing to displacements of neurotic attention. If a hysterical is surprised at having to be so frightened of something trivial or if a man suffering from obsessions is surprised at such distressing self-reproaches arising out of a mere nothing, they have both gone astray, because they regard the ideational content - the triviality or the mere nothing - as what is essential; and they put up an unsuccessful fight because they take this ideational content as the starting-point of their thought-activity. Psychoanalysis can put them upon the right path by recognizing the affect as being, on the contrary, justified and by seeking out the idea which belongs to it but has been repressed and replaced by a substitute. A necessary premise to all this is that the release of affect and the ideational content do not constitute the indissoluble organic unity as which we are in the habit of treating them, but that these two separate entities may be merely soldered together and can thus be detached from each other by analysis. Dream-interpretation shows that this is in fact the case. [1900a, 905]

Our discussion cannot be carried any further without examining the part played by the affects in these processes; but we can only do so imperfectly in the present connection. Let us assume, then, that the suppression of the Ucs. is necessary above all because, if the course of ideas in the Ucs. were left to itself, it would generate an affect which was originally of a pleasurable nature, but became unpleasurable after the process of 'repression' occurred. The purpose, and the result too, of suppression is to prevent this release of unpleasure. The suppression extends over the ideational content of the Ucs., since the release of unpleasure might start from that content. This presupposes a quite specific assumption as to the nature of the generation of affect. It is viewed as a motor or secretory function, the key to whose innervation lies in the ideas in the Ucs. Owing to the domination established by the Pcs. these ideas are, as it were, throttled, and inhibited from sending out impulses which would generate affect. If, therefore, the cathexis from the Pcs. ceases, the danger is that the unconscious excitations may release affect of a kind which (as a result of the repression which has already occurred) can only be experienced as unpleasure, as anxiety. [1900a, 1010]

In 1896, shortly after the appearance of my Studies on Hysteria (written in conjunction with Dr. J. Breuer, 1895), I asked an eminent fellow-specialist for his opinion on the psychological theory of hysteria put forward in that work. He bluntly replied that he considered it an unjustifiable generalization of conclusions which might hold good for a few cases. Since then I have seen an abundance of cases of hysteria, and I have been occupied with each case for a number of days, weeks, or years. In not a single one of them have I failed to discover the psychological determinants which were postulated in the Studies, namely, a psychical trauma, a conflict of affects, and an additional factor which I brought forward in later publications - a disturbance in the sphere of sexuality. It is of course not to be expected that the patient will come to meet the physician half-way with material which has become pathogenic for the very reason of its efforts to lie concealed; nor must the enquirer rest content with the first 'No' that crosses his path.¹ [1905e, 1364]
In this scene - second in order of mention, but first in order of time - the behaviour of this child of fourteen was already entirely and completely hysterical. I should without question consider a person hysterical in whom an occasion for sexual excitement elicited feelings that were preponderantly or exclusively unpleasurable; and I should do so whether or no the person were capable of producing somatic symptoms. The elucidation of the mechanism of this reversal of affect is one of the most important and at the same time one of the most difficult problems in the psychology of the neuroses. In my own judgement I am still some way from having achieved this end; and I may add that within the limits of the present paper I shall be able to bring forward only a part of such knowledge on the subject as I do possess.

In order to particularize Dora's case it is not enough merely to draw attention to the reversal of affect; there has also been a displacement of sensation. Instead of the genital sensation which would certainly have been felt by a healthy girl in such circumstances,¹ Dora was overcome by the unpleasurable feeling which is proper to the tract of mucous membrane at the entrance to the alimentary canal - that is by disgust. The stimulation of her lips by the kiss was no doubt of importance in localizing the feeling at that particular place; but I think I can also recognize another factor in operation.²

In certain mental states described as 'affects', the part played by the body is so obvious and on so large a scale that some psychologists have even adopted the view that the essence of these affects consists only in their physical manifestations. It is a matter of common knowledge that extraordinary changes occur in the facial expression, in the circulation, in the excretions and in the state of tension of the voluntary muscles under the influence of fear, of rage, of mental pain and of sexual delight. What is less well known, though equally well established, is the occurrence of other physical results of the affects which cannot be counted as their expression. Persistent affective states of a distressing or 'depressive' nature (as they are called), such as sorrow, worry or grief, reduce the state of nourishment of the whole body, cause the hair to turn white, the fat to disappear and the walls of the blood-vessels to undergo morbid changes. On the other hand, under the influence of feelings of joy, of 'happiness', we find that the whole body blossoms out and shows signs of a renewal of youth. The major affects evidently have a large bearing on the capacity to resist infectious illness; a good example of this is to be seen in the medical observation that there is a far greater liability to contract such diseases as typhus and dysentery in defeated armies than in victorious ones. The affects, moreover, - this applies almost exclusively to depressive affects - are often sufficient in themselves to bring about both diseases of the nervous system accompanied by manifest anatomical changes and also diseases of other organs. In such cases it must be assumed that the patient already had a predisposition, though hitherto an inoperative one, to the disease in question.

States of illness that are already present can be very considerably influenced by violent affects. Such changes are usually for the worse; but there is no lack of instances in which a severe shock or a sudden bereavement brings about a peculiar alteration in the tone of the organism which may have a favourable influence on some well-established pathological condition or may even bring it to an end. Finally, there can be no doubt that the duration of life can be appreciably shortened by depressive affects and that a violent shock, or a deep humiliation or disgrace, may put a sudden end to life. Strange to say, this same result may be found to follow too from the unexpected impact of a great joy.
The affects in the narrower sense are, it is true, characterized by a quite special connection with somatic processes; but, strictly speaking, all mental states, including those that we usually regard as 'processes of thought', are to some degree 'affective', and not one of them is without its physical manifestations or is incapable of modifying somatic processes. Even when a person is engaged in quietly thinking in a string of 'ideas', there are a constant series of excitations, corresponding to the content of these ideas, which are discharged into the smooth or striated muscles. These excitations can be made apparent if they are appropriately reinforced, and certain striking and, indeed, ostensibly 'supernatural' phenomena can be explained by this means. Thus, what is known as 'thought-reading' [Gedanken erraten] may be explained by small, involuntary muscular movements carried out by the 'medium' in the course of an experiment - when, for instance, he has to make someone discover a hidden object. The whole phenomenon might more suitably be described as 'thought-betraying' [Gedanken verraten].

[1890a, 1590]

There are many very effective mental procedures which the physician is obliged to renounce. He either has not the power or has not the right to invoke them. This applies in particular to the provocation of strong affects - the most powerful of all the means by which the mind affects the body. The vicissitudes of life often cure illnesses through the experience of great joy, through the satisfaction of needs or the fulfilment of wishes. The physician, who is often impotent outside his profession, cannot compete along these lines. It might be more within his power to employ fear and fright for therapeutic ends; but, except in the case of children, he must have the gravest doubts about the use of such double-edged tools. On the other hand, the physician must rule out any relations with his patient that are bound up with tender feelings, owing to their implications in practical life. Thus from the first his power to bring about mental changes in his patients seems so restricted that mental treatment conducted on a deliberate plan would seem to offer no advantages over the earlier haphazard method.

[1890a, 1595]

I will illustrate the first of these theses by a few examples. Hysterical attacks have long been recognized as signs of increased emotional excitement and equated with outbreaks of affect. Charcot attempted to reduce the multiplicity of their modes of manifestation by means of descriptive formulas; Pierre Janet recognized the unconscious ideas operating behind such attacks; while psycho-analysis has shown that they are mimetic representations of scenes (whether actually experienced or only invented) with which the patient's imagination is occupied without his becoming conscious of them. The meaning of these pantomimes is concealed from the spectators by means of condensations and distortions of the acts which they represent. And this applies equally to what are described as the 'chronic' symptoms of hysterical patients. All of them are mimetic or hallucinatory representations of phantasies which unconsciously dominate the subject's emotional life and which have the meaning of fulfillsments of secret and repressed wishes. The tormenting character of these symptoms is due to the internal conflict into which these patients' minds are driven by the need to combat such unconscious wishes.

[1913j, 2809]
We should be glad to be able to say something general about the vicissitudes of both; and having taken our bearings a little we shall in fact be able to do so. The general vicissitude which overtakes the idea that represents the instinct can hardly be anything else than that it should vanish from the conscious if it was previously conscious, or that it should be held back from consciousness if it was about to become conscious. The difference is not important; it amounts to much the same thing as the difference between my ordering an undesirable guest out of my drawing-room (or out of my front hall), and my refusing, after recognizing him, to let him cross my threshold at all.¹ The quantitative factor of the instinctual representative has three possible vicissitudes, as we can see from a cursory survey of the observations made by psycho-analysis: either the instinct is altogether suppressed, so that no trace of it is found, or it appears as an affect which is in some way or other qualitatively coloured, or it is changed into anxiety. The two latter possibilities set us the task of taking into account, as a further instinctual vicissitude, the transformation into affects, and especially into anxiety, of the psychical energies of instincts.

¹ Affectivity manifests itself essentially in motor (secretory and vasomotor) discharge resulting in an (internal) alteration of the subject's own body without reference to the external world; motility, in actions designed to effect changes in the external world.

Unconscious processes only become cognizable by us under the conditions of dreaming and of neurosis - that is to say, when processes of the higher, Pcs., system are set back to an earlier stage by being lowered (by regression). In themselves they cannot be cognized, indeed are even incapable of carrying on their existence; for the system Ucs. is at a very early moment overlaid by the Pcs. which has taken over access to consciousness and to motility. Discharge from the system Ucs. passes into somatic innervation that leads to development of affect; but even this path of discharge is, as we have seen, contested by the Pcs. By itself, the system Ucs. would not in normal conditions be able to bring about any expedient muscular acts, with the exception of those already organized as reflexes.

The third of the forms of neurotic anxiety faces us with the puzzling fact that here the connection between anxiety and a threatening danger is completely lost to view. For instance, anxiety may appear in hysteria as an accompaniment to hysterical symptoms, or in some chance condition of excitement in which, it is true, we should expect some manifestation of affect but least of all one of anxiety; or it may make its appearance, divorced from any determinants and equally incomprehensible to us and to the patient, as an unrelated attack of anxiety. Here there is no sign whatever of any danger or of any cause that could be exaggerated into one. We next learn from these spontaneous attacks that the complex which we describe as a state of anxiety is capable of fragmentation. The total attack can be represented by a single, intensely developed symptom, by a tremor, a vertigo, by palpitation of the heart, or by dyspnoea; and the general feeling by which we recognize anxiety may be absent or have become indistinct. Yet these conditions, which we describe as 'anxiety-equivalents', have to be equated with anxiety in all clinical and aetiological respects.

[1915d, 2983]
[1915e, 3002]
[1915e, 3010]
[1916-1917, 3448]
(b) A second pointer is to be found in the analysis of the psychoneuroses, and especially of hysteria. We have seen that in this illness anxiety often appears in company with the symptoms, but that unbound anxiety appears, too, manifested as an attack or as a chronic condition. The patients cannot say what it is they are afraid of, and, by the help of an unmistakable secondary revision, link it to the first phobias that come to hand - such as dying, going mad, or having a stroke. If the situation out of which the anxiety (or the symptoms accompanied by anxiety) arose is subjected to analysis, we can as a rule discover what normal course of psychical events has failed to occur and has been replaced by phenomena of anxiety. To express it in another way: we construct the unconscious process as it would have been if it had not experienced any repression and had proceeded unhindered into consciousness. This process would have been accompanied by a particular affect, and we now learn to our surprise that this affect accompanying the normal course of events is invariably replaced by anxiety after repression has occurred, no matter what its own quality may be. Thus, when we have a hysterical anxiety-state before us, its unconscious correlate may be an impulse of a similar character - anxiety, shame, embarrassment - or, just as easily, a positive libidinal excitation or a hostile aggressive one, such as rage or anger. Anxiety is therefore the universally current coinage for which any affective impulse is or can be exchanged if the ideational content attached to it is subjected to repression.

[1916-1917, 3450]

(c) We make a third discovery when we come to patients suffering from obsessional actions, who seem in a remarkable way exempt from anxiety. If we try to hinder their carrying out of their obsessional action - their washing or their ceremonial - or if they themselves venture upon an attempt to give up one of their compulsions, they are forced by the most terrible anxiety to yield to the compulsion. We can see that the anxiety was screened by the obsessional action, and that the latter was only performed in order to avoid the anxiety. In an obsessional neurosis, therefore, anxiety which would otherwise inevitably set in is replaced by the formation of a symptom, and if we turn to hysteria we find a similar relation: the result of the process of repression is either a generating of anxiety pure and simple, or anxiety accompanied by the formation of a symptom, or a more complete formation of a symptom without anxiety. It would thus seem not to be wrong in an abstract sense to assert that in general symptoms are only formed to escape an otherwise unavoidable generating of anxiety. If we adopt this view, anxiety is placed, as it were, in the very centre of our interest in the problems of neurosis.

[1916-1917, 3451]
In hysteria it is the rule that the precipitating causes of the illness are overtaken by amnesia no less than the infantile experiences by whose help the precipitating causes are able to transform their affective energy into symptoms. And where the amnesia cannot be complete, it nevertheless subjects the recent traumatic precipitating cause to a process of erosion and robs it at least of its most important components. In this amnesia we see the evidence of the repression which has taken place. The case is different in obsessional neuroses. The infantile preconditions of the neurosis may be overtaken by amnesia, though this is often an incomplete one; but the immediate occasions of the illness are, on the contrary, retained in the memory. Repression makes use of another, and in reality a simpler, mechanism. The trauma, instead of being forgotten, is deprived of its affective cathexis; so that what remains in consciousness is nothing but its ideational content, which is perfectly colourless and is judged to be unimportant. The distinction between what occurs in hysteria and in an obsessional neurosis lies in the psychological processes which we can reconstruct behind the phenomena; the result is almost always the same, for the colourless mnemonic content is rarely reproduced and plays no part in the patient's mental activity. In order to differentiate between the two kinds of repression we have on the surface nothing to rely upon but the patient's assurance that he has a feeling in the one case of having always known the thing and in the other of having long ago forgotten it.¹ [1909d, 2154]
This is quite a typical example of the way in which symptoms arise from exciting causes which appear to be entirely unconnected with sexuality.

In hysteria it is the rule that the precipitating causes of the illness are overtaken by amnesia no less than the infantile experiences by whose help the precipitating causes are able to transform their affective energy into symptoms. And where the amnesia cannot be complete, it nevertheless subjects the recent traumatic precipitating cause to a process of erosion and robs it at least of its most important components. In this amnesia we see the evidence of the repression which has taken place. The case is different in obsessional neuroses. The infantile preconditions of the neurosis may be overtaken by amnesia, though this is often an incomplete one; but the immediate occasions of the illness are, on the contrary, retained in the memory. Repression makes use of another, and in reality a simpler, mechanism. The trauma, instead of being forgotten, is deprived of its affective cathexis; so that what remains in consciousness is nothing but its ideational content, which is perfectly colourless and is judged to be unimportant. The distinction between what occurs in hysteria and in an obsessional neurosis lies in the psychological processes which we can reconstruct behind the phenomena; the result is almost always the same, for the colourless mnemonic content is rarely reproduced and plays no part in the patient's mental activity. In order to differentiate between the two kinds of repression we have on the surface nothing to rely upon but the patient's assurance that he has a feeling in the one case of having always known the thing and in the other of having long ago forgotten it.
The onset of hysterical attacks follows laws that are easily understandable. Since the repressed complex consists of a libidinal cathexis and an ideational content (the phantasy), the attack can be evoked (1) associatively, when the content of the complex (if sufficiently cathected) is touched on by something connected with it in conscious life; (2) organically, when, for internal somatic reasons and as a result of psychical influences from outside, the libidinal cathexis rises above a certain degree; (3) in the service of the primary purpose - as an expression of a 'flight into illness', when reality becomes distressing or frightening - that is, as a consolation; (4) in the service of the secondary purposes, with which the illness allies itself, as soon as, by producing an attack, the patient can achieve an aim that is useful to him. In the last case the attack is directed at particular individuals; it can be put off till they are present, and it gives an impression of being consciously simulated.

Investigation of the childhood history of hysterical patients shows that the hysterical attack is designed to take the place of an auto-erotic satisfaction previously practised and since given up. In a great number of cases this satisfaction (masturbation by contact or by pressure of the thighs, or, again, by movements of the tongue, and so on) recurs during the attack itself, while the subject's consciousness is deflected. Moreover, the onset of an attack that is due to an increase of libido and is in the service of the primary purpose - as a consolation - exactly repeats the conditions under which, at the earlier time, the patient had intentionally sought this auto-erotic satisfaction. The anamnesis of the patient shows the following stages: (a) auto-erotic satisfaction, without ideational content; (b) the same satisfaction, connected with a phantasy which leads to the act of satisfaction; (c) renunciation of the act, with retention of the phantasy; (d) repression of the phantasy, which then comes into effect as a hysterical attack, either in an unchanged form, or in a modified one and adapted to new environmental impressions. Furthermore, (e) the phantasy may even reinstate the act of satisfaction belonging to it which had ostensibly been given up. This is a typical cycle of infantile sexual activity: repression, failure of repression, and return of the repressed.

Yet another line of thought extending into organic research branches off from psycho-analysis. We may ask ourselves whether the suppression of sexual component instincts which is brought about by environmental influences is sufficient in itself to call up functional disturbances in organs, or whether special constitutional conditions must be present in order that the organs may be led to an exaggeration of their erotogenic role and consequently provoke repression of the instincts. We should have to see in those conditions the constitutional part of the disposition to fall ill of psychogenic and neurotic disorders. This is the factor to which, as applied to hysteria, I gave the provisional name of 'somatic compliance'.
In my *Interpretation of Dreams*, published in 1900, I showed that dreams in general can be interpreted, and that after the work of interpretation has been completed they can be replaced by perfectly correctly constructed thoughts which can be assigned a recognizable position in the chain of mental events. I wish to give an example in the following pages of the only practical application of which the art of interpreting dreams seems to admit. I have already mentioned in my book¹ how it was that I came upon the problem of dreams. The problem crossed my path as I was endeavouring to cure psychoneuroses by means of a particular psychotherapeutic method. For, among their other mental experiences, my patients told me their dreams, and these dreams seemed to call for insertion in the long thread of connections which spun itself out between a symptom of the disease and a pathogenic idea. At that time I learnt how to translate the language of dreams into the forms of expression of our own thought-language, which can be understood without further help. And I may add that this knowledge is essential for the psycho-analyst; for the dream is one of the roads along which consciousness can be reached by the psychical material which, on account of the opposition aroused by its content, has been cut off from consciousness and repressed, and has thus become pathogenic. The dream, in short, is one of the *détours by which repression can be evaded*; it is one of the principal means employed by what is known as the indirect method of representation in the mind. The following fragment from the history of the treatment of a hysterical girl is intended to show the way in which the interpretation of dreams plays a part in the work of analysis. It will at the same time give me a first opportunity of publishing at sufficient length to prevent further misunderstanding some of my views upon the psychical processes of hysteria and upon its organic determinants. I need no longer apologize on the score of length, since it is now agreed that the exacting demands which hysteria makes upon physician and investigator can be met only by the most sympathetic spirit of inquiry and not by an attitude of superiority and contempt. For,

[1905e, 1357]
Am I now going on to assert that in every instance in which there are periodical attacks of aphonia we are to diagnose the existence of a loved person who is at times away from the patient? Nothing could be further from my intention. The determination of Dora's symptoms is far too specific for it to be possible to expect a frequent recurrence of the same accidental aetiology. But, if so, what is the value of our elucidation of the aphonia in the present case? Have we not merely allowed ourselves to become the victims of a *jeu d'esprit*? I think not. In this connection we must recall the question which has so often been raised, whether the symptoms of hysteria are of psychical or of somatic origin, or whether, if the former is granted, they are necessarily *all* of them psychically determined. Like so many other questions to which we find investigators returning again and again without success, this question is not adequately framed. The alternatives stated in it do not cover the real essence of the matter. As far as I can see, every hysterical symptom involves the participation of *both* sides. It cannot occur without the presence of a certain degree of *somatic compliance* offered by some normal or pathological process in or connected with one of the bodily organs. And it cannot occur more than once - and the capacity for repeating itself is one of the characteristics of a hysterical symptom - unless it has a psychical significance, a *meaning*. The hysterical symptom does not carry this meaning with it, but the meaning is lent to it, soldered to it, as it were; and in every instance the meaning can be a different one, according to the nature of the suppressed thoughts which are struggling for expression. However, there are a number of factors at work which tend to make less arbitrary the relations between the unconscious thoughts and the somatic processes that are at their disposal as a means of expression, and which tend to make those relations approximate to a few typical forms. For therapeutic purposes the most important determinants are those given by the fortuitous psychical material; the clearing-up of the symptoms is achieved by looking for their psychical significance. When everything that can be got rid of by psycho-analysis has been cleared away, we are in a position to form all kinds of conjectures, which probably meet the facts, as regards the somatic basis of the symptoms - a basis which is as a rule constitutional and organic. Thus in Dora's case we shall not content ourselves with a psycho-analytic interpretation of her attacks of coughing and aphonia; but we shall also indicate the organic factor which was the source of the 'somatic compliance' that enabled her to express her love for a man who was periodically absent. And if the connection between the symptomatic expression and the unconscious mental content should strike us as being in this case a clever *tour de force*, we shall be relieved to hear that it succeeds in creating the same impression in every other case and in every other instance. [1905e, 1378]

A sexual constitution like that of little Hans does not appear to carry with it a predisposition to the development either of perversions or of their negative (we will limit ourselves to a consideration of hysteria). As far as my experience goes (and there is still a real need for speaking with caution on this point) the innate constitution of hysterics - that this is also true of perverts is almost self-evident - is marked by the genital zone being relatively less prominent than the other erotogenic zones. But we must expressly except from this rule one particular 'aberration' of sexual life. In those who later become homosexuals we meet with the same predominance in infancy of the genital zone (and especially of the penis) as in normal persons. Indeed it is the high esteem felt by the homosexual for the male organ which decides his fate. In his childhood he chooses women as his sexual object, so long as he assumes that they too possess what in his eyes is an indispensable part of the body; when he becomes convinced that women have deceived him in this particular, they cease to be acceptable to him as a sexual object. He cannot forgo a penis in any one who is to attract him to sexual intercourse; and if circumstances are favourable he will fix his libido upon the 'woman with a penis', a youth of feminine appearance. Homosexuals, then, are persons who, owing to the erotogenic importance of their own genitals, cannot do without a similar feature in their sexual object. In the course of their development from auto-erotism to object-love, they have remained at a point of fixation between the two. [1909b, 2093]
In this scene - second in order of mention, but first in order of time - the behaviour of this child of fourteen was already entirely and completely hysterical. I should without question consider a person hysterical in whom an occasion for sexual excitement elicited feelings that were preponderantly or exclusively unpleasurable; and I should do so whether or no the person were capable of producing somatic symptoms. The elucidation of the mechanism of this reversal of affect is one of the most important and at the same time one of the most difficult problems in the psychology of the neuroses. In my own judgement I am still some way from having achieved this end; and I may add that within the limits of the present paper I shall be able to bring forward only a part of such knowledge on the subject as I do possess.

[1905e, 1368]

Am I now going on to assert that in every instance in which there are periodical attacks of aphonia we are to diagnose the existence of a loved person who is at times away from the patient? Nothing could be further from my intention. The determination of Dora's symptoms is far too specific for it to be possible to expect a frequent recurrence of the same accidental aetiology. But, if so, what is the value of our elucidation of the aphonia in the present case? Have we not merely allowed ourselves to become the victims of a jeu d'esprit? I think not. In this connection we must recall the question which has so often been raised, whether the symptoms of hysteria are of psychical or of somatic origin, or whether, if the former is granted, they are necessarily all of them psychically determined. Like so many other questions to which we find investigators returning again and again without success, this question is not adequately framed. The alternatives stated in it do not cover the real essence of the matter. As far as I can see, every hysterical symptom involves the participation of both sides. It cannot occur without the presence of a certain degree of somatic compliance offered by some normal or pathological process in or connected with one of the bodily organs. And it cannot occur more than once - and the capacity for repeating itself is one of the characteristics of a hysterical symptom - unless it has a psychical significance, a meaning. The hysterical symptom does not carry this meaning with it, but the meaning is lent to it, soldered to it, as it were; and in every instance the meaning can be a different one, according to the nature of the suppressed thoughts which are struggling for expression. However, there are a number of factors at work which tend to make less arbitrary the relations between the unconscious thoughts and the somatic processes that are at their disposal as a means of expression, and which tend to make those relations approximate to a few typical forms. [1905e, 1378]

I am prepared to be told at this point that there is no very great advantage in having been taught by psycho-analysis that the clue to the problem of hysteria is to be found not in 'a peculiar instability of the molecules of the nerves' or in a liability to 'hypnoid states' - but in a 'somatic compliance'. But in reply to the objection I may remark that this new view has not only to some extent pushed the problem further back, but has also to some extent diminished it. We have no longer to deal with the *whole* problem, but only with the portion of it involving that particular characteristic of hysteria which *differentiates it* from other psychoneuroses. The mental events in all psycho-neuroses proceed for a considerable distance along the same lines before any question arises of the 'somatic compliance' which may afford the unconscious mental processes a physical outlet. When this factor is not forthcoming, something other than a hysterical symptom will arise out of the total situation; yet it will still be something of an allied nature, a phobia, perhaps, or an obsession - in short, a psychical symptom.

[1905e, 1379]
We have already learnt that it quite regularly happens that a single symptom corresponds to several meanings simultaneously. We may now add that it can express several meanings in succession. In the course of years a symptom can change its meaning or its chief meaning, or the leading role can pass from one meaning to another. It is as though there were a conservative trait in the character of neuroses which ensures that a symptom that has once been formed shall if possible be retained, even though the unconscious thought to which it gave expression has lost its meaning. Moreover, there is no difficulty in explaining this tendency towards the retention of a symptom upon a mechanical basis. The production of a symptom of this kind is so difficult, the translation of a purely psychical excitation into physical terms - the process which I have called 'conversion' - depends on the concurrence of so many favourable conditions, the somatic compliance necessary for conversion is so seldom forthcoming, that an impulsion towards the discharge of an unconscious excitation will so far as possible make use of any channel for discharge which may already be in existence. It appears to be far more difficult to create a fresh conversion than to form paths of association between a new thought which is in need of discharge and the old one which is no longer in need of it. The current flows along these paths from the new source of excitation to the old point of discharge - pouring into the symptom, in the words of the Gospel, like new wine into an old bottle. These remarks would make it seem that the somatic side of a hysterical symptom is the more stable of the two and the harder to replace, while the psychical side is a variable element for which a substitute can more easily be found. Yet we should not try to infer anything from this comparison as regards the relative importance of the two elements. From the point of view of mental therapeutics the mental side must always be the more significant.

But, once again, in the present paper I have not gone fully into all that might be said to-day about 'somatic compliance', about the infantile germs of perversion, about the erotogenic zones, and about our predisposition towards bisexuality; I have merely drawn attention to the points at which the analysis comes into contact with these organic bases of the symptoms. More than this could not be done with a single case. And I had the same reasons that I have already mentioned for wishing to avoid a cursory discussion of these factors. There is a rich opportunity here for further works, based upon the study of a large number of analyses.

Yet another line of thought extending into organic research branches off from psycho-analysis. We may ask ourselves whether the suppression of sexual component instincts which is brought about by environmental influences is sufficient in itself to call up functional disturbances in organs, or whether special constitutional conditions must be present in order that the organs may be led to an exaggeration of their erotogenic role and consequently provoke repression of the instincts. We should have to see in those conditions the constitutional part of the disposition to fall ill of psychogenic and neurotic disorders. This is the factor to which, as applied to hysteria, I gave the provisional name of 'somatic compliance'.

[1905e, 1390]

[1905e, 1447]

[1910i, 2371]
Others of the patient's somatic symptoms were not of a hysterical nature at all. This is true, for example, of the neck-cramps, which I regard as a modified form of migraine and which as such are not to be classed as a neurosis but as an organic disorder. Hysterical symptoms, however, regularly become attached to these. Frau von N.'s neck-cramps, for instance, were employed for the purpose of hysterical attacks, whereas she did not have the typical symptomatology of hysterical attacks at her disposal.

[1895d, 87]

To begin with there was no explanation of the unusual localization of her hysterogenic zone. The fact that the hyperalgesia mainly affected the muscles also gave food for thought. The disorder which is most usually responsible for diffuse and local sensitivity to pressure in the muscles is a rheumatic infiltration of those muscles - common chronic muscular rheumatism. I have already spoken of its tendency to simulate nervous affections. This possibility was not contradicted by the consistency of the patient's hyperalgic muscles. There were numerous hard fibres in the muscular substance, and these seemed especially sensitive. Thus it was probable that an organic change in the muscles of the kind indicated was present and that the neurosis attached itself to this and made it seem of exaggerated importance.

[1895d, 123]

A number of comments might of course be made at this point. I must emphasize the fact that I did not succeed in establishing from her memory that the conversion took place at the moment of her return home. I therefore looked about for similar experiences during the time she was nursing her father and elicited a number of them. Among these, special prominence attached, on account of their frequent occurrence, to scenes in which, at her father's call, she had jumped out of bed with bare feet in a cold room. I was inclined to attribute some importance to these factors, since in addition to complaining about the pain in her legs she also complained of tormenting sensations of cold. Nevertheless, even here I was unable to get hold of any scene which it was possible to identify as that at which the conversion had occurred. I was inclined for this reason to think that there was a gap in the explanation at this point, until I recollected that the hysterical pains in the legs had in fact not made their appearance during the period when she was nursing her father. She only remembered a single attack of pain, which had only lasted a day or two and had not attracted her attention. I was inclined for this reason to think that there was a gap in the explanation at this point, until I recollected that the hysterical pains in the legs had in fact not made their appearance during the period when she was nursing her father. She only remembered a single attack of pain, which had only lasted a day or two and had not attracted her attention. I now directed my enquiries to this first appearance of the pains. I succeeded in reviving the patient's memory of it with certainty. At that very time a relative had visited them and she had been unable to receive him, owing to being laid up in bed. This same man had been unlucky enough, when he visited them again two years later, to find her in bed once more. But in spite of repeated attempts we failed to trace any psychical cause for the first pains. I thought it safe to assume that they had in fact appeared without any psychical cause and were a mild rheumatic affection; and I was able to establish that this organic disorder, which was the model copied in her later hysteria, had in any case to be dated before the scene of her being accompanied back from the party. From the nature of things it is nevertheless possible that these pains, being of organic origin, may have persisted for some time to a mitigated degree without being very noticeable. The obscurity due to the fact that the analysis pointed to the occurrence of a conversion of psychical excitation into physical pain though that pain was certainly not perceived at the time in question or remembered afterwards - this is a problem which I hope to be able to solve later on the basis of further considerations and later examples.¹

[1895d, 133]
I have now discussed the motives and mechanism of this case of hysteria; it remains for me to consider how precisely the hysterical symptom was determined. Why was it that the patient's mental pain came to be represented by pains in the legs rather than elsewhere? The circumstances indicate that the somatic pain was not created by the neurosis but merely used, increased and maintained by it. I may add at once that I have found a similar state of things in almost all the instances of hysterical pains into which I have been able to obtain an insight.

There had always been a genuine, organically-founded pain present at the start. It is the commonest and most widespread human pains that seem to be most often chosen to play a part in hysteria: in particular, the periosteal and neuralgic pains accompanying dental disease, the headaches that arise from so many different sources and, not less often, the rheumatic muscular pains that are so often unrecognized. In the same way I attribute an organic foundation to Fräulein Elisabeth von R.'s first attack of pain which occurred as far back as while she was nursing her father. I obtained no result when I tried to discover a psychical cause for it - and I am inclined, I must confess, to attribute a power of differential diagnosis to my method of evoking concealed memories, provided it is carefully handled. This pain, which was rheumatic in its origin,¹ then became a mnemonic symbol of her painful psychical excitations; and this happened, so far as I can see, for more than one reason. The first and no doubt the most important of these reasons was that the pain was present in her consciousness at about the same time as the excitations. In the second place, it was connected, or could be connected, along a number of lines with the ideas in her mind at the time. The pain, indeed, may actually have been a consequence, though only a remote one, of the period of nursing - of the lack of exercise and reduced diet that her duties as a sick-nurse entailed. But the girl had no clear knowledge of this. More importance should probably be attached to the fact that she must have felt the pain during that time at significant moments, for instance, when she sprang out of bed in the cold of winter in response to a call from her father. But what must have had a positively decisive influence on the direction taken by the conversion was another line of associative connection: the fact that on a long succession of days one of her painful legs came into contact with her father's swollen leg while his bandages were being changed. The area of her right leg which was marked out by this contact remained thereafter the focus of her pains and the point from which they radiated. It formed an artificial hysterogenic zone whose origin could in the present case be clearly observed.

[1895d, 158]

But ultimately we were able to make our way back to her first attack of neuralgia, more than fifteen years earlier. Here there was no symbolization but a conversion through simultaneity. She saw a painful sight which was accompanied by feelings of self-reproach, and this led her to force back another set of thoughts. Thus it was a case of conflict and defence. The generation of the neuralgia at that moment was only explicable on the assumption that she was suffering at the time from slight toothache or pains in the face, and this was not improbable, since she was just then in the early months of her first pregnancy.

[1895d, 161]

I will give a second example which demonstrates the action of symbolization under other conditions. At a particular period, Frau Cäcilie was afflicted with a violent pain in her right heel - a shooting pain at every step she took, which made walking impossible. Analysis led us in connection with this to a time when the patient had been in a sanatorium abroad. She had spent a week in bed and was going to be taken down to the common dining-room for the first time by the house physician. The pain came on at the moment when she took his arm to leave the room with him; it disappeared during the reproduction of the scene, when the patient told me she had been afraid at the time that she might not 'find herself on a right footing' with these strangers.

[1895d, 162]
It is a matter of daily observation to find that in people with normal nerves peripheral pains are brought on by pathological processes, not in themselves painful, in other organs. Thus headaches arise from relatively insignificant changes in the nose or neighbouring cavities, and again, neuralgias of the intercostal and brachial nerves from the heart, etc. If the abnormal excitability, which we have been obliged to postulate as a necessary condition of hallucinations of pain, is present in a patient, that excitability is also at the disposal, so to speak, of the irradiations that I have just mentioned. The irradiations that occur also in non-neurotic people are made more intense, and irradiations are formed of a sort which, it is true, we only find in neurotic patients but which are based on the same mechanism as the others. Thus, ovarian neuralgia depends, I believe, on states of the genital apparatus. That its causes are psychical would have to be proved, and this is not achieved by showing that that particular kind of pain, like any other, can be produced under hypnosis as a hallucination, or that its cause can be psychical. Like erythema or one of the normal secretions, it arises both from psychical and from purely somatic causes. Are we to describe only the first kind as hysterical - cases which we know have a psychical origin? If so, the commonly observed cases of ovarian neuralgia would have to be excluded from the hysterical syndrome, and this will hardly do. [1895d [Breuer], 169]

The symptomatology of hysteria and anxiety neurosis show many points in common which have not yet been sufficiently considered. The appearance of symptoms either in a chronic form or in attacks, the paraesthesias, grouped like auras, the hyperaesthesias and pressure-points which are found in certain surrogates of an anxiety attack (in dyspnoea and heart-attacks), the intensification, through conversion, of pains which perhaps have an organic justification - these and other features which the two illnesses have in common even allow of a suspicion that not a little of what is attributed to hysteria might with more justice be put to the account of anxiety neurosis. If one goes into the mechanism of the two neuroses, so far as it has been possible to discover it hitherto, aspects come to light which suggest that anxiety neurosis is actually the somatic counterpart to hysteria. In the latter just as in the former there is an accumulation of excitation (which is perhaps the basis for the similarity between their symptoms we have mentioned). In the latter just as in the former we find a psychical insufficiency, as a consequence of which abnormal somatic processes arise. In the latter just as in the former, too, instead of a psychical working-over of the excitation, a deflection of it occurs into the somatic field; the difference is merely that in anxiety neurosis the excitation, in whose displacement the neurosis expresses itself, is purely somatic (somatic sexual excitation), whereas in hysteria it is psychical (provoked by conflict). Thus it is not to be wondered at that hysteria and anxiety neurosis regularly combine with each other, as is seen in 'virginal anxiety' or in 'sexual hysteria', and that hysteria simply borrows a number of its symptoms from anxiety neurosis, and so on. These intimate relations which anxiety neurosis has with hysteria provide a fresh argument, moreover, for insisting on the detachment of anxiety neurosis from neurasthenia; for if this detachment is not granted, we shall also be unable any longer to maintain the distinction which has been acquired with so much labour and which is so indispensable for the theory of the neuroses, between neurasthenia and hysteria. [1895b, 349]
In the days while I was engaged in writing these pages the following almost incredible instance of forgetting happened to me. On the first of January I was going through my medical engagement book so that I could send out my accounts. Under the month of June I came across the name 'M---l' but could not recall who it belonged to. My bewilderment grew when I turned the pages and discovered that I treated the case in a sanatorium and made daily visits over a period of weeks. A patient treated under such conditions cannot be forgotten by a doctor after scarcely six months. Could it have been a man, I asked myself, a case of general paralysis, an uninteresting case? Finally the record of the fees I had received brought back to me all the facts that had striven to escape my memory. M---l was a fourteen-year-old girl, the most remarkable case I had had in recent years, one which taught me a lesson I am not likely ever to forget and whose outcome cost me moments of the greatest distress. The child fell ill of an unmistakable hysteria, which did in fact clear up quickly and radically under my care. After this improvement the child was taken away from me by her parents. She still complained of abdominal pains which had played the chief part in the clinical picture of her hysteria. Two months later she died of sarcoma of the abdominal glands. The hysteria, to which she was at the same time predisposed, used the tumour as a provoking cause, and I, with my attention held by the noisy but harmless manifestations of the hysteria, had perhaps overlooked the first signs of the insidious and incurable disease.

The little girl went through the usual infectious diseases of childhood without suffering any lasting damage. As she herself told me - and her words were intended to convey a deeper meaning - her brother was as a rule the first to start the illness and used to have it very slightly, and she would then follow suit with a severe form of it. When she was about twelve she began to suffer from unilateral headaches in the nature of a migraine, and from attacks of nervous coughing. At first these two symptoms always appeared together, but they became separated later on and ran different courses. The migraine grew rarer, and by the time she was sixteen she had quite got over it. But attacks of tussis nervosa, which had no doubt been started by a common catarrh, continued to occur over the whole period. When, at the age of eighteen, she came to me for treatment, she was again coughing in a characteristic manner. The number of these attacks could not be determined; but they lasted from three to five weeks, and on one occasion for several months. The most troublesome symptom during the first half of an attack of this kind, at all events in the last few years, used to be a complete loss of voice. The diagnosis that this was once more a nervous complaint had been established long since; but the various methods of treatment which are usual, including hydrotherapy and the local application of electricity, had produced no result. It was in such circumstances as these that the child had developed into a mature young woman of very independent judgement, who had grown accustomed to laugh at the efforts of doctors, and in the end to renounce their help entirely. Moreover, she had always been against calling in medical advice, though she had no personal objection to her family doctor. Every proposal to consult a new physician aroused her resistance, and it was only her father's authority which induced her to come to me at all.
Am I now going on to assert that in every instance in which there are periodical attacks of aphonia we are to diagnose the existence of a loved person who is at times away from the patient? Nothing could be further from my intention. The determination of Dora's symptoms is far too specific for it to be possible to expect a frequent recurrence of the same accidental aetiology. But, if so, what is the value of our elucidation of the aphonia in the present case? Have we not merely allowed ourselves to become the victims of a jeu d'esprit? I think not. In this connection we must recall the question which has so often been raised, whether the symptoms of hysteria are of psychical or of somatic origin, or whether, if the former is granted, they are necessarily all of them psychically determined. Like so many other questions to which we find investigators returning again and again without success, this question is not adequately framed. The alternatives stated in it do not cover the real essence of the matter. As far as I can see, every hysterical symptom involves the participation of both sides. It cannot occur without the presence of a certain degree of somatic compliance offered by some normal or pathological process in or connected with one of the bodily organs. And it cannot occur more than once - and the capacity for repeating itself is one of the characteristics of a hysterical symptom - unless it has a psychical significance, a meaning. The hysterical symptom does not carry this meaning with it, but the meaning is lent to it, soldered to it, as it were; and in every instance the meaning can be a different one, according to the nature of the suppressed thoughts which are struggling for expression. However, there are a number of factors at work which tend to make less arbitrary the relations between the unconscious thoughts and the somatic processes that are at their disposal as a means of expression, and which tend to make those relations approximate to a few typical forms. For therapeutic purposes the most important determinants are those given by the fortuitous psychical material; the clearing-up of the symptoms is achieved by looking for their psychical significance. When everything that can be got rid of by psycho-analysis has been cleared away, we are in a position to form all kinds of conjectures, which probably meet the facts, as regards the somatic basis of the symptoms - a basis which is as a rule constitutional and organic. Thus in Dora's case we shall not content ourselves with a psycho-analytic interpretation of her attacks of coughing and aphonia; but we shall also indicate the organic factor which was the source of the 'somatic compliance' that enabled her to express her love for a man who was periodically absent. And if the connection between the symptomatic expression and the unconscious mental content should strike us as being in this case a clever tour de force, we shall be relieved to hear that it succeeds in creating the same impression in every other case and in every other instance.

[1905e, 1378]

A consideration of the significance of the leucorrhoea to which Dora admitted promises to give us a still better understanding of her symptoms. She had learnt to call her affection a 'catarrh' at the time when her mother had had to visit Franzensbad on account of a similar complaint; and the word 'catarrh' acted once again as a 'switch-word' and enabled the whole set of thoughts upon her father's responsibility for her illness to manifest themselves in the symptom of the cough. The cough, which no doubt originated in the first instance from a slight actual catarrh, was, moreover, an imitation of her father (whose lungs were affected), and could serve as an expression of her sympathy and concern for him. But besides this, it proclaimed aloud, as it were, something of which she may then have been still unconscious: 'I am my father's daughter. I have a catarrh, just as he has. He has made me ill, just as he has made Mother ill. It is from him that I have got my evil passions, which are punished by illness.'

[1905e, 1418]
Let us next attempt to put together the various determinants that we have found for Dora's attacks of coughing and hoarseness. In the lowest stratum we must assume the presence of real and organically determined irritation of the throat - which acted like the grain of sand around which an oyster forms its pearl. This irritation was susceptible to fixation, because it concerned a part of the body which in Dora had to a high degree retained its significance as an erotogenic zone. And the irritation was consequently well fitted to give expression to excited states of the libido. It was brought to fixation by what was probably its first psychical coating - her sympathetic imitation of her father - and by her subsequent self-reproaches on account of her 'catarrh'. The same group of symptoms, moreover, showed itself capable of representing her relations with Herr K.; it could express her regret at his absence and her wish to make him a better wife. After a part of her libido had once more turned towards her father, the symptom obtained what was perhaps its last meaning; it came to represent sexual intercourse with her father by means of Dora's identifying herself with Frau K. I can guarantee that this series is by no means complete. Unfortunately, an incomplete analysis cannot enable us to follow the chronological sequence of the changes in a symptom's meaning, or to display clearly the succession and coexistence of its various meanings. It may legitimately be expected of a complete analysis that it should fulfil these demands.

I suspect that we are here concerned with unconscious processes of thought which are twined around a pre-existing structure of organic connections, much as festoons of flowers are twined around a wire; so that on another occasion one might find other lines of thought inserted between the same points of departure and termination. Yet a knowledge of the thought connections which have been effective in the individual case is of a value which cannot be exaggerated for clearing up the symptoms. It is only because the analysis was prematurely broken off that we have been obliged in Dora's case to resort to framing conjectures and filling in deficiencies. Whatever I have brought forward for filling up the gaps is based upon other cases which have been more thoroughly analysed.

I naturally required a special determinant for this. Dora objected that she would anyhow have had to go upstairs if she had wanted to get to her flat, which was on an upper floor. It was easy to brush aside this objection (which was probably not very seriously intended) by pointing out that if she had been able to travel in her dream from the unknown town to Vienna without making a railway journey she ought also to have been able to leave out a flight of stairs. She then proceeded to relate that after the appendicitis she had not been able to walk properly and had dragged her right foot. This state of things had continued for a long time, and on that account she had been particularly glad to avoid stairs. Even now her foot sometimes dragged. The doctors whom she had consulted at her father's desire had been very much astonished at this most unusual after-effect of an appendicitis, especially as the abdominal pains had not recurred and did not in any way accompany the dragging of the foot.

¹ We must assume the existence of some somatic connection between the painful abdominal sensations known as 'ovarian neuralgia' and locomotor disturbances in the leg on the same side; and we must suppose that in Dora's case the somatic connection had been given an interpretation of a particularly specialized sort, that is to say, that it had been overlaid with and brought into the service of a particular psychological meaning. The reader is referred to my analogous remarks in connection with the analysis of Dora's symptom of coughing and with the relation between catarrh and loss of appetite.
Here, then, we have a true hysterical symptom. The fever may have been organically determined - perhaps by one of those very frequent attacks of influenza that are not localized in any particular part of the body. Nevertheless it was now established that the neurosis had seized upon this chance event and made use of it for an utterance of its own. Dora had therefore given herself an illness which she had read up about in the encyclopaedia, and she had punished herself for dipping into its pages. But she was forced to recognize that the punishment could not possibly apply to her reading the innocent article in question. It must have been inflicted as the result of a process of displacement, after another occasion of more guilty reading had become associated with this one: and the guilty occasion must lie concealed in her memory behind the contemporaneous innocent one.¹ It might still be possible, perhaps, to discover the nature of the subjects she had read about on that other occasion.

What, then, was the meaning of this condition, of this attempted simulation of a perityphlitis? The remainder of the disorder, the dragging of one leg, was entirely out of keeping with perityphlitis. It must, no doubt, fit in better with the secret and possibly sexual meaning of the clinical picture; and if it were elucidated might in its turn throw light on the meaning which we were in search of. I looked about for a method of approaching the puzzle. Periods of time had been mentioned in the dream; and time is assuredly never a matter of indifference in any biological event. I therefore asked Dora when this attack of appendicitis had taken place; whether it had been before or after the scene by the lake. Every difficulty was resolved at a single blow by her prompt reply: 'Nine months later.'  The period of time is sufficiently characteristic. Her supposed attack of appendicitis had thus enabled the patient with the modest means at her disposal (the pains and the menstrual flow) to realize a phantasy of childbirth.² Dora was naturally aware of the significance of this period of time, and could not dispute the probability of her having, on the occasion under discussion, read up in the encyclopaedia about pregnancy and childbirth. But what was all this about her dragging her leg? I could now hazard a guess. That is how people walk when they have twisted a foot. So she had made a 'false step': which was true indeed if she could give birth to a child nine months after the scene by the lake. But there was still another requirement upon the fulfilment of which I had to insist. I am convinced that a symptom of this kind can only arise where it has an infantile prototype. All my experience hitherto has led me to hold firmly to the view that recollections derived from the impressions of later years do not possess sufficient force to enable them to establish themselves as symptoms. I scarcely dared hope that Dora would provide me with the material that I wanted from her childhood, for the fact is that I am not yet in a position to assert the general validity of this rule, much as I should like to be able to do so. But in this case there came an immediate confirmation of it. Yes, said Dora, once when she was a child she had twisted the same foot; she had slipped on one of the steps as she was going downstairs. The foot - and it was actually the same one that she afterwards dragged - had swelled up and had to be bandaged and she had had to lie up for some weeks. This had been a short time before the attack of nervous asthma in her eighth year.
A similar course of events affords peculiar diagnostic and therapeutic interest. It not at all infrequently happens in the case of a person who is disposed to a neurosis without actually suffering from a manifest one, that a pathological somatic change (through inflammation or injury perhaps) sets the activity of symptom-formation going; so that this activity hastily turns the symptom which has been presented to it by reality into the representative of all the unconscious phantasies which have only been lying in wait to seize hold of some means of expression. In such a case the physician will adopt sometimes one and sometimes another line of treatment. He will either endeavour to remove the organic basis, without bothering about its noisy neurotic elaboration; or he will attack the neurosis which has taken this favourable opportunity for arising and will pay little attention to its organic precipitating cause. The outcome will prove the one or the other line of approach right or wrong; it is impossible to make general recommendations to meet such mixed cases.
[1916-1917, 3441]
I have not found such an extensive use of symbolization in any other patient. It is true that Frau Cäcilie M. was a woman who possessed quite unusual gifts, particularly artistic ones, and whose highly developed sense of form was revealed in some poems of great perfection. It is my opinion, however, that when a hysteric creates a somatic expression for an emotionally coloured idea by symbolization, this depends less than one would imagine on personal or voluntary factors. In taking a verbal expression literally and in feeling the 'stab in the heart' or the 'slap in the face' after some slighting remark as a real event, the hysteric is not taking liberties with words, but is simply reviving once more the sensations to which the verbal expression owes its justification. How has it come about that we speak of someone who has been slighted as being 'stabbed to the heart' unless the slight had in fact been accompanied by a precordial sensation which could suitably be described in that phrase and unless it was identifiable by that sensation? What could be more probable than that the figure of speech 'swallowing something', which we use in talking of an insult to which no rejoinder has been made, did in fact originate from the innervatory sensations which arise in the pharynx when we refrain from speaking and prevent ourselves from reacting to the insult? All these sensations and innervations belong to the field of 'The Expression of the Emotions', which, as Darwin has taught us, consists of actions which originally had a meaning and served a purpose. These may now for the most part have become so much weakened that the expression of them in words seems to us only to be a figurative picture of them, whereas in all probability the description was once meant literally; and hysteria is right in restoring the original meaning of the words in depicting its unusually strong innervations. Indeed, it is perhaps wrong to say that hysteria creates these sensations by symbolization. It may be that it does not take linguistic usage as its model at all, but that both hysteria and linguistic usage alike draw their material from a common source.¹

A dream, as we have discovered, takes the place of a number of thoughts which are derived from our daily life and which form a completely logical sequence. We cannot doubt, then, that these thoughts originate from our normal mental life. All the attributes which we value highly in our trains of thought, and which characterize them as complex achievements of a high order, are to be found once more in dream-thoughts. There is no need to assume, however, that this activity of thought is performed during sleep - a possibility which would gravely confuse what has hitherto been our settled picture of the psychical state of sleep. On the contrary, these thoughts may very well have originated from the previous day, they may have proceeded unobserved by our consciousness from their start, and may already have been completed at the onset of sleep. The most that we can conclude from this is that it proves that the most complicated achievements of thought are possible without the assistance of consciousness - a fact which we could not fail to learn in any case from every psycho-analysis of a patient suffering from hysteria or from obsessional ideas. These dream-thoughts are certainly not in themselves inadmissible to consciousness; there may have been a number of reasons for their not having become conscious to us during the day. Becoming conscious is connected with the application of a particular psychical function, that of attention - a function which, as it seems, is only available in a specific quantity, and this may have been diverted from the train of thought in question on to some other purpose. There is another way, too, in which trains of thought of this kind may be withheld from consciousness. The course of our conscious reflections shows us that we follow a particular path in our application of attention. If, as we follow this path, we come upon an idea which will not bear criticism, we break off: we drop the cathexis of attention. Now it seems that the train of thought which has thus been initiated and dropped can continue to spin itself out without attention being turned to it again, unless at some point or other it reaches a specially high degree of intensity which forces attention to it. Thus, if a train of thought is initially rejected (consciously, perhaps) by a judgement that it is wrong or that it is useless for the immediate intellectual purposes in view, the result may be that this train of thought will proceed, unobserved by consciousness, until the onset of sleep.²

¹[1895d, 163]
²[1900a, 1020]
A consideration of the significance of the leucorrhoea to which Dora admitted promises to give us a still better understanding of her symptoms. She had learnt to call her affection a 'catarrh' at the time when her mother had had to visit Franzensbad on account of a similar complaint; and the word 'catarrh' acted once again as a 'switch-word' and enabled the whole set of thoughts upon her father's responsibility for her illness to manifest themselves in the symptom of the cough. The cough, which no doubt originated in the first instance from a slight actual catarrh, was, moreover, an imitation of her father (whose lungs were affected), and could serve as an expression of her sympathy and concern for him. But besides this, it proclaimed aloud, as it were, something of which she may then have been still unconscious: 'I am my father's daughter. I have a catarrh, just as he has. He has made me ill, just as he has made Mother ill. It is from him that I have got my evil passions, which are punished by illness.'¹

The removal of the symptoms of hysterical patients by psycho-analysis proceeds on the supposition that those symptoms are substitutes - transcriptions as it were - for a number of emotionally cathected mental processes, wishes and desires, which, by the operation of a special psychical procedure (repression), have been prevented from obtaining discharge in psychical activity that is admissible to consciousness. These mental processes, therefore, being held back in a state of unconsciousness, strive to obtain an expression that shall be appropriate to their emotional importance - to obtain discharge; and in the case of hysteria they find such an expression (by means of the process of 'conversion') in somatic phenomena, that is, in hysterical symptoms. By systematically turning these symptoms back (with the help of a special technique) into emotionally cathected ideas - ideas that will now have become conscious - it is possible to obtain the most accurate knowledge of the nature and origin of these formerly unconscious psychical structures.

Unconscious phantasies have either been unconscious all along and have been formed in the unconscious; or - as is more often the case - they were once conscious phantasies, daydreams, and have since been purposely forgotten and have become unconscious through 'repression'. Their content may afterwards either have remained the same or have undergone alterations, so that the present unconscious phantasies are derivatives of the once conscious ones. Now an unconscious phantasy has a very important connection with the subject's sexual life; for it is identical with the phantasy which served to give him sexual satisfaction during a period of masturbation. At that time the masturbatory act (in the widest sense of the term) was compounded of two parts. One was the evocation of a phantasy and the other some active behaviour for obtaining self-gratification at the height of the phantasy. This compound, as we know, was itself merely soldered together.¹ Originally the action was a purely auto-erotic procedure for the purpose of obtaining pleasure from some particular part of the body, which could be described as erotogenic. Later, this action became merged with a wishful idea from the sphere of object-love and served as a partial realization of the situation in which the phantasy culminated. When, subsequently, the subject renounces this type of satisfaction, composed of masturbation and phantasy, the action is given up, while the phantasy, from being conscious, becomes unconscious. If no other mode of sexual satisfaction supervenes, the subject remains abstinent; and if he does not succeed in sublimating his libido - that is, in deflecting his sexual excitation to higher aims - , the condition is now fulfilled for his unconscious phantasy to be revived and to proliferate, and, at least as regards some part of its content, to put itself into effect, with the whole force of his need for love, in the form of a pathological symptom.

[1905e, 1418]

[1905d, 1489]

[1908a, 1934]
This method of psycho-analytic investigation, which leads from the conspicuous symptoms to the hidden unconscious phantasies, tells us everything that can be known about the sexuality of psychoneurotics, including the fact which is to be the main subject-matter of this short preliminary publication.

[1908a, 1935]

When one carries out the psycho-analysis of a hysterical woman patient whose complaint is manifested in attacks, one soon becomes convinced that these attacks are nothing else but phantasies translated into the motor sphere, projected on to motility and portrayed in pantomime. It is true that the phantasies are unconscious; but apart from this they are of the same nature as the phantasies which can be observed directly in day-dreams or which can be elicited by interpretation from dreams at night. Often a dream takes the place of an attack, and still more often it explains it, since the same phantasy finds a different expression in a dream and in an attack. We might expect then that by observing an attack we should be able to get to know the phantasy represented in it; but this is seldom possible. As a rule, owing to the influence of the censorship, the pantomimic portrayal of the phantasy has undergone distortions which are completely analogous to the hallucinatory distortions of a dream, so that both of them have, in the first resort, become unintelligible to the subject's own consciousness as well as to the observer's comprehension. A hysterical attack, therefore, needs to be subjected to the same interpretative revision as we employ for night-dreams. But not only are the forces from which the distortion proceeds and the purpose of the distortion the same as those we have come to know through the interpretation of dreams; the technique employed in the distortion is the same too.

[1909a, 1981]

It soon emerged, as though by chance, that this process of sweeping the mind clean could accomplish more than the merely temporary relief of her ever-recurring mental confusion. It was actually possible to bring about the disappearance of the painful symptoms of her illness, if she could be brought to remember under hypnosis, with an accompanying expression of affect, on what occasion and in what connection the symptom had first appeared. 'It was in the summer during a period of extreme heat, and the patient was suffering very badly from thirst; for, without being able to account for it in any way, she suddenly found it impossible to drink. She would take up the glass of water that she longed for, but as soon as it touched her lips she would push it away like someone suffering from hydrophobia. As she did this, she was obviously in an absence for a couple of seconds. She lived only on fruit, such as melons, etc., so as to lessen her tormenting thirst. This had lasted for some six weeks, when one day during hypnosis she grumbled about her English "lady-companion", whom she did not care for, and went on to describe, with every sign of disgust, how she had once gone into this lady's room and how her little dog - horrid creature! - had drunk out of a glass there. The patient had said nothing, as she had wanted to be polite. After giving further energetic expression to the anger she had held back, she asked for something to drink, drank a large quantity of water without any difficulty, and awoke from her hypnosis with the glass at her lips; and thereupon the disturbance vanished, never to return.'

[1910a, 2203]
I will illustrate the first of these theses by a few examples. Hysterical attacks have long been recognized as signs of increased emotional excitement and equated with outbreaks of affect. Charcot attempted to reduce the multiplicity of their modes of manifestation by means of descriptive formulas; Pierre Janet recognized the unconscious ideas operating behind such attacks; while psycho-analysis has shown that they are mimetic representations of scenes (whether actually experienced or only invented) with which the patient's imagination is occupied without his becoming conscious of them. The meaning of these pantomimes is concealed from the spectators by means of condensations and distortions of the acts which they represent. And this applies equally to what are described as the 'chronic' symptoms of hysterical patients. All of them are mimetic or hallucinatory representations of phantasies which unconsciously dominate the subject's emotional life and which have the meaning of fulfilsments of secret and repressed wishes. The tormenting character of these symptoms is due to the internal conflict into which these patients' minds are driven by the need to combat such unconscious wishes.

[1913j, 2809]

The physical movement of 'changing her position', Tausk remarks, depicted the words 'putting her in a false position' and her identification with her lover. I would call attention once more to the fact that the whole train of thought is dominated by the element which has for its content a bodily innervation (or, rather, the sensation of it). Furthermore, a hysterical woman would, in the first example, have in fact convulsively twisted her eyes, and, in the second, have given actual jerks, instead of having the impulse to do so or the sensation of doing so: and in neither example would she have any accompanying conscious thoughts, nor would she have been able to express any such thoughts afterwards.

[1915e, 3020]

'Nothing has entered into you from without; a part of the activity of your own mind has been withdrawn from your knowledge and from the command of your will. That, too, is why you are so weak in your defence; you are using one part of your force to fight the other part and you cannot concentrate the whole of your force as you would against an external enemy. And it is not even the worst or least important part of your mental forces that has thus become antagonistic to you and independent of you. The blame, I am bound to say, lies with yourself. You over-estimated your strength when you thought you could treat your sexual instincts as you liked and could utterly ignore their intentions. The result is that they have rebelled and have taken their own obscure paths to escape this suppression; they have established their rights in a manner you cannot approve. How they have achieved this, and the paths which they have taken, have not come to your knowledge. All you have learned is the outcome of their work - the symptom which you experience as suffering. Thus you do not recognize it as a derivative of your own rejected instincts and do not know that it is a substitutive satisfaction of them.

[1917a, 3613]

It is essentially in hysteria and in states of a hysterical type that this is found. Here the mechanism by which the sense of guilt remains unconscious is easy to discover. The hysterical ego fends off a distressing perception with which the criticisms of its super-ego threaten it, in the same way in which it is in the habit of fending off an unendurable object-cathexis - by an act of repression. It is the ego, therefore, that is responsible for the sense of guilt remaining unconscious. We know that as a rule the ego carries out repressions in the service and at the behest of its super-ego; but this is a case in which it has turned the same weapon against its harsh taskmaster. In obsessional neurosis, as we know, the phenomena of reaction-formation predominate; but here the ego succeeds only in keeping at a distance the material to which the sense of guilt refers.

[1923b, 3985]
The removal of the symptoms of hysterical patients by psycho-analysis proceeds on the supposition that those symptoms are substitutes - transcriptions as it were - for a number of emotionally cathected mental processes, wishes and desires, which, by the operation of a special psychical procedure (repression), have been prevented from obtaining discharge in psychical activity that is admissible to consciousness. These mental processes, therefore, being held back in a state of unconsciousness, strive to obtain an expression that shall be appropriate to their emotional importance - to obtain discharge; and in the case of hysteria they find such an expression (by means of the process of 'conversion') in somatic phenomena, that is, in hysterical symptoms. By systematically turning these symptoms back (with the help of a special technique) into emotionally cathected ideas - ideas that will now have become conscious - it is possible to obtain the most accurate knowledge of the nature and origin of these formerly unconscious psychical structures.

I think it is worth emphasizing the fact that, whatever modifications my views on the aetiology of the psychoneuroses have passed through, there are two positions which I have never repudiated or abandoned - the importance of sexuality and of infantilism. Apart from this, accidental influences have been replaced by constitutional factors and 'defence' in the purely psychological sense has been replaced by organic 'sexual repression'. The question may, however, be raised of where convincing evidence is to be found in favour of the alleged aetiological importance of sexual factors in the psychoneuroses, in view of the fact that the onset of these illnesses may be observed in response to the most commonplace emotions or even to somatic precipitating causes, and since I have had to abandon a specific aetiology depending on the particular form of the childhood experiences concerned. To such a question I would reply that the psycho-analytic examination of neurotics is the source from which this disputed conviction of mine is derived. If we make use of that irreplaceable method of research, we discover that the patient's symptoms constitute his sexual activity (whether wholly or in part), which arises from the sources of the normal or perverse component instincts of sexuality. Not only is a large part of the symptomatology of hysteria derived directly from expressions of sexual excitement, not only do a number of erotogenic zones attain the significance of genitals during neuroses owing to an intensification of infantile characteristics, but the most complicated symptoms are themselves revealed as representing, by means of 'conversion', phantasies which have a sexual situation as their subject-matter. Anyone who knows how to interpret the language of hysteria will recognize that the neurosis is concerned only with the patient's repressed sexuality. The sexual function must, however, be understood in its true extent, as it is laid down by disposition in infancy. Wherever some commonplace emotion must be included among the determinants of the onset of the illness, analysis invariably shows that it is the sexual component of the traumatic experience - a component that is never lacking which has produced the pathogenic result.

[1905d, 1489]

[1906a, 1582]
The field I have in mind is indeed very different from yours. I am referring to the therapy employed for certain 'nervous diseases' - what are known as the psychoneuroses - of which hysteria and obsessional ideas may be taken as samples. The method is called 'psychoanalysis'; it was evolved by me from the 'cathartic' method of therapy first practised by Josef Breuer in Vienna.¹ To combat your surprise, I must draw an analogy between the criminal and the hysteric. In both we are concerned with a secret, with something hidden. But in order not to be paradoxical I must at once point out the difference. In the case of the criminal it is a secret which he knows and hides from you, whereas in the case of the hysteric it is a secret which he himself does not know either, which is hidden even from himself. How is this possible? Now we know, through laborious research, that all these illnesses are the result of the patient's having succeeded in repressing certain ideas and memories that are strongly cathected with affect, together with the wishes that arise from them, in such a way that they play no part in his thinking - do not enter into his consciousness - and thus remain unknown to him. But from this repressed psychical material (these 'complexes') are generated the somatic and psychical symptoms which plague the patient in just the same way as a guilty conscience does. In this one respect, therefore, the difference between the criminal and the hysteric is fundamental.

In this way, unconscious phantasies are the immediate psychical precursors of a whole number of hysterical symptoms. Hysterical symptoms are nothing other than unconscious phantasies brought into view through 'conversion'; and in so far as the symptoms are somatic ones, they are often enough taken from the circle of the same sexual sensations and motor innervations as those which had originally accompanied the phantasy when it was still conscious. In this way the giving up of the habit of masturbation is in fact undone, and the purpose of the whole pathological process, which is a restoration of the original, primary sexual satisfaction, is achieved - though never completely, it is true, but always in a sort of approximation.

For the sake of general interest I will at this point go outside the framework of this paper and interpolate a series of formulas which attempt to give a progressively fuller description of the nature of hysterical symptoms. These formulas do not contradict one another, but some represent an increasingly complete and precise approach to the facts, while others represent the application of different points of view:

Among these various definitions the seventh brings out the nature of hysterical symptoms most completely as the realization of an unconscious phantasy; and the eighth recognizes the proper significance of the sexual factor. Some of the preceding formulas lead up to these two and are contained in them.
This connection between symptoms and phantasies makes it easy to arrive from a psycho-
analysis of the former at a knowledge of the components of the sexual instincts which dominate
the individual, as I have demonstrated in my *Three Essays on the Theory of Sexuality*. In some
cases, however, investigation by this means yields an unexpected result. It shows that there are
many symptoms where the uncovering of a sexual phantasy (or of a number of phantasies, one
of which, the most significant and the earliest, is of a sexual nature) is not enough to bring about
a resolution of the symptoms. To resolve it one has to have two sexual phantasies, of which one
has a masculine and the other a feminine character. Thus one of these phantasies springs from
a homosexual impulse. This new finding does not alter our seventh formula. It remains true that
a hysterical symptom must necessarily represent a compromise between a libidinal and a
repressing impulse; but it may also represent a union of two libidinal phantasies of an opposite
sexual character.

[1908a, 1937]

(9) Hysterical symptoms are the expression on the one hand of a masculine unconscious
sexual phantasy, and on the other hand of a feminine one.

[1908a, 1938]

I must expressly state that I cannot claim the same general validity for this formula as I have
done for the others. As far as I can see, it applies neither to all the symptoms of a given case
nor to all cases. On the contrary, it is not hard to adduce cases in which the impulses belonging
to the opposite sexes have found separate symptomatic expression, so that the symptoms of
heterosexual and those of homosexuality can be as clearly distinguished from each other as
the phantasies concealed behind them. Nevertheless, the condition of things stated in the ninth
formula is common enough, and, when it occurs, important enough to deserve special
emphasis. It seems to me to mark the highest degree of complexity to which the determination
of a hysterical symptom can attain, and one may therefore only expect to find it in a neurosis
which has persisted for a long time and within which a great deal of organization has taken
place.¹

[1908a, 1938]

The bisexual nature of hysterical symptoms, which can in any event be demonstrated in
numerous cases, is an interesting confirmation of my view that the postulated existence of an
innate bisexual disposition in man is especially clearly visible in the analysis of
psychoneurotics.² An exactly analogous state of affairs occurs in the same field when a person
who is masturbating tries in his conscious phantasies to have the feelings both of the man and
of the woman in the situation which he is picturing. Further counterparts are to be found in
certain hysterical attacks in which the patient simultaneously plays both parts in the underlying
sexual phantasy. In one case which I observed, for instance, the patient pressed her dress up
against her body with one hand (as the woman), while she tried to tear it off with the other (as
the man). This simultaneity of contradictory actions serves to a large extent to obscure the
situation, which is otherwise so plastically portrayed in the attack, and it is thus well suited to
conceal the unconscious phantasy that is at work.

[1908a, 1938]
(1) The attack becomes unintelligible through the fact that it represents several phantasies in the same material simultaneously - that is to say through condensation. The elements common to the two (or more) phantasies constitute the nucleus of the representation, as they do in dreams. The phantasies which are thus made to coincide are often of quite a different nature. They may, for instance, be a recent wish and the re-activation of an infantile impression. The same innervations are in that case made to serve both purposes, often in a most ingenious way. Hysterical patients who make a very extensive use of condensation may find a single form of attack sufficient; others express their numerous pathogenic phantasies by a multiplication of the forms of attack.
[1909a, 1982]

(4) Scarcely less confusing and misleading is a reversal of the chronological order within the phantasy that is portrayed, which once more has its complete counterpart in a number of dreams which begin with the end of the action and end with its beginning. Supposing, for instance, that a hysterical woman has a phantasy of seduction in which she is sitting reading in a park with her skirt slightly lifted so that her foot is visible; a gentleman approaches and speaks to her; they then go somewhere and make love to one another. This phantasy is acted out in the attack by her beginning with the convulsive stage, which corresponds to the coitus, by her then getting up, going into another room, sitting down and reading and presently answering an imaginary remark addressed to her.
[1909a, 1982]

Investigation of the childhood history of hysterical patients shows that the hysterical attack is designed to take the place of an auto-erotic satisfaction previously practised and since given up. In a great number of cases this satisfaction (masturbation by contact or by pressure of the thighs, or, again, by movements of the tongue, and so on) recurs during the attack itself, while the subject's consciousness is deflected. Moreover, the onset of an attack that is due to an increase of libido and is in the service of the primary purpose - as a consolation - exactly repeats the conditions under which, at the earlier time, the patient had intentionally sought this auto-erotic satisfaction. The anamnesis of the patient shows the following stages: (a) auto-erotic satisfaction, without ideational content; (b) the same satisfaction, connected with a phantasy which leads to the act of satisfaction; (c) renunciation of the act, with retention of the phantasy; (d) repression of the phantasy, which then comes into effect as a hysterical attack, either in an unchanged form, or in a modified one and adapted to new environmental impressions. Furthermore, (e) the phantasy may even reinstate the act of satisfaction belonging to it which had ostensibly been given up. This is a typical cycle of infantile sexual activity: repression, failure of repression, and return of the repressed.
[1909a, 1983]

Speaking as a whole, hysterical attacks, like hysteria in general, revive a piece of sexual activity in women which existed during their childhood and at that time revealed an essentially masculine character. It can often be observed that girls who have shown a boyish nature and inclinations up to the years before puberty are precisely those who become hysterical from puberty onwards. In a whole number of cases the hysterical neurosis merely represents an excessive accentuation of the typical wave of repression which, by doing away with her masculine sexuality, allows the woman to emerge.
[1909a, 1984]
No doubt all kinds of objections can still be raised to the assertion that neurotic symptoms are substitutes for sexual satisfactions. I will mention two of them to-day. When you yourselves have carried out analytic examinations of a considerable number of neurotics, you will perhaps tell me, shaking your head, that in a lot of cases my assertion is simply not true; the symptoms seem rather to have the contrary purpose of excluding or of stopping sexual satisfaction. I will not dispute the correctness of your interpretation. The facts in psycho-analysis have a habit of being rather more complicated than we like. If they were as simple as all that, perhaps it might not have needed psycho-analysis to bring them to light. Indeed, some of the features of our second patient’s ceremonial show signs of this ascetic character with its hostility to sexual satisfaction: when, for instance, she got rid of the clocks and watches, which had the magical meaning of avoiding erections during the night, or when she tried to guard against flower-pots falling and breaking, which was equivalent to protecting her virginity. In some other cases of bed ceremonials, which I have been able to analyse, this negative character was far more outspoken; the ceremonial might consist exclusively of defensive measures against sexual memories and temptations. However, we have already found often enough that in psycho-analysis opposites imply no contradiction. We might extend our thesis and say that symptoms aim either at a sexual satisfaction or at fending it off, and that on the whole the positive, wish-fulfilling character prevails in hysteria and the negative, ascetic one in obsessional neurosis. If symptoms can serve the purpose both of sexual satisfaction and of its opposite, there is an excellent basis for this double-sidedness or polarity in a part of their mechanism which I have so far not been able to mention. For, as we shall hear, they are the products of a compromise and arise from the mutual interference between two opposing currents; they represent not only the repressed but also the repressing force which had a share in their origin. One side or the other may be more strongly represented; but it is rarely that one influence is entirely absent. In hysteria a convergence of both intentions in the same symptom is usually achieved. In obsessional neurosis the two portions are often separated; the symptom then becomes diphasic and consists in two actions, one after the other, which cancel each other out.

[1916-1917, 3373]

The third of the forms of neurotic anxiety faces us with the puzzling fact that here the connection between anxiety and a threatening danger is completely lost to view. For instance, anxiety may appear in hysteria as an accompaniment to hysterical symptoms, or in some chance condition of excitement in which, it is true, we should expect some manifestation of affect but least of all one of anxiety; or it may make its appearance, divorced from any determinants and equally incomprehensible to us and to the patient, as an unrelated attack of anxiety. Here there is no sign whatever of any danger or of any cause that could be exaggerated into one. We next learn from these spontaneous attacks that the complex which we describe as a state of anxiety is capable of fragmentation. The total attack can be represented by a single, intensely developed symptom, by a tremor, a vertigo, by palpitation of the heart, or by dyspnoea; and the general feeling by which we recognize anxiety may be absent or have become indistinct. Yet these conditions, which we describe as ‘anxiety-equivalents’, have to be equated with anxiety in all clinical and aetiological respects.

[1916-1917, 3448]
The Theory of Repression. - These theoretical considerations, taken together with the immediate impressions derived from analytic work, lead to a view of the neuroses which may be described in the roughest outline as follows. The neuroses are the expression of conflicts between the ego and such of the sexual impulses as seem to the ego incompatible with its integrity or with its ethical standards. Since these impulses are not ego-syntonic, the ego has repressed them: that is to say, it has withdrawn its interest from them and has shut them off from becoming conscious as well as from obtaining satisfaction by motor discharge. If in the course of analytic work one attempts to make these repressed impulses conscious, one becomes aware of the repressive forces in the form of resistance. But the achievement of repression fails particularly readily in the case of the sexual instincts. Their dammed-up libido finds other ways out from the unconscious: for it regresses to earlier phases of development and earlier attitudes towards objects, and, at weak points in the libidinal development where there are infantile fixations, it breaks through into consciousness and obtains discharge. What results is a symptom and consequently in its essence a substitutive sexual satisfaction. Nevertheless the symptom cannot entirely escape from the repressive forces of the ego and must therefore submit to modifications and displacements exactly as happens with dreams - by means of which its characteristic of being a sexual satisfaction becomes unrecognizable. Consequently symptoms are in the nature of compromises between the repressed sexual instincts and the repressing ego-instincts; they represent a wish-fulfilment for both partners to the conflict simultaneously, but one which is incomplete for each of them. This is quite strictly true of the symptoms of hysteria, while in the symptoms of obsessional neurosis there is often a stronger emphasis upon the side of the repressing function owing to the erection of reaction-formations, which are assurances against sexual satisfaction.

[1923a, 3923]
To return to the problem of the ego. The apparent contradiction is due to our having taken abstractions too rigidly and attended exclusively now to the one side and now to the other of what is in fact a complicated state of affairs. We were justified, I think, in dividing the ego from the id, for there are certain considerations which necessitate that step. On the other hand the ego is identical with the id, and is merely a specially differentiated part of it. If we think of this part by itself in contradistinction to the whole, or if a real split has occurred between the two, the weakness of the ego becomes apparent. But if the ego remains bound up with the id and indistinguishable from it, then it displays its strength. The same is true of the relation between the ego and the super-ego. In many situations the two are merged; and as a rule we can only distinguish one from the other when there is a tension or conflict between them. In repression the decisive fact is that the ego is an organization and the id is not. The ego is, indeed, the organized portion of the id. We should be quite wrong if we pictured the ego and the id as two opposing camps and if we supposed that, when the ego tries to suppress a part of the id by means of repression, the remainder of the id comes to the rescue of the endangered part and measures its strength with the ego. This may often be what happens, but it is certainly not the initial situation in repression. As a rule the instinctual impulse which is to be repressed remains isolated. Although the act of repression demonstrates the strength of the ego, in one particular it reveals the ego's powerlessness and how impervious to influence are the separate instinctual impulses of the id. For the mental process which has been turned into a symptom owing to repression now maintains its existence outside the organization of the ego and independently of it. Indeed, it is not that process alone but all its derivatives which enjoy, as it were, this same privilege of extra-territoriality; and whenever they come into associative contact with a part of the ego-organization, it is not at all certain that they will not draw that part over to themselves and thus enlarge themselves at the expense of the ego. An analogy with which we have long been familiar compared a symptom to a foreign body which was keeping up a constant succession of stimuli and reactions in the tissue in which it was embedded. It does sometimes happen that the defensive struggle against an unwelcome instinctual impulse is brought to an end with the formation of a symptom. As far as can be seen, this is most often possible in hysterical conversion. But usually the outcome is different. The initial act of repression is followed by a tedious or interminable sequel in which the struggle against the instinctual impulse is prolonged into a struggle against the symptom.

[1926d, 4258]
In this secondary defensive struggle the ego presents two faces with contradictory expressions. The one line of behaviour it adopts springs from the fact that its very nature obliges it to make what must be regarded as an attempt at restoration or reconciliation. The ego is an organization. It is based on the maintenance of free intercourse and of the possibility of reciprocal influence between all its parts. Its desexualized energy still shows traces of its origin in its impulsion to bind together and unify, and this necessity to synthesize grows stronger in proportion as the strength of the ego increases. It is therefore only natural that the ego should try to prevent symptoms from remaining isolated and alien by using every possible method to bind them to itself in one way or another, and to incorporate them into its organization by means of those bonds. As we know, a tendency of this kind is already operative in the very act of forming a symptom. A classical instance of this are those hysterical symptoms which have been shown to be a compromise between the need for satisfaction and the need for punishment. Such symptoms participate in the ego from the very beginning, since they fulfil a requirement of the super-ego, while on the other hand they represent positions occupied by the repressed and points at which an irruption has been made by it into the ego-organization. They are a kind of frontier-station with a mixed garrison. (Whether all primary hysterical symptoms are constructed on these lines would be worth enquiring into very carefully.) The ego now proceeds to behave as though it recognized that the symptom had come to stay and that the only thing to do was to accept the situation in good part and draw as much advantage from it as possible. It makes an adaptation to the symptom - to this piece of the internal world which is alien to it - just as it normally does to the real external world. It can always find plenty of opportunities for doing so. The presence of a symptom may entail a certain impairment of capacity, and this can be exploited to appease some demand on the part of the super-ego or to refuse some claim from the external world. In this way the symptom gradually comes to be the representative of important interests; it is found to be useful in asserting the position of the self and becomes more and more closely merged with the ego and more and more indispensable to it. It is only very rarely that the physical process of "healing" round a foreign body follows such a course as this. There is a danger, too, of exaggerating the importance of a secondary adaptation of this kind to a symptom, and of saying that the ego has created the symptom merely in order to enjoy its advantages. It would be equally true to say that a man who had lost his leg in the war had got it shot away so that he might thenceforward live on his pension without having to do any more work.

[1926d, 4259]
Even if I ignore the ill-will of narrow-minded critics such as these, the presentation of my case histories remains a problem which is hard for me to solve. The difficulties are partly of a technical kind, but are partly due to the nature of the circumstances themselves. If it is true that the causes of hysterical disorders are to be found in the intimacies of the patients' psycho-sexual life, and that hysterical symptoms are the expression of their most secret and repressed wishes, then the complete elucidation of a case of hysteria is bound to involve the revelation of those intimacies and the betrayal of those secrets. It is certain that the patients would never have spoken if it had occurred to them that their admissions might possibly be put to scientific uses; and it is equally certain that to ask them themselves for leave to publish their case would be quite unavailing. In such circumstances persons of delicacy, as well as those who were merely timid, would give first place to the duty of medical discretion and would declare with regret that the matter was one upon which they could offer science no enlightenment. But in my opinion the physician has taken upon himself duties not only towards the individual patient but towards science as well; and his duties towards science mean ultimately nothing else than his duties towards the many other patients who are suffering or will some day suffer from the same disorder. Thus it becomes the physician's duty to publish what he believes he knows of the causes and structure of hysteria, and it becomes a disgraceful piece of cowardice on his part to neglect doing so, as long as he can avoid causing direct personal injury to the single patient concerned. I think I have taken every precaution to prevent my patient from suffering any such injury. I have picked out a person the scenes of whose life were laid not in Vienna but in a remote provincial town, and whose personal circumstances must therefore be practically unknown in Vienna. I have from the very beginning kept the fact of her being under my treatment such a careful secret that only one other physician - and one in whose discretion I have complete confidence - can be aware that the girl was a patient of mine. I have waited for four whole years since the end of the treatment and have postponed publication till hearing that a change has taken place in the patient's life of such a character as allows me to suppose that her own interest in the occurrences and psychological events which are to be related here may now have grown faint. Needless to say, I have allowed no name to stand which could put a non-medical reader upon the scent; and the publication of the case in a purely scientific, and technical periodical should, further, afford a guarantee against unauthorized readers of this sort. I naturally cannot prevent the patient herself from being pained if her own case history should accidentally fall into her hands. But she will learn nothing from it that she does not already know; and she may ask herself who besides her could discover from it that she is the subject of this paper.

[1905e, 1351]
Am I now going on to assert that in every instance in which there are periodical attacks of aphonia we are to diagnose the existence of a loved person who is at times away from the patient? Nothing could be further from my intention. The determination of Dora's symptoms is far too specific for it to be possible to expect a frequent recurrence of the same accidental aetiology. But, if so, what is the value of our elucidation of the aphonia in the present case? Have we not merely allowed ourselves to become the victims of a jeu d'esprit? I think not. In this connection we must recall the question which has so often been raised, whether the symptoms of hysteria are of psychical or of somatic origin, or whether, if the former is granted, they are necessarily all of them psychically determined. Like so many other questions to which we find investigators returning again and again without success, this question is not adequately framed. The alternatives stated in it do not cover the real essence of the matter. As far as I can see, every hysterical symptom involves the participation of both sides. It cannot occur without the presence of a certain degree of somatic compliance offered by some normal or pathological process in or connected with one of the bodily organs. And it cannot occur more than once - and the capacity for repeating itself is one of the characteristics of a hysterical symptom - unless it has a psychical significance, a meaning. The hysterical symptom does not carry this meaning with it, but the meaning is lent to it, soldered to it, as it were; and in every instance the meaning can be a different one, according to the nature of the suppressed thoughts which are struggling for expression. However, there are a number of factors at work which tend to make less arbitrary the relations between the unconscious thoughts and the somatic processes that are at their disposal as a means of expression, and which tend to make those relations approximate to a few typical forms. For therapeutic purposes the most important determinants are those given by the fortuitous psychical material; the clearing-up of the symptoms is achieved by looking for their psychical significance. When everything that can be got rid of by psycho-analysis has been cleared away, we are in a position to form all kinds of conjectures, which probably meet the facts, as regards the somatic basis of the symptoms - a basis which is as a rule constitutional and organic. Thus in Dora's case we shall not content ourselves with a psycho-analytic interpretation of her attacks of coughing and aphonia; but we shall also indicate the organic factor which was the source of the 'somatic compliance' that enabled her to express her love for a man who was periodically absent. And if the connection between the symptomatic expression and the unconscious mental content should strike us as being in this case a clever tour de force, we shall be relieved to hear that it succeeds in creating the same impression in every other case and in every other instance.

[1905e, 1378]
What, then, was the meaning of this condition, of this attempted simulation of a perityphlitis? The remainder of the disorder, the dragging of one leg, was entirely out of keeping with perityphlitis. It must, no doubt, fit in better with the secret and possibly sexual meaning of the clinical picture; and if it were elucidated might in its turn throw light on the meaning which we were in search of. I looked about for a method of approaching the puzzle. Periods of time had been mentioned in the dream; and time is assuredly never a matter of indifference in any biological event. I therefore asked Dora when this attack of appendicitis had taken place; whether it had been before or after the scene by the lake. Every difficulty was resolved at a single blow by her prompt reply: 'Nine months later.' The period of time is sufficiently characteristic. Her supposed attack of appendicitis had thus enabled the patient with the modest means at her disposal (the pains and the menstrual flow) to realize a phantasy of childbirth. Dora was naturally aware of the significance of this period of time, and could not dispute the probability of her having, on the occasion under discussion, read up in the encyclopaedia about pregnancy and childbirth. But what was all this about her dragging her leg? I could now hazard a guess. That is how people walk when they have twisted a foot. So she had made a 'false step': which was true indeed if she could give birth to a child nine months after the scene by the lake. But there was still another requirement upon the fulfilment of which I had to insist. I am convinced that a symptom of this kind can only arise where it has an infantile prototype. All my experience hitherto has led me to hold firmly to the view that recollections derived from the impressions of later years do not possess sufficient force to enable them to establish themselves as symptoms. I scarcely dared hope that Dora would provide me with the material that I wanted from her childhood, for the fact is that I am not yet in a position to assert the general validity of this rule, much as I should like to be able to do so. But in this case there came an immediate confirmation of it. Yes, said Dora, once when she was a child she had twisted the same foot; she had slipped on one of the steps as she was going downstairs. The foot - and it was actually the same one that she afterwards dragged - had swelled up and had to be bandaged and she had had to lie up for some weeks. This had been a short time before the attack of nervous asthma in her eighth year.

The removal of the symptoms of hysterical patients by psycho-analysis proceeds on the supposition that those symptoms are substitutes - transcriptions as it were - for a number of emotionally catheted mental processes, wishes and desires, which, by the operation of a special psychical procedure (repression), have been prevented from obtaining discharge in psychical activity that is admissible to consciousness. These mental processes, therefore, being held back in a state of unconsciousness, strive to obtain an expression that shall be appropriate to their emotional importance - to obtain discharge; and in the case of hysteria they find such an expression (by means of the process of 'conversion') in somatic phenomena, that is, in hysterical symptoms. By systematically turning these symptoms back (with the help of a special technique) into emotionally catheted ideas - ideas that will now have become conscious - it is possible to obtain the most accurate knowledge of the nature and origin of these formerly unconscious psychical structures.
The field I have in mind is indeed very different from yours. I am referring to the therapy employed for certain 'nervous diseases' - what are known as the psychoneuroses - of which hysteria and obsessional ideas may be taken as samples. The method is called 'psycho-analysis'; it was evolved by me from the 'cathartic' method of therapy first practised by Josef Breuer in Vienna.¹ To combat your surprise, I must draw an analogy between the criminal and the hysteric. In both we are concerned with a secret, with something hidden. But in order not to be paradoxical I must at once point out the difference. In the case of the criminal it is a secret which he knows and hides from you, whereas in the case of the hysteric it is a secret which he himself does not know either, which is hidden even from himself. How is this possible? Now we know, through laborious research, that all these illnesses are the result of the patient's having succeeding in repressing certain ideas and memories that are strongly cathected with affect, together with the wishes that arise from them, in such a way that they play no part in his thinking - do not enter into his consciousness - and thus remain unknown to him. But from this repressed psychological material (these 'complexes') are generated the somatic and psychological symptoms which plague the patient in just the same way as a guilty conscience does. In this one respect, therefore, the difference between the criminal and the hysteric is fundamental.

[1906c, 1892]

In this way, unconscious phantasies are the immediate psychological precursors of a whole number of hysterical symptoms. Hysterical symptoms are nothing other than unconscious phantasies brought into view through 'conversion'; and in so far as the symptoms are somatic ones, they are often enough taken from the circle of the same sexual sensations and motor innervations as those which had originally accompanied the phantasy when it was still conscious. In this way the giving up of the habit of masturbation is in fact undone, and the purpose of the whole pathological process, which is a restoration of the original, primary sexual satisfaction, is achieved - though never completely, it is true, but always in a sort of approximation.

[1908a, 1935]

(4) Hysterical symptoms are the realization of an unconscious phantasy which serves the fulfillment of a wish.

[1908a, 1936]

Among these various definitions the seventh brings out the nature of hysterical symptoms most completely as the realization of an unconscious phantasy; and the eighth recognizes the proper significance of the sexual factor. Some of the preceding formulas lead up to these two and are contained in them.

[1908a, 1937]

(4) Scarce less confusing and misleading is a reversal of the chronological order within the phantasy that is portrayed, which once more has its complete counterpart in a number of dreams which begin with the end of the action and end with its beginning. Supposing, for instance, that a hysterical woman has a phantasy of seduction in which she is sitting reading in a park with her skirt slightly lifted so that her foot is visible; a gentleman approaches and speaks to her; they then go somewhere and make love to one another. This phantasy is acted out in the attack by her beginning with the convulsive stage, which corresponds to the coitus, by her then getting up, going into another room, sitting down and reading and presently answering an imaginary remark addressed to her.

[1909a, 1982]
Among these various definitions the seventh brings out the nature of hysterical symptoms most completely as the realization of an unconscious phantasy; and the eighth recognizes the proper significance of the sexual factor. Some of the preceding formulas lead up to these two and are contained in them.

[1908a, 1937]

(9) Hysterical symptoms are the expression on the one hand of a masculine unconscious sexual phantasy, and on the other hand of a feminine one.

[1908a, 1938]

When one carries out the psycho-analysis of a hysterical woman patient whose complaint is manifested in attacks, one soon becomes convinced that these attacks are nothing else but phantasies translated into the motor sphere, projected on to motility and portrayed in pantomime. It is true that the phantasies are unconscious; but apart from this they are of the same nature as the phantasies which can be observed directly in day-dreams or which can be elicited by interpretation from dreams at night. Often a dream takes the place of an attack, and still more often it explains it, since the same phantasy finds a different expression in a dream and in an attack. We might expect then that by observing an attack we should be able to get to know the phantasy represented in it; but this is seldom possible. As a rule, owing to the influence of the censorship, the pantomimic portrayal of the phantasy has undergone distortions which are completely analogous to the hallucinatory distortions of a dream, so that both of them have, in the first resort, become unintelligible to the subject's own consciousness as well as to the observer's comprehension. A hysterical attack, therefore, needs to be subjected to the same interpretative revision as we employ for night-dreams. But not only are the forces from which the distortion proceeds and the purpose of the distortion the same as those we have come to know through the interpretation of dreams; the technique employed in the distortion is the same too.

[1909a, 1981]

(1) The attack becomes unintelligible through the fact that it represents several phantasies in the same material simultaneously - that is to say through condensation. The elements common to the two (or more) phantasies constitute the nucleus of the representation, as they do in dreams. The phantasies which are thus made to coincide are often of quite a different nature. They may, for instance, be a recent wish and the re-activation of an infantile impression. The same innervations are in that case made to serve both purposes, often in a most ingenious way. Hysterical patients who make a very extensive use of condensation may find a single form of attack sufficient; others express their numerous pathogenic phantasies by a multiplication of the forms of attack.

[1909a, 1982]

(4) Scarcely less confusing and misleading is a reversal of the chronological order within the phantasy that is portrayed, which once more has its complete counterpart in a number of dreams which begin with the end of the action and end with its beginning. Supposing, for instance, that a hysterical woman has a phantasy of seduction in which she is sitting reading in a park with her skirt slightly lifted so that her foot is visible; a gentleman approaches and speaks to her; they then go somewhere and make love to one another. This phantasy is acted out in the attack by her beginning with the convulsive stage, which corresponds to the coitus, by her then getting up, going into another room, sitting down and reading and presently answering an imaginary remark addressed to her.

[1909a, 1982]
Investigation of the childhood history of hysterical patients shows that the hysterical attack is designed to take the place of an auto-erotic satisfaction previously practised and since given up. In a great number of cases this satisfaction (masturbation by contact or by pressure of the thighs, or, again, by movements of the tongue, and so on) recurs during the attack itself, while the subject's consciousness is deflected. Moreover, the onset of an attack that is due to an increase of libido and is in the service of the primary purpose - as a consolation - exactly repeats the conditions under which, at the earlier time, the patient had intentionally sought this auto-erotic satisfaction. The anamnesis of the patient shows the following stages: (a) auto-erotic satisfaction, without ideational content; (b) the same satisfaction, connected with a phantasy which leads to the act of satisfaction; (c) renunciation of the act, with retention of the phantasy; (d) repression of the phantasy, which then comes into effect as a hysterical attack, either in an unchanged form, or in a modified one and adapted to new environmental impressions. Furthermore, (e) the phantasy may even reinstate the act of satisfaction belonging to it which had ostensibly been given up. This is a typical cycle of infantile sexual activity: repression, failure of repression, and return of the repressed.
[1909a, 1983]
What, then, was the meaning of this condition, of this attempted simulation of a perityphlitis? The remainder of the disorder, the dragging of one leg, was entirely out of keeping with perityphlitis. It must, no doubt, fit in better with the secret and possibly sexual meaning of the clinical picture; and if it were elucidated might in its turn throw light on the meaning which we were in search of. I looked about for a method of approaching the puzzle. Periods of time had been mentioned in the dream; and time is assuredly never a matter of indifference in any biological event. I therefore asked Dora when this attack of appendicitis had taken place; whether it had been before or after the scene by the lake. Every difficulty was resolved at a single blow by her prompt reply: 'Nine months later.' The period of time is sufficiently characteristic. Her supposed attack of appendicitis had thus enabled the patient with the modest means at her disposal (the pains and the menstrual flow) to realize a phantasy of childbirth.² Dora was naturally aware of the significance of this period of time, and could not dispute the probability of her having, on the occasion under discussion, read up in the encyclopaedia about pregnancy and childbirth. But what was all this about her dragging her leg? I could now hazard a guess. That is how people walk when they have twisted a foot. So she had made a 'false step': which was true indeed if she could give birth to a child nine months after the scene by the lake. But there was still another requirement upon the fulfilment of which I had to insist. I am convinced that a symptom of this kind can only arise where it has an infantile prototype. All my experience hitherto has led me to hold firmly to the view that recollections derived from the impressions of later years do not possess sufficient force to enable them to establish themselves as symptoms. I scarcely dared hope that Dora would provide me with the material that I wanted from her childhood, for the fact is that I am not yet in a position to assert the general validity of this rule, much as I should like to be able to do so. But in this case there came an immediate confirmation of it. Yes, said Dora, once when she was a child she had twisted the same foot; she had slipped on one of the steps as she was going downstairs. The foot - and it was actually the same one that she afterwards dragged - had swollen up and had to be bandaged and she had had to lie up for some weeks. This had been a short time before the attack of nervous asthma in her eighth year.

[1905e, 1438]

² I have already indicated that the majority of hysterical symptoms, when they have attained their full pitch of development, represent an imagined situation of sexual life - such as a scene of sexual intercourse, pregnancy, childbirth, confinement, etc.

[1905e, 1438]

The next thing to do was to turn to account our knowledge of the existence of this phantasy: 'If it is true that you were delivered of a child nine months after the scene by the lake, and that you are going about to this very day carrying the consequences of your false step with you, then it follows that in your unconscious you must have regretted the upshot of the scene. In your unconscious thoughts, that is to say, you have made an emendation in it. The assumption that underlies your phantasy of childbirth is that on that occasion something took place,¹ that on that occasion you experienced and went through everything that you were in fact obliged to pick up later on from the encyclopaedia. So you see that your love for Herr K. did not come to an end with the scene, but that (as I maintained) it has persisted down to the present day - though it is true that you are unconscious of it.' - And Dora disputed the fact no longer.²

[1905e, 1439]

¹ The phantasy of defloration is thus found to have an application to Herr K., and we begin to see why this part of the dream contained material taken from the scene by the lake - the refusal, two and a half hours, the wood, the invitation to L--.

[1905e, 1439]
In this way, unconscious phantasies are the immediate psychical precursors of a whole number of hysterical symptoms. Hysterical symptoms are nothing other than unconscious phantasies brought into view through ‘conversion’; and in so far as the symptoms are somatic ones, they are often enough taken from the circle of the same sexual sensations and motor innervations as those which had originally accompanied the phantasy when it was still conscious. In this way the giving up of the habit of masturbation is in fact undone, and the purpose of the whole pathological process, which is a restoration of the original, primary sexual satisfaction, is achieved - though never completely, it is true, but always in a sort of approximation.

[1908a, 1935]

(8) Hysterical symptoms may take over the representation of various unconscious impulses which are not sexual, but they can never be without a sexual significance.

[1908a, 1936]

Among these various definitions the seventh brings out the nature of hysterical symptoms most completely as the realization of an unconscious phantasy; and the eighth recognizes the proper significance of the sexual factor. Some of the preceding formulas lead up to these two and are contained in them.

[1908a, 1937]

(4) Scarcely less confusing and misleading is a reversal of the chronological order within the phantasy that is portrayed, which once more has its complete counterpart in a number of dreams which begin with the end of the action and end with its beginning. Supposing, for instance, that a hysterical woman has a phantasy of seduction in which she is sitting reading in a park with her skirt slightly lifted so that her foot is visible; a gentleman approaches and speaks to her; they then go somewhere and make love to one another. This phantasy is acted out in the attack by her beginning with the convulsive stage, which corresponds to the coitus, by her then getting up, going into another room, sitting down and reading and presently answering an imaginary remark addressed to her.

[1909a, 1982]

Speaking as a whole, hysterical attacks, like hysteria in general, revive a piece of sexual activity in women which existed during their childhood and at that time revealed an essentially masculine character. It can often be observed that girls who have shown a boyish nature and inclinations up to the years before puberty are precisely those who become hysterical from puberty onwards. In a whole number of cases the hysterical neurosis merely represents an excessive accentuation of the typical wave of repression which, by doing away with her masculine sexuality, allows the woman to emerge.

[1909a, 1984]
Thus forearmed we can proceed to the consideration of a suggestion which we shall certainly not be spared. 'Why', we shall be asked, 'are you so obstinate in describing as being already sexuality what on your own evidence are indefinable manifestations in childhood out of which sexual life will later develop? Why should you not be content instead with giving them a physiological description and simply say that in an infant at the breast we already observe activities, such as sensual sucking or holding back the excreta, which show us that he is striving for "organ-pleasure"? In that way you would have avoided the hypothesis, so repugnant to every feeling, of the smallest babies having a sexual life.' - Indeed, Gentlemen, I have no objection at all to organ-pleasure. I know that even the supreme pleasure of sexual union is only an organ-pleasure attached to the activity of the genitals. But can you tell me when this originally indifferent organ-pleasure acquires the sexual character which it undoubtedly possesses in the later phases of development? Do we know any more about 'organ-pleasure' than about sexuality? You will reply that it gains its sexual character precisely when the genitals begin to play their part; 'sexual' coincides with 'genital'. You will even reject the objection raised by the perversions by pointing out to me that in the majority of perversions a genital orgasm is after all aimed at, even if it is arrived at by a method other than the union of the genitals. You are certainly taking up a much stronger position in determining the characteristics of what is sexual if you knock out of it the relation to reproduction which is made untenable by the perversions and put genital activity in its place. But, if so, we are no longer far apart: it is only a question of the genital organs versus the other organs. What are you going to do, however, about the numerous experiences which show you that the genitals can be represented as regards their yield of pleasure by other organs, as in the case of kissing or of the perverse practices of voluptuaries or of the symptoms of hysteria? In that neurosis it is quite usual for signs of stimulation, sensations and innervations, and even the processes of erection, which belong properly to the genitals, to be displaced on to other, remote regions of the body - as, for instance, by transposition upwards, to the head and face. Being thus convinced that you have nothing to catch hold of for your characterization of what is sexual, you will no doubt have to make up your minds to follow my example and extend the description of being 'sexual' to the activities of early childhood, too, which strive for organ-pleasure.

[1916-1917, 3392]
¹ [Footnote added 1909:] Hysterical attacks sometimes make use of the same kind of chronological reversal in order to disguise their meaning from observers. For instance, a hysterical girl needed to represent something in the nature of a brief romance in one of her attacks - a romance of which she had had a phantasy in her unconscious after an encounter with someone on the suburban railway. She imagined how the man had been attracted by the beauty of her foot and had spoken to her while she was reading; whereupon she had gone off with him and had had a passionate love-scene. Her attack began with a representation of this love-scene by convulsive twitching of her body, accompanied by movements of her lips to represent kissing and tightening of her arms to represent embracing. She then hurried into the next room, sat down on a chair, raised her skirt so as to show her foot, pretended to be reading a book and spoke to me (that is, answered me). - [Added 1914:] Cf. in this connection what Artemidorus says: 'In interpreting the images seen in dreams one must sometimes follow them from the beginning to the end and sometimes from the end to the beginning . . .' [1900a, 797]
The other members of this class of wish-fulfillments - hysterical symptoms, for instance - possess one essential characteristic, however, which I cannot discover in dreams. I have learnt from the researches which I have mentioned so often in the course of this work that in order to bring about the formation of a hysterical symptom both currents of our mind must converge. A symptom is not merely the expression of a realized unconscious wish; a wish from the preconscious which is fulfilled by the same symptom must also be present. So that the symptom will have of at least two determinants, one arising from each of the systems involved in the conflict. As in the case of dreams, there are no limits to the further determinants that may be present - to the 'overdetermination' of the symptoms. The determinant which does not arise from the Ucs. is invariably, so far as I know, a train of thought reacting against the unconscious wish - a self-punishment, for instance. I can therefore make the quite general assertion that a hysterical symptom develops only where the fulfilments of two opposing wishes, arising each from a different psychical system, are able to converge in a single expression. (Compare in this connection my most recent formulations on the origin of hysterical symptoms in my paper on hysterical phantasies and their relation to bisexuality.) Examples would serve very little purpose here, since nothing but an exhaustive elucidation of the complications involved could carry conviction. I will therefore leave my assertion to stand for itself and only quote an example in order to make the point clear, and not to carry conviction. In one of my women patients, then, hysterical vomiting turned out to be on the one hand the fulfilment of an unconscious phantasy dating from her puberty - of a wish, that is, that she might be continuously pregnant and have innumerable children, with a further wish, added later, that she might have them by as many men as possible. A powerful defensive impulse had sprung up against this unbridled wish. And, since the patient might lose her figure and her good looks as a result of her vomiting, and so might cease to be attractive to anyone, the symptom was acceptable to the punitive train of thought as well; and since it was permitted by both sides it could become a reality. This was the same method of treating a wish-fulfilment as was adopted by the Parthian queen towards the Roman triumvir Crassus. Believing that he had embarked on his expedition out of love of gold, she ordered molten gold to be poured down his throat when he was dead: 'Now', she said, 'you have what you wanted.' But all that we so far know about dreams is that they express the fulfilment of a wish from the unconscious; it seems as though the dominant, preconscious system acquiesces in this after insisting upon a certain number of distortions. Nor is it possible as a general rule to find a train of thought opposed to the dream-wish and, like its counterpart, realized in the dream. Only here and there in dream-analyses do we come upon signs of reactive creations, like, for instance, my affectionate feelings for my friend R. in the dream of my uncle (cf. p. 637 ff.). But we can find the missing ingredient from the preconscious elsewhere. Whereas the wish from the Ucs. is able to find expression in the dream after undergoing distortions of every kind, the dominant system withdraws into a wish to sleep, realizes that wish by bringing about the modifications which it is able to produce in the cathexes within the psychical apparatus, and persists in that wish throughout the whole duration of sleep.¹ [1900a, 999]
Even if I ignore the ill-will of narrow-minded critics such as these, the presentation of my case histories remains a problem which is hard for me to solve. The difficulties are partly of a technical kind, but are partly due to the nature of the circumstances themselves. If it is true that the causes of hysterical disorders are to be found in the intimacies of the patients' psychosexual life, and that hysterical symptoms are the expression of their most secret and repressed wishes, then the complete elucidation of a case of hysteria is bound to involve the revelation of those intimacies and the betrayal of those secrets. It is certain that the patients would never have spoken if it had occurred to them that their admissions might possibly be put to scientific uses; and it is equally certain that to ask them themselves for leave to publish their case would be quite unavailing. In such circumstances persons of delicacy, as well as those who were merely timid, would give first place to the duty of medical discretion and would declare with regret that the matter was one upon which they could offer science no enlightenment. But in my opinion the physician has taken upon himself duties not only towards the individual patient but towards science as well; and his duties towards science mean ultimately nothing else than his duties towards the many other patients who are suffering or will some day suffer from the same disorder. Thus it becomes the physician's duty to publish what he believes he knows of the causes and structure of hysteria, and it becomes a disgraceful piece of cowardice on his part to neglect doing so, as long as he can avoid causing direct personal injury to the single patient concerned. I think I have taken every precaution to prevent my patient from suffering any such injury. I have picked out a person the scenes of whose life were laid not in Vienna but in a remote provincial town, and whose personal circumstances must therefore be practically unknown in Vienna. I have from the very beginning kept the fact of her being under my treatment such a careful secret that only one other physician - and one in whose discretion I have complete confidence - can be aware that the girl was a patient of mine. I have waited for four whole years since the end of the treatment and have postponed publication till hearing that a change has taken place in the patient's life of such a character as allows me to suppose that her own interest in the occurrences and psychological events which are to be related here may now have grown faint. Needless to say, I have allowed no name to stand which could put a non-medical reader upon the scent; and the publication of the case in a purely scientific, and technical periodical should, further, afford a guarantee against unauthorized readers of this sort. I naturally cannot prevent the patient herself from being pained if her own case history should accidentally fall into her hands. But she will learn nothing from it that she does not already know; and she may ask herself who besides her could discover from it that she is the subject of this paper.
[1905e, 1351]

(3) Hysterical symptoms are - like other psychical structures - an expression of the fulfilment of a wish.
[1908a, 1936]

Among these various definitions the seventh brings out the nature of hysterical symptoms most completely as the realization of an unconscious phantasy; and the eighth recognizes the proper significance of the sexual factor. Some of the preceding formulas lead up to these two and are contained in them.
[1908a, 1937]
(1) The attack becomes unintelligible through the fact that it represents several phantasies in the same material simultaneously - that is to say through condensation. The elements common to the two (or more) phantasies constitute the nucleus of the representation, as they do in dreams. The phantasies which are thus made to coincide are often of quite a different nature. They may, for instance, be a recent wish and the re-activation of an infantile impression. The same innervations are in that case made to serve both purposes, often in a most ingenious way. Hysterical patients who make a very extensive use of condensation may find a single form of attack sufficient; others express their numerous pathogenic phantasies by a multiplication of the forms of attack.

[1909a, 1922]

The Theory of Repression. - These theoretical considerations, taken together with the immediate impressions derived from analytic work, lead to a view of the neuroses which may be described in the roughest outline as follows. The neuroses are the expression of conflicts between the ego and such of the sexual impulses as seem to the ego incompatible with its integrity or with its ethical standards. Since these impulses are not ego-syntonic, the ego has repressed them: that is to say, it has withdrawn its interest from them and has shut them off from becoming conscious as well as from obtaining satisfaction by motor discharge. If in the course of analytic work one attempts to make these repressed impulses conscious, one becomes aware of the repressive forces in the form of resistance. But the achievement of repression fails particularly readily in the case of the sexual instincts. Their dammed-up libido finds other ways out from the unconscious: for it regresses to earlier phases of development and earlier attitudes towards objects, and, at weak points in the libidinal development where there are infantile fixations, it breaks through into consciousness and obtains discharge. What results is a symptom and consequently in its essence a substitutive sexual satisfaction. Nevertheless the symptom cannot entirely escape from the repressive forces of the ego and must therefore submit to modifications and displacements exactly as happens with dreams - by means of which its characteristic of being a sexual satisfaction becomes unrecognizable. Consequently symptoms are in the nature of compromises between the repressed sexual instincts and the repressing ego-instincts; they represent a wish-fulfilment for both partners to the conflict simultaneously, but one which is incomplete for each of them. This is quite strictly true of the symptoms of hysteria, while in the symptoms of obsessional neurosis there is often a stronger emphasis upon the side of the repressing function owing to the erection of reaction-formations, which are assurances against sexual satisfaction.

[1923a, 3923]
(7) Hysterical symptoms arise as a compromise between two opposite affective and instinctual impulses, of which one is attempting to bring to expression a component instinct or a constituent of the sexual constitution, and the other is attempting to suppress it. [1908a, 1936]

This connection between symptoms and phantasies makes it easy to arrive from a psychoanalysis of the former at a knowledge of the components of the sexual instincts which dominate the individual, as I have demonstrated in my *Three Essays on the Theory of Sexuality*. In some cases, however, investigation by this means yields an unexpected result. It shows that there are many symptoms where the uncovering of a sexual phantasy (or of a number of phantasies, one of which, the most significant and the earliest, is of a sexual nature) is not enough to bring about a resolution of the symptoms. To resolve it one has to have two sexual phantasies, of which one has a masculine and the other a feminine character. Thus one of these phantasies springs from a homosexual impulse. This new finding does not alter our seventh formula. It remains true that a hysterical symptom must necessarily represent a compromise between a libidinal and a repressing impulse; but it may also represent a union of two libidinal phantasies of an opposite sexual character. [1908a, 1937]

Compulsive acts like this, in two successive stages, of which the second neutralizes the first, are a typical occurrence in obsessional neuroses. The patient's consciousness naturally misunderstands them and puts forward a set of secondary motives to account for them - rationalizes them, in short. (Cf. Jones, 1908.) But their true significance lies in their being a representation of a conflict between two opposing impulses of approximately equal strength: and hitherto I have invariably found that this opposition has been one between love and hate. Compulsive acts of this sort are theoretically of special interest, for they show us a new type of method of constructing symptoms. What regularly occurs in hysteria is that a compromise is arrived at which enables both the opposing tendencies to find expression simultaneously - which kills two birds with one stone;¹ whereas here each of the two opposing tendencies finds satisfaction singly, first one and then the other, though naturally an attempt is made to establish some sort of logical connection (often in defiance of all logic) between the antagonists.² [1909d, 2151]
No doubt all kinds of objections can still be raised to the assertion that neurotic symptoms are substitutes for sexual satisfactions. I will mention two of them to-day. When you yourselves have carried out analytic examinations of a considerable number of neurotics, you will perhaps tell me, shaking your head, that in a lot of cases my assertion is simply not true; the symptoms seem rather to have the contrary purpose of excluding or of stopping sexual satisfaction. I will not dispute the correctness of your interpretation. The facts in psycho-analysis have a habit of being rather more complicated than we like. If they were as simple as all that, perhaps it might not have needed psycho-analysis to bring them to light. Indeed, some of the features of our second patient's ceremonial show signs of this ascetic character with its hostility to sexual satisfaction: when, for instance, she got rid of the clocks and watches, which had the magical meaning of avoiding erections during the night, or when she tried to guard against flower-pots falling and breaking, which was equivalent to protecting her virginity. In some other cases of bed ceremonials, which I have been able to analyse, this negative character was far more outspoken; the ceremonial might consist exclusively of defensive measures against sexual memories and temptations. However, we have already found often enough that in psycho-analysis opposites imply no contradiction. We might extend our thesis and say that symptoms aim either at a sexual satisfaction or at fending it off, and that on the whole the positive, wish-fulfilling character prevails in hysteria and the negative, ascetic one in obsessional neurosis. If symptoms can serve the purpose both of sexual satisfaction and of its opposite, there is an excellent basis for this double-sidedness or polarity in a part of their mechanism which I have so far not been able to mention. For, as we shall hear, they are the products of a compromise and arise from the mutual interference between two opposing currents; they represent not only the repressed but also the repressing force which had a share in their origin. One side or the other may be more strongly represented; but it is rarely that one influence is entirely absent. In hysteria a convergence of both intentions in the same symptom is usually achieved. In obsessional neurosis the two portions are often separated; the symptom then becomes biphasic and consists in two actions, one after the other, which cancel each other out.

The Theory of Repression. - These theoretical considerations, taken together with the immediate impressions derived from analytic work, lead to a view of the neuroses which may be described in the roughest outline as follows. The neuroses are the expression of conflicts between the ego and such of the sexual impulses as seem to the ego incompatible with its integrity or with its ethical standards. Since these impulses are not ego-syntonic, the ego has repressed them: that is to say, it has withdrawn its interest from them and has shut them off from becoming conscious as well as from obtaining satisfaction by motor discharge. If in the course of analytic work one attempts to make these repressed impulses conscious, one becomes aware of the repressive forces in the form of resistance. But the achievement of repression fails particularly readily in the case of the sexual instincts. Their dammed-up libido finds other ways out from the unconscious: for it regresses to earlier phases of development and earlier attitudes towards objects, and, at weak points in the libidinal development where there are infantile fixations, it breaks through into consciousness and obtains discharge. What results is a symptom and consequently in its essence a substitutive sexual satisfaction. Nevertheless the symptom cannot entirely escape from the repressive forces of the ego and must therefore submit to modifications and displacements exactly as happens with dreams - by means of which its characteristic of being a sexual satisfaction becomes unrecognizable. Consequently symptoms are in the nature of compromises between the repressed sexual instincts and the repressing ego-instincts; they represent a wish-fulfilment for both partners to the conflict simultaneously, but one which is incomplete for each of them. This is quite strictly true of the symptoms of hysteria, while in the symptoms of obsessional neurosis there is often a stronger emphasis upon the side of the repressing function owing to the erection of reaction-formations, which are assurances against sexual satisfaction.
The analysis of dreams led further: it was brought to public notice by the present writer as early as in 1900 in *The Interpretation of Dreams*. This showed that dreams are constructed in just the same way as neurotic symptoms. Like them, they may appear strange and senseless; but, if we examine them by a technique which differs little from the free association used in psycho-analysis, we are led from their manifest content to a secret meaning, to the latent dream-thoughts. This latent meaning is always a wishful impulse which is represented as fulfilled at the moment of the dream. But, except in young children and under the pressure of imperative physical needs, this secret wish can never be expressed recognizably. It has first to submit to a distortion, which is the work of restrictive, censoring forces in the dreamer's ego. In this way the manifest dream, as it is remembered in waking life, comes about. It is distorted, to the pitch of being unrecognizable, by concessions made to the dream-censorship; but it can be revealed once more by analysis as an expression of a situation of satisfaction or as the fulfilment of a wish. It is a compromise between two conflicting groups of mental trends, just as we have found to be the case with hysterical symptoms. The formula which, at bottom, best meets the essence of the dream is this: a dream is a (disguised) fulfilment of a (repressed) wish. The study of the process which transforms the latent dream-wish into the manifest content of the dream - a process known as the 'dream-work' - has taught us the best part of what we know of unconscious mental life.

[1924f, 4109]

It was now easy to reconstruct the pathogenic process. Let us keep to a simple example, in which a particular impulsion had arisen in the subject's mind but was opposed by other powerful impulsions. We should have expected the mental conflict which now arose to take the following course. The two dynamic quantities - for our present purposes let us call them 'the instinct' and 'the resistance' - would struggle with each other for some time in the fullest light of consciousness, until the instinct was repudiated and the cathexis of energy withdrawn from its impulsion. This would have been the normal solution. In a neurosis, however (for reasons which were still unknown), the conflict found a different outcome. The ego drew back, as it were, on its first collision with the objectionable instinctual impulse; it debarred the impulse from access to consciousness and to direct motor discharge, but at the same time the impulse retained its full cathexis of energy. I named this process repression; it was a novelty, and nothing like it had ever before been recognized in mental life. It was obviously a primary mechanism of defence, comparable to an attempt at flight, and was only a forerunner of the later-developed normal condemning judgement. The first act of repression involved further consequences. In the first place the ego was obliged to protect itself against the constant threat of a renewed advance on the part of the repressed impulse by making a permanent expenditure of energy, an anticathexis; and it thus impoverished itself. On the other hand, the repressed impulse, which was now unconscious, was able to find means of discharge and of substitutive satisfaction by circuitous routes and thus to bring the whole purpose of the repression to nothing. In the case of conversion hysteria the circuitous route led to the somatic innervation; the repressed impulse broke its way through at some point or other and produced symptoms. The symptoms were thus results of a compromise, for although they were substitutive satisfactions they were nevertheless distorted and deflected from their aim owing to the resistance of the ego.

[1925d, 4206]
In this secondary defensive struggle the ego presents two faces with contradictory expressions. The one line of behaviour it adopts springs from the fact that its very nature obliges it to make what must be regarded as an attempt at restoration or reconciliation. The ego is an organization. It is based on the maintenance of free intercourse and of the possibility of reciprocal influence between all its parts. Its desexualized energy still shows traces of its origin in its impulsion to bind together and unify, and this necessity to synthesize grows stronger in proportion as the strength of the ego increases. It is therefore only natural that the ego should try to prevent symptoms from remaining isolated and alien by using every possible method to bind them to itself in one way or another, and to incorporate them into its organization by means of those bonds. As we know, a tendency of this kind is already operative in the very act of forming a symptom. A classical instance of this are those hysterical symptoms which have been shown to be a compromise between the need for satisfaction and the need for punishment. Such symptoms participate in the ego from the very beginning, since they fulfil a requirement of the super-ego, while on the other hand they represent positions occupied by the repressed and points at which an irruption has been made by it into the ego-organization. They are a kind of frontier-station with a mixed garrison. (Whether all primary hysterical symptoms are constructed on these lines would be worth enquiring into very carefully.) The ego now proceeds to behave as though it recognized that the symptom had come to stay and that the only thing to do was to accept the situation in good part and draw as much advantage from it as possible. It makes an adaptation to the symptom - to this piece of the internal world which is alien to it - just as it normally does to the real external world. It can always find plenty of opportunities for doing so. The presence of a symptom may entail a certain impairment of capacity, and this can be exploited to appease some demand on the part of the super-ego or to refuse some claim from the external world. In this way the symptom gradually comes to be the representative of important interests; it is found to be useful in asserting the position of the self and becomes more and more closely merged with the ego and more and more indispensable to it. It is only very rarely that the physical process of 'healing' round a foreign body follows such a course as this. There is a danger, too, of exaggerating the importance of a secondary adaptation of this kind to a symptom, and of saying that the ego has created the symptom merely in order to enjoy its advantages. It would be equally true to say that a man who had lost his leg in the war had got it shot away so that he might thenceforward live on his pension without having to do any more work.

[1926d, 4259]
I remembered that long before, while I was working at Charcot's clinic, I had seen and heard how in cases of hysterical mutism writing operated vicariously in the place of speech. Such patients were able to write more fluently, quicker, and better than others did or than they themselves had done previously. The same thing had happened with Dora. In the first days of her attacks of aphonia 'writing had always come specially easy to her'. No psychological elucidation was really required for this peculiarity, which was the expression of a physiological substitutive function enforced by necessity; it was noticeable, however, that such an elucidation was easily to be found. Herr K. used to write to her at length while he was travelling and to send her picture post-cards. It used to happen that she alone was informed as to the date of his return, and that his arrival took his wife by surprise. Moreover, that a person will correspond with an absent friend whom he cannot talk to is scarcely less obvious than that if he has lost his voice he will try to make himself understood in writing. Dora's aphonia, then, allowed of the following symbolic interpretation. When the man she loved was away she gave up speaking; speech had lost its value since she could not speak to him. On the other hand, writing gained in importance, as being the only means of communication with him in his absence.

[1905e, 1377]

Am I now going on to assert that in every instance in which there are periodical attacks of aphonia we are to diagnose the existence of a loved person who is at times away from the patient? Nothing could be further from my intention. The determination of Dora's symptoms is far too specific for it to be possible to expect a frequent recurrence of the same accidental aetiology. But, if so, what is the value of our elucidation of the aphonia in the present case? Have we not merely allowed ourselves to become the victims of a jeu d'esprit? I think not. In this connection we must recall the question which has so often been raised, whether the symptoms of hysteria are of psychical or of somatic origin, or whether, if the former is granted, they are necessarily all of them psychically determined. Like so many other questions to which we find investigators returning again and again without success, this question is not adequately framed. The alternatives stated in it do not cover the real essence of the matter. As far as I can see, every hysterical symptom involves the participation of both sides. It cannot occur without the presence of a certain degree of somatic compliance offered by some normal or pathological process in or connected with one of the bodily organs. And it cannot occur more than once - and the capacity for repeating itself is one of the characteristics of a hysterical symptom - unless it has a psychical significance, a meaning. The hysterical symptom does not carry this meaning with it, but the meaning is lent to it, soldered to it, as it were; and in every instance the meaning can be a different one, according to the nature of the suppressed thoughts which are struggling for expression. However, there are a number of factors at work which tend to make less arbitrary the relations between the unconscious thoughts and the somatic processes that are at their disposal as a means of expression, and which tend to make those relations approximate to a few typical forms. For therapeutic purposes the most important determinants are those given by the fortuitous psychical material; the clearing-up of the symptoms is achieved by looking for their psychical significance. When everything that can be got rid of by psycho-analysis has been cleared away, we are in a position to form all kinds of conjectures, which probably meet the facts, as regards the somatic basis of the symptoms - a basis which is as a rule constitutional and organic. Thus in Dora's case we shall not content ourselves with a psycho-analytic interpretation of her attacks of coughing and aphonia; but we shall also indicate the organic factor which was the source of the 'somatic compliance' that enabled her to express her love for a man who was periodically absent. And if the connection between the symptomatic expression and the unconscious mental content should strike us as being in this case a clever tour de force, we shall be relieved to hear that it succeeds in creating the same impression in every other case and in every other instance.

[1905e, 1378]
All these discussions contain much that is typical and valid for hysteria in general. The subject of erection solves some of the most interesting hysterical symptoms. The attention that women pay to the outlines of men's genitals as seen through their clothing becomes, when it has been repressed, a source of the very frequent cases of avoiding company and of dreading society. - It is scarcely possible to exaggerate the pathogenic significance of the comprehensive tie uniting the sexual and the excremental, a tie which is at the basis of a very large number of hysterical phobias.

Or again our patient - and this time let us make her a woman - may suffer in another way and in a different field. She is a pianist, but her fingers are overcome by cramp and refuse to serve her. Or when she thinks of going to a party she promptly becomes aware of a call of nature the satisfaction of which would be incompatible with a social gathering. She has therefore given up going to parties, dances, theatres or concerts. She is overcome by violent headaches or other painful sensations at times when they are most inconvenient. She may even be unable to keep down any meal she eats which can become dangerous in the long run. And, finally, it is a lamentable fact that she cannot tolerate any agitations, which after all are inevitable in life. On such occasions she falls in a faint, often accompanied by muscular spasms that recall sinister pathological states.
My first interview with this young woman of twenty-four years of age did not help me to make much further progress in understanding the case. She seemed intelligent and mentally normal and bore her troubles, which interfered with her social life and pleasures, with a cheerful air - the *belle indifférence* of a hysteric, I could not help thinking. She walked with the upper part of her body bent forward, but without making use of any support. Her gait was not of any recognized pathological type, and moreover was by no means strikingly bad. All that was apparent was that she complained of great pain in walking and of being quickly overcome by fatigue both in walking and in standing, and that after a short time she had to rest, which lessened the pains but did not do away with them altogether. The pain was of an indefinite character; I gathered that it was something in the nature of a painful fatigue. A fairly large, ill defined area of the anterior surface of the right thigh was indicated as the focus of the pains, from which they most often radiated and where they reached their greatest intensity. In this area the skin and muscles were also particularly sensitive to pressure and pinching (though the prick of a needle was, if anything, met with a certain amount of unconcern). This hyperalgesia of the skin and muscles was not restricted to this area but could be observed more or less over the whole of both legs. The muscles were perhaps even more sensitive to pain than the skin; but there could be no question that the thighs were the parts most sensitive to both these kinds of pain. The motor power of the legs could not be described as small, and the reflexes were of medium strength. There were no other symptoms, so that there was no ground for suspecting the presence of any serious organic affection. The disorder had developed gradually during the previous two years and varied greatly in intensity. [1895d, 121]

Here then my material leaves me in the lurch, as might be expected, and I have to fall back on conjectures and inferences. It is well known that in the severer cases of psychoneurosis instances of self-injury are occasionally found as symptoms and that in such cases suicide can never be ruled out as a possible outcome of the psychical conflict. I have now learnt and can prove from convincing examples that many apparently accidental injuries that happen to such patients are really instances of self-injury. What happens is that an impulse to self-punishment, which is constantly on the watch and which normally finds expression in self-reproach or contributes to the formation of a symptom, takes ingenious advantage of an external situation that chance happens to offer, or lends assistance to that situation until the desired injurious effect is brought about. Such occurrences are by no means uncommon in cases even of moderate severity, and they betray the part which the unconscious intention plays by a number of special features - e. g by the striking composure that the patients retain in what is supposed to be an accident.³ [1901b, 1258]
We are obliged to take quite another view of the process of repression when we consider the picture of a true conversion hysteria. Here the salient point is that it is possible to bring about a total disappearance of the quota of affect. When this is so, the patient displays towards his symptoms what Charcot called 'la belle indifférence hystériques'. In other cases this suppression is not so completely successful: some distressing sensations may attach to the symptoms themselves, or it may prove impossible to prevent some release of anxiety, which in turn sets to work the mechanism of forming a phobia. The ideational content of the instinctual representative is completely withdrawn from consciousness; as a substitute - and at the same time as a symptom - we have an over-strong innervation (in typical cases, a somatic one), sometimes of a sensory, sometimes of a motor character, either as an excitation or an inhibition. The over-innervated area proves on a closer view to be a part of the repressed instinctual representative itself - a part which, as though by a process of condensation, has drawn the whole cathexis on to itself. These remarks do not of course bring to light the whole mechanism of a conversion hysteria; in especial the factor of regression, which will be considered in another connection, has also to be taken into account. In so far as repression in hysteria is made possible only by the extensive formation of substitutes, it may be judged to be entirely unsuccessful; as regards dealing with the quota of affect, however, which is the true task of repression, it generally signifies a total success. In conversion hysteria the process of repression is completed with the formation of the symptom and does not, as in anxiety hysteria, need to continue to a second phase - or rather, strictly speaking, to continue endlessly. [1915d, 2986]
Among the various factors, therefore, which contribute to a failure in recollection or a loss of memory, the part played by repression must not be overlooked; and it can be demonstrated not only in neurotics but (in a manner that is qualitatively the same) in normal people as well. It may be asserted quite generally that the ease (and ultimately the faithfulness, too) with which a given impression is awakened in the memory depends not only on the psychical constitution of the individual, the strength of the impression when it was fresh, the interest directed towards it at the time, the psychical constellation at the present time, the interest that is now devoted to its awakening, the connections into which the impression has been drawn, and so on - not only on such things but also on the favourable or unfavourable attitude of a particular psychical factor which refuses to reproduce anything that might liberate unpleasure, or that might subsequently lead to the liberation of unpleasure. Thus the function of memory, which we like to regard as an archive open to anyone who is curious, is in this way subjected to restriction by a trend of the will, just as is any part of our activity directed to the external world. Half the secret of hysterical amnesia is uncovered when we say that hysterical people do not know what they do not want to know; and psycho-analytic treatment, which endeavours to fill up such gaps of memory in the course of its work, leads us to the discovery that the bringing back of those lost memories is opposed by a certain resistance which has to be counterbalanced by work proportionate to its magnitude. In the case of psychical processes which are on the whole normal, it cannot, of course, be claimed that the influence of this one-sided factor in the revival of memories in any way regularly overcomes all the other factors that must be taken into account.

It is only in certain pathological mental conditions that the relation holding in normal adults between the psychical significance of an event and its retention in memory once more ceases to apply. For instance, a hysteric habitually shows amnesia for some or all of the experiences which led to the onset of his illness and which from that very fact have become important to him and, apart from that fact, may have been important on their own account. The analogy between pathological amnesia of this kind and the normal amnesia affecting our early years seems to me to give a valuable hint at the intimate connection that exists between the psychical content of neuroses and our infantile life.

In my opinion we take the fact of infantile amnesia - the loss, that is, of the memories of the first years of our life - much too easily; and we fail to look upon it as a strange riddle. We forget how high are the intellectual achievements and how complicated the emotional impulses of which a child of some four years is capable, and we ought to be positively astonished that the memory of later years has as a rule preserved so little of these mental processes, especially as we have every reason to suppose that these same forgotten childhood achievements have not, as might be thought, slipped away without leaving their mark on the subject's development, but have exercised a determining influence for the whole of his later life. And in spite of this unique efficacy they have been forgotten! This suggests that there are conditions for remembering (in the sense of conscious reproducing) of a quite special kind, which have evaded recognition by us up to now. It may very well be that the forgetting of childhood can supply us with the key to the understanding of those amnesias which lie, according to our more recent discoveries, at the basis of the formation of all neurotic symptoms.
That this state of affairs should exist in regard to the memories relating to the history of the illness is a necessary correlate of the symptoms and one which is theoretically requisite. In the further course of the treatment the patient supplies the facts which, though he had known them all along, had been kept back by him or had not occurred to his mind. The paramnesias prove untenable, and the gaps in his memory are filled in. It is only towards the end of the treatment that we have before us all intelligible, consistent, and unbroken case history. Whereas the practical aim of the treatment is to remove all possible symptoms and to replace them by conscious thoughts, we may regard it as a second and theoretical aim to repair all the damages to the patient's memory. These two aims are coincident. When one is reached, so is the other; and the same path leads to them both.

[1905e, 1359]

Dora was by that time in the first bloom of youth - a girl of intelligent and engaging looks. But she was a source of heavy trials for her parents. Low spirits and an alteration in her character had now become the main features of her illness. She was clearly satisfied neither with herself nor with her family; her attitude towards her father was unfriendly, and she was on very bad terms with her mother, who was bent upon drawing her into taking a share in the work of the house. She tried to avoid social intercourse, and employed herself - so far as she was allowed to by the fatigue and lack of concentration of which she complained - with attending lectures for women and with carrying on more or less serious studies. One day her parents were thrown into a state of great alarm by finding on the girl's writing-desk, or inside it, a letter in which she took leave of them because, as she said, she could no longer endure her life.¹ Her father, indeed, being a man of some perspicacity, guessed that the girl had no serious suicidal intentions. But he was none the less very much shaken; and when one day, after a slight passage of words between him and his daughter, she had a first attack of loss of consciousness² - an event which was subsequently covered by an amnesia - it was determined, in spite of her reluctance, that she should come to me for treatment.

[1905e, 1363]

On the other hand we must assume, or we can convince ourselves by a psychological examination of other people, that the very same impressions that we have forgotten have none the less left the deepest traces on our minds and have had a determing effect upon the whole of our later development. There can, therefore, be no question of any real abolition of the impressions of childhood, but rather of an amnesia similar to that which neurotics exhibit for later events, and of which the essence consists in a simple withholding of these impressions from consciousness, viz., in their repression. But what are the forces which bring about this repression of the impressions of childhood? Whoever could solve this riddle would, I think, have explained hysterical amnesia as well.

[1905e, 1498]

Moreover, the connection between infantile and hysterical amnesia is more than a mere play upon words. Hysterical amnesia, which occurs at the bidding of repression, is only explicable by the fact that the subject is already in possession of a store of memory-traces which have been withdrawn from conscious disposal, and which are now, by an associative link, attracting to themselves the material which the forces of repression are engaged in repelling from consciousness.¹ It may be said that without infantile amnesia there would be no hysterical amnesia.

[1905d, 1498]
A disturbance of memory of this kind is enough for obsessional neurosis; but the case is different with hysteria. As a rule the latter neurosis is marked by amnesias on a really large scale. In analysing each separate hysterical symptom one is usually led to a whole chain of impressions of events, which, when they recur, are expressly described by the patient as having been till then forgotten. On the one hand, this chain reaches back to the earliest years of life, so that the hysterical amnesia can be recognized as an immediate continuation of the infantile amnesia which, for us normal people, conceals the beginnings of our mental life. On the other hand, we learn with astonishment that even the patient's most recent experiences can be subject to forgetting, and that the occasions which precipitated the outbreak of the illness or led to its intensification are in particular encroached upon, if not completely swallowed up, by amnesia. It regularly happens that important details have disappeared from the total picture of a recent recollection of this sort or that they have been replaced by falsifications of memory. Indeed it happens with almost equal regularity that certain memories of recent experiences only emerge shortly before the end of an analysis - memories which had been held back till that late moment and had left perceptible gaps in the continuity of the case.

[1916-1917, 3360]

Such restrictions upon the faculty of memory are, as I have said, characteristic of hysteria, in which, indeed, states also arise as symptoms - hysterical attacks - which need leave no trace behind them in the memory. If things are different in obsessional neurosis, you may conclude that what we are dealing with in these amnesias is a psychological characteristic of the change that occurs in hysteria and is not a universal feature of neuroses in general. The importance of this distinction is reduced by the following consideration. We have comprised two things as the 'sense' of a symptom: its 'whence' and its 'whither' or 'what for' - that is, the impressions and experiences from which it arose and the intentions which it serves. Thus the 'whence' of a symptom resolves itself into impressions which came from outside, which were necessarily once conscious and may have since become unconscious through forgetting. The 'whither' of a symptom, its purpose, is invariably, however, an endopsychic process, which may possibly have been conscious at first but may equally well never have been conscious and may have remained in the unconscious from the very start. Thus it is not of great importance whether the amnesia has laid hold on the 'whence' as well - the experiences on which the symptom is supported - as happens in hysteria; it is on the 'whither', the purpose of the symptom, which may have been unconscious from the beginning, that its dependence on the unconscious is founded - and no less firmly in obsessional neurosis than in hysteria.

[1916-1917, 3360]
The second of these techniques which we are setting out to describe for the first time, that of isolation, is peculiar to obsessional neurosis. It, too, takes place in the motor sphere. When something unpleasant has happened to the subject or when he himself has done something which has a significance for his neurosis, he interpolates an interval during which nothing further must happen - during which he must perceive nothing and do nothing. This behaviour, which seems strange at first sight, is soon seen to have a relation to repression. We know that in hysteria it is possible to cause a traumatic experience to be overtaken by amnesia. In obsessional neurosis this can often not be achieved: the experience is not forgotten, but, instead, it is deprived of its affect, and its associative connections are suppressed or interrupted so that it remains as though isolated and is not reproduced in the ordinary processes of thought. The effect of this isolation is the same as the effect of repression with amnesia. This technique, then, is reproduced in the isolations of obsessional neurosis; and it is at the same time given motor reinforcement for magical purposes. The elements that are held apart in this way are precisely those which belong together associatively. The motor isolation is meant to ensure an interruption of the connection in thought. The normal phenomenon of concentration provides a pretext for this kind of neurotic procedure: what seems to us important in the way of an impression or a piece of work must not be interfered with by the simultaneous claims of any other mental processes or activities. But even a normal person uses concentration to keep away not only what is irrelevant or unimportant, but, above all, what is unsuitable because it is contradictory. He is most disturbed by those elements which once belonged together but which have been torn apart in the course of his development - as, for instance, by manifestations of the ambivalence of his father-complex in his relation to God, or by impulses attached to his excretory organs in his emotions of love. Thus, in the normal course of things, the ego has a great deal of isolating work to do in its function of directing the current of thought. And, as we know, we are obliged, in carrying out our analytic technique, to train it to relinquish that function for the time being, eminently justified as it usually is.

[1926d, 4279]
It is perfectly true that unconscious wishes always remain active. They represent paths which can always be traversed, whenever a quantity of excitation makes use of them. Indeed it is a prominent feature of unconscious processes that they are indestructible. In the unconscious nothing can be brought to an end, nothing is past or forgotten. This is brought most vividly home to one in studying the neuroses, and especially hysteria. The unconscious path of thoughts, which leads to discharge in a hysterical attack, immediately becomes traversable once more, when sufficient excitation has accumulated. A humiliation that was experienced thirty years ago acts exactly like a fresh one throughout the thirty years, as soon as it has obtained access to the unconscious sources of emotion. As soon as the memory of it is touched, it springs into life again and shows itself cathected with excitation which finds a motor discharge in an attack. This precisely the point at which psychotherapy has to intervene. Its task is to make it possible for the unconscious processes to be dealt with finally and be forgotten. For the fading of memories and the emotional weakness of impressions which are no longer recent, which we are inclined to regard as self-evident and to explain as a primary effect of time upon mental memory-traces, are in reality secondary modifications which are only brought about by laborious work. What performs this work is the preconscious, and psychotherapy can pursue no other course than to bring the Ucs. under the domination of the Pcs.

[1900a, 1007]

The bisexual nature of hysterical symptoms, which can in any event be demonstrated in numerous cases, is an interesting confirmation of my view that the postulated existence of an innate bisexual disposition in man is especially clearly visible in the analysis of psychoneurotics.² An exactly analogous state of affairs occurs in the same field when a person who is masturbating tries in his conscious phantasies to have the feelings both of the man and of the woman in the situation which he is picturing. Further counterparts are to be found in certain hysterical attacks in which the patient simultaneously plays both parts in the underlying sexual phantasy. In one case which I observed, for instance, the patient pressed her dress up against her body with one hand (as the woman), while she tried to tear it off with the other (as the man). This simultaneity of contradictory actions serves to a large extent to obscure the situation, which is otherwise so plastically portrayed in the attack, and it is thus well suited to conceal the unconscious phantasy that is at work.

[1908a, 1938]

When one carries out the psycho-analysis of a hysterical woman patient whose complaint is manifested in attacks, one soon becomes convinced that these attacks are nothing else but phantasies translated into the motor sphere, projected on to motility and portrayed in pantomime. It is true that the phantasies are unconscious; but apart from this they are of the same nature as the phantasies which can be observed directly in day-dreams or which can be elicited by interpretation from dreams at night. Often a dream takes the place of an attack, and still more often it explains it, since the same phantasy finds a different expression in a dream and in an attack. We might expect then that by observing an attack we should be able to get to know the phantasy represented in it; but this is seldom possible. As a rule, owing to the influence of the censorship, the pantomimic portrayal of the phantasy has undergone distortions which are completely analogous to the hallucinatory distortions of a dream, so that both of them have, in the first resort, become unintelligible to the subject's own consciousness as well as to the observer's comprehension. A hysterical attack, therefore, needs to be subjected to the same interpretative revision as we employ for night-dreams. But not only are the forces from which the distortion proceeds and the purpose of the distortion the same as those we have come to know through the interpretation of dreams; the technique employed in the distortion is the same too.

[1909a, 1981]
(1) The attack becomes unintelligible through the fact that it represents several phantasies in the same material simultaneously - that is to say through condensation. The elements common to the two (or more) phantasies constitute the nucleus of the representation, as they do in dreams. The phantasies which are thus made to coincide are often of quite a different nature. They may, for instance, be a recent wish and the re-activation of an infantile impression. The same innervations are in that case made to serve both purposes, often in a most ingenious way. Hysterical patients who make a very extensive use of condensation may find a single form of attack sufficient; others express their numerous pathogenic phantasies by a multiplication of the forms of attack.
[1909a, 1982]

(2) The attack becomes obscured through the fact that the patient attempts to carry out the activities of both the figures who appear in the phantasy, that is to say, through multiple identification. Compare, for instance, the example I mentioned in my paper on 'Hysterical Phantasies and their Relation to Bisexuality' (1908a), in which the patient tore off her dress with one hand (as the man) while she pressed it to her body with the other (as the woman).
[1909a, 1982]

(3) A particularly extensive distortion is effected by an antagonistic inversion of the innervations. This is analogous to the transformation of an element into its opposite, which commonly happens in the dream-work. For instance, an embrace may be represented in the attack by drawing back the arms convulsively till the hands meet over the spinal column. It is possible that the well-known arc de cercle which occurs during attacks in major hysteria is nothing else than an energetic repudiation like this, through antagonistic innervation, of a posture of the body that is suitable for sexual intercourse.
[1909a, 1982]

(4) Scarcely less confusing and misleading is a reversal of the chronological order within the phantasy that is portrayed, which once more has its complete counterpart in a number of dreams which begin with the end of the action and end with its beginning. Supposing, for instance, that a hysterical woman has a phantasy of seduction in which she is sitting reading in a park with her skirt slightly lifted so that her foot is visible; a gentleman approaches and speaks to her; they then go somewhere and make love to one another. This phantasy is acted out in the attack by her beginning with the convulsive stage, which corresponds to the coitus, by her then getting up, going into another room, sitting down and reading and presently answering an imaginary remark addressed to her.
[1909a, 1982]

The two last-mentioned forms of distortion give us some idea of the intensity of the resistances which the repressed material must take into account even when it breaks through in a hysterical attack.
[1909a, 1982]
The onset of hysterical attacks follows laws that are easily understandable. Since the repressed complex consists of a libidinal cathexis and an ideational content (the phantasy), the attack can be evoked (1) **associatively**, when the content of the complex (if sufficiently cathected) is touched on by something connected with it in conscious life; (2) **organically**, when, for internal somatic reasons and as a result of psychical influences from outside, the libidinal cathexis rises above a certain degree; (3) in the service of the **primary purpose** - as an expression of a 'flight into illness', when reality becomes distressing or frightening - that is, as a **consolation**; (4) in the service of the **secondary purposes**, with which the illness allies itself, as soon as, by producing an attack, the patient can achieve an aim that is useful to him. In the last case the attack is directed at particular individuals; it can be put off till they are present, and it gives an impression of being consciously simulated.

Investigation of the childhood history of hysterical patients shows that the hysterical attack is designed to take the place of an **auto-erotic** satisfaction previously practised and since given up. In a great number of cases this satisfaction (masturbation by contact or by pressure of the thighs, or, again, by movements of the tongue, and so on) recurs during the attack itself, while the subject's consciousness is deflected. Moreover, the onset of an attack that is due to an increase of libido and is in the service of the primary purpose - as a consolation - exactly repeats the conditions under which, at the earlier time, the patient had intentionally sought this auto-erotic satisfaction. The anamnesis of the patient shows the following stages: (a) auto-erotic satisfaction, without ideational content; (b) the same satisfaction, connected with a phantasy which leads to the act of satisfaction; (c) renunciation of the act, with retention of the phantasy; (d) repression of the phantasy, which then comes into effect as a hysterical attack, either in an unchanged form, or in a modified one and adapted to new environmental impressions. Furthermore, (e) the phantasy may even reinstate the act of satisfaction belonging to it which had ostensibly been given up. This is a typical cycle of infantile sexual activity: repression, failure of repression, and return of the repressed.

The involuntary passing of urine is certainly not to be regarded as incompatible with the diagnosis of a hysterical attack; it is merely repeating the infantile form of a violent pollution. Moreover, biting the tongue may also be met with in undoubted cases of hysteria. It is no more inconsistent with hysteria than it is with love-making. It occurs more readily in attacks if the patient's attention had been drawn by the doctor's questions to the difficulties of making a differential diagnosis. Self-injury may occur in hysterical attacks (more frequently in the case of men) where it repeats an accident in childhood - as, for instance, the result of a romp.

The loss of consciousness, the *absence*, in a hysterical attack is derived from the fleeting but unmistakable lapse of consciousness which is observable at the climax of every intense sexual satisfaction, including auto-erotic ones. This course of development can be traced with most certainty where hysterical **absences** arise from the onset of pollutions in young people of the female sex. The so-called 'hypnoid states' - **absences** during day-dreaming -, which are so common in hysterical subjects, show the same origin. The mechanism of these **absences** is comparatively simple. All the subject's attention is concentrated to begin with on the course of the process of satisfaction; with the occurrence of the satisfaction, the whole of this cathexis of attention is suddenly removed, so that there ensues a momentary void in her consciousness. This gap in consciousness, which might be termed a **physiological** one, is then widened in the service of repression, till it can swallow up everything that the repressing agency rejects.
What points the way for the motor discharge of the repressed libido in a hysterical attack is the reflex mechanism of the act of coition - a mechanism which is ready to hand in everybody, including women, and which we see coming into manifest operation when an unrestrained surrender is made to sexual activity. Already in ancient times coition was described as a 'minor epilepsy'. We might alter this and say that a convulsive hysterical attack is an equivalent of coition. The analogy with an epileptic fit helps us little, since its genesis is even less understood than that of hysterical attacks. [1909a, 1984]

Speaking as a whole, hysterical attacks, like hysteria in general, revive a piece of sexual activity in women which existed during their childhood and at that time revealed an essentially masculine character. It can often be observed that girls who have shown a boyish nature and inclinations up to the years before puberty are precisely those who become hysterical from puberty onwards. In a whole number of cases the hysterical neurosis merely represents an excessive accentuation of the typical wave of repression which, by doing away with her masculine sexuality, allows the woman to emerge.² [1909a, 1984]

It is in obsessional neuroses that the survival of the omnipotence of thoughts is most clearly visible and that the consequences of this primitive mode of thinking come closest to consciousness. But we must not be misled into supposing that it is a distinguishing feature of this particular neurosis, for analytic investigation reveals the same thing in the other neuroses as well. In all of them what determines the formation of symptoms is the reality not of experience but of thought. Neurotics live in a world apart, where, as I have said elsewhere, only 'neurotic currency' is legal tender; that is to say, they are only affected by what is thought with intensity and pictured with emotion, whereas agreement with external reality is a matter of no importance. What hysterics repeat in their attacks and fix by means of their symptoms are experiences which have occurred in that form only in their imagination though it is true that in the last resort those imagined experiences go back to actual events or are based upon them. To attribute the neurotic sense of guilt to real misdeeds would show an equal misunderstanding. An obsessional neurotic may be weighed down by a sense of guilt that would be appropriate in a mass-murderer, while in fact, from his childhood onwards, he has behaved to his fellow-men as the most considerate and scrupulous member of society. Nevertheless, his sense of guilt has a justification: it is founded on the intense and frequent death wishes against his fellows which are unconsciously at work in him. It has a justification if what we take into account are unconscious thoughts and not intentional deeds. Thus the omnipotence of thoughts, the overvaluation of mental processes as compared with reality, is seen to have unrestricted play in the emotional life of neurotic patients and in everything that derives from it. If one of them undergoes psychoanalytic treatment, which makes what is unconscious in him conscious, he will be unable to believe that thoughts are free and will constantly be afraid of expressing evil wishes, as though their expression would lead inevitably to their fulfilment. This behaviour, as well as the superstitions which he practises in ordinary life, reveals his resemblance to the savages who believe they can alter the external world by mere thinking. [1912-1913, 2729]
I will illustrate the first of these theses by a few examples. Hysterical attacks have long been recognized as signs of increased emotional excitement and equated with outbreaks of affect. Charcot attempted to reduce the multiplicity of their modes of manifestation by means of descriptive formulas; Pierre Janet recognized the unconscious ideas operating behind such attacks; while psycho-analysis has shown that they are mimetic representations of scenes (whether actually experienced or only invented ) with which the patient's imagination is occupied without his becoming conscious of them. The meaning of these pantomimes is concealed from the spectators by means of condensations and distortions of the acts which they represent. And this applies equally to what are described as the 'chronic' symptoms of hysterical patients. All of them are mimetic or hallucinatory representations of phantasies which unconsciously dominate the subject's emotional life and which have the meaning of fulfilments of secret and repressed wishes. The tormenting character of these symptoms is due to the internal conflict into which these patients' minds are driven by the need to combat such unconscious wishes.

[1913], 2809

Such restrictions upon the faculty of memory are, as I have said, characteristic of hysteria, in which, indeed, states also arise as symptoms - hysterical attacks - which need leave no trace behind them in the memory. If things are different in obsessional neurosis, you may conclude that what we are dealing with in these amnesias is a psychological characteristic of the change that occurs in hysteria and is not a universal feature of neuroses in general. The importance of this distinction is reduced by the following consideration. We have comprised two things as the 'sense' of a symptom: its 'whence' and its 'whither' or 'what for' - that is, the impressions and experiences from which it arose and the intentions which it serves. Thus the 'whence' of a symptom resolves itself into impressions which came from outside, which were necessarily once conscious and may have since become unconscious through forgetting. The 'whither' of a symptom, its purpose, is invariably, however, an endopsychic process, which may possibly have been conscious at first but may equally well never have been conscious and may have remained in the unconscious from the very start. Thus it is not of great importance whether the amnesia has laid hold on the 'whence' as well - the experiences on which the symptom is supported - as happens in hysteria; it is on the 'whither', the purpose of the symptom, which may have been unconscious from the beginning, that its dependence on the unconscious is founded - and no less firmly in obsessional neurosis than in hysteria.

[1916-1917, 3360]

A certain ambiguity and indefiniteness in the use of the word 'Angst' will not have escaped you. By 'anxiety' we usually understand the subjective state into which we are put by perceiving the 'generation of anxiety' and we call this an affect. And what is an affect in the dynamic sense? It is in any case something highly composite. An affect includes in the first place particular motor innervations or discharges and secondly certain feelings; the latter are of two kinds - perceptions of the motor actions that have occurred and the direct feelings of pleasure and unpleasure which, as we say, give the affect its keynote. But I do not think that with this enumeration we have arrived at the essence of an affect. We seem to see deeper in the case of some affects and to recognize that the core which holds the combination we have described together is the repetition of some particular significant experience. This experience could only be a very early impression of a very general nature, placed in the prehistory not of the individual but of the species. To make myself more intelligible - an affective state would be constructed in the same way as a hysterical attack; and, like it, would be the precipitate of a reminiscence. A hysterical attack may thus be likened to a freshly constructed individual affect, and a normal affect to the expression of a general hysteria which has become a heritage.

[1916-1917, 3444]
The third of the forms of neurotic anxiety faces us with the puzzling fact that here the connection between anxiety and a threatening danger is completely lost to view. For instance, anxiety may appear in hysteria as an accompaniment to hysterical symptoms, or in some chance condition of excitement in which, it is true, we should expect some manifestation of affect but least of all one of anxiety; or it may make its appearance, divorced from any determinants and equally incomprehensible to us and to the patient, as an unrelated attack of anxiety. Here there is no sign whatever of any danger or of any cause that could be exaggerated into one. We next learn from these spontaneous attacks that the complex which we describe as a state of anxiety is capable of fragmentation. The total attack can be represented by a single, intensely developed symptom, by a tremor, a vertigo, by palpitation of the heart, or by dyspnoea; and the general feeling by which we recognize anxiety may be absent or have become indistinct. Yet these conditions, which we describe as 'anxiety-equivalents', have to be equated with anxiety in all clinical and aetiological respects.

(b) A second pointer is to be found in the analysis of the psychoneuroses, and especially of hysteria. We have seen that in this illness anxiety often appears in company with the symptoms, but that unbound anxiety appears, too, manifested as an attack or as a chronic condition. The patients cannot say what it is they are afraid of, and, by the help of an unmistakable secondary revision, link it to the first phobias that come to hand - such as dying, going mad, or having a stroke. If the situation out of which the anxiety (or the symptoms accompanied by anxiety) arose is subjected to analysis, we can as a rule discover what normal course of psychical events has failed to occur and has been replaced by phenomena of anxiety. To express it in another way: we construct the unconscious process as it would have been if it had not experienced any repression and had proceeded unhindered into consciousness. This process would have been accompanied by a particular affect, and we now learn to our surprise that this affect accompanying the normal course of events is invariably replaced by anxiety after repression has occurred, no matter what its own quality may be. Thus, when we have a hysterical anxiety-state before us, its unconscious correlate may be an impulse of a similar character - anxiety, shame, embarrassment - or, just as easily, a positive libidinal excitation or a hostile aggressive one, such as rage or anger. Anxiety is therefore the universally current coinage for which any affective impulse is or can be exchanged if the ideational content attached to it is subjected to repression.

What impressed me most of all while I was with Charcot were his latest investigations upon hysteria, some of which were carried out under my own eyes. He had proved, for instance, the genuineness of hysterical phenomena and their conformity to laws ('introire et hic dix sunt'), the frequent occurrence of hysteria in men, the production of hysterical paralyses and contractures by hypnotic suggestion and the fact that such artificial products showed, down to their smallest details, the same features as spontaneous attacks, which were often brought on traumatically. Many of Charcot's demonstrations began by provoking in me and in other visitors a sense of astonishment and an inclination to scepticism, which we tried to justify by an appeal to one of the theories of the day. He was always friendly and patient in dealing with such doubts, but he was also most decided; it was in one of these discussions that (speaking of theory) he remarked, 'Ca n'empêche pas d'exister', a mot which left an indelible mark upon my mind.
This brings us to a further question: how is it possible, from an economic point of view, for a mere process of withdrawal and discharge, like the withdrawing of a preconscious ego-cathexis, to produce unpleasure or anxiety, seeing that, according to our assumptions, unpleasure and anxiety can only arise as a result of an increase in cathexis? The reply is that this causal sequence should not be explained from an economic point of view. Anxiety is not newly created in repression; it is reproduced as an affective state in accordance with an already existing mnemic image. If we go further and enquire into the origin of that anxiety - and of affects in general - we shall be leaving the realm of pure psychology and entering the borderland of physiology. Affective states have become incorporated in the mind as precipitates of primaeval traumatic experiences, and when a similar situation occurs they are revived like mnemic symbols. I do not think I have been wrong in likening them to the more recent and individually acquired hysterical attack and in regarding them as its normal prototypes. In man and the higher animals it would seem that the act of birth, as the individual's first experience of anxiety, has given the affect of anxiety certain characteristic forms of expression. But, while acknowledging this connection, we must not lay undue stress on it nor overlook the fact that biological necessity demands that a situation of danger should have an affective symbol, so that a symbol of this kind would have to be created in any case. Moreover, I do not think that we are justified in assuming that whenever there is an outbreak of anxiety something like a reproduction of the situation of birth goes on in the mind. It is not even certain whether hysterical attacks, though they were originally traumatic reproductions of this sort, retain that character permanently.

[1926d, 4254]

This does not imply that anxiety occupies an exceptional position among the affective states. In my opinion the other affects are also reproductions of very early, perhaps even pre-individual, experiences of vital importance; and I should be inclined to regard them as universal, typical and innate hysterical attacks, as compared to the recently and individually acquired attacks which occur in hysterical neuroses and whose origin and significance as mnemic symbols have been revealed by analysis. It would be very desirable, of course, to be able to demonstrate the truth of this view in a number of such affects - a thing which is still very far from being the case.

[1926d, 4289]

This answer, however, raises further considerations. The innervations involved in the original state of anxiety probably had a meaning and purpose, in just the same way as the muscular movements which accompany a first hysterical attack. In order to understand a hysterical attack, all one has to do is to look for the situation in which the movements in question formed part of an appropriate and expedient action. Thus at birth it is probable that the innervation, in being directed to the respiratory organs, is preparing the way for the activity of the lungs, and, in accelerating the heartbeat, is helping to keep the blood free from toxic substances. Naturally, when the anxiety-state is reproduced later as an affect it will be lacking in any such expediency, just as are the repetitions of a hysterical attack. When the individual is placed in a new situation of danger it may well be quite inexpedient for him to respond with an anxiety-state (which is a reaction to an earlier danger) instead of initiating a reaction appropriate to the current danger. But his behaviour may become expedient once more if the danger-situation is recognized as it approaches and is signalled by an outbreak of anxiety. In that case he can at once get rid of his anxiety by having recourse to more suitable measures. Thus we see that there are two ways in which anxiety can emerge: in an inexpedient way, when a new situation of danger has occurred, or in an expedient way in order to give a signal and prevent such a situation from occurring.

[1926d, 4290]
We know the meaning and intention of such deathlike attacks. They signify an identification with a dead person, either with someone who is really dead or with someone who is still alive and whom the subject wishes dead. The latter case is the more significant. The attack then has the value of a punishment. One has wished another person dead, and now one is this other person and is dead oneself. At this point psycho-analytical theory brings in the assertion that for a boy this other person is usually his father and that the attack (which is termed hysterical) is thus a self-punishment for a death-wish against a hated father.

We have not yet succeeded in fixing the boundary line between them. It will be observed that here the largest share in the outcome is ascribed to the passive component of repressed femininity. In addition, it must be of importance as an accidental factor whether the father, who is feared in any case, is also especially violent in reality. This was true in Dostoevsky's case, and we can trace back the fact of his extraordinary sense of guilt and of his masochistic conduct of life to a specially strong feminine component. Thus the formula for Dostoevsky is as follows: a person with a specially strong innate bisexual disposition, who can defend himself with special intensity against dependence on a specially severe father. This characteristic of bisexuality comes as an addition to the components of his nature that we have already recognized. His early symptoms of death-like attacks can thus be understood as a father-identification on the part of his ego, which is permitted by his super-ego as a punishment. 'You wanted to kill your father in order to be your father yourself. Now you are your father, but a dead father' - the regular mechanism of hysterical symptoms. And further: 'Now your father is killing you.' For the ego the death symptom is a satisfaction in phantasy of the masculine wish and at the same time a masochistic satisfaction; for the super-ego it is a punitive satisfaction - that is, a sadistic satisfaction. Both of them, the ego and the super-ego, carry on the role of father.

To sum up, the relation between the subject and his father-object, while retaining its content, has been transformed into a relation between the ego and the super-ego - a new setting on a fresh stage. Infantile reactions from the Oedipus complex such as these may disappear if reality gives them no further nourishment. But the father's character remained the same, or rather, it deteriorated with the years, and thus Dostoevsky's hatred for his father and his death-wish against that wicked father were maintained. Now it is a dangerous thing if reality fulfils such repressed wishes. The phantasy has become reality and all defensive measures are thereupon reinforced. Dostoevsky's attacks now assumed an epileptic character; they still undoubtedly signified an identification with his father as a punishment, but they had become terrible, like his father's frightful death itself. What further content they had absorbed, particularly what sexual content, escapes conjecture.
GENTLEMEN, - I propose to take the example of psychogenic disturbance of vision, in order to show you the modifications which have taken place in our view of the genesis of disorders of this kind under the influence of psycho-analytic methods of investigation. As you know, hysterical blindness is taken as the type of a psychogenic visual disturbance. It is generally believed, as a result of the researches of the French School (including such men as Charcot, Janet and Binet), that the genesis of these cases is understood. For we are in a position to produce blindness of this kind experimentally if we have at our disposal someone who is susceptible to somnambulism. If we put him into deep hypnosis and suggest the idea to him that he sees nothing with one of his eyes, he will in fact behave as though he had become blind in that eye, like a hysteric who has developed a visual disturbance spontaneously. We may thus construct the mechanism of spontaneous hysterical disturbances of vision on the model of suggested hypnotic ones. In a hysteric the idea of being blind arises, not from the prompting of a hypnotist, but spontaneously - by autosuggestion, as people say; and in both cases this idea is so powerful that it turns into reality, exactly like a suggested hallucination, paralysis, etc.

[1910i, 2366]

Appropriate experiments have shown that people who are hysterically blind do nevertheless see in some sense, though not in the full sense. Excitations of the blind eye may have certain psychical consequences (for instance, they may produce affects) even though they do not become conscious. Thus hysterically blind people are only blind as far as consciousness is concerned; in their unconscious they see. It is precisely observations such as this that compel us to distinguish between conscious and unconscious mental processes.

[1910i, 2367]

How does it happen that such people develop the unconscious 'autosuggestion' that they are blind, while nevertheless they see in their unconscious? The reply given by the French researches is to explain that in patients predisposed to hysteria there is an inherent tendency to dissociation - to a falling apart of the connections in their mental field - as a consequence of which some unconscious processes do not continue as far as into the conscious. Let us leave entirely on one side the value that this attempted explanation may have as regards an understanding of the phenomena in question, and let us look at the matter from another angle. As you see, Gentlemen, the identity of hysterical blindness with the blindness provoked by suggestion, on which so much stress was laid to begin with, has now been given up. The hysterical patient is blind, not as the result of an autosuggestive idea that he cannot see, but as the result of a dissociation between unconscious and conscious processes in the act of seeing; his idea that he does not see is the well-founded expression of the psychical state of affairs and not its cause.

[1910i, 2367]

If, Gentlemen, you complain of the obscurity of this exposition I shall not find it easy to defend. I have tried to give you a synthesis of the views of different investigators, and in doing so I have probably coupled them together too closely. I wanted to condense into a single composite whole the concepts that have been brought up to make psychogenic disturbances intelligible - their origin from excessively powerful ideas, the distinction between conscious and unconscious mental processes and the assumption of mental dissociation. And I have been no more successful in this than the French writers, at whose head stands Pierre Janet. I hope, therefore, that you will excuse not only the obscurity but the inaccuracy of my exposition, and will allow me to tell you how psycho-analysis has led us to a view of psychogenic disturbances of vision which is more self-consistent and probably closer to the facts.

[1910i, 2367]
If, then, as we have learnt, psychogenic disturbances of vision depend on certain ideas connected with seeing being cut off from consciousness, we must, on the psycho-analytic view, assume that these ideas have come into opposition to other, more powerful ones, for which we use the collective concept of the 'ego'- a compound which is made up variously at different times - and have for that reason come under repression. But what can be the origin of this opposition, which makes for repression, between the ego and various groups of ideas? You will no doubt notice that it was not possible to frame such a question before the advent of psycho-analysis, for nothing was known earlier of psychical conflict and repression. Our researches, however, have put us in a position to give us the desired answer. Our attention has been drawn to the importance of the instincts in ideational life. We have discovered that every instinct tries to make itself effective by activating ideas that are in keeping with its aims. These instincts are not always compatible with one another; their interests often come into conflict. Opposition between ideas is only an expression of struggles between the various instincts. From the point of view of our attempted explanation, a quite specially important part is played by the undeniable opposition between the instincts which subserve sexuality, the attainment of sexual pleasure, and those other instincts, which have as their aim the self-preservation of the individual - the ego-instincts. As the poet has said, all the organic instincts that operate in our mind may be classified as 'hunger' or 'love'. We have traced the 'sexual instinct' from its first manifestations in children to its final form, which is described as 'normal'. We have found that it is put together from numerous 'component instincts' which are attached to excitations of regions of the body; and we have come to see that these separate instincts have to pass through a complicated development before they can be brought effectively to serve the aims of reproduction. The light thrown by psychology on the evolution of our civilization has shown us that it originates mainly at the cost of the sexual component instincts, and that these must be suppressed, restricted, transformed and directed to higher aims, in order that the mental constructions of civilization may be established. We have been able to recognize as a valuable outcome of these researches something that our colleagues have not yet been willing to believe, namely that the human ailments known as 'neuroses' are derived from the many different ways in which these processes of transformation in the sexual component instincts may miscarry. The 'ego' feels threatened by the claims of the sexual instincts and.fends them off by repressions; these, however, do not always have the desired result, but lead to the formation of dangerous substitutes for the repressed and to burdensome reactions on the part of the ego. From these two classes of phenomena taken together there emerge what we call the symptoms of neuroses.

[1910i, 2368]
We have apparently digressed widely from our problem, though in doing so we have touched on the manner in which neurotic pathological conditions are related to our mental life as a whole. But let us now return to the narrower question. The sexual and ego-instincts alike have in general the same organs and systems of organs at their disposal. Sexual pleasure is not attached merely to the function of the genitals. The mouth serves for kissing as well as for eating and communication by speech; the eyes perceive not only alterations in the external world which are important for the preservation of life, but also characteristics of objects which lead to their being chosen as objects of love - their charms. The saying that it is not easy for anyone to serve two masters is thus confirmed. The closer the relation into which an organ with a dual function of this kind enters with one of the major instincts, the more it with holds itself from the other. This principle is bound to lead to pathological consequences if the two fundamental instincts are disunited and if the ego maintains a repression of the sexual component instinct concerned. It is easy to apply this to the eye and to seeing. Let us suppose that the sexual component instinct which makes use of looking - sexual pleasure in looking - has drawn upon itself defensive action by the ego-instincts in consequence of its excessive demands, so that the ideas in which its desires are expressed succumb to repression and are prevented from becoming conscious; in that case there will be a general disturbance of the relation of the eye and of the act of seeing to the ego and consciousness. The ego will have lost its dominance over the organ, which will now be wholly at the disposal of the repressed sexual instinct. It looks as though the repression had been carried too far by the ego, as though it had emptied the baby out with the bath-water: the ego refuses to see anything at all any more, now that the sexual interest in seeing has made itself so prominent. But the alternative picture seems more to the point. This attributes the active role instead to the repressed pleasure in looking. The repressed instinct takes its revenge for being held back from further psychical expansion, by becoming able to extend its dominance over the organ that is in its service. The loss of conscious dominance over the organ is the detrimental substitute for the repression which had miscarried and was only made possible at that price.

[1910i, 2369]

This relation of an organ with a double claim on it - its relation to the conscious ego and to repressed sexuality - is to be seen even more clearly in motor organs than in the eye: as when, for instance, a hand which has tried to carry out an act of sexual aggression, and has become paralysed hysterically, is unable, after that act has been inhibited, to do anything else as though it were obstinately insisting on carrying out a repressed innervation; or as when the fingers of people who have given up masturbation refuse to learn the delicate movements required for playing the piano or the violin. As regards the eye, we are in the habit of translating the obscure psychical processes concerned in the repression of sexual scopophilia and in the development of the psychogenic disturbance of vision as though a punishing voice was speaking from within the subject, and saying: 'Because you sought to misuse your organ of sight for evil sensual pleasures, it is fitting that you should not see anything at all any more', and as though it was in this way approving the outcome of the process. The idea of talion punishment is involved in this, and in fact our explanation of psychogenic visual disturbance coincides with what is suggested by myths and legends. The beautiful legend of Lady Godiva tells how all the town's inhabitants hid behind their shuttered windows, so as to make easier the lady's task of riding naked through the streets in broad daylight, and how the only man who peeped through the shutters at her revealed loveliness was punished by going blind. Nor is this the only example which suggests that neurotic illness holds the hidden key to mythology as well.

[1910i, 2370]
Psycho-analysis is unjustly reproached, Gentlemen, for leading to purely psychological theories of pathological problems. The emphasis which it lays on the pathogenic role of sexuality, which, after all, is certainly not an exclusively psychical factor should alone protect it from this reproach. Psycho-analysts never forget that the mental is based on the organic, although their work can only carry them as far as this basis and no beyond it. Thus psycho-analysis is ready to admit, and indeed to postulate, that not all disturbances of vision need be psychogenic, like those that are evoked by the repression of erotic scopophilia. If an organ which serves the two sorts of instinct increases its erotogenic role, it is in general to be expected that this will not occur without the excitability and innervation of the organ undergoing changes which will manifest themselves as disturbances of its function in the service of the ego. Indeed, if we find that an organ normally serving the purpose of sense-perception begins to behave like an actual genital when its erotogenic role is increased, we shall not regard it as improbable that toxic changes are also occurring in it. For lack of a better name we must retain the old unsuitable term of ‘neurotic’ disturbances for both classes of functional disturbances - those of physiological as well as those of toxic origin - which follow from an increase in the erotogenic factor. Generally speaking, the neurotic disturbances of vision stand in the same relation to the psychogenic ones as the ‘actual neuroses’ do to the psychoneuroses: psychogenic visual disturbances can no doubt hardly ever appear without neurotic ones, but the latter can appear without the former. These neurotic symptoms are unfortunately little appreciated and understood even today; for they are not directly accessible to psycho-analysis, and other methods of research have left the standpoint of sexuality out of account.

[1910i, 2370]
It is not possible to assign the same origin to all the somatic symptoms of these patients. On the contrary, even from this case, which was not rich in them, we find that the somatic symptoms of a hysteria can arise in a variety of ways. I will venture, in the first place, to include pains among somatic symptoms. So far as I can see, one set of Frau von N.'s pains were certainly determined organically by the slight mortifications (of a rheumatic kind) in the muscles, tendons or fascia which cause so much more pain to neurotics than to normal people. Another set of pains were in all probability memories of pains - were mnemic symbols of the times of agitation and sick-nursing which played such a large part in the patient's life. These pains, too, may well have been originally justified on organic grounds but had since then been adapted for the purposes of the neurosis. I base these assertions about Frau von N.'s pains mainly on observations made elsewhere which I shall report on a later page. On this particular point little information could be gathered from the patient herself.

The symptomatology of hysteria and anxiety neurosis show many points in common which have not yet been sufficiently considered. The appearance of symptoms either in a chronic form or in attacks, the paraesthesias, grouped like auras, the hyperaesthesias and pressure-points which are found in certain surrogates of an anxiety attack (in dyspnoea and heart-attacks), the intensification, through conversion, of pains which perhaps have an organic justification - these and other features which the two illnesses have in common even allow of a suspicion that not a little of what is attributed to hysteria might with more justice be put to the account of anxiety neurosis. If one goes into the mechanism of the two neuroses, so far as it has been possible to discover it hitherto, aspects come to light which suggest that anxiety neurosis is actually the somatic counterpart to hysteria. In the latter just as in the former there is an accumulation of excitation (which is perhaps the basis for the similarity between their symptoms we have mentioned). In the latter just as in the former we find a psychological insufficiency, as a consequence of which abnormal somatic processes arise. In the latter just as in the former, too, instead of a psychological working-over of the excitation, a deflection of it occurs into the somatic field; the difference is merely that in anxiety neurosis the excitation, in whose displacement the neurosis expresses itself, is purely somatic (somatic sexual excitation), whereas in hysteria it is psychological (provoked by conflict). Thus it is not to be wondered at that hysteria and anxiety neurosis regularly combine with each other, as is seen in 'virginal anxiety' or in 'sexual hysteria', and that hysteria simply borrows a number of its symptoms from anxiety neurosis, and so on.

These intimate relations which anxiety neurosis has with hysteria provide a fresh argument, moreover, for insisting on the detachment of anxiety neurosis from neurasthenia; for if this detachment is not granted, we shall also be unable any longer to maintain the distinction which has been acquired with so much labour and which is so indispensable for the theory of the neuroses, between neurasthenia and hysteria.

Incidentally, the same objection arises in a specially marked manner when we are dealing with a neurosis in which the exciting cause (the 'traumatic scene') is known, and in which one can see how the person concerned turns away from the experience and consigns it to amnesia. Let me go back by way of example to a case analysed a great many years ago,¹ in which the patient, a young woman, was in love with her brother-in-law. Standing beside her sister's deathbed, she was horrified at having the thought: 'Now he is free and can marry me.' This scene was instantly forgotten, and thus the process of regression, which led to her hysterical pains, was set in motion. It is instructive precisely in this case, moreover, to learn along what path the neurosis attempted to solve the conflict. It took away from the value of the change that had occurred in reality, by repressing the instinctual demand which had emerged - that is, her love for her brother-in-law. The psychotic reaction would have been a disavowal of the fact of her sister's death.

[1895d, 82]

[1895b, 349]

[1924e, 4095]
The commonest symptoms of conversion hysteria - motor paralyses, contractures, involuntary actions or discharges, pains and hallucinations - are cathetic processes which are either permanently maintained or intermittent. But this puts fresh difficulties in the way. Not much is actually known about these symptoms. Analysis can show what the disturbed excitatory process is which the symptoms replace. It usually turns out that they themselves have a share in that process. It is as though the whole energy of the process had been concentrated in this one part of it. For instance, it will be found that the pains from which a patient suffers were present in the situation in which the repression occurred; or that his hallucination was, at that time, a perception; or that his motor paralysis is a defence against an action which should have been performed in that situation but was inhibited; or that his contracture is usually a displacement of an intended innervation of the muscles in some other part of his body; or that his convulsions are the expression of an outburst of affect which has been withdrawn from the normal control of the ego. The sensation of unpleasure which accompanies the appearance of the symptoms varies in a striking degree. In chronic symptoms which have been displaced on to motility, like paralyses and contractures, it is almost always entirely absent; the ego behaves towards the symptoms as though it had nothing to do with them. In intermittent symptoms and in those concerned with the sensory sphere, sensations of unpleasure are as a rule distinctly felt; and in symptoms of pain these may reach an extreme degree. The picture presented is so manifold that it is difficult to discover the factor which permits of all these variations and yet allows a uniform explanation of them. There is, moreover, little to be seen in conversion hysteria of the ego's struggle against the symptom after it has been formed. It is only when sensitivity to pain in some part of the body constitutes the symptom that that symptom is in a position to play a dual role. The symptom of pain will appear no less regularly whenever the part of the body concerned is touched from outside than when the pathogenic situation which it represents is associatively activated from within; and the ego will take precautions to prevent the symptom from being aroused through external perceptions. Why the formation of symptoms in conversion hysteria should be such a peculiarly obscure thing I cannot tell; but the fact affords us a good reason for quitting such an unproductive field of enquiry without delay.
[1926d, 4270]

Or again our patient - and this time let us make her a woman - may suffer in another way and in a different field. She is a pianist, but her fingers are overcome by cramp and refuse to serve her. Or when she thinks of going to a party she promptly becomes aware of a call of nature the satisfaction of which would be incompatible with a social gathering. She has therefore given up going to parties, dances, theatres or concerts. She is overcome by violent headaches or other painful sensations at times when they are most inconvenient. She may even be unable to keep down any meal she eats which can become dangerous in the long run. And, finally, it is a lamentable fact that she cannot tolerate any agitations, which after all are inevitable in life. On such occasions she falls in a faint, often accompanied by muscular spasms that recall sinister pathological states.
[1926e, 4329]
At this point I may perhaps refer to a short paper in which I have tried to give a psychological explanation of hysterical paralyses (Freud 1893c). I there arrived at a hypothesis that the cause of these paralyses lay in the inaccessibility to fresh associations of a group of ideas connected, let us say, with one of the extremities of the body; this associative inaccessibility depended in turn on the fact that the idea of the paralysed limb was involved in the recollection of the trauma - a recollection loaded with affect that had not been disposed of. I showed from examples from ordinary life that a cathexis such as this of an idea whose affect is unresolved always involves a certain amount of associative inaccessibility and of incompatibility with new cathexes. [1895d, 81]

Though the preceding considerations have reduced the importance of the part played by the day's residues in dreams, it is worth while devoting a little more attention to them. It must be that they are essential ingredients in the formation of dreams, since experience has revealed the surprising fact that in the content of every dream some link with a recent daytime impression - often of the most insignificant sort - is to be detected. We have not hitherto been able to explain the necessity for this addition to the mixture that constitutes a dream (see p. 669). And it is only possible to do so if we bear firmly in mind the part played by the unconscious wish and then seek for information from the psychology of the neuroses. We learn from the latter that an unconscious idea is as such quite incapable of entering the preconscious and that it can only exercise any effect there by establishing a connection with an idea which already belongs to the preconscious, by transferring its intensity on to it and by getting itself 'covered' by it. Here we have the fact of 'transference', which provides an explanation of so many striking phenomena in the mental life of neurotics. The preconscious idea, which thus acquires an undeserved degree of intensity may either be left unaltered by the transference, or it may have a modification forced upon it, derived from the content of the idea which effects the transference. I hope I may be forgiven for drawing analogies from everyday life, but I am tempted to say that the position of a repressed idea resembles that of an American dentist in this country: he is not allowed to set up in practice unless he can make use of a legally qualified medical practitioner to serve as a stalking-horse and to act as a 'cover' in the eyes of the law. And just as it is not exactly the physicians with the largest practices who form alliances of this kind with dentists, so in the same way preconscious or conscious ideas which have already attracted a sufficient amount of the attention that is operating in the preconscious will not be the ones to be chosen to act as covers for a repressed idea. The unconscious prefers to weave its connections round preconscious impressions and ideas which are either indifferent and have thus had no attention paid to them, or have been rejected and have thus had attention promptly withdrawn from them. It is a familiar article in the doctrine of association, and one that is entirely confirmed by experience, that an idea which is bound by a very intimate tie in one direction, tends, as it were, to repel whole groups of new ties. I once attempted to base a theory of hysterical paralyses on this proposition. [1900a, 993]
This relation of an organ with a double claim on it - its relation to the conscious ego and to repressed sexuality - is to be seen even more clearly in motor organs than in the eye: as when, for instance, a hand which has tried to carry out an act of sexual aggression, and has become paralysed hysterically, is unable, after that act has been inhibited, to do anything else as though it were obstinately insisting on carrying out a repressed innervation; or as when the fingers of people who have given up masturbation refuse to learn the delicate movements required for playing the piano or the violin. As regards the eye, we are in the habit of translating the obscure psychical processes concerned in the repression of sexual scopophilia and in the development of the psychogenic disturbance of vision as though a punishing voice was speaking from within the subject, and saying: 'Because you sought to misuse your organ of sight for evil sensual pleasures, it is fitting that you should not see anything at all any more', and as though it was in this way approving the outcome of the process. The idea of talion punishment is involved in this, and in fact our explanation of psychogenic visual disturbance coincides with what is suggested by myths and legends. The beautiful legend of Lady Godiva tells how all the town's inhabitants hid behind their shuttered windows, so as to make easier the lady's task of riding naked through the streets in broad daylight, and how the only man who peeped through the shutters at her revealed loveliness was punished by going blind. Nor is this the only example which suggests that neurotic illness holds the hidden key to mythology as well.

[1910i, 2370]

(d) In inhibition in work - a thing which we so often have to deal with as an isolated symptom in our therapeutic work - the subject feels a decrease in his pleasure in it or becomes less able to do it well; or he has certain reactions to it, like fatigue, giddiness or sickness, if he is obliged to go on with it. If he is a hysterical he will have to give up his work owing to the appearance of organic and functional paralyses which make it impossible for him to carry it on. If he is an obsessional neurotic he will be perpetually being distracted from his work or losing time over it through the introduction of delays and repetitions.

[1926d, 4250]
The commonest symptoms of conversion hysteria - motor paralyses, contractures, involuntary actions or discharges, pains and hallucinations - are cathetic processes which are either permanently maintained or intermittent. But this puts fresh difficulties in the way. Not much is actually known about these symptoms. Analysis can show what the disturbed excitatory process is which the symptoms replace. [1926e, 4329]
There is no longer anything contradictory to us in the notion that a psychical process which develops anxiety can nevertheless be the fulfilment of a wish. We know that it can be explained by the fact that the wish belongs to one system, the Ucs., while it has been repudiated and suppressed by the other system, the Pcs.¹ Even where psychical health is perfect, the subjugation of the Ucs. by the Pcs. is not complete; the measure of suppression indicates the degree of our psychical normality. Neurotic symptoms show that the two systems are in conflict with each other; they are the products of a compromise which brings the conflict to an end for the time being. On the one hand, they allow the Ucs. an outlet for the discharge of its excitation, and provide it with a kind of sally-port, while, on the other hand they make it possible for the Pcs. to control the Ucs. to some extent. It is instructive to consider, for instance, the significance of a hysterical phobia or an agoraphobia. Let us suppose that a neurotic patient is unable to cross the street alone - a condition which we rightly regard as a 'symptom.' If we remove this symptom by compelling him to carry out the act of which he believes himself incapable, the consequence will be an attack of anxiety; and indeed the occurrence of an anxiety-attack in the street is often the precipitating cause of the onset of an agoraphobia. We see, therefore, that the symptom has been constructed in order to avoid an outbreak of anxiety; the phobia is erected like a frontier fortification against the anxiety.

³ All these discussions contain much that is typical and valid for hysteria in general. The subject of erection solves some of the most interesting hysterical symptoms. The attention that women pay to the outlines of men's genitals as seen through their clothing becomes, when it has been repressed, a source of the very frequent cases of avoiding company and of dreading society. - It is scarcely possible to exaggerate the pathogenic significance of the comprehensive tie uniting the sexual and the excremental, a tie which is at the basis of a very large number of hysterical phobias.

[1900a, 1009]

[1905e, 1370]
A deeper insight into the mechanism of obsessional neurosis is gained if we take into account the primary fact which lies at the bottom of it. This is always the repression of an instinctual impulse (a component of the sexual instinct) which was present in the subject's constitution and which was allowed to find expression for a while during his childhood but later succumbed to suppression. In the course of the repression of this instinct a special conscientiousness is created which is directed against the instinct's aims; but this psychical reaction-formation feels insecure and constantly threatened by the instinct which is lurking in the unconscious. The influence of the repressed instinct is felt as a temptation, and during the process of repression itself anxiety is generated, which gains control over the future in the form of expectant anxiety. The process of repression which leads to obsessional neurosis must be considered as one which is only partly successful and which increasingly threatens to fail. It may thus be compared to an unending conflict; fresh psychical efforts are continually required to counterbalance the forward pressure of the instinct. Thus the ceremonial and obsessive actions arise partly as a defence against the temptation and partly as a protection against the ill which is expected. Against the temptation the protective measures seem soon to become inadequate; then the prohibitions come into play, with the purpose of keeping at a distance situations that give rise to temptation. Prohibitions take the place of obsessive actions, it will be seen, just as a phobia is designed to avert a hysterical attack. Again, a ceremonial represents the sum of the conditions subject to which something that is not yet absolutely forbidden is permitted, just as the Church's marriage ceremony signifies for the believer a sanctioning of sexual enjoyment which would otherwise be sinful. A further characteristic of obsessional neurosis, as of all similar affections, is that its manifestations (its symptoms, including the obsessive actions) fulfil the condition of being a compromise between the warring forces of the mind. They thus always reproduce something of the pleasure which they are designed to prevent; they serve the repressed instinct no less than the agencies which are repressing it. As the illness progresses, indeed, actions which were originally mostly concerned with maintaining the defence come to approximate more and more to the proscribed actions through which the instinct was able to find expression in childhood.

[1907b, 1907]

We are obliged to take quite another view of the process of repression when we consider the picture of a true conversion hysteria. Here the salient point is that it is possible to bring about a total disappearance of the quota of affect. When this is so, the patient displays towards his symptoms what Charcot called 'la belle indifférence hystériques'. In other cases this suppression is not so completely successful: some distressing sensations may attach to the symptoms themselves, or it may prove impossible to prevent some release of anxiety, which in turn sets to work the mechanism of forming a phobia. The ideational content of the instinctual representative is completely withdrawn from consciousness; as a substitute - and at the same time as a symptom - we have an over-strong innervation (in typical cases, a somatic one), sometimes of a sensory, sometimes of a motor character, either as an excitation or an inhibition. The over-innervated area proves on a closer view to be a part of the repressed instinctual representative itself - a part which, as though by a process of condensation, has drawn the whole cathexis on to itself. These remarks do not of course bring to light the whole mechanism of a conversion hysteria; in especial the factor of regression, which will be considered in another connection, has also to be taken into account. In so far as repression in hysteria is made possible only by the extensive formation of substitutes, it may be judged to be entirely unsuccessful; as regards dealing with the quota of affect, however, which is the true task of repression, it generally signifies a total success. In conversion hysteria the process of repression is completed with the formation of the symptom and does not, as in anxiety hysteria, need to continue to a second phase - or rather, strictly speaking, to continue endlessly.

[1915d, 2986]
Here is an instance of this. Another physician in Vienna, whose conviction of the unimportance of sexual factors in hysteria has probably been very much strengthened by such experiences as this, was consulted in the case of a fourteen-year-old girl who suffered from dangerous hysterical vomiting. He made up his mind to ask her the painful question whether by any chance she had ever had a love-affair with a man. 'No!' answered the child, no doubt with well-affected astonishment; and then repeated to her mother in her irreverent way: 'Only fancy! the old stupid asked me if I was in love!' She afterwards came to me for treatment, and proved - though not during our very first conversation, to be sure - to have been a masturbator for many years, with a considerable leucorrhoeal discharge (which had a close bearing on her vomiting). She had finally broken herself of the habit, but was tormented in her abstinence by the most acute sense of guilt, so that she looked upon every misfortune that befell her family as a divine punishment for her transgression. Besides this, she was under the influence of the romance of an unmarried aunt, whose pregnancy (a second determinant for her vomiting) was supposed to have been happily hidden from her. The girl was looked upon as a 'mere child,' but she turned out to be initiated into all the essentials of sexual relations.

If I may suppose that the scene of the kiss took place in this way, I can arrive at the following derivation for the feelings of disgust. Such feelings seem originally to be a reaction to the smell (and afterwards also to the sight) of excrement. But the genitals can act as a reminder of the excretory functions; and this applies especially to the male member, for that organ performs the function of micturition as well as the sexual function. Indeed, the function of micturition is the earlier known of the two, and the only one known during the pre-sexual period. Thus it happens that disgust becomes one of the means of affective expression in the sphere of sexual life. The Early Christian Father's 'inter urinas et faeces nascimur' clings to sexual life and cannot be detached from it in spite of every effort at idealization. I should like, however, expressly to emphasize my opinion that the problem is not solved by the mere pointing out of this path of association. The fact that this association can be called up does not show that it actually will be called up. And indeed in normal circumstances it will not be. A knowledge of the paths does not render less necessary a knowledge of the forces which travel along them.

I must now proceed to touch upon some further relations existing between Dora's genital catarrh and her hysterical symptoms. At a time when any psychological elucidation of hysteria was still very remote, I used to hear experienced fellow-doctors who were my seniors maintain that in the case of hysterical patients suffering from leucorrhoea any increase in the catarrh was regularly followed by an intensification of the hysterical troubles, and especially of loss of appetite and vomiting. No one was very clear about the nature of the connection but I fancy the general inclination was towards the opinion held by gynaecologists. According to their hypothesis, as is well known, disorders of the genitals exercise upon the nervous functions a direct and far-reaching influence in the nature of an organic disturbance - though a therapeutic test of this theory is apt to leave one in the lurch. In the light of our present knowledge we cannot exclude the possibility of the existence of a direct organic influence of this sort; but it is at all events easier to indicate its psychical coating. The pride taken by women in the appearance of their genitals is quite a special feature of their vanity; and disorders of the genitals which they think calculated to inspire feelings of repugnance or even disgust have an incredible power of humiliating them, of lowering their self-esteem, and of making them irritable, sensitive, and distrustful. An abnormal secretion of the mucous membrane of the vagina is looked upon as a source of disgust.
It is not every child who sucks in this way. It may be assumed that those children do so in whom there is a constitutional intensification of the erotogenic significance of the labial region. If that significance persists, these same children when they are grown up will become epicures in kissing, will be inclined to perverse kissing, or, if males, will have a powerful motive for drinking and smoking. If, however, repression ensues, they will feel disgust at food and will produce hysterical vomiting. The repression extends to the nutritional instinct owing to the dual purpose served by the labial zone. Many of my women patients who suffer from disturbances of eating, globus hystericus, constriction of the throat and vomiting, have indulged energetically in sucking during their childhood.

[1905d, 1503]

The language of dreams may be looked upon as the method by which unconscious mental activity expresses itself. But the unconscious speaks more than one dialect. According to the differing psychological conditions governing and distinguishing the various forms of neurosis, we find regular modifications in the way in which unconscious mental impulses are expressed. While the gesture-language of hysteria agrees on the whole with the picture-language of dreams and visions, etc., the thought-language of obsessional neurosis and of the paraphrenias (dementia praecox and paranoia) exhibits special idiomatic peculiarities which, in a number of instances, we have been able to understand and interrelate. For instance, what a hysteric expresses by vomiting an obsessional will express by painstaking protective measures against infection, while a paraphrenic will be led to complaints or suspicions that he is being poisoned. These are all of them different representations of the patient's wish to become pregnant which have been repressed into the unconscious, or of his defensive reaction against that wish.

[1913j, 2814]
If any of you undertakes exertions of this kind, he will certainly gain a powerful impression of the wealth of evidential material. But he will also come up against a difficulty. The sense of a symptom lies, as we have found, in some connection with the patient's experience. The more individual is the form of the symptom the more reason we shall have for expecting to be able to establish this connection. The task is then simply to discover, in respect to a senseless idea and a pointless action, the past situation in which the idea was justified and the action served a purpose. The obsessional action of our patient who ran to the table and rang for the housemaid is a perfect model of this kind of symptom. But there are - and they are very frequent symptoms of quite another character. They must be described as 'typical' symptoms of an illness; they are approximately the same in all cases, individual distinctions disappear in them or at least shrink up to such an extent that it is difficult to bring them into connection with the patients' individual experience and to relate them to particular situations they have experienced. Let us look once more at obsessional neurosis. The sleep-ceremonial of our second patient already has much that is typical about it, though at the same time it has enough individual traits to make what I might call a 'historical' interpretation possible. But all these obsessional patients have a tendency to repeat, to make their performances rhythmical and to keep them isolated from other actions. The majority of them wash too much. Patients who suffer from agoraphobia (topophobia or fear of spaces), which we no longer regard as obsessional neurosis but describe as 'anxiety hysteria', often repeat the same features in their symptoms with wearisome monotony: they are afraid of enclosed spaces, of large open squares, of lengthy roads and streets. They feel protected if they are accompanied by an acquaintance or followed by a vehicle, and so on. On this similar background, however, different patients nevertheless display their individual requirements - whims, one is inclined to say - which in some cases contradict one another directly. One patient avoids only narrow streets and another only wide ones; one can go out only if there are few people in the street, another only if there are many. In the same way, hysteria, in spite of its wealth of individual traits, has a superfluity of common, typical symptoms, which seem to resist any easy historical derivation. And we must not forget that it is these typical symptoms, indeed, which give us our bearings when we make our diagnosis. Suppose, in a case of hysteria, we have really traced a typical symptom back to an experience or a chain of similar experiences - a case of hysterical vomiting, for instance, to a series of disgusting impressions - then we are at a loss when the analysis in a similar case of vomiting reveals a series of a quite different kind of ostensibly effective experiences. It looks, then, as though for unknown reasons hysterical patients are bound to produce vomiting and as though the historical precipitating causes revealed by analysis were only pretexts which, if they happen to be there, are exploited by this internal necessity.

[1916-1917, 3349]

(b) The function of nutrition is most frequently disturbed by a disinclination to eat, brought about by a withdrawal of libido. An increase in the desire to eat is also a not uncommon thing. The compulsion to eat is attributed to a fear of starving; but this is a subject which has been but little studied. The symptom of vomiting is known to us as a hysterical defence against eating. Refusal to eat owing to anxiety is a concomitant of psychotic states (delusions of being poisoned).

[1926d, 4249]
Or again our patient - and this time let us make her a woman - may suffer in another way and in a different field. She is a pianist, but her fingers are overcome by cramp and refuse to serve her. Or when she thinks of going to a party she promptly becomes aware of a call of nature the satisfaction of which would be incompatible with a social gathering. She has therefore given up going to parties, dances, theatres or concerts. She is overcome by violent headaches or other painful sensations at times when they are most inconvenient. She may even be unable to keep down any meal she eats which can become dangerous in the long run. And, finally, it is a lamentable fact that she cannot tolerate any agitations, which after all are inevitable in life. On such occasions she falls in a faint, often accompanied by muscular spasms that recall sinister pathological states.

[1926e, 4329]
I must now proceed to touch upon some further relations existing between Dora's genital catarrh and her hysterical symptoms. At a time when any psychological elucidation of hysteria was still very remote, I used to hear experienced fellow-doctors who were my seniors maintain that in the case of hysterical patients suffering from leucorrhoea any increase in the catarrh was regularly followed by an intensification of the hysterical troubles, and especially of loss of appetite and vomiting. An abnormal secretion of the mucous membrane of the vagina is looked upon as a source of disgust.

[1905e, 1419]
Some of the striking motor phenomena exhibited by Frau von N. were simply an expression of the emotions and could easily be recognized in that light. Thus, the way in which she stretched her hands in front of her with her fingers spread out and crooked expressed horror, and similarly her facial play. This, of course, was a more lively and uninhibited way of expressing her emotions than was usual with women of her education and race. Indeed, she herself was restrained, almost stiff in her expressive movements when she was not in a hysterical state. Others of her motor symptoms were, according to herself, directly related to her pains. She played restlessly with her fingers (1888) or rubbed her hands against one another (1889) so as to prevent herself from screaming. This reason reminds one forcibly of one of the principles laid down by Darwin to explain the expression of the emotions - the principle of the overflow of excitation, which accounts, for instance, for dogs wagging their tails. We are all of us accustomed, when we are affected by painful stimuli, to replace screaming by other sorts of motor innervations. A person who has made up his mind at the dentist’s to keep his head and mouth still and not to put his hand in the way, may at least start drumming with his feet.

A more complicated method of conversion is revealed by Frau von N.’s tic-like movements, such as clicking with the tongue and stammering, calling out the name ‘Emmy’ in confusional states, using the composite formula ‘Keep still! Don’t say anything! Don’t touch me!’ (1888). Of these motor manifestations, the stammering and clacking can be explained in accordance with a mechanism which I have described, in a short paper on the treatment of a case by hypnotic suggestion (1892-93), as ‘the putting into effect of antithetic ideas’. The process, as exemplified in our present instance, would be as follows. Our hysterical patient, exhausted by worry and long hours of watching by the bedside of her sick child which had at last fallen asleep, said to herself: ‘Now you must be perfectly still so as not to awaken the child.’ This intention probably gave rise to an antithetic idea in the form of a fear that she might make a noise all the same that would wake the child from the sleep which she had so long hoped for. Similar antithetic ideas arise in us in a marked manner when we feel uncertain whether we can carry out some important intention.

[1895d, 83]
One thing more, Gentlemen. It is true that earlier I put the relation between recent and infantile aetiology aside as a separate theme. Nevertheless, I cannot leave the subject without overstepping this resolution at least with one remark. You will agree with me that there is one fact above all which leads us astray in the psychological understanding of hysterical phenomena, and which seems to warn us against measuring psychical acts in hystericst and in normal people with the same yardstick. That fact is the discrepancy between psychically exciting stimuli and psychical reactions which we come upon in hysterical subjects. We try to account for it by assuming the presence in them of a general abnormal sensitivity to stimuli, and we often endeavour to explain it on a physiological basis, as if in such patients certain organs of the brain which serve to transmit stimuli were in a peculiar chemical state (like the spinal centres of a frog, perhaps, which has been injected with strychnine) or as if these cerebral organs had withdrawn from the influence of higher inhibiting centres (as in animals being experimented on under vivisection). Occasionally one or other of these concepts may be perfectly valid as an explanation of hysterical phenomena; I do not dispute this. But the main part of the phenomenon - of the abnormal, exaggerated, hysterical reaction to psychical stimuli - admits of another explanation, an explanation which is supported by countless examples from the analyses of patients. And this is as follows: The reaction of hystericst is only apparently exaggerated; it is bound to appear exaggerated to us because we only know a small part of the motives from which it arises.

I would ask you to carry this line of thought over on to hysterical patients. It is not the latest slight - which, in itself, is minimal - that produces the fit of crying, the outburst of despair or the attempt at suicide, in disregard of the axiom that an effect must be proportionate to its cause; the small slight of the present moment has aroused and set working the memories of very many, more intense, earlier slights, behind all of which there lies in addition the memory of a serious slight in childhood which has never been overcome. Or again, let us take the instance of a young girl who blames herself most frightfully for having allowed a boy to stroke her hand in secret, and who from that time on has been overtaken by a neurosis. You can, of course, answer the puzzle by pronouncing her an abnormal, eccentrically disposed and over-sensitive person; but you will think differently when analysis shows you that the touching of her hand reminded her of another, similar touching, which had happened very early in her childhood and which formed part of a less innocent whole, so that her self-reproaches were actually reproaches about that old occasion. Finally, the problem of the hysterogenic points is of the same kind. If you touch a particular spot, you do something you did not intend: you awaken a memory which may start off a convulsive attack, and since you know nothing of this psychical intermediate link you refer the attack directly to the operation of your touch. The patients are in the same state of ignorance and therefore fall into similar errors. ie they too are unaware of the re-awakening of the unconscious memory. They constantly establish 'false connections' between the most recent cause, which they are conscious of, and the effect, which depends on so many intermediate links. If, however, the physician has been able to bring together the conscious and unconscious motives for the purpose of explaining a hysterical reaction, he is almost always obliged to recognize that the seemingly exaggerated reaction is appropriate and is abnormal only in its form.
You may, however, rightly object to this justification of the hysterical reaction to psychical stimuli and say that nevertheless the reaction is not a normal one. For why do healthy people behave differently? Why do not all their excitations of long ago come into operation once more when a new, present-day, excitation takes place? One has an impression, indeed, that with hysterical patients it is as if all their old experiences - to which they have already reacted so often and, moreover, so violently - had retained their effective power; as if such people were incapable of disposing of their psychical stimuli. Quite true, Gentlemen, something of the sort must really be assumed. You must not forget that in hysterical people when there is a present-day precipitating cause, the old experiences come into operation in the form of unconscious memories. It looks as though the difficulty of disposing of a present impression, the impossibility of transforming it into a powerless memory, is attached precisely to the character of the psychical unconscious. You see that the remainder of the problem lies once more in the field of psychology - and, what is more, a psychology of a kind for which philosophers have done little to prepare the way for us.

A striking feature in neurotic characters - the fact that a cause capable of releasing an affect is apt to produce in them a result which is qualitatively justified but quantitatively excessive is to be explained along these same lines, in so far as it admits of any psychological explanation at all. The excess arises from sources of affect which had previously remained unconscious and suppressed. These sources have succeeded in setting up an associative link with the real releasing cause, and the desired path from the release of their own affect has been opened by the other source of affect, which is unobjectionable and legitimate. Our attention is thus drawn to the fact that in considering the suppressed and suppressing agencies, we must not regard their relation as being exclusively one of mutual inhibition. Just as much regard must be paid to cases in which the two agencies bring about a pathological effect by working side by side and by intensifying each other.

It is perfectly true that unconscious wishes always remain active. They represent paths which can always be traversed, whenever a quantity of excitation makes use of them. Indeed it is a prominent feature of unconscious processes that they are indestructible. In the unconscious nothing can be brought to an end, nothing is past or forgotten. This is brought most vividly home to one in studying the neuroses, and especially hysteria. The unconscious path of thoughts, which leads to discharge in a hysterical attack, immediately becomes traversable once more, when sufficient excitation has accumulated. A humiliation that was experienced thirty years ago acts exactly like a fresh one throughout the thirty years, as soon as it has obtained access to the unconscious sources of emotion. As soon as the memory of it is touched, it springs into life again and shows itself cathexed with excitation which finds a motor discharge in an attack. This is precisely the point at which psychotherapy has to intervene. Its task is to make it possible for the unconscious processes to be dealt with finally and be forgotten. For the fading of memories and the emotional weakness of impressions which are no longer recent, which we are inclined to regard as self-evident and to explain as a primary effect of time upon mental memory-traces, are in reality secondary modifications which are only brought about by laborious work. What performs this work is the preconscious, and psychotherapy can pursue no other course than to bring the Ucs. under the domination of the Pcs.
Or again our patient - and this time let us make her a woman - may suffer in another way and in a different field. She is a pianist, but her fingers are overcome by cramp and refuse to serve her. Or when she thinks of going to a party she promptly becomes aware of a call of nature the satisfaction of which would be incompatible with a social gathering. She has therefore given up going to parties, dances, theatres or concerts. She is overcome by violent headaches or other painful sensations at times when they are most inconvenient. She may even be unable to keep down any meal she eats which can become dangerous in the long run. And, finally, it is a lamentable fact that she cannot tolerate any agitations, which after all are inevitable in life. On such occasions she falls in a faint, often accompanied by muscular spasms that recall sinister pathological states.

[1926e, 4329]
In the same connection I will give the explanation of a vision that was described to me by another hysterical patient (a woman of forty) as having happened before she fell ill. One morning she opened her eyes and saw her brother in the room, though, as she knew, he was in fact in an insane asylum. Her small son was sleeping in the bed beside her. To save the child from having a fright and falling into convulsions when he saw his uncle, she pulled the sheet over his face, whereupon the apparition vanished. This vision was a modified version of a memory from the lady’s childhood; and, though it was conscious, it was intimately related to all the unconscious material in her mind. Her nurse had told her that her mother (who had died very young, when my patient was only eighteen months old) had suffered from epileptic or hysterical convulsions, which went back to a fright caused by her brother (my patient’s uncle) appearing to her disguised as a ghost with a sheet over his head. Thus the vision contained the same elements as the memory: the brother’s appearance, the sheet, the fright and its results. But the elements had been arranged in a different context and transferred on to other figures. The obvious motive of the vision, or of the thoughts which it replaced, was her concern lest her little boy might follow in the footsteps of his uncle, whom he greatly resembled physically.

I hope the reader will restrain himself and not allow a surge of indignation to prevent his following psycho-analysis any further because it leads to an unpardonable aspersion on the memory of a great and pure man the very first time it is applied to his case. Such indignation, it is clear, will never be able to tell us the significance of Leonardo’s childhood phantasy; at the same time Leonardo has acknowledged the phantasy in the most unambiguous fashion, and we cannot abandon our expectation - or, if it sounds better, our prejudice - that a phantasy of this kind must have some meaning, in the same way as any other psychical creation: a dream, a vision or a delirium. Let us rather therefore give a fair hearing for a while to the work of analysis, which indeed has not yet spoken its last word.

[1900a, 978]

[1910c, 2262]
The commonest symptoms of conversion hysteria - motor paralyses, contractures, involuntary actions or discharges, pains and hallucinations - are cathetic processes which are either permanently maintained or intermittent. But this puts fresh difficulties in the way. Not much is actually known about these symptoms. Analysis can show what the disturbed excitatory process is which the symptoms replace. It usually turns out that they themselves have a share in that process. It is as though the whole energy of the process had been concentrated in this one part of it. For instance, it will be found that the pains from which a patient suffers were present in the situation in which the repression occurred; or that his hallucination was, at that time, a perception; or that his motor paralysis is a defence against an action which should have been performed in that situation but was inhibited; or that his contracture is usually a displacement of an intended innervation of the muscles in some other part of his body; or that his convulsions are the expression of an outburst of affect which has been withdrawn from the normal control of the ego. The sensation of unpleasure which accompanies the appearance of the symptoms varies in a striking degree. In chronic symptoms which have been displaced on to motility, like paralyses and contractures, it is almost always entirely absent; the ego behaves towards the symptoms as though it had nothing to do with them. In intermittent symptoms and in those concerned with the sensory sphere, sensations of unpleasure are as a rule distinctly felt; and in symptoms of pain these may reach an extreme degree. The picture presented is so manifold that it is difficult to discover the factor which permits of all these variations and yet allows a uniform explanation of them. There is, moreover, little to be seen in conversion hysteria of the ego's struggle against the symptom after it has been formed. It is only when sensitivity to pain in some part of the body constitutes the symptom that that symptom is in a position to play a dual role. The symptom of pain will appear no less regularly whenever the part of the body concerned is touched from outside than when the pathogenic situation which it represents is associatively activated from within; and the ego will take precautions to prevent the symptom from being aroused through external perceptions. Why the formation of symptoms in conversion hysteria should be such a peculiarly obscure thing I cannot tell; but the fact affords us a good reason for quitting such an unproductive field of enquiry without delay.

[1926d, 4270]
In the case of a psychical complex which has come under the influence of the censorship imposed by resistance, the affects are the constituent which is least influenced and which alone can give us a pointer as to how we should fill in the missing thoughts. This is seen even more clearly in the psychoneuroses than in dreams. Their affects are always appropriate, at least in their quality though we must allow for their intensity being increased owing to displacements of neurotic attention. If a hysteric is surprised at having to be so frightened of something trivial or if a man suffering from obsessions is surprised at such distressing self-reproaches arising out of a mere nothing, they have both gone astray, because they regard the ideational content - the triviality or the mere nothing - as what is essential; and they put up an unsuccessful fight because they take this ideational content as the starting-point of their thought-activity. Psycho-analysis can put them upon the right path by recognizing the affect as being, on the contrary, justified and by seeking out the idea which belongs to it but has been repressed and replaced by a substitute. A necessary premise to all this is that the release of affect and the ideational content do not constitute the indissoluble organic unity as which we are in the habit of treating them, but that these two separate entities may be merely soldered together and can thus be detached from each other by analysis. Dream-interpretation shows that this is in fact the case. [1900a, 905]

It is perfectly true that unconscious wishes always remain active. They represent paths which can always be traversed, whenever a quantity of excitation makes use of them. Indeed it is a prominent feature of unconscious processes that they are indestructible. In the unconscious nothing can be brought to an end, nothing is past or forgotten. This is brought most vividly home to one in studying the neuroses, and especially hysteria. The unconscious path of thoughts, which leads to discharge in a hysterical attack, immediately becomes traversable once more, when sufficient excitation has accumulated. A humiliation that was experienced thirty years ago acts exactly like a fresh one throughout the thirty years, as soon as it has obtained access to the unconscious sources of emotion. As soon as the memory of it is touched, it springs into life again and shows itself cathected with excitation which finds a motor discharge in an attack. This is precisely the point at which psychotherapy has to intervene. Its task is to make it possible for the unconscious processes to be dealt with finally and be forgotten. For the fading of memories and the emotional weakness of impressions which are no longer recent, which we are inclined to regard as self-evident and to explain as a primary effect of time upon mental memory-traces, are in reality secondary modifications which are only brought about by laborious work. What performs this work is the preconscious, and psychotherapy can pursue no other course than to bring the Ucs. under the domination of the Pcs. [1900a, 1007]
In my *Interpretation of Dreams*, published in 1900, I showed that dreams in general can be interpreted, and that after the work of interpretation has been completed they can be replaced by perfectly correctly constructed thoughts which can be assigned a recognizable position in the chain of mental events. I wish to give an example in the following pages of the only practical application of which the art of interpreting dreams seems to admit. I have already mentioned in my book¹ how it was that I came upon the problem of dreams. The problem crossed my path as I was endeavouring to cure psychoneuroses by means of a particular psychotherapeutic method. For, among their other mental experiences, my patients told me their dreams, and these dreams seemed to call for insertion in the long thread of connections which spun itself out between a symptom of the disease and a pathogenic idea. At that time I learnt how to translate the language of dreams into the forms of expression of our own thought-language, which can be understood without further help. And I may add that this knowledge is essential for the psycho-analyst; for the dream is one of the roads along which consciousness can be reached by the psychical material which, on account of the opposition aroused by its content, has been cut off from consciousness and repressed, and has thus become pathogenic. The dream, in short, is one of the *détours by which repression can be evaded*; it is one of the principal means employed by what is known as the indirect method of representation in the mind. The following fragment from the history of the treatment of a hysterical girl is intended to show the way in which the interpretation of dreams plays a part in the work of analysis. It will at the same time give me a first opportunity of publishing at sufficient length to prevent further misunderstanding some of my views upon the psychical processes of hysteria and upon its organic determinants. I need no longer apologize on the score of length, since it is now agreed that the exacting demands which hysteria makes upon physician and investigator can be met only by the most sympathetic spirit of inquiry and not by an attitude of superiority and contempt. For,

[1905e, 1357]

That this state of affairs should exist in regard to the memories relating to the history of the illness is a necessary correlate of the symptoms and one which is theoretically requisite. In the further course of the treatment the patient supplies the facts which, though he had known them all along, had been kept back by him or had not occurred to his mind. The paramnesias prove untenable, and the gaps in his memory are filled in. It is only towards the end of the treatment that we have before us all intelligible, consistent, and unbroken case history. Whereas the practical aim of the treatment is to remove all possible symptoms and to replace them by conscious thoughts, we may regard it as a second and theoretical aim to repair all the damages to the patient's memory. These two aims are coincident. When one is reached, so is the other; and the same path leads to them both.

[1905e, 1359]

It follows from the nature of the facts which form the material of psycho-analysis that we are obliged to pay as much attention in our case histories to the purely human and social circumstances of our patients as to the somatic data and the symptoms of the disorder. Above all, our interest will be directed towards their family circumstances - and not only, as will be seen later, for the purpose of enquiring into their heredity.

[1905e, 1359]
Am I now going on to assert that in every instance in which there are periodical attacks of aphonia we are to diagnose the existence of a loved person who is at times away from the patient? Nothing could be further from my intention. The determination of Dora's symptoms is far too specific for it to be possible to expect a frequent recurrence of the same accidental aetiology. But, if so, what is the value of our elucidation of the aphonia in the present case? Have we not merely allowed ourselves to become the victims of a jeu d'esprit? I think not. In this connection we must recall the question which has so often been raised, whether the symptoms of hysteria are of psychical or of somatic origin, or whether, if the former is granted, they are necessarily all of them psychically determined. Like so many other questions to which we find investigators returning again and again without success, this question is not adequately framed. The alternatives stated in it do not cover the real essence of the matter. As far as I can see, every hysterical symptom involves the participation of both sides. It cannot occur without the presence of a certain degree of somatic compliance offered by some normal or pathological process in or connected with one of the bodily organs. And it cannot occur more than once - and the capacity for repeating itself is one of the characteristics of a hysterical symptom - unless it has a psychical significance, a meaning. The hysterical symptom does not carry this meaning with it, but the meaning is lent to it, soldered to it, as it were; and in every instance the meaning can be a different one, according to the nature of the suppressed thoughts which are struggling for expression. However, there are a number of factors at work which tend to make less arbitrary the relations between the unconscious thoughts and the somatic processes that are at their disposal as a means of expression, and which tend to make those relations approximate to a few typical forms. For therapeutic purposes the most important determinants are those given by the fortuitous psychical material; the clearing-up of the symptoms is achieved by looking for their psychical significance. When everything that can be got rid of by psycho-analysis has been cleared away, we are in a position to form all kinds of conjectures, which probably meet the facts, as regards the somatic basis of the symptoms - a basis which is as a rule constitutional and organic. Thus in Dora's case we shall not content ourselves with a psycho-analytic interpretation of her attacks of coughing and aphonia; but we shall also indicate the organic factor which was the source of the 'somatic compliance' that enabled her to express her love for a man who was periodically absent. And if the connection between the symptomatic expression and the unconscious mental content should strike us as being in this case a clever tour de force, we shall be relieved to hear that it succeeds in creating the same impression in every other case and in every other instance.

[1905e, 1378]
We have already learnt that it quite regularly happens that a single symptom corresponds to several meanings simultaneously. We may now add that it can express several meanings in succession. In the course of years a symptom can change its meaning or its chief meaning, or the leading role can pass from one meaning to another. It is as though there were a conservative trait in the character of neuroses which ensures that a symptom that has once been formed shall if possible be retained, even though the unconscious thought to which it gave expression has lost its meaning. Moreover, there is no difficulty in explaining this tendency towards the retention of a symptom upon a mechanical basis. The production of a symptom of this kind is so difficult, the translation of a purely psychical excitation into physical terms - the process which I have called 'conversion' - depends on the concurrence of so many favourable conditions, the somatic compliance necessary for conversion is so seldom forthcoming, that an impulsion towards the discharge of an unconscious excitation will so far as possible make use of any channel for discharge which may already be in existence. It appears to be far more difficult to create a fresh conversion than to form paths of association between a new thought which is in need of discharge and the old one which is no longer in need of it. The current flows along these paths from the new source of excitation to the old point of discharge - pouring into the symptom, in the words of the Gospel, like new wine into an old bottle. These remarks would make it seem that the somatic side of a hysterical symptom is the more stable of the two and the harder to replace, while the psychical side is a variable element for which a substitute can more easily be found. Yet we should not try to infer anything from this comparison as regards the relative importance of the two elements. From the point of view of mental therapeutics the mental side must always be the more significant.

The removal of the symptoms of hysterical patients by psycho-analysis proceeds on the supposition that those symptoms are substitutes - transcriptions as it were - for a number of emotionally cathected mental processes, wishes and desires, which, by the operation of a special psychical procedure (repression), have been prevented from obtaining discharge in psychical activity that is admissible to consciousness. These mental processes, therefore, being held back in a state of unconsciousness, strive to obtain an expression that shall be appropriate to their emotional importance - to obtain discharge; and in the case of hysteria they find such an expression (by means of the process of 'conversion') in somatic phenomena, that is, in hysterical symptoms. By systematically turning these symptoms back (with the help of a special technique) into emotionally cathected ideas - ideas that will now have become conscious - it is possible to obtain the most accurate knowledge of the nature and origin of these formerly unconscious psychical structures.

Anyone who studies hysteria, therefore, soon finds his interest turned away from its symptoms to the phantasies from which they proceed. The technique of psycho-analysis enables us in the first place to infer from the symptoms what those unconscious phantasies are and then to make them conscious to the patient. By this means it has been found that the content of the hysterics' unconscious phantasies corresponds completely to the situations in which satisfaction is consciously obtained by perverts; and if anyone is at a loss for examples of such situations he has only to recall the world-famous performances of the Roman Emperors, the wild excesses of which were, of course, determined only by the enormous and unreserved power possessed by the authors of the phantasies. The delusions of paranoics are phantasies of the same nature, though they are phantasies which have become directly conscious. They rest on the sadomasochistic components of the sexual instinct, and they, too, may find their complete counterpart in certain unconscious phantasies of hysterical subjects. We also know of cases - cases which have their practical importance as well - in which hysterics do not give expression to their phantasies in the form of symptoms but as conscious realizations, and in that way devise and stage assaults, attacks or acts of sexual aggression.
This method of psycho-analytic investigation, which leads from the conspicuous symptoms to the hidden unconscious phantasies, tells us everything that can be known about the sexuality of psychoneurotics, including the fact which is to be the main subject-matter of this short preliminary publication.

[1908a, 1935]

This connection between symptoms and phantasies makes it easy to arrive from a psycho-analysis of the former at a knowledge of the components of the sexual instincts which dominate the individual, as I have demonstrated in my Three Essays on the Theory of Sexuality. In some cases, however, investigation by this means yields an unexpected result. It shows that there are many symptoms where the uncovering of a sexual phantasy (or of a number of phantasies, one of which, the most significant and the earliest, is of a sexual nature) is not enough to bring about a resolution of the symptoms. To resolve it one has to have two sexual phantasies, of which one has a masculine and the other a feminine character. Thus one of these phantasies springs from a homosexual impulse. This new finding does not alter our seventh formula. It remains true that a hysterical symptom must necessarily represent a compromise between a libidinal and a repressing impulse; but it may also represent a union of two libidinal phantasies of an opposite sexual character.

[1908a, 1937]

When one carries out the psycho-analysis of a hysterical woman patient whose complaint is manifested in attacks, one soon becomes convinced that these attacks are nothing else but phantasies translated into the motor sphere, projected on to motility and portrayed in pantomime. It is true that the phantasies are unconscious; but apart from this they are of the same nature as the phantasies which can be observed directly in day-dreams or which can be elicited by interpretation from dreams at night. Often a dream takes the place of an attack, and still more often it explains it, since the same phantasy finds a different expression in a dream and in an attack. We might expect then that by observing an attack we should be able to get to know the phantasy represented in it; but this is seldom possible. As a rule, owing to the influence of the censorship, the pantomimic portrayal of the phantasy has undergone distortions which are completely analogous to the hallucinatory distortions of a dream, so that both of them have, in the first resort, become unintelligible to the subject's own consciousness as well as to the observer's comprehension. A hysterical attack, therefore, needs to be subjected to the same interpretative revision as we employ for night-dreams. But not only are the forces from which the distortion proceeds and the purpose of the distortion the same as those we have come to know through the interpretation of dreams; the technique employed in the distortion is the same too.

[1909a, 1931]

Psycho-analysis finds a constantly increasing amount of support as a therapeutic procedure, owing to the fact that it can do more for its patients than any other method of treatment. The principle field of its application is in the milder neuroses - hysteria, phobias and obsessional states; and in malformations of character and sexual inhibitions or abnormalities it can also bring about marked improvements or even recoveries. Its influence upon dementia praecox and paranoia is doubtful; on the other hand, in favourable circumstances it can cope with depressive states, even if they are of a severe type.

[1926f, 4402]
We had often compared the symptomatology of hysteria with a pictographic script which hasecome intelligible after the discovery of a few bilingual inscriptions. In that alphabet being sick
means disgust. So I said: 'If you were sick three days later, I believe that means that when you
looked into the room you felt disgusted.'
[1895d, 115]

¹ [Footnote added 1909:] Hysterical attacks sometimes make use of the same kind of chronological
reversal in order to disguise their meaning from observers. For instance, a hysterical girl needed to
represent something in the nature of a brief romance in one of her attacks - a romance of which she had
had a phantasy in her unconscious after an encounter with someone on the suburban railway. She
imagined how the man had been attracted by the beauty of her foot and had spoken to her while she was
reading; whereupon she had gone off with him and had had a passionate love-scene. Her attack began
with a representation of this love-scene by convulsive twitching of her body, accompanied by movements
of her lips to represent kissing and tightening of her arms to represent embracing. She then hurried into
the next room, sat down on a chair, raised her skirt so as to show her foot, pretended to be reading a book
and spoke to me (that is, answered me). - [Added 1914:] Cf. in this connection what Artemidorus says: 'In
interpreting the images seen in dreams one must sometimes follow them from the beginning to the end
and sometimes from the end to the beginning . . .'
[1900a, 797]

I think it is worth emphasizing the fact that, whatever modifications my views on the aetiology
of the psychoneuroses have passed through, there are two positions which I have never
repudiated or abandoned - the importance of sexuality and of infantilism. Apart from this,
accidental influences have been replaced by constitutional factors and 'defence' in the purely
psychological sense has been replaced by organic 'sexual repression'. The question may,
however, be raised of where convincing evidence is to be found in favour of the alleged
aetiological importance of sexual factors in the psychoneuroses, in view of the fact that the
onset of these illnesses may be observed in response to the most commonplace emotions or
even to somatic precipitating causes, and since I have had to abandon a specific aetiology
depending on the particular form of the childhood experiences concerned. To such a question I
would reply that the psycho-analytic examination of neurotics is the source from which this
disputed conviction of mine is derived. If we make use of that irreplaceable method of research,
we discover that the patient's symptoms constitute his sexual activity (whether wholly or in part),
which arises from the sources of the normal or perverse component instincts of sexuality. Not
only is a large part of the symptomatology of hysteria derived directly from expressions of
sexual excitement, not only do a number of erotogenic zones attain the significance of genitals
during neuroses owing to an intensification of infantile characteristics, but the most complicated
symptoms are themselves revealed as representing, by means of 'conversion', phantasies
which have a sexual situation as their subject-matter. Anyone who knows how to interpret the
language of hysteria will recognize that the neurosis is concerned only with the patient's
repressed sexuality. The sexual function must, however, be understood in its true extent, as it is
laid down by disposition in infancy. Wherever some commonplace emotion must be included
among the determinants of the onset of the illness, analysis invariably shows that it is the sexual
component of the traumatic experience - a component that is never lacking which has produced
the pathogenic result.
[1906a, 1582]
Anyone who studies hysteria, therefore, soon finds his interest turned away from its symptoms to the phantasies from which they proceed. The technique of psycho-analysis enables us in the first place to infer from the symptoms what those unconscious phantasies are and then to make them conscious to the patient. By this means it has been found that the content of the hysteric's unconscious phantasies corresponds completely to the situations in which satisfaction is consciously obtained by perverts; and if anyone is at a loss for examples of such situations he has only to recall the world-famous performances of the Roman Emperors, the wild excesses of which were, of course, determined only by the enormous and unrestrained power possessed by the authors of the phantasies. The delusions of paranoids are phantasies of the same nature, though they are phantasies which have become directly conscious. They rest on the sadomasochistic components of the sexual instinct, and they, too, may find their complete counterpart in certain unconscious phantasies of hysterical subjects. We also know of cases - cases which have their practical importance as well - in which hysterics do not give expression to their phantasies in the form of symptoms but as conscious realizations, and in that way devise and stage assaults, attacks or acts of sexual aggression. [1908a, 1935]

When one carries out the psycho-analysis of a hysterical woman patient whose complaint is manifested in attacks, one soon becomes convinced that these attacks are nothing else but phantasies translated into the motor sphere, projected on to motility and portrayed in pantomime. It is true that the phantasies are unconscious; but apart from this they are of the same nature as the phantasies which can be observed directly in day-dreams or which can be elicited by interpretation from dreams at night. Often a dream takes the place of an attack, and still more often it explains it, since the same phantasy finds a different expression in a dream and in an attack. We might expect then that by observing an attack we should be able to get to know the phantasy represented in it; but this is seldom possible. As a rule, owing to the influence of the censorship, the pantomimic portrayal of the phantasy has undergone distortions which are completely analogous to the hallucinatory distortions of a dream, so that both of them have, in the first resort, become unintelligible to the subject's own consciousness as well as to the observer's comprehension. A hysterical attack, therefore, needs to be subjected to the same interpretative revision as we employ for night-dreams. But not only are the forces from which the distortion proceeds and the purpose of the distortion the same as those we have come to know through the interpretation of dreams; the technique employed in the distortion is the same too. [1909a, 1981]

Such is my excuse for having curtailed so drastically the history of this case and its treatment. And I can offer still more cogent reasons for having confined myself to the statement only of some disconnected results of the psycho-analytic investigation of obsessional neuroses. I must confess that I have not yet succeeded in completely penetrating the complicated texture of a severe case of obsessional neurosis, and that, if I were to reproduce the analysis, it would be impossible for me to make the structure, such as by the help of analysis we know or suspect it to be, visible to others through the mass of therapeutic work superimposed upon it. What add so greatly to the difficulty of doing this are the resistances of the patients and the forms in which they are expressed. But even apart from this it must be admitted that an obsessional neurosis is in itself not an easy thing to understand - much less so than a case of hysteria. Actually, indeed, we should have expected to find the contrary. The language of an obsessional neurosis - the means by which it expresses its secret thoughts - is, as it were, only a dialect of the language of hysteria; but it is a dialect in which we ought to be able to find our way about more easily, since it is more nearly related to the forms of expression adopted by our conscious thought than is the language of hysteria. Above all, it does not involve the leap from a mental process to a somatic innervation - hysterical conversion - which can never be fully comprehensible to us. [1909d, 2128]
In the days while I was engaged in writing these pages the following almost incredible instance of forgetting happened to me. On the first of January I was going through my medical engagement book so that I could send out my accounts. Under the month of June I came across the name 'M---l' but could not recall who it belonged to. My bewilderment grew when I turned the pages and discovered that I treated the case in a sanatorium and made daily visits over a period of weeks. A patient treated under such conditions cannot be forgotten by a doctor after scarcely six months. Could it have been a man, I asked myself, a case of general paralysis, an uninteresting case? Finally the record of the fees I had received brought back to me all the facts that had striven to escape my memory. M---l was a fourteen-year-old girl, the most remarkable case I had had in recent years, one which taught me a lesson I am not likely ever to forget and whose outcome cost me moments of the greatest distress. The child fell ill of an unmistakable hysteria, which did in fact clear up quickly and radically under my care. After this improvement the child was taken away from me by her parents. She still complained of abdominal pains which had played the chief part in the clinical picture of her hysteria. Two months later she died of sarcoma of the abdominal glands. The hysteria, to which she was at the same time predisposed, used the tumour as a provoking cause, and I, with my attention held by the noisy but harmless manifestations of the hysteria, had perhaps overlooked the first signs of the insidious and incurable disease.

But why this abusive language? At this point we must look into the situation. I was hurrying to a consultation at a place on the Western railway line, to visit a patient who, according to the anamnesis I had received by letter, had fallen from a balcony some months earlier and had since then been unable to walk. The doctor who called me in wrote that he was nevertheless uncertain whether it was a case of spinal injury or of a traumatic neurosis - hysteria. That was what I was now to decide. It would therefore be advisable for me to be particularly wary in the delicate task of making a differential diagnosis. As it is, my colleagues are of the opinion that I make a diagnosis of hysteria far too carelessly where graver things are in question. But so far this did not justify the abusive language. Why, of course! it now occurred to me that the little railway station was at the same place at which some years before I had seen a young man who had not been able to walk properly after an emotional experience. At the time I made a diagnosis of hysteria and I subsequently took the patient on for psychical treatment. It then turned out that though my diagnosis had not, it is true, been incorrect, it had not been correct either. A whole number of the patient's symptoms had been hysterical, and they rapidly disappeared in the course of treatment. But behind these a remnant now became visible which was inaccessible to my therapy; this remnant could only be accounted for by multiple sclerosis. It was easy for those who saw the patient after me to recognize the organic affection. I could hardly have behaved otherwise or formed a different judgement, yet the impression left was that a grave error had been made; the promise of a cure which I had given him could naturally not be kept.

The error of picking up the tuning fork instead of the hammer could thus be translated into words as follows; 'You idiot! you ass! Pull yourself together this time, and see that you don't diagnose hysteria again where there's an incurable illness, as you did years ago with the poor man from that same place!' And fortunately for this little analysis, if not fortunately for my mood, the same man, suffering from severe spastic paralysis, had visited me during my consulting hour a few days before, and a day after the imbecile child.
Another physician once sent his sister to me for psychotherapeutic treatment, telling me that she had for years been treated without success for hysteria (pains and defective gait). The short account which he gave me seemed quite consistent with the diagnosis. In my first hour with the patient I got her to tell me her history herself. When the story came out perfectly clearly and connectedly in spite of the remarkable events it dealt with, I told myself that the case could not be one of hysteria, and immediately instituted a careful physical examination. This led to the diagnosis of a not very advanced state of tabes, which was later treated with Hg injections (Ol. cinereum) by Professor Lang with markedly beneficial results.

In this scene - second in order of mention, but first in order of time - the behaviour of this child of fourteen was already entirely and completely hysterical. I should without question consider a person hysterical in whom an occasion for sexual excitement elicited feelings that were preponderantly or exclusively unpleasurable; and I should do so whether or no the person were capable of producing somatic symptoms. The elucidation of the mechanism of this reversal of affect is one of the most important and at the same time one of the most difficult problems in the psychology of the neuroses. In my own judgement I am still some way from having achieved this end; and I may add that within the limits of the present paper I shall be able to bring forward only a part of such knowledge on the subject as I do possess.

I then remembered that shortly after her aunt's death Dora had had an attack of what had been alleged to be appendicitis. Up till then I had not ventured to count that illness among her hysterical productions. She told me that during the first few days she had had high fever and had felt the pain in her abdomen that she had read about in the encyclopaedia. She had been given cold fomentations but had not been able to bear them. On the second day her period had set in, accompanied by violent pains. (Since her health had been bad, the periods had been very irregular.) At that time she used to suffer continually from constipation.

It was not really possible to regard this state as a purely hysterical one. Although hysterical fever does undoubtedly occur, yet it seemed too arbitrary to put down the fever accompanying this questionable illness to hysteria instead of to some organic cause operative at the time. I was on the point of abandoning the track, when she herself helped me along it by producing her last addendum to the dream: she saw herself particularly distinctly going up the stairs.

I naturally required a special determinant for this. Dora objected that she would anyhow have had to go upstairs if she had wanted to get to her flat, which was on an upper floor. It was easy to brush aside this objection (which was probably not very seriously intended) by pointing out that if she had been able to travel in her dream from the unknown town to Vienna without making a railway journey she ought also to have been able to leave out a flight of stairs. She then proceeded to relate that after the appendicitis she had not been able to walk properly and had dragged her right foot. This state of things had continued for a long time, and on that account she had been particularly glad to avoid stairs. Even now her foot sometimes dragged. The doctors whom she had consulted at her father's desire had been very much astonished at this most unusual after-effect of an appendicitis, especially as the abdominal pains had not recurred and did not in any way accompany the dragging of the foot.
We must assume the existence of some somatic connection between the painful abdominal sensations known as 'ovarian neuralgia' and locomotor disturbances in the leg on the same side; and we must suppose that in Dora's case the somatic connection had been given an interpretation of a particularly specialized sort, that is to say, that it had been overlaid with and brought into the service of a particular psychological meaning. The reader is referred to my analogous remarks in connection with the analysis of Dora's symptom of coughing and with the relation between catarrh and loss of appetite.

[1905e, 1437]

When you hear such an enumeration of symptoms, you will be inclined to think it safe to assume, even though you are not doctors, that what we have before us is a severe illness, probably affecting the brain, that it offers small prospect of recovery and will probably lead to the patient's early decease. You must be prepared to learn from the doctors, however, that, in a number of cases which display severe symptoms such as these, it is justifiable to take a different and a far more favourable view. If a picture of this kind is presented by a young patient of the female sex, whose vital internal organs (heart, kidneys, etc.) are shown on objective examination to be normal, but who has been subjected to violent emotional shocks - if, moreover, her various symptoms differ in certain matters of detail from what would have been expected - then doctors are not inclined to take the case too seriously. They decide that what they have before them is not an organic disease of the brain, but the enigmatic condition which, from the time of ancient Greek medicine, has been known as 'hysteria' and which has the power of producing illusory pictures of a whole number of serious diseases. They consider that there is then no risk to life but that a return to health - even a complete one - is probable. It is not always quite easy to distinguish a hysteria like this from a severe organic illness. There is no need for us to know, however, how a differential diagnosis of that kind is made; it will suffice to have an assurance that the case of Breuer's patient was precisely of a kind in which no competent physician could fail to make a diagnosis of hysteria. And here we may quote from the report of the patient's illness the further fact that it made its appearance at a time when she was nursing her father, of whom she was devotedly fond, through the grave illness which led to his death, and that, as a result of her own illness, she was obliged to give up nursing him.

[1910a, 2200]

A similar course of events affords peculiar diagnostic and therapeutic interest. It not at all infrequently happens in the case of a person who is disposed to a neurosis without actually suffering from a manifest one, that a pathological somatic change (through inflammation or injury perhaps) sets the activity of symptom-formation going; so that this activity hastily turns the symptom which has been presented to it by reality into the representative of all the unconscious phantasies which have only been lying in wait to seize hold of some means of expression. In such a case the physician will adopt sometimes one and sometimes another line of treatment. He will either endeavour to remove the organic basis, without bothering about its noisy neurotic elaboration; or he will attack the neurosis which has taken this favourable opportunity for arising and will pay little attention to its organic precipitating cause. The outcome will prove the one or the other line of approach right or wrong; it is impossible to make general recommendations to meet such mixed cases.

[1916-1917, 3441]
But there is a second factor which is even more decisively in favour of this view of the pains. If one stimulates an area sensitive to pain in someone with an organic illness or in a neurasthenic, the patient's face takes on an expression of discomfort or physical pain. Moreover he flinches and draws back from the examination and resists it. In the case of Fräulein von R., however, if one pressed or pinched the hyperalgesic skin and muscles of her legs, her face assumed a peculiar expression, which was one of pleasure rather than pain. She cried out - and I could not help thinking that it was as though she was having a voluptuous tickling sensation - her face flushed, she threw back her head and shut her eyes and her body bent backwards. None of this was very exaggerated but it was distinctly noticeable, and it could only be reconciled with the view that her disorder was hysterical, and that the stimulation had touched upon a hysterogenic zone.

[1895d, 123]

When you hear such an enumeration of symptoms, you will be inclined to think it safe to assume, even though you are not doctors, that what we have before us is a severe illness, probably affecting the brain, that it offers small prospect of recovery and will probably lead to the patient's early decease. You must be prepared to learn from the doctors, however, that, in a number of cases which display severe symptoms such as these, it is justifiable to take a different and a far more favourable view. If a picture of this kind is presented by a young patient of the female sex, whose vital internal organs (heart, kidneys, etc.) are shown on objective examination to be normal, but who has been subjected to violent emotional shocks - if, moreover, her various symptoms differ in certain matters of detail from what would have been expected - then doctors are not inclined to take the case too seriously. They decide that what they have before them is not an organic disease of the brain, but the enigmatic condition which, from the time of ancient Greek medicine, has been known as 'hysteria' and which has the power of producing illusory pictures of a whole number of serious diseases. They consider that there is then no risk to life but that a return to health - even a complete one - is probable. It is not always quite easy to distinguish a hysteria like this from a severe organic illness. There is no need for us to know, however, how a differential diagnosis of that kind is made; it will suffice to have an assurance that the case of Breuer's patient was precisely of a kind in which no competent physician could fail to make a diagnosis of hysteria. And here we may quote from the report of the patient's illness the further fact that it made its appearance at a time when she was nursing her father, of whom she was devotedly fond, through the grave illness which led to his death, and that, as a result of her own illness, she was obliged to give up nursing him.

[1910a, 2200]
'Some points for a comparative study of organic and hysterical motor paralyses.'
[1897b, 445]

When you hear such an enumeration of symptoms, you will be inclined to think it safe to assume, even though you are not doctors, that what we have before us is a severe illness, probably affecting the brain, that it offers small prospect of recovery and will probably lead to the patient's early decease. You must be prepared to learn from the doctors, however, that, in a number of cases which display severe symptoms such as these, it is justifiable to take a different and a far more favourable view. If a picture of this kind is presented by a young patient of the female sex, whose vital internal organs (heart, kidneys, etc.) are shown on objective examination to be normal, but who has been subjected to violent emotional shocks - if, moreover, her various symptoms differ in certain matters of detail from what would have been expected - then doctors are not inclined to take the case too seriously. They decide that what they have before them is not an organic disease of the brain, but the enigmatic condition which, from the time of ancient Greek medicine, has been known as 'hysteria' and which has the power of producing illusory pictures of a whole number of serious diseases. They consider that there is then no risk to life but that a return to health - even a complete one - is probable. It is not always quite easy to distinguish a hysteria like this from a severe organic illness. There is no need for us to know, however, how a differential diagnosis of that kind is made; it will suffice to have an assurance that the case of Breuer's patient was precisely of a kind in which no competent physician could fail to make a diagnosis of hysteria. And here we may quote from the report of the patient's illness the further fact that it made its appearance at a time when she was nursing her father, of whom she was devotedly fond, through the grave illness which led to his death, and that, as a result of her own illness, she was obliged to give up nursing him.
[1910a, 2200]
I did not find it easy to arrive at a diagnosis, but I decided for two reasons to assent to the one proposed by my colleague, viz. that it was a case of hysteria. In the first place I was struck by the indefiniteness of all the descriptions of the character of her pains given me by the patient, who was nevertheless a highly intelligent person. A patient suffering from organic pains will, unless he is neurotic in addition, describe them definitely and calmly. He will say, for instance, that they are shooting pains, that they occur at certain intervals, that they extend from this place to that and that they seem to him to be brought on by one thing or another. Again, when a neurasthenic describes his pains, he gives an impression of being engaged on a difficult intellectual task to which his strength is quite unequal. His features are strained and distorted as though under the influence of a distressing affect. His voice grows more shrill and he struggles to find a means of expression. He rejects any description of his pains proposed by the physician, even though it may turn out afterwards to have been unquestionably apt. He is clearly of opinion that language is too poor to find words for his sensations and that those sensations are something unique and previously unknown, of which it would be quite impossible to give an exhaustive description. For this reason he never tires of constantly adding fresh details, and when he is obliged to break off he is sure to be left with the conviction that he has not succeeded in making himself understood by the physician. All this is because his pains have attracted his whole attention to themselves. Fräulein von R. behaved in quite an opposite way; and we are driven to conclude that, since she nevertheless attached sufficient importance to her symptoms, her attention must be dwelling on something else, of which the pains were only an accessory phenomenon - probably on thoughts and feelings, therefore, which were connected with them.
[1895d, 122]
I now return to the reproach of malingering which Dora brought against her father. It soon became evident that this reproach corresponded to self-reproaches not only concerning her earlier states of ill-health but also concerning the present time. At such points the physician is usually faced by the task of guessing and filling in what the analysis offers him in the shape only of hints and allusions. I was obliged to point out to the patient that her present ill-health was just as much actuated by motives and was just as tendentious as had been Frau K.'s illness, which she had understood so well. There could be no doubt, I said, that she had an aim in view which she hoped to gain by her illness. That aim could be none other than to detach her father from Frau K. She had been unable to achieve this by prayers or arguments; perhaps she hoped to succeed by frightening her father (there was her farewell letter), or by awakening his pity (there were her fainting-fits), or if all this was in vain, at least she would be taking her revenge on him. She knew very well, I went on, how much he was attached to her, and that tears used to come into his eyes whenever he was asked after his daughter's health. I felt quite convinced that she would recover at once if only her father were to tell her that he had sacrificed Frau K., for the sake of her health. But, I added, I hoped he would not let himself be persuaded to do this, for then she would have learned what a powerful weapon she had in her hands, and she would certainly not fail on every future occasion to make use once more of her liability to ill health. Yet if her father refused to give way to her, I was quite sure she would not let herself be deprived of her illness so easily.

But if this is so, we should be dealing not with a neurosis but with a deception, and the painter would be a malingerer and forger instead of a sick man suffering from possession. But the transitional stages between neurosis and malingering are, as we know, very fluid. Nor do I see any difficulty in supposing that the painter wrote this paper and the later one, and took them with him, in a peculiar state, similar to the one in which he had his visions. Indeed there was no other course open to him if he wished to carry into effect his phantasy of his pact with the Devil and of his redemption.
Medical research has at last shown that people of this kind are not to be looked upon as suffering from a disease of the stomach or of the eyes or whatever it may be, but that it must be a question in their case of an illness of the nervous system as a whole. Examination of the brain and nerves of these patients has so far, however, revealed no perceptible changes; and, indeed, some of the features of their symptomatology prohibit any expectation that even more accurate methods of investigation could ever discover changes of a sort that would throw light upon the illness. This condition has been described as 'nervousness' (neurasthenia or hysteria) and has been characterized as a merely 'functional' disorder of the nervous system.¹ Incidentally, an exhaustive examination of the brain (after the patient's death) has been equally without results in the case of many more permanent nervous disorders, as well as in illnesses with exclusively mental symptoms, such as what are known as obsessions and delusional insanity.

[1890a, 1587]

There are a large number of phenomena related to facial and other expressive movements and to speech, as well as many processes of thought (both in normal and sick people), which have hitherto escaped the notice of psychology because they have been regarded as no more than the results of organic disorder or of some abnormal failure in function of the mental apparatus. What I have in mind are 'parapraxes' (slips of the tongue or pen, forgetfulness, etc.), haphazard actions and dreams in normal people, and convulsive attacks, deliria, visions, and obsessive ideas or acts in neurotic subjects. These phenomena (in so far as they were not entirely neglected, as was the case with the parapraxes) were relegated to pathology and an attempt was made to find 'physiological' explanations of them, though these were invariably unsatisfactory. Psycho-analysis, on the contrary, has been able to show that all these things can be explained by means of hypotheses of a purely psychological nature and can be fitted into the chain of psychical events already known to us. Thus on the one hand psycho-analysis has narrowed the region subject to the physiological point of view and on the other hand has brought a large section of pathology into the sphere of psychology. In this instance the normal phenomena provide the more convincing evidence. Psycho-analysis cannot be accused of having applied to normal cases findings arrived at from pathological material. The evidence in the latter and in the former was reached independently and shows that normal processes and what are described as pathological ones follow the same rules.

[1913j, 2803]
(1) A girl suffered from obsessional self-reproaches. If she read something in the papers about coiners, the thought would occur to her that she, too, had made counterfeit money; if a murder had been committed by an unknown person, she would ask herself anxiously whether it was not she who had done the deed. At the same time she was perfectly conscious of the absurdity of these obsessional reproaches. For a time, this sense of guilt gained such an ascendancy over her that her powers of criticism were stifled and she accused herself to her relatives and her doctor of having really committed all these crimes. (This was an example of a psychosis through simple intensification - an 'Überwältigungspsychose'.) Close questioning then revealed the source from which her sense of guilt arose. Stimulated by a chance voluptuous sensation, she had allowed herself to be led astray by a woman friend into masturbating, and had practised it for years, fully conscious of her wrong-doing and to the accompaniment of the most violent, but, as usual, ineffective self-reproaches. An excessive indulgence after going to a ball had produced the intensification that led to the psychosis. After a few months of treatment and the strictest surveillance, the girl recovered.

[1894a, 310]

(3) A young married woman who, in five years of marriage, had had only one child, complained to me of an obsessional impulse to throw herself out of the window or from the balcony, and also of a fear which seized her when she saw a sharp knife, of stabbing her child with it. She admitted that marital intercourse seldom occurred, and only subject to precautions against conception, but she did not miss it, she said, as hers was not a sensual nature. At this point I ventured to tell her that at the sight of a man she had erotic ideas and that she had therefore lost confidence in herself and regarded herself as a depraved person, capable of anything. The translation back of the obsessional idea into sexual terms was successful. In tears, she at once confessed the long-concealed poverty of her marriage; and later she told me also of distressing ideas of an unmodified sexual character such as the often-recurring sensation of something forcing itself under her skirt.

[1894a, 312]

Two constituents are found in every obsession: (1) an idea that forces itself upon the patient (2) an associated emotional state. Now in the group of phobias this emotional state is always one of 'anxiety', while in true obsessions other emotional states, such as doubt, remorse, or anger, may occur just as well as anxiety. I will first attempt to explain the really remarkable psychological mechanism of true obsessions, a mechanism quite different from that of the phobias.

[1895c, 317]

Reinstatement: This girl had been an involuntary witness of a love-scene in which her mother had taken part. She had hidden her face, had stopped up her ears, and had done her utmost to forget it, as it disgusted her and would have made it impossible for her to remain with her mother, whom she loved tenderly. She succeeded in her efforts, but her anger at her idea of love having been defiled persisted within her, and this emotional state soon linked itself to the idea of a person who could take her mother's place.

[1895c, 319]

Case 10. Folie du doute. (Fear of scraps of paper.) - A young woman had suffered from scruples after having written a letter; at the same time she collected all the pieces of paper she saw. She explained this by confessing to a love which she had formerly refused to admit. As a result of constantly repeating her lover's name, she was seized with a fear that the name might have slipped off the end of her pen, that she might have written it upon some scrap of paper in a pensive moment.

[1895c, 322]
It seems to be the expression of a special inherited mental disposition. At any rate, ‘similar heredity’ is often enough found in obsessional cases, and in hysteria. Thus the patient in Case 2 told me that his father had suffered from similar symptoms. He once introduced me to a first cousin who had obsessions and a tic convulsif, and to his sister's daughter, aged eleven, who already gave evidence of obsessions (probably of remorse).

[1895c, 322]

This period is brought to a close by the advent of sexual ‘maturation’, often itself unduly early. A self-reproach now becomes attached to the memory of these pleasurable actions; and the connection with the initial experience of passivity makes it possible - often only after conscious and remembered efforts - to repress them and to replace them by a primary symptom of defence. Conscientiousness, shame and self-distrust are symptoms of this kind, with which the third period begins - the period of apparent health, but actually, of successful defence.

[1896b, 389]

Secondary defence against the obsessional ideas may be effected by a forcible diversion on to other thoughts with a content as contrary as possible. This is why obsessional brooding, if it succeeds, regularly deals with abstract and suprasensual things; because the ideas that have been repressed are always concerned with sensuality. Or else the patient tries to make himself master of each of his obsessional ideas singly by logical work and by having recourse to his conscious memories. This leads to obsessional thinking, to a compulsion to test things and to doubting mania. The advantage which perception has over memory in such tests at first causes the patient, and later compels him, to collect and store up all the objects with which he has come into contact. Secondary defence against obsessional affects leads to a still wider set of protective measures which are capable of being transformed into obsessional acts. These may be grouped according to their purpose: penitential measures (burdensome ceremonials, the observation of numbers), precautionary measures (all sorts of phobias, superstition, pedantry, increase of the primary symptom of conscientiousness); measures to do with fear of betrayal (collecting scraps of paper, seclusiveness), or to ensure numbing (dipsomania). Among these obsessional acts and obsessional impulses, phobias, since they circumscribe the patient's existence, play the greatest part.

[1896b, 393]

There are cases in which one can observe how the obsession is transferred from the idea or from the affect on to the protective measure; others in which the obsession oscillates periodically between the symptom of the return of the repressed and the symptom of the secondary defence; and yet other cases in which no obsessional idea is constructed at all, but, instead, the repressed memory is at once represented by what is apparently a primary measure of defence. Here we reach at one bound the stage which elsewhere only completes the course run by the obsessional neurosis after the defensive struggle has taken place. Severe cases of this disorder end in the ceremonial actions becoming fixated, or in a general state of doubting mania, or in a life of eccentricity conditioned by phobias.

[1896b, 393]
Obsessions and phobias are to be distinguished from neurasthenia as independent neurotic affections. In both it is a question of the linkage between an idea and an affective state. In phobias the latter is always the same, namely anxiety; in true obsessions it can be of various kinds (self-reproach, sense of guilt, doubt, etc.). The affective state emerges as the essential element of the obsession, since it remains unaltered in the individual case, whereas the idea attached to it is changed. Psychical analysis shows that the affect of the obsession is justified in every instance, but that the idea attached to it represents a substitute for an idea derived from sexual life which is more appropriate to the affect and which has succumbed to repression. This state of affairs is illustrated by numerous short analyses of cases of folie du doute, washing mania, arithmomania, etc., in which the reinstatement of the repressed idea was successful and accompanied by useful therapeutic effects. The phobias in the strict sense are reserved for the paper on anxiety neurosis (No. XXXII).

On another occasion I had an opportunity of obtaining a deep insight into the unconscious mind of a young man whose life was made almost impossible by an obsessional neurosis. He was unable to go out into the street because he was tortured by the fear that he would kill everyone he met. He spent his days in preparing his alibi in case he might be charged with one of the murders committed in the town. It is unnecessary to add that he was a man of equally high morals and education. The analysis (which, incidentally, led to his recovery) showed that the basis of this distressing obsession was an impulse to murder his somewhat over-severe father. This impulse, to his astonishment, had been consciously expressed when he was seven years old, but it had, of course, originated much earlier in his childhood. After his father's painful illness and death, the patient's obsessional self-reproaches appeared - he was in his thirty-first year at the time - taking the shape of a phobia transferred on to strangers. A person, he felt, who was capable of wanting to push his own father over a precipice from the top of a mountain was not to be trusted to respect the lives of those less closely related to him; he was quite right to shut himself up in his room.

¹ [Footnote added 1909:] Not long ago I found a single exception to this rule in the case of a young man who suffered from obsessions while retaining intact his highly developed intellectual powers. The spoken words which occurred in his dreams were not derived from remarks which he had heard or made himself. They contained the undistorted text of his obsessional thoughts, which in his waking life only reached his consciousness in a modified form.
Analysis made it possible to find another solution. The attempt at an explanation, which seemed so striking when I was obliged to ascribe it to the dream-work, was not an original one of my own, but was copied from the neurosis of one of my patients. I have already spoken elsewhere of a highly educated and, in real life, soft-hearted man who, shortly after the death of his parents, began to reproach himself with having murderous inclinations, and then fell a victim to the precautionary measures which he was obliged to adopt as a safeguard. It was a case of severe obsessions accompanied by complete insight. To begin with, walking through the streets was made a burden to him by a compulsion to make certain where every single person he met disappeared to; if anyone suddenly escaped his watchful eye, he was left with a distressing feeling and the idea that he might possibly have got rid of him. What lay behind this was, among other things, a 'Cain' phantasy - for 'all men are brothers.' Owing to the impossibility of carrying out this task, he gave up going for walks and spent his life incarcerated between his own four walls. But reports of murders which had been committed outside were constantly being brought into his room by the newspapers, and his conscience suggested to him, in the form of a doubt, that he might be the wanted murderer. The certainty that he had in fact not left his house for weeks protected him from these charges for a while, till one day the possibility came into his head that he might have left his house while he was in an unconscious state and have thus been able to commit the murder without knowing anything about it. From that time onwards he locked the front door of the house and gave the key to his old housekeeper with strict instructions never to let it fall into his hands even if he asked for it.

[1900a, 902]

In the case of a psychical complex which has come under the influence of the censorship imposed by resistance, the affects are the constituent which is least influenced and which alone can give us a pointer as to how we should fill in the missing thoughts. This is seen even more clearly in the psychoneuroses than in dreams. Their affects are always appropriate, at least in their quality though we must allow for their intensity being increased owing to displacements of neurotic attention. If a hysterical is surprised at having to be so frightened of something trivial or if a man suffering from obsessions is surprised at such distressing self-reproaches arising out of a mere nothing, they have both gone astray, because they regard the ideational content - the triviality or the mere nothing - as what is essential; and they put up an unsuccessful fight because they take this ideational content as the starting-point of their thought-activity. Psycho-analysis can put them upon the right path by recognizing the affect as being, on the contrary, justified and by seeking out the idea which belongs to it but has been repressed and replaced by a substitute. A necessary premise to all this is that the release of affect and the ideational content do not constitute the indissoluble organic unity as which we are in the habit of treating them, but that these two separate entities may be merely soldered together and can thus be detached from each other by analysis. Dream-interpretation shows that this is in fact the case.

[1900a, 905]
Making slips of the tongue was a symptom of a woman patient of mine which persisted until it was traced back to the childhood joke of replacing 'ruinieren [ruin]' by 'urinieren [urinate]' - [Added 1924:] The temptation to employ the artifice of a slip of the tongue for enabling improper and forbidden words to be freely used forms the basis of Abraham's observations on parapraxes 'with an overcompensating purpose' (Abraham, 1922a). A woman patient was very liable to duplicate the first syllable of proper names by stammering. She changed the name 'Protagoras' to 'Protragoras', shortly after having said 'A-alexander' instead of 'Alexander'. Inquiry revealed that in childhood she had been especially fond of the vulgar joke of repeating the syllables 'a' and 'po' when they occurred at the beginnings of words, a form of amusement which quite commonly leads to stammering in children. ['A-a' and 'Popo' are the German nursery words for 'faeces' and 'buttocks.'] On approaching the name 'Protagoras' she became aware of the risk that she might omit the 'r' in the first syllable and say 'Po-potagoras'. As a protection against this danger she held on firmly to this 'r', and inserted another 'r' in the second syllable. She acted in the same way on other occasions, distorting the words 'Parterre [ground floor]' and 'Kondolenz [condolence]' so as to avoid 'Pater (father)' and 'Kondom [condom]' which were closely linked to them in her associations. Another of Abraham's patients confessed to an inclination to say 'Angora' every time for 'angina' - very probably because of a fear of being tempted to replace 'angina' by 'vagina'. These slips of the tongue owed their existence therefore to the fact that a defensive trend had retained the upper hand instead of the distorting one; and Abraham justly draws attention to the analogy between this process and the formation of symptoms in obsessional neurosis.

Adler gives similar explanations of the origin of obsessive numbers.

(8) A good example of the derivation of an obsessive word - a word that cannot be got rid of - is to be found in Jung (1906). 'A lady told me that for some days the word "Taganrog" had been constantly on her lips without her having any idea where it came from. I asked the lady for information about the affectively stressed events and repressed wishes of the very recent past. After some hesitation she told me that she would very much like a morning gown, but her husband did not take the interest in it that she had hoped. "Morgenrock", "Tag-an-rock" - their partial similarity in sound and meaning is obvious. The Russian form was determined by the fact that at about the same time the lady had come to know someone from Taganrog.'

The sympathies of the girl herself, who, as I have said, became my patient at the age of eighteen, had always been with the father's side of the family, and ever since she had fallen ill she had taken as her model the aunt who has just been mentioned. There could be no doubt, too, that it was from her father's family that she had derived not only her natural gifts and her intellectual precocity but also the predisposition to her illness. I never made her mother's acquaintance. From the accounts given me by the girl and her father I was led to imagine her as an uncultivated woman and above all as a foolish one, who had concentrated all her interests upon domestic affairs, especially since her husband's illness and the estrangement to which it led. She presented the picture, in fact, of what might be called the 'housewife's psychosis'. She had no understanding of her children's more active interests, and was occupied all day long in cleaning the house with its furniture and utensils and in keeping them clean - to such an extent as to make it almost impossible to use or enjoy them. This condition, traces of which are to be found often enough in normal housewives, inevitably reminds one of forms of obsessional washing and other kinds of obsessional cleanliness. But such women (and this applied to the patient's mother) are entirely without insight into their illness, so that one essential characteristic of an 'obsessional neurosis' is lacking. The relations between the girl and her mother had been unfriendly for years. The daughter looked down on her mother and used to criticize her mercilessly, and she had withdrawn completely from her influence.
The proof of infantile masturbation in other cases is established in a precisely similar way. The evidence for it is mostly of a similar nature: indications of the presence of leucorrhoea, bed-wetting, hand-ceremonials (obsessional washing), and such things. It is always possible to discover with certainty from the nature of the symptoms of the case whether the habit was discovered by the person in charge of the child or not, or whether this sexual activity was brought to an end by long efforts on the child's part to break itself of the habit, or by a sudden change. In Dora's case the masturbation had remained undiscovered, and had come to an end at a single blow (cf. her secret, her fear of doctors, and the replacement by dyspnoea). The patients, it is true, invariably dispute the conclusiveness of circumstantial evidence such as this, and they do so even when they have retained a conscious recollection of the catarrh or of their mother's warning (e.g. 'That makes people stupid; it's dangerous'). But some time later the memory, which has been so long repressed, of this piece of infantile sexual life emerges with certainty, and it does so in every instance. I am reminded of the case of a patient of mine suffering from obsessions, which were direct derivatives of infantile masturbation. Her peculiarities, such as self-prohibitions and self-punishments, the feeling that if she had done this she must not do that, the idea that she must not be interrupted, the introduction of pauses between one procedure (with her hands) and the next, her hand-washing, etc, - all of these turned out to be unaltered fragments of her nurse's efforts to break her of the habit. The only thing which had remained permanently in her memory were the words of warning: "Ugh! That's dangerous!" Compare also in this connection my *Three Essays on the Theory of Sexuality*, 1905d. [1905e, 1416]

The significance of the erotogenic zones as apparatuses subordinate to the genitals and as substitutes for them is, among all the psychoneuroses, most clearly to be seen in hysteria; but this does not imply that that significance is any the less in the other forms of illness. It is only that in them it is less recognizable, because in their case (obsessional neurosis and paranoia) the formation of the symptoms takes place in regions of the mental apparatus which are more remote from the particular centres concerned with somatic control. In obsessional neurosis what is more striking is the significance of those impulses which create new sexual aims and seem independent of erotogenic zones. Nevertheless, in scopophilia and exhibitionism the eye corresponds to an erotogenic zone; while in the case of those components of the sexual instinct which involve pain and cruelty the same role is assumed by the skin - the skin, which in particular parts of the body has become differentiated into sense organs or modified into mucous membrane, and is thus the erotogenic zone *par excellence*.¹

People who carry out obsessive actions or ceremonials belong to the same class as those who suffer from obsessive thinking, obsessive ideas, obsessive impulses and the like. Taken together, these form a particular clinical entity, to which the name of 'obsessional neurosis' ['Zwangsneurose'] is customarily applied.¹ But one should not attempt to deduce the character of the illness from its name; for, strictly speaking, other kinds of morbid mental phenomena have an equal claim to possessing what are spoken of as 'obsessional' characteristics. In place of a definition we must for the time being be content with obtaining a detailed knowledge of these states, since we have not yet been able to arrive at a criterion of obsessional neuroses; it probably lies very deep, although we seem to sense its presence everywhere in the manifestations of the illness. [1907b, 1901]

Any activities whatever may become obsessive actions in the wider sense of the term if they are elaborated by small additions or given a rhythmic character by means of pauses and repetitions. We shall not expect to find a sharp distinction between 'ceremonials' and 'obsessive actions'. As a rule obsessive actions have grown out of ceremonials. Besides these two, prohibitions and hindrances (abulias) make up the content of the disorder; these, in fact, only continue the work of the obsessive actions, inasmuch as some things are completely forbidden to the patient and others only allowed subject to his following a prescribed ceremonial. [1907b, 1902]
It is remarkable that both compulsions and prohibitions (having to do something and having not to do something) apply in the first instance only to the subject's solitary activities and for a long time leave his social behaviour unaffected. Sufferers from this illness are consequently able to treat their affliction as a private matter and keep it concealed for many years. And, indeed, many more people suffer from these forms of obsessional neurosis than doctors hear of. For many sufferers, too, concealment is made easier from the fact that they are quite well able to fulfil their social duties during a part of the day, once they have devoted a number of hours to their secret doings, hidden from view like Mélusine.

[1907b, 1903]

A deeper insight into the mechanism of obsessional neurosis is gained if we take into account the primary fact which lies at the bottom of it. This is always the repression of an instinctual impulse (a component of the sexual instinct) which was present in the subject's constitution and which was allowed to find expression for a while during his childhood but later succumbed to suppression. In the course of the repression of this instinct a special conscientiousness is created which is directed against the instinct's aims; but this psychical reaction-formation feels insecure and constantly threatened by the instinct which is lurking in the unconscious. The influence of the repressed instinct is felt as a temptation, and during the process of repression itself anxiety is generated, which gains control over the future in the form of expectant anxiety. The process of repression which leads to obsessional neurosis must be considered as one which is only partly successful and which increasingly threatens to fail. It may thus be compared to an unending conflict; fresh psychical efforts are continually required to counterbalance the forward pressure of the instinct. Thus the ceremonial and obsessive actions arise partly as a defence against the temptation and partly as a protection against the ill which is expected. Against the temptation the protective measures seem soon to become inadequate; then the prohibitions come into play, with the purpose of keeping at a distance situations that give rise to temptation. Prohibitions take the place of obsessive actions, it will be seen, just as a phobia is designed to avert a hysterical attack. Again, a ceremonial represents the sum of the conditions subject to which something that is not yet absolutely forbidden is permitted, just as the Church's marriage ceremony signifies for the believer a sanctioning of sexual enjoyment which would otherwise be sinful. A further characteristic of obsessional neurosis, as of all similar affections, is that its manifestations (its symptoms, including the obsessive actions) fulfil the condition of being a compromise between the warring forces of the mind. They thus always reproduce something of the pleasure which they are designed to prevent; they serve the repressed instinct no less than the agencies which are repressing it. As the illness progresses, indeed, actions which were originally mostly concerned with maintaining the defence come to approximate more and more to the proscribed actions through which the instinct was able to find expression in childhood.

[1907b, 1907]
Such is my excuse for having curtailed so drastically the history of this case and its treatment. And I can offer still more cogent reasons for having confined myself to the statement only of some disconnected results of the psycho-analytic investigation of obsessional neuroses. I must confess that I have not yet succeeded in completely penetrating the complicated texture of a severe case of obsessional neurosis, and that, if I were to reproduce the analysis, it would be impossible for me to make the structure, such as by the help of analysis we know or suspect it to be, visible to others through the mass of therapeutic work superimposed upon it. What add so greatly to the difficulty of doing this are the resistances of the patients and the forms in which they are expressed. But even apart from this it must be admitted that an obsessional neurosis is in itself not an easy thing to understand - much less so than a case of hysteria. Actually, indeed, we should have expected to find the contrary. The language of an obsessional neurosis - the means by which it expresses its secret thoughts - is, as it were, only a dialect of the language of hysteria; but it is a dialect in which we ought to be able to find our way about more easily, since it is more nearly related to the forms of expression adopted by our conscious thought than is the language of hysteria. Above all, it does not involve the leap from a mental process to a somatic innervation - hysterical conversion - which can never be fully comprehensible to us.

Perhaps it is only because we are less familiar with obsessional neuroses that we do not find these expectations confirmed by the facts. Persons suffering from a severe degree of obsessional neurosis present themselves far less frequently for analytic treatment than hysterical patients. They dissimulate their condition in daily life, too, as long as they possibly can, and often call in a physician only when their complaint has reached such an advanced stage as, had they been suffering, for instance, from tuberculosis of the lungs, would have led to their being refused admission to a sanatorium. I make this comparison, moreover, because, as with the chronic infectious disease which I have just mentioned, we can point to a number of brilliant therapeutic successes in severe no less than in light cases of obsessional neurosis, where these have been taken in hand at an early stage.

A youngish man of university education introduced himself to me with the statement that he had suffered from obsessions ever since his childhood, but with particular intensity for the last four years. The chief features of his disorder were fears that something might happen to two people of whom he was very fond - his father and a lady whom he admired. Besides this he was aware of compulsive impulses - such as an impulse, for instance, to cut his throat with a razor; and further he produced prohibitions, sometimes in connection with quite unimportant things. He had wasted years, he told me, in fighting against these ideas of his, and in this way had lost much ground in the course of his life. He had tried various treatments, but none had been of any use to him except a course of hydrotherapy at a sanatorium near ---; and this, he thought, had probably only been because he had made an acquaintance there which had led to regular sexual intercourse. Here he had no opportunities of the sort, and he seldom had intercourse and only at irregular intervals. He felt disgust at prostitutes. Altogether, he said, his sexual life had been stunted; masturbation had played only a small part in it, in his sixteenth or seventeenth year. His potency was normal; he had first had intercourse at the age of twenty-six.
He had a friend, he told me, of whom he had an extraordinarily high opinion. He used always to go to him when he was tormented by some criminal impulse, and ask him whether he despised him as a criminal. His friend used then to give him moral support by assuring him that he was a man of irreproachable conduct, and had probably been in the habit, from his youth onwards, of taking a dark view of his own life. At an earlier date, he went on, another person had exercised a similar influence over him. This was a nineteen-year-old student (he himself had been fourteen or fifteen at the time) who had taken a liking to him, and had raised his self-esteem to an extraordinary degree, so that he appeared to himself to be a genius. This student had subsequently become his tutor, and had suddenly altered his behaviour and begun treating him as though he were an idiot. At length he had noticed that the student was interested in one of his sisters, and had realized that he had only taken him up in order to gain admission into the house. This had been the first great blow of his life.

The events in his sixth or seventh year which the patient described in the first hour of his treatment were not merely, as he supposed, the beginning of his illness, but were already the illness itself. It was a complete obsessional neurosis, wanting in no essential element, at once the nucleus and the prototype of the later disorder, - an elementary organism, as it were, the study of which could alone enable us to obtain a grasp of the complicated organization of his subsequent illness. The child, as we have seen, was under the domination of a component of the sexual instinct, the desire to look, as a result of which there was a constant recurrence in him of a very intense wish connected with persons of the female sex who pleased him - the wish, that is, to see them naked. This wish corresponds to the later obsessional or compulsive idea; and if the quality of compulsion was not yet present in the wish, this was because the ego had not yet placed itself in complete opposition to it and did not yet regard it as something foreign to itself. Nevertheless, opposition to this wish from some source or other was already in activity, for its occurrence was regularly accompanied by a distressing affect.① A conflict was evidently in progress in the mind of this young libertine. Side by side with the obsessive wish, and intimately associated with it, was an obsessive fear: every time he had a wish of this kind he could not help fearing that something dreadful would happen. This something dreadful was already clothed in a characteristic indeterminateness which was thenceforward to be an invariable feature of every manifestation of the neurosis. But in a child it is not hard to discover what it is that is veiled behind an indeterminateness of this kind. If the patient can once be induced to give a particular instance in place of the vague generalities which characterize an obsessional neurosis, it may be confidently assumed that the instance is the original and actual thing which has tried to hide itself behind the generalization. Our present patient's obsessive fear, therefore, when restored to its original meaning, would run as follows: 'If I have this wish to see a woman naked, my father will be bound to die.' The distressing affect was distinctly coloured with a tinge of uncanniness and superstition, and was already beginning to give rise to impulses to do something to ward off the impending evil. These impulses were subsequently to develop into the protective measures which the patient adopted.

① [1909d, 2133]
To find a chronic obsessional neurosis beginning like this in early childhood, with lascivious wishes of this sort connected with uncanny apprehensions and an inclination to the performance of defensive acts, is no new thing to me. I have come across it in a number of other cases. It is absolutely typical, although probably not the only possible type. Before proceeding to the events of the second session, I should like to add one more word on the subject of the patient's early sexual experiences. It will hardly be disputed that they may be described as having been considerable both in themselves and in their consequences. But it has been the same with the other cases of obsessional neurosis that I have had the opportunity of analysing. Such cases, unlike those of hysteria, invariably possess the characteristic of premature sexual activity. Obsessional neuroses make it much more obvious than hysterias that the factors which go to form a psychoneurosis are to be found in the patient's infantile sexual life and not in his present one. The current sexual life of an obsessional neurotic may often appear perfectly normal to a superficial observer; indeed, it frequently offers to the eye far fewer pathogenic elements and abnormalities than in the instance we are now considering.

That evening, he continued, the same captain had handed him a packet that had arrived by the post and had said: 'Lieutenant A.¹ has paid the charges for you. You must pay him back.' The packet had contained the pince-nez that he had wired for. At that instant, however, a 'sanction' had taken shape in his mind, namely, that he was not to pay back the money or it would happen - (that is, the phantasy about the rats would come true as regards his father and the lady). And immediately, in accordance with a type of procedure with which he was familiar, to combat this sanction there had arisen a command in the shape of a vow: 'You must pay back the 3.80 Kronen to Lieutenant A.' He had said these words to himself almost half aloud.

The only other piece of information that I obtained from him during this hour was that from the very first, on all the previous occasions on which he had had a fear that something would happen to people he loved no less than on the present one, he had referred the punishments not only to our present life but also to eternity - to the next world. Up to his fourteenth or fifteenth year he had been devoutly religious, but from that time on he had gradually developed into the free-thinker that he was to-day. He reconciled the contradiction between his beliefs and his obsessions by saying to himself: 'What do you know about the next world? Nothing can be known about it. You're not risking anything - so do it.' This form of argument seemed unobjectionable to a man who was in other respects particularly clear-headed, and in this way he exploited the uncertainty of reason in the face of these questions to the benefit of the religious attitude which he had outgrown.
At the third session he completed his very characteristic story of his efforts at fulfilling his obsessional vow. That evening the last gathering of officers had taken place before the end of the manoeuvres. It had fallen to him to reply to the toast of 'The Gentlemen of the Reserve'. He had spoken well, but as if he were in a dream, for at the back of his mind he was being incessantly tormented by his vow. He had spent a terrible night. Arguments and counter-arguments had struggled with one another. The chief argument, of course, had been that the premise upon which his vow had been based - that Lieutenant A. had paid the money for him - had proved to be false. However, he had consoled himself with the thought that the business was not yet finished, as A. would be riding with him next morning part of the way to the railway station at P--, so that he would still have time to ask him the necessary favour. As a matter of fact he had not done this, and had allowed A. to go off without him; but he had given instructions to his orderly to let A. know that he intended to pay him a visit that afternoon. He himself had reached the station at half-past nine in the morning. He had deposited his luggage there and had seen to various things he had to do in the small town, with the intention of afterwards paying his visit to A. The village in which A. was stationed was about an hour's drive from the town of P--. The railway journey to the place where the post office was would take three hours. He had calculated, therefore, that the execution of his complicated plan would just leave him time to catch the evening train from P--- to Vienna. The ideas that were struggling within him had been, on the one hand, that he was simply being cowardly and was obviously only trying to save himself the unpleasantness of asking A. to make the sacrifice in question and of cutting a foolish figure before him, and that that was why he was disregarding his vow; and, on the other hand, that it would, on the contrary, be cowardly of him to fulfil his vow, since he only wanted to do so in order to be left in peace by his obsessions. When in the course of his deliberations, the patient added, he found the arguments so evenly balanced as these, it was his custom to allow his actions to be decided by chance events as though by the hand of God. When, therefore, a porter at the station had addressed him with the words, 'Ten o'clock train, sir? ' he had answered 'Yes', and in fact had gone off by the ten o'clock train. In this way he had produced fait accompli and felt greatly relieved. He had proceeded to book a seat for luncheon in the restaurant car. At the first station they had stopped at it had suddenly struck him that he still had time to get out, wait for the next down train, travel back in it to P--., drive to the place where Lieutenant A. was quartered, from there make the three hours' train journey with him to the post office, and so forth. It had only been the consideration that he had booked his seat for luncheon with the steward of the restaurant car that had prevented his carrying out this design. He had not abandoned it, however; he had only put off getting out until a later stop. In this way he had struggled through from station to station, till he had reached one at which it had seemed to him impossible to get out because he had relatives living there. He had then determined to travel through to Vienna, to look up his friend there and lay the whole matter before him, and then, after his friend had made his decision, to catch the night train back to P--. When I expressed a doubt whether this would have been feasible, he assured me that he would have had half an hour to spare between the arrival of the one train and the departure of the other. When he had arrived in Vienna, however, he had failed to find his friend at the restaurant at which he had counted on meeting him, and had not reached his friend's house till eleven o'clock at night. He told him the whole story that very night. His friend had held up his hands in amazement to think that he could still be in doubt whether he was suffering from an obsession, and had calmed him down for the night, so that he had slept excellently. Next morning they had gone together to the post office, to dispatch the 3.80 kronen to the post office at which the packet containing the pince-nez had arrived.

[1909d, 2140]
At the next session the patient showed great interest in what I had said, but ventured, so he told me, to bring for ward a few doubts. - How, he asked, could the information that the self-reproach, the sense of guilt, was justified have a therapeutic effect? - I explained that it was not the information that had this effect, but the discovery of the unknown content to which the self-reproach was really attached. - Yes, he said, that was the precise point to which his question had been directed. - I then made some short observations upon the psychological differences between the conscious and the unconscious, and upon the fact that everything conscious was subject to a process of wearing-away, while what was unconscious was relatively unchangeable; and I illustrated my remarks by pointing to the antiques standing about in my room. They were, in fact, I said, only objects found in a tomb, and their burial had been their preservation: the destruction of Pompeii was only beginning now that it had been dug up. - Was there any guarantee, he next enquired, of what one’s attitude would be towards what was discovered? One man, he thought, would no doubt behave in such a way as to get the better of his self-reproach, but another would not. - No, I said, it followed from the nature of the circumstances that in every case the affect would be overcome - for the most part during the progress of the work itself. Every effort was made to preserve Pompeii, whereas people were anxious to be rid of tormenting ideas like his. - He had said to himself, he went on, that a self-reproach could only arise from a breach of a person’s own inner moral principles and not from that of any external ones. - I agreed, and said that the man who merely breaks an external law often regards himself as a hero. - Such an occurrence, he continued, was thus only possible where a disintegration of the personality was already present. Was there a possibility of his effecting a reintegration of his personality? If this could be done, he thought he would be able to make a success of his life, perhaps more of one than most people. - I replied that I was in complete agreement with this notion of a splitting of his personality. He had only to assimilate this new contrast, between a moral self and an evil one, with the contrast I had already mentioned, between the conscious and the unconscious. The moral self was the conscious, the evil self was the unconscious.¹ - He then said that, though he considered himself a moral person, he could quite definitely remember having done things in his childhood which came from his other self. - I remarked that here he had incidentally hit upon one of the chief characteristics of the unconscious, namely, its relation to the infantile. The unconscious, I explained, was the infantile; it was that part of the self which had become separated off from it in infancy, which had not shared the later stages of its development, and which had in consequence become repressed. It was the derivatives of this repressed unconscious that were responsible for the involuntary thoughts which constituted his illness. He might now, I added, discover yet another characteristic of the unconscious; it was a discovery which I should be glad to let him make for himself. - He found nothing more to say in this immediate connection, but instead he expressed a doubt whether it was possible to undo modifications of such long standing. What, in particular, could be done against his idea about the next world, for it could not be refuted by logic? - I told him I did not dispute the gravity of his case nor the significance of his pathological constrictions; but at the same time his youth was very much in his favour as well as the intactness of his personality. In this connection I said a word or two upon the good opinion I had formed of him, and this gave him visible pleasure.

[1909d, 2143]
He admitted that all of this sounded quite plausible, but he was naturally not in the very least convinced by it. He would venture to ask, he said, how it was that an idea of this kind could have remissions, how it could appear for a moment when he was twelve years old, and again when he was twenty, and then once more two years later, this time for good. He could not believe that his hostility had been extinguished in the intervals, and yet during them there had been no sign of self-reproaches. - To this I replied that whenever any one asked a question like that, he was already prepared with an answer; he needed only to be encouraged to go on talking. - He then proceeded, somewhat disconnectedly as it seemed, to say that he had been his father's best friend, and that his father had been his. Except on a few subjects, upon which fathers and sons usually hold aloof from one another - (What could he mean by that?) -, there had been a greater intimacy between them than there now was between him and his best friend. As regards the lady for whose sake he had sacrificed his father in that idea of his, it was true that he had loved her very much, but he had never felt really sensual wishes towards her, such as he had constantly had in his childhood. Altogether, in his childhood his sensual impulses had been much stronger than during his puberty. - At this I told him I thought he had now produced the answer we were waiting for, and had at the same time discovered the third great characteristic of the unconscious. The source from which his hostility to his father derived its indestructibility was evidently something in the nature of sensual desires, and in that connection he must have felt his father as in some way or other an interference. A conflict of this kind, I added, between sensuality and childish love was entirely typical. The remissions he had spoken of had occurred because the premature explosion of his sensual feelings had had as its immediate consequence a considerable diminution of their violence. It was not until he was once more seized with intense erotic desires that his hostility reappeared again owing to the revival of the old situation. I then got him to agree that I had not led him on to the subject either of childhood or of sex, but that he had raised them both of his own free will. - He then went on to ask why he had not simply come to a decision, at the time he was in love with the lady, that his father's interference with that love could not for a moment weigh against his love of his father. - I replied that it was scarcely possible to destroy a person in absentia. Such a decision would only have been possible if the wish that he took objection to had made its first appearance on that occasion; whereas, as a matter of fact, it was a long-repressed wish, towards which he could not behave otherwise than he had formerly done, and which was consequently immune from destruction. This wish (to get rid of his father as being an interference) must have originated at a time when circumstances had been very different - at a time, perhaps, when he had not loved his father more than the person whom he desired sensually, or when he was incapable of making a clear decision. It must have been in his very early childhood, therefore, before he had reached the age of six, and before the date at which his memory became continuous; and things must have remained in the same state ever since. - With this piece of construction our discussion was broken off for the time being.

[1909d, 2145]
Some other of the patient's obsessions, however, though they too were centred upon his lady, exhibited a different mechanism and owed their origin to a different instinct. Besides his slimming mania he produced a whole series of other obsessional activities at the period during which the lady was stopping at his summer resort; and, in part at least, these directly related to her. One day, when he was out with her in a boat and there was a stiff breeze blowing, he was obliged to make her put on his cap, because a command had been formulated in his mind that *nothing must happen to her.*¹ This was a kind of *obsession for protecting,* and it bore other fruit besides this. Another time, as they were sitting together during a thunderstorm, he was obsessed, he could not tell why, with the necessity for counting up to forty or fifty between each flash of lightning and its accompanying thunder-clap. On the day of her departure he knocked his foot against a stone lying in the road, and was obliged to put it out of the way by the side of the road, because the idea struck him that her carriage would be driving along the same road in a few hours' time and might come to grief against this stone. But a few minutes later it occurred to him that this was absurd, and he was obliged to go back and replace the stone in its original position in the middle of the road. After her departure he became a prey to an *obsession for understanding,* which made him a curse to all his companions. He forced himself to understand the precise meaning of every syllable that was addressed to him, as though he might otherwise be missing some priceless treasure. Accordingly he kept asking: 'What was it you said just then?' And after it had been repeated to him he could not help thinking it had sounded different the first time, so he remained dissatisfied.  
[1909d, 2149]
For this reason it not uncommonly happens that obsessional neurotics, who are troubled with self-reproaches but have connected their affects with the wrong causes, will also tell the physician the true causes, without any suspicion that their self-reproaches have simply become detached from them. In relating such an incident they will sometimes add with astonishment or even with an air of pride: 'But I think nothing of that.' This happened in the first case of obsessional neurosis which gave me an insight many years ago into the nature of the malady. The patient, who was a government official, was troubled by innumerable scruples. He was the man whose compulsive act in connection with the branch in the park at Schönbrunn I have already described. I was struck by the fact that the florin notes with which he paid his consultation fees were invariably clean and smooth. (This was before we had a silver coinage in Austria.) I once remarked to him that one could always tell a government official by the brand-new florins that he drew from the State treasury, and he then informed me that his florins were by no means new, but that he had them ironed out at home. It was a matter of conscience with him, he explained, not to hand any one dirty paper florins; for they harboured all sorts of dangerous bacteria and might do some harm to the recipient. At that time I already had a vague suspicion of the connection between neuroses and sexual life, so on another occasion I ventured to ask the patient how he stood in regard to that matter. 'Oh, that's quite all right,' he answered airily, 'I'm not at all badly off in that respect. I play the part of a dear old uncle in a number of respectable families, and now and then I make use of my position to invite some young girl to go out with me for a day's excursion in the country. Then I arrange that we shall miss the train home and be obliged to spend the night out of town. I always engage two rooms - I do things most handsomely; but when the girl has gone to bed I go in to her and masturbate her with my fingers.' - 'But aren't you afraid of doing her some harm, fiddling about in her genitals with your dirty hand?' - At this he flared up: 'Harm? Why, what harm should it do her? It hasn't done a single one of them any harm yet, and they've all of them enjoyed it. Some of them are married now, and it hasn't done them any harm at all.' - He took my remonstrance in very bad part, and never appeared again. But I could only account for the contrast between his fastidiousness with the paper florins and his unscrupulousness in abusing the girls entrusted to him by supposing that the self-reproachful affect had become displaced. The aim of this displacement was obvious enough: if his self-reproaches had been allowed to remain where they belonged he would have had to abandon a form of sexual gratification to which he was probably impelled by some powerful infantile determinants. The displacement therefore ensured his deriving a considerable advantage from his illness.

[1909d, 2155]
A discussion of this childhood scene will be found in the footnote, and here I will only remark that its emergence shook the patient for the first time in his refusal to believe that at some prehistoric period in his childhood he had been seized with fury (which had subsequently become latent) against the father whom he loved so much. I must confess that I had expected it to have a greater effect, for the incident had been described to him so often - even by his father himself - that there could be no doubt of its objective reality. But, with that capacity for being illogical which never fails to bewilder one in such highly intelligent people as obsessional neurotics, he kept urging against the evidential value of the story the fact that he himself could not remember the scene. And so it was only along the painful road of transference that he was able to reach a conviction that his relation to his father really necessitated the postulation of this unconscious complement. Things soon reached a point at which, in his dreams, his waking phantasies, and his associations, he began heaping the grossest and filthiest abuse upon me and my family, though in his deliberate actions he never treated me with anything but the greatest respect. His demeanour as he repeated these insults to me was that of a man in despair. 'How can a gentleman like you, sir,' he used to ask, 'let yourself be abused in this way by a low, good-for-nothing fellow like me? You ought to turn me out: that's all I deserve.' While he talked like this, he would get up from the sofa and roam about the room, - a habit which he explained at first as being due to delicacy of feeling: he could not bring himself, he said, to utter such horrible things while he was lying there so comfortably. But soon he himself found a more cogent explanation, namely, that he was avoiding my proximity for fear of my giving him a beating. If he stayed on the sofa he behaved like some one in desperate terror trying to save himself from castigations of terrific violence; he would bury his head in his hands, cover his face with his arm, jump up suddenly and rush away, his features distorted with pain, and so on. He recalled that his father had had a passionate temper, and sometimes in his violence had not known where to stop. Thus, little by little, in this school of suffering, the patient won the sense of conviction which he had lacked - though to any disinterested mind the truth would have been almost self-evident.

In the year 1896 I defined obsessional ideas as 'transformed self-reproaches which have re-emerged from repression and which always relate to some sexual act that was performed with pleasure in childhood'. This definition now seems to me to be open to criticism upon formal grounds, though its component elements are unobjectionable. It was aiming too much at unification, and took as its model the practice of obsessional neurotics themselves, when, with their characteristic liking for indeterminateness, they heap together under the name of 'obsessional ideas' the most heterogeneous psychical structures.² In point of fact, it would be more correct to speak of 'obsessive thinking', and to make it clear that obsessional structures can correspond to every sort of psychical act. They can be classed as wishes, temptations, impulses, reflections, doubts, commands, or prohibitions. Patients endeavour in general to tone down such distinctions and to regard what remains of these psychical acts after they have been deprived of their affective index simply as 'obsessional ideas'. Our present patient gave an example of this type of behaviour in one of his first sessions, when he attempted to reduce a wish to the level of a mere 'train of thought' (p. 2144).

The distinction between a primary and a secondary defensive struggle is no doubt well founded, but we find its value unexpectedly diminished when we discover that the patients themselves do not know the wording of their own obsessional ideas. This may sound paradoxical, but it is perfectly good sense. During the progress of a psycho-analysis it is not only the patient who plucks up courage, but his disease as well; it grows bold enough to speak more plainly than before. To drop the metaphor, what happens is that the patient, who his hitherto turned his eyes away in terror from his own pathological productions, begins to attend to them and obtains a clearer and more detailed view of them.¹

[1909d, 2163]

[1909d, 2172]
There are, besides this, two special ways in which a more precise knowledge of obsessional structures can be gained. In the first place, experience shows that an obsessional command (or whatever it may be), which in waking life is known only in a truncated and distorted form, like a mutilated telegraph message, may have its actual text brought to light in a dream. Such texts appear in dreams in the shape of speeches, and are thus an exception to the rule that speeches in dreams are derived from speeches in real life. Secondly, in the course of the analytic examination of a case history, one becomes convinced that if a number of obsessions succeed one another they are often - even though their wording is not identical - ultimately one and the same. The obsession may have been successfully shaken off on its first appearance, but it comes back a second time in a distorted form and without being recognized, and may then perhaps be able to hold its own in the defensive struggle more effectively, precisely because of its distortion. But the original form is the correct one, and often displays its meaning quite openly. When we have at great pains elucidated an unintelligible obsessional idea, it often happens that the patient informs us that just such a notion, wish, or temptation as the one we have constructed did in fact make its appearance on one occasion before the obsessional idea had arisen, but that it did not persist. It would unfortunately involve us in too lengthy a digression if we were to give instances of this from the history of our present patient.

¹ Some patients carry the diversion of their attention to such lengths that they are totally unable to give the content of an obsessional idea or to describe an obsessional act though they have performed it over and over again.

² This misapprehension on the part of consciousness can be seen at work not only in reference to the obsessional ideas themselves, but also in reference to the products of the secondary defensive struggle, such, for instance, as the protective formulas. I can produce two good examples of this. Our patient used to employ as a defensive formula a rapidly pronounced 'aber' ['but'] accompanied by a gesture of repudiation. He told me on one occasion that this formula had become altered recently; he now no longer said 'aber' but 'abér'. When he was asked to give the reason for this new departure, he declared that the mute 'e' of the second syllable gave him no sense of security against the intrusion, which he so much dreaded, of some foreign and contradictory element, and that he had therefore decided to accent the 'e'. This explanation (an excellent sample of the obsessional neurotic style) was, however, clearly inadequate; the most that it could claim to be was a rationalization. The truth was that 'abér' was an approximation towards the similar-sounding 'abwehr' ['defence'], a term which he had learnt in the course of our theoretical discussions of psycho-analysis. He had thus put the treatment to an illegitimate and 'delirious' use in order to strengthen a defensive formula. Another time he told me about his principal magic word, which was an apotropaic against every evil; he had put it together out of the initial letters of the most powerfully beneficent of his prayers and had clapped on an 'amen' at the end of it. I cannot reproduce the word itself, for reasons which will become apparent immediately. For, when he told it me, I could not help noticing that the word was in fact an anagram of the name of his lady. Her name contained an 's', and this he had put last, that is, immediately before the 'amen' at the end. We may say, therefore, that by this process he had brought his 'Samen' ['semen'] into contact with the woman he loved; in imagination, that is to say, he had masturbated with her. He himself, however, had never noticed this very obvious connection; his defensive forces had allowed themselves to be fooled by the repressed ones. This is also a good example of the rule that in time the thing which is meant to be warded off invariably finds its way into the very means which is being used for warding it off.

[1909d, 2174]
For instance, one of the patient's oldest and favourite obsessions (which corresponded to an admonition or warning) ran as follows: 'If I marry the lady, some misfortune will befall my father (in the next world).’ If we insert the intermediate steps, which had been skipped but were known to us from the analysis, we get the following train of thought: 'If my father were alive, he would be as furious over my design of marrying the lady as he was in the scene in my childhood; so that I should fly into a rage with him once more and wish him every possible evil; and thanks to the omnipotence of my wishes¹ these evils would be bound to come upon him.'

[1909d, 2176]

The technique of distortion by ellipsis seems to be typical of obsessional neuroses; I have come across it in the obsessional thoughts of other patients as well. One example, a particularly transparent one, is of especial interest on account of a certain structural similarity with the rat idea. It was a case of doubting, and occurred in a lady who suffers principally from obsessional acts. This lady was going for a walk with her husband in Nuremberg, and made him take her into a shop, where she purchased various objects for her child and amongst them a comb. Her husband, finding that the shopping was too long a business for his taste, said that he had noticed some coins in an antique shop on the way which he was anxious to secure, adding that after he had made his purchase he would come and fetch her in the shop in which they at present were. But he stayed away, as she thought, far too long. When he came back she accordingly asked him where he had been. 'Why,’ he replied, ‘at the antique shop I told you about.’ At the same instant she was seized by a tormenting doubt whether she had not as a matter of fact always possessed the comb which she had just bought for her child. She was naturally quite unable to discover the simple mental link that was involved. There is nothing for it but to regard the doubt as having become displaced, and to reconstruct the complete chain of unconscious thoughts as follows: 'If it is true that you were only at the antique shop, if I am really to believe that, then I may just as well believe that this comb that I bought a moment ago has been in my possession for years.’ Here, therefore, the lady was drawing a derisive and ironical parallel, just as when our patient thought: 'Oh yes, as sure as those two' (his father and the lady) 'will have children, I shall pay back the money to A.’ In the lady's case the doubt was dependent upon her unconscious jealousy, which led her to suppose that her husband had spent the interval of his absence in paying a visit of gallantry.

[1909d, 2177]

I shall not in the present paper attempt any discussion of the psychological significance of obsessional thinking. Such a discussion would be of extraordinary value in its results, and would do more to clarify our ideas upon the nature of the conscious and the unconscious than any study of hysteria or the phenomena of hypnosis. It would be a most desirable thing if the philosophers and psychologists who develop brilliant theoretical views on the unconscious upon a basis of hearsay knowledge or from their own conventional definitions would first submit to the convincing impressions which may be gained from a first-hand study of the phenomena of obsessional thinking. We might almost go to the length of requiring it of them, if the task were not so far more laborious than the methods of work to which they are accustomed. I will only add here that in obsessional neuroses the unconscious mental processes occasionally break through into consciousness in their pure and undistorted form, that such incursions may take place at every possible stage of the unconscious process of thought, and that at the moment of the incursion the obsessional ideas can, for the most part, be recognized as formations of very long standing. This accounts for the striking circumstance that, when the analyst tries, with the patient's help, to discover the date of the first occurrence of an obsessional idea, the patient is obliged to place it further and further back as the analysis proceeds, and is constantly finding fresh 'first' occasions for the appearance of the obsession.

[1909d, 2178]
In this section I intend to deal with a few mental characteristics of obsessional neurotics which, though they do not seem important in themselves, nevertheless lie upon the road to a comprehension of more important things. They were strongly marked in our present patient; but I know that they are not attributable to his individual character, but to his disorder, and that they are to be met with quite typically in other obsessional patients.

[1909d, 2179]

There can be no doubt that the patient felt a need for finding experiences of this kind to act as props for his superstition, and that it was for that reason that he occupied himself so much with the inexplicable coincidences of everyday life with which we are all familiar, and helped out their shortcomings with unconscious activity of his own. I have come across a similar need in many other obsessional patients and have suspected its presence in many more besides. It seems to me easily explicable in view of the psychological characteristics of the obsessional neurosis. In this disorder, as I have already explained (p. 2155), repression is effected not by means of amnesia but by a severance of causal connections brought about by a withdrawal of affect. These repressed connections appear to persist in some kind of shadowy form (which I have elsewhere compared to an endopsychic perception),¹ and they are thus transferred, by a process of projection, into the external world, where they bear witness to what has been effaced from consciousness.

[1909d, 2181]

Another mental need, which is also shared by obsessional neurotics and which is in some respects related to the one just mentioned, is the need for uncertainty in their life, or for doubt. An enquiry into this characteristic leads deep into the investigation of instinct. The creation of uncertainty is one of the methods employed by the neurosis for drawing the patient away from reality and isolating him from the world - which is among the objects of every psychoneurotic disorder. Again, it is only too obvious what efforts are made by the patients themselves in order to be able to avoid certainty and remain in doubt. Some of them, indeed, give a vivid expression to this tendency in a dislike of clocks and watches (for these at least make the time of day certain), and in the unconscious artifices which they employ in order to render these doubt removing instruments innocuous. Our present patient had developed a peculiar talent for avoiding a knowledge of any facts which would have helped him in deciding his conflict. Thus he was in ignorance upon those matters relating to his lady which were the most relevant to the question of his marriage: he was ostensibly unable to say who had operated upon her and whether the operation had been unilateral or bilateral. He had to be forced into remembering what he had forgotten and into finding out what he had overlooked.

[1909d, 2182]

The predilection felt by obsessional neurotics for uncertainty and doubt leads them to turn their thoughts by preference to those subjects upon which all mankind are uncertain and upon which our knowledge and judgements must necessarily remain open to doubt. The chief subjects of this kind are paternity, length of life, life after death, and memory - in the last of which we are all in the habit of believing, without having the slightest guarantee of its trustworthiness.¹

[1909d, 2182]

In obsessional neuroses the uncertainty of memory is used to the fullest extent as a help in the formation of symptoms; and we shall learn directly the part played in the actual content of the patients' thoughts by the questions of length of life and life after death. But as an appropriate transition I will first consider one particular superstitious trait in our patient to which I have already alluded (p. 2176) and which will no doubt have puzzled more than one of my readers.

[1909d, 2183]
I refer to the omnipotence which he ascribed to his thoughts and feelings, and to his wishes, whether good or evil. It is, I must admit, decidedly tempting to declare that this idea was a delusion and that it oversteps the limits of obsessional neurosis. I have, however, come across the same conviction in another obsessional patient; and he was long ago restored to health and is leading a normal life. Indeed, all obsessional neurotics behave as though they shared this conviction. It will be our business to throw some light upon these patients' over-estimation of their powers. Assuming, without more ado, that this belief is a frank acknowledgement of a relic of the old megalomania of infancy, we will proceed to ask our patient for the grounds of his conviction. In reply, he adduces two experiences. When he returned for a second visit to the hydropathic establishment at which his disorder had been relieved for the first and only time, he was told that the room was already taken and that it was occupied by an old professor. This piece of news considerably diminished his prospects of successful treatment, and he reacted to it with the unamiable thought: 'I wish he may be struck dead for it!' A fortnight later he was woken up from his sleep by the disturbing idea of a corpse; and in the morning he heard that the professor had really had a stroke, and that he had been carried up into his room at about the time he himself had woken up. The second experience related to an unmarried woman, no longer young, though with a great desire to be loved, who had paid him a great deal of attention and had once asked him point blank whether he could not love her. He had given her an evasive answer. A few days afterwards he heard that she had thrown herself out of a window. He then began to reproach himself, and said to himself that it would have been in his power to save her life by giving her his love. In this way he became convinced of the omnipotence of his love and of his hatred. Without denying the omnipotence of love we may point out that both these instances were concerned with death, and we may adopt the obvious explanation that, like other obsessional neurotics, our patient was compelled to overestimate the effects of his hostile feelings upon the external world, because a large part of their internal, mental effects escaped his conscious knowledge. His love - or rather his hatred - was in truth overpowering; it was precisely they that created the obsessional thoughts, of which he could not understand the origin and against which he strove in vain to defend himself.¹

But the behaviour of other obsessional neurotics does not differ greatly from that of our present patient, even though it has not been their fate to come face to face with the phenomenon of death at such an early age. Their thoughts are unceasingly occupied with other people's length of life and possibility of death; their superstitious propensities have had no other content to begin with, and have perhaps no other source whatever. But these neurotics need the help of the possibility of death chiefly in order that it may act as a solution of conflicts they have left unsolved. Their essential characteristic is that they are incapable of coming to a decision, especially in matters of love; they endeavour to postpone every decision, and, in their doubt which person they shall decide for or what measures they shall take against a person, they are obliged to choose as their model the old German courts of justice, in which the suits were usually brought to an end, before judgement had been given, by the death of the parties to the dispute. Thus in every conflict which enters their lives they are on the look out for the death of some one who is of importance to them, usually of some one they love - such as one of their parents, or a rival, or one of the objects of their love between which their inclinations are wavering. But at this point our discussion of the death-complex in obsessional neuroses touches upon the problem of the instinctual life of obsessional neurotics. And to this problem we must now turn.

[1909d, 2183]
If we wish to obtain a grasp of the psychical forces whose interplay built up this neurosis, we must turn back to what we have learnt from the patient on the subject of the precipitating causes of his falling ill as a grown-up man and as a child. He fell ill when he was in his twenties on being faced with a temptation to marry another woman instead of the one whom he had loved so long; and he avoided a decision of this conflict by postponing all the necessary preliminary actions. The means for doing this was given him by his neurosis. His hesitation between the lady he loved and the other girl can be reduced to a conflict between his father's influence and his love for his lady, or, in other words, to a conflicting choice between his father and his sexual object, such as had already subsisted (judging from his recollections and obsessional ideas) in his remote childhood. All through his life, moreover, he was unmistakably victim to a conflict between love and hatred, in regard both to his lady and to his father. His phantasies of revenge and such obsessional phenomena as his obsession for understanding and his exploit with the stone in the road bore witness to his divided feelings; and they were to a certain degree comprehensible and normal, for the lady by her original refusal and subsequently by her coolness had given him some excuse for hostility. But his relations with his father were dominated by a similar division of feeling, as we have seen from our translation of his obsessional thoughts; and his father, too, must have given him an excuse for hostility in his childhood, as indeed we have been able to establish almost beyond question. His attitude towards the lady - a compound of tenderness and hostility - came to a great extent within the scope of his conscious knowledge; at most he deceived himself over the degree and violence of his negative feelings. But his hostility towards his father, on the contrary, though he had once been acutely conscious of it, had long since vanished from his ken, and it was only in the teeth of the most violent resistance that it could be brought back into his consciousness. We may regard the repression of his infantile hatred of his father as the event which brought his whole subsequent career under the dominion of the neurosis.

[1909d, 2185]

If we consider a number of analyses of obsessional neurotics we shall find it impossible to escape the impression that a relation between love and hatred such as we have found in our present patient is among the most frequent, the most marked, and probably, therefore, the most important characteristics of obsessional neurosis. But however tempting it may be to bring the problem of the 'choice of neurosis' into connection with instinctual life, there are reasons enough for avoiding such a course. For we must remember that in every neurosis we come upon the same suppressed instincts behind the symptoms. After all, hatred, kept suppressed in the unconscious by love, plays a great part in the pathogenesis of hysteria and paranoia. We know too little of the nature of love to be able to arrive at any definite conclusion here; and, in particular, the relation between the negative factor in love and the sadistic components of the libido remains completely obscure. What follows is therefore to be regarded as no more than a provisional explanation. We may suppose, then, that in the cases of unconscious hatred with which we are concerned the sadistic components of love have, from constitutional causes, been exceptionally strongly developed, and have consequently undergone a premature and all too thorough suppression, and that the neurotic phenomena we have observed arise on the one hand from conscious feelings of affection which have become exaggerated as a reaction, and on the other hand from sadism persisting in the unconscious in the form of hatred.

[1909d, 2187]
It is this same doubt that leads the patient to uncertainty about his protective measures, and to his continual repetition of them in order to banish that uncertainty; and it is this doubt, too, that eventually brings it about that the patient's protective acts themselves become as impossible to carry out as his original inhibited decision in connection with his love. At the beginning of my investigations I was led to assume another and more general origin for the uncertainty of obsessional neurotics and one which seemed to be nearer the normal. If, for instance, while I am writing a letter some one interrupts me with questions, I afterwards feel a quite justifiable uncertainty as to what I may not have written under the influence of the disturbance, and, to make sure, I am obliged to read the letter over after I have finished it. In the same way I might suppose that the uncertainty of obsessional neurotics, when they are praying, for instance, is due to unconscious phantasies constantly mingling with their prayers and disturbing them. This hypothesis is correct, but it may be easily reconciled with what I have just said. It is true that the patient's uncertainty whether he has carried through a protective measure is due to the disturbing effect of unconscious phantasies; but the content of these phantasies is precisely the contrary impulse - which it was the very aim of the prayer to ward off. This became clearly evident in our patient on one occasion, for the disturbing element did not remain unconscious but made its appearance openly. The words he wanted to use in his prayer were, 'May God protect her', but a hostile 'not' suddenly darted out of his unconscious and inserted itself into the sentence; and he understood that this was an attempt at a curse (p. 2152). If the 'not' had remained mute, he would have found himself in a state of uncertainty and would have kept on prolonging his prayers indefinitely. But since it became articulate he eventually gave up praying. Before doing so, however, he, like other obsessional patients, tried every kind of method for preventing the opposite feeling from insinuating itself. He shortened his prayers, for instance, or said them more rapidly. And similarly other patients will endeavour to 'isolate' all such protective acts from other things. But none of these technical procedures are of any avail in the long run. If the impulse of love achieves any success by displacing itself on to some trivial act, the impulse of hostility will very soon follow it on to its new ground and once more proceed to undo all that it has done.

And when the obsessional patient lays his finger on the weak spot in the security of our mental life - on the untrustworthiness of our memory - the discovery enables him to extend his doubt over everything, even over actions which have already been performed and which have so far had no connection with the love-hatred complex, and over the entire past. I may recall the instance of the woman who had just bought a comb for her little daughter in a shop, and, becoming suspicious of her husband, began to doubt whether she had not as a matter of fact been in possession of the comb for a long time. Was not this woman saying point-blank: 'If I can doubt your love' (and this was only a projection of her doubt of her own love for him), 'then I can doubt this too, then I can doubt everything' - thus revealing to us the hidden meaning of neurotic doubt?
Furthermore, by a sort of regression, preparatory acts become substituted for the final decision, thinking replaces acting, and, instead of the substitutive act, some thought preliminary to it asserts itself with all the force of compulsion. According as this regression from acting to thinking is more or less marked, a case of obsessional neurosis will exhibit the characteristics of obsessive thinking (that is, of obsessional ideas) or of obsessive acting in the narrower sense of the word. True obsessional acts such as these, however, are only made possible because they constitute a kind of reconciliation, in the shape of a compromise, between the two antagonistic impulses. For obsessional acts tend to approximate more and more - and the longer the disorder lasts the more evident does this become - to infantile sexual acts of a masturbatory character. Thus in this form of the neurosis acts of love are carried out in spite of everything, but only by the aid of a new kind of regression; for such acts no longer relate to another person, the object of love and hatred, but are auto-erotic acts such as occur in infancy.

In bringing this paper to a close I may express a hope that, though my communication is incomplete in every sense, it may at least stimulate other workers to throw more light upon the obsessional neurosis by a deeper investigation of the subject. What is characteristic of this neurosis - what differentiates it from hysteria - is not, in my opinion, to be found in instinctual life but in the psychological field. I cannot take leave of my patient without putting on paper my impression that he had, as it were, disintegrated into three personalities: into one unconscious personality, that is to say, and into two preconscious ones between which his consciousness could oscillate. His unconscious comprised those of his impulses which had been suppressed at an early age and which might be described as passionate and evil impulses. In his normal state he was kind, cheerful, and sensible - an enlightened and superior kind of person - while in his third psychological organization he paid homage to superstition and asceticism. Thus he was able to have two different creeds and two different outlooks upon life. This second preconscious personality comprised chiefly the reaction-formations against his repressed wishes, and it was easy to foresee that it would have swallowed up the normal personality if the illness had lasted much longer. I have at present an opportunity of studying a lady suffering severely from obsessional acts. She has become similarly disintegrated into an easy-going and lively personality and into an exceedingly gloomy and ascetic one. She puts forward the first of them as her official ego, while in fact she is dominated by the second. Both of these psychical organizations have access to her consciousness, but behind her ascetic personality may be discerned the unconscious part of her being - quite unknown to her and composed of ancient and long-repressed wishful impulses.

¹ The very high average of intellectual capacity among obsessional patients is probably also connected with this fact.
We must expressly insist that we have never reckoned Leonardo as a neurotic or a 'nerve case', as the awkward phrase goes. Anyone who protests at our so much as daring to examine him in the light of discoveries gained in the field of pathology is still clinging to prejudices which we have to-day rightly abandoned. We no longer think that health and illness, normal and neurotic people, are to be sharply distinguished from each other, and that neurotic traits must necessarily be taken as proofs of a general inferiority. To-day we know that neurotic symptoms are structures which are substitutes for certain achievements of repression that we have to carry out in the course of our development from a child to a civilized human being. We know too that we all produce such substitutive structures, and that it is only their number, intensity and distribution which justify us in using the practical concept of illness and in inferring the presence of constitutional inferiority. From the slight indications we have about Leonardo's personality we should be inclined to place him close to the type of neurotic that we describe as 'obsessional'; and we may compare his researches to the 'obsessive brooding' of neurotics, and his inhibitions to what are known as their 'abullas'.

In the many different forms of obsessional neurosis in particular, forgetting is mostly restricted to dissolving thought-connections, failing to draw the right conclusions and isolating memories.

First and foremost, the initiation of the treatment in itself brings about a change in the patient's conscious attitude to his illness. He has usually been content with lamenting it, despising it as nonsensical and under-estimating its importance; for the rest, he has extended to its manifestations the ostrich-like policy of repression which he adopted towards its origins. Thus it can happen that he does not properly know under what conditions his phobia breaks out or does not listen to the precise wording of his obsessional ideas or does not grasp the actual purpose of his obsessional impulse. The treatment, of course, is not helped by this. He must find the courage to direct his attention to the phenomena of his illness. His illness itself must no longer seem to him contemptible, but must become an enemy worthy of his mettle, a piece of his personality, which has solid ground for its existence and out of which things of value for his future life have to be derived. The way is thus paved from the beginning for a reconciliation with the repressed material which is coming to expression in his symptoms, while at the same time place is found for a certain tolerance for the state of being ill. If this new attitude towards the illness intensifies the conflicts and brings to the fore symptoms which till then had been indistinct, one can easily console the patient by pointing out that these are only necessary and temporary aggravations and that one cannot overcome an enemy who is absent or not within range. The resistance, however, may exploit the situation for its own ends and abuse the licence to be ill. It seems to say: 'See what happens if I really give way to such things. Was I not right to consign them to repression?' Young and childish people in particular are inclined to make the necessity imposed by the treatment for paying attention to their illness a welcome excuse for luxuriating in their symptoms.

A lady suffering from doubting mania and obsessive ceremonials insisted that her nurses should never let her out of their sight for a single moment: otherwise she would begin to brood about forbidden actions that she might have committed while she was not being watched. One evening, while she was resting on the sofa, she thought she saw that the nurse on duty had fallen asleep. She called out: 'Did you see me?' The nurse started up and replied: 'Of course I did.' This gave the patient grounds for a fresh doubt, and after a time she repeated her question, which the nurse met with renewed protestations; just at that moment another attendant came in bringing the patient's supper.
Let us now go back to the nurse’s dream, in order to demonstrate the quality of depth in the wish-fulfilment contained in it. We already know that the lady’s interpretation of the dream was by no means complete; there were portions of it to which she was unable to do justice. Moreover she suffered from an obsessional neurosis, a condition which, from what I have observed, makes it considerably harder to understand dream-symbols, just as dementia praecox makes it easier. [1913a, 2591]

Unfortunately I am unable, for familiar reasons, to enter into the history of the case as far as I should like, and I must restrict myself to the account which follows. Up to the time of her falling ill the patient had been a happy and almost completely satisfied wife. She wanted to have children, from motives based on an infantile fixation of her wishes, and she fell ill when she learned that it was impossible for her to have any by the husband who was the only object of her love. The anxiety hysteria with which she reacted to this frustration corresponded, as she herself soon learned to understand, to the repudiation of phantasies of seduction in which her firmly implanted wish for a child found expression. She now did all she could to prevent her husband from guessing that she had fallen ill owing to the frustration of which he was the cause. But I have had good reason for asserting that everyone possesses in his own unconscious an instrument with which he can interpret the utterances of the unconscious in other people. Her husband understood, without any admission or explanation on her part, what his wife’s anxiety meant; he felt hurt, without showing it, and in his turn reacted neurotically by - for the first time - failing in sexual intercourse with her. Immediately afterwards he started on a journey. His wife believed that he had become permanently impotent, and produced her first obsessional symptoms on the day before his expected return. [1913i, 2626]

The content of her obsessional neurosis was a compulsion for scrupulous washing and cleanliness and extremely energetic protective measures against severe injuries which she thought other people had reason to fear from her - that is to say, reaction-formations against her own anal-erotic and sadistic impulses. Her sexual need was obliged to find expression in these shapes after her genital life had lost all its value owing to the impotence of the only man of whom there could be any question for her. [1913i, 2626]

(d) Our hypothesis of a pregenital sexual organization is incomplete in two respects. In the first place, it takes no account of the behaviour of other component instincts, in regard to which there is plenty that would repay examination and discussion, and it is content with stressing the striking primacy of sadism and anal eroticism. In particular we often gain an impression that the instinct for knowledge can actually take the place of sadism in the mechanism of obsessional neurosis. Indeed it is at bottom a sublimated off-shoot of the instinct of mastery exalted into something intellectual, and its repudiation in the form of doubt plays a large part in the picture of obsessional neurosis. [1913i, 2630]
The second gap in our hypothesis is far more important. As we know, the developmental disposition to a neurosis is only complete if the phase of the development of the ego at which fixation occurs is taken into account as well as that of the libido. But our hypothesis has only related to the latter, and therefore does not include all the knowledge that we should demand. The stages of development of the ego-instincts are at present very little known to us; I know of only one attempt - the highly promising one made by Ferenczi (1913) - to approach these questions. I cannot tell if it may seem too rash if, on the basis of such indications as we possess, I suggest the possibility that a chronological outstripping of libidinal development by ego development should be included in the disposition to obsessional neurosis. A precocity of this kind would necessitate the choice of an object under the influence of the ego-instincts, at a time at which the sexual instincts had not yet assumed their final shape, and a fixation at the stage of the pregenital sexual organization would thus be left. If we consider that obsessional neurotics have to develop a super-morality in order to protect their object-love from the hostility lurking behind it, we shall be inclined to regard some degree of this precocity of ego development as typical of human nature and to derive the capacity for the origin of morality from the fact that in the order of development hate is the precursor of love. This is perhaps the meaning of an assertion by Stekel (1911a, 536), which at the time I found incomprehensible, to the effect that hate and not love is the primary emotional relation between men. [1913i, 2630]

Anyone approaching the problem of taboo from the angle of psycho-analysis, that is to say, of the investigation of the unconscious portion of the individual mind, will recognize, after a moment's reflection, that these phenomena are far from unfamiliar to him. He has come across people who have created for themselves individual taboo prohibitions of this very kind and who obey them just as strictly as savages obey the communal taboos of their tribe or society. If he were not already accustomed to describing such people as 'obsessional' patients, he would find 'taboo sickness' a most appropriate name for their condition. Having learnt so much, however, about this obsessional sickness from psycho-analytic examination - its clinical aetiology and the essence of its psychical mechanism - he can scarcely refrain from applying the knowledge he has thus acquired to the parallel sociological phenomenon. [1912-1913, 2674]

The most obvious and striking point of agreement between the obsessional prohibitions of neurotics and taboos is that these prohibitions are equally lacking in motive and equally puzzling in their origin. Having made their appearance at some unspecified moment, they are forcibly maintained by an irresistible fear. No external threat of punishment is required, for there is an internal certainty, a moral conviction, that any violation will lead to intolerable disaster. The most that an obsessional patient can say on this point is that he has an undefined feeling that some particular person in his environment will be injured as result of the violation. Nothing is known of the nature of the injury; and indeed even this wretchedly small amount of information is more often obtained in connection with the expiatory and defensive actions which we shall have to discuss later than with the prohibitions themselves. [1912-1913, 2674]

As in the case of taboo, the principal prohibition, the nucleus of the neurosis, is against touching; and thence it is sometimes known as 'touching phobia' or 'délire du toucher'. The prohibition does not merely apply to immediate physical contact but has an extent as wide as the metaphorical use of the phrase 'to come in contact with'. Anything that directs the patient's thoughts to the forbidden object, anything that brings him into intellectual contact with it, is just as much prohibited as direct physical contact. This same extension also occurs in the case of taboo. [1912-1913, 2675]
Obsessional prohibitions involve just as extensive renunciations and restrictions in the lives of those who are subject to them as do taboo prohibitions; but some of them can be lifted if certain actions are performed. Thereafter, these actions must be performed: they become compulsive or obsessive acts, and there can be no doubt that they are in the nature of expiation, penance, defensive measures and purification. The commonest of these obsessive acts is washing in water (‘washing mania’). Some taboo prohibitions can be replaced in just the same way; or rather their violation can be made good by a similar ‘ceremonial’; and here again lustration with water is the preferred method.

[1912-1913, 2676]

Let us now summarize the points in which agreement between taboo usages and obsessional symptoms is most clearly shown: (1) the fact that the prohibitions lack any assignable motive; (2) the fact that they are maintained by an internal necessity; (3) the fact that they are easily displaceable and that there is a risk of infection from the prohibited object; and (4) the fact that they give rise to injunctions for the performance of ceremonial acts.

[1912-1913, 2676]

Now both the clinical history and the psychical mechanism of obsessional neurosis have become known to us through psycho-analysis. The clinical history of a typical case of ‘touching phobia’ is as follows. Right at the beginning, in very early childhood, the patient shows a strong desire to touch, the aim of which is of a far more specialized kind that one would have been inclined to expect. This desire is promptly met by an external prohibition against carrying out that particular kind of touching.¹ The prohibition is accepted, since it finds support from powerful internal forces,² and proves stronger than the instinct which is seeking to express itself in the touching. In consequence, however, of the child’s primitive psychical constitution, the prohibition does not succeed in abolishing the instinct. Its only result is to repress the instinct (the desire to touch) and banish it into the unconscious. Both the prohibition and the instinct persist: the instinct because it has only been repressed and not abolished, and the prohibition because, if it ceased, the instinct would force its way through into consciousness and into actual operation. A situation is created which remains undealt with - a psychical fixation - and everything else follows from the continuing conflict between the prohibition and the instinct.

[1912-1913, 2677]

There is also another path open to us. We can start an inquiry as to whether some of the hypotheses which we have carried over from neuroses to taboo or some of the results to which that procedure has led us may not be directly verifiable in the phenomena of taboo. But we must decide what we are to look for. Our assertion that taboo originated in a primaeval prohibition imposed at one time or other by some external authority is obviously incapable of demonstration. What we shall rather endeavour to confirm, therefore, are the psychological determinants of taboo, which we have learnt to know from obsessional neurosis. How did we arrive at our knowledge of these psychological factors in the case of the neurosis? Through the analytical study of its symptoms, and particularly of obsessional acts, defensive measures and obsessional commands. We found that they showed every sign of being derived from ambivalent impulses, either corresponding simultaneously to both a wish and a counter-wish or operating predominantly on behalf of one of the two opposing trends. If, now, we could succeed in demonstrating that ambivalence, that is, the dominance of opposing trends, is also to be found in the observances of taboo, or if we could point to some of them which, like obsessional acts, give simultaneous expression to both currents, we should have established the psychological agreement between taboo and obsessional neurosis in what is perhaps their most important feature.

[1912-1913, 2683]
So far so good; but the technique of psycho-analysis allows us to go into the question further and to enter more into the details of these various impulses. If we submit the recorded facts to analysis, as though they formed part of the symptoms presented by a neurosis, our starting-point must be the excessive apprehensiveness and solicitude which is put forward as the reason for the taboo ceremonials. The occurrence of excessive solicitude of this kind is very common in neuroses, and especially in obsessional neuroses, with which our comparison is chiefly drawn. We have come to understand its origin quite clearly. It appears wherever, in addition to a predominant feeling of affection, there is also a contrary, but unconscious, current of hostility - a state of affairs which represents a typical instance of an ambivalent emotional attitude. The hostility is then shouted down, as it were, by an excessive intensification of the affection, which is expressed as solicitude and becomes compulsive, because it might otherwise be inadequate to perform its task of keeping the unconscious contrary current of feeling under repression. Every psycho-analyst knows from experience with what certainty this explanation of solicitous over-affection is found to apply even in the most unlikely circumstances - in cases, for instance, of attachments between a mother and child or between a devoted married couple. If we now apply this to the case of privileged persons, we shall realize that alongside the veneration, and indeed idolization, felt towards them, there is in the unconscious an opposing current of intense hostility; that, in fact, as we expected, we are faced by a situation of emotional ambivalence. The distrust which provides one of the unmistakable elements in kingly taboos would thus be another, more direct, expression of the same unconscious hostility. Indeed, owing to the variety of outcomes of a conflict of this kind which are reached among different peoples, we are not at a loss for examples in which the existence of this hostility is still more obviously shown. 'The savage Timmes of Sierra Leone', we learn from Frazer, 'who elect their king, reserve to themselves the right of beating him on the eve of his coronation; and they avail themselves of this constitutional privilege with such hearty goodwill that sometimes the unhappy monarch does not long survive his elevation to the throne. Hence when the leading chiefs have a spite at a man and wish to rid themselves of him, they elect him king.' Even in glaring instances like this, however, the hostility is not admitted as such, but masquerades as a ceremonial.

[1912-1913, 2695]

As was only to be expected, obsessional neurotics behave exactly like savages in relation to names. Like other neurotics, they show a high degree of 'complexive sensitiveness' in regard to uttering or hearing particular words and names; and their attitude towards their own names imposes numerous, and often serious, inhibitions upon them. One of these taboo patients of my acquaintance had adopted a rule against writing her own name, for fear that it might fall into the hands of someone who would then be in possession of a portion of her personality. She was obliged to fight with convulsive loyalty against the temptations to which her imagination subjected her, and so forbade herself 'to surrender any part of her person'. This included in the first place her name, and later extended to her handwriting, till finally she gave up writing altogether.

[1912-1913, 2700]
When a wife has lost her husband or a daughter her mother, it not infrequently happens that the survivor is overwhelmed by tormenting doubts (to which we give the name of 'obsessive self-reproaches') as to whether she may not herself have been responsible for the death of this cherished being through some act of carelessness or neglect. No amount of recollection of the care she lavished on the sufferer, no amount of objective disproof of the accusation, serves to bring the torment to an end. It may be regarded as a pathological form of mourning, and with the passage of time it gradually dies away. The psycho-analytic investigation of such cases has revealed the secret motives of the disorder. We find that in a certain sense these obsessive self-reproaches are justified, and that this is why they are proof against contradictions and protests. It is not that the mourner was really responsible for the death or was really guilty of neglect, as the self-reproaches declare to be the case. None the less there was something in her - a wish that was unconscious to herself - which would not have been dissatisfied by the occurrence of death and which might actually have brought it about if it had had the power. And after death has occurred, it is against this unconscious wish that the reproaches are a reaction. In almost every case where there is an intense emotional attachment to a particular person we find that behind the tender love there is a concealed hostility in the unconscious. This is the classical example, the prototype, of the ambivalence of human emotions. This ambivalence is present to a greater or less amount in the innate disposition of everyone; normally, there is not so much of it as to produce the obsessive self-reproaches we are considering. Where, however, it is copiously present in the disposition, it will manifest itself precisely in the subject's relation to those of whom he is most fond, in the place, in fact, where one would least expect to find it. It must be supposed that the presence of a particularly large amount of this original emotional ambivalence is characteristic of the disposition of obsessional neurotics - whom I have so often brought up for comparison in this discussion upon taboo. [1912-1913, 2704]

We have now discovered a motive which can explain the idea that the souls of those who have just died are transformed into demons and the necessity felt by survivors to protect themselves by taboos against their hostility. Let us suppose that the emotional life of primitive peoples is characterized by an amount of ambivalence as great as that which we are led by the findings of psycho-analysis to attribute to obsessional patients. It then becomes easy to understand how after a painful bereavement savages should be obliged to produce a reaction against the hostility latent in their unconscious similar to that expressed as obsessive self-reproach in the case of neurotics. But this hostility, distressingly felt in the unconscious as satisfaction over the death, is differently dealt with among primitive peoples. The defence against it takes the form of displacing it on to the object of the hostility, on to the dead themselves. This defensive procedure, which is a common one both in normal and in pathological mental life, is known as a 'projection'. The survivor thus denies that he has ever harboured any hostile feelings against the dead loved one; the soul of the dead harbours them instead and seeks to put them into action during the whole period of mourning. In spite of the successful defence which the survivor achieves by means of projection, his emotional reaction shows the characteristics of punishment and remorse, for he is the subject of fears and submits to renunciations and restrictions, though these are in part disguised as measures of protection against the hostile demon. Once again, therefore, we find that the taboo has grown up on the basis of an ambivalent emotional attitude. The taboo upon the dead arises, like the others, from the contrast between conscious pain and unconscious satisfaction over the death that has occurred. Since such is the origin of the ghost's resentment, it follows naturally that the survivors who have the most to fear will be those who were formerly its nearest and dearest. [1912-1913, 2705]
In the first place, we have found that a feature in the character of obsessional neurotics is a scrupulous conscientiousness which is a symptom reacting against the temptation lurking in their unconscious. If their illness becomes more acute, they develop a sense of guilt of the most intense degree. In fact, one may venture to say that if we cannot trace the origin of the sense of guilt in obsessional neurotics, there can be no hope of our ever tracing it. This task can be directly achieved in the case of individual neurotic patients, and we may rely upon reaching a similar solution by inference in the case of primitive peoples.

Once again I will take a single fact as my starting-point. It is feared among primitive peoples that the violation of a taboo will be followed by a punishment, as a rule by some serious illness or by death. The punishment threatens to fall on whoever was responsible for violating the taboo. In obsessional neuroses the case is different. What the patient fears if he performs some forbidden action is that a punishment will fall not on himself but on someone else. This person's identity is as a rule left unstated, but can usually be shown without difficulty by analysis to be one of those closest and most dear to the patient. Here, then, the neurotic seems to be behaving altruistically and the primitive man egoistically. Only if the violation of a taboo is not automatically avenged upon the wrong-doer does a collective feeling arise among savages that they are all threatened by the outrage; and they thereupon hasten to carry out the omitted punishment themselves. There is no difficulty in explaining the mechanism of this solidarity. What is in question is fear of an infectious example, of the temptation to imitate - that is, of the contagious character of taboo. If one person succeeds in gratifying the repressed desire, the same desire is bound to be kindled in all the other members of the community. In order to keep the temptation down, the envied transgressor must be deprived of the fruit of his enterprise; and the punishment will not infrequently give those who carry it out an opportunity of committing the same outrage under colour of an act of expiation. This is indeed one of the foundations of the human penal system and it is based, no doubt correctly, on the assumption that the prohibited impulses are present alike in the criminal and in the avenging community. In this, psycho-analysis is no more than confirming the habitual pronouncement of the pious: we are all miserable sinners.

How, then, are we to account for the unexpected nobility of mind of the neurotic, who fears nothing on his own account but everything for someone he loves? Analytical inquiry shows that this attitude is not primary. Originally, that is to say at the beginning of the illness, the threat of punishment applied, as in the case of savages, to the patient himself; he was invariably in fear for his own life; it was not until later that the mortal fear was displaced on to another and a loved person. The process is a little complicated, but we can follow it perfectly. At the root of the prohibition there is invariably a hostile impulse against someone the patient loves - a wish that that person should die. This impulse is repressed by a prohibition and the prohibition is attached to some particular act, which, by displacement, represents, it may be, a hostile act against the loved person. There is a threat of death if this act is performed. But the process goes further, and the original wish that the loved person may die is replaced by fear that he may die. So that when the neurosis appears to be so tenderly altruistic, it is merely compensating for an underlying contrary attitude of brutal egoism. We may describe as 'social' the emotions which are determined by showing consideration for another person without taking him as a sexual object. The receding into the background of these social factors may be stressed as a fundamental characteristic of the neurosis, though one which is later disguised by overcompensation.

[1912-1913, 2712]

[1912-1913, 2715]

[1912-1913, 2716]
I have adopted the term 'omnipotence of thoughts' from a highly intelligent man who suffered from obsessional ideas and who, after having been set right by psycho-analytic treatment, was able to give evidence of his efficiency and good sense. (Cf. Freud, 1909d.) He had coined the phrase as an explanation of all the strange and uncanny events by which he, like others afflicted with the same illness, seemed to be pursued. If he thought of someone, he would be sure to meet that very person immediately afterwards, as though by magic. If he suddenly asked after the health of an acquaintance whom he had not seen for a long time, he would hear that he had just died, so that it would look as though a telepathic message had arrived from him. If, without any really serious intention, he swore at some stranger, he might be sure that the man would die soon afterwards, so that he would feel responsible for his death. In the course of the treatment he himself was able to tell me how the deceptive appearance arose in most of these cases, and by what contrivances he himself had helped to strengthen his own superstitious beliefs. All obsessional neurotics are superstitious in this way, usually against their better judgement.

It is in obsessional neuroses that the survival of the omnipotence of thoughts is most clearly visible and that the consequences of this primitive mode of thinking come closest to consciousness. But we must not be misled into supposing that it is a distinguishing feature of this particular neurosis, for analytic investigation reveals the same thing in the other neuroses as well. In all of them what determines the formation of symptoms is the reality not of experience but of thought. Neurotics live in a world apart, where, as I have said elsewhere, only 'neurotic currency' is legal tender; that is to say, they are only affected by what is thought with intensity and pictured with emotion, whereas agreement with external reality is a matter of no importance. What hysterics repeat in their attacks and fix by means of their symptoms are experiences which have occurred in that form only in their imagination though it is true that in the last resort those imagined experiences go back to actual events or are based upon them. To attribute the neurotic sense of guilt to real misdeeds would show an equal misunderstanding. An obsessional neurotic may be weighed down by a sense of guilt that would be appropriate in a mass-murderer, while in fact, from his childhood onwards, he has behaved to his fellow-men as the most considerate and scrupulous member of society. Nevertheless, his sense of guilt has a justification: it is founded on the intense and frequent death wishes against his fellows which are unconsciously at work in him. It has a justification if what we take into account are unconscious thoughts and not intentional deeds. Thus the omnipotence of thoughts, the overvaluation of mental processes as compared with reality, is seen to have unrestricted play in the emotional life of neurotic patients and in everything that derives from it. If one of them undergoes psycho-analytic treatment, which makes what is unconscious in him conscious, he will be unable to believe that thoughts are free and will constantly be afraid of expressing evil wishes, as though their expression would lead inevitably to their fulfilment. This behaviour, as well as the superstitions which he practises in ordinary life, reveals his resemblance to the savages who believe they can alter the external world by mere thinking.
The primary obsessive acts of these neurotics are of an entirely magical character. If they are not charms, they are at all events counter-charms, designed to ward off the expectations of disaster with which the neurosis usually starts. Whenever I have succeeded in penetrating the mystery, I have found that the expected disaster was death. Schopenhauer has said that the problem of death stands at the outset of every philosophy; and we have already seen that the origin of the belief in souls and in demons, which is the essence of animism, goes back to the impression which is made upon men by death. It is difficult to judge whether the obsessive or protective acts performed by obsessional neurotics follow the law of similarity (or, as the case may be, of contrast); for as a rule, owing to the prevailing conditions of the neurosis, they have been distorted by being displaced on to something very small, some action in itself of the greatest triviality.¹ The protective formulas of obsessional neuroses, too, have their counterpart in the formulas of magic. It is possible, however, to describe the course of development of obsessive acts: we can show how they begin by being as remote as possible from anything sexual - magical defences against evil wishes - and how they end by being substitutes for the forbidden sexual act and the closest possible imitations of it.

[1912-1913, 2730]

The secondary revision of the product of the dream-work is an admirable example of the nature and pretensions of a system. There is an intellectual function in us which demands unity, connection and intelligibility from any material, whether of perception or thought, that comes within its grasp; and if, as a result of special circumstances, it is unable to establish a true connection, it does not hesitate to fabricate a false one. Systems constructed in this way are known to us not only from dreams, but also from phobias, from obsessive thinking and from delusions. The construction of systems is seen most strikingly in delusional disorders (in paranoia), where it dominates the symptomatic picture; but its occurrence in other forms of neuro-psychosis must not be overlooked. In all these cases it can be shown that a rearrangement of the psychical material has been made with a fresh aim in view; and the rearrangement may often have to be a drastic one if the outcome is to be made to appear intelligible from the point of view of the system. Thus a system is best characterized by the fact that at least two reasons can be discovered for each of its products: a reason based upon the premises of the system (a reason, then, which may be delusional) and a concealed reason, which we must judge to be the truly operative and the real one.

[1912-1913, 2737]
This may be illustrated by an example from a neurosis. In my essay on taboo I mentioned a woman patient of mine whose obsessional prohibitions showed the most perfect agreement with a Maori taboo (p. 2676). This woman's neurosis was aimed at her husband and culminated in her defence against an unconscious wish that he should die. Her manifest, systematic phobia, however, related to the mention of death in general, while her husband was entirely excluded from it and was never an object of her conscious solicitude. One day she heard her husband giving instructions that his razors, which had lost their edge, were to be taken to a particular shop to be re-set. Driven by a strange uneasiness, she herself set off for the shop. After reconnoitring the ground, she came back and insisted that her husband should get rid of the razors for good and all, since she had discovered that next door to the shop he had named there was an undertaker's establishment: owing to the plan he had made, she said, the razors had become inextricably involved with thoughts of death. This, then, was the systematic reason for her prohibition. We may be quite sure that, even without her discovery of the next-door shop, the patient would have come home with a prohibition against the razors. It would have been enough if she had met a hearse on her way to the shop, or someone dressed in mourning or carrying a funeral wreath. The net of possible determinants for the prohibition was spread wide enough to catch the quarry in any event; it merely depended on her decision whether to draw it together or not. It could be shown that on other occasions she would not put the determinants into operation, and she would explain this by saying it had been 'a better day'. The real cause of her prohibition upon the razors was, of course, as it was easy to discover, her repugnance to attaching any pleasurable feeling to the idea that her husband might cut his throat with the newly ground razors.

[1912-1913, 2738]

Here we are faced by a decision which is indeed no easy one. First, however, it must be confessed that the distinction, which may seem fundamental to other people, does not in our judgement affect the heart of the matter. If wishes and impulses have the full value of facts for primitive men, it is our business to give their attitude our understanding attention instead of correcting it in accordance with our own standards. Let us, then, examine more closely the case of neurosis - comparison with which led us into our present uncertainty. It is not accurate to say that obsessional neurotics, weighed down under the burden of an excessive morality, are defending themselves only against psychical reality and are punishing themselves for impulses which were merely felt. Historical reality has a share in the matter as well. In their childhood they had these evil impulses pure and simple, and turned them into acts so far as the impotence of childhood allowed. Each of these excessively virtuous individuals passed though an evil period in his infancy - a phase of perversion which was the forerunner and precondition of the later period of excessive morality. The analogy between primitive men and neurotics will therefore be far more fully established if we suppose that in the former instance, too, psychical reality - as to the form taken by which we are in no doubt - coincided at the beginning with factual reality: that primitive men actually did what all the evidence shows that they intended to do.

[1912-1913, 2799]
There are a large number of phenomena related to facial and other expressive movements and to speech, as well as many processes of thought (both in normal and sick people), which have hitherto escaped the notice of psychology because they have been regarded as no more than the results of organic disorder or of some abnormal failure in function of the mental apparatus. What I have in mind are 'parapraxes' (slips of the tongue or pen, forgetfulness, etc.), haphazard actions and dreams in normal people, and convulsive attacks, deliria, visions, and obsessive ideas or acts in neurotic subjects. These phenomena (in so far as they were not entirely neglected, as was the case with the parapraxes) were relegated to pathology and an attempt was made to find 'physiological' explanations of them, though these were invariably unsatisfactory. Psycho-analysis, on the contrary, has been able to show that all these things can be explained by means of hypotheses of a purely psychological nature and can be fitted into the chain of psychical events already known to us. Thus on the one hand psycho-analysis has narrowed the region subject to the physiological point of view and on the other hand has brought a large section of pathology into the sphere of psychology. In this instance the normal phenomena provide the more convincing evidence. Psycho-analysis cannot be accused of having applied to normal cases findings arrived at from pathological material. The evidence in the latter and in the former was reached independently and shows that normal processes and what are described as pathological ones follow the same rules.

In another neurotic disorder, obsessional neurosis, the patients become the victims of distressing and apparently senseless ceremonials which take the form of the rhythmical repetition of the most trivial acts (such as washing or dressing) or of carrying out meaningless injunctions or of obeying mysterious prohibitions. It was nothing less than a triumph of psycho-analytic research when it succeeded in showing that all these obsessive acts, even the most insignificant and trivial of them, have a meaning, and that they are reflections, translated into indifferent terms, of conflicts in the patients' lives, of the struggle between temptations and moral restraints - reflections of the proscribed wish itself and of the punishment and atonement which that wish incurs. In another form of the same disorder the victim suffers from tormenting ideas (obsessions) which force themselves upon him and are accompanied by affects whose character and intensity are often only quite inadequately accounted for by the terms of the obsessive ideas themselves. Analytic investigation has shown in their case that the affects are entirely justified, since they correspond to self-reproaches which are based on something that is at least psychically real. But the ideas to which these affects are attached are not the original ones, but have found their way into their present position by a process of displacement - by being substituted for something that has been repressed. If these displacements can be reversed, the way is open to the discovery of the repressed ideas, and the relation between affect and idea is found to be perfectly appropriate.
Before we draw any conclusion from impressions such as these, let us consider further the distinctions between the formation of substitutes in schizophrenia on the one hand, and in hysteria and obsessional neurosis on the other - subtle distinctions which nevertheless make a strange impression. A patient whom I have at present under observation has allowed himself to be withdrawn from all the interests of life on account of a bad condition of the skin of his face. He declares that he has black heads and deep holes in his face which everyone notices. Analysis shows that he is playing out his castration complex upon his skin. At first he worked at these blackheads remorselessly; and it gave him great satisfaction to squeeze them out, because, as he said, something spurted out when be did so. Then he began to think that a deep cavity appeared wherever he had got rid of a blackhead, and he reproached himself most vehemently with having ruined his skin for ever by 'constantly fiddling about with his hand'. Pressing out the content of the blackheads is clearly to him a substitute for masturbation. The cavity which then appears owing to his fault is the female genital, i.e. the fulfilment of the threat of castration (or the phantasy representing that threat) provoked by his masturbating. This substitutive formation has, in spite of its hypochondriacal character, considerable resemblance to a hysterical conversion; and yet we have a feeling that something different must be going on here, that a substitutive formation such as this cannot be attributed to hysteria, even before we can say in what the difference consists. A tiny little cavity such as a pore of the skin would hardly be used by a hysteric as a symbol for the vagina, which he is otherwise ready to compare with every imaginable object that encloses a hollow space. Besides, we should expect the multiplicity of these little cavities to prevent him from using them as a substitute for the female genital. The same applies to the case of a young patient reported by Tausk some years ago to the Vienna Psycho-Analytical Society. This patient behaved in other respects exactly as though he were suffering from an obsessional neurosis; he took hours to wash and dress, and so on. It was noticeable, however, that he was able to give the meaning of his inhibitions without any resistance. In putting on his stockings, for instance, he was disturbed by the idea that he must pull apart the stitches in the knitting, i.e. the holes, and to him every hole was a symbol of the female genital aperture. This again is a thing which we cannot attribute to an obsessional neurotic. Reitler observed a patient of the latter sort, who also suffered from having to take a long time over putting on his stockings; this man, after overcoming his resistances, found as the explanation that his foot symbolized a penis, that putting on the stocking stood for a masturbatory act, and that he had to keep on pulling the stocking on and off, partly in order to complete the picture of masturbation, and partly in order to undo that act.

It will help to explain this more than usually absurd symptom if I mention that the patient, who was a man of fully developed intellect and high moral ideals, manifested a very lively anal erotism in the most various ways until after his tenth year. After this had been got over, his sexual life was once again forced back to the preliminary anal stage by his later struggle against genital erotism. He loved and respected his father greatly, and also feared him not a little; judged by his own high standards in regard to asceticism and the suppression of the instincts, however, his father seemed to him a person who stood for debauchery and the pursuit of enjoyment in material things.
This neurosis, known as 'obsessional neurosis', is not so popular as the universally familiar hysteria. It is not, if I may express myself thus, so obtrusively noisy, it behaves more like a private affair of the patient's, it dispenses almost entirely with somatic phenomena, and creates all its symptoms in the mental sphere. Obsessional neurosis and hysteria are the forms of neurotic illness upon the study of which psycho-analysis was first built, and in the treatment of which, too, our therapy celebrates its triumphs. But obsessional neurosis, in which the puzzling leap from the mental to the physical plays no part, has actually, through the efforts of psycho-analysis, become more perspicuous and familiar to us than hysteria, and we have learnt that it displays certain extreme characteristics of the nature of neurosis far more glaringly. [1916-1917, 3339]

Obsessional neurosis is shown in the patient's being occupied with thoughts in which he is in fact not interested, in his being aware of impulses in himself which appear very strange to him and in his being led to actions the performance of which give him no enjoyment, but which it is quite impossible for him to omit. The thoughts (obsessions) may be senseless in themselves, or merely a matter of indifference to the subject; often they are completely silly, and invariably they are the starting-point of a strenuous mental activity, which exhausts the patient and to which he only surrenders himself most unwillingly. He is obliged against his will to brood and speculate as though it were a question of his most important vital problems. The impulses which the patient is aware of in himself may also make a childish and senseless impression; but as a rule they have a content of the most frightful kind, tempting him, for instance, to commit serious crimes, so that he not merely disavows them as alien to himself, but flies from them in horror and protects himself from carrying them out by prohibitions, renunciations and restrictions upon his freedom. At the same time, these impulses never - literally never - force their way through to performance; the outcome lies always in victory for the flight and the precautions. What the patient actually carries out - his so called obsessional actions - are very harmless and certainly trivial things, for the most part repetitions or ceremonial elaborations of the activities of ordinary life. But these necessary activities (such as going to bed, washing, dressing or going for a walk) become extremely tedious and almost insoluble tasks. In different forms and cases of obsessional neurosis the pathological ideas, impulses and actions are not combined in equal proportions; it is the rule, rather, that one or other of these factors dominates the picture and gives its name to the illness, but the common element in all these forms is sufficiently unmistakable. [1916-1917, 3339]
Certainly this is a crazy illness. The most extravagant psychiatric imagination would not, I think, have succeeded in constructing anything like it; and if one did not see it before one every day one would never bring oneself to believe in it. Do not suppose, however, that you will help the patient in the least by calling on him to take a new line, to cease to occupy himself with such foolish thoughts and to do something sensible instead of his childish pranks. He would like to do so himself, for he is completely clear in his head, shares your opinion of his obsessional symptoms and even puts it forward to you spontaneously. Only he cannot help himself. What is carried into action in an obsessional neurosis is sustained by an energy to which we probably know nothing comparable in normal mental life. There is only one thing he can do: he can make displacements, and exchanges, he can replace one foolish idea by another somewhat milder, he can proceed from one precaution or prohibition to another, instead of one ceremonial he can perform another. He can displace the obsession but not remove it. The ability to displace any symptom into something far removed from its original conformation is a main characteristic of his illness. Moreover it is a striking fact that in his condition the contradictions (polarities) with which mental life is interlaced emerge especially sharply differentiated. Alongside of obsessions with a positive and negative content, doubt makes itself felt in the intellectual field and little by little it begins to gnaw even at what is usually most certain. The whole position ends up in an ever-increasing degree of indecision, loss of energy and restriction of freedom. At the same time, the obsessional neurotic starts off with a very energetic disposition, he is often extraordinarily self-willed and as a rule he has intellectual gifts above the average. He has usually reached a satisfactorily high level of ethical development; he exhibits over-conscientiousness, and is more than ordinarily correct in his behaviour. You can imagine that no small amount of work is needed before one can make one's way any distance into this contradictory hotch-potch of character-traits and symptoms. And to begin with we aim at nothing whatever else than understanding a few of the symptoms and being able to interpret them.

[1916-1917, 3340]
A lady, nearly thirty years of age, who suffered from the most severe obsessional manifestations and whom I might perhaps have helped if a malicious chance had not brought my work to nothing - I may be able to tell you more about this later on - performed (among others) the following remarkable obsessional action many times a day. She ran from her room into another neighbouring one, took up a particular position there beside a table that stood in the middle, rang the bell for her housemaid, sent her on some indifferent errand or let her go without one, and then ran back into her own room. This was certainly not a very distressing symptom, but was nevertheless calculated to excite curiosity. The explanation was reached in the most unequivocal and unobjectionable manner, free from any possible contribution on the doctor's part. I cannot see how I could possibly have formed any suspicion of the sense of this obsessional action or could have offered any suggestion on how it was to be interpreted. Whenever I asked the patient ‘Why do you do that? What sense has it?’ she answered: ‘I don’t know.’ But one day, after I had succeeded in defeating a major, fundamental doubt of hers, she suddenly knew the answer and told me what it was that was connected with the obsessional action. More than ten years before, she had married a man very much older than herself, and on the wedding-night he was impotent. Many times during the night he had come running from his room into hers to try once more, but every time without success. Next morning he had said angrily: ‘I should feel ashamed in front of the housemaid when she makes the bed,’ took up a bottle of red ink that happened to be in the room and poured its contents over the sheet, but not on the exact place where a stain would have been appropriate. I could not understand at first what this recollection had to do with the obsessional action in question; the only resemblance I could find was in the repeated running from one room into the other, and perhaps also in the entrance of the housemaid. My patient then led me up to the table in the second room and showed me a big stain on the tablecloth. She further explained that she took up her position in relation to the table in such a way that the maid who had been sent for could not fail to see the stain. There could no longer be any doubt of the intimate connection between the scene on her wedding-night and her present obsessional action, though all kinds of other things remained to be learnt.

[1916-1917, 3342]

And one thing more. Were you not struck by the way in which this unobtrusive obsessional action has led us into the intimacies of the patient's life? A woman cannot have anything much more intimate to tell than the story of her wedding-night. Is it a matter of chance and of no further significance that we have arrived precisely at the intimacies of sexual life? No doubt it might be the result of the choice I have made on this occasion. Do not let us be too hasty in forming our judgement, and let us turn to my second example, which is of quite a different kind - a sample of a very common species, a sleep-ceremonial.

[1916-1917, 3344]
A nineteen-year-old girl, well developed and gifted, was the only child of parents to whom she was superior in education and intellectual liveliness. As a child she had been wild and high spirited, and in the course of the last few years had changed, without any visible cause, into a neurotic. She was very irritable, particularly towards her mother, always dissatisfied and depressed, and inclined to indecisiveness and doubt; finally she admitted that she was no longer able to walk by herself across squares or along comparatively wide streets. We will not concern ourselves much with her complicated illness, which called for at least two diagnoses - agoraphobia and obsessional neurosis - but will dwell only on the fact that she also developed a sleep-ceremonial, with which she tormented her parents. In a certain sense it may be said that every normal person has his sleep-ceremonial or that he has established certain necessary conditions the non-fulfilment of which interferes with his going to sleep; he has imposed certain forms on the transition from the waking to the sleeping state and repeats them in the same manner every evening. But everything that a healthy person requires as a necessary condition for sleep can be understood rationally, and if external circumstances call for a change he will comply easily and without waste of time. A pathological ceremonial, however, is unyielding and insists on being carried through, even at the cost of great sacrifices; it too is screened by having a rational basis and at a superficial glance seems to diverge from the normal only by a certain exaggerated meticulousness. On closer examination, nevertheless, we can see that the screen is insufficient, that the ceremonial comprises some stipulations which go far beyond its rational basis and others which positively run counter to it. Our present patient put forward as a pretext for her nightly precautions that she needed quiet in order to sleep and must exclude every source of noise. With that end in view she did two kinds of things. The big clock in her room was stopped, all the other clocks or watches in the room were removed, and her tiny wrist-watch was not allowed even to be inside her bedside table. Flower-pots and vases were collected on the writing-table so that they might not fall over in the night and break, and disturb her in her sleep. She was aware that these measures could find only an ostensible justification in the rule in favour of quiet: the ticking of the little watch would not have been audible even if it had been left lying on the top of the bedside table, and we have all had experience of the fact that the regular ticking of a pendulum-clock never disturbs sleep but acts, rather, as a soporific. She admitted too that her fear that flower-pots and vases, if they were left in their places, might fall over and break of their own accord lacked all plausibility. In the case of other stipulations made by the ceremonial the need for quiet was dropped as a basis. Indeed, the requirement that the door between her room and her parents' bedroom should stay half-open - the fulfilment of which she ensured by placing various objects in the open doorway - seemed on the contrary to act as a source of disturbing noises. But the most important stipulations related to the bed itself. The pillow at the top end of the bed must not touch the wooden back of the bedstead. The small top pillow must lie on this large pillow in one specific way only - namely, so as to form a diamond shape. Her head had then to lie exactly along the long diameter of the diamond. The eiderdown (or 'Duchent' as we call it in Austria) had to be shaken before being laid on the bed so that its bottom end became very thick; afterwards, however, she never failed to even out this accumulation of feathers by pressing them apart.

With your leave I will pass over the remaining, often very trivial, details of the ceremonial; they would teach us nothing new, and would lead us too far afield from our aims. But you must not overlook the fact that all this was not carried out smoothly. There was always an apprehension that things might not have been done properly. Everything must be checked and repeated, doubts assailed first one and then another of the safety measures, and the result was that one or two hours were spent, during which the girl herself could not sleep and would not allow her intimidated parents to sleep either.

[1916-1917, 3345]
If any of you undertakes exertions of this kind, he will certainly gain a powerful impression of the wealth of evidential material. But he will also come up against a difficulty. The sense of a symptom lies, as we have found, in some connection with the patient's experience. The more individual is the form of the symptom the more reason we shall have for expecting to be able to establish this connection. The task is then simply to discover, in respect to a senseless idea and a pointless action, the past situation in which the idea was justified and the action served a purpose. The obsessional action of our patient who ran to the table and rang for the housemaid is a perfect model of this kind of symptom. But there are - and they are very frequent symptoms of quite another character. They must be described as 'typical' symptoms of an illness; they are approximately the same in all cases, individual distinctions disappear in them or at least shrink up to such an extent that it is difficult to bring them into connection with the patients' individual experience and to relate them to particular situations they have experienced. Let us look once more at obsessional neurosis. The sleep-ceremonial of our second patient already has much that is typical about it, though at the same time it has enough individual traits to make what I might call a 'historical' interpretation possible. But all these obsessional patients have a tendency to repeat, to make their performances rhythmical and to keep them isolated from other actions. The majority of them wash too much. Patients who suffer from agoraphobia (topophobia or fear of spaces), which we no longer regard as obsessional neurosis but describe as 'anxiety hysteria', often repeat the same features in their symptoms with wearisome monotony: they are afraid of enclosed spaces, of large open squares, of lengthy roads and streets. They feel protected if they are accompanied by an acquaintance or followed by a vehicle, and so on. On this similar background, however, different patients nevertheless display their individual requirements - whims, one is inclined to say - which in some cases contradict one another directly. One patient avoids only narrow streets and another only wide ones; one can go out only if there are few people in the street, another only if there are many. In the same way, hysteria, in spite of its wealth of individual traits, has a superfluity of common, typical symptoms, which seem to resist any easy historical derivation. And we must not forget that it is these typical symptoms, indeed, which give us our bearings when we make our diagnosis. Suppose, in a case of hysteria, we have really traced a typical symptom back to an experience or a chain of similar experiences - a case of hysterical vomiting, for instance, to a series of disgusting impressions - then we are at a loss when the analysis in a similar case of vomiting reveals a series of a quite different kind of ostensibly effective experiences. It looks, then, as though for unknown reasons hysterical patients are bound to produce vomiting and as though the historical precipitating causes revealed by analysis were only pretexts which, if they happen to be there, are exploited by this internal necessity.

[1916-1917, 3349]
So we are now faced by the depressing discovery that, though we can give a satisfactory explanation of the individual neurotic symptoms by their connection with experiences, our skill leaves us in the lurch when we come to the far more frequent typical symptoms. Furthermore, I am far from having made you acquainted with all the difficulties that arise when consistently pursuing the historical interpretation of symptoms. Nor do I intend to do so; for, though it is my intention not to gloss things over to you or conceal them, I cannot throw you into perplexity and confusion at the very beginning of our common studies. It is true that we have only made a beginning with our efforts at understanding the significance of symptoms; but we will hold fast to what we have achieved and pursue our way step by step to a mastery of what we have not yet understood. I will try to console you, therefore, with the reflection that any fundamental distinction between one kind of symptom and the other is scarcely to be assumed. If the individual symptoms are so unmistakably dependent on the patient's experience, it remains possible that the typical symptoms may go back to an experience which is in itself typical - common to all human beings. Other features which recur regularly in neuroses may be general reactions which are imposed on the patients by the nature of their pathological change, like the repetitions or doubts in obsessional neurosis. In short, we have no grounds for premature despair; we shall see what remains to be seen.

[1916-1917, 3350]

Let us turn now to the second of the discoveries which follow from our analyses; in its case we need not fear having to make a subsequent qualification of our views. I have described to you how our first patient carried out a senseless obsessional action and how she reported an intimate memory from her past life as having some connection with it: and how afterwards I examined the connection between the two and discovered the intention of the obsessional action from its relation to the memory. But there is one factor which I have entirely neglected, though it deserves our fullest attention. However often the patient repeated her obsessional action, she knew nothing of its being derived from the experience she had had. The connection between the two was hidden from her; she could only quite truthfully reply that she did not know what it was that was making her carry out her action. Then suddenly one day, under the influence of the treatment, she succeeded in discovering the connection and reported it to me. But she still knew nothing of the intention with which she was performing the obsessional action - the intention of correcting a distressing portion of the past and of putting her beloved husband in a better light. It took a fairly long time and called for much labour before she understood and admitted to me that such a motive alone could have been the driving force of her obsessional action.

[1916-1917, 3354]
And we meet with what is in essence the same thing in our second patient. She had made a rule that the pillow must not touch the back of the bedstead, and she had to obey this rule though she did not know where it came from, what it meant or to what motives it owed its power. Whether she herself regarded the rule as a matter of indifference, or whether she struggled against it or raged against it or decided to transgress it - none of this made any difference to her carrying it out. It had to be obeyed, and she asked herself vainly why. We must recognize, however, that these symptoms of obsessional neurosis, these ideas and impulses which emerge one knows not whence, which prove so resistant to every influence from an otherwise normal mind, which give the patient himself the impression of being all-powerful guests from an alien world, immortal beings intruding into the turmoil of mortal life - these symptoms offer the plainest indication of there being a special region of the mind, shut off from the rest. They lead, by a path that cannot be missed, to a conviction of the existence of the unconscious in the mind; and that is precisely why clinical psychiatry, which is acquainted only with a psychology of consciousness, can deal with these symptoms in no other way than by declaring them to be signs of a special sort of degeneracy. Obsessional ideas and obsessional impulses are not, of course, themselves unconscious, any more than the performance of obsessional actions escapes conscious perception. They would not have become symptoms if they had not forced their way into consciousness. But their psychical predeterminants which we infer by means of analysis, the connections into which we insert them by interpretation, are unconscious, at least until we have made them conscious to the patient by the work of analysis. [1916-1917, 3355]

Obsessional neurotics understand perfectly how to make the technical rule almost useless by applying their over-conscientiousness and doubts to it. Patients suffering from anxiety hysteria occasionally succeed in carrying the rule *ad absurdum* by producing only associations which are so remote from what we are in search of that they contribute nothing to the analysis. But it is not my intention to induct you into the handling of these technical difficulties. It is enough to say that in the end, through resolution and perseverance, we succeed in extorting a certain amount of obedience to the fundamental technical rule from the resistance - which thereupon jumps over to another sphere. [1916-1917, 3364]

It now appears as an *intellectual* resistance, it fights by means of arguments and exploits all the difficulties and improbabilities which normal but uninstructed thinking finds in the theories of analysis. It is now our fate to hear from this single voice all the criticisms and objections which assail our ears in a chorus in the scientific literature of the subject. And for this reason none of the shouts that reach us from outside sound unfamiliar. It is a regular storm in a tea-cup. But the patient is willing to be argued with; he is anxious to get us to instruct him, teach him, contradict him, introduce him to the literature, so that he can find further instruction. He is quite ready to become an adherent of psycho-analysis - on condition that analysis spares him personally. But we recognize this curiosity as a resistance, as a diversion from our particular tasks, and we repel it. In the case of an obsessional neurotic we have to expect special tactics of resistance. He will often allow the analysis to proceed on its way uninhibited, so that it is able to shed an ever-increasing light upon the riddle of his illness. We begin to wonder in the end, however, why this enlightenment is accompanied by no practical advance, no diminution of the symptoms. We are then able to realize that resistance has withdrawn on to the doubt belonging to the obsessional neurosis and from that position is successfully defying us. It is as though the patient were saying: 'Yes, that's all very nice and interesting, and I'll be very glad to go on with it further. It would change my illness a lot if it were true. But I don't in the least believe that it is true; and, so long as I don't believe it, it makes no difference to my illness.' Things can proceed like this for a long time, till finally one comes up against this uncommitted attitude itself, and the decisive struggle then breaks out. [1916-1917, 3364]
I have treated this point in such great detail because I must now inform you that this experience of ours with the resistance of neurotics to the removal of their symptoms became the basis of our dynamic view of the neuroses. Originally Breuer and I myself carried out psychotherapy by means of hypnosis; Breuer's first patient was treated throughout under hypnotic influence, and to begin with I followed him in this. I admit that at that period the work proceeded more easily and pleasantly, and also in a much shorter time. But results were capricious and not lasting; and for that reason I finally dropped hypnosis. And I then understood that an insight into the dynamics of these illnesses had not been possible so long as hypnosis was employed. That state was precisely able to withhold the existence of the resistance from the doctor's perception. It pushed the resistance back, making a certain area free for analytic work, and dammed it up at the frontiers of that area in such a way as to be impenetrable, just as doubt does in obsessional neurosis. For that reason I have been able to say that psycho-analysis proper began when I dispensed with the help of hypnosis.

[1916-1917, 3367]

No doubt all kinds of objections can still be raised to the assertion that neurotic symptoms are substitutes for sexual satisfactions. I will mention two of them to-day. When you yourselves have carried out analytic examinations of a considerable number of neurotics, you will perhaps tell me, shaking your head, that in a lot of cases my assertion is simply not true; the symptoms seem rather to have the contrary purpose of excluding or of stopping sexual satisfaction. I will not dispute the correctness of your interpretation. The facts in psycho-analysis have a habit of being rather more complicated than we like. If they were as simple as all that, perhaps it might not have needed psycho-analysis to bring them to light. Indeed, some of the features of our second patient's ceremonial show signs of this ascetic character with its hostility to sexual satisfaction: when, for instance, she got rid of the clocks and watches, which had the magical meaning of avoiding erections during the night, or when she tried to guard against flower-pots falling and breaking, which was equivalent to protecting her virginity. In some other cases of bed ceremonials, which I have been able to analyse, this negative character was far more outspoken; the ceremonial might consist exclusively of defensive measures against sexual memories and temptations. However, we have already found often enough that in psycho-analysis opposites imply no contradiction. We might extend our thesis and say that symptoms aim either at a sexual satisfaction or at fending it off, and that on the whole the positive, wish-fulfilling character prevails in hysteria and the negative, ascetic one in obsessional neurosis. If symptoms can serve the purpose both of sexual satisfaction and of its opposite, there is an excellent basis for this double-sidedness or polarity in a part of their mechanism which I have so far not been able to mention. For, as we shall hear, they are the products of a compromise and arise from the mutual interference between two opposing currents; they represent not only the repressed but also the repressing force which had a share in their origin. One side or the other may be more strongly represented; but it is rarely that one influence is entirely absent. In hysteria a convergence of both intentions in the same symptom is usually achieved. In obsessional neurosis the two portions are often separated; the symptom then becomes diphasic and consists in two actions, one after the other, which cancel each other out.

[1916-1917, 3373]
We shall not be able to dismiss a second objection so easily. If you survey a fairly long series of interpretations of symptoms, you will probably start by judging that the concept of a substitutive sexual satisfaction has been stretched to its extreme limits in them. You will not fail to emphasize the fact that these symptoms offer nothing real in the way of satisfaction, that often enough they are restricted to the revival of a sensation or the representation of a phantasy derived from a sexual complex. And you will further point out that these supposed sexual satisfactions often take on a childish and discreditable form, approximate to an act of masturbation perhaps, or recall dirty kinds of naughtiness which are forbidden even to children - habits of which they have been broken. And, going on from this, you will also express surprise that we are representing as a sexual satisfaction what would rather have to be described as the satisfaction of lusts that are cruel or horrible or would even have to be called unnatural. We shall come to no agreement, Gentlemen, on this latter point till we have made a thorough investigation of the sexual life of human beings and till, in doing so, we have decided what it is that we are justified in calling 'sexual'. [1916-1917, 3374]

Of the many symptomatic pictures in which obsessional neurosis appears, the most important turn out to be those provoked by the pressure of excessively strong sadistic sexual impulses (perverse, therefore, in their aim). The symptoms, indeed, in accordance with the structure of an obsessional neurosis, serve predominantly as a defence against these wishes or give expression to the struggle between satisfaction and defence. But satisfaction does not come off too badly either; it succeeds in roundabout ways in putting itself into effect in the patients’ behaviour and is preferably directed against themselves and makes them into self-tormentors. Other forms of the neurosis, the brooding kinds, correspond to an excessive sexualization of actions which ordinarily have their place on the path to normal sexual satisfaction - an excessive sexualization of wanting to look or to touch or to explore. Here we have the explanation of the great importance of the fear of touching and of the obsession for washing. An unsuspectedly large proportion of obsessional actions may be traced back to masturbation, of which they are disguised repetitions and modifications; it is a familiar fact that masturbation, though a single and uniform action, accompanies the most various forms of sexual phantasying. [1916-1917, 3380]

(c) We make a third discovery when we come to patients suffering from obsessional actions, who seem in a remarkable way exempt from anxiety. If we try to hinder their carrying out of their obsessional action - their washing or their ceremonial - or if they themselves venture upon an attempt to give up one of their compulsions, they are forced by the most terrible anxiety to yield to the compulsion. We can see that the anxiety was screened by the obsessional action, and that the latter was only performed in order to avoid the anxiety. In an obsessional neurosis, therefore, anxiety which would otherwise inevitably set in is replaced by the formation of a symptom, and if we turn to hysteria we find a similar relation: the result of the process of repression is either a generating of anxiety pure and simple, or anxiety accompanied by the formation of a symptom, or a more complete formation of a symptom without anxiety. It would thus seem not to be wrong in an abstract sense to assert that in general symptoms are only formed to escape an otherwise unavoidable generating of anxiety. If we adopt this view, anxiety is placed, as it were, in the very centre of our interest in the problems of neurosis. [1916-1917, 3451]
The patient had preserved his memory of this naughty period. According to his belief he made the first of his scenes one Christmas, when he was not given a double quantity of presents - which were his due, because Christmas Day was at the same time his birthday. He did not spare even his beloved Nanya with his importunity and touchiness, and even tormented her more remorselessly perhaps than anyone. But the phase which brought with it his change in character was inextricably connected in his memory with many other strange and pathological phenomena which he was unable to arrange in chronological sequence. He threw all the incidents that I am now about to relate (which cannot possibly have been contemporaneous, and which are full of internal contradictions) into one and the same period of time, to which he gave the name 'still on the first estate'. He thought they must have left that estate by the time he was five years old. Thus he could recollect how he had suffered from a fear, which his sister exploited for the purpose of tormenting him. There was a particular picture-book, in which a wolf was represented, standing upright and striding along. Whenever he caught sight of this picture he began to scream like a lunatic that he was afraid of the wolf coming and eating him up. His sister, however, always succeeded in arranging so that he was obliged to see this picture, and was delighted at his terror. Meanwhile he was also frightened at other animals as well, big and little. Once he was running after a beautiful big butterfly, with striped yellow wings which ended in points, in the hope of catching it. (It was no doubt a 'swallow-tail') He was suddenly seized with a terrible fear of the creature, and, screaming, gave up the chase. He also felt fear and loathing of beetles and caterpillars. Yet he could also remember that at this very time he used to torment beetles and cut caterpillars to pieces. Horses, too, gave him an uncanny feeling. If a horse was beaten he began to scream, and he was once obliged to leave a circus on that account. On other occasions he himself enjoyed beating horses. Whether these contradictory sorts of attitudes towards animals were really in operation simultaneously, or whether they did not more probably replace one another, but if so in what order and when - to all these questions his memory could offer no decisive reply. He was also unable to say whether his naughty period was replaced by a phase of illness or whether it persisted right through the latter. But, in any case, the statements of his that follow justified the assumption that during these years of his childhood he went through an easily recognizable attack of obsessional neurosis. He related how during a long period he was very pious. Before he went to sleep he was obliged to pray for a long time and to make an endless series of signs of the cross. In the evening, too, he used to make the round of all the holy pictures that hung in the room, taking a chair with him, upon which he climbed, and used to kiss each one of them devoutly. It was utterly inconsistent with this pious ceremonial - or, on the other hand, perhaps it was quite consistent with it - that he should recollect some blasphemous thoughts which used to come into his head like an inspiration from the devil. He was obliged to think 'God-swine' or 'God-shit'. Once while he was on a journey to a health resort in Germany he was tormented by the obsession of having to think of the Holy Trinity whenever he saw three heaps of horse-dung or other excrement lying in the road. At that time he used to carry out another peculiar ceremonial when he saw people that he felt sorry for, such as beggars, cripples, or very old men. He had to breathe out noisily, so as not to become like them; and under certain conditions he had to draw in his breath vigorously. I naturally assumed that these obvious symptoms of an obsessional neurosis belonged to a somewhat later time and stage of development than the signs of anxiety and the cruel treatment of animals.

[1918b, 3510]
The wolf that he was afraid of was undoubtedly his father; but his fear of the wolf was conditional upon the creature being in an upright posture. His recollection asserted most definitely that he had not been terrified by pictures of wolves going on all fours or, as in the story of 'Little Red Riding-Hood', lying in bed. The posture which, according to our construction of the primal scene, he had seen the woman assume, was of no less significance; though in this case the significance was limited to the sexual sphere. The most striking phenomenon of his erotic life after maturity was his liability to compulsive attacks of falling physically in love which came on and disappeared again in the most puzzling succession. These attacks released a tremendous energy in him even at times when he was otherwise inhibited, and they were quite beyond his control. I must, for a specially important reason, postpone a full consideration of this compulsive love; but I may mention here that it was subject to a definite condition, which was concealed from his consciousness and was discovered only during the treatment. It was necessary that the woman should have assumed the posture which we have ascribed to his mother in the primal scene. From his puberty he had felt large and conspicuous buttocks as the most powerful attraction in a woman; to copulate except from behind gave him scarcely any enjoyment. At this point a criticism may justly be raised: it may be objected that a sexual preference of this kind for the hind parts of the body is a general characteristic of people who are inclined to an obsessional neurosis, and that its presence does not justify us in referring it back to a special impression in childhood. It is part of the fabric of the anal-erotic disposition and is one of the archaic traits which distinguish that constitution. Indeed, copulation from behind - more feraurum [in the fashion of animals] - may, after all, be regarded as phylogenetically the older form. We shall return to this point too in a later discussion, when we have brought forward the supplementary material which showed the basis of the unconscious condition upon which his falling in love depended.

[1918b, 3531]

What is in dispute, therefore, is the significance of the infantile factor. The problem is to find a case which can establish that significance beyond any doubt. Such, however, is the case which is being dealt with so exhaustively in these pages and which is distinguished by the characteristic that the neurosis in later life was preceded by a neurosis in early childhood. It is for that very reason, indeed, that I have chosen it to report upon. Should any one feel inclined to reject it because the animal phobia strikes him as not sufficiently serious to be recognized as an independent neurosis, I may mention that the phobia was succeeded without any interval by an obsessional ceremonial, and by obsessional acts and thoughts, which will be discussed in the following sections of this paper.

[1918b, 3541]

At an earlier stage in the discussion we were brought up against an ambiguity in regard to the patient's predilection for female nates and for sexual intercourse in the posture in which they are especially prominent. It seemed necessary to trace this predilection back to the intercourse which he had observed between his parents, while at the same time a preference of this kind is a general characteristic of archaic constitutions which are predisposed to an obsessional neurosis. But the contradiction is easily resolved if we regard it as a case of overdetermination. The person who was the subject of his observation of this posture during intercourse was, after all, his father in the flesh, and it may also have been from him that he had inherited this constitutional predilection. Neither his father's subsequent illness nor his family history contradicts this; as has been mentioned already, a brother of his father's died in a condition which must be regarded as the outcome of a severe obsessional disorder.

[1918b, 3542]
Now for the third time the patient came under a new influence that gave a decisive turn to his development. When he was four and a half years old, and as his state of irritability and apprehensiveness had still not improved, his mother determined to make him acquainted with the Bible story in the hope of distracting and elevating him. Moreover, she succeeded; his initiation into religion brought the previous phase to an end, but at the same time it led to the anxiety symptoms being replaced by obsessional symptoms. Up to then he had not been able to get to sleep easily because he had been afraid of having bad dreams like the one he had had that night before Christmas; now he was obliged before he went to bed to kiss all the holy pictures in the room, to recite prayers, and to make innumerable signs of the cross upon himself and upon his bed.

[1918b, 3546]

A part of the pious ritual by means of which he eventually atoned for his blasphemies was the command to breathe in a ceremonious manner under certain conditions. Each time he made the sign of the cross he was obliged to breathe in deeply or to exhale forcibly. In his native tongue 'breath' is the same word as 'spirit', so that here the Holy Ghost came in. He was obliged to breathe in the Holy Spirit, or to breathe out the evil spirits which he had heard and read about.¹ He ascribed too to these evil spirits the blasphemous thoughts for which he had to inflict such heavy penance upon himself. He was, however, also obliged to exhale when he saw beggars, or cripples, or ugly, old, or wretched-looking people; but he could think of no way of connecting this obsession with the spirits. The only account he could give to himself was that he did it so as not to become like such people.

[1918b, 3550]

In certain diseases - including the very neuroses of which we have made special study - things are different. The ego feels uneasy; it comes up against limits to its power in its own house, the mind. Thoughts emerge suddenly without one's knowing where they come from, nor can one do anything to drive them away. These alien guests even seem to be more powerful than those which are at the ego's command. They resist all the well-proved measures of enforcement used by the will, remain unmoved by logical refutation, and are unaffected by the contradictory assertions of reality. Or else impulses appear which seem like those of a stranger, so that the ego disowns them; yet it has to fear them and take precautions against them. The ego says to itself: 'This is an illness, a foreign invasion.' It increases its vigilance, but cannot understand why it feels so strangely paralysed.

[1917a, 3612]
In the story of 'The Ring of Polycrates', the King of Egypt turns away in horror from his host, Polycrates, because he sees that his friend's every wish is at once fulfilled, his every care promptly removed by kindly fate. His host has become 'uncanny' to him. His own explanation, that the too fortunate man has to fear the envy of the gods, seems obscure to us; its meaning is veiled in mythological language. We will therefore turn to another example in a less grandiose setting. In the case history of an obsessional neurotic,¹ I have described how the patient once stayed in a hydropathic establishment and benefited greatly by it. He had the good sense, however, to attribute his improvement not to the therapeutic properties of the water, but to the situation of his room, which immediately adjoined that of a very accommodating nurse. So on his second visit to the establishment he asked for the same room, but was told that it was already occupied by an old gentleman, whereupon he gave vent to his annoyance in the words: 'I wish he may be struck dead for it.' A fortnight later the old gentleman really did have a stroke. My patient thought this an 'uncanny' experience. The impression of uncanniness would have been stronger still if less time had elapsed between his words and the untoward event, or if he had been able to report innumerable similar coincidences. As a matter of fact, he had no difficulty in producing coincidences of this sort; but then not only he but every obsessional neurotic I have observed has been able to relate analogous experiences. They are never surprised at their invariably running up against someone they have just been thinking of, perhaps for the first time for a long while. If they say one day 'I haven't had any news of so-and-so for a long time', they will be sure to get a letter from him the next morning, and an accident or a death will rarely take place without having passed through their mind a little while before. They are in the habit of referring to this state of affairs in the most modest manner, saying that they have 'presentiments' which 'usually' come true.

A little reflection was bound to show that it would be impossible to restrict to the provinces of dreams and nervous disorders a view such as this of the life of the human mind. If that view has hit upon a truth, it must apply equally to normal mental events, and even the highest achievements of the human spirit must bear a demonstrable relation to the factors found in pathology - to repression, to the efforts at mastering the unconscious and to the possibilities of satisfying the primitive instincts. There was thus an irresistible temptation and, indeed, a scientific duty, to apply the research methods of psycho-analysis, in regions far remote from its native soil, to the various mental sciences. And indeed psycho-analytic work upon patients itself pointed persistently in the direction of this new task, for it was obvious that the forms assumed by the different neuroses echoed the most highly admired productions of our culture. Thus hysterics are undoubtedly imaginative artists, even if they express their phantasies mimesitically in the main and without considering their intelligibility to other people; the ceremonials and prohibitions of obsessional neurotics drive us to suppose that they have created a private religion of their own; and the delusions of paranoics have an unpalatable external similarity and internal kinship to the systems of our philosophers. It is impossible to escape the conclusion that these patients are, in an asocial fashion, making the very attempts at solving their conflicts and appeasing their pressing needs which, when those attempts are carried out in a fashion that is acceptable to the majority, are known as poetry, religion and philosophy.

We have pointed out that this predominance of the life of phantasy and of the illusion born of an unfulfilled wish is the ruling factor in the psychology of neuroses. We have found that what neurotics are guided by is not ordinary objective reality but psychological reality. A hysterical symptom is based upon phantasy instead of upon the repetition of real experience, and the sense of guilt in an obsessional neurosis is based upon the fact of an evil intention which was never carried out. Indeed, just as in dreams and in hypnosis, in the mental operations of a group the function for testing the reality of things falls into the background in comparison with the strength of wishful impulses with their affective cathexis.
It is certainly not clear why the sense of guilt reaches such an extraordinary strength in these two neurotic disorders; but the main problem presented in this state of affairs lies in another direction. We shall postpone discussion of it until we have dealt with the other cases in which the sense of guilt remains unconscious.

The reproaches of conscience in certain forms of obsessional neurosis are as distressing and tormenting, but here the situation is less perspicuous. It is noteworthy that the obsessional neurotic, in contrast to the melancholic, never in fact takes the step of self-destruction; it is as though he were immune against the danger of suicide, and he is far better protected from it than the hysterical. We can see that what guarantees the safety of the ego is the fact that the object has been retained. In obsessional neurosis it has become possible, through a regression to the pregenital organization, for the love-impulses to transform themselves into impulses of aggression against the object. Here again the instinct of destruction has been set free and it seeks to destroy the object, or at least it appears to have that intention. These purposes have not been adopted by the ego and it struggles against them with reaction-formations and precautionary measures; they remain in the id. The super-ego, however, behaves as if the ego were responsible for them and shows at the same time by the seriousness with which it chastises these destructive intentions that they are no mere semblance evoked by regression but an actual substitution of hate for love. Helpless in both directions, the ego defends itself vainly, alike against the instigations of the murderous id and against the reproaches of the punishing conscience. It succeeds in holding in check at least the most brutal actions of both sides; the first outcome is interminable self-torment, and eventually there follows a systematic torturing of the object, in so far as it is within reach.

Moreover, if I were to give way to my moral pride and tried to decree that for purposes of moral valuation I might disregard the evil in the id and need not make my ego responsible for it, what use would that be to me? Experience shows me that I nevertheless do take that responsibility, that I am somehow compelled to do so. Psycho-analysis has made us familiar with a pathological condition, obsessional neurosis, in which the poor ego feels itself responsible for all sorts of evil impulses of which it knows nothing, impulses which are brought up against it in consciousness but which it is unable to acknowledge. Something of this is present in every normal person. It is a remarkable fact that the more moral he is the more sensitive is his 'conscience'. It is just as though we could say that the healthier a man is, the more liable he is to contagions and to the effects of injuries. This is no doubt because conscience is itself a reaction-formation against the evil that is perceived in the id. The more strongly the latter is suppressed, the more active is the conscience.

In obsessional neurosis and paranoia the forms which the symptoms assume become very valuable to the ego because they obtain for it, not certain advantages, but a narcissistic satisfaction which it would otherwise be without. The systems which the obsessional neurotic constructs flatter his self-love by making him feel that he is better than other people because he is specially cleanly or specially conscientious. The delusional constructions of the paranoic offer to his acute perceptive and imaginative powers a field of activity which he could not easily find elsewhere.
Let us turn to the obsessional neuroses in the hope of learning more about the formation of symptoms. The symptoms belonging to this neurosis fall, in general, into two groups, each having an opposite trend. They are either prohibitions, precautions and expiations - that is, negative in character - or they are, on the contrary, substitutive satisfactions which often appear in symbolic disguise. The negative, defensive group of symptoms is the older of the two; but as illness is prolonged, the satisfactions, which scoff at all defensive measures, gain the upper hand. The symptom-formation scores a triumph if it succeeds in combining the prohibition with satisfaction so that what was originally a defensive command or prohibition acquires the significance of a satisfaction as well; and in order to achieve this end it will often make use of the most ingenious associative paths. Such an achievement demonstrates the tendency of the ego to synthesize, which we have already observed. In extreme cases the patient manages to make most of his symptoms acquire, in addition to their original meaning, a directly contrary one. This is a tribute to the power of ambivalence, which, for some unknown reason, plays such a large part in obsessional neuroses. In the crudest instance the symptom is diphasic: an action which carries out a certain injunction is immediately succeeded by another action which stops or undoes the first one even if it does not go quite so far as to carry out its opposite.

[1926d, 4271]

Two impressions at once emerge from this brief survey of obsessional symptoms. The first is that a ceaseless struggle is being waged against the repressed, in which the repressing forces steadily lose ground; the second is that the ego and the super-ego have a specially large share in the formation of the symptoms.

[1926d, 4272]

Another possibility has to be considered. Perhaps regression is the result not of a constitutional factor but of a time-factor. It may be that regression is rendered possible not because the genital organization of the libido is too feeble but because the opposition of the ego begins too early, while the sadistic phase is at its height. I am not prepared to express a definite opinion on this point, but I may say that analytic observation does not speak in favour of such an assumption. It shows rather that, by the time an obsessional neurosis is entered upon, the phallic stage has already been reached. Moreover, the onset of this neurosis belongs to a later time of life than that of hysteria - to the second period of childhood, after the latency period has set in. In a woman patient whose case I was able to study and who was overtaken by this disorder at a very late date, it became clear that the determining cause of her regression and of the emergence of her obsessional neurosis was a real occurrence through which her genital life, which had up till then been intact, lost all its value.¹

[1926d, 4272]
The advent of puberty opens a decisive chapter in the history of an obsessional neurosis. The genital organization which has been broken off in childhood starts again with great vigour. But, as we know, the sexual development in childhood determines what direction this new start at puberty will take. Not only will the early aggressive impulses be re-awakened; but a greater or lesser proportion of the new libidinal impulses - in bad cases the whole of them - will have to follow the course prescribed for them by regression and will emerge as aggressive and destructive tendencies. In consequence of the erotic trends being disguised in this way and owing to the powerful reaction-formation in the ego, the struggle against sexuality will henceforward be carried on under the banner of ethical principles. The ego will recoil with astonishment from promptings to cruelty and violence which enter consciousness from the id, and it has no notion that in them it is combating erotic wishes, including some to which it would not otherwise have taken exception. The overstrict super-ego insists all the more strongly on the suppression of sexuality, since this has assumed such repellent forms. Thus in obsessional neurosis the conflict is aggravated in two directions: the defensive forces become more intolerant and the forces that are to be fended off become more intolerable. Both effects are due to a single factor, namely, regression of the libido.

[1926d, 4275]

A good deal of what has been said may be objected to on the ground that the unpleasant obsessive ideas are themselves quite conscious. But there is no doubt that before becoming conscious they have been though the process of repression. In most of them the actual wording of the aggressive instinctual impulse is altogether unknown to the ego, and it requires a good deal of analytic work to make it conscious. What does penetrate into consciousness is usually only a distorted substitute which is either of a vague, dream-like and indeterminate nature or so travestied as to be unrecognizable. Even where repression has not encroached upon the content of the aggressive impulse it has certainly got rid of its accompanying affective character. As a result, the aggressiveness appears to the ego not to be an impulsion but, as the patients themselves say, merely a 'thought' which awakens no feeling. But the remarkable thing is that this is not the case. What happens is that the affect left out when the obsessional idea is perceived appears in a different place. The super-ego behaves as though repression had not occurred and as though it knew the real wording and full affective character of the aggressive impulse, and it treats the ego accordingly. The ego which, on the one hand, knows that it is innocent is obliged, on the other hand, to be aware of a sense of guilt and to carry a responsibility which it cannot account for. This state of affairs is, however, not so puzzling as it would seem at first sight. The behaviour of the super-ego is perfectly intelligible, and the contradiction in the ego merely shows that it has shut out the id by means of repression while remaining fully accessible to the influence of the super-ego.1 If it is asked why the ego does not also attempt to withdraw from the tormenting criticism of the super-ego, the answer is that it does manage to do so in a great number of instances. There are obsessional neuroses in which no sense of guilt whatever is present. In them, as far as can be seen, the ego has avoided becoming aware of it by instituting a fresh set of symptoms, penances or restrictions of a self-punishing kind. These symptoms, however, represent at the same time a satisfaction of masochistic impulses which, in their turn, have been reinforced by regression.

[1926d, 4276]
In the course of these struggles we come across two activities of the ego which form symptoms and which deserve special attention because they are obviously surrogates of repression and therefore well calculated to illustrate its purpose and technique. The fact that such auxiliary and substitutive techniques emerge may argue that true repression has met with difficulties in its functioning. If one considers how much more the ego is the scene of action of symptom-formation in obsessional neurosis than it is in hysteria and with what tenacity the ego clings to its relations to reality and to consciousness, employing all its intellectual faculties to that end - and indeed how the very process of thinking becomes hypercathected and erotized - then one may perhaps come to a better understanding of these variations of repression.

We have all found by experience that it is especially difficult for an obsessional neurotic to carry out the fundamental rule of psycho-analysis. His ego is more watchful and makes sharper isolations, probably because of the high degree of tension due to conflict that exists between his super-ego and his id. While he is engaged in thinking, his ego has to keep off too much - the intrusion of unconscious phantasies and the manifestation of ambivalent trends. It must not relax, but is constantly prepared for a struggle. It fortifies this compulsion to concentrate and to isolate by the help of the magical acts of isolation which, in the form of symptoms, grow to be so noticeable and to have so much practical importance for the patient, but which are, of course, useless in themselves and are in the nature of ceremonials.

What we have learnt about anxiety in phobias is applicable to obsessional neuroses as well. In this respect it is not difficult for us to put obsessional neuroses on all fours with phobias. In the former, the mainspring of all later symptom-formation is clearly the ego's fear of its super-ego. The danger-situation from which the ego must get away is the hostility of the super-ego. There is no trace of projection here; the danger is completely internalized. But if we ask ourselves what it is that the ego fears from the super-ego, we cannot but think that the punishment threatened by the latter must be an extension of the punishment of castration. Just as the father has become depersonalized in the shape of the super-ego, so has the fear of castration at his hands become transformed into an undefined social or moral anxiety. But this anxiety is concealed. The ego escapes it by obediently carrying out the commands, precautions and penances that have been enjoined on it. If it is impeded in doing so, it is at once overtaken by an extremely distressing feeling of discomfort which may be regarded as an equivalent of anxiety and which the patients themselves liken to anxiety.

When, in an earlier part of this discussion, we found that the danger of castration was of importance in more than one neurotic illness, we put ourselves on guard against overestimating that factor, since it could not be a decisive one for the female sex, who are undoubtedly more subject to neuroses than men. We now see that there is no danger of our regarding castration anxiety as the sole motive force of the defensive processes which lead to neurosis. I have shown elsewhere how little girls, in the course of their development, are led into making a tender object-cathexis by their castration complex. It is precisely in women that the danger situation of loss of object seems to have remained the most effective. All we need to do is to make a slight modification in our description of their determinant of anxiety, in the sense that it is no longer a matter of feeling the want of, or actually losing the object itself, but of losing the object's love. Since there is no doubt that hysteria has a strong affinity with femininity, just as obsessional neurosis has with masculinity, it appears probable that, as a determinant of anxiety, loss of love plays much the same part in hysteria as the threat of castration does in phobias and fear of the super-ego in obsessional neurosis.
One objection to it is that loss of an object (or loss of love on the part of the object) and the threat of castration are just as much dangers coming from outside as, let us say, a ferocious animal would be; they are not instinctual dangers. Nevertheless, the two cases are not the same. A wolf would probably attack us irrespectively of our behaviour towards it; but the loved person would not cease to love us nor should we be threatened with castration if we did not entertain certain feelings and intentions within us. Thus such instinctual impulses are determinants of external dangers and so become dangerous in themselves; and we can now proceed against the external danger by taking measures against the internal ones. In phobias of animals the danger seems to be still felt entirely as an external one, just as it has undergone an external displacement in the symptom. In obsessional neuroses the danger is much more internalized. That portion of anxiety in regard to the super-ego which constitutes social anxiety still represents an internal substitute for an external danger, while the other portion - moral anxiety - is already completely endopsychic.

[1926d, 4300]

An important element in the theory of repression is the view that repression is not an event that occurs once but that it requires a permanent expenditure. If this expenditure were to cease, the repressed impulse, which is being fed all the time from its sources, would on the next occasion flow along the channels from which it had been forced away, and the repression would either fail in its purpose or would have to be repeated an indefinite number of times. Thus it is because instincts are continuous in their nature that the ego has to make its defensive action secure by a permanent expenditure. This action undertaken to protect repression is observable in analytic treatment as resistance. Resistance presupposes the existence of what I have called anticathexis. An anticathexis of this kind is clearly seen in obsessional neurosis. It appears there in the form of an alteration of the ego, as a reaction-formation in the ego, and is effected by the reinforcement of the attitude which is the opposite of the instinctual trend that has to be repressed - as, for instance, in pity, conscientiousness and cleanliness. These reaction-formations of obsessional neurosis are essentially exaggerations of the normal traits of character which develop during the latency period. The presence of an anticathexis in hysteria is much more difficult to detect, though theoretically it is equally indispensable. In hysteria, too, a certain amount of alteration of the ego through reaction-formation is unmistakable and in some circumstances becomes so marked that it forces itself on our attention as the principal symptom. The conflict due to ambivalence, for instance, is resolved in hysteria by this means. The subject's hatred of a person whom he loves is kept down by an exaggerated amount of tenderness for him and apprehensiveness about him. But the difference between reaction-formations in obsessional neurosis and in hysteria is that in the latter they do not have the universality of a character-trait but are confined to particular relationships. A hysterical woman, for instance, may be specially affectionate with her own children whom at bottom she hates; but she will not on that account be more loving in general than other women or even more affectionate to other children. The reaction-formation of hysteria clings tenaciously to a particular object and never spreads over into a general disposition of the ego, whereas what is characteristic of obsessional neurosis is precisely a spreading-over of this kind - a loosening of relations to the object and a facilitation of displacement in the choice of object.

[1926d, 4310]
A patient, then, may be suffering from fluctuations in his moods which he cannot control, or from a sense of despondency by which his energy feels paralysed because he thinks he is incapable of doing anything properly, or from a nervous embarrassment among strangers. He may perceive, without understanding the reason for it, that he has difficulties in carrying out his professional work, or indeed any comparatively important decision or any undertaking. He may one day have suffered from a distressing attack - unknown in its origin - of feelings of anxiety, and since then have been unable, without a struggle, to walk along the street alone, or to travel by train; he may perhaps have had to give up both entirely. Or, a very remarkable thing, his thoughts may go their own way and refuse to be directed by his will. They pursue problems that are quite indifferent to him, but from which he cannot get free. Quite ludicrous tasks, too, are imposed on him, such as counting up the windows on the fronts of houses. And when he has performed simple actions such as posting a letter or turning off a gas-jet, he finds himself a moment later doubting whether he has really done so. This may be no more than an annoyance and a nuisance. But his state becomes intolerable if he suddenly finds he is unable to fend off the idea that he has pushed a child under the wheels of a car or has thrown a stranger off the bridge into the water, or if he has to ask himself whether he is not the murderer whom the police are looking for in connection with a crime that was discovered that day. It is obvious nonsense, as he himself knows; he has never done any harm to anyone; but if he were really the murderer who is being looked for, his feeling - his sense of guilt - could not be stronger.

We now observe that the store of religious ideas includes not only wish-fulfilments but important historical recollections. This concurrent influence of past and present must give religion a truly incomparable wealth of power. But perhaps with the help of an analogy yet another discovery may begin to dawn on us. Though it is not a good plan to transplant ideas far from the soil in which they grew up, yet here is a conformity which we cannot avoid pointing out. We know that a human child cannot successfully complete its development to the civilized stage without passing through a phase of neurosis sometimes of greater and sometimes of less distinctness. This is because so many instinctual demands which will later be unserviceable cannot be suppressed by the rational operation of the child's intellect but have to be tamed by acts of repression, behind which, as a rule, lies the motive of anxiety. Most of these infantile neuroses are overcome spontaneously in the course of growing up, and this is especially true of the obsessional neuroses of childhood. The remainder can be cleared up later still by psychoanalytic treatment. In just the same way, one might assume, humanity as a whole, in its development through the ages, fell into states analogous to the neuroses, and for the same reasons - namely because in the times of its ignorance and intellectual weakness the instinctual renunciations indispensable for man's communal existence had only been achieved by it by means of purely affective forces. The precipitates of these processes resembling repression which took place in prehistoric times still remained attached to civilization for long periods. Religion would thus be the universal obsessional neurosis of humanity; like the obsessional neurosis of children, it arose out of the Oedipus complex, out of the relation to the father. If this view is right, it is to be supposed that a turning-away from religion is bound to occur with the fatal inevitability of a process of growth, and that we find ourselves at this very juncture in the middle of that phase of development. Our behaviour should therefore be modelled on that of a sensible teacher who does not oppose an impending new development but seeks to ease its path and mitigate the violence of its irruption. Our analogy does not, to be sure, exhaust the essential nature of religion. If, on the one hand, religion brings with it obsessional restrictions, exactly as an individual obsessional neurosis does, on the other hand it comprises a system of wishful illusions together with a disavowal of reality, such as we find in an isolated form nowhere else but in amnesia, in a state of blissful hallucinatory confusion. But these are only analogies, by the help of which we endeavour to understand a social phenomenon; the pathology of the individual does not supply us with a fully valid counterpart.

[1926e, 4328]

[1927c, 4452]
In the first place, I suspect that the reader has the impression that our discussions on the sense of guilt disrupt the framework of this essay: that they take up too much space, so that the rest of its subject-matter, with which they are not always closely connected, is pushed to one side. This may have spoiled the structure of my paper; but it corresponds faithfully to my intention to represent the sense of guilt as the most important problem in the development of civilization and to show that the price we pay for our advance in civilization is a loss of happiness through the heightening of the sense of guilt.¹ Anything that still sounds strange about this statement, which is the final conclusion of our investigation, can probably be traced to the quite peculiar relationship - as yet completely unexplained - which the sense of guilt has to our consciousness. In the common case of remorse, which we regard as normal, this feeling makes itself clearly enough perceptible to consciousness. Indeed, we are accustomed to speak of a 'consciousness of guilt' instead of a 'sense of guilt'. Our study of the neuroses, to which, after all we owe the most valuable pointers to an understanding of normal conditions, brings us up against some contradictions. In one of those affections, obsessional neurosis, the sense of guilt makes itself noisily heard in consciousness; it dominates the clinical picture and the patient's life as well, and it hardly allows anything else to appear alongside of it. But in most other cases and forms of neurosis it remains completely unconscious, without on that account producing any less important effects. Our patients do not believe us when we attribute an 'unconscious sense of guilt' to them. In order to make ourselves at all intelligible to them, we tell them of an unconscious need for punishment, in which the sense of guilt finds expression. But its connection with a particular form of neurosis must not be over-estimated. Even in obsessional neurosis there are types of patients who are not aware of their sense of guilt, or who only feel it as a tormenting uneasiness, a kind of anxiety, if they are prevented from carrying out certain actions. It ought to be possible eventually to understand these things; but as yet we cannot. Here perhaps we may be glad to have it pointed out that the sense of guilt is at bottom nothing else but a topographical variety of anxiety; in its later phases it coincides completely with fear of the super-ego. And the relations of anxiety to consciousness exhibit the same extraordinary variations. Anxiety is always present somewhere or other behind every symptom; but at one time it takes noisy possession of the whole of consciousness, while at another it conceals itself so completely that we are obliged to speak of unconscious anxiety or, if we want to have a clearer psychological conscience, since anxiety is in the first instance simply a feeling, of possibilities of anxiety. Consequently it is very conceivable that the sense of guilt produced by civilization is not perceived as such either, and remains to a large extent unconscious, or appears as a sort of malaise, a dissatisfaction, for which people seek other motivations. Religions, at any rate, have never overlooked the part played in civilization by a sense of guilt. Furthermore - a point which I failed to appreciate elsewhere² - they claim to redeem mankind from this sense of guilt, which they call sin. From the manner in which, in Christianity, this redemption is achieved - by the sacrificial death of a single person, who in this manner takes upon himself a guilt that is common to everyone - we have been able to infer what the first occasion may have been on which this primal guilt, which was also the beginning of civilization, was acquired.³  

¹[1930a, 4523]
One day I discovered to my great astonishment that the view of dreams which came nearest to the truth was not the medical but the popular one, half-involved though it still was in superstition. For I had been led to fresh conclusions on the subject of dreams by applying to them a new method of psychological investigation which had done excellent service in the solution of phobias, obsessions and delusions, etc. Since then, under the name of 'psycho-analysis', it has found acceptance by a whole school of research workers. The numerous analogies that exist between dream-life and a great variety of conditions of psychical illness in waking life have indeed been correctly observed by many medical investigators. There seemed, therefore, good ground for hoping that a method of investigation which had given satisfactory results in the case of psychopathic structures would also be of use in throwing light upon dreams. Phobias and obsessions are as alien to normal consciousness as dreams are to waking consciousness; their origin is as unknown to consciousness as that of dreams. In the case of these psychopathic structures practical considerations led to an investigation of their origin and mode of development; for experience had shown that the discovery of the trains of thought which, concealed from consciousness, connect the pathological ideas with the remaining contents of the mind is equivalent to a resolution of the symptoms and has as its consequence the mastering of ideas which till then could not be inhibited. Thus psychotherapy was the starting-point of the procedure of which I made use for the explanation of dreams.
[1901a, 1053]

(8) A good example of the derivation of an obsessive word - a word that cannot be got rid of - is to be found in Jung (1906). 'A lady told me that for some days the word "Taganrog" had been constantly on her lips without her having any idea where it came from. I asked the lady for information about the affectively stressed events and repressed wishes of the very recent past. After some hesitation she told me that she would very much like a morning gown, but her husband did not take the interest in it that she had hoped. "Morgenrock", "Tag-an-rock" - their partial similarity in sound and meaning is obvious. The Russian form was determined by the fact that at about the same time the lady had come to know someone from Taganrog.'
[1901b, 1323]

A train of thought such as this may be described as excessively intense, or better reinforced, or 'supervalent' ['überwertig'] in Wernicke's sense. It shows its pathological character in spite of its apparently reasonable content, by the single peculiarity that no amount of conscious and voluntary effort of thought on the patient's part is able to dissipate or remove it. A normal train of thought, however intense it may be, can eventually be disposed of. Dora felt quite rightly that her thoughts about her father required to be judged in a special way. 'I can think of nothing else', she complained again and again. 'I know my brother says we children have no right to criticize this behaviour of Father's. He declares that we ought not to trouble ourselves about it, and ought even to be glad, perhaps, that he has found a woman he can love, since Mother understands him so little. I can quite see that, and I should like to think the same as my brother, but I can't. I can't forgive him for it.'
[1905e, 1391]
Now what is one to do in the face of a supervalent thought like this, after one has heard what its conscious grounds are and listened to the ineffectual protests made against it? Reflection will suggest that this excessively intense train of thought must owe its reinforcement to the unconscious. It cannot be resolved by any effort of thought, either because it itself reaches with its root down into unconscious, repressed material, or because another unconscious thought lies concealed behind it. In the latter case, the concealed thought is usually the direct contrary of the supervalent one. Contrary thoughts are always closely connected with each other and are often paired off in such a way that the one thought is excessively intensely conscious while its counterpart is repressed and unconscious. This relation between the two thoughts is an effect of the process of repression. For repression is often achieved by means of an excessive reinforcement of the thought contrary to the one which is to be repressed. This process I call reactive reinforcement, and the thought which asserts itself with excessive intensity in consciousness and (in the same way as a prejudice) cannot be removed I call a reactive thought. The two thoughts then act towards each other much like the two needles of an astatic galvanometer. The reactive thought keeps the objectionable one under repression by means of a certain surplus of intensity; but for that reason it itself is 'damped' and proof against conscious efforts of thought. So that the way to deprive the excessively intense thought of its reinforcement is by bringing its repressed contrary into consciousness.

Neurotic ceremonials consist in making small adjustments to particular everyday actions, small additions or restrictions or arrangements, which have always to be carried out in the same, or in a methodically varied, manner. These activities give the impression of being mere formalities, and they seem quite meaningless to us. Nor do they appear otherwise to the patient himself; yet he is incapable of giving them up, for any deviation from the ceremonial is visited by intolerable anxiety, which obliges him at once to make his omission good. Just as trivial as the ceremonial actions themselves are the occasions and activities which are embellished, encumbered and in any case prolonged by the ceremonial - for instance, dressing and undressing, going to bed or satisfying bodily needs. The performance of a ceremonial can be described by replacing it, as it were, by a series of unwritten laws. For instance, to take the case of the bed ceremonial: the chair must stand in a particular place beside the bed; the clothes must lie upon it folded in a particular order; the blanket must be tucked in at the bottom and the sheet smoothed out; the pillows must be arranged in such and such a manner, and the subject's own body must lie in a precisely defined position. Only after all this may he go to sleep. Thus in slight cases the ceremonial seems to be no more than an exaggeration of an orderly procedure that is customary and justifiable; but the special conscientiousness with which it is carried out and the anxiety which follows upon its neglect stamp the ceremonial as a 'sacred act'. Any interruption of it is for the most part badly tolerated, and the presence of other people during its performance is almost always ruled out.
A youngish man of university education introduced himself to me with the statement that he had suffered from obsessions ever since his childhood, but with particular intensity for the last four years. The chief features of his disorder were fears that something might happen to two people of whom he was very fond - his father and a lady whom he admired. Besides this he was aware of compulsive impulses - such as an impulse, for instance, to cut his throat with a razor; and further he produced prohibitions, sometimes in connection with quite unimportant things. He had wasted years, he told me, in fighting against these ideas of his, and in this way had lost much ground in the course of his life. He had tried various treatments, but none had been of any use to him except a course of hydrotherapy at a sanatorium near ---; and this, he thought, had probably only been because he had made an acquaintance there which had led to regular sexual intercourse. Here he had no opportunities of the sort, and he seldom had intercourse and only at irregular intervals. He felt disgust at prostitutes. Altogether, he said, his sexual life had been stunted; masturbation had played only a small part in it, in his sixteenth or seventeenth year. His potency was normal; he had first had intercourse at the age of twenty-six.

He broke off his story in order to assure me that these thoughts were entirely foreign and repugnant to him, and to tell me that everything which had followed in their train had passed through his mind with the most extraordinary rapidity. Simultaneously with the idea there always appeared a 'sanction', that is to say, the defensive measure which he was obliged to adopt in order to prevent the phantasy from being fulfilled. When the captain had spoken of this ghastly punishment, he went on, and these ideas had come into his head, by employing his usual formulas (a 'but' accompanied by a gesture of repudiation, and the phrase 'whatever are you thinking of?') he had just succeeded in warding off both of them.

This 'both' took me aback, and it has no doubt also mystified the reader. For so far we have heard only of one idea - of the rat punishment being carried out upon the lady. He was now obliged to admit that a second idea had occurred to him simultaneously, namely, the idea of the punishment being applied to his father. As his father had died many years previously, this obsessive fear was much more nonsensical even than the first, and accordingly it had attempted to escape being confessed to for a little while longer.
'I have decided to tell you something which I consider most important and which has tormented me from the very first.' He then told me at great length the story of the last illness of his father, who had died of emphysema nine years previously. One evening, thinking that the condition was one which would come to a crisis, he had asked the doctor when the danger could be regarded as over. 'The evening of the day after to-morrow', had been the reply. It had never entered his head that his father might not survive that limit. At half-past eleven at night he had lain down for an hour's rest. He had woken up at one o'clock, and had been told by a medical friend that his father had died. He had reproached himself with not having been present at his death; and the reproach had been intensified when the nurse told him that his father had spoken his name once during the last days, and had said to her as she came up to the bed: 'Is that Paul?' He had thought he noticed that his mother and sisters had been inclined to reproach themselves in a similar way; but they had never spoken about it. At first, however, the reproach had not tormented him. For a long time he had not realized the fact of his father's death. It had constantly happened that, when he heard a good joke, he would say to himself: 'I must tell Father that.' His imagination, too, had been occupied with his father, so that often, when there was a knock at the door, he would think: 'Here comes Father', and when he walked into a room he would expect to find his father in it. And although he had never forgotten that his father was dead, the prospect of seeing a ghostly apparition of this kind had had no terrors for him; on the contrary, he had greatly desired it. It had not been until eighteen months later that the recollection of his neglect had recurred to him and begun to torment him terribly, so that he had come to treat himself as a criminal. The occasion of this happening had been the death of an aunt by marriage and of a visit of condolence that he had paid at her house. From that time forward he had extended the structure of his obsessional thoughts so as to include the next world. The immediate consequence of this development had been that he became seriously incapacitated from working.¹ He told me that the only thing that had kept him going at that time had been the consolation given him by his friend, who had always brushed his self-reproaches aside on the ground that they were grossly exaggerated. Hearing this, I took the opportunity of giving him a first glance at the underlying principles of psycho-analytic therapy. When there is a mésalliance, I began, between an affect and its ideational content (in this instance, between the intensity of the self-reproach and the occasion for it), a layman will say that the affect is too great for the occasion - that it is exaggerated and that consequently the inference following from the self-reproach (the inference that the patient is a criminal) is false. On the contrary, the physician says: 'No. The affect is justified. The sense of guilt is not in itself open to further criticism. But it belongs to some other content, which is unknown (unconscious), and which requires to be looked for. The known ideational content has only got into its actual position owing to a false connection. We are not used to feeling strong affects without their having any ideational content, and therefore, if the content is missing, we seize as a substitute upon some other content which is in some way or other suitable, much as our police, when they cannot catch the right murderer, arrest a wrong one instead. Moreover, this fact of there being a false connection is the only way of accounting for the powerlessness of logical processes to combat the tormenting idea.' I concluded by admitting that this new way of looking at the matter gave immediate rise to some hard problems; for how could he admit that his self-reproach of being a criminal towards his father was justified, when he must know that as a matter of fact he had never committed any crime against him?

[1909d, 2142]
Obsessional ideas, as is well known, have an appearance of being either without motive or without meaning, just as dreams have. The first problem is how to give them a sense and a status in the subject's mental life, so as to make them comprehensible and even obvious. The problem of translating them may seem insoluble; but we must never let ourselves be misled by that illusion. The wildest and most eccentric obsessional ideas can be cleared up if they are investigated deeply enough. The solution is effected by bringing the obsessional ideas into temporal relationship with the patient's experiences, that is to say, by enquiring when a particular obsessional idea made its first appearance and in what external circumstances it is apt to recur. When, as so often happens, an obsessional idea has not succeeded in establishing itself permanently, the task of clearing it up is correspondingly simplified. We can easily convince ourselves that, when once the interconnections between an obsessional idea and the patient's experiences have been discovered, there will be no difficulty in obtaining access to whatever else may be puzzling or worth knowing in the pathological structure we are dealing with - its meaning, the mechanism of its origin, and its derivation from the preponderant motive forces of the patient's mind.

[1909d, 2147]

I refer to the omnipotence which he ascribed to his thoughts and feelings, and to his wishes, whether good or evil. It is, I must admit, decidedly tempting to declare that this idea was a delusion and that it oversteps the limits of obsessional neurosis. I have, however, come across the same conviction in another obsessional patient; and he was long ago restored to health and is leading a normal life. Indeed, all obsessional neurotics behave as though they shared this conviction. It will be our business to throw some light upon these patients' over-estimation of their powers. Assuming, without more ado, that this belief is a frank acknowledgement of a relic of the old megalomania of infancy, we will proceed to ask our patient for the grounds of his conviction. In reply, he adduces two experiences. When he returned for a second visit to the hydropathic establishment at which his disorder had been relieved for the first and only time, he asked to be given his old room, for its position had facilitated his relations with one of the nurses. He was told that the room was already taken and that it was occupied by an old professor. This piece of news considerably diminished his prospects of successful treatment, and he reacted to it with the unamiable thought: 'I wish he may be struck dead for it!' A fortnight later he was woken up from his sleep by the disturbing idea of a corpse; and in the morning he heard that the professor had really had a stroke, and that he had been carried up into his room at about the time he himself had woken up. The second experience related to an unmarried woman, no longer young, though with a great desire to be loved, who had paid him a great deal of attention and had once asked him point blank whether he could not love her. He had given her an evasive answer. A few days afterwards he heard that she had thrown herself out of a window. He then began to reproach himself, and said to himself that it would have been in his power to save her life by giving her his love. In this way he became convinced of the omnipotence of his love and of his hatred. Without denying the omnipotence of love we may point out that both these instances were concerned with death, and we may adopt the obvious explanation that, like other obsessional neurotics, our patient was compelled to overestimate the effects of his hostile feelings upon the external world, because a large part of their internal, mental effects escaped his conscious knowledge. His love - or rather his hatred - was in truth overpowering; it was precisely they that created the obsessional thoughts, of which he could not understand the origin and against which he strove in vain to defend himself.¹

[1909d, 2183]
I may now venture, upon the basis of the preceding discussion, to determine the psychological characteristic, so long sought after, which lends to the products of an obsessional neurosis their 'obsessive' or compulsive quality. A thought-process is obsessive or compulsive when, in consequence of an inhibition (due to a conflict of opposing impulses) at the motor end of the psychical system, it is undertaken with an expenditure of energy which (as regards both quality and quantity) is normally reserved for actions alone; or, in other words, an obsessive or compulsive thought is one whose function it is to represent an act regressively. No one, I think, will question my assumption that processes of thought are ordinarily conducted (on grounds of economy) with smaller displacements of energy, probably at a higher level, than are acts intended to bring about discharge or to modify the external world.

This interpretation by the psychological novelist cannot be put to the proof, but it can claim so much inner probability, and is so much in harmony with all that we otherwise know of Leonardo's emotional activity, that I cannot refrain from accepting it as correct. He had succeeded in subjecting his feelings to the yoke of research and in inhibiting their free utterance; but even for him there were occasions when what had been suppressed obtained expression forcibly. The death of the mother he had once loved so dearly was one of these. What we have before us in the account of the costs of the funeral is the expression - distorted out of all recognition - of his mourning for his mother. We wonder how such distortion could come about, and indeed we cannot understand it if we treat it as a normal mental process. But similar processes are well known to us in the abnormal conditions of neurosis and especially of what is known as 'obsessional neurosis'. There we can see how the expression of intense feelings, which have however become unconscious through repression, is displaced on to trivial and even foolish actions. The expression of these repressed feelings has been lowered by the forces opposed to them to such a degree that one would have had to form a most insignificant estimate of their intensity; but the imperative compulsonessiveness with which this trivial expressive act is performed betrays the real force of the impulses - a force which is rooted in the unconscious and which consciousness would like to deny. Only a comparison such as this with what happens in obsessional neurosis can explain Leonardo's account of the expenses of his mother's funeral. In his unconscious he was still tied to her by erotically coloured feelings, as he had been in childhood. The opposition that came from the subsequent repression of this childhood love did not allow him to set up a different and worthier memorial to her in his diary. But what emerged as a compromise from this neurotic conflict had to be carried out; and thus it was that the account was entered in the diary, and has come to the knowledge of posterity as something unintelligible.

It does not seem a very extravagant step to apply what we have learnt from the funeral account to the reckonings of the pupils' expenses. They would then be another instance of the scanty remnants of Leonardo's libidinal impulses finding expression in a compulsive manner and in a distorted form. On that view, his mother and his pupils, the likenesses of his own boyish beauty, had been his sexual objects - so far as the sexual repression which dominated his nature allows us so to describe them - and the compulsion to note in laborious detail the sums he spent on them betrayed in this strange way his rudimentary conflicts. From this it would appear that Leonardo's erotic life did really belong to the type of homosexuality whose psychical development we have succeeded in disclosing, and the emergence of the homosexual situation in his phantasy of the vulture would become intelligible to us: for its meaning was exactly what we have already asserted of that type. We should have to translate it thus: "It was through this erotic relation with my mother that I became a homosexual."
(1) To what extent should the patient's intellectual co-operation be sought for in the treatment? It is difficult to say anything of general applicability on this point: the patient's personality is the determining factor. But in any case caution and self-restraint must be observed in this connection. It is wrong to set a patient tasks, such as collecting his memories or thinking over some particular period of his life. On the contrary, he has to learn above all - what never comes easily to anyone - that mental activities such as thinking something over or concentrating the attention solve none of the riddles of a neurosis; that can only be done by patiently obeying the psycho-analytic rule, which enjoins the exclusion of all criticism of the unconscious or of its derivatives. One must be especially unyielding about obedience to that rule with patients who practise the art of sheering off into intellectual discussion during their treatment, who speculate a great deal and often very wisely about their condition and in that way avoid doing anything to overcome it. For this reason I dislike making use of analytic writings as an assistance to my patients; I require them to learn by personal experience, and I assure them that they will acquire wider and more valuable knowledge than the whole literature of psycho-analysis could teach them. I recognize, however, that under institutional conditions it may be of great advantage to employ reading as a preparation for patients in analysis and as a means of creating an atmosphere of influence.

[1912e, 2474]

The purpose of some of the prohibitions is immediately obvious. Others, on the contrary, strike us as incomprehensible, senseless and silly, and prohibitions of this latter sort are described as 'ceremonial'. This distinction, too, is found in the observances of taboo.

[1912-1913, 2675]

Let us now summarize the points in which agreement between taboo usages and obsessional symptoms is most clearly shown: (1) the fact that the prohibitions lack any assignable motive; (2) the fact that they are maintained by an internal necessity; (3) the fact that they are easily displaceable and that there is a risk of infection from the prohibited object; and (4) the fact that they give rise to injunctions for the performance of ceremonial acts.

[1912-1913, 2676]

The principal characteristic of the psychological constellation which becomes fixed in this way is what might be described as the subject's ambivalent⁴ attitude towards a single object, or rather towards one act in connection with that object. He is constantly wishing to perform this act (the touching), and detests it as well. The conflict between these two currents cannot be promptly settled because - there is no other way of putting it - they are localized in the subject's mind in such a manner that they cannot come up against each other. The prohibition is noisily conscious, while the persistent desire to touch is unconscious and the subject knows nothing of it. If it were not for this psychological factor, an ambivalence like this could neither last so long nor lead to such consequences.

[1912-1913, 2677]
In our clinical history of a case we have insisted that the imposition of the prohibition in very early childhood is the determining point; a similar importance attaches in the subsequent developments to the mechanism of repression at the same early age. As a result of the repression which has been enforced and which involves a loss of memory - an amnesia - the motives for the prohibition (which is conscious) remain unknown; and all attempts at disposing of it by intellectual processes must fail, since they cannot find any base of attack. The prohibition owes its strength and its obsessive character precisely to its unconscious opponent, the concealed and undiminished desire - that is to say, to an internal necessity inaccessible to conscious inspection. The ease with which the prohibition can be transferred and extended reflects a process which falls in with the unconscious desire and is greatly facilitated by the psychological conditions that prevail in the unconscious. The instinctual desire is constantly shifting in order to escape from the impasse and endeavours to find substitutes - substitute objects and substitute acts - in place of the prohibited ones. In consequence of this, the prohibition itself shifts about as well, and extends to any new aims which the forbidden impulse may adopt. Any fresh advance made by the repressed libido is answered by a fresh sharpening of the prohibition. The mutual inhibition of the two conflicting forces produces a need for discharge, for reducing the prevailing tension; and to this may be attributed the reason for the performance of obsessive acts. In the case of a neurosis these are clearly compromise actions: from one point of view they are evidences of remorse, efforts at expiation, and so on, while on the other hand they are at the same time substitutive acts to compensate the instinct for what has been prohibited. It is a law of neurotic illness that these obsessive acts fall more and more under the sway of the instinct and approach nearer and nearer to the activity which was originally prohibited.

[1912-1913, 2678]

In the first place, then, it must be said that there is no sense in asking savages to tell us the real reason for their prohibitions - the origin of taboo. It follows from our postulates that they cannot answer, since their real reason must be 'unconscious'. We can, however, reconstruct the history of taboo as follows on the model of obsessional prohibitions. Taboos, we must suppose, are prohibitions of primaeval antiquity which were at some time externally imposed upon a generation of primitive men; they must, that is to say, no doubt have been impressed on them violently by the previous generation. These prohibitions must have concerned activities towards which there was a strong inclination. They must then have persisted from generation to generation, perhaps merely as a result of tradition transmitted through parental and social authority. Possibly, however, in later generations they may have become 'organized' as an inherited psychical endowment. Who can decide whether such things as 'innate ideas' exist, or whether in the present instance they have operated, either alone or in conjunction with education, to bring about the permanent fixing of taboos? But one thing would certainly follow from the persistence of the taboo, namely that the original desire to do the prohibited thing must also still persist among the tribes concerned. They must therefore have an ambivalent attitude towards their taboos. In their unconscious there is nothing they would like more than to violate them, but they are afraid to do so; they are afraid precisely because they would like to, and the fear is stronger than the desire. The desire is unconscious, however, in every individual member of the tribe just as it is in neurotics.

[1912-1913, 2679]
This transmissibility of taboo is a reflection of the tendency, on which we have already remarked, for the unconscious instinct in the neurosis to shift constantly along associative paths on to new objects. Our attention is thus directed to the fact that the dangerous magical force of mana corresponds to two powers of a more realistic sort: the power of reminding a man of his own prohibited wishes and the apparently more important one of inducing him to transgress the prohibition in obedience to those wishes. These two functions can be reduced to one, however, if we suppose that in a primitive mind the awakening of the memory of a forbidden action is naturally linked with the awakening of an impulse to put that action into effect. Thus recollection and temptation come together again. It must be admitted, too, that, in so far as the example of a man transgressing a prohibition tempts another man to do the same, disobedience to prohibitions spreads like a contagion, in just the same way as a taboo is transferred from a person to a material object and from one material object to another.

[1912-1913, 2682]

When a wife has lost her husband or a daughter her mother, it not infrequently happens that the survivor is overwhelmed by tormenting doubts (to which we give the name of 'obsessive self-reproaches') as to whether she may not herself have been responsible for the death of this cherished being through some act of carelessness or neglect. No amount of recollection of the care she lavished on the sufferer, no amount of objective disproof of the accusation, serves to bring the torment to an end. It may be regarded as a pathological form of mourning, and with the passage of time it gradually dies away. The psycho-analytic investigation of such cases has revealed the secret motives of the disorder. We find that in a certain sense these obsessive self-reproaches are justified, and that this is why they are proof against contradictions and protests. It is not that the mourner was really responsible for the death or was really guilty of neglect, as the self-reproaches declare to be the case. None the less there was something in her - a wish that was unconscious to herself - which would not have been dissatisfied by the occurrence of death and which might actually have brought it about if it had had the power. And after death has occurred, it is against this unconscious wish that the reproaches are a reaction. In almost every case where there is an intense emotional attachment to a particular person we find that behind the tender love there is a concealed hostility in the unconscious. This is the classical example, the prototype, of the ambivalence of human emotions. This ambivalence is present to a greater or less amount in the innate disposition of everyone; normally, there is not so much of it as to produce the obsessive self-reproaches we are considering. Where, however, it is copiously present in the disposition, it will manifest itself precisely in the subject's relation to those of whom he is most fond, in the place, in fact, where one would least expect to find it. It must be supposed that the presence of a particularly large amount of this original emotional ambivalence is characteristic of the disposition of obsessional neurotics - whom I have so often brought up for comparison in this discussion upon taboo.

[1912-1913, 2704]

One of the characteristics of this ambivalent relation which I have repeatedly stressed as fundamental - the fact that the positive current of desire is an unconscious one - opens the way to further considerations and to further possible explanations. Psychical processes in the unconscious are not in every respect identical with those with which our conscious mind is familiar; they enjoy some remarkable liberties that are forbidden to the latter. An unconscious impulse need not have arisen at the point where it makes its appearance; it may arise from some quite other region and have applied originally to quite other persons and connections; it may have reached the place at which it attracts our attention though the mechanism of 'displacement'. Owing, moreover, to the indestructibility and insusceptibility to correction which are attributes of unconscious processes, it may have survived from very early times to which it was appropriate into later times and circumstances in which its manifestations are bound to seem strange. These are no more than hints, but if they were attentively developed their importance for our understanding of the growth of civilization would become apparent.

[1912-1913, 2714]
In another neurotic disorder, obsessional neurosis, the patients become the victims of distressing and apparently senseless ceremonials which take the form of the rhythmical repetition of the most trivial acts (such as washing or dressing) or of carrying out meaningless injunctions or of obeying mysterious prohibitions. It was nothing less than a triumph of psychoanalytic research when it succeeded in showing that all these obsessive acts, even the most insignificant and trivial of them, have a meaning, and that they are reflections, translated into indifferent terms, of conflicts in the patients’ lives, of the struggle between temptations and moral restraints - reflections of the proscribed wish itself and of the punishment and atonement which that wish incurs. In another form of the same disorder the victim suffers from tormenting ideas (obsessions) which force themselves upon him and are accompanied by affects whose character and intensity are often only quite inadequately accounted for by the terms of the obsessive ideas themselves. Analytic investigation has shown in their case that the affects are entirely justified, since they correspond to self-reproaches which are based on something that is at least psychically real. But the ideas to which these affects are attached are not the original ones, but have found their way into their present position by a process of displacement - by being substituted for something that has been repressed. If these displacements can be reversed, the way is open to the discovery of the repressed ideas, and the relation between affect and idea is found to be perfectly appropriate.

[1913j, 2810]

Certainly this is a crazy illness. The most extravagant psychiatric imagination would not, I think, have succeeded in constructing anything like it; and if one did not see it before one every day one would never bring oneself to believe in it. Do not suppose, however, that you will help the patient in the least by calling on him to take a new line, to cease to occupy himself with such foolish thoughts and to do something sensible instead of his childish pranks. He would like to do so himself, for he is completely clear in his head, shares your opinion of his obsessional symptoms and even puts it forward to you spontaneously. Only he cannot help himself. What is carried into action in an obsessional neurosis is sustained by an energy to which we probably know nothing comparable in normal mental life. There is only one thing he can do: he can make displacements, and exchanges, he can replace one foolish idea by another somewhat milder, he can proceed from one precaution or prohibition to another, instead of one ceremonial he can perform another. He can displace the obsession but not remove it. The ability to displace any symptom into something far removed from its original conformation is a main characteristic of his illness. Moreover it is a striking fact that in his condition the contradictions (polarities) with which mental life is interlaced emerge especially sharply differentiated. Alongside of obsessions with a positive and negative content, doubt makes itself felt in the intellectual field and little by little it begins to gnaw even at what is usually most certain. The whole position ends up in an ever-increasing degree of indecision, loss of energy and restriction of freedom. At the same time, the obsessional neurotic starts off with a very energetic disposition, he is often extraordinarily self-willed and as a rule he has intellectual gifts above the average. He has usually reached a satisfactorily high level of ethical development; he exhibits over-conscientiousness, and is more than ordinarily correct in his behaviour. You can imagine that no small amount of work is needed before one can make one's way any distance into this contradictory hotch-potch of character-traits and symptoms. And to begin with we aim at nothing whatever else than understanding a few of the symptoms and being able to interpret them.

[1916-1917, 3340]
No doubt all kinds of objections can still be raised to the assertion that neurotic symptoms are substitutes for sexual satisfactions. I will mention two of them to-day. When you yourselves have carried out analytic examinations of a considerable number of neurotics, you will perhaps tell me, shaking your head, that in a lot of cases my assertion is simply not true; the symptoms seem rather to have the contrary purpose of excluding or of stopping sexual satisfaction. I will not dispute the correctness of your interpretation. The facts in psycho-analysis have a habit of being rather more complicated than we like. If they were as simple as all that, perhaps it might not have needed psycho-analysis to bring them to light. Indeed, some of the features of our second patient’s ceremonial show signs of this ascetic character with its hostility to sexual satisfaction: when, for instance, she got rid of the clocks and watches, which had the magical meaning of avoiding erections during the night, or when she tried to guard against flower-pots falling and breaking, which was equivalent to protecting her virginity. In some other cases of bed ceremonials, which I have been able to analyse, this negative character was far more outspoken; the ceremonial might consist exclusively of defensive measures against sexual memories and temptations. However, we have already found often enough that in psycho-analysis opposites imply no contradiction. We might extend our thesis and say that symptoms aim either at a sexual satisfaction or at fending it off, and that on the whole the positive, wish-fulfilling character prevails in hysteria and the negative, ascetic one in obsessional neurosis. If symptoms can serve the purpose both of sexual satisfaction and of its opposite, there is an excellent basis for this double-sidedness or polarity in a part of their mechanism which I have so far not been able to mention. For, as we shall hear, they are the products of a compromise and arise from the mutual interference between two opposing currents; they represent not only the repressed but also the repressing force which had a share in their origin. One side or the other may be more strongly represented; but it is rarely that one influence is entirely absent. In hysteria a convergence of both intentions in the same symptom is usually achieved. In obsessional neurosis the two portions are often separated; the symptom then becomes diphasic and consists in two actions, one after the other, which cancel each other out.

[1916-1917, 3373]

In obsessional neurosis, on the contrary, it is the regression of the libido to the preliminary stage of the sadistic-anal organization that is the most striking fact and the one which is decisive for what is manifested in symptoms. The love-impulse is obliged, when this has happened, to disguise itself as a sadistic impulse. The obsessional idea ‘I should like to kill you’, when it has been freed from certain additions which are not a matter of chance but are indispensable, means at bottom nothing other than ‘I should like to enjoy you in love’. If you consider further that there has been a simultaneous regression in regard to the object, so that these impulses apply only to those who are nearest and dearest to the patient, you can form some idea of the horror which these obsessions arouse in him and at the same time of the alien appearance which they present to his conscious perception. But repression, too, plays a great part in the mechanism of these neuroses, though in a cursory introduction like ours this is not easily demonstrated. A regression of the libido without repression would never produce a neurosis but would lead to a perversion. From this you can see that repression is the process which is most peculiar to neuroses and is most characteristic of them. Perhaps I may have an opportunity later of telling you what we know of the mechanism of the perversions, and you will see that in their case too things are not so simple as we should be glad to make them out.

[1916-1917, 3407]
I have credited you with a wish that I might have started my description of the neuroses from the behaviour of neurotic people, from an account of the manner in which they suffer under their neurosis, of how they defend themselves against it and how they come to terms with it. No doubt that is an interesting topic, worth investigating; nor would it be very difficult to handle. But it would be of debatable wisdom to start with it. There would be a risk of not discovering the unconscious and at the same time of overlooking the great importance of the libido and of judging everything as it appears to the ego of the neurotic subject. It is obvious that this ego is not a trustworthy or impartial agency. The ego is indeed the power which disavows the unconscious and has degraded it into being repressed; so how can we trust it to be fair to the unconscious? The most prominent elements in what is thus repressed are the repudiated demands of sexuality, and it is quite self-evident that we should never be able to guess their extent and importance from the ego's conceptions. From the moment the notion of repression dawns on us, we are warned against making one of the two contesting parties (and the victorious one, at that) into being judge in the dispute. We are prepared to find that the ego's assertions will lead us astray. If we are to believe the ego, it was active at every point and itself willed and created its symptoms. But we know that it puts up with a good amount of passivity, which it afterwards tries to disguise and gloss over. It is true that it does not always venture on such an attempt; in the symptoms of obsessional neurosis it is obliged to admit that there is something alien which is confronting it and against which it can only defend itself with difficulty.

You will recall that at our first meeting of the present academic year I described a case to you of a woman suffering from delusions of jealousy. Now that we are so near its end you would no doubt like to hear how delusions are explained by psycho-analysis. But I have less to tell you about that than you expect. The fact that a delusion cannot be shaken by logical arguments or real experiences is explained in the same way as in the case of an obsession - by its relation to the unconscious, which is represented and held down by the delusion or by the obsession. The difference between the two is based on the difference between the topography and dynamics of the two illnesses.

In certain diseases - including the very neuroses of which we have made special study - things are different. The ego feels uneasy; it comes up against limits to its power in its own house, the mind. Thoughts emerge suddenly without one's knowing where they come from, nor can one do anything to drive them away. These alien guests even seem to be more powerful than those which are at the ego's command. They resist all the well-proved measures of enforcement used by the will, remain unmoved by logical refutation, and are unaffected by the contradictory assertions of reality. Or else impulses appear which seem like those of a stranger, so that the ego disowns them; yet it has to fear them and take precautions against them. The ego says to itself: 'This is an illness, a foreign invasion.' It increases its vigilance, but cannot understand why it feels so strangely paralysed.

[1916-1917, 3433]

[1916-1917, 3471]

[1917a, 3612]
A patient, then, may be suffering from fluctuations in his moods which he cannot control, or from a sense of despondency by which his energy feels paralysed because he thinks he is incapable of doing anything properly, or from a nervous embarrassment among strangers. He may perceive, without understanding the reason for it, that he has difficulties in carrying out his professional work, or indeed any comparatively important decision or any undertaking. He may one day have suffered from a distressing attack - unknown in its origin - of feelings of anxiety, and since then have been unable, without a struggle, to walk along the street alone, or to travel by train; he may perhaps have had to give up both entirely. Or, a very remarkable thing, his thoughts may go their own way and refuse to be directed by his will. They pursue problems that are quite indifferent to him, but from which he cannot get free. Quite ludicrous tasks, too, are imposed on him, such as counting up the windows on the fronts of houses. And when he has performed simple actions such as posting a letter or turning off a gas-jet, he finds himself a moment later doubting whether he has really done so. This may be no more than an annoyance and a nuisance. But his state becomes intolerable if he suddenly finds he is unable to fend off the idea that he has pushed a child under the wheels of a car or has thrown a stranger off the bridge into the water, or if he has to ask himself whether he is not the murderer whom the police are looking for in connection with a crime that was discovered that day. It is obvious nonsense, as he himself knows; he has never done any harm to anyone; but if he were really the murderer who is being looked for, his feeling - his sense of guilt - could not be stronger.
[1926e, 4328]
Moreover, if I were to give way to my moral pride and tried to decree that for purposes of moral valuation I might disregard the evil in the id and need not make my ego responsible for it, what use would that be to me? Experience shows me that I nevertheless do take that responsibility, that I am somehow compelled to do so. Psycho-analysis has made us familiar with a pathological condition, obsessional neurosis, in which the poor ego feels itself responsible for all sorts of evil impulses of which it knows nothing, impulses which are brought up against it in consciousness but which it is unable to acknowledge. Something of this is present in every normal person. It is a remarkable fact that the more moral he is the more sensitive is his 'conscience'. It is just as though we could say that the healthier a man is, the more liable he is to contagions and to the effects of injuries. This is no doubt because conscience is itself a reaction-formation against the evil that is perceived in the id. The more strongly the latter is suppressed, the more active is the conscience.

[1925i, 4050]
In many true obsessions it is quite plain that the emotional state is the principal thing, since that state persists unchanged while the idea associated with it varies. The girl in Case 1 quoted below, for example, felt remorse in some degree for all sorts of reasons - for having stolen, for having ill-treated her sisters, for having made counterfeit money, etc. People who doubt have many doubts at the same time or in succession. It is the emotional state which remains constant in them; the idea changes. In other cases the idea, too, seems fixated, as in Case 4, of the girl who pursued the servants in the house with an incomprehensible hatred, though constantly changing the individual object.

Now a careful psychological analysis of these cases shows that the emotional state, as such, is always justified. The girl in Case 1, who suffered from remorse, had good reasons for it; the women in Case 3 who doubted their powers of resistance to temptation knew very well why. The girl in Case 4, who detested servants, had good reasons for complaining, etc. Only, and it is in these two characteristics that the pathological mark lies, (1) the emotional state persists indefinitely, and, (2) the associated idea is no longer the appropriate original one, related to the aetiology of the obsession, but is one which replaces it, a substitute for it.

As regards the theory of this process of substitution, I will content myself with answering three questions that arise here.

I think it may be regarded as an act of defence (Abwehr) of the ego against the incompatible idea. Among my patients there are some who remember a deliberate effort to banish the distressing idea or recollection from the field of consciousness. (See Cases 3, 4, 11.) In other cases the expulsion of the incompatible idea is brought about which has left no trace in the patient's memory.

The relation of these phobias to the phobias of obsessional neurosis, whose mechanism I made clear in an earlier paper¹ in this periodical, is of the following kind. What they have in common is that in both an idea becomes obsessional as a result of being attached to an available affect. The mechanism of transposition of affect thus holds good for both kinds of phobia. But in the phobias of anxiety neurosis (1) this affect always has the same colour, which is that of anxiety; and (2) the affect does not originate in a repressed idea, but turns out to be not further reducible by psychological analysis, nor amenable to psychotherapy. The mechanism of substitution, therefore, does not hold good for the phobias of anxiety neurosis.

Both kinds of phobias (and also obsessions) often appear side by side; although the atypical phobias, which are based on obsessions, need not necessarily spring from the soil of anxiety neurosis. A very frequent and apparently complicated mechanism makes its appearance if, in what was originally a simple phobia belonging to an anxiety neurosis, the content of the phobia is replaced by another idea, so that the substitute is subsequent to the phobia. What are most often employed as substitutes are the 'protective measures' that were originally used to combat the phobia. Thus, for instance, 'brooding mania' arises from the subject's endeavours to disprove that he is mad, as his hypochondriacal phobia maintains; the hesitations and doubt, and still more the repetitions, of folie du doute arise from a justifiable doubt about the certainty of one's own train of thought, since one is conscious of its persistent disturbance by ideas of an obsessional sort, and so on. We can therefore assert that many syndromes, too, of obsessional neurosis, such as folie du doute and the like, are also to be reckoned, clinically if not conceptually, as belonging to anxiety neurosis.²
For a considerable time I have harboured a suspicion that paranoia, too - or classes of cases which fall under the heading of paranoia - is a psychosis of defence; that is to say, that, like hysteria and obsessions, it proceeds from the repression of distressing memories and that its symptoms are determined in their form by the content of what has been repressed. Paranoia must, however, have a special method or mechanism of repression which is peculiar to it, in the same way as hysteria effects repression by the method of conversion into somatic innervation, and obsessional neurosis by the method of substitution (viz. by displacement along the lines of certain categories of associations). I had observed several cases which favoured this interpretation, but had found none which proved it; until, a few months ago, I had an opportunity, through the kindness of Dr. Josef Breuer, of undertaking the psycho-analysis for therapeutic purposes of an intelligent woman of thirty-two, in whose case a diagnosis of chronic paranoia could not be questioned. I am reporting in these pages, without waiting further, some of the information I have been able to obtain from this piece of work, because I have no prospect of studying paranoia except in very isolated instances, and because I think it possible that my remarks may encourage a psychiatrist better placed than I am in this matter to give its rightful place to the factor of 'defence' in the discussion as to the nature and psychical mechanism of paranoia which is being carried on so actively just now. I have, of course, on the strength of the following single observation, no intention of saying more than: 'This case is a psychosis of defence and there are most probably others in the class of "paranoia" which are equally so.'

A young woman after the birth of her first child was compelled to give up breast-feeding it owing to a complex of hysterical symptoms (loss of appetite, sleeplessness, pains in her breasts, failure of milk-secretion, agitation). When, after the birth of a second child, these obstacles recurred, deep hypnosis on two occasions, accompanied by counter-suggestions, succeeded in removing the obstacles, so that the patient became an excellent nursing mother. The same result was brought about a year later in similar circumstances after two more hypnoses. Some remarks are appended on the fact that it is possible in hysterical patients for distressing antithetic or anxious ideas to be realized which normal people are able to inhibit; several observations of tic are traced back to this mechanism of 'counter-will'.

This is just the situation in our dream. It is hardly rash to assume that the unintelligibility of the dream's content, as it exists in the memory has led to its being recast in a form designed to make sense of the situation. That situation, however, is in the process deprived of its original meaning and put to extraneous uses. But, as we shall see later, it is a common thing for the conscious thought-activity of a second psychical system to misunderstand the content of a dream in this way, and this misunderstanding must be regarded as one of the factors in determining the final form assumed by dreams. Moreover we shall learn that similar misunderstandings (taking place, once again, within one and the same psychical personality) play a major part in the construction of obsessions and phobias.

¹ [Footnote added 1909:] Not long ago I found a single exception to this rule in the case of a young man who suffered from obsessions while retaining intact his highly developed intellectual powers. The spoken words which occurred in his dreams were not derived from remarks which he had heard or made himself. They contained the undistorted text of his obsessional thoughts, which in his waking life only reached his consciousness in a modified form.
The matter contained in the following pages will be of two kinds. In the first place I shall give some fragmentary extracts from the history of a case of obsessional neurosis. This case judged by its length, the injuriousness of its effects, and the patient's own view of it, deserves to be classed as a moderately severe one; the treatment, which lasted for about a year, led to the complete restoration of the patient's personality, and to the removal of his inhibitions. In the second place, starting out from this case, and also taking other cases into account which I have previously analysed, I shall make some disconnected statements of an aphoristic character upon the genesis and finer psychological mechanism of obsessional processes, and I shall thus hope to develop my first observations on the subject, published in 1896.¹

[1909d, 2127]

As a particularly clear example I will begin with one of the suicidal impulses which appeared so frequently in our patient. This instance almost analysed itself in the telling. He had once, he told me, lost some weeks of study owing to his lady's absence: she had gone away to nurse her grandmother, who was seriously ill. Just as he was in the middle of a very hard piece of work the idea had occurred to him: 'If you received a command to take your examination this term at the first possible opportunity, you might manage to obey it. But if you were commanded to cut your throat with a razor, what then?' He had at once become aware that this command had already been given, and was hurrying to the cupboard to fetch his razor when he thought: 'No, it's not so simple as that. You must go and kill the old woman.' Upon that, he had fallen to the ground, beside himself with horror.

[1909d, 2147]

In this instance the connection between the compulsive idea and the patient's life is contained in the opening words of his story. His lady was absent, while he was working very hard for an examination so as to bring the possibility of an alliance with her nearer. While he was working he was overcome by a longing for his absent lady, and he thought of the cause of her absence. And now there came over him something which, if he had been a normal man, would probably have been some kind of feeling of annoyance with her grandmother: 'Why must the old woman get ill just at the very moment when I'm longing for her so frightfully?' We must suppose that something similar but far more intense passed through our patient's mind - an unconscious fit of rage which could combine with his longing and find expression in the exclamation: 'Oh, I should like to go and kill that old woman for robbing me of my love!' Thereupon followed the command: 'Kill yourself, as a punishment for these savage and murderous passions!' The whole process then passed into the obsessional patient's consciousness accompanied by the most violent affect and in a reverse order - the punitive command coming first, and the mention of the guilty outburst afterwards. I cannot think that this attempt at an explanation will seem forced or that it involves many hypothetical elements.

[1909d, 2147]

Compulsive acts like this, in two successive stages, of which the second neutralizes the first, are a typical occurrence in obsessional neuroses. The patient's consciousness naturally misunderstands them and puts forward a set of secondary motives to account for them - rationalizes them, in short. (Cf. Jones, 1908.) But their true significance lies in their being a representation of a conflict between two opposing impulses of approximately equal strength: and hitherto I have invariably found that this opposition has been one between love and hate. Compulsive acts of this sort are theoretically of special interest, for they show us a new type of method of constructing symptoms. What regularly occurs in hysteria is that a compromise is arrived at which enables both the opposing tendencies to find expression simultaneously - which kills two birds with one stone:¹ whereas here each of the two opposing tendencies finds satisfaction singly, first one and then the other, though naturally an attempt is made to establish some sort of logical connection (often in defiance of all logic) between the antagonists.²

[1909d, 2151]
But the information that the young lady at the post office at Z-- had herself paid the charges due upon the packet, with a complimentary remark about himself,¹ had intensified his identification with his father in quite another direction. At this stage in the analysis he brought out some new information, to the effect that the landlord of the inn at the little place where the post office was had had a pretty daughter. She had been decidedly encouraging to the smart young officer, so that he had thought of returning there after the manoeuvres were over and of trying his luck with her. Now, however, she had a rival in the shape of the young lady at the post office. Like his father in the tale of his marriage, he could afford now to hesitate upon which of the two he should bestow his favours when he had finished his military service. We can see at once that his singular indecision whether he should travel to Vienna or go back to the place where the post office was, and the constant temptation he felt to turn back while he was on the journey (p. 2140), were not so senseless as they seemed to us at first. To his conscious mind, the attraction exercised upon him by Z--, the place where the post office was, was explained by the necessity of seeing Lieutenant A. and fulfilling the vow with his assistance. But in reality what was attracting him was the young lady at the post office, and the lieutenant was merely a good substitute for her, since he had lived at the same place and had himself been in charge of the military postal service. And when subsequently he heard that it was not Lieutenant A. but another officer B., who had been on duty at the post office that day, he drew him into his combination as well; and he was then able to reproduce in his deliria in connection with the two officers the hesitation he felt between the two girls who were so kindly disposed towards him.²

There can be no doubt that the patient felt a need for finding experiences of this kind to act as props for his superstition, and that it was for that reason that he occupied himself so much with the inexplicable coincidences of everyday life with which we are all familiar, and helped out their shortcomings with unconscious activity of his own. I have come across a similar need in many other obsessional patients and have suspected its presence in many more besides. It seems to me easily explicable in view of the psychological characteristics of the obsessional neurosis. In this disorder, as I have already explained (p. 2155), repression is effected not by means of amnesia but by a severance of causal connections brought about by a withdrawal of affect. These repressed connections appear to persist in some kind of shadowy form (which I have elsewhere compared to an endopsychic perception),¹ and they are thus transferred, by a process of projection, into the external world, where they bear witness to what has been effaced from consciousness.

[1909d, 2165]

[1909d, 2181]
If we wish to obtain a grasp of the psychical forces whose interplay built up this neurosis, we must turn back to what we have learnt from the patient on the subject of the precipitating causes of his falling ill as a grown-up man and as a child. He fell ill when he was in his twenties on being faced with a temptation to marry another woman instead of the one whom he had loved so long; and he avoided a decision of this conflict by postponing all the necessary preliminary actions. The means for doing this was given him by his neurosis. His hesitation between the lady he loved and the other girl can be reduced to a conflict between his father's influence and his love for his lady, or, in other words, to a conflicting choice between his father and his sexual object, such as had already subsisted (judging from his recollections and obsessional ideas) in his remote childhood. All through his life, moreover, he was unmistakably victim to a conflict between love and hatred, in regard both to his lady and to his father. His phantasies of revenge and such obsessional phenomena as his obsession for understanding and his exploit with the stone in the road bore witness to his divided feelings; and they were to a certain degree comprehensible and normal, for the lady by her original refusal and subsequently by her coolness had given him some excuse for hostility. But his relations with his father were dominated by a similar division of feeling, as we have seen from our translation of his obsessional thoughts; and his father, too, must have given him an excuse for hostility in his childhood, as indeed we have been able to establish almost beyond question. His attitude towards the lady - a compound of tenderness and hostility - came to a great extent within the scope of his conscious knowledge; at most he deceived himself over the degree and violence of his negative feelings. But his hostility towards his father, on the contrary, though he had once been acutely conscious of it, had long since vanished from his ken, and it was only in the teeth of the most violent resistance that it could be brought back into his consciousness. We may regard the repression of his infantile hatred of his father as the event which brought his whole subsequent career under the dominion of the neurosis.

[1909d, 2185]

The other conflict, that between love and hatred, strikes us more strangely. We know that incipient love is often perceived as hatred, and that love, if it is denied satisfaction, may easily be partly converted into hatred, and poets tell us that in the more tempestuous stages of love the two opposed feelings may subsist side by side for a while as though in rivalry with each other. But the chronic co-existence of love and hatred, both directed towards the same person and both of the highest degree of intensity, cannot fail to astonish us. We should have expected that the passionate love would long ago have conquered the hatred or been devoured by it. And in fact such a protracted survival of two opposites is only possible under quite peculiar psychological conditions and with the co-operation of the state of affairs in the unconscious. The love has not succeeded in extinguishing the hatred but only in driving it down into the unconscious; and in the unconscious the hatred, safe from the danger of being destroyed by the operations of consciousness, is able to persist and even to grow. In such circumstances the conscious love attains as a rule, by way of reaction, an especially high degree of intensity, so as to be strong enough for the perpetual task of keeping its opponent under repression. The necessary condition for the occurrence of such a strange state of affairs in a person's erotic life appears to be that at a very early age, somewhere in the prehistoric period of his infancy, the two opposites should have been split apart and one of them, usually the hatred, have been repressed.¹

[1909d, 2186]
If we consider a number of analyses of obsessional neurotics we shall find it impossible to escape the impression that a relation between love and hatred such as we have found in our present patient is among the most frequent, the most marked, and probably, therefore, the most important characteristics of obsessional neurosis. But however tempting it may be to bring the problem of the 'choice of neurosis' into connection with instinctual life, there are reasons enough for avoiding such a course. For we must remember that in every neurosis we come upon the same suppressed instincts behind the symptoms. After all, hatred, kept suppressed in the unconscious by love, plays a great part in the pathogenesis of hysteria and paranoia. We know too little of the nature of love to be able to arrive at any definite conclusion here; and, in particular, the relation between the negative factor in love and the sadistic components of the libido remains completely obscure. What follows is therefore to be regarded as no more than a provisional explanation. We may suppose, then, that in the cases of unconscious hatred with which we are concerned the sadistic components of love have, from constitutional causes, been exceptionally strongly developed, and have consequently undergone a premature and all too thorough suppression, and that the neurotic phenomena we have observed arise on the one hand from conscious feelings of affection which have become exaggerated as a reaction, and on the other hand from sadism persisting in the unconscious in the form of hatred.

The compulsion on the other hand is an attempt at a compensation for the doubt and at a correction of the intolerable conditions of inhibition to which the doubt bears witness. If the patient, by the help of displacement, succeeds at last in bringing one of his inhibited intentions to a decision, then the intention must be carried out. It is true that this intention is not his original one, but the energy dammed up in the latter cannot let slip the opportunity of finding an outlet for its discharge in the substitutive act. Thus this energy makes itself felt now in commands and now in prohibitions, according as the affectionate impulse or the hostile one snatches control of the pathway leading to discharge. If it happens that a compulsive command cannot be obeyed, the tension becomes intolerable and is perceived by the patient in the form of extreme anxiety. (But the pathway leading to a substitutive act, even where the displacement has been on to something very small, is so hotly contested, that such an act can as a rule be carried out only in the shape of a protective measure intimately associated with the very impulse which it is designed to ward off.

Furthermore, by a sort of regression, preparatory acts become substituted for the final decision, thinking replaces acting, and, instead of the substitutive act, some thought preliminary to it asserts itself with all the force of compulsion. According as this regression from acting to thinking is more or less marked, a case of obsessional neurosis will exhibit the characteristics of obsessive thinking (that is, of obsessional ideas) or of obsessive acting in the narrower sense of the word. True obsessional acts such as these, however, are only made possible because they constitute a kind of reconciliation, in the shape of a compromise, between the two antagonistic impulses. For obsessional acts tend to approximate more and more - and the longer the disorder lasts the more evident does this become - to infantile sexual acts of a masturbatory character. Thus in this form of the neurosis acts of love are carried out in spite of everything, but only by the aid of a new kind of regression; for such acts no longer relate to another person, the object of love and hatred, but are auto-erotic acts such as occur in infancy.

The first kind of regression, that from acting to thinking, is facilitated by another factor concerned in the production of the neurosis. The histories of obsessional patients almost invariably reveal an early development and premature repression of the sexual instinct of looking and knowing; and, as we know, a part of the infantile sexual activity of our present patient was governed by that instinct.

[1909d, 2187]

[1909d, 2190]

[1909d, 2191]

[1909d, 2191]
The obsessive thought which has forced its way into consciousness with such excessive violence has next to be secured against the efforts made by conscious thought to resolve it. As we already know, this protection is afforded by the distortion which the obsessive thought has undergone before becoming conscious. But this is not the only means employed. In addition, each separate obsessional idea is almost invariably removed from the situation in which it originated and in which, in spite of its distortion, it would be most easily comprehensible. With this end in view, in the first place an interval of time is inserted between the pathogenic situation and the obsession that arises from it, so as to lead astray any conscious investigation of its causal connections, and in the second place the content of the obsession is taken out of its particular setting by being generalized. Our patient's 'obsession for understanding' is an example of this (p. 2150). But perhaps a better one is afforded by another patient. This was a woman who prohibited herself from wearing any sort of personal adornment, though the exciting cause of the prohibition related only to one particular piece of jewellery: she had envied her mother the possession of it and had had hopes that one day she would inherit it. Finally, if we care to distinguish verbal distortion from distortion of content, there is yet another means by which the obsession is protected against conscious attempts at solution. And that is the choice of an indefinite or ambiguous wording. After being misunderstood, the wording may find its way into the patient's 'deliria', and whatever further processes of development or substitution his obsession undergoes will then be based upon the misunderstanding and not upon the proper sense of the text. Observation will show, however, that the deliria constantly tend to form new connections with that part of the matter and wording of the obsession which is not present in consciousness.

This interpretation by the psychological novelist cannot be put to the proof, but it can claim so much inner probability, and is so much in harmony with all that we otherwise know of Leonardo's emotional activity, that I cannot refrain from accepting it as correct. He had succeeded in subjecting his feelings to the yoke of research and in inhibiting their free utterance; but even for him there were occasions when what had been suppressed obtained expression forcibly. The death of the mother he had once loved so dearly was one of these. What we have before us in the account of the costs of the funeral is the expression - distorted out of all recognition - of his mourning for his mother. We wonder how such distortion could come about, and indeed we cannot understand it if we treat it as a normal mental process. But similar processes are well known to us in the abnormal conditions of neurosis and especially of what is known as 'obsessional neurosis'. There we can see how the expression of intense feelings, which have however become unconscious through repression, is displaced on to trivial and even foolish actions. The expression of these repressed feelings has been lowered by the forces opposed to them to such a degree that one would have had to form a most insignificant estimate of their intensity; but the imperative compulsiveness with which this trivial expressive act is performed betrays the real force of the impulses - a force which is rooted in the unconscious and which consciousness would like to deny. Only a comparison such as this with what happens in obsessional neurosis can explain Leonardo's account of the expenses of his mother's funeral. In his unconscious he was still tied to her by erotically coloured feelings, as he had been in childhood. The opposition that came from the subsequent repression of this childhood love did not allow him to set up a different and worthier memorial to her in his diary. But what emerged as a compromise from this neurotic conflict had to be carried out; and thus it was that the account was entered in the diary, and has come to the knowledge of posterity as something unintelligible.

[1910c, 2279]
But even if the historical material at our disposal were very abundant, and if the psychical mechanisms could be dealt with with the greatest assurance, there are two important points at which a psycho-analytic enquiry would not be able to make us understand how inevitable it was that the person concerned should have turned out in the way he did and in no other way. In Leonardo's case we have had to maintain the view that the accident of his illegitimate birth and the excessive tenderness of his mother had the most decisive influence on the formation of his character and on his later fortune, since the sexual repression which set in after this phase of childhood caused him to sublimate his libido into the urge to know, and established his sexual inactivity for the whole of his later life. But this repression after the first erotic satisfactions of childhood need not necessarily have taken place; in someone else it might perhaps not have taken place or might have assumed much less extensive proportions. We must recognize here a degree of freedom which cannot be resolved any further by psycho-analytic means. Equally, one has no right to claim that the consequence of this wave of repression was the only possible one. It is probable that another person would not have succeeded in withdrawing the major portion of his libido from repression by sublimating it into a craving for knowledge; under the same influences he would have sustained a permanent injury to his intellectual activity or have acquired an insurmountable disposition to obsessional neurosis. We are left, then, with these two characteristics of Leonardo which are inexplicable by the efforts of psycho-analysis: his quite special tendency towards instinctual repressions, and his extraordinary capacity for sublimating the primitive instincts.

[1910c, 2303]

Unfortunately I am unable, for familiar reasons, to enter into the history of the case as far as I should like, and I must restrict myself to the account which follows. Up to the time of her falling ill the patient had been a happy and almost completely satisfied wife. She wanted to have children, from motives based on an infantile fixation of her wishes, and she fell ill when she learned that it was impossible for her to have any by the husband who was the only object of her love. The anxiety hysteria with which she reacted to this frustration corresponded, as she herself soon learned to understand, to the repudiation of phantasies of seduction in which her firmly implanted wish for a child found expression. She now did all she could to prevent her husband from guessing that she had fallen ill owing to the frustration of which he was the cause. But I have had good reason for asserting that everyone possesses in his own unconscious an instrument with which he can interpret the utterances of the unconscious in other people. Her husband understood, without any admission or explanation on her part, what his wife's anxiety meant; he felt hurt, without showing it, and in his turn reacted neurotically by - for the first time - failing in sexual intercourse with her. Immediately afterwards he started on a journey. His wife believed that he had become permanently impotent, and produced her first obsessional symptoms on the day before his expected return.

[1913i, 2626]
The second gap in our hypothesis is far more important. As we know, the developmental disposition to a neurosis is only complete if the phase of the development of the ego at which fixation occurs is taken into account as well as that of the libido. But our hypothesis has only related to the latter, and therefore does not include all the knowledge that we should demand. The stages of development of the ego-instincts are at present very little known to us; I know of only one attempt - the highly promising one made by Ferenczi (1913) - to approach these questions. I cannot tell if it may seem too rash if, on the basis of such indications as we possess, I suggest the possibility that a chronological outstripping of libido development by ego development should be included in the disposition to obsessional neurosis. A precocity of this kind would necessitate the choice of an object under the influence of the ego-instincts, at a time at which the sexual instincts had not yet assumed their final shape, and a fixation at the stage of the pregenital sexual organization would thus be left. If we consider that obsessional neurotics have to develop a super-morality in order to protect their object-love from the hostility lurking behind it, we shall be inclined to regard some degree of this precocity of ego development as typical of human nature and to derive the capacity for the origin of morality from the fact that in the order of development hate is the precursor of love. This is perhaps the meaning of an assertion by Stekel (1911a, 536), which at the time I found incomprehensible, to the effect that hate and not love is the primary emotional relation between men. [1913i, 2630]

In our clinical history of a case we have insisted that the imposition of the prohibition in very early childhood is the determining point; a similar importance attaches in the subsequent developments to the mechanism of repression at the same early age. As a result of the repression which has been enforced and which involves a loss of memory - an amnesia - the motives for the prohibition (which is conscious) remain unknown; and all attempts at disposing of it by intellectual processes must fail, since they cannot find any base of attack. The prohibition owes its strength and its obsessive character precisely to its unconscious opponent, the concealed and undiminished desire - that is to say, to an internal necessity inaccessible to conscious inspection. The ease with which the prohibition can be transferred and extended reflects a process which falls in with the unconscious desire and is greatly facilitated by the psychological conditions that prevail in the unconscious. The instinctual desire is constantly shifting in order to escape from the impasse and endeavours to find substitutes - substitute objects and substitute acts - in place of the prohibited ones. In consequence of this, the prohibition itself shifts about as well, and extends to any new aims which the forbidden impulse may adopt. Any fresh advance made by the repressed libido is answered by a fresh sharpening of the prohibition. The mutual inhibition of the two conflicting forces produces a need for discharge, for reducing the prevailing tension; and to this may be attributed the reason for the performance of obsessive acts. In the case of a neurosis these are clearly compromise actions: from one point of view they are evidences of remorse, efforts at expiation, and so on, while on the other hand they are at the same time substitutive acts to compensate the instinct for what has been prohibited. It is a law of neurotic illness that these obsessive acts fall more and more under the sway of the instinct and approach nearer and nearer to the activity which was originally prohibited. [1912-1913, 2678]
But the strongest support for our effort to equate taboo prohibitions with neurotic symptoms is to be found in the taboo ceremonials themselves, the effect of which upon the position of royalty has already been discussed. These ceremonials unmistakably reveal their double meaning and their derivation from ambivalent impulses, as soon as we are ready to allow that the results which they bring about were intended from the first. The taboo does not only pick out the king and exalt him above all common mortals, it also makes his existence a torment and an intolerable burden and reduces him to a bondage far worse than that of his subjects. Here, then, we have an exact counterpart of the obsessional act in the neurosis, in which the suppressed impulse and the impulse that suppresses it find simultaneous and common satisfaction. The obsessional act is *ostensibly* a protection against the prohibited act; but *actually*, in our view, it is a repetition of it. The 'ostensibly' applies to the conscious part of the mind, and the 'actually' to the *unconscious* part. In exactly the same way, the ceremonial taboo of kings is *ostensibly* the highest honour and protection for them, while *actually* it is a punishment for their exaltation, a revenge taken on them by their subjects. The experiences of Sancho Panza (as described by Cervantes) when he was Governor of his island convinced him that this view of court ceremonial was the only one that met the case. If we could hear the views of modern kings and rulers on the subject, we might find that there were many others who agreed with him.

[1912-1913, 2696]

How, then, are we to account for the unexpected nobility of mind of the neurotic, who fears nothing on his own account but everything for someone he loves? Analytical inquiry shows that this attitude is not primary. Originally, that is to say at the beginning of the illness, the threat of punishment applied, as in the case of savages, to the patient himself; he was invariably in fear for his own life; it was not until later that the mortal fear was displaced on to another and a loved person. The process is a little complicated, but we can follow it perfectly. At the root of the prohibition there is invariably a hostile impulse against someone the patient loves - a wish that that person should die. This impulse is repressed by a prohibition and the prohibition is attached to some particular act, which, by displacement, represents, it may be, a hostile act against the loved person. There is a threat of death if this act is performed. But the process goes further, and the original wish that the loved person may die is replaced by fear that he may die. So that when the neurosis appears to be so tenderly altruistic, it is merely *compensating* for an underlying contrary attitude of brutal egoism. We may describe as 'social' the emotions which are determined by showing consideration for another person without taking him as a sexual object. The receding into the background of these social factors may be stressed as a fundamental characteristic of the neurosis, though one which is later disguised by overcompensation.

[1912-1913, 2716]
A totally different picture of repression is shown, once more, in the third disorder which we shall consider for the purposes of our illustration - in obsessional neurosis. Here we are at first in doubt what it is that we have to regard as the instinctual representative that is subjected to repression - whether it is a libidinal or a hostile trend. This uncertainty arises because obsessional neurosis has as its basis a regression owing to which a sadistic trend has been substituted for an affectionate one. It is this hostile impulsion against someone who is loved which is subjected to repression. The effect at an early stage of the work of repression is quite different from what it is at a later one. At first the repression is completely successful; the ideational content is rejected and the affect made to disappear. As a substitutive formation there arises an alteration in the ego in the shape of an increased conscientiousness, and this can hardly be called a symptom. Here, substitute and symptom do not coincide. From this we learn something, too, about the mechanism of repression. In this instance, as in all others, repression has brought about a withdrawal of libido; but here it has made use of reaction-formation for this purpose, by intensifying an opposite. Thus in this case the formation of a substitute has the same mechanism as repression and at bottom coincides with it, while chronologically, as well as conceptually, it is distinct from the formation of a symptom. It is very probable that the whole process is made possible by the ambivalent relationship into which the sadistic impulsion that has to be repressed has been introduced. But the repression, which was at first successful, does not hold firm; in the further course of things its failure becomes increasingly marked. The ambivalence which has enabled repression through reaction-formation to take place is also the point at which the repressed succeeds in returning. The vanished affect comes back in its transformed shape as social anxiety, moral anxiety and unlimited self-reproaches; the rejected idea is replaced by a substitute by displacement, often a displacement on to something very small or indifferent. A tendency to a complete re-establishment of the repressed idea is as a rule unmistakably present. The failure in the repression of the quantitative, affective factor brings into play the same mechanism of flight, by means of avoidance and prohibitions, as we have seen at work in the formation of hysterical phobias. The rejection of the idea from the conscious is, however, obstinately maintained, because it entails abstention from action, a motor fettering of the impulsion. Thus in obsessional neurosis the work of repression is prolonged in a sterile and interminable struggle.

Of the many symptomatic pictures in which obsessional neurosis appears, the most important turn out to be those provoked by the pressure of excessively strong sadistic sexual impulses (perverse, therefore, in their aim). The symptoms, indeed, in accordance with the structure of an obsessional neurosis, serve predominantly as a defence against these wishes or give expression to the struggle between satisfaction and defence. But satisfaction does not come off too badly either; it succeeds in roundabout ways in putting itself into effect in the patients' behaviour and is preferably directed against themselves and makes them into self-tormentors. Other forms of the neurosis, the brooding kinds, correspond to an excessive sexualization of actions which ordinarily have their place on the path to normal sexual satisfaction - an excessive sexualization of wanting to look or to touch or to explore. Here we have the explanation of the great importance of the fear of touching and of the obsession for washing. An unsuspectedly large proportion of obsessional actions may be traced back to masturbation, of which they are disguised repetitions and modifications; it is a familiar fact that masturbation, though a single and uniform action, accompanies the most various forms of sexual phantasying.
This, then, is what I wanted to tell you about the formation of symptoms in the neuroses. But I must not fail to lay emphasis expressly once again on the fact that everything I have said here applies only to the formation of symptoms in hysteria. Even in obsessional neurosis there is much - apart from fundamentals, which remain unaltered - that will be found different. The anticathexes opposing the demands of the instincts (which we have already spoken of in the case of hysteria as well) become prominent in obsessional neurosis and dominate the clinical picture in the form of what are known as 'reaction formations'. We discover similar and even more far-reaching divergences in the other neuroses, where our researches into the mechanisms of symptom-formation are not yet concluded at any point.

[1916-1917, 3430]

One of the ways in which the ego is related to its neuroses is, however, so obvious that it was possible to take it into account from the first. It seems never to be absent; but it is most clearly recognizable in a disorder which we are even to-day far from understanding - traumatic neurosis. For you must know that the same factors always come into operation in the causation and mechanism of every possible form of neurosis; but the chief importance in the construction of the symptoms falls now upon one and now upon another of these factors. The position is like that among the members of a theatrical company. Each of them is regularly cast for his own stock role - hero, confidant, villain, and so on; but each of them will choose a different piece for his benefit performance. In the same way phantasies which turn into symptoms are nowhere more obvious than in hysteria; the anticathexes or reaction-formations of the ego dominate the picture in obsessional neurosis; what in the case of dreams we have termed 'secondary revision' stands in the forefront in paranoia in the shape of delusions, and so on.

[1916-1917, 3434]

The transformation did not occur spontaneously, through internal development, but through an outside influence. Its visible effect was that the patient's relation to his father, which stood in the foreground, and which had so far found expression in the wolf phobia, was now manifested in obsessional piety. I cannot refrain from pointing out that the course of events in this part of the patient's history affords an unmistakable confirmation of an assertion which I made in Totem and Taboo upon the relation of the totem animal to the deity.¹ I there decided in favour of the view that the idea of God was not a development from the totem, but replaced it after arising independently from a root common to both ideas. The totem, I maintained, was the first father-surrogate, and the god was a later one, in which the father had regained his human shape. And we find the same thing with our patient. In his wolf phobia he had gone through the stage of the totemic father-surrogate; but that stage was now broken off, and, as a result of new relations between him and his father, was replaced by a phase of religious piety.

[1918b, 3590]
The Theory of Repression. - These theoretical considerations, taken together with the immediate impressions derived from analytic work, lead to a view of the neuroses which may be described in the roughest outline as follows. The neuroses are the expression of conflicts between the ego and such of the sexual impulses as seem to the ego incompatible with its integrity or with its ethical standards. Since these impulses are not ego-syntonic, the ego has repressed them: that is to say, it has withdrawn its interest from them and has shut them off from becoming conscious as well as from obtaining satisfaction by motor discharge. If in the course of analytic work one attempts to make these repressed impulses conscious, one becomes aware of the repressive forces in the form of resistance. But the achievement of repression fails particularly readily in the case of the sexual instincts. Their damned-up libido finds other ways out from the unconscious: for it regresses to earlier phases of development and earlier attitudes towards objects, and, at weak points in the libidinal development where there are infantile fixations, it breaks through into consciousness and obtains discharge. What results is a symptom and consequently in its essence a substitutive sexual satisfaction. Nevertheless the symptom cannot entirely escape from the repressive forces of the ego and must therefore submit to modifications and displacements exactly as happens with dreams - by means of which its characteristic of being a sexual satisfaction becomes unrecognizable. Consequently symptoms are in the nature of compromises between the repressed sexual instincts and the repressing ego-instincts; they represent a wish-fulfilment for both partners to the conflict simultaneously, but one which is incomplete for each of them. This is quite strictly true of the symptoms of hysteria, while in the symptoms of obsessional neurosis there is often a stronger emphasis upon the side of the repressing function owing to the erection of reaction-formations, which are assurances against sexual satisfaction.

[1923a, 3923]

An interpretation of the normal, conscious sense of guilt (conscience) presents no difficulties; it is based on the tension between the ego and the ego ideal and is the expression of a condemnation of the ego by its critical agency. The feelings of inferiority so well known in neurotics are presumably not far removed from it. In two very familiar maladies the sense of guilt is over-strongly conscious; in them the ego ideal displays particular severity and often rages against the ego in a cruel fashion. The attitude of the ego ideal in these two conditions, obsessional neurosis and melancholia, presents, alongside of this similarity, differences that are no less significant.

[1923b, 3985]

In certain forms of obsessional neurosis the sense of guilt is over-noisy but cannot justify itself to the ego. Consequently the patient's ego rebels against the imputation of guilt and seeks the physician's support in repudiating it. It would be folly to acquiesce in this, for to do so would have no effect. Analysis eventually shows that the super-ego is being influenced by processes that have remained unknown to the ego. It is possible to discover the repressed impulses which are really at the bottom of the sense of guilt. Thus in this case the super-ego knew more than the ego about the unconscious id.

[1923b, 3985]
It is essentially in hysteria and in states of a hysterical type that this is found. Here the mechanism by which the sense of guilt remains unconscious is easy to discover. The hysterical ego fends off a distressing perception with which the criticisms of its super-ego threaten it, in the same way in which it is in the habit of fending off an unendurable object-cathexis - by an act of repression. It is the ego, therefore, that is responsible for the sense of guilt remaining unconscious. We know that as a rule the ego carries out repressions in the service and at the behest of its super-ego; but this is a case in which it has turned the same weapon against its harsh taskmaster. In obsessional neurosis, as we know, the phenomena of reaction-formation predominate; but here the ego succeeds only in keeping at a distance the material to which the sense of guilt refers. [1923b, 3985]

The reproaches of conscience in certain forms of obsessional neurosis are as distressing and tormenting, but here the situation is less perspicuous. It is noteworthy that the obsessional neurotic, in contrast to the melancholic, never in fact takes the step of self-destruction; it is as though he were immune against the danger of suicide, and he is far better protected from it than the hysterical. We can see that what guarantees the safety of the ego is the fact that the object has been retained. In obsessional neurosis it has become possible, through a regression to the pregenital organization, for the love-impulses to transform themselves into impulses of aggression against the object. Here again the instinct of destruction has been set free and it seeks to destroy the object, or at least it appears to have that intention. These purposes have not been adopted by the ego and it struggles against them with reaction-formations and precautionary measures; they remain in the id. The super-ego, however, behaves as if the ego were responsible for them and shows at the same time by the seriousness with which it chastises these destructive intentions that they are no mere semblance evoked by regression but an actual substitution of hate for love. Helpless in both directions, the ego defends itself vainly, alike against the instigations of the murderous id and against the reproaches of the punishing conscience. It succeeds in holding in check at least the most brutal actions of both sides; the first outcome is interminable self-torment, and eventually there follows a systematic torturing of the object, in so far as it is within reach. [1923b, 3987]

Let us again consider obsessional neurosis for a moment. The state of affairs is different here. The defusion of love into aggressiveness has not been effected by the work of the ego, but is the result of a regression which has come about in the id. But this process has extended beyond the id to the super-ego, which now increases its severity towards the innocent ego. It would seem, however, that in this case, no less than in that of melancholia, the ego, having gained control over the libido by means of identification, is punished for doing so by the super-ego through the instrumentality of the aggressiveness which was mixed with the libido. [1923b, 3989]
To take an instance from another field. It is impossible to escape the impression of the perfect correspondence which can be discovered between the obsessive actions of certain obsessional patients and the religious observances of believers all over the world. Some cases of obsessional neurosis actually behave like a caricature of a private religion, so that it is tempting to liken the official religions to an obsessional neurosis that has been mitigated by becoming universalized. This comparison, which is no doubt highly objectionable to all believers, has nevertheless proved most fruitful psychologically. For psycho-analysis soon discovered in the case of obsessional neurosis what the forces are that struggle with one another in it till their conflicts find a remarkable expression in the ceremonial of obsessive actions. Nothing similar was suspected in the case of religious ceremonial until, by tracing back religious feeling to the relation with the father as its deepest root, it became possible to point to an analogous dynamic situation in that case too. This instance, moreover, may warn the reader that even in its application to non-medical fields psycho-analysis cannot avoid wounding cherished prejudices, touching upon deeply-rooted sensibilities and thus provoking enmities which have an essentially emotional basis.

I myself set a higher value on my contributions to the psychology of religion, which began with the establishment of a remarkable similarity between obsessive actions and religious practices or ritual (1907). Without as yet understanding the deeper connections, I described the obsessional neurosis as a distorted private religion and religion as a kind of universal obsessional neurosis. Later on, in 1912, Jung's forcible indication of the far-reaching analogies between the mental products of neurotics and of primitive peoples led me to turn my attention to that subject. In four essays, which were collected into a book with the title of Totem and Taboo, I showed that the horror of incest was even more marked among primitive than among civilized races and had given rise to very special measures of defence against it. I examined the relations between taboo-prohibitions (the earliest form in which moral restrictions make their appearance) and emotional ambivalence; and I discovered under the primitive scheme of the universe known as 'animism' the principle of the over-estimation of the importance of psychical reality - the belief in 'the omnipotence of thoughts' - which lies at the root of magic as well. I developed the comparison with the obsessional neurosis at every point, and showed how many of the postulates of primitive mental life are still in force in that remarkable illness. Above all, however, I was attracted by totemism, the first system of organization in primitive tribes, a system in which the beginnings of social order are united with a rudimentary religion and the implacable domination of a small number of taboo-prohibitions. The being that is revered is ultimately always an animal, from which the clan also claims to be descended. Many indications pointed to the conclusion that every race, even the most highly developed, had once passed through the stage of totemism.

Obsessional neurosis is unquestionably the most interesting and repaying subject of analytic research. But as a problem it has not yet been mastered. It must be confessed that, if we endeavour to penetrate more deeply into its nature, we still have to rely upon doubtful assumptions and unconfirmed suppositions. Obsessional neurosis originates, no doubt, in the same situation as hysteria, namely, the necessity of fending off the libidinal demands of the Oedipus complex. Indeed, every obsessional neurosis seems to have a substratum of hysterical symptoms that have been formed at a very early stage. But it is subsequently shaped along quite different lines owing to a constitutional factor. The genital organization of the libido turns out to be feeble and insufficiently resistant, so that when the ego begins its defensive efforts the first thing it succeeds in doing is to throw back the genital organization (of the phallic phase), in whole or in part, to the earlier sadistic-anal level. This fact of regression is decisive for all that follows.
In enforcing regression, the ego scores its first success in its defensive struggle against the demands of the libido. (In this connection it is of advantage to distinguish the more general notion of 'defence' from 'repression'. Repression is only one of the mechanisms which defence makes use of.) It is perhaps in obsessional cases more than in normal or hysterical ones that we can most clearly recognize that the motive force of defence is the castration complex and that what is being fended off are the trends of the Oedipus complex. We are at present dealing with the beginning of the latency period, a period which is characterized by the dissolution of the Oedipus complex, the creation or consolidation of the super-ego and the erection of ethical and aesthetic barriers in the ego. In obsessional neuroses these processes are carried further than is normal. In addition to the destruction of the Oedipus complex a regressive degradation of the libido takes place, the super-ego becomes exceptionally severe and unkind, and the ego, in obedience to the super-ego, produces strong reaction-formations in the shape of conscientiousness, pity and cleanliness. Implacable, though not always on that account successful, severity is shown in condemning the temptation to continue early infantile masturbation, which now attaches itself to regressive (sadistic-anal) ideas but which nevertheless represents the unsubjugated part of the phallic organization. There is an inherent contradiction about this state of affairs, in which, precisely in the interests of masculinity (that is to say, from fear of castration), every activity belonging to masculinity is stopped. But here, too, obsessional neurosis is only overdoing the normal method of getting rid of the Oedipus complex. We once more find here an illustration of the truth that every exaggeration contains the seed of its own undoing. For, under the guise of obsessional acts, the masturbation that has been suppressed approaches ever more closely to satisfaction.

We can either simply accept it as a fact that in obsessional neurosis a super-ego of this severe kind emerges, or we can take the regression of the libido as the fundamental characteristic of the affection and attempt to relate the severity of the super-ego to it. And indeed the super-ego, originating as it does from the id, cannot dissociate itself from the regression and defusion of instinct which have taken place there. We cannot be surprised if it becomes harsher, unkind and more tormenting than where development has been normal.

The advent of puberty opens a decisive chapter in the history of an obsessional neurosis. The genital organization which has been broken off in childhood starts again with great vigour. But, as we know, the sexual development in childhood determines what direction this new start at puberty will take. Not only will the early aggressive impulses be re-awakened; but a greater or lesser proportion of the new libidinal impulses - in bad cases the whole of them - will have to follow the course prescribed for them by regression and will emerge as aggressive and destructive tendencies. In consequence of the erotic trends being disguised in this way and owing to the powerful reaction-formations in the ego, the struggle against sexuality will henceforward be carried on under the banner of ethical principles. The ego will recoil with astonishment from promptings to cruelty and violence which enter consciousness from the id, and it has no notion that in them it is combating erotic wishes, including some to which it would not otherwise have taken exception. The overstrict super-ego insists all the more strongly on the suppression of sexuality, since this has assumed such repellent forms. Thus in obsessional neurosis the conflict is aggravated in two directions: the defensive forces become more intolerant and the forces that are to be fended off become more intolerable. Both effects are due to a single factor, namely, regression of the libido.
A good deal of what has been said may be objected to on the ground that the unpleasant obsessive ideas are themselves quite conscious. But there is no doubt that before becoming conscious they have been though the process of repression. In most of them the actual wording of the aggressive instinctual impulse is altogether unknown to the ego, and it requires a good deal of analytic work to make it conscious. What does penetrate into consciousness is usually only a distorted substitute which is either of a vague, dream-like and indeterminate nature or so travestied as to be unrecognizable. Even where repression has not encroached upon the content of the aggressive impulse it has certainly got rid of its accompanying affective character. As a result, the aggressiveness appears to the ego not to be an impulsion but, as the patients themselves say, merely a 'thought' which awakens no feeling. But the remarkable thing is that this is not the case. What happens is that the affect left out when the obsessional idea is perceived appears in a different place. The super-ego behaves as though repression had not occurred and as though it knew the real wording and full affective character of the aggressive impulse, and it treats the ego accordingly. The ego which, on the one hand, knows that it is innocent is obliged, on the other hand, to be aware of a sense of guilt and to carry a responsibility which it cannot account for. This state of affairs is, however, not so puzzling as it would seem at first sight. The behaviour of the super-ego is perfectly intelligible, and the contradiction in the ego merely shows that it has shut out the id by means of repression while remaining fully accessible to the influence of the super-ego. If it is asked why the ego does not also attempt to withdraw from the tormenting criticism of the super-ego, the answer is that it does manage to do so in a great number of instances. There are obsessional neuroses in which no sense of guilt whatever is present. In them, as far as can be seen, the ego has avoided becoming aware of it by instituting a fresh set of symptoms, penances or restrictions of a self-punishing kind. These symptoms, however, represent at the same time a satisfaction of masochistic impulses which, in their turn, have been reinforced by regression.

In the course of these struggles we come across two activities of the ego which form symptoms and which deserve special attention because they are obviously surrogates of repression and therefore well calculated to illustrate its purpose and technique. The fact that such auxiliary and substitutive techniques emerge may argue that true repression has met with difficulties in its functioning. If one considers how much more the ego is the scene of action of symptom-formation in obsessional neurosis than it is in hysteria and with what tenacity the ego clings to its relations to reality and to consciousness, employing all its intellectual faculties to that end - and indeed how the very process of thinking becomes hypercathected and erotized - then one may perhaps come to a better understanding of these variations of repression.
The two techniques I refer to are *undoing what has been done* and *isolating*. The first of these has a wide range of application and goes back very far. It is, as it were, negative magic, and endeavours, by means of motor symbolism, to 'blow away' not merely the *consequences* of some event (or experience or impression) but the event itself. I choose the term 'blow away' advisedly, so as to remind the reader of the part played by this technique not only in neuroses but in magical acts, popular customs and religious ceremonies as well. In obsessional neurosis the technique of undoing what has been done is first met with in the 'diphasic' symptoms, in which one action is cancelled out by a second, so that it is as though neither action had taken place, whereas, in reality, both have. This aim of undoing is the second underlying motive of obsessional ceremonials, the first being to take precautions in order to prevent the occurrence or recurrence of some particular event. The difference between the two is easily seen: the precautionary measures are rational, while trying to get rid of something by 'making it not to have happened' is irrational and in the nature of magic. It is of course to be suspected that the latter is the earlier motive of the two and proceeds from the animistic attitude towards the environment. This endeavour to undo shades off into normal behaviour in the case in which a person decides to regard an event as not having happened. But whereas he will take no direct steps against the event, and will simply pay no further attention to it or its consequences, the neurotic person will try to make the past itself non-existent. He will try to repress it by motor means. The same purpose may perhaps account for the obsession for *repeating* which is so frequently met with in this neurosis and the carrying out of which serves a number of contradictory intentions at once. When anything has not happened in the desired way it is undone by being repeated in a different way; and thereupon all the motives that exist for lingering over such repetitions come into play as well. As the neurosis proceeds, we often find that the endeavour to undo a traumatic experience is a motive of first-rate importance in the formation of symptoms. We thus unexpectedly discover a new, motor technique of defence, or (as we may say in this case with less inaccuracy) of repression. [1926d, 4278]
The second of these techniques which we are setting out to describe for the first time, that of isolation, is peculiar to obsessional neurosis. It, too, takes place in the motor sphere. When something unpleasant has happened to the subject or when he himself has done something which has a significance for his neurosis, he interpolates an interval during which nothing further must happen - during which he must perceive nothing and do nothing. This behaviour, which seems strange at first sight, is soon seen to have a relation to repression. We know that in hysteria it is possible to cause a traumatic experience to be overtaken by amnesia. In obsessional neurosis this can often not be achieved: the experience is not forgotten, but, instead, it is deprived of its affect, and its associative connections are suppressed or interrupted so that it remains as though isolated and is not reproduced in the ordinary processes of thought. The effect of this isolation is the same as the effect of repression with amnesia. This technique, then, is reproduced in the isolations of obsessional neurosis; and it is at the same time given motor reinforcement for magical purposes. The elements that are held apart in this way are precisely those which belong together associatively. The motor isolation is meant to ensure an interruption of the connection in thought. The normal phenomenon of concentration provides a pretext for this kind of neurotic procedure: what seems to us important in the way of an impression or a piece of work must not be interfered with by the simultaneous claims of any other mental processes or activities. But even a normal person uses concentration to keep away not only what is irrelevant or unimportant, but, above all, what is unsuitable because it is contradictory. He is most disturbed by those elements which once belonged together but which have been torn apart in the course of his development - as, for instance, by manifestations of the ambivalence of his father-complex in his relation to God, or by impulses attached to his excretory organs in his emotions of love. Thus, in the normal course of things, the ego has a great deal of isolating work to do in its function of directing the current of thought. And, as we know, we are obliged, in carrying out our analytic technique, to train it to relinquish that function for the time being, eminently justified as it usually is.

[1926d, 4279]

We have all found by experience that it is especially difficult for an obsessional neurotic to carry out the fundamental rule of psycho-analysis. His ego is more watchful and makes sharper isolations, probably because of the high degree of tension due to conflict that exists between his super-ego and his id. While he is engaged in thinking, his ego has to keep off too much - the intrusion of unconscious phantasies and the manifestation of ambivalent trends. It must not relax, but is constantly prepared for a struggle. It fortifies this compulsion to concentrate and to isolate by the help of the magical acts of isolation which, in the form of symptoms, grow to be so noticeable and to have so much practical importance for the patient, but which are, of course, useless in themselves and are in the nature of ceremonials.

[1926d, 4280]

That this latter opinion is at least in part true is shown by some striking examples. If an agoraphobic patient who has been accompanied into the street is left alone there, he will produce an anxiety attack. Or if an obsessional neurotic is prevented from washing his hands after having touched something, he will become a prey to almost unbearable anxiety. It is plain, then, that the purpose and the result of the imposed condition of being accompanied in the street and the obsessional act of washing the hands were to obviate outbreaks of anxiety of this kind. In this sense every inhibition which the ego imposes on itself can be called a symptom.

[1926d, 4299]
One objection to it is that loss of an object (or loss of love on the part of the object) and the
threat of castration are just as much dangers coming from outside as, let us say, a ferocious
animal would be; they are not instinctual dangers. Nevertheless, the two cases are not the
same. A wolf would probably attack us irrespectively of our behaviour towards it; but the loved
person would not cease to love us nor should we be threatened with castration if we did not
entertain certain feelings and intentions within us. Thus such instinctual impulses are
determinants of external dangers and so become dangerous in themselves; and we can now
proceed against the external danger by taking measures against the internal ones. In phobias of
animals the danger seems to be still felt entirely as an external one, just as it has undergone an
external displacement in the symptom. In obsessional neuroses the danger is much more
internalized. That portion of anxiety in regard to the super-ego which constitutes social anxiety
still represents an internal substitute for an external danger, while the other portion—moral
anxiety—is already completely endopsychic.
[1926d, 4300]

We now observe that the store of religious ideas includes not only wish-fulfilments but
important historical recollections. This concurrent influence of past and present must give
religion a truly incomparable wealth of power. But perhaps with the help of an analogy yet
another discovery may begin to dawn on us. Though it is not a good plan to transplant ideas far
from the soil in which they grew up, yet here is a conformity which we cannot avoid pointing out.
We know that a human child cannot successfully complete its development to the civilized stage
without passing through a phase of neurosis sometimes of greater and sometimes of less
distinctness. This is because so many instinctual demands which will later be unserviceable
cannot be suppressed by the rational operation of the child's intellect but have to be tamed by
acts of repression, behind which, as a rule, lies the motive of anxiety. Most of these infantile
neuroses are overcome spontaneously in the course of growing up, and this is especially true of
the obsessional neuroses of childhood. The remainder can be cleared up later still by psycho-
analytic treatment. In just the same way, one might assume, humanity as a whole, in its
development through the ages, fell into states analogous to the neuroses, and for the same
reasons—namely because in the times of its ignorance and intellectual weakness the instinctual
renunciations indispensable for man's communal existence had only been achieved by it by
means of purely affective forces. The precipitates of these processes resembling repression
which took place in prehistoric times still remained attached to civilization for long periods.
Religion would thus be the universal obsessional neurosis of humanity; like the obsessional
neurosis of children, it arose out of the Oedipus complex, out of the relation to the father. If this
view is right, it is to be supposed that a turning-away from religion is bound to occur with the
fatal inevitability of a process of growth, and that we find ourselves at this very juncture in the
middle of that phase of development. Our behaviour should therefore be modelled on that of a
sensible teacher who does not oppose an impending new development but seeks to ease its
path and mitigate the violence of its irruption. Our analogy does not, to be sure, exhaust the
essential nature of religion. If, on the one hand, religion brings with it obsessional restrictions,
exact as an individual obsessional neurosis does, on the other hand it comprises a system of
wishful illusions together with a disavowal of reality, such as we find in an isolated form nowhere
else but in amnesia, in a state of blissful hallucinatory confusion. But these are only analogies,
by the help of which we endeavour to understand a social phenomenon; the pathology of the
individual does not supply us with a fully valid counterpart.
[1927c, 4452]
It has long since become common knowledge that the experiences of a person's first five years exercise a determining effect on his life, which nothing later can withstand. Much that deserves knowing might be said about the way in which these early impressions maintain themselves against any influences in more mature periods of life - but it would not be relevant here. It may, however, be less well known that the strongest compulsive influence arises from impressions which impinge upon a child at a time when we would have to regard his psychical apparatus as not yet completely receptive. The fact itself cannot be doubted; but it is so puzzling that we may make it more comprehensible by comparing it with a photographic exposure which can be developed after any interval of time and transformed into a picture. I am nevertheless glad to point out that this uncomfortable discovery of ours has been anticipated by an imaginative writer, with the boldness that is permitted to poets. E. T. A. Hoffmann used to trace back the wealth of figures that put themselves at his disposal for his creative writings to the changing images and impressions which he had experienced during a journey of some weeks in a post-chaise while he was still an infant at his mother's breast. What children have experienced at the age of two and have not understood, need never be remembered by them except in dreams; they may only come to know of it through psycho-analytic treatment. But at some later time it will break into their life with obsessional impulses, it will govern their actions, it will decide their sympathies and antipathies and will quite often determine their choice of a love-object, for which it is so frequently impossible to find a rational basis. The two points at which these facts touch upon our problem cannot be mistaken.
[1939a, 4944]
As regards classification of the subject, I propose in the first place to exclude a group of intense obsessions which are nothing but memories, unaltered images of important events. As an example, I may cite Pascal's obsession: he always thought he saw an abyss on his left hand 'after he had nearly been thrown into the Seine in his coach'. Such obsessions and phobias, which might be called traumatic, are allied to the symptoms of hysteria. [1895c, 317]

The two techniques I refer to are undoing what has been done and isolating. The first of these has a wide range of application and goes back very far. It is, as it were, negative magic, and endeavours, by means of motor symbolism, to 'blow away' not merely the consequences of some event (or experience or impression) but the event itself. I choose the term 'blow away' advisedly, so as to remind the reader of the part played by this technique not only in neuroses but in magical acts, popular customs and religious ceremonies as well. In obsessional neurosis the technique of undoing what has been done is first met with in the 'diphasic' symptoms, in which one action is cancelled out by a second, so that it is as though neither action had taken place, whereas, in reality, both have. This aim of undoing is the second underlying motive of obsessional ceremonials, the first being to take precautions in order to prevent the occurrence or recurrence of some particular event. The difference between the two is easily seen: the precautionary measures are rational, while trying to get rid of something by 'making it not to have happened' is irrational and in the nature of magic. It is of course to be suspected that the latter is the earlier motive of the two and proceeds from the animistic attitude towards the environment. This endeavour to undo shades off into normal behaviour in the case in which a person decides to regard an event as not having happened. But whereas he will take no direct steps against the event, and will simply pay no further attention to it or its consequences, the neurotic person will try to make the past itself non-existent. He will try to repress it by motor means. The same purpose may perhaps account for the obsession for repeating which is so frequently met with in this neurosis and the carrying out of which serves a number of contradictory intentions at once. When anything has not happened in the desired way it is undone by being repeated in a different way; and thereupon all the motives that exist for lingering over such repetitions come into play as well. As the neurosis proceeds, we often find that the endeavour to undo a traumatic experience is a motive of first-rate importance in the formation of symptoms. We thus unexpectedly discover a new, motor technique of defence, or (as we may say in this case with less inaccuracy) of repression. [1926d, 4278]
The second of these techniques which we are setting out to describe for the first time, that of isolation, is peculiar to obsessional neurosis. It, too, takes place in the motor sphere. When something unpleasant has happened to the subject or when he himself has done something which has a significance for his neurosis, he interpolates an interval during which nothing further must happen - during which he must perceive nothing and do nothing. This behaviour, which seems strange at first sight, is soon seen to have a relation to repression. We know that in hysteria it is possible to cause a traumatic experience to be overtaken by amnesia. In obsessional neurosis this can often not be achieved: the experience is not forgotten, but, instead, it is deprived of its affect, and its associative connections are suppressed or interrupted so that it remains as though isolated and is not reproduced in the ordinary processes of thought. The effect of this isolation is the same as the effect of repression with amnesia. This technique, then, is reproduced in the isolations of obsessional neurosis; and it is at the same time given motor reinforcement for magical purposes. The elements that are held apart in this way are precisely those which belong together associatively. The motor isolation is meant to ensure an interruption of the connection in thought. The normal phenomenon of concentration provides a pretext for this kind of neurotic procedure: what seems to us important in the way of an impression or a piece of work must not be interfered with by the simultaneous claims of any other mental processes or activities. But even a normal person uses concentration to keep away not only what is irrelevant or unimportant, but, above all, what is unsuitable because it is contradictory. He is most disturbed by those elements which once belonged together but which have been torn apart in the course of his development - as, for instance, by manifestations of the ambivalence of his father-complex in his relation to God, or by impulses attached to his excretory organs in his emotions of love. Thus, in the normal course of things, the ego has a great deal of isolating work to do in its function of directing the current of thought. And, as we know, we are obliged, in carrying out our analytic technique, to train it to relinquish that function for the time being, eminently justified as it usually is.

[1926d, 4279]
A deeper insight into the mechanism of obsessional neurosis is gained if we take into account the primary fact which lies at the bottom of it. This is always the repression of an instinctual impulse (a component of the sexual instinct) which was present in the subject's constitution and which was allowed to find expression for a while during his childhood but later succumbed to suppression. In the course of the repression of this instinct a special conscientiousness is created which is directed against the instinct's aims; but this psychical reaction-formation feels insecure and constantly threatened by the instinct which is lurking in the unconscious. The influence of the repressed instinct is felt as a temptation, and during the process of repression itself anxiety is generated, which gains control over the future in the form of expectant anxiety. The process of repression which leads to obsessional neurosis must be considered as one which is only partly successful and which increasingly threatens to fail. It may thus be compared to an unending conflict; fresh psychical efforts are continually required to counterbalance the forward pressure of the instinct. Thus the ceremonial and obsessive actions arise partly as a defence against the temptation and partly as a protection against the ill which is expected. Against the temptation the protective measures seem soon to become inadequate; then the prohibitions come into play, with the purpose of keeping at a distance situations that give rise to temptation. Prohibitions take the place of obsessive actions, it will be seen, just as a phobia is designed to avert a hysterical attack. Again, a ceremonial represents the sum of the conditions subject to which something that is not yet absolutely forbidden is permitted, just as the Church's marriage ceremony signifies for the believer a sanctioning of sexual enjoyment which would otherwise be sinful. A further characteristic of obsessional neurosis, as of all similar affections, is that its manifestations (its symptoms, including the obsessive actions) fulfil the condition of being a compromise between the warring forces of the mind. They thus always reproduce something of the pleasure which they are designed to prevent; they serve the repressed instinct no less than the agencies which are repressing it. As the illness progresses, indeed, actions which were originally mostly concerned with maintaining the defence come to approximate more and more to the proscribed actions through which the instinct was able to find expression in childhood.

[1907b, 1907]
The events in his sixth or seventh year which the patient described in the first hour of his treatment were not merely, as he supposed, the beginning of his illness, but were already the illness itself. It was a complete obsessional neurosis, wanting in no essential element, at once the nucleus and the prototype of the later disorder, - an elementary organism, as it were, the study of which could alone enable us to obtain a grasp of the complicated organization of his subsequent illness. The child, as we have seen, was under the domination of a component of the sexual instinct, the desire to look, as a result of which there was a constant recurrence in him of a very intense wish connected with persons of the female sex who pleased him - the wish, that is, to see them naked. This wish corresponds to the later obsessional or compulsive idea; and if the quality of compulsion was not yet present in the wish, this was because the ego had not yet placed itself in complete opposition to it and did not yet regard it as something foreign to itself. Nevertheless, opposition to this wish from some source or other was already in activity, for its occurrence was regularly accompanied by a distressing affect.¹ A conflict was evidently in progress in the mind of this young libertine. Side by side with the obsessive wish, and intimately associated with it, was an obsessive fear: every time he had a wish of this kind he could not help fearing that something dreadful would happen. This something dreadful was already clothed in a characteristic indeterminateness which was thenceforward to be an invariable feature of every manifestation of the neurosis. But in a child it is not hard to discover what it is that is veiled behind an indeterminateness of this kind. If the patient can once be induced to give a particular instance in place of the vague generalities which characterize an obsessional neurosis, it may be confidently assumed that the instance is the original and actual thing which has tried to hide itself behind the generalization. Our present patient's obsessive fear, therefore, when restored to its original meaning, would run as follows: 'If I have this wish to see a woman naked, my father will be bound to die.' The distressing affect was distinctly coloured with a tinge of uncanniness and superstition, and was already beginning to give rise to impulses to do something to ward off the impending evil. These impulses were subsequently to develop into the protective measures which the patient adopted.

¹ [1909d, 2133]

We find, accordingly: an erotic instinct and a revolt against it; a wish which has not yet become compulsive and, struggling against it, a fear which is already compulsive; a distressing affect and an impulsion towards the performance of defensive acts. The inventory of the neurosis has reached its full muster. Indeed, something more is present, namely, a kind of delusion or delirium with the strange content that his parents knew his thoughts because he spoke them out loud without his hearing himself do it. We shall not go far astray if we suppose that in making this attempt at an explanation the child had some inkling of those remarkable mental processes which we describe as unconscious and which we cannot dispense with if we are to throw any scientific light upon this obscure subject. 'I speak my thoughts out loud, without hearing them' sounds like a projection into the external world of our own hypothesis that he had thoughts without knowing anything about them; it sounds like an endopsychic perception of what has been repressed.

[1909d, 2134]

If we apply knowledge gained elsewhere to this case of childhood neurosis, we shall not be able to avoid a suspicion that in this instance as in others (that is to say, before the child had reached his sixth year) there had been conflicts and repressions, which had themselves been overtaken by amnesia, but had left behind them as a residuum the particular content of this obsessive fear. Later on we shall learn how far it is possible for us to rediscover those forgotten experiences or to reconstruct them with some degree of certainty. In the meantime stress may be laid on the fact, which is probably more than a mere coincidence, that the patient's infantile amnesia ended precisely with his sixth year.

[1909d, 2134]
At the next session the patient showed great interest in what I had said, but ventured, so he told me, to bring forward a few doubts. - How, he asked, could the information that the self-reproach, the sense of guilt, was justified have a therapeutic effect? - I explained that it was not the information that had this effect, but the discovery of the unknown content to which the self-reproach was really attached. - Yes, he said, that was the precise point to which his question had been directed. - I then made some short observations upon the psychological differences between the conscious and the unconscious, and upon the fact that everything conscious was subject to a process of wearing-away, while what was unconscious was relatively unchangeable; and I illustrated my remarks by pointing to the antiques standing about in my room. They were, in fact, I said, only objects found in a tomb, and their burial had been their preservation: the destruction of Pompeii was only beginning now that it had been dug up. - Was there any guarantee, he next enquired, of what one's attitude would be towards what was discovered? One man, he thought, would no doubt behave in such a way as to get the better of his self-reproach, but another would not. - No, I said, it followed from the nature of the circumstances that in every case the affect would be overcome - for the most part during the progress of the work itself. Every effort was made to preserve Pompeii, whereas people were anxious to be rid of tormenting ideas like his. - He had said to himself, he went on, that a self-reproach could only arise from a breach of a person's own inner moral principles and not from that of any external ones. - I agreed, and said that the man who merely breaks an external law often regards himself as a hero. - Such an occurrence, he continued, was thus only possible where a disintegration of the personality was already present. Was there a possibility of his effecting a reintegration of his personality? If this could be done, he thought he would be able to make a success of his life, perhaps more of one than most people. - I replied that I was in complete agreement with this notion of a splitting of his personality. He had only to assimilate this new contrast, between a moral self and an evil one, with the contrast I had already mentioned, between the conscious and the unconscious. The moral self was the conscious, the evil self was the unconscious.¹ - He then said that, though he considered himself a moral person, he could quite definitely remember having done things in his childhood which came from his other self. - I remarked that here he had incidentally hit upon one of the chief characteristics of the unconscious, namely, its relation to the infantile. The unconscious, I explained, was the infantile; it was that part of the self which had become separated off from it in infancy, which had not shared the later stages of its development, and which had in consequence become repressed. It was the derivatives of this repressed unconscious that were responsible for the involuntary thoughts which constituted his illness. He might now, I added, discover yet another characteristic of the unconscious; it was a discovery which I should be glad to let him make for himself. - He found nothing more to say in this immediate connection, but instead he expressed a doubt whether it was possible to undo modifications of such long standing. What, in particular, could be done against his idea about the next world, for it could not be refuted by logic? - I told him I did not dispute the gravity of his case nor the significance of his pathological constructions; but at the same time his youth was very much in his favour as well as the intactness of his personality. In this connection I said a word or two upon the good opinion I had formed of him, and this gave him visible pleasure.

[1909d, 2143]
At the next session he began by saying that he must tell me an event in his childhood. From the age of seven, as he had already told me, he had had a fear that his parents guessed his thoughts, and this fear had in fact persisted all through his life. When he was twelve years old he had been in love with a little girl, the sister of a friend of his. (In answer to a question he said that his love had not been sensual; he had not wanted to see her naked for she was too small.) But she had not shown him as much affection as he had desired. And thereupon the idea had come to him that she would be kind to him if some misfortune were to befall him; and as an instance of such a misfortune his father's death had forced itself upon his mind. He had at once rejected the idea with energy. And even now he could not admit the possibility that what had arisen in this way could have been a 'wish'; it had clearly been no more than a 'train of thought'¹ - By way of objection I asked him why, if it had not been a wish, he had repudiated it. - Merely, he replied, on account of the content of the idea, the notion that his father might die. - I remarked that he was treating the phrase as though it were one that involved lèse-majesté; it was well known, of course, that it was equally punishable to say 'The Emperor is an ass' or to disguise the forbidden words by saying 'If any one says, etc., . . . then he will have me to reckon with.' I added that I could easily insert the idea which he had so energetically repudiated into a context which would exclude the possibility of any such repudiation: for instance, 'If my father dies, I shall kill myself upon his grave.' - He was shaken, but did not abandon his objection. I therefore broke off the argument with the remark that I felt sure this had not been the first occurrence of his idea of his father's dying; it had evidently originated at an earlier date, and some day we should have to trace back its history. - He then proceeded to tell me that a precisely similar thought had flashed through his mind a second time, six months before his father's death. At that time² he had already been in love with his lady, but financial obstacles made it impossible to think of an alliance with her. The idea had then occurred to him that his father's death might make him rich enough to marry her. In defending himself against this idea he had gone to the length of wishing that his father might leave him nothing at all, so that he might have no compensation for his terrible loss. The same idea, though in a much milder form, had come to him for a third time, on the day before his father's death. He had then thought: 'Now I may be going to lose what I love most'; and then had come the contradiction: 'No, there is some one else whose loss would be even more painful to you.'³ These thoughts surprised him very much, for he was quite certain that his father's death could never have been an object of his desire but only of his fear. - After his forcible enunciation of these words I thought it advisable to bring a fresh piece of theory to his notice. According to psycho-analytic theory, I told him, every fear corresponded to a former wish which was now repressed; we were therefore obliged to believe the exact contrary of what he had asserted. This would also fit in with another theoretical requirement, namely, that the unconscious must be the precise contrary of the conscious. - He was much agitated at this and very incredulous. He wondered how he could possibly have had such a wish, considering that he loved his father more than any one else in the world; there could be no doubt that he would have renounced all his own prospects of happiness if by so doing he could have saved his father's life.

[1909d, 2144]
- I answered that it was precisely such intense love as his that was the necessary precondition of the repressed hatred. In the case of people to whom he felt indifferent he would certainly have no difficulty in maintaining side by side inclinations to a moderate liking and to an equally moderate dislike: supposing, for instance, that he were an official, he might think that his chief was agreeable as a superior, but at the same time pettyfogging as a lawyer and inhuman as a judge. (Shakespeare makes Brutus speak in a similar way of Julius Caesar: 'As Caesar loved me, I weep for him; as he was fortunate, I rejoice at it; as he was valiant, I honour him; but, as he was ambitious, I slew him.' But these words already strike us as rather strange, and for the very reason that we had imagined Brutus's feeling for Caesar as something deeper.) In the case of some one who was closer to him, of his wife for instance, he would wish his feelings to be unmixed, and consequently, as was only human, he would overlook her faults, since they might make him dislike her - he would ignore them as though he were blind to them. So it was precisely the intensity of his love that would not allow his hatred - though to give it such a name was to caricature the feeling - to remain conscious. To be sure, the hatred must have a source, and to discover that source was certainly a problem; his own statements pointed to the time when he was afraid that his parents guessed his thoughts. On the other hand, too, it might be asked why this intense love of his had not succeeded in extinguishing his hatred, as usually happened where there were two opposing impulses. We could only presume that the hatred must flow from some source, must be connected with some particular cause, which made it indestructible. On the one hand, then, some connection of this sort must be keeping his hatred for his father alive, while on the other hand, his intense love prevented it from becoming conscious. Therefore nothing remained for it but to exist in the unconscious, though it was able from time to time to flash out for a moment into consciousness.

[1909d, 2144]

Another impulse, which might be described as indirectly suicidal and which was of longer duration, was not so easily explicable. For its relation to the patient's experiences succeeded in concealing itself behind one of those purely external associations which are so obnoxious to our consciousness. One day while he was away on his summer holidays the idea suddenly occurred to him that he was too fat [German 'dick'] and that he must make himself slimmer. So he began getting up from table before the pudding came round and tearing along the road without a hat in the blazing heat of an August sun. Then he would dash up a mountain at the double, till, dripping with perspiration, he was forced to come to a stop. On one occasion his suicidal intentions actually emerged without any disguise from behind this mania for slimming: as he was standing on the edge of a steep precipice he suddenly received a command to jump over, which would have been certain death. Our patient could think of no explanation of this senseless obsessional behaviour until it suddenly occurred to him that at that time his lady had also been stopping at the same resort; but she had been in the company of an English cousin, who was very attentive to her and of whom the patient had been very jealous. This cousin's name was Richard, and, according to the usual practice in England, he was known as Dick. Our patient, then, had wanted to kill this Dick; he had been far more jealous of him and enraged with him than he could admit to himself, and that was why he had imposed on himself this course of slimming by way of a punishment. This obsessional impulse may seem very different from the directly suicidal command which was discussed above, but they have nevertheless one important feature in common. For they both arose as reactions to a tremendous feeling of rage, which was inaccessible to the patient's consciousness and was directed against some one who had cropped up as an interference with the course of his love.¹

[1909d, 2148]
In hysteria it is the rule that the precipitating causes of the illness are overtaken by amnesia no less than the infantile experiences by whose help the precipitating causes are able to transform their affective energy into symptoms. And where the amnesia cannot be complete, it nevertheless subjects the recent precipitating cause to a process of erosion and robs it at least of its most important components. In this amnesia we see the evidence of the repression which has taken place. The case is different in obsessional neuroses. The infantile preconditions of the neurosis may be overtaken by amnesia, though this is often an incomplete one; but the immediate occasions of the illness are, on the contrary, retained in the memory. Repression makes use of another, and in reality a simpler, mechanism. The trauma, instead of being forgotten, is deprived of its affective cathectis; so that what remains in consciousness is nothing but its ideational content, which is perfectly colourless and is judged to be unimportant. The distinction between what occurs in hysteria and in an obsessional neurosis lies in the psychological processes which we can reconstruct behind the phenomena; the result is almost always the same, for the colourless mnemonic content is rarely reproduced and plays no part in the patient's mental activity. In order to differentiate between the two kinds of repression we have on the surface nothing to rely upon but the patient's assurance that he has a feeling in the one case of having always known the thing and in the other of having long ago forgotten it.¹

[1909d, 2154]

There can be no doubt that the patient felt a need for finding experiences of this kind to act as props for his superstition, and that it was for that reason that he occupied himself so much with the inexplicable coincidences of everyday life with which we are all familiar, and helped out their shortcomings with unconscious activity of his own. I have come across a similar need in many other obsessional patients and have suspected its presence in many more besides. It seems to me easily explicable in view of the psychological characteristics of the obsessional neurosis. In this disorder, as I have already explained (p. 2155), repression is effected not by means of amnesia but by a severance of causal connections brought about by a withdrawal of affect. These repressed connections appear to persist in some kind of shadowy form (which I have elsewhere compared to an endopsychic perception),¹ and they are thus transferred, by a process of projection, into the external world, where they bear witness to what has been effaced from consciousness.

[1909d, 2181]
If we wish to obtain a grasp of the psychical forces whose interplay built up this neurosis, we must turn back to what we have learnt from the patient on the subject of the precipitating causes of his falling ill as a grown-up man and as a child. He fell ill when he was in his twenties on being faced with a temptation to marry another woman instead of the one whom he had loved so long; and he avoided a decision of this conflict by postponing all the necessary preliminary actions. The means for doing this was given him by his neurosis. His hesitation between the lady he loved and the other girl can be reduced to a conflict between his father's influence and his love for his lady, or, in other words, to a conflicting choice between his father and his sexual object, such as had already subsisted (judging from his recollections and obsessional ideas) in his remote childhood. All through his life, moreover, he was unmistakably victim to a conflict between love and hatred, in regard both to his lady and to his father. His phantasies of revenge and such obsessional phenomena as his obsession for understanding and his exploit with the stone in the road bore witness to his divided feelings; and they were to a certain degree comprehensible and normal, for the lady by her original refusal and subsequently by her coolness had given him some excuse for hostility. But his relations with his father were dominated by a similar division of feeling, as we have seen from our translation of his obsessional thoughts; and his father, too, must have given him an excuse for hostility in his childhood, as indeed we have been able to establish almost beyond question. His attitude towards the lady - a compound of tenderness and hostility - came to a great extent within the scope of his conscious knowledge; at most he deceived himself over the degree and violence of his negative feelings. But his hostility towards his father, on the contrary, though he had once been acutely conscious of it, had long since vanished from his ken, and it was only in the teeth of the most violent resistance that it could be brought back into his consciousness. We may regard the repression of his infantile hatred of his father as the event which brought his whole subsequent career under the dominion of the neurosis.

The other conflict, that between love and hatred, strikes us more strangely. We know that incipient love is often perceived as hatred, and that love, if it is denied satisfaction, may easily be partly converted into hatred, and poets tell us that in the more tempestuous stages of love the two opposed feelings may subsist side by side for a while as though in rivalry with each other. But the *chronic* co-existence of love and hatred, both directed towards the same person and both of the highest degree of intensity, cannot fail to astonish us. We should have expected that the passionate love would long ago have conquered the hatred or been devoured by it. And in fact such a protracted survival of two opposites is only possible under quite peculiar psychological conditions and with the co-operation of the state of affairs in the unconscious. The love has not succeeded in extinguishing the hatred but only in driving it down into the unconscious; and in the unconscious the hatred, safe from the danger of being destroyed by the operations of consciousness, is able to persist and even to grow. In such circumstances the conscious love attains as a rule, by way of reaction, an especially high degree of intensity, so as to be strong enough for the perpetual task of keeping its opponent under repression. The necessary condition for the occurrence of such a strange state of affairs in a person's erotic life appears to be that at a very early age, somewhere in the prehistoric period of his infancy, the two opposites should have been split apart and one of them, usually the hatred, have been repressed.¹

¹ [1909d, 2186]
If we consider a number of analyses of obsessional neurotics we shall find it impossible to escape the impression that a relation between love and hatred such as we have found in our present patient is among the most frequent, the most marked, and probably, therefore, the most important characteristics of obsessional neurosis. But however tempting it may be to bring the problem of the 'choice of neurosis' into connection with instinctual life, there are reasons enough for avoiding such a course. For we must remember that in every neurosis we come upon the same suppressed instincts behind the symptoms. After all, hatred, kept suppressed in the unconscious by love, plays a great part in the pathogenesis of hysteria and paranoia. We know too little of the nature of love to be able to arrive at any definite conclusion here; and, in particular, the relation between the negative factor¹ in love and the sadistic components of the libido remains completely obscure. What follows is therefore to be regarded as no more than a provisional explanation. We may suppose, then, that in the cases of unconscious hatred with which we are concerned the sadistic components of love have, from constitutional causes, been exceptionally strongly developed, and have consequently undergone a premature and all too thorough suppression, and that the neurotic phenomena we have observed arise on the one hand from conscious feelings of affection which have become exaggerated as a reaction, and on the other hand from sadism persisting in the unconscious in the form of hatred. [1909d, 2187]

The first kind of regression, that from acting to thinking, is facilitated by another factor concerned in the production of the neurosis. The histories of obsessional patients almost invariably reveal an early development and premature repression of the sexual instinct of looking and knowing; and, as we know, a part of the infantile sexual activity of our present patient was governed by that instinct.¹ [1909d, 2191]

In the many different forms of obsessional neurosis in particular, forgetting is mostly restricted to dissolving thought-connections, failing to draw the right conclusions and isolating memories. [1914g, 2500]

Now both the clinical history and the psychical mechanism of obsessional neurosis have become known to us through psycho-analysis. The clinical history of a typical case of 'touching phobia' is as follows. Right at the beginning, in very early childhood, the patient shows a strong desire to touch, the aim of which is of a far more specialized kind that one would have been inclined to expect. This desire is promptly met by an external prohibition against carrying out that particular kind of touching.¹ The prohibition is accepted, since it finds support from powerful internal forces,² and proves stronger than the instinct which is seeking to express itself in the touching. In consequence, however, of the child's primitive psychical constitution, the prohibition does not succeed in abolishing the instinct. Its only result is to repress the instinct (the desire to touch) and banish it into the unconscious. Both the prohibition and the instinct persist: the instinct because it has only been repressed and not abolished, and the prohibition because, if it ceased, the instinct would force its way through into consciousness and into actual operation. A situation is created which remains undealt with - a psychical fixation - and everything else follows from the continuing conflict between the prohibition and the instinct. [1912-1913, 2677]
In our clinical history of a case we have insisted that the imposition of the prohibition in very early childhood is the determining point; a similar importance attaches in the subsequent developments to the mechanism of repression at the same early age. As a result of the repression which has been enforced and which involves a loss of memory - an amnesia - the motives for the prohibition (which is conscious) remain unknown; and all attempts at disposing of it by intellectual processes must fail, since they cannot find any base of attack. The prohibition owes its strength and its obsessive character precisely to its unconscious opponent, the concealed and undiminished desire - that is to say, to an internal necessity inaccessible to conscious inspection. The ease with which the prohibition can be transferred and extended reflects a process which falls in with the unconscious desire and is greatly facilitated by the psychological conditions that prevail in the unconscious. The instinctual desire is constantly shifting in order to escape from the impasse and endeavours to find substitutes - substitute objects and substitute acts - in place of the prohibited ones. In consequence of this, the prohibition itself shifts about as well, and extends to any new aims which the forbidden impulse may adopt. Any fresh advance made by the repressed libido is answered by a fresh sharpening of the prohibition. The mutual inhibition of the two conflicting forces produces a need for discharge, for reducing the prevailing tension; and to this may be attributed the reason for the performance of obsessive acts. In the case of a neurosis these are clearly compromise actions: from one point of view they are evidences of remorse, efforts at expiation, and so on, while on the other hand they are at the same time substitutive acts to compensate the instinct for what has been prohibited. It is a law of neurotic illness that these obsessive acts fall more and more under the sway of the instinct and approach nearer and nearer to the activity which was originally prohibited.
[1912-1913, 2678]
A totally different picture of repression is shown, once more, in the third disorder which we shall consider for the purposes of our illustration - in obsessional neurosis. Here we are at first in doubt what it is that we have to regard as the instinctual representative that is subjected to repression - whether it is a libidinal or a hostile trend. This uncertainty arises because obsessional neurosis has as its basis a regression owing to which a sadistic trend has been substituted for an affectionate one. It is this hostile impulsion against someone who is loved which is subjected to repression. The effect at an early stage of the work of repression is quite different from what it is at a later one. At first the repression is completely successful; the ideational content is rejected and the affect made to disappear. As a substitutive formation there arises an alteration in the ego in the shape of an increased conscientiousness, and this can hardly be called a symptom. Here, substitute and symptom do not coincide. From this we learn something, too, about the mechanism of repression. In this instance, as in all others, repression has brought about a withdrawal of libido; but here it has made use of reaction-formation for this purpose, by intensifying an opposite. Thus in this case the formation of a substitute has the same mechanism as repression and at bottom coincides with it, while chronologically, as well as conceptually, it is distinct from the formation of a symptom. It is very probable that the whole process is made possible by the ambivalent relationship into which the sadistic impulsion that has to be repressed has been introduced. But the repression, which was at first successful, does not hold firm; in the further course of things its failure becomes increasingly marked. The ambivalence which has enabled repression through reaction-formation to take place is also the point at which the repressed succeeds in returning. The vanished affect comes back in its transformed shape as social anxiety, moral anxiety and unlimited self-reproaches; the rejected idea is replaced by a substitute by displacement, often a displacement on to something very small or indifferent. A tendency to a complete re-establishment of the repressed idea is as a rule unmistakably present. The failure in the repression of the quantitative, affective factor brings into play the same mechanism of flight, by means of avoidance and prohibitions, as we have seen at work in the formation of hysterical phobias. The rejection of the idea from the conscious is, however, obstinately maintained, because it entails abstention from action, a motor fettering of the impulsion. Thus in obsessional neurosis the work of repression is prolonged in a sterile and interminable struggle.

[1915d, 2987]

In obsessional neurosis, on the contrary, it is the regression of the libido to the preliminary stage of the sadistic-anal organization that is the most striking fact and the one which is decisive for what is manifested in symptoms. The love-impulse is obliged, when this has happened, to disguise itself as a sadistic impulse. The obsessional idea 'I should like to kill you', when it has been freed from certain additions which are not a matter of chance but are indispensable, means at bottom nothing other than 'I should like to enjoy you in love'. If you consider further that there has been a simultaneous regression in regard to the object, so that these impulses apply only to those who are nearest and dearest to the patient, you can form some idea of the horror which these obsessions arouse in him and at the same time of the alien appearance which they present to his conscious perception. But repression, too, plays a great part in the mechanism of these neuroses, though in a cursory introduction like ours this is not easily demonstrated. A regression of the libido without repression would never produce a neurosis but would lead to a perversion. From this you can see that repression is the process which is most peculiar to neuroses and is most characteristic of them. Perhaps I may have an opportunity later of telling you what we know of the mechanism of the perversions, and you will see that in their case too things are not so simple as we should be glad to make them out.

[1916-1917, 3407]
The Theory of Repression. - These theoretical considerations, taken together with the immediate impressions derived from analytic work, lead to a view of the neuroses which may be described in the roughest outline as follows. The neuroses are the expression of conflicts between the ego and such of the sexual impulses as seem to the ego incompatible with its integrity or with its ethical standards. Since these impulses are not ego-syntonic, the ego has repressed them: that is to say, it has withdrawn its interest from them and has shut them off from becoming conscious as well as from obtaining satisfaction by motor discharge. If in the course of analytic work one attempts to make these repressed impulses conscious, one becomes aware of the repressive forces in the form of resistance. But the achievement of repression fails particularly readily in the case of the sexual instincts. Their dammed-up libido finds other ways out from the unconscious: for it regresses to earlier phases of development and earlier attitudes towards objects, and, at weak points in the libidinal development where there are infantile fixations, it breaks through into consciousness and obtains discharge. What results is a symptom and consequently in its essence a substitutive sexual satisfaction. Nevertheless the symptom cannot entirely escape from the repressive forces of the ego and must therefore submit to modifications and displacements exactly as happens with dreams - by means of which its characteristic of being a sexual satisfaction becomes unrecognizable. Consequently symptoms are in the nature of compromises between the repressed sexual instincts and the repressing ego-instincts; they represent a wish-fulfilment for both partners to the conflict simultaneously, but one which is incomplete for each of them. This is quite strictly true of the symptoms of hysteria, while in the symptoms of obsessional neurosis there is often a stronger emphasis upon the side of the repressing function owing to the erection of reaction-formations, which are assurances against sexual satisfaction.

There is another kind of anticathexis, however, which seems more suited to the peculiar character of hysteria. A repressed instinctual impulse can be activated (newly cathected) from two directions: from within, through reinforcement from its internal sources of excitation, and from without, through the perception of an object that it desires. The hysterical anticathexis is mainly directed outwards, against dangerous perceptions. It takes the form of a special kind of vigilance which, by means of restrictions of the ego, causes situations to be avoided that would entail such perceptions, or, if they do occur, manages to withdraw the subject's attention from them. Some French analysts, in particular Laforgue, have recently given this action of hysteria the special name of 'scotomization'. This technique of anticathexis is still more noticeable in the phobias, whose interest is concentrated on removing the subject ever further from the possibility of the occurrence of the feared perception. The fact that anticathexis has an opposite direction in hysteria and the phobias from what it has in obsessional neurosis - though the distinction is not an absolute one - seems to be significant. It suggests that there is an intimate connection between repression and external anticathexis on the one hand and between regression and internal anticathexis (i.e. alteration in the ego through reaction-formation) on the other. The task of defence against a dangerous perception is, incidentally, common to all neuroses. Various commands and prohibitions in obsessional neurosis have the same end in view.
Even a purely terminological innovation ought to justify its adoption; it ought to reflect some new point of view or some extension of knowledge. The revival of the concept of defence and the restriction of that of repression takes into account a fact which has long since been known but which has received added importance owing to some new discoveries. Our first observations of repression and of the formation of symptoms were made in connection with hysteria. We found that the perceptual content of exciting experiences and the ideational content of pathogenic structures of thought were forgotten and debarred from being reproduced in memory, and we therefore concluded that the keeping away from consciousness was a main characteristic of hysterical repression. Later on, when we came to study the obsessional neuroses, we found that in that illness pathogenic occurrences are not forgotten. They remain conscious but they are 'isolated' in some way that we cannot as yet grasp, so that much the same result is obtained as in hysterical amnesia. Nevertheless the difference is great enough to justify the belief that the process by which instinctual demands are set aside in obsessional neurosis cannot be the same as in hysteria. Further investigations have shown that in obsessional neurosis a regression of the instinctual impulses to an earlier libidinal stage is brought about through the opposition of the ego, and that this regression, although it does not make repression unnecessary, clearly works in the same sense as repression. We have seen, too, that in obsessional neurosis anticathexis, which is also presumably present in hysteria, plays a specially large part in protecting the ego by effecting a reactive alteration in it. Our attention has, moreover, been drawn to a process of 'isolation' (whose technique cannot as yet be elucidated) which finds direct symptomatic manifestation, and to a procedure, that may be called magical, of 'undoing' what has been done - a procedure about whose defensive purpose there can be no doubt, but which has no longer any resemblance to the process of 'repression'. These observations provide good enough grounds for re-introducing the old concept of defence, which can cover all these processes that have the same purpose - namely, the protection of the ego against instinctual demands - and for subsuming repression under it as a special case. The importance of this nomenclature is heightened if we consider the possibility that further investigations may show that there is an intimate connection between special forms of defence and particular illnesses, as, for instance, between repression and hysteria. In addition we may look forward to the possible discovery of yet another important correlation. It may well be that before its sharp cleavage into an ego and an id, and before the formation of a super-ego, the mental apparatus makes use of different methods of defence from those which it employs after it has reached these stages of organization.

[1926d, 4316]
Now let us go back and turn to the id. It is not so easy to guess what occurs during repression in connection with the instinctual impulse that is being fought against. The main question which our interest raises is as to what happens to the energy, to the libidinal charge, of that excitation - how is it employed? You recollect that the earlier hypothesis was that it is precisely this that is transformed by repression into anxiety. We no longer feel able to say that. The modest reply will rather be that what happens to it is probably not always the same thing. There is probably an intimate correspondence which we ought to get to know about between what is occurring at the time in the ego and in the id in connection with the repressed impulse. For since we have decided that the pleasure-unpleasure principle, which is set in action by the signal of anxiety, plays a part in repression, we must alter our expectations. That principle exercises an entirely unrestricted dominance over what happens in the id. We can rely on its bringing about quite profound changes in the instinctual impulse in question. We are prepared to find that repression will have very various consequences, more or less far-reaching. In some cases the repressed instinctual impulse may retain its libidinal cathexis, and may persist in the id unchanged, although subject to constant pressure from the ego. In other cases what seems to happen is that it is totally destroyed, while its libido is permanently diverted along other paths. I expressed the view that this is what happens when the Oedipus complex is dealt with normally - in this desirable case, therefore, being not simply repressed but destroyed in the id. Clinical experience has further shown us that in many cases, instead of the customary result of repression, a degradation of the libido takes place - a regression of the libidinal organization to an earlier stage. This can, of course, only occur in the id, and if it occurs it will be under the influence of the same conflict which was introduced by the signal of anxiety. The most striking example of this kind is provided by the obsessional neurosis, in which libidinal regression and repression operate together.

[1933a, 4698]
To provide this secondary connection for the liberated affect, any idea can be made use of which is either able, from its nature, to be united with an affect of the *quality* in question, or which has certain relations to the incompatible idea which make it seem as though it could serve as a surrogate for it. Thus, for example, liberated anxiety, whose sexual origin must not be remembered by the patient, will seize upon the common primary phobias of mankind about animals, thunderstorms, darkness and so on, or upon things which are unmistakably associated in one way or another with what is sexual—such as micturition, defaecation, or dirtying and contagion generally.

[1894a, 309]

In many true obsessions it is quite plain that the emotional state is the principal thing, since that state persists unchanged while the idea associated with it varies. The girl in Case 1 quoted below, for example, felt remorse in some degree for all sorts of reasons - for having stolen, for having ill-treated her sisters, for having made counterfeit money, etc. People who doubt have many doubts at the same time or in succession. It is the emotional state which remains constant in them; the idea changes. In other cases the idea, too, seems fixated, as in Case 4, of the girl who pursued the servants in the house with an incomprehensible hatred, though constantly changing the individual object.

[1895c, 318]

The relation of these phobias to the phobias of obsessional neurosis, whose mechanism I made clear in an earlier paper¹ in this periodical, is of the following kind. What they have in common is that in both an idea becomes obsession as a result of being attached to an available affect. The mechanism of *transposition of affect* thus holds good for both kinds of phobia. But in the phobias of anxiety neurosis (1) this affect always has the same colour, which is that of anxiety; and (2) the affect does not originate in a repressed idea, but turns out to be *not further reducible by psychological analysis, nor amenable to psychotherapy*. The mechanism of *substitution*, therefore, does not hold good for the phobias of anxiety neurosis.

[1895b, 334]
The situation is this. Either residues of the previous day have been left over from the activity of waking life and it has not been possible to withdraw the whole cathexis of energy from them; or the activity of waking life during the course of the day has led to the stirring up of an unconscious wish; or these two events have happened to coincide. (We have already discussed the various possibilities in this connection.) The unconscious wish links itself up with the day’s residues and effects a transference on to them; this may happen either in the course of the day or not until a state of sleep has been established. A wish now arises which has been transferred on to the recent material; or a recent wish, having been suppressed, gains fresh life by being reinforced from the unconscious. This wish seeks to force its way along the normal path taken by thought processes, though the Pcs. (to which, indeed, it in part belongs) to consciousness. But it comes up against the censorship, which is still functioning and to the influence of which it now submits. At this point it takes on the distortion for which the way has already been paved by the transference of the wish on to recent material. So far it is on the way to becoming an obsessive idea or a delusion or something of the kind - that is, a thought which has been intensified by transference and distorted in its expression by censorship. Its further advance is halted, however, by the sleeping state of the preconscious. (The probability is that that system has protected itself against the invasion by diminishing its own excitations.) The dream-process consequently enters on a regressive path, which lies open to it precisely owing to the peculiar nature of the state of sleep, and it is led along that path by the attraction exercised on it by groups of memories; some of these memories themselves exist only in the form of visual cathexes and not as translations into the terminology of the later systems. In the course of its regressive path the dream-process acquires the attribute of representability. (I shall deal later with the question of compression.) It has now completed the second portion of its zigzag journey. The first portion was a progressive one, leading from the unconscious scenes or phantasies to the preconscious; the second portion led from the frontier of the censorship back again to perceptions. But when the content of the dream process has become perceptual, by that fact it has, as it were, found a way of evading the obstacle put in its way by the censorship and the state of sleep in the Pcs. It succeeds in drawing attention to itself and in being noticed by consciousness.

We have noted as a curious and derogatory characteristic of obsessional neurosis that its ceremonials are concerned with the small actions of daily life and are expressed in foolish regulations and restrictions in connection with them. We cannot understand this remarkable feature of the clinical picture until we have realized that the mechanism of psychical displacement, which was first discovered by me in the construction of dreams,¹ dominates the mental processes of obsessional neurosis. It is already clear from the few examples of obsessive actions given above that their symbolism and the detail of their execution are brought about by a displacement from the actual, important thing on to a small one which takes its place - for instance, from a husband on to a chair. It is this tendency to displacement which progressively changes the clinical picture and eventually succeeds in turning what is apparently the most trivial matter into something of the utmost importance and urgency. It cannot be denied that in the religious field as well there is a similar tendency to a displacement of psychical values, and in the same direction, so that the petty ceremonials of religious practice gradually become the essential thing and push aside the underlying thoughts. That is why religions are subject to reforms which work retroactively and aim at a re-establishment of the original balance of values.

¹[1900a, 1002]

²[1907b, 1908]
It would not surprise me to hear that at this point the reader had ceased to be able to follow. For even the detailed account which the patient gave me of the external events of these days and of his reactions to them was full of self-contradictions and sounded hopelessly confused. It was only when he told the story for the third time that I could get him to realize its obscurities and could lay bare the errors of memory and the displacements in which he had become involved. I shall spare myself the trouble of reproducing these details, the essentials of which we shall easily be able to pick up later on, and I will only add that at the end of this second session the patient behaved as though he were dazed and bewildered. He repeatedly addressed me as 'Captain', probably because at the beginning of the hour I had told him that I myself was not fond of cruelty like Captain N., and that I had no intention of tormenting him unnecessarily.

[1909d, 2139]
'I have decided to tell you something which I consider most important and which has tormented me from the very first.' He then told me at great length the story of the last illness of his father, who had died of emphysema nine years previously. One evening, thinking that the condition was one which would come to a crisis, he had asked the doctor when the danger could be regarded as over. 'The evening of the day after to-morrow', had been the reply. It had never entered his head that his father might not survive that limit. At half-past eleven at night he had lain down for an hour's rest. He had woken up at one o'clock, and had been told by a medical friend that his father had died. He had reproached himself with not having been present at his death; and the reproach had been intensified when the nurse told him that his father had spoken his name once during the last days, and had said to her as she came up to the bed: 'Is that Paul?' He had thought he noticed that his mother and sisters had been inclined to reproach themselves in a similar way; but they had never spoken about it. At first, however, the reproach had not tormented him. For a long time he had not realized the fact of his father's death. It had constantly happened that, when he heard a good joke, he would say to himself: 'I must tell Father that.' His imagination, too, had been occupied with his father, so that often, when there was a knock at the door, he would think: 'Here comes Father', and when he walked into a room he would expect to find his father in it. And although he had never forgotten that his father was dead, the prospect of seeing a ghostly apparition of this kind had had no terrors for him; on the contrary, he had greatly desired it. It had not been until eighteen months later that the recollection of his neglect had recurred to him and begun to torment him terribly, so that he had come to treat himself as a criminal. The occasion of this happening had been the death of an aunt by marriage and of a visit of condolence that he had paid at her house. From that time forward he had extended the structure of his obsessional thoughts so as to include the next world. The immediate consequence of this development had been that he became seriously incapacitated from working.¹ He told me that the only thing that had kept him going at that time had been the consolation given him by his friend, who had always brushed his self-reproaches aside on the ground that they were grossly exaggerated. Hearing this, I took the opportunity of giving him a first glance at the underlying principles of psycho-analytic therapy. When there is a mésalliance, I began, between an affect and its ideational content (in this instance, between the intensity of the self-reproach and the occasion for it ), a layman will say that the affect is too great for the occasion - that it is exaggerated and that consequently the inference following from the self-reproach (the inference that the patient is a criminal) is false. On the contrary, the physician says: 'No. The affect is justified. The sense of guilt is not in itself open to further criticism. But it belongs to some other content, which is unknown (unconscious), and which requires to be looked for. The known ideational content has only got into its actual position owing to a false connection. We are not used to feeling strong affects without their having any ideational content, and therefore, if the content is missing, we seize as a substitute upon some other content which is in some way or other suitable, much as our police, when they cannot catch the right murderer, arrest a wrong one instead. Moreover, this fact of there being a false connection is the only way of accounting for the powerlessness of logical processes to combat the tormenting idea.' I concluded by admitting that this new way of looking at the matter gave immediate rise to some hard problems; for how could he admit that his self-reproach of being a criminal towards his father was justified, when he must know that as a matter of fact he had never committed any crime against him?

[1909d, 2142]
At the next session the patient showed great interest in what I had said, but ventured, so he
told me, to bring forward a few doubts. - How, he asked, could the information that the self-
reproach, the sense of guilt, was justified have a therapeutic effect? - I explained that it was not
the information that had this effect, but the discovery of the unknown content to which the self-
reproach was really attached. - Yes, he said, that was the precise point to which his question
had been directed. - I then made some short observations upon the psychological differences
between the conscious and the unconscious, and upon the fact that everything conscious was
subject to a process of wearing-away, while what was unconscious was relatively
unchangeable; and I illustrated my remarks by pointing to the antiques standing about in my
room. They were, in fact, I said, only objects found in a tomb, and their burial had been their
preservation: the destruction of Pompeii was only beginning now that it had been dug up. - Was
there any guarantee, he next enquired, of what one's attitude would be towards what was
discovered? One man, he thought, would no doubt behave in such a way as to get the better of
his self-reproach, but another would not. - No, I said, it followed from the nature of the
circumstances that in every case the effect would be overcome - for the most part during the
progress of the work itself. Every effort was made to preserve Pompeii, whereas people were
anxious to be rid of tormenting ideas like his. - He had said to himself, he went on, that a self-
reproach could only arise from a breach of a person's own inner moral principles and not from
that of any external ones. - I agreed, and said that the man who merely breaks an external law
often regards himself as a hero. - Such an occurrence, he continued, was thus only possible
where a disintegration of the personality was already present. Was there a possibility of his
effecting a reintegration of his personality? If this could be done, he thought he would be able to
make a success of his life, perhaps more of one than most people. - I replied that I was in
complete agreement with this notion of a splitting of his personality. He had only to assimilate
this new contrast, between a moral self and an evil one, with the contrast I had already
mentioned, between the conscious and the unconscious. The moral self was the conscious, the
evil self was the unconscious.¹ - He then said that, though he considered himself a moral
person, he could quite definitely remember having done things in his childhood which came
from his other self. - I remarked that here he had incidentally hit upon one of the chief
characteristics of the unconscious, namely, its relation to the infantile. The unconscious, I
explained, was the infantile; it was that part of the self which had become separated off from it
in infancy, which had not shared the later stages of its development, and which had in
consequence become repressed. It was the derivatives of this repressed unconscious that were
responsible for the involuntary thoughts which constituted his illness. He might now, I added,
discover yet another characteristic of the unconscious; it was a discovery which I should be glad
to let him make for himself. - He found nothing more to say in this immediate connection, but
instead he expressed a doubt whether it was possible to undo modifications of such long
standing. What, in particular, could be done against his idea about the next world, for it could
not be refuted by logic? - I told him I did not dispute the gravity of his case nor the significance
of his pathological constructions; but at the same time his youth was very much in his favour as
well as the intactness of his personality. In this connection I said a word or two upon the good
opinion I had formed of him, and this gave him visible pleasure.

[1909d, 2143]
For this reason it not uncommonly happens that obsessional neurotics, who are troubled with self-reproaches but have connected their affects with the wrong causes, will also tell the physician the true causes, without any suspicion that their self-reproaches have simply become detached from them. In relating such an incident they will sometimes add with astonishment or even with an air of pride: 'But I think nothing of that.' This happened in the first case of obsessional neurosis which gave me an insight many years ago into the nature of the malady. The patient, who was a government official, was troubled by innumerable scruples. He was the man whose compulsive act in connection with the branch in the park at Schönbrunn I have already described. I was struck by the fact that the florin notes with which he paid his consultation fees were invariably clean and smooth. (This was before we had a silver coinage in Austria.) I once remarked to him that one could always tell a government official by the brand-new florins that he drew from the State treasury, and he then informed me that his florins were by no means new, but that he had them ironed out at home. It was a matter of conscience with him, he explained, not to hand any one dirty paper florins; for they harboured all sorts of dangerous bacteria and might do some harm to the recipient. At that time I already had a vague suspicion of the connection between neuroses and sexual life, so on another occasion I ventured to ask the patient how he stood in regard to that matter. ‘Oh, that's quite all right,’ he answered airily, 'I'm not at all badly off in that respect. I play the part of a dear old uncle in a number of respectable families, and now and then I make use of my position to invite some young girl to go out with me for a day's excursion in the country. Then I arrange that we shall miss the train home and be obliged to spend the night out of town. I always engage two rooms - I do things most handsomely; but when the girl has gone to bed I go in to her and masturbate her with my fingers.' - 'But aren't you afraid of doing her some harm, fiddling about in her genitals with your dirty hand?' - At this he flared up: 'Harm? Why, what harm should it do her? It hasn't done a single one of them any harm yet, and they've all of them enjoyed it. Some of them are married now, and it hasn't done them any harm at all.' - He took my remonstrance in very bad part, and never appeared again. But I could only account for the contrast between his fastidiousness with the paper florins and his unscrupulousness in abusing the girls entrusted to him by supposing that the self-reproachful affect had become displaced. The aim of this displacement was obvious enough: if his self-reproaches had been allowed to remain where they belonged he would have had to abandon a form of sexual gratification to which he was probably impelled by some powerful infantile determinants. The displacement therefore ensured his deriving a considerable advantage from his illness.

[1909d, 2155]
But the information that the young lady at the post office at Z– had herself paid the charges
due upon the packet, with a complimentary remark about himself,¹ had intensified his
identification with his father in quite another direction. At this stage in the analysis he brought
out some new information, to the effect that the landlord of the inn at the little place where the
post office was had had a pretty daughter. She had been decidedly encouraging to the smart
young officer, so that he had thought of returning there after the manoeuvres were over and of
trying his luck with her. Now, however, she had a rival in the shape of the young lady at the post
office. Like his father in the tale of his marriage, he could afford now to hesitate upon which of
the two he should bestow his favours when he had finished his military service. We can see at
once that his singular indecision whether he should travel to Vienna or go back to the place
where the post office was, and the constant temptation he felt to turn back while he was on the
journey (p. 2140), were not so senseless as they seemed to us at first. To his conscious mind,
the attraction exercised upon him by Z–, the place where the post office was, was explained by
the necessity of seeing Lieutenant A. and fulfilling the vow with his assistance. But in reality
what was attracting him was the young lady at the post office, and the lieutenant was merely a
good substitute for her, since he had lived at the same place and had himself been in charge
of the military postal service. And when subsequently he heard that it was not Lieutenant A. but
another officer B., who had been on duty at the post office that day, he drew him into his
combination as well; and he was then able to reproduce in his deliria in connection with the two
officers the hesitation he felt between the two girls who were so kindly disposed towards him.²
[1909d, 2165]

The technique of distortion by ellipsis seems to be typical of obsessional neuroses; I have
come across it in the obsessional thoughts of other patients as well. One example, a particularly
transparent one, is of especial interest on account of a certain structural similarity with the rat
idea. It was a case of doubting, and occurred in a lady who suffers principally from obsessional
acts. This lady was going for a walk with her husband in Nuremberg, and made him take her
into a shop, where she purchased various objects for her child and amongst them a comb. Her
husband, finding that the shopping was too long a business for his taste, said that he had
noticed some coins in an antique shop on the way which he was anxious to secure, adding that
after he had made his purchase he would come and fetch her in the shop in which they at
present were. But he stayed away, as she thought, far too long. When he came back she
accordingly asked him where he had been. 'Why,' he replied, 'at the antique shop I told you
about.' At the same instant she was seized by a tormenting doubt whether she had not as a
matter of fact always possessed the comb which she had just bought for her child. She was
naturally quite unable to discover the simple mental link that was involved. There is nothing for
it but to regard the doubt as having become displaced, and to reconstruct the complete chain of
unconscious thoughts as follows: 'If it is true that you were only at the antique shop, if I am
really to believe that, then I may just as well believe that this comb that I bought a moment ago
has been in my possession for years.' Here, therefore, the lady was drawing a derisive and
ironical parallel, just as when our patient thought: 'Oh yes, as sure as those two' (his father and
the lady) 'will have children, I shall pay back the money to A.' In the lady's case the doubt was
dependent upon her unconscious jealousy, which led her to suppose that her husband had
spent the interval of his absence in paying a visit of gallantry.
[1909d, 2177]
There can be no doubt that the patient felt a need for finding experiences of this kind to act as props for his superstition, and that it was for that reason that he occupied himself so much with the inexplicable coincidences of everyday life with which we are all familiar, and helped out their shortcomings with unconscious activity of his own. I have come across a similar need in many other obsessional patients and have suspected its presence in many more besides. It seems to me easily explicable in view of the psychological characteristics of the obsessional neurosis. In this disorder, as I have already explained (p. 2155), repression is effected not by means of amnesia but by a severance of causal connections brought about by a withdrawal of affect. These repressed connections appear to persist in some kind of shadowy form (which I have elsewhere compared to an endopsychic perception),¹ and they are thus transferred, by a process of projection, into the external world, where they bear witness to what has been effaced from consciousness.

[1909d, 2181]

But in whatever way this remarkable relation of love and hatred is to be explained, its occurrence is established beyond any possibility of doubt by the observations made in the present case; and it is gratifying to find how easily we can now follow the puzzling processes of an obsessional neurosis by bringing them into relation with this one factor. If an intense love is opposed by an almost equally powerful hatred, and is at the same time inseparably bound up with it, the immediate consequence is certain to be a partial paralysis of the will and an incapacity for coming to a decision upon any of those actions for which love ought to provide the motive power. But this indecision will not confine itself for long to a single group of actions. For, in the first place, what actions of a lover are not brought into relation with his one principal motive? And secondly a man's attitude in sexual things has the force of a model to which the rest of his reactions tend to conform. And thirdly, it is an inherent characteristic in the psychology of an obsessional neurotic to make the fullest possible use of the mechanism of displacement. So the paralysis of his powers of decision gradually extends itself over the entire field of the patient's behaviour.

[1909d, 2188]

The doubt corresponds to the patient's internal perception of his own indecision, which, in consequence of the inhibition of his love by his hatred, takes possession of him in the face of every intended action. The doubt is in reality a doubt of his own love - which ought to be the most certain thing in his whole mind; and it becomes diffused over everything else, and is especially apt to become displaced on to what is most insignificant and small.¹ A man who doubts his own love may, or rather must, doubt every lesser thing.²

[1909d, 2188]
It is this same doubt that leads the patient to uncertainty about his protective measures, and to his continual repetition of them in order to banish that uncertainty; and it is this doubt, too, that eventually brings it about that the patient's protective acts themselves become as impossible to carry out as his original inhibited decision in connection with his love. At the beginning of my investigations I was led to assume another and more general origin for the uncertainty of obsessional neurotics and one which seemed to be nearer the normal. If, for instance, while I am writing a letter some one interrupts me with questions, I afterwards feel a quite justifiable uncertainty as to what I may not have written under the influence of the disturbance, and, to make sure, I am obliged to read the letter over after I have finished it. In the same way I might suppose that the uncertainty of obsessional neurotics, when they are praying, for instance, is due to unconscious phantasies constantly mingling with their prayers and disturbing them. This hypothesis is correct, but it may be easily reconciled with what I have just said. It is true that the patient's uncertainty whether he has carried through a protective measure is due to the disturbing effect of unconscious phantasies; but the content of these phantasies is precisely the contrary impulse - which it was the very aim of the prayer to ward off. This became clearly evident in our patient on one occasion, for the disturbing element did not remain unconscious but made its appearance openly. The words he wanted to use in his prayer were, "May God protect her," but a hostile 'not' suddenly darted out of his unconscious and inserted itself into the sentence; and he understood that this was an attempt at a curse (p. 2152). If the 'not' had remained mute, he would have found himself in a state of uncertainty and would have kept on prolonging his prayers indefinitely. But since it became articulate he eventually gave up praying. Before doing so, however, he, like other obsessional patients, tried every kind of method for preventing the opposite feeling from insinuating itself. He shortened his prayers, for instance, or said them more rapidly. And similarly other patients will endeavour to 'isolate' all such protective acts from other things. But none of these technical procedures are of any avail in the long run. If the impulse of love achieves any success by displacing itself on to some trivial act, the impulse of hostility will very soon follow it on to its new ground and once more proceed to undo all that it has done.

The *compulsion* on the other hand is an attempt at a compensation for the doubt and at a correction of the intolerable conditions of inhibition to which the doubt bears witness. If the patient, by the help of displacement, succeeds at last in bringing one of his inhibited intentions to a decision, then the intention *must* be carried out. It is true that this intention is not his original one, but the energy dammed up in the latter cannot let slip the opportunity of finding an outlet for its discharge in the substitutive act. Thus this energy makes itself felt now in commands and now in prohibitions, according as the affectionate impulse or the hostile one snatches control of the pathway leading to discharge. If it happens that a compulsive command cannot be obeyed, the tension becomes intolerable and is perceived by the patient in the form of extreme anxiety. (But the pathway leading to a substitutive act, even where the displacement has been on to something very small, is so hotly contested, that such an act can as a rule be carried out only in the shape of a protective measure intimately associated with the very impulse which it is designed to ward off.)
We have already mentioned the important part played by the sadistic instinctual components in the genesis of obsessional neuroses. Where the epistemophilic instinct is a preponderant feature in the constitution of an obsessional patient, brooding becomes the principal symptom of the neurosis. The thought-process itself becomes sexualized, for the sexual pleasure which is normally attached to the content of thought becomes shifted on to the act of thinking itself, and the satisfaction derived from reaching the conclusion of a line of thought is experienced as a sexual satisfaction. In the various forms of obsessional neurosis in which the epistemophilic instinct plays a part, its relation to thought-processes makes it particularly well adapted to attract the energy which is vainly endeavouring to make its way forward into action, and divert it into the sphere of thought, where there is a possibility of its obtaining pleasurable satisfaction of another sort. In this way, with the help of the epistemophilic instinct, the substitutive act may in its turn be replaced by preparatory acts of thought. But procrastination in action is soon replaced by lingering over thoughts, and eventually the whole process, together with all its peculiarities, is transferred into the new sphere, just as in America an entire house will sometimes be shifted from one site to another.

This interpretation by the psychological novelist cannot be put to the proof, but it can claim so much inner probability, and is so much in harmony with all that we otherwise know of Leonardo's emotional activity, that I cannot refrain from accepting it as correct. He had succeeded in subjecting his feelings to the yoke of research and in inhibiting their free utterance; but even for him there were occasions when what had been suppressed obtained expression forcibly. The death of the mother he had once loved so dearly was one of these. What we have before us in the account of the costs of the funeral is the expression - distorted out of all recognition - of his mourning for his mother. We wonder how such distortion could come about, and indeed we cannot understand it if we treat it as a normal mental process. But similar processes are well known to us in the abnormal conditions of neurosis and especially of what is known as 'obsessional neurosis'. There we can see how the expression of intense feelings, which have however become unconscious through repression, is displaced on to trivial and even foolish actions. The expression of these repressed feelings has been lowered by the forces opposed to them to such a degree that one would have had to form a most insignificant estimate of their intensity; but the imperative compulsiveness with which this trivial expressive act is performed betrays the real force of the impulses - a force which is rooted in the unconscious and which consciousness would like to deny. Only a comparison such as this with what happens in obsessional neurosis can explain Leonardo's account of the expenses of his mother's funeral. In his unconscious he was still tied to her by erotically coloured feelings, as he had been in childhood. The opposition that came from the subsequent repression of this childhood love did not allow him to set up a different and worthier memorial to her in his diary. But what emerged as a compromise from this neurotic conflict had to be carried out; and thus it was that the account was entered in the diary, and has come to the knowledge of posterity as something unintelligible.

The purpose of some of the prohibitions is immediately obvious. Others, on the contrary, strike us as incomprehensible, senseless and silly, and prohibitions of this latter sort are described as 'ceremonial'. This distinction, too, is found in the observances of taboo.

I will now put side by side two instances of the transference (or, as it is better to say, the displacement) of a prohibition. One of these is taken from the life of the Maoris and the other from an observation of my own on a female obsessional patient.
Let us now summarize the points in which agreement between taboo usages and obsessional symptoms is most clearly shown: (1) the fact that the prohibitions lack any assignable motive; (2) the fact that they are maintained by an internal necessity; (3) the fact that they are easily displaceable and that there is a risk of infection from the prohibited object; and (4) the fact that they give rise to injunctions for the performance of ceremonial acts.

[1912-1913, 2676]

In our clinical history of a case we have insisted that the imposition of the prohibition in very early childhood is the determining point; a similar importance attaches in the subsequent developments to the mechanism of repression at the same early age. As a result of the repression which has been enforced and which involves a loss of memory - an amnesia - the motives for the prohibition (which is conscious) remain unknown; and all attempts at disposing of it by intellectual processes must fail, since they cannot find any base of attack. The prohibition owes its strength and its obsessive character precisely to its unconscious opponent, the concealed and undiminished desire - that is to say, to an internal necessity inaccessible to conscious inspection. The ease with which the prohibition can be transferred and extended reflects a process which falls in with the unconscious desire and is greatly facilitated by the psychological conditions that prevail in the unconscious. The instinctual desire is constantly shifting in order to escape from the impasse and endeavour to find substitutes - substitute objects and substitute acts - in place of the prohibited ones. In consequence of this, the prohibition itself shifts about as well, and extends to any new aims which the forbidden impulse may adopt. Any fresh advance made by the repressed libido is answered by a fresh sharpening of the prohibition. The mutual inhibition of the two conflicting forces produces a need for discharge, for reducing the prevailing tension; and to this may be attributed the reason for the performance of obsessive acts. In the case of a neurosis these are clearly compromise actions: from one point of view they are evidences of remorse, efforts at expiation, and so on, while on the other hand they are at the same time substitutive acts to compensate the instinct for what has been prohibited. It is a law of neurotic illness that these obsessive acts fall more and more under the sway of the instinct and approach nearer and nearer to the activity which was originally prohibited.

[1912-1913, 2678]

Let us now make the experiment of treating taboo as though it were of the same nature as an obsessional prohibition in one of our patients. We must make it clear beforehand, however, that many of the taboo prohibitions that come under our notice are of a secondary, displaced and distorted kind, and that we shall have to be satisfied if we can throw only a little light on the most fundamental and significant taboos. Moreover, the differences between the situation of a savage and of a neurotic are no doubt of sufficient importance to make any exact agreement impossible and to prevent our carrying the comparison to the point of identity in every detail.

[1912-1913, 2679]

This transmissibility of taboo is a reflection of the tendency, on which we have already remarked, for the unconscious instinct in the neurosis to shift constantly along associative paths on to new objects. Our attention is thus directed to the fact that the dangerous magical force of mana corresponds to two powers of a more realistic sort: the power of reminding a man of his own prohibited wishes and the apparently more important one of inducing him to transgress the prohibition in obedience to those wishes. These two functions can be reduced to one, however, if we suppose that in a primitive mind the awakening of the memory of a forbidden action is naturally linked with the awakening of an impulse to put that action into effect. Thus recollection and temptation come together again. It must be admitted, too, that, in so far as the example of a man transgressing a prohibition tempts another man to do the same, disobedience to prohibitions spreads like a contagion, in just the same way as a taboo is transferred from a person to a material object and from one material object to another.

[1912-1913, 2682]
I will now sum up the respects in which light has been thrown on the nature of taboo by comparing it with the obsessional prohibitions of neurotics. Taboo is a primaeval prohibition forcibly imposed (by some authority) from outside, and directed against the most powerful longings to which human beings are subject. The desire to violate it persists in their unconscious; those who obey the taboo have an ambivalent attitude to what the taboo prohibits. The magical power that is attributed to taboo is based on the capacity for arousing temptation; and it acts like a contagion because examples are contagious and because the prohibited desire in the unconscious shifts from one thing to another. The fact that the violation of a taboo can be atoned for by a renunciation shows that renunciation lies at the basis of obedience to taboo.

[1912-1913, 2682]

One of the characteristics of this ambivalent relation which I have repeatedly stressed as fundamental - the fact that the positive current of desire is an unconscious one - opens the way to further considerations and to further possible explanations. Psychical processes in the unconscious are not in every respect identical with those with which our conscious mind is familiar; they enjoy some remarkable liberties that are forbidden to the latter. An unconscious impulse need not have arisen at the point where it makes its appearance; it may arise from some quite other region and have applied originally to quite other persons and connections; it may have reached the place at which it attracts our attention though the mechanism of 'displacement'. Owing, moreover, to the indestructibility and insusceptibility to correction which are attributes of unconscious processes, it may have survived from very early times to which it was appropriate into later times and circumstances in which its manifestations are bound to seem strange. These are no more than hints, but if they were attentively developed their importance for our understanding of the growth of civilization would become apparent.

[1912-1913, 2714]

It is in obsessional neuroses that the survival of the omnipotence of thoughts is most clearly visible and that the consequences of this primitive mode of thinking come closest to consciousness. But we must not be misled into supposing that it is a distinguishing feature of this particular neurosis, for analytic investigation reveals the same thing in the other neuroses as well. In all of them what determines the formation of symptoms is the reality not of experience but of thought. Neurotics live in a world apart, where, as I have said elsewhere, only 'neurotic currency' is legal tender; that is to say, they are only affected by what is thought with intensity and pictured with emotion, whereas agreement with external reality is a matter of no importance. What hysterics repeat in their attacks and fix by means of their symptoms are experiences which have occurred in that form only in their imagination though it is true that in the last resort those imagined experiences go back to actual events or are based upon them. To attribute the neurotic sense of guilt to real misdeeds would show an equal misunderstanding. An obsessional neurotic may be weighed down by a sense of guilt that would be appropriate in a mass-murderer, while in fact, from his childhood onwards, he has behaved to his fellow-men as the most considerate and scrupulous member of society. Nevertheless, his sense of guilt has a justification: it is founded on the intense and frequent death wishes against his fellows which are unconsciously at work in him. It has a justification if what we take into account are unconscious thoughts and not intentional deeds. Thus the omnipotence of thoughts, the overvaluation of mental processes as compared with reality, is seen to have unrestricted play in the emotional life of neurotic patients and in everything that derives from it. If one of them undergoes psychoanalytic treatment, which makes what is unconscious in him conscious, he will be unable to believe that thoughts are free and will constantly be afraid of expressing evil wishes, as though their expression would lead inevitably to their fulfilment. This behaviour, as well as the superstitions which he practises in ordinary life, reveals his resemblance to the savages who believe they can alter the external world by mere thinking.

[1912-1913, 2729]
The primary obsessive acts of these neurotics are of an entirely magical character. If they are not charms, they are at all events counter-charms, designed to ward off the expectations of disaster with which the neurosis usually starts. Whenever I have succeeded in penetrating the mystery, I have found that the expected disaster was death. Schopenhauer has said that the problem of death stands at the outset of every philosophy; and we have already seen that the origin of the belief in souls and in demons, which is the essence of animism, goes back to the impression which is made upon men by death. It is difficult to judge whether the obsessive or protective acts performed by obsessional neurotics follow the law of similarity (or, as the case may be, of contrast); for as a rule, owing to the prevailing conditions of the neurosis, they have been distorted by being displaced on to something very small, some action in itself of the greatest triviality.¹ The protective formulas of obsessional neuroses, too, have their counterpart in the formulas of magic. It is possible, however, to describe the course of development of obsessive acts: we can show how they begin by being as remote as possible from anything sexual - magical defences against evil wishes - and how they end by being substitutes for the forbidden sexual act and the closest possible imitations of it.

¹ A further motive for such displacement on to a very small action will appear in what follows.

In another neurotic disorder, obsessional neurosis, the patients become the victims of distressing and apparently senseless ceremonials which take the form of the rhythmical repetition of the most trivial acts (such as washing or dressing) or of carrying out meaningless injunctions or of obeying mysterious prohibitions. It was nothing less than a triumph of psychoanalytic research when it succeeded in showing that all these obsessive acts, even the most insignificant and trivial of them, have a meaning, and that they are reflections, translated into indifferent terms, of conflicts in the patients' lives, of the struggle between temptations and moral restraints - reflections of the proscribed wish itself and of the punishment and atonement which that wish incurs. In another form of the same disorder the victim suffers from tormenting ideas (obsessions) which force themselves upon him and are accompanied by affects whose character and intensity are often only quite inadequately accounted for by the terms of the obsessive ideas themselves. Analytic investigation has shown in their case that the affects are entirely justified, since they correspond to self-reproaches which are based on something that is at least psychically real. But the ideas to which these affects are attached are not the original ones, but have found their way into their present position by a process of displacement - by being substituted for something that has been repressed. If these displacements can be reversed, the way is open to the discovery of the repressed ideas, and the relation between affect and idea is found to be perfectly appropriate.

[1912-1913, 2730]
A totally different picture of repression is shown, once more, in the third disorder which we shall consider for the purposes of our illustration - in obsessive neurosis. Here we are at first in doubt what it is that we have to regard as the instinctual representative that is subjected to repression - whether it is a libidinal or a hostile trend. This uncertainty arises because obsessional neurosis has as its basis a regression owing to which a sadistic trend has been substituted for an affectionate one. It is this hostile impulsion against someone who is loved which is subjected to repression. The effect at an early stage of the work of repression is quite different from what it is at a later one. At first the repression is completely successful; the ideational content is rejected and the affect made to disappear. As a substitutive formation there arises an alteration in the ego in the shape of an increased conscientiousness, and this can hardly be called a symptom. Here, substitute and symptom do not coincide. From this we learn something, too, about the mechanism of repression. In this instance, as in all others, repression has brought about a withdrawal of libido; but here it has made use of reaction-formation for this purpose, by intensifying an opposite. Thus in this case the formation of a substitute has the same mechanism as repression and at bottom coincides with it, while chronologically, as well as conceptually, it is distinct from the formation of a symptom. It is very probable that the whole process is made possible by the ambivalent relationship into which the sadistic impulsion that has to be repressed has been introduced. But the repression, which was at first successful, does not hold firm; in the further course of things its failure becomes increasingly marked. The ambivalence which has enabled repression through reaction-formation to take place is also the point at which the repressed succeeds in returning. The vanished affect comes back in its transformed shape as social anxiety, moral anxiety and unlimited self-reproaches; the rejected idea is replaced by a substitute by displacement, often a displacement on to something very small or indifferent. A tendency to a complete re-establishment of the repressed idea is as a rule unmistakably present. The failure in the repression of the quantitative, affective factor brings into play the same mechanism of flight, by means of avoidance and prohibitions, as we have seen at work in the formation of hysterical phobias. The rejection of the idea from the conscious is, however, obstinately maintained, because it entails abstention from action, a motor fettering of the impulsion. Thus in obsessional neurosis the work of repression is prolonged in a sterile and interminable struggle.

[1915d, 2987]
Certainly this is a crazy illness. The most extravagant psychiatric imagination would not, I think, have succeeded in constructing anything like it; and if one did not see it before one every day one would never bring oneself to believe in it. Do not suppose, however, that you will help the patient in the least by calling on him to take a new line, to cease to occupy himself with such foolish thoughts and to do something sensible instead of his childish pranks. He would like to do so himself, for he is completely clear in his head, shares your opinion of his obsessional symptoms and even puts it forward to you spontaneously. Only he cannot help himself. What is carried into action in an obsessional neurosis is sustained by an energy to which we probably know nothing comparable in normal mental life. There is only one thing he can do: he can make displacements, and exchanges, he can replace one foolish idea by another somewhat milder, he can proceed from one precaution or prohibition to another, instead of one ceremonial he can perform another. He can displace the obsession but not remove it. The ability to displace any symptom into something far removed from its original conformation is a main characteristic of his illness. Moreover it is a striking fact that in his condition the contradictions (polarities) with which mental life is interlaced emerge especially sharply differentiated. Alongside of obsessions with a positive and negative content, doubt makes itself felt in the intellectual field and little by little it begins to gnaw even at what is usually most certain. The whole position ends up in an ever-increasing degree of indecision, loss of energy and restriction of freedom. At the same time, the obsessional neurotic starts off with a very energetic disposition, he is often extraordinarily self-willed and as a rule he has intellectual gifts above the average. He has usually reached a satisfactorily high level of ethical development; he exhibits over-conscientiousness, and is more than ordinarily correct in his behaviour. You can imagine that no small amount of work is needed before one can make one's way any distance into this contradictory hotch-potch of character-traits and symptoms. And to begin with we aim at nothing whatever else than understanding a few of the symptoms and being able to interpret them.

[1916-1917, 3340]
But the information that the young lady at the post office at Z-- had herself paid the charges due upon the packet, with a complimentary remark about himself,¹ had intensified his identification with his father in quite another direction. At this stage in the analysis he brought out some new information, to the effect that the landlord of the inn at the little place where the post office was had had a pretty daughter. She had been decidedly encouraging to the smart young officer, so that he had thought of returning there after the manoeuvres were over and of trying his luck with her. Now, however, she had a rival in the shape of the young lady at the post office. Like his father in the tale of his marriage, he could afford now to hesitate upon which of the two he should bestow his favours when he had finished his military service. We can see at once that his singular indecision whether he should travel to Vienna or go back to the place where the post office was, and the constant temptation he felt to turn back while he was on the journey (p. 2140), were not so senseless as they seemed to us at first. To his conscious mind, the attraction exercised upon him by Z--, the place where the post office was, was explained by the necessity of seeing Lieutenant A. and fulfilling the vow with his assistance. But in reality what was attracting him was the young lady at the post office, and the lieutenant was merely a good substitute for her, since he had lived at the same place and had himself been in charge of the military postal service. And when subsequently he heard that it was not Lieutenant A. but another officer B., who had been on duty at the post office that day, he drew him into his combination as well; and he was then able to reproduce in his deliria in connection with the two officers the hesitation he felt between the two girls who were so kindly disposed towards him.²

[1909d, 2165]

The compulsion on the other hand is an attempt at a compensation for the doubt and at a correction of the intolerable conditions of inhibition to which the doubt bears witness. If the patient, by the help of displacement, succeeds at last in bringing one of his inhibited intentions to a decision, then the intention must be carried out. It is true that this intention is not his original one, but the energy dammed up in the latter cannot let slip the opportunity of finding an outlet for its discharge in the substitutive act. Thus this energy makes itself felt now in commands and now in prohibitions, according as the affectionate impulse or the hostile one snatches control of the pathway leading to discharge. If it happens that a compulsive command cannot be obeyed, the tension becomes intolerable and is perceived by the patient in the form of extreme anxiety. (But the pathway leading to a substitutive act, even where the displacement has been on to something very small, is so hotly contested, that such an act can as a rule be carried out only in the shape of a protective measure intimately associated with the very impulse which it is designed to ward off.

[1909d, 2190]
Furthermore, by a sort of regression, preparatory acts become substituted for the final decision, thinking replaces acting, and, instead of the substitutive act, some thought preliminary to it asserts itself with all the force of compulsion. According as this regression from acting to thinking is more or less marked, a case of obsessional neurosis will exhibit the characteristics of obsessive thinking (that is, of obsessional ideas) or of obsessive acting in the narrower sense of the word. True obsessional acts such as these, however, are only made possible because they constitute a kind of reconciliation, in the shape of a compromise, between the two antagonistic impulses. For obsessional acts tend to approximate more and more - and the longer the disorder lasts the more evident does this become - to infantile sexual acts of a masturbatory character. Thus in this form of the neurosis acts of love are carried out in spite of everything, but only by the aid of a new kind of regression; for such acts no longer relate to another person, the object of love and hatred, but are auto-erotic acts such as occur in infancy.

\[1909d, 2191\]

The reproaches of conscience in certain forms of obsessional neurosis are as distressing and tormenting, but here the situation is less perspicuous. It is noteworthy that the obsessional neurotic, in contrast to the melancholic, never in fact takes the step of self-destruction; it is as though he were immune against the danger of suicide, and he is far better protected from it than the hysterical. We can see that what guarantees the safety of the ego is the fact that the object has been retained. In obsessional neurosis it has become possible, through a regression to the pregenital organization, for the love-impulses to transform themselves into impulses of aggression against the object. Here again the instinct of destruction has been set free and it seeks to destroy the object, or at least it appears to have that intention. These purposes have not been adopted by the ego and it struggles against them with reaction-formations and precautionary measures; they remain in the id. The super-ego, however, behaves as if the ego were responsible for them and shows at the same time by the seriousness with which it chastises these destructive intentions that they are no mere semblance evoked by regression but an actual substitution of hate for love. Helpless in both directions, the ego defends itself vainly, alike against the instigations of the murderous id and against the reproaches of the punishing conscience. It succeeds in holding in check at least the most brutal actions of both sides; the first outcome is interminable self-torment, and eventually there follows a systematic torturing of the object, in so far as it is within reach.

\[1923b, 3987\]
Not everyone who suffers from obsessions is as clear as this about their origin. As a rule, when one draws a patient's attention to the original idea of a sexual kind, the answer is: 'It can't come from that. I didn't think at all much about that. For a moment I was frightened, but I turned my mind away from it and I haven't been troubled by it since.' In this frequent objection we have evidence that the obsession represents a substitute or surrogate for the incompatible sexual idea and has taken its place in consciousness.

[1894a, 308]

So long as the patients are aware of the sexual origin of their obsessions, they often keep them secret. If they do complain about them, they usually express their astonishment that they should be subject to the affect in question - that they should feel anxiety, or have certain impulses, and so on. To the experienced physician, on the contrary, the affect seems justified and comprehensible; what he finds noticeable is only that an affect of that kind should be linked with an idea which does not merit it. The affect of the obsession appears to him, in other words, as being dislodged or transposed; and if he has accepted what has been said in these pages, he will be able, in a number of cases of obsessions, to attempt to re-translate them into sexual terms.

[1894a, 309]

The proof of this is the fact that we can always find in the previous history of the patient, at the beginning of the obsession, the original idea that has been replaced. The replaced ideas all have common attributes; they correspond to really distressing experiences in the subject’s sexual life which he is striving to forget. He succeeds merely in replacing the incompatible idea by another ill-adapted for being associated with the emotional state, which for its part remains unchanged. It is this mésalliance between the emotional state and the associated idea that accounts for the absurdity so characteristic of obsessions.

[1895c, 318]

Reinstatement: Obsessions based on typical temptations. These were women who, not being at all satisfied in marriage, had to struggle against the desires and voluptuous ideas that constantly troubled them at the sight of other men.

[1895c, 319]

(e) Anxiety neurosis also occurs as anxiety in widows and intentionally abstinent women, not seldom in a typical combination with obsessional ideas; and

[1895b, 337]

The significance of the erotogenic zones as apparatuses subordinate to the genitals and as substitutes for them is, among all the psychoneuroses, most clearly to be seen in hysteria; but this does not imply that that significance is any the less in the other forms of illness. It is only that in them it is less recognizable, because in their case (obsessional neurosis and paranoia) the formation of the symptoms takes place in regions of the mental apparatus which are more remote from the particular centres concerned with somatic control. In obsessional neurosis what is more striking is the significance of those impulses which create new sexual aims and seem independent of erotogenic zones. Nevertheless, in scopophilia and exhibitionism the eye corresponds to an erotogenic zone; while in the case of those components of the sexual instinct which involve pain and cruelty the same role is assumed by the skin - the skin, which in particular parts of the body has become differentiated into sense organs or modified into mucous membrane, and is thus the erotogenic zone par excellence.¹

[1905d, 1493]
I will postpone until later in this paper a more thorough going discussion of the question whether we are to regard the sexual experiences of childhood as the causes of hysteria (and obsessional neurosis), and I will now return to the form taken by the theory in some of my shorter preliminary publications during the years 1895 and 1896 (Freud, 1896b and 1896c). By laying stress on the supposed aetiological factors it was possible at that time to draw a contrast between the common neuroses as disorders with a contemporary aetiology and psychoneuroses whose aetiology was chiefly to be looked for in the sexual experiences of the remote past. The theory culminated in this thesis: if the vita sexualis is normal, there can be no neurosis. [1906a, 1577]

A deeper insight into the mechanism of obsessional neurosis is gained if we take into account the primary fact which lies at the bottom of it. This is always the repression of an instinctual impulse (a component of the sexual instinct) which was present in the subject's constitution and which was allowed to find expression for a while during his childhood but later succumbed to suppression. In the course of the repression of this instinct a special conscientiousness is created which is directed against the instinct's aims; but this psychical reaction-formation feels insecure and constantly threatened by the instinct which is lurking in the unconscious. The influence of the repressed instinct is felt as a temptation, and during the process of repression itself anxiety is generated, which gains control over the future in the form of expectant anxiety. The process of repression which leads to obsessional neurosis must be considered as one which is only partly successful and which increasingly threatens to fail. It may thus be compared to an unending conflict; fresh psychical efforts are continually required to counterbalance the forward pressure of the instinct. Thus the ceremonial and obsessive actions arise partly as a defence against the temptation and partly as a protection against the ill which is expected. Against the temptation the protective measures seem soon to become inadequate; then the prohibitions come into play, with the purpose of keeping at a distance situations that give rise to temptation. Prohibitions take the place of obsessive actions, it will be seen, just as a phobia is designed to avert a hysterical attack. Again, a ceremonial represents the sum of the conditions subject to which something that is not yet absolutely forbidden is permitted, just as the Church's marriage ceremony signifies for the believer a sanctioning of sexual enjoyment which would otherwise be sinful. A further characteristic of obsessional neurosis, as of all similar affections, is that its manifestations (its symptoms, including the obsessive actions) fulfil the condition of being a compromise between the warring forces of the mind. They thus always reproduce something of the pleasure which they are designed to prevent; they serve the repressed instinct no less than the agencies which are repressing it. As the illness progresses, indeed, actions which were originally mostly concerned with maintaining the defence come to approximate more and more to the proscribed actions through which the instinct was able to find expression in childhood. [1907b, 1907]

We find, accordingly: an erotic instinct and a revolt against it; a wish which has not yet become compulsive and, struggling against it, a fear which is already compulsive; a distressing affect and an impulse towards the performance of defensive acts. The inventory of the neurosis has reached its full muster. Indeed, something more is present, namely, a kind of delusion or delirium with the strange content that his parents knew his thoughts because he spoke them out loud without his hearing himself do it. We shall not go far astray if we suppose that in making this attempt at an explanation the child had some inkling of those remarkable mental processes which we describe as unconscious and which we cannot dispense with if we are to throw any scientific light upon this obscure subject. 'I speak my thoughts out loud, without hearing them' sounds like a projection into the external world of our own hypothesis that he had thoughts without knowing anything about them; it sounds like an endopsychic perception of what has been repressed. [1909d, 2134]
Another impulse, which might be described as indirectly suicidal and which was of longer duration, was not so easily explicable. For its relation to the patient's experiences succeeded in concealing itself behind one of those purely external associations which are so obnoxious to our consciousness. One day while he was away on his summer holidays the idea suddenly occurred to him that he was too fat [German ‘dick’] and that he must make himself slimmer. So he began getting up from table before the pudding came round and tearing along the road without a hat in the blazing heat of an August sun. Then he would dash up a mountain at the double, till, dripping with perspiration, he was forced to come to a stop. On one occasion his suicidal intentions actually emerged without any disguise from behind this mania for slimming: as he was standing on the edge of a steep precipice he suddenly received a command to jump over, which would have been certain death. Our patient could think of no explanation of this senseless obsessional behaviour until it suddenly occurred to him that at that time his lady had also been stopping at the same resort; but she had been in the company of an English cousin, who was very attentive to her and of whom the patient had been very jealous. This cousin's name was Richard, and, according to the usual practice in England, he was known as Dick. Our patient, then, had wanted to kill this Dick; he had been far more jealous of him and enraged with him than he could admit to himself, and that was why he had imposed on himself this course of slimming by way of a punishment. This obsessional impulse may seem very different from the directly suicidal command which was discussed above, but they have nevertheless one important feature in common. For they both arose as reactions to a tremendous feeling of rage, which was inaccessible to the patient's consciousness and was directed against some one who had cropped up as an interference with the course of his love.¹

[1909d, 2148]

There can be no question that there was something in the sphere of sexuality that stood between the father and son, and that the father had come into some sort of opposition to the son's prematurely developed erotic life. Several years after his father's death, the first time he experienced the pleasurable sensations of copulation, an idea sprang into his mind: 'This is glorious! One might murder one's father for this!' This was at once an echo and an elucidation of the obsessional ideas of his childhood. Moreover, his father, shortly before his death, had directly opposed what later became our patient's dominating passion. He had noticed that his son was always in the lady's company, and had advised him to keep away from her, saying that it was imprudent of him and that he would only make a fool of himself.

[1909d, 2158]
The technique of distortion by ellipsis seems to be typical of obsessional neuroses; I have come across it in the obsessional thoughts of other patients as well. One example, a particularly transparent one, is of especial interest on account of a certain structural similarity with the rat idea. It was a case of doubting, and occurred in a lady who suffers principally from obsessional acts. This lady was going for a walk with her husband in Nuremberg, and made him take her into a shop, where she purchased various objects for her child and amongst them a comb. Her husband, finding that the shopping was too long a business for his taste, said that he had noticed some coins in an antique shop on the way which he was anxious to secure, adding that after he had made his purchase he would come and fetch her in the shop in which they at present were. But he stayed away, as she thought, far too long. When he came back she accordingly asked him where he had been. 'Why,' he replied, 'at the antique shop I told you about.' At the same instant she was seized by a tormenting doubt whether she had not as a matter of fact always possessed the comb which she had just bought for her child. She was naturally quite unable to discover the simple mental link that was involved. There is nothing for it but to regard the doubt as having become displaced, and to reconstruct the complete chain of unconscious thoughts as follows: 'If it is true that you were only at the antique shop, if I am really to believe that, then I may just as well believe that this comb that I bought a moment ago has been in my possession for years.' Here, therefore, the lady was drawing a derisive and ironical parallel, just as when our patient thought: 'Oh yes, as sure as those two' (his father and the lady) 'will have children, I shall pay back the money to A.' In the lady's case the doubt was dependent upon her unconscious jealousy, which led her to suppose that her husband had spent the interval of his absence in paying a visit of gallantry.

Wild thoughts, you will say, to be running through an unmarried girl's head. I admit that is so. But you must not forget that I did not make these things but only interpreted them. A sleep-ceremonial like this is a strange thing too, and you will not fail to see how the ceremonial corresponds to the phantasies which are revealed by the interpretation. But I attach more importance to your noticing that what was seen in the ceremonial was a precipitate not of a single phantasy but of a number of them, though they had a nodal point somewhere, and, further, that the rules laid down by the ceremonial reproduced the patient's sexual wishes at one point positively and at another negatively - in part they represented them, but in part they served as a defence against them.

[1909d, 2177]
No doubt all kinds of objections can still be raised to the assertion that neurotic symptoms are substitutes for sexual satisfactions. I will mention two of them to-day. When you yourselves have carried out analytic examinations of a considerable number of neurotics, you will perhaps tell me, shaking your head, that in a lot of cases my assertion is simply not true; the symptoms seem rather to have the contrary purpose of excluding or of stopping sexual satisfaction. I will not dispute the correctness of your interpretation. The facts in psycho-analysis have a habit of being rather more complicated than we like. If they were as simple as all that, perhaps it might not have needed psycho-analysis to bring them to light. Indeed, some of the features of our second patient's ceremonial show signs of this ascetic character with its hostility to sexual satisfaction: when, for instance, she got rid of the clocks and watches, which had the magical meaning of avoiding erections during the night, or when she tried to guard against flower-pots falling and breaking, which was equivalent to protecting her virginity. In some other cases of bed ceremonials, which I have been able to analyse, this negative character was far more outspoken; the ceremonial might consist exclusively of defensive measures against sexual memories and temptations. However, we have already found often enough that in psycho-analysis opposites imply no contradiction. We might extend our thesis and say that symptoms aim either at a sexual satisfaction or at fending it off, and that on the whole the positive, wish-fulfilling character prevails in hysteria and the negative, ascetic one in obsessional neurosis. If symptoms can serve the purpose both of sexual satisfaction and of its opposite, there is an excellent basis for this double-sidedness or polarity in a part of their mechanism which I have so far not been able to mention. For, as we shall hear, they are the products of a compromise and arise from the mutual interference between two opposing currents; they represent not only the repressed but also the repressing force which had a share in their origin. One side or the other may be more strongly represented; but it is rarely that one influence is entirely absent. In hysteria a convergence of both intentions in the same symptom is usually achieved. In obsessional neurosis the two portions are often separated; the symptom then becomes diphasic and consists in two actions, one after the other, which cancel each other out.

[1916-1917, 3373]

The Theory of Repression.- These theoretical considerations, taken together with the immediate impressions derived from analytic work, lead to a view of the neuroses which may be described in the roughest outline as follows. The neuroses are the expression of conflicts between the ego and such of the sexual impulses as seem to the ego incompatible with its integrity or with its ethical standards. Since these impulses are not ego-syntonic, the ego has repressed them: that is to say, it has withdrawn its interest from them and has shut them off from becoming conscious as well as from obtaining satisfaction by motor discharge. If in the course of analytic work one attempts to make these repressed impulses conscious, one becomes aware of the repressive forces in the form of resistance. But the achievement of repression fails particularly readily in the case of the sexual instincts. Their damned-up libido finds other ways out from the unconscious: for it regresses to earlier phases of development and earlier attitudes towards objects, and, at weak points in the libidinal development where there are infantile fixations, it breaks through into consciousness and obtains discharge. What results is a symptom and consequently in its essence a substitutive sexual satisfaction. Nevertheless the symptom cannot entirely escape from the repressive forces of the ego and must therefore submit to modifications and displacements exactly as happens with dreams - by means of which its characteristic of being a sexual satisfaction becomes unrecognizable. Consequently symptoms are in the nature of compromises between the repressed sexual instincts and the repressing ego-instincts; they represent a wish-fulfilment for both partners to the conflict simultaneously, but one which is incomplete for each of them. This is quite strictly true of the symptoms of hysteria, while in the symptoms of obsessional neurosis there is often a stronger emphasis upon the side of the repressing function owing to the erection of reaction-formations, which are assurances against sexual satisfaction.

[1923a, 3923]
Obsessional neurosis is unquestionably the most interesting and repaying subject of analytic research. But as a problem it has not yet been mastered. It must be confessed that, if we endeavour to penetrate more deeply into its nature, we still have to rely upon doubtful assumptions and unconfirmed suppositions. Obsessional neurosis originates, no doubt, in the same situation as hysteria, namely, the necessity of fending off the libidinal demands of the Oedipus complex. Indeed, every obsessional neurosis seems to have a substratum of hysterical symptoms that have been formed at a very early stage. But it is subsequently shaped along quite different lines owing to a constitutional factor. The genital organization of the libido turns out to be feeble and insufficiently resistant, so that when the ego begins its defensive efforts the first thing it succeeds in doing is to throw back the genital organization (of the phallic phase), in whole or in part, to the earlier sadistic-anal level. This fact of regression is decisive for all that follows.

[1926d, 4272]

In enforcing regression, the ego scores its first success in its defensive struggle against the demands of the libido. (In this connection it is of advantage to distinguish the more general notion of 'defence' from 'repression'. Repression is only one of the mechanisms which defence makes use of.) It is perhaps in obsessional cases more than in normal or hysterical ones that we can most clearly recognize that the motive force of defence is the castration complex and that what is being fended off are the trends of the Oedipus complex. We are at present dealing with the beginning of the latency period, a period which is characterized by the dissolution of the Oedipus complex, the creation or consolidation of the super-ego and the erection of ethical and aesthetic barriers in the ego. In obsessional neuroses these processes are carried further than is normal. In addition to the destruction of the Oedipus complex a regressive degradation of the libido takes place, the super-ego becomes exceptionally severe and unkind, and the ego, in obedience to the super-ego, produces strong reaction-formations in the shape of conscientiousness, pity and cleanliness. Implacable, though not always on that account successful, severity is shown in condemning the temptation to continue early infantile masturbation, which now attaches itself to regressive (sadistic-anal) ideas but which nevertheless represents the unsubjugated part of the phallic organization. There is an inherent contradiction about this state of affairs, in which, precisely in the interests of masculinity (that is to say, from fear of castration), every activity belonging to masculinity is stopped. But here, too, obsessional neurosis is only overdoing the normal method of getting rid of the Oedipus complex. We once more find here an illustration of the truth that every exaggeration contains the seed of its own undoing. For, under the guise of obsessional acts, the masturbation that has been suppressed approaches ever more closely to satisfaction.

[1926d, 4273]
The advent of puberty opens a decisive chapter in the history of an obsessional neurosis. The genital organization which has been broken off in childhood starts again with great vigour. But, as we know, the sexual development in childhood determines what direction this new start at puberty will take. Not only will the early aggressive impulses be re-awakened; but a greater or lesser proportion of the new libidinal impulses - in bad cases the whole of them - will have to follow the course prescribed for them by regression and will emerge as aggressive and destructive tendencies. In consequence of the erotic trends being disguised in this way and owing to the powerful reaction-formation in the ego, the struggle against sexuality will henceforward be carried on under the banner of ethical principles. The ego will recoil with astonishment from promptings to cruelty and violence which enter consciousness from the id, and it has no notion that in them it is combating erotic wishes, including some to which it would not otherwise have taken exception. The overstrict super-ego insists all the more strongly on the suppression of sexuality, since this has assumed such repellent forms. Thus in obsessional neurosis the conflict is aggravated in two directions: the defensive forces become more intolerant and the forces that are to be fended off become more intolerable. Both effects are due to a single factor, namely, regression of the libido.

[1926d, 4275]

But in thus endeavouring to prevent associations and connections of thought, the ego is obeying one of the oldest and most fundamental commands of obsessional neurosis, the taboo on touching. If we ask ourselves why the avoidance of touching, contact or contagion should play such a large part in this neurosis and should become the subject-matter of complicated systems, the answer is that touching and physical contact are the immediate aim of the aggressive as well as the loving object-cathexes. Eros desires contact because it strives to make the ego and the loved object one, to abolish all spatial barriers between them. But destructiveness, too, which (before the invention of long-range weapons) could only take effect at close quarters, must presuppose physical contact, a coming to grips. To 'touch' a woman has become a euphemism for using her as a sexual object. Not to 'touch' one's genitals is the phrase employed for forbidding auto-erotic satisfaction. Since obsessional neurosis begins by persecuting erotic touching and then, after regression has taken place, goes on to persecute touching in the guise of aggressiveness, it follows that nothing is so strongly proscribed in that illness as touching nor so well suited to become the central point of a system of prohibitions. But isolating is removing the possibility of contact; it is a method of withdrawing a thing from being touched in any way. And when a neurotic isolates an impression or an activity by interpolating an interval, he is letting it be understood symbolically that he will not allow his thoughts about that impression or activity to come into associative contact with other thoughts.

[1926d, 4280]
The events in his sixth or seventh year which the patient described in the first hour of his treatment were not merely, as he supposed, the beginning of his illness, but were already the illness itself. It was a complete obsessional neurosis, wanting in no essential element, at once the nucleus and the prototype of the later disorder, - an elementary organism, as it were, the study of which could alone enable us to obtain a grasp of the complicated organization of his subsequent illness. The child, as we have seen, was under the domination of a component of the sexual instinct, the desire to look, as a result of which there was a constant recurrence in him of a very intense wish connected with persons of the female sex who pleased him - the wish, that is, to see them naked. This wish corresponds to the later obsessional or compulsive idea; and if the quality of compulsion was not yet present in the wish, this was because the ego had not yet placed itself in complete opposition to it and did not yet regard it as something foreign to itself. Nevertheless, opposition to this wish from some source or other was already in activity, for its occurrence was regularly accompanied by a distressing affect.¹ A conflict was evidently in progress in the mind of this young libertine. Side by side with the obsessive wish, and intimately associated with it, was an obsessive fear: every time he had a wish of this kind he could not help fearing that something dreadful would happen. This something dreadful was already clothed in a characteristic indeterminateness which was thenceforward to be an invariable feature of every manifestation of the neurosis. But in a child it is not hard to discover what it is that is veiled behind an indeterminateness of this kind. If the patient can once be induced to give a particular instance in place of the vague generalities which characterize an obsessional neurosis, it may be confidently assumed that the instance is the original and actual thing which has tried to hide itself behind the generalization. Our present patient's obsessive fear, therefore, when restored to its original meaning, would run as follows: 'If I have this wish to see a woman naked, my father will be bound to die.' The distressing affect was distinctly coloured with a tinge of uncanniness and superstition, and was already beginning to give rise to impulses to do something to ward off the impending evil. These impulses were subsequently to develop into the protective measures which the patient adopted.

¹ [1909d, 2133]

If the sexual component which has broken loose prematurely is the sadistic one, then we may expect, on the basis of knowledge derived from other sources, that its subsequent repression will result in a disposition to an obsessional neurosis. This expectation cannot be said to be contradicted by the results of enquiry. The present short paper is based on the exhaustive study of six cases (four female and two male). Of these, two were cases of obsessional neurosis; one extremely severe and incapacitating, the other of moderate severity and quite well accessible to influence. There was also a third case which at all events exhibited clearly marked individual traits of obsessional neurosis. The fourth case, it must be admitted, was one of straightforward hysteria, with pains and inhibitions; and the fifth patient, who had come to be analysed merely on account of indecisiveness in life, would not have been classified at all by coarse clinical diagnosis, or would have been dismissed as 'psychasthenic'. There is no need for feeling disappointed over these statistics. In the first place, we know that not every disposition is necessarily developed into a disorder; in the second place, we ought to be content to explain the facts before us, and ought as a rule to avoid the additional task of making it clear why something has not taken place.

² [1919e, 3646]
The events in his sixth or seventh year which the patient described in the first hour of his treatment were not merely, as he supposed, the beginning of his illness, but were already the illness itself. It was a complete obsessional neurosis, wanting in no essential element, at once the nucleus and the prototype of the later disorder, - an elementary organism, as it were, the study of which could alone enable us to obtain a grasp of the complicated organization of his subsequent illness. The child, as we have seen, was under the domination of a component of the sexual instinct, the desire to look, as a result of which there was a constant recurrence in him of a very intense wish connected with persons of the female sex who pleased him - the wish, that is, to see them naked. This wish corresponds to the later obsessional or compulsive idea; and if the quality of compulsion was not yet present in the wish, this was because the ego had not yet placed itself in complete opposition to it and did not yet regard it as something foreign to itself. Nevertheless, opposition to this wish from some source or other was already in activity, for its occurrence was regularly accompanied by a distressing affect.¹ A conflict was evidently in progress in the mind of this young libertine. Side by side with the obsessive wish, and intimately associated with it, was an obsessive fear: every time he had a wish of this kind he could not help fearing that something dreadful would happen. This something dreadful was already clothed in a characteristic indeterminateness which was thenceforward to be an invariable feature of every manifestation of the neurosis. But in a child it is not hard to discover what it is that is veiled behind an indeterminateness of this kind. If the patient can once be induced to give a particular instance in place of the vague generalities which characterize an obsessional neurosis, it may be confidently assumed that the instance is the original and actual thing which has tried to hide itself behind the generalization. Our present patient's obsessive fear, therefore, when restored to its original meaning, would run as follows: 'If I have this wish to see a woman naked, my father will be bound to die.' The distressing affect was distinctly coloured with a tinge of uncanniness and superstition, and was already beginning to give rise to impulses to do something to ward off the impending evil. These impulses were subsequently to develop into the protective measures which the patient adopted.

[1909d, 2133]

In elucidating the effects produced by the captain's rat story we must follow the course of the analysis more closely. The patient began by producing an enormous mass of associative material, which at first, however, threw no light upon the circumstances in which the formation of his obsession had taken place. The idea of the punishment carried out by means of rats had acted as a stimulus to a number of his instincts and had called up a whole quantity of recollections; so that, in the short interval between the captain's story and his request to him to pay back the money, rats had acquired a series of symbolic meanings, to which, during the period which followed, fresh ones were continually being added. I must confess that I can only give a very incomplete account of the whole business. What the rat punishment stirred up more than anything else was his anal erotism, which had played an important part in his childhood and had been kept in activity for many years by a constant irritation due to worms. In this way rats came to have the meaning of 'money'.¹ The patient gave an indication of this connection by reacting to the word 'Ratten' ['rats'] with the association 'Raten' ['instalments']. In his obsessional deliria he had coined himself a regular rat currency. When, for instance, in reply to a question, I told him the amount of my fee for an hour's treatment, he said to himself (as I learned six months later): 'So many florins, so many rats'. Little by little he translated into this language the whole complex of money interests which centred round his father's legacy to him, that is to say, all his ideas connected with that subject were, by way of the verbal bridge 'Raten - Ratten', carried over into his obsessional life and brought under the dominion of his unconscious.

Moreover, the captain's request to him to pay back the charges due upon the packet served to strengthen the money significance of rats, by way of another verbal bridge 'Spielratte', which led back to his father's gambling debt.

[1909d, 2166]
We shall not be able to dismiss a second objection so easily. If you survey a fairly long series of interpretations of symptoms, you will probably start by judging that the concept of a substitutive sexual satisfaction has been stretched to its extreme limits in them. You will not fail to emphasize the fact that these symptoms offer nothing real in the way of satisfaction, that often enough they are restricted to the revival of a sensation or the representation of a phantasy derived from a sexual complex. And you will further point out that these supposed sexual satisfactions often take on a childish and discreditable form, approximate to an act of masturbation perhaps, or recall dirty kinds of naughtiness which are forbidden even to children - habits of which they have been broken. And, going on from this, you will also express surprise that we are representing as a sexual satisfaction what would rather have to be described as the satisfaction of lusts that are cruel or horrible or would even have to be called unnatural. We shall come to no agreement, Gentlemen, on this latter point till we have made a thorough investigation of the sexual life of human beings and till, in doing so, we have decided what it is that we are justified in calling 'sexual'.

[1916-1917, 3374]
Dr. Alfred Adler, who was formerly an analyst, once drew attention in a privately delivered paper to the peculiar importance which attaches to the very first communications made by patients. Here is an instance of this. The patient's opening words laid stress upon the influence exercised over him by men, that is to say, upon the part played in his life by homosexual object-choice; but immediately afterwards they touched upon a second motif, which was to become of great importance later on, namely, the conflict between man and woman and the opposition of their interests. Even the fact that he remembered his first pretty governess by her surname, which happened to be a man's first name, must be taken into account in this connection. In middle-class circles in Vienna it is more usual to call a governess by her first name, and it is by that name that she is more commonly remembered.

[1909d, 2131]
The first kind of regression, that from acting to thinking, is facilitated by another factor concerned in the production of the neurosis. The histories of obsessional patients almost invariably reveal an early development and premature repression of the sexual instinct of looking and knowing; and, as we know, a part of the infantile sexual activity of our present patient was governed by that instinct.¹

[1909d, 2191]

We have already mentioned the important part played by the sadistic instinctual components in the genesis of obsessional neuroses. Where the epistemophilic instinct is a preponderant feature in the constitution of an obsessional patient, brooding becomes the principal symptom of the neurosis. The thought-process itself becomes sexualized, for the sexual pleasure which is normally attached to the content of thought becomes shifted on to the act of thinking itself, and the satisfaction derived from reaching the conclusion of a line of thought is experienced as a sexual satisfaction. In the various forms of obsessional neurosis in which the epistemophilic instinct plays a part, its relation to thought-processes makes it particularly well adapted to attract the energy which is vainly endeavouring to make its way forward into action, and divert it into the sphere of thought, where there is a possibility of its obtaining pleasurable satisfaction of another sort. In this way, with the help of the epistemophilic instinct, the substitutive act may in its turn be replaced by preparatory acts of thought. But procrastination in action is soon replaced by lingering over thoughts, and eventually the whole process, together with all its peculiarities, is transferred into the new sphere, just as in America an entire house will sometimes be shifted from one site to another.

[1909d, 2191]

But even if the historical material at our disposal were very abundant, and if the psychical mechanisms could be dealt with with the greatest assurance, there are two important points at which a psycho-analytic enquiry would not be able to make us understand how inevitable it was that the person concerned should have turned out in the way he did and in no other way. In Leonardo's case we have had to maintain the view that the accident of his illegitimate birth and the excessive tenderness of his mother had the most decisive influence on the formation of his character and on his later fortune, since the sexual repression which set in after this phase of childhood caused him to sublimate his libido into the urge to know, and established his sexual inactivity for the whole of his later life. But this repression after the first erotic satisfactions of childhood need not necessarily have taken place; in someone else it might perhaps not have taken place or might have assumed much less extensive proportions. We must recognize here a degree of freedom which cannot be resolved any further by psycho-analytic means. Equally, one has no right to claim that the consequence of this wave of repression was the only possible one. It is probable that another person would not have succeeded in withdrawing the major portion of his libido from repression by sublimating it into a craving for knowledge; under the same influences he would have sustained a permanent injury to his intellectual activity or have acquired an insurmountable disposition to obsessional neurosis. We are left, then, with these two characteristics of Leonardo which are inexplicable by the efforts of psycho-analysis: his quite special tendency towards instinctual repressions, and his extraordinary capacity for sublimating the primitive instincts.

[1910c, 2303]
(d) Our hypothesis of a pregenital sexual organization is incomplete in two respects. In the first place, it takes no account of the behaviour of other component instincts, in regard to which there is plenty that would repay examination and discussion, and it is content with stressing the striking primacy of sadism and anal erotism. In particular we often gain an impression that the instinct for knowledge can actually take the place of sadism in the mechanism of obsessional neurosis. Indeed it is at bottom a sublimated off-shoot of the instinct of mastery exalted into something intellectual, and its repudiation in the form of doubt plays a large part in the picture of obsessional neurosis. [1913i, 2630]
I will postpone until later in this paper a more thorough-going discussion of the question whether we are to regard the sexual experiences of childhood as the causes of hysteria (and obsessional neurosis), and I will now return to the form taken by the theory in some of my shorter preliminary publications during the years 1895 and 1896 (Freud, 1896b and 1896c). By laying stress on the supposed aetiological factors it was possible at that time to draw a contrast between the common neuroses as disorders with a contemporary aetiology and psychoneuroses whose aetiology was chiefly to be looked for in the sexual experiences of the remote past. The theory culminated in this thesis: if the vita sexualis is normal, there can be no neurosis.

[1906a, 1577]

At the next session the patient showed great interest in what I had said, but ventured, so he told me, to bring forward a few doubts. - How, he asked, could the information that the self-reproach, the sense of guilt, was justified have a therapeutic effect? - I explained that it was not the information that had this effect, but the discovery of the unknown content to which the self-reproach was really attached. - Yes, he said, that was the precise point to which his question had been directed. - I then made some short observations upon the psychological differences between the conscious and the unconscious, and upon the fact that everything conscious was subject to a process of wearing-away, while what was unconscious was relatively unchangeable, and I illustrated my remarks by pointing to the antiques standing about in my room. They were, in fact, I said, only objects found in a tomb, and their burial had been their preservation: the destruction of Pompeii was only beginning now that it had been dug up. - Was there any guarantee, he next enquired, of what one's attitude would be towards what was discovered? One man, he thought, would no doubt behave in such a way as to get the better of his self-reproach, but another would not. - No, I said, it followed from the nature of the circumstances that in every case the affect would be overcome - for the most part during the progress of the work itself. Every effort was made to preserve Pompeii, whereas people were anxious to be rid of tormenting ideas like his. - He had said to himself, he went on, that a self-reproach could only arise from a breach of a person's own inner moral principles and not from that of any external ones. - I agreed, and said that the man who merely breaks an external law often regards himself as a hero. - Such an occurrence, he continued, was thus only possible where a disintegration of the personality was already present. Was there a possibility of his effecting a reintegration of his personality? If this could be done, he thought he would be able to make a success of his life, perhaps more of one than most people. - I replied that I was in complete agreement with this notion of a splitting of his personality. He had only to assimilate this new contrast, between a moral self and an evil one, with the contrast I had already mentioned, between the conscious and the unconscious. The moral self was the conscious, the evil self was the unconscious.¹ - He then said that, though he considered himself a moral person, he could quite definitely remember having done things in his childhood which came from his other self. - I remarked that here he had incidentally hit upon one of the chief characteristics of the unconscious, namely, its relation to the infantile. The unconscious, I explained, was the infantile; it was that part of the self which had become separated off from it in infancy, which had not shared the later stages of its development, and which had in consequence become repressed. It was the derivatives of this repressed unconscious that were responsible for the involuntary thoughts which constituted his illness. He might now, I added, discover yet another characteristic of the unconscious; it was a discovery which I should be glad to let him make for himself. - He found nothing more to say in this immediate connection, but instead he expressed a doubt whether it was possible to undo modifications of such long standing. What, in particular, could be done against his idea about the next world, for it could not be refuted by logic? - I told him I did not dispute the gravity of his case nor the significance of his pathological constructions; but at the same time his youth was very much in his favour as well as the intactness of his personality. In this connection I said a word or two upon the good opinion I had formed of him, and this gave him visible pleasure.

[1909d, 2143]
He then went on to say that he would like to speak of a criminal act, whose author he did not recognize as himself, though he quite clearly recollected committing it. He quoted a saying of Nietzsche's:² "I did this," says my Memory. "I cannot have done this," says my Pride and remains inexorable. In the end - Memory yields. 'Well,' he continued, 'my memory has not yielded on this point.' - 'That is because you derive pleasure from your self-reproaches as a means of self-punishment.' - 'My younger brother - I am really very fond of him now, and he is causing me a great deal of worry just at present, for he wants to make what I consider a preposterous match; I have thought before now of going and killing the person concerned so as to prevent his marrying her - well, my younger brother and I used to fight a lot when we were children. We were very fond of each other at the same time, and were inseparable; but I was plainly filled with jealousy, as he was the stronger and better-looking of the two and consequently the favourite.' - 'Yes. You have already given me a description of a scene of jealousy in connection with Fräulein Lina.' - 'Very well then, on some such occasion (it was certainly before I was eight years old, for I was not going to school yet, which I began to do when I was eight) - on some such occasion, this is what I did. We both had toy guns of the usual make. I loaded mine with the ram rod and told him that if he looked up the barrel he would see something. Then, while he was looking in, I pulled the trigger. He was hit on the forehead and not hurt; but I had meant to hurt him very much indeed. Afterwards I was quite beside myself, and threw myself on the ground and asked myself however I could have done such a thing. But I did do it.' - I took the opportunity of urging my case. If he had preserved the recollection of an action so foreign to him as this, he could not, I maintained, deny the possibility of something similar, which he had now forgotten entirely, having happened at a still earlier age in relation to his father. - He then told me he was aware of having felt other vindictive impulses, this time towards the lady he admired so much, of whose character he painted a glowing picture. It might be true, he said, that she could not love easily; but she was reserving her whole self for the one man to whom she would some day belong. She did not love him. When he had become certain of that, a conscious phantasy had taken shape in his mind of how he should grow very rich and marry some one else, and should then take her to call on the lady in order to hurt her feelings. But at that point the phantasy had broken down, for he had been obliged to own to himself that the other woman, his wife, was completely indifferent to him; then his thoughts had become confused, till finally it had been clearly borne in upon him that this other woman would have to die. In this phantasy, just as in his attempt upon his brother, he recognized the quality of cowardice which was so particularly horrible to him.³ - In the further course of our conversation I pointed out to him that he ought logically to consider himself as in no way responsible for any of these traits in his character; for all of these reprehensible impulses originated from his infancy, and were only derivatives of his infantile character surviving in his unconscious; and he must know that moral responsibility could not be applied to children. It was only by a process of development, I added, that a man, with his moral responsibility, grew up out of the sum of his infantile predispositions.⁴ He expressed a doubt, however, whether all his evil impulses had originated from that source. But I promised to prove it to him in the course of the treatment.

[1909d, 2146]

From the precipitating cause of the patient's illness in his adult years there was a thread leading back to his childhood. He had found himself in a situation similar to that in which, as he knew or suspected, his father had been before his marriage; and he had thus been able to identify himself with his father. But his dead father was involved in his recent attack in yet another way. The conflict at the root of his illness was in essentials a struggle between the persisting influence of his father's wishes and his own amatory predilections. If we take into consideration what the patient reported in the course of the first hours of his treatment, we shall not be able to avoid a suspicion that this struggle was a very ancient one and had arisen as far back as in his childhood.

[1909d, 2158]
It was only then that it became possible to understand the inexplicable process by which his obsessional idea had been formed. With the assistance of our knowledge of infantile sexual theories and of symbolism (as learnt from the interpretation of dreams) the whole thing could be translated and given a meaning. When, at the afternoon halt (during which he had lost his pince-nez), the captain had told him about the rat punishment, the patient had only been struck at first by the combined cruelty and lasciviousness of the situation depicted. But immediately afterwards a connection had been set up with the scene from his childhood in which he himself had bitten some one. The captain - a man who could defend such punishments - had become a substitute for his father, and had thus drawn down upon himself a part of the reviving animosity which had burst out, on the original occasion, against his cruel father. The idea which came into his consciousness for a moment, to the effect that something of the sort might happen to some one he was fond of, is probably to be translated into a wish such as 'You ought to have the same thing done to you!' aimed at the teller of the story, but through him at his father. A day and a half later,¹ when the captain had handed him the packet upon which the charges were due and had requested him to pay back the 3.80 kronen to Lieutenant A., he had already been aware that his 'cruel superior' was making a mistake, and that the only person he owed anything to was the young lady at the post office. It might easily, therefore, have occurred to him to think of some derisive reply, such as, 'Will I, though?' or 'Pay your grandmother!' or 'Yes! You bet I'll pay him back the money!' - answers which would have been subject to no compulsive force. But instead, out of the stirrings of his father-complex and out of his memory of the scene from his childhood, there formed in his mind some such answer as: 'Yes! I'll pay back the money to A. when my father and the lady have children!' or 'As sure as my father and the lady can have children, I'll pay him back the money!' In short, a derisive affirmation attached to an absurd condition which could never be fulfilled.²

The other conflict, that between love and hatred, strikes us more strangely. We know that incipient love is often perceived as hatred, and that love, if it is denied satisfaction, may easily be partly converted into hatred, and poets tell us that in the more tempestuous stages of love the two opposed feelings may subsist side by side for a while as though in rivalry with each other. But the chronic co-existence of love and hatred, both directed towards the same person and both of the highest degree of intensity, cannot fail to astonish us. We should have expected that the passionate love would long ago have conquered the hatred or been devoured by it. And in fact such a protracted survival of two opposites is only possible under quite peculiar psychological conditions and with the co-operation of the state of affairs in the unconscious. The love has not succeeded in extinguishing the hatred but only in driving it down into the unconscious; and in the unconscious the hatred, safe from the danger of being destroyed by the operations of consciousness, is able to persist and even to grow. In such circumstances the conscious love attains as a rule, by way of reaction, an especially high degree of intensity, so as to be strong enough for the perpetual task of keeping its opponent under repression. The necessary condition for the occurrence of such a strange state of affairs in a person's erotic life appears to be that at a very early age, somewhere in the prehistoric period of his infancy, the two opposites should have been split apart and one of them, usually the hatred, have been repressed.¹

¹ [1909d, 2169]
² [1909d, 2186]
In bringing this paper to a close I may express a hope that, though my communication is incomplete in every sense, it may at least stimulate other workers to throw more light upon the obsessional neurosis by a deeper investigation of the subject. What is characteristic of this neurosis - what differentiates it from hysteria - is not, in my opinion, to be found in instinctual life but in the psychological field. I cannot take leave of my patient without putting on paper my impression that he had, as it were, disintegrated into three personalities: into one unconscious personality, that is to say, and into two preconscious ones between which his consciousness could oscillate. His unconscious comprised those of his impulses which had been suppressed at an early age and which might be described as passionate and evil impulses. In his normal state he was kind, cheerful, and sensible - an enlightened and superior kind of person - while in his third psychological organization he paid homage to superstition and asceticism. Thus he was able to have two different creeds and two different outlooks upon life. This second preconscious personality comprised chiefly the reaction-formations against his repressed wishes, and it was easy to foresee that it would have swallowed up the normal personality if the illness had lasted much longer. I have at present an opportunity of studying a lady suffering severely from obsessional acts. She has become similarly disintegrated into an easy-going and lively personality and into an exceedingly gloomy and ascetic one. She puts forward the first of them as her official ego, while in fact she is dominated by the second. Both of these psychical organizations have access to her consciousness, but behind her ascetic personality may be discerned the unconscious part of her being - quite unknown to her and composed of ancient and long-repressed wishful impulses.¹

[1909d, 2194]

But even if the historical material at our disposal were very abundant, and if the psychical mechanisms could be dealt with with the greatest assurance, there are two important points at which a psycho-analytic enquiry would not be able to make us understand how inevitable it was that the person concerned should have turned out in the way he did and in no other way. In Leonardo's case we have had to maintain the view that the accident of his illegitimate birth and the excessive tenderness of his mother had the most decisive influence on the formation of his character and on his later fortune, since the sexual repression which set in after this phase of childhood caused him to sublimate his libido into the urge to know, and established his sexual inactivity for the whole of his later life. But this repression after the first erotic satisfactions of childhood need not necessarily have taken place; in someone else it might perhaps not have taken place or might have assumed much less extensive proportions. We must recognize here a degree of freedom which cannot be resolved any further by psycho-analytic means. Equally, one has no right to claim that the consequence of this wave of repression was the only possible one. It is probable that another person would not have succeeded in withdrawing the major portion of his libido from repression by sublimating it into a craving for knowledge; under the same influences he would have sustained a permanent injury to his intellectual activity or have acquired an insurmountable disposition to obsessional neurosis. We are left, then, with these two characteristics of Leonardo which are inexplicable by the efforts of psycho-analysis: his quite special tendency towards instinctual repressions, and his extraordinary capacity for sublimating the primitive instincts.

[1910c, 2303]
Here we are faced by a decision which is indeed no easy one. First, however, it must be confessed that the distinction, which may seem fundamental to other people, does not in our judgement affect the heart of the matter. If wishes and impulses have the full value of facts for primitive men, it is our business to give their attitude our understanding attention instead of correcting it in accordance with our own standards. Let us, then, examine more closely the case of neurosis - comparison with which led us into our present uncertainty. It is not accurate to say that obsessional neurotics, weighed down under the burden of an excessive morality, are defending themselves only against psychical reality and are punishing themselves for impulses which were merely felt. Historical reality has a share in the matter as well. In their childhood they had these evil impulses pure and simple, and turned them into acts so far as the impotence of childhood allowed. Each of these excessively virtuous individuals passed though an evil period in his infancy - a phase of perversion which was the forerunner and precondition of the later period of excessive morality. The analogy between primitive men and neurotics will therefore be far more fully established if we suppose that in the former instance, too, psychical reality - as to the form taken by which we are in no doubt - coincided at the beginning with factual reality: that primitive men actually did what all the evidence shows that they intended to do.

[1912-1913, 2799]

It has long since become common knowledge that the experiences of a person's first five years exercise a determining effect on his life, which nothing later can withstand. Much that deserves knowing might be said about the way in which these early impressions maintain themselves against any influences in more mature periods of life - but it would not be relevant here. It may, however, be less well known that the strongest compulsive influence arises from impressions which impinge upon a child at a time when we would have to regard his psychical apparatus as not yet completely receptive. The fact itself cannot be doubted; but it is so puzzling that we may make it more comprehensible by comparing it with a photographic exposure which can be developed after any interval of time and transformed into a picture. I am nevertheless glad to point out that this uncomfortable discovery of ours has been anticipated by an imaginative writer, with the boldness that is permitted to poets. E. T. A. Hoffmann used to trace back the wealth of figures that put themselves at his disposal for his creative writings to the changing images and impressions which he had experienced during a journey of some weeks in a post-chaise while he was still an infant at his mother's breast. What children have experienced at the age of two and have not understood, need never be remembered by them except in dreams; they may only come to know of it through psycho-analytic treatment. But at some later time it will break into their life with obsessional impulses, it will govern their actions, it will decide their sympathies and antipathies and will quite often determine their choice of a love-object, for which it is so frequently impossible to find a rational basis. The two points at which these facts touch upon our problem cannot be mistaken.

[1939a, 4944]
At the next session the patient showed great interest in what I had said, but ventured, so he
told me, to bring for ward a few doubts. - How, he asked, could the information that the self-
reproach, the sense of guilt, was justified have a therapeutic effect? - I explained that it was not
the information that had this effect, but the discovery of the unknown content to which the self-
reproach was really attached. - Yes, he said, that was the precise point to which his question
had been directed. - I then made some short observations upon the psychological differences
between the conscious and the unconscious, and upon the fact that everything conscious was
subject to a process of wearing-away, while what was unconscious was relatively
unchangeable; and I illustrated my remarks by pointing to the antiques standing about in my
room. They were, in fact, I said, only objects found in a tomb, and their burial had been their
preservation: the destruction of Pompeii was only beginning now that it had been dug up. - Was
there any guarantee, he next enquired, of what one’s attitude would be towards what was
discovered? One man, he thought, would no doubt behave in such a way as to get the better of
his self-reproach, but another would not. - No, I said, it followed from the nature of the
circumstances that in every case the affect would be overcome - for the most part during the
progress of the work itself. Every effort was made to preserve Pompeii, whereas people were
anxious to be rid of tormenting ideas like his. - He had said to himself, he went on, that a self-
reproach could only arise from a breach of a person’s own inner moral principles and not from
that of any external ones. - I agreed, and said that the man who merely breaks an external law
often regards himself as a hero. - Such an occurrence, he continued, was thus only possible
where a disintegration of the personality was already present. Was there a possibility of his
effecting a reintegration of his personality? If this could be done, he thought he would be able to
make a success of his life, perhaps more of one than most people. - I replied that I was in
complete agreement with this notion of a splitting of his personality. He had only to assimilate
this new contrast, between a moral self and an evil one, with the contrast I had already
mentioned, between the conscious and the unconscious. The moral self was the conscious, the
evil self was the unconscious.¹ - He then said that, though he considered himself a moral
person, he could quite definitely remember having done things in his childhood which came
from his other self. - I remarked that here he had incidentally hit upon one of the chief
characteristics of the unconscious, namely, its relation to the infantile. The unconscious, I
explained, was the infantile; it was that part of the self which had become separated off from it
in infancy, which had not shared the later stages of its development, and which had in
consequence become repressed. It was the derivatives of this repressed unconscious that were
responsible for the involuntary thoughts which constituted his illness. He might now, I added,
discover yet another characteristic of the unconscious; it was a discovery which I should be glad
to let him make for himself. - He found nothing more to say in this immediate connection, but
instead he expressed a doubt whether it was possible to undo modifications of such long
standing. What, in particular, could be done against his idea about the next world, for it could
not be refuted by logic? - I told him I did not dispute the gravity of his case nor the significance
of his pathological constructions; but at the same time his youth was very much in his favour as
well as the intactness of his personality. In this connection I said a word or two upon the good
opinion I had formed of him, and this gave him visible pleasure.
[1909d, 2143]
He then went on to say that he would like to speak of a criminal act, whose author he did not recognize as himself, though he quite clearly recollected committing it. He quoted a saying of Nietzsche's:² "I did this," says my Memory. "I cannot have done this," says my Pride and remains inexorable. In the end - Memory yields. 'Well,' he continued, 'my memory has not yielded on this point.' - 'That is because you derive pleasure from your self-reproaches as a means of self-punishment.' - 'My younger brother - I am really very fond of him now, and he is causing me a great deal of worry just at present, for he wants to make what I consider a preposterous match; I have thought before now of going and killing the person concerned so as to prevent his marrying her -well, my younger brother and I used to fight a lot when we were children. We were very fond of each other at the same time, and were inseparable; but I was plainly filled with jealousy, as he was the stronger and better-looking of the two and consequently the favourite.' - 'Yes. You have already given me a description of a scene of jealousy in connection with Fräulein Lina.' - 'Very well then, on some such occasion (it was certainly before I was eight years old, for I was not going to school yet, which I began to do when I was eight) - on some such occasion, this is what I did. We both had toy guns of the usual make. I loaded mine with the ram rod and told him that if he looked up the barrel he would see something. Then, while he was looking in, I pulled the trigger. He was hit on the forehead and not hurt; but I had meant to hurt him very much indeed. Afterwards I was quite beside myself, and threw myself on the ground and asked myself however I could have done such a thing. But I did do it.' - I took the opportunity of urging my case. If he had preserved the recollection of an action so foreign to him as this, he could not, I maintained, deny the possibility of something similar, which he had now forgotten entirely, having happened at a still earlier age in relation to his father. - He then told me he was aware of having felt other vindictive impulses, this time towards the lady he admired so much, of whose character he painted a glowing picture. It might be true, he said, that she could not love easily; but she was reserving her whole self for the one man to whom she would some day belong. She did not love him. When he had become certain of that, a conscious phantasy had taken shape in his mind of how he should grow very rich and marry some one else, and should then take her to call on the lady in order to hurt her feelings. But at that point the phantasy had broken down, for he had been obliged to own to himself that the other woman, his wife, was completely indifferent to him; then his thoughts had become confused, till finally it had been clearly borne in upon him that this other woman would have to die. In this phantasy, just as in his attempt upon his brother, he recognized the quality of cowardice which was so particularly horrible to him.³ - In the further course of our conversation I pointed out to him that he ought logically to consider himself as in no way responsible for any of these traits in his character; for all of these reprehensible impulses originated from his infancy, and were only derivatives of his infantile character surviving in his unconscious; and he must know that moral responsibility could not be applied to children. It was only by a process of development, I added, that a man, with his moral responsibility, grew up out of the sum of his infantile predispositions.⁴ He expressed a doubt, however, whether all his evil impulses had originated from that source. But I promised to prove it to him in the course of the treatment.

[1909d, 2146]
In hysteria it is the rule that the precipitating causes of the illness are overtaken by amnesia no less than the infantile experiences by whose help the precipitating causes are able to transform their affective energy into symptoms. And where the amnesia cannot be complete, it nevertheless subjects the recent traumatic precipitating cause to a process of erosion and robs it at least of its most important components. In this amnesia we see the evidence of the repression which has taken place. The case is different in obsessional neuroses. The infantile preconditions of the neurosis may be overtaken by amnesia, though this is often an incomplete one; but the immediate occasions of the illness are, on the contrary, retained in the memory. Repression makes use of another, and in reality a simpler, mechanism. The trauma, instead of being forgotten, is deprived of its affective catheexis; so that what remains in consciousness is nothing but its ideational content, which is perfectly colourless and is judged to be unimportant. The distinction between what occurs in hysteria and in an obsessional neurosis lies in the psychological processes which we can reconstruct behind the phenomena; the result is almost always the same, for the colourless mnemic content is rarely reproduced and plays no part in the patient's mental activity. In order to differentiate between the two kinds of repression we have on the surface nothing to rely upon but the patient's assurance that he has a feeling in the one case of having always known the thing and in the other of having long ago forgotten it.¹

Furthermore, by a sort of regression, preparatory acts become substituted for the final decision, thinking replaces acting, and, instead of the substitutive act, some thought preliminary to it asserts itself with all the force of compulsion. According as this regression from acting to thinking is more or less marked, a case of obsessional neurosis will exhibit the characteristics of obsessive thinking (that is, of obsessional ideas) or of obsessive acting in the narrower sense of the word. True obsessional acts such as these, however, are only made possible because they constitute a kind of reconciliation, in the shape of a compromise, between the two antagonistic impulses. For obsessional acts tend to approximate more and more - and the longer the disorder lasts the more evident does this become - to infantile sexual acts of a masturbatory character. Thus in this form of the neurosis acts of love are carried out in spite of everything, but only by the aid of a new kind of regression; for such acts no longer relate to another person, the object of love and hatred, but are auto-erotic acts such as occur in infancy.

¹ Both the desire and the prohibition relate to the child's touching his own genitals.

[1909d, 2191]
In our clinical history of a case we have insisted that the imposition of the prohibition in very early childhood is the determining point; a similar importance attaches in the subsequent developments to the mechanism of repression at the same early age. As a result of the repression which has been enforced and which involves a loss of memory - an amnesia - the motives for the prohibition (which is conscious) remain unknown; and all attempts at disposing of it by intellectual processes must fail, since they cannot find any base of attack. The prohibition owes its strength and its obsessive character precisely to its unconscious opponent, the concealed and undiminished desire - that is to say, to an internal necessity inaccessible to conscious inspection. The ease with which the prohibition can be transferred and extended reflects a process which falls in with the unconscious desire and is greatly facilitated by the psychological conditions that prevail in the unconscious. The instinctual desire is constantly shifting in order to escape from the impasse and endeavours to find substitutes - substitute objects and substitute acts - in place of the prohibited ones. In consequence of this, the prohibition itself shifts about as well, and extends to any new aims which the forbidden impulse may adopt. Any fresh advance made by the repressed libido is answered by a fresh sharpening of the prohibition. The mutual inhibition of the two conflicting forces produces a need for discharge, for reducing the prevailing tension; and to this may be attributed the reason for the performance of obsessive acts. In the case of a neurosis these are clearly compromise actions: from one point of view they are evidences of remorse, efforts at expiation, and so on, while on the other hand they are at the same time substitutive acts to compensate the instinct for what has been prohibited. It is a law of neurotic illness that these obsessive acts fall more and more under the sway of the instinct and approach nearer and nearer to the activity which was originally prohibited. [1912-1913, 2678]

One of the characteristics of this ambivalent relation which I have repeatedly stressed as fundamental - the fact that the positive current of desire is an unconscious one - opens the way to further considerations and to further possible explanations. Psychical processes in the unconscious are not in every respect identical with those with which our conscious mind is familiar; they enjoy some remarkable liberties that are forbidden to the latter. An unconscious impulse need not have arisen at the point where it makes its appearance; it may arise from some quite other region and have applied originally to quite other persons and connections; it may have reached the place at which it attracts our attention though the mechanism of 'displacement'. Owing, moreover, to the indestructibility and insusceptibility to correction which are attributes of unconscious processes, it may have survived from very early times to which it was appropriate into later times and circumstances in which its manifestations are bound to seem strange. These are no more than hints, but if they were attentively developed their importance for our understanding of the growth of civilization would become apparent. [1912-1913, 2714]
Anyone who has had the opportunity of studying the hidden mental impulses of human beings by means of psycho-analysis can also say something new about the quality of the unconscious motives that find expression in superstition. It can be recognized most clearly in neurotics suffering from obsessional thinking or obsessional states - people who are often of high intelligence - that superstition derives from suppressed hostile and cruel impulses. Superstition is in large part the expectation of trouble; and a person who has harboured frequent evil wishes against others, but has been brought up to be good and has therefore repressed such wishes into the unconscious, will be especially ready to expect punishment for his unconscious wickedness in the form of trouble threatening him from without.

[1901b, 1330]

Another impulse, which might be described as indirectly suicidal and which was of longer duration, was not so easily explicable. For its relation to the patient's experiences succeeded in concealing itself behind one of those purely external associations which are so obnoxious to our consciousness. One day while he was away on his summer holidays the idea suddenly occurred to him that he was too fat [German 'dick'] and that he must make himself slimmer. So he began getting up from table before the pudding came round and tearing along the road without a hat in the blazing heat of an August sun. Then he would dash up a mountain at the double, till, dripping with perspiration, he was forced to come to a stop. On one occasion his suicidal intentions actually emerged without any disguise from behind this mania for slimming: as he was standing on the edge of a steep precipice he suddenly received a command to jump over, which would have been certain death. Our patient could think of no explanation of this senseless obsessional behaviour until it suddenly occurred to him that at that time his lady had also been stopping at the same resort; but she had been in the company of an English cousin, who was very attentive to her and of whom the patient had been very jealous. This cousin's name was Richard, and, according to the usual practice in England, he was known as Dick. Our patient, then, had wanted to kill this Dick; he had been far more jealous of him and enraged with him than he could admit to himself, and that was why he had imposed on himself this course of slimming by way of a punishment. This obsessional impulse may seem very different from the directly suicidal command which was discussed above, but they have nevertheless one important feature in common. For they both arose as reactions to a tremendous feeling of rage, which was inaccessible to the patient's consciousness and was directed against some one who had cropped up as an interference with the course of his love.¹

[1909d, 2148]
The other compulsive commands that have been mentioned put us upon the track of this other element. His obsession for protecting can only have been a reaction - as an expression of remorse and penitence - to a contrary, that is a hostile, impulse which he must have felt towards his lady before they had their éclaircissement. His obsession for counting during the thunderstorm can be interpreted, with the help of some material which he produced, as having been a defensive measure against fears that some one was in danger of death. The analysis of the obsessions which we first considered has already warned us to regard our patient's hostile impulses as particularly violent and as being in the nature of senseless rage; and now we find that even after their reconciliation his rage against the lady continued to play a part in the formation of his obsessions. His doubting mania as to whether he had heard correctly was an expression of the doubt still lurking in his mind, whether he had really understood his lady correctly this time and whether he had been justified in taking her words as a proof of her affection for him. The doubt implied in his obsession for understanding was a doubt of her love. A battle between love and hate was ringing in the lover's breast, and the object of both these feelings was one and the same person. The battle was represented in a plastic form by his compulsive and symbolic act of removing the stone from the road along which she was to drive, and then of undoing this deed of love by replacing the stone where it had lain, so that her carriage might come to grief against it and she herself be hurt. We shall not be forming a correct judgement of this second part of the compulsive act if we take it at its face value as having merely been a critical repudiation of a pathological action. The fact that it was accompanied by a sense of compulsion betrays it as having itself been a part of the pathological action, though a part which was determined by a motive contrary to that which produced the first part.

[1909d, 2150]

The mutual antagonism between his feelings for his lady was too marked to have escaped his conscious perception entirely, although we may conclude from the obsessions in which it was manifested that he did not rightly appreciate the depth of his negative impulses. The lady had refused his first proposal, ten years earlier. Since then he had to his own knowledge passed through alternating periods, in which he either believed that he loved her intensely, or felt indifferent to her. Whenever in the course of the treatment he was faced by the necessity of taking some step which would bring him nearer the successful end of his courtship, his resistance usually began by taking the form of a conviction that after all he did not very much care for her - though this resistance, it is true, used soon to break down. Once when she was lying seriously ill in bed and he was most deeply concerned about her, there crossed his mind as he looked at her a wish that she might lie like that for ever. He explained this idea by an ingenious piece of sophistry: maintaining that he had only wished her to be permanently ill so that he might be relieved of his intolerable fear that she would have a repeated succession of attacks!¹ Now and then he used to occupy his imagination with day-dreams, which he himself recognized as 'phantasies of revenge' and felt ashamed of. Believing, for instance, that the lady set great store by the social standing of a suitor, he made up a phantasy in which she was married to a man of that kind, who was in some government office. He himself then entered the same department, and rose much more rapidly than her husband, who eventually became his subordinate. One day, his phantasy proceeded, this man committed some act of dishonesty. The lady threw herself at his feet and implored him to save her husband. He promised to do so, and informed her that it had only been for love of her that he had entered the service, because he had foreseen that such a moment would occur; and now that her husband was saved, his own mission was fulfilled and he would resign his post.

[1909d, 2153]
He produced other phantasies in which he did the lady some great service without her knowing that it was he who was doing it. In these he only recognized his affection, without sufficiently appreciating the origin and aim of his magnanimity, which was designed to repress his thirst for revenge, after the manner of Dumas' Count of Monte-Cristo. Moreover he admitted that occasionally he was overcome by quite distinct impulses to do some mischief to the lady he admired. These impulses were mostly in abeyance when she was there, and only appeared in her absence.

[1909d, 2153]

¹ It cannot be doubted that another contributory motive to this compulsive idea was a wish to know that she was powerless against his designs.
[1909d, 2153]

It was only then that it became possible to understand the inexplicable process by which his obsessional idea had been formed. With the assistance of our knowledge of infantile sexual theories and of symbolism (as learnt from the interpretation of dreams) the whole thing could be translated and given a meaning. When, at the afternoon halt (during which he had lost his pince-nez), the captain had told him about the rat punishment, the patient had only been struck at first by the combined cruelty and lasciviousness of the situation depicted. But immediately afterwards a connection had been set up with the scene from his childhood in which he himself had bitten some one. The captain - a man who could defend such punishments - had become a substitute for his father, and had thus drawn down upon himself a part of the reviving animosity which had burst out, on the original occasion, against his cruel father. The idea which came into his consciousness for a moment, to the effect that something of the sort might happen to some one he was fond of, is probably to be translated into a wish such as 'You ought to have the same thing done to you!' aimed at the teller of the story, but through him at his father. A day and a half later,¹ when the captain had handed him the packet upon which the charges were due and had requested him to pay back the 3.80 kronen to Lieutenant A., he had already been aware that his 'cruel superior' was making a mistake, and that the only person he owed anything to was the young lady at the post office. It might easily, therefore, have occurred to him to think of some derisive reply, such as, 'Will I, though?' or 'Pay your grandmother!' or 'Yes! You bet I'II pay him back the money!' - answers which would have been subject to no compulsive force. But instead, out of the stirrings of his father-complex and out of his memory of the scene from his childhood, there formed in his mind some such answer as: 'Yes! I'II pay back the money to A. when my father and the lady have children!' or 'As sure as my father and the lady can have children, I'II pay him back the money!' In short, a derisive affirmation attached to an absurd condition which could never be fulfilled.²
[1909d, 2169]
I refer to the omnipotence which he ascribed to his thoughts and feelings, and to his wishes, whether good or evil. It is, I must admit, decidedly tempting to declare that this idea was a delusion and that it oversteps the limits of obsessional neurosis. I have, however, come across the same conviction in another obsessional patient; and he was long ago restored to health and is leading a normal life. Indeed, all obsessional neurotics behave as though they shared this conviction. It will be our business to throw some light upon these patients' over-estimation of their powers. Assuming, without more ado, that this belief is a frank acknowledgement of a relic of the old megalomania of infancy, we will proceed to ask our patient for the grounds of his conviction. In reply, he adduces two experiences. When he returned for a second visit to the hydropathic establishment at which his disorder had been relieved for the first and only time, he asked to be given his old room, for its position had facilitated his relations with one of the nurses. He was told that the room was already taken and that it was occupied by an old professor. This piece of news considerably diminished his prospects of successful treatment, and he reacted to it with the unamiable thought: 'I wish he may be struck dead for it!' A fortnight later he was woken up from his sleep by the disturbing idea of a corpse; and in the morning he heard that the professor had really had a stroke, and that he had been carried up into his room at about the time he himself had woken up. The second experience related to an unmarried woman, no longer young, though with a great desire to be loved, who had paid him a great deal of attention and had once asked him point blank whether he could not love her. He had given her an evasive answer. A few days afterwards he heard that she had thrown herself out of a window. He then began to reproach himself, and said to himself that it would have been in his power to save her life by giving her his love. In this way he became convinced of the omnipotence of his love and of his hatred. Without denying the omnipotence of love we may point out that both these instances were concerned with death, and we may adopt the obvious explanation that, like other obsessional neurotics, our patient was compelled to overestimate the effects of his hostile feelings upon the external world, because a large part of their internal, mental effects escaped his conscious knowledge. His love - or rather his hatred - was in truth overpowering; it was precisely they that created the obsessional thoughts, of which he could not understand the origin and against which he strove in vain to defend himself.¹

Our patient had a quite peculiar attitude towards the question of death. He showed the deepest sympathy whenever any one died, and religiously attended the funeral; so that among his brothers and sisters he earned the nickname of 'carrion crow'. In his imagination, too, he was constantly making away with people so as to show his heartfelt sympathy for their bereaved relatives. The death of an elder sister, which took place when he was between three and four years old, played a great part in his phantasies, and was brought into intimate connection with his childish misdemeanours during the same period. We know, moreover, at what an early age thoughts about his father's death had occupied his mind, and we may regard his illness itself as a reaction to that event, for which he had felt an obsessional wish fifteen years earlier. The strange extension of his obsessional fears to the 'next world' was nothing else than a compensation for these death-wishes which he had felt against his father. It was introduced eighteen months after his father had died, at a time when there had been a revival of his sorrow at the loss, and it was designed - in defiance of reality, and in deference to the wish which had previously been showing itself in phantasies of every kind - were intended to undo the fact of his father's death. We have had occasion in several places (pp. 2173, and 2176) to translate the phrase 'in the next world' by the words 'if my father were still alive'.¹

[1909d, 2183]
But the behaviour of other obsessional neurotics does not differ greatly from that of our present patient, even though it has not been their fate to come face to face with the phenomenon of death at such an early age. Their thoughts are unceasingly occupied with other people's length of life and possibility of death; their superstitious propensities have had no other content to begin with, and have perhaps no other source whatever. But these neurotics need the help of the possibility of death chiefly in order that it may act as a solution of conflicts they have left unsolved. Their essential characteristic is that they are incapable of coming to a decision, especially in matters of love; they endeavour to postpone every decision, and, in their doubt which person they shall decide for or what measures they shall take against a person, they are obliged to choose as their model the old German courts of justice, in which the suits were usually brought to an end, before judgement had been given, by the death of the parties to the dispute. Thus in every conflict which enters their lives they are on the look out for the death of some one who is of importance to them, usually of some one they love - such as one of their parents, or a rival, or one of the objects of their love between which their inclinations are wavering. But at this point our discussion of the death-complex in obsessional neuroses touches upon the problem of the instinctual life of obsessional neurotics. And to this problem we must now turn.

[1909d, 2184]

If we wish to obtain a grasp of the psychical forces whose interplay built up this neurosis, we must turn back to what we have learnt from the patient on the subject of the precipitating causes of his falling ill as a grown-up man and as a child. He fell ill when he was in his twenties on being faced with a temptation to marry another woman instead of the one whom he had loved so long; and he avoided a decision of this conflict by postponing all the necessary preliminary actions. The means for doing this was given him by his neurosis. His hesitation between the lady he loved and the other girl can be reduced to a conflict between his father's influence and his love for his lady, or, in other words, to a conflicting choice between his father and his sexual object, such as had already subsisted (judging from his recollections and obsessional ideas) in his remote childhood. All through his life, moreover, he was unmistakably victim to a conflict between love and hatred, in regard both to his lady and to his father. His phantasies of revenge and such obsessional phenomena as his obsession for understanding and his exploit with the stone in the road bore witness to his divided feelings; and they were to a certain degree comprehensible and normal, for the lady by her original refusal and subsequently by her coolness had given him some excuse for hostility. But his relations with his father were dominated by a similar division of feeling, as we have seen from our translation of his obsessional thoughts; and his father, too, must have given him an excuse for hostility in his childhood, as indeed we have been able to establish almost beyond question. His attitude towards the lady - a compound of tenderness and hostility - came to a great extent within the scope of his conscious knowledge; at most he deceived himself over the degree and violence of his negative feelings. But his hostility towards his father, on the contrary, though he had once been acutely conscious of it, had long since vanished from his ken, and it was only in the teeth of the most violent resistance that it could be brought back into his consciousness. We may regard the repression of his infantile hatred of his father as the event which brought his whole subsequent career under the dominion of the neurosis.

[1909d, 2185]
If we consider a number of analyses of obsessional neurotics we shall find it impossible to escape the impression that a relation between love and hatred such as we have found in our present patient is among the most frequent, the most marked, and probably, therefore, the most important characteristics of obsessional neurosis. But however tempting it may be to bring the problem of the 'choice of neurosis' into connection with instinctual life, there are reasons enough for avoiding such a course. For we must remember that in every neurosis we come upon the same suppressed instincts behind the symptoms. After all, hatred, kept suppressed in the unconscious by love, plays a great part in the pathogenesis of hysteria and paranoia. We know too little of the nature of love to be able to arrive at any definite conclusion here; and, in particular, the relation between the negative factor¹ in love and the sadistic components of the libido remains completely obscure. What follows is therefore to be regarded as no more than a provisional explanation. We may suppose, then, that in the cases of unconscious hatred with which we are concerned the sadistic components of love have, from constitutional causes, been exceptionally strongly developed, and have consequently undergone a premature and all too thorough suppression, and that the neurotic phenomena we have observed arise on the one hand from conscious feelings of affection which have become exaggerated as a reaction, and on the other hand from sadism persisting in the unconscious in the form of hatred.

[1909d, 2187]

We have already mentioned the important part played by the sadistic instinctual components in the genesis of obsessional neuroses. Where the epistemophilic instinct is a preponderant feature in the constitution of an obsessional patient, brooding becomes the principal symptom of the neurosis. The thought-process itself becomes sexualized, for the sexual pleasure which is normally attached to the content of thought becomes shifted on to the act of thinking itself, and the satisfaction derived from reaching the conclusion of a line of thought is experienced as a sexual satisfaction. In the various forms of obsessional neurosis in which the epistemophilic instinct plays a part, its relation to thought-processes makes it particularly well adapted to attract the energy which is vainly endeavouring to make its way forward into action, and divert it into the sphere of thought, where there is a possibility of its obtaining pleasurable satisfaction of another sort. In this way, with the help of the epistemophilic instinct, the substitutive act may in its turn be replaced by preparatory acts of thought. But procrastination in action is soon replaced by lingering over thoughts, and eventually the whole process, together with all its peculiarities, is transferred into the new sphere, just as in America an entire house will sometimes be shifted from one site to another.

[1909d, 2191]

We are also now coming to the opinion that analytic technique must be modified in certain ways according to the nature of the disease and the dominant instinctual trends in the patient. We started out from the treatment of conversion hysteria; in anxiety hysteria (phobias) we must to some extent alter our procedure. For these patient cannot bring out the material necessary for resolving their phobia so long as they feel protected by obeying the condition which it lays down. One cannot, of course, succeed in getting them to give up their protective measures and work under the influence of anxiety from the beginning of the treatment. One must therefore help them by interpreting their unconscious to them until they can make up their minds to do without the protection of their phobia and expose themselves to a now greatly mitigated anxiety. Only after they have done so does the material become accessible, which, when it has been mastered, leads to a solution of the phobia. Other modifications of technique, which seem to me not yet ripe for discussion, will be required in the treatment of obsessional neurosis. In this connection very important questions arise, which have not hitherto been elucidated: how far the instincts which the patient is combating are to be allowed some satisfaction during the treatment, and what difference it makes whether these impulses are active (sadistic) or passive (masochistic) in their nature.

[1910d, 2310]
The content of her obsessional neurosis was a compulsion for scrupulous washing and cleanliness and extremely energetic protective measures against severe injuries which she thought other people had reason to fear from her - that is to say, reaction- formations against her own anal-erotic and sadistic impulses. Her sexual need was obliged to find expression in these shapes after her genital life had lost all its value owing to the impotence of the only man of whom there could be any question for her.

(a) The extraordinary part played by impulses of hatred and anal erotism in the symptomatology of obsessional neurosis has already struck many observers and has recently been emphasized with particular clarity by Ernest Jones (1913). This follows directly from our hypothesis if we suppose that in that neurosis the component instincts in question have once more taken over the representation of the genital instincts, whose forerunners they were in the process of development.

At this point a portion of our case history fits in, which I have so far kept back. The patient's sexual life began in her earliest childhood with beating-phantasies. After they were suppressed, an unusually long period of latency set in, during which the girl passed through a period of exalted moral growth, without any awakening of female sexual feelings. Her marriage, which took place at an early age, opened a time of normal sexual activity. This period, during which she was a happy wife, continued for a number of years, until her first great frustration brought on the hysterical neurosis. When this was followed by her genital life losing all its value, her sexual life, as I have said, returned to the infantile stage of sadism.

If we take a general survey of the relations of primitive men to their rulers, we are left with an expectation that we shall have no great difficulty in advancing from a description of them to a psycho-analytic understanding of them. Those relations are of a complex kind and not free from contradictions. Rulers are allowed great privileges, which coincide exactly with the taboo prohibitions imposed on other people. They are privileged persons: they may do or enjoy precisely what other people are forbidden by taboo. As against this freedom, however, we find that they are restricted by other taboos from which common people are exempt. Here we have a first contrast - a contradiction, almost - the fact, that is, of the same individual being both more free and more restricted. Again, they are regarded as possessing extraordinary powers of magic, so that people are afraid of coming into contact with their persons or their property, while on the other hand the most beneficial consequences are expected from that same contact. Here there seems to be another, particularly glaring, contradiction; but, as we have already seen, it is only an apparent one. Contacts originating from the king himself are healing and protective; the dangerous contacts are those effected by common men upon the king or his belongings - probably because they may hint at aggressive impulses. Yet another contradiction, and one not so easily resolved, is to be found in the fact that the ruler is believed to exercise great authority over the forces of Nature, but that he has to be most carefully protected against the threat of danger - as though his own power, which can do so much, cannot do this. The situation is made still more difficult by the fact that the ruler cannot be trusted to make use of his immense powers in the right way, that is, for the benefit of his subjects and for his own protection. Thus people distrust his and feel justified in keeping a watch on him. The etiquette of taboos to which the king's whole life is subjected serves all these protective purposes at once: his own protection from dangers and the protection of his subjects from the dangers with which he threatens them.
So far so good; but the technique of psycho-analysis allows us to go into the question further and to enter more into the details of these various impulses. If we submit the recorded facts to analysis, as though they formed part of the symptoms presented by a neurosis, our starting-point must be the excessive apprehensiveness and solicitude which is put forward as the reason for the taboo ceremonials. The occurrence of excessive solicitude of this kind is very common in neuroses, and especially in obsessional neuroses, with which our comparison is chiefly drawn. We have come to understand its origin quite clearly. It appears wherever, in addition to a predominant feeling of affection, there is also a contrary, but unconscious, current of hostility—a state of affairs which represents a typical instance of an ambivalent emotional attitude. The hostility is then shouted down, as it were, by an excessive intensification of the affection, which is expressed as solicitude and becomes compulsive, because it might otherwise be inadequate to perform its task of keeping the unconscious contrary current of feeling under repression. Every psycho-analyst knows from experience with what certainty this explanation of solicitous over-affection is found to apply even in the most unlikely circumstances—in cases, for instance, of attachments between a mother and child or between a devoted married couple. If we now apply this to the case of privileged persons, we shall realize that alongside the veneration, and indeed idolization, felt towards them, there is in the unconscious an opposing current of intense hostility; that, in fact, as we expected, we are faced by a situation of emotional ambivalence. The distrust which provides one of the unmistakable elements in kingly taboos would thus be another, more direct, expression of the same unconscious hostility. Indeed, owing to the variety of outcomes of a conflict of this kind which are reached among different peoples, we are not at a loss for examples in which the existence of this hostility is still more obviously shown. 'The savage Timmes of Sierra Leone', we learn from Frazer, 'who elect their king, reserve to themselves the right of beating him on the eve of his coronation; and they avail themselves of this constitutional privilege with such hearty goodwill that sometimes the unhappy monarch does not long survive his elevation to the throne. Hence when the leading chiefs have a spite at a man and wish to rid themselves of him, they elect him king.' Even in glaring instances like this, however, the hostility is not admitted as such, but masquerades as a ceremonial.

Here we are faced by a decision which is indeed no easy one. First, however, it must be confessed that the distinction, which may seem fundamental to other people, does not in our judgement affect the heart of the matter. If wishes and impulses have the full value of facts for primitive men, it is our business to give their attitude our understanding attention instead of correcting it in accordance with our own standards. Let us, then, examine more closely the case of neurosis—comparison with which led us into our present uncertainty. It is not accurate to say that obsessional neurotics, weighed down under the burden of an excessive morality, are defending themselves only against psychical reality and are punishing themselves for impulses which were merely felt. Historical reality has a share in the matter as well. In their childhood they had these evil impulses pure and simple, and turned them into acts so far as the impotence of childhood allowed. Each of these excessively virtuous individuals passed though an evil period in his infancy—a phase of perversion which was the forerunner and precondition of the later period of excessive morality. The analogy between primitive men and neurotics will therefore be far more fully established if we suppose that in the former instance, too, psychical reality—as to the form taken by which we are in no doubt—coincided at the beginning with factual reality: that primitive men actually did what all the evidence shows that they intended to do.
Case (c) is what is commonly termed masochism. Here, too, satisfaction follows along the path of the original sadism, the passive ego placing itself back in phantasy in its first role, which has now in fact been taken over by the extraneous subject. Whether there is, besides this, a more direct masochistic satisfaction is highly doubtful. A primary masochism, not derived from sadism in the manner I have described, seems not to be met with.¹ That it is not superfluous to assume the existence of stage (b) is to be seen from the behaviour of the sadistic instinct in obsessional neurosis. There there is a turning round upon the subject's self without an attitude of passivity towards another person: the change has only got as far as stage (b). The desire to torture has turned into self-torture and self-punishment, not into masochism. The active voice is changed, not into the passive, but into the reflexive, middle voice.

[1915c, 2965]

A totally different picture of repression is shown, once more, in the third disorder which we shall consider for the purposes of our illustration - in obsessional neurosis. Here we are at first in doubt what it is that we have to regard as the instinctual representative that is subjected to repression - whether it is a libidinal or a hostile trend. This uncertainty arises because obsessional neurosis has as its basis a regression owing to which a sadistic trend has been substituted for an affectionate one. It is this hostile impulsion against someone who is loved which is subjected to repression. The effect at an early stage of the work of repression is quite different from what it is at a later one. At first the repression is completely successful; the ideational content is rejected and the affect made to disappear. As a substitutive formation there arises an alteration in the ego in the shape of an increased conscientiousness, and this can hardly be called a symptom. Here, substitute and symptom do not coincide. From this we learn something, too, about the mechanism of repression. In this instance, as in all others, repression has brought about a withdrawal of libido; but here it has made use of reaction-formation for this purpose, by intensifying an opposite. Thus in this case the formation of a substitute has the same mechanism as repression and at bottom coincides with it, while chronologically, as well as conceptually, it is distinct from the formation of a symptom. It is very probable that the whole process is made possible by the ambivalent relationship into which the sadistic impulsion that has to be repressed has been introduced. But the repression, which was at first successful, does not hold firm; in the further course of things its failure becomes increasingly marked. The ambivalence which has enabled repression through reaction-formation to take place is also the point at which the repressed succeeds in returning. The vanished affect comes back in its transformed shape as social anxiety, moral anxiety and unlimited self-reproaches; the rejected idea is replaced by a substitute by displacement, often a displacement on to something very small or indifferent. A tendency to a complete re-establishment of the repressed idea is as a rule unmistakably present. The failure in the repression of the quantitative, affective factor brings into play the same mechanism of flight, by means of avoidance and prohibitions, as we have seen at work in the formation of hysterical phobias. The rejection of the idea from the conscious is, however, obstinately maintained, because it entails abstention from action, a motor fettering of the impulsion. Thus in obsessional neurosis the work of repression is prolonged in a sterile and interminable struggle.

[1915d, 2987]
Melancholia, therefore, borrows some of its features from mourning, and the others from the process of regression from narcissistic object-choice to narcissism. It is on the one hand, like mourning, a reaction to the real loss of a loved object; but over and above this, it is marked by a determinant which is absent in normal mourning or which, if it is present, transforms the latter into pathological mourning. The loss of a love-object is an excellent opportunity for the ambivalence in love-relationships to make itself effective and come into the open. Where there is a disposition to obsessional neurosis the conflict due to ambivalence gives a pathological cast to mourning and forces it to express itself in the form of self-reproaches to the effect that the mourner himself is to blame for the loss of the loved object, i.e. that he has willed it. These obsessional states of depression following upon the death of a loved person show us what the conflict due to ambivalence can achieve by itself when there is no regressive drawing-in of libido as well. In melancholia, the occasions which give rise to the illness extend for the most part beyond the clear case of a loss by death, and include all those situations of being slighted, neglected or disappointed, which can import opposed feelings of love and hate into the relationship or reinforce an already existing ambivalence. This conflict due to ambivalence, which sometimes arises more from real experiences, sometimes more from constitutional factors, must not be overlooked among the preconditions of melancholia. If the love for the object - a love which cannot be given up though the object itself is given up - takes refuge in narcissistic identification, then the hate comes into operation on this substitutive object, abusing it, debasing it, making it suffer and deriving sadistic satisfaction from its suffering. The self-tormenting in melancholia, which is without doubt enjoyable, signifies, just like the corresponding phenomenon in obsessional neurosis, a satisfaction of trends of sadism and hate which relate to an object, and which have been turned round upon the subject's own self in the ways we have been discussing. In both disorders the patients usually still succeed, by the circuitous path of self-punishment, in taking revenge on the original object and in tormenting their loved one through their illness, having resorted to it in order to avoid the need to express their hostility to him openly. After all, the person who has occasioned the patient's emotional disorder, and on whom his illness is centred, is usually to be found in his immediate environment. The melancholic's erotic cathexis in regard to his object has thus undergone a double vicissitude: part of it has regressed to identification, but the other part, under the influence of the conflict due to 'ambivalence, has been carried back to the stage of sadism which is nearer to that conflict.

Let us begin with the second point and try to formulate, in a few brief words, the point of view that we wish to criticize. How, in point of fact, do we imagine the process by which an individual rises to a comparatively high plane of morality? The first answer will no doubt simply be that he is virtuous and noble from birth - from the very start. We shall not consider this view any further here. A second answer will suggest that we are concerned with a developmental process, and will probably assume that the development consists in eradicating his evil human tendencies and, under the influence of education and a civilized environment, replacing them by good ones. If so, it is nevertheless surprising that evil should re-emerge with such force in anyone who has been brought up in this way.
Once we have admitted the idea of a fusion of the two classes of instincts with each other, the possibility of a - more or less complete - 'defusion' of them forces itself upon us. The sadistic component of the sexual instinct would be a classical example of a serviceable instinctual fusion; and the sadism which has made itself independent as a perversion would be typical of a defusion, though not of one carried to extremes. From this point we obtain a view of a great domain of facts which has not before been considered in this light. We perceive that for purposes of discharge the instinct of destruction is habitually brought into the service of Eros; we suspect that the epileptic fit is a product and indication of an instinctual defusion; and we come to understand that instinctual defusion and the marked emergence of the death instinct call for particular consideration among the effects of some severe neuroses - for instance, the obsessional neuroses. Making a swift generalization, we might conjecture that the essence of a regression of libido (e. g. from the genital to the sadistic-anal phase) lies in a defusion of instincts, just as, conversely, the advance from the earlier phase to the definitive genital one would be conditioned by an accession of erotic components. The question also arises whether ordinary ambivalence, which is so often unusually strong in the constitutional disposition to neurosis, should not be regarded as the product of a defusion; ambivalence, however, is such a fundamental phenomenon that it more probably represents an instinctual fusion that has not been completed.

[1923b, 3975]

The reproaches of conscience in certain forms of obsessional neurosis are as distressing and tormenting, but here the situation is less perspicuous. It is noteworthy that the obsessional neurotic, in contrast to the melancholic, never in fact takes the step of self-destruction; it is as though he were immune against the danger of suicide, and he is far better protected from it than the hysterical. We can see that what guarantees the safety of the ego is the fact that the object has been retained. In obsessional neurosis it has become possible, through a regression to the pregenital organization, for the love-impulses to transform themselves into impulses of aggression against the object. Here again the instinct of destruction has been set free and it seeks to destroy the object, or at least it appears to have that intention. These purposes have not been adopted by the ego and it struggles against them with reaction-formations and precautionary measures; they remain in the id. The super-ego, however, behaves as if the ego were responsible for them and shows at the same time by the seriousness with which it chastises these destructive intentions that they are no mere semblance evoked by regression but an actual substitution of hate for love. Helpless in both directions, the ego defends itself vainly, alike against the instigations of the murderous id and against the reproaches of the punishing conscience. It succeeds in holding in check at least the most brutal actions of both sides; the first outcome is interminable self-torment, and eventually there follows a systematic torturing of the object, in so far as it is within reach.

[1923b, 3987]

Let us again consider obsessional neurosis for a moment. The state of affairs is different here. The defusion of love into aggressiveness has not been effected by the work of the ego, but is the result of a regression which has come about in the id. But this process has extended beyond the id to the super-ego, which now increases its severity towards the innocent ego. It would seem, however, that in this case, no less than in that of melancholia, the ego, having gained control over the libido by means of identification, is punished for doing so by the super-ego through the instrumentality of the aggressiveness which was mixed with the libido.

[1923b, 3989]
The advent of puberty opens a decisive chapter in the history of an obsessional neurosis. The genital organization which has been broken off in childhood starts again with great vigour. But, as we know, the sexual development in childhood determines what direction this new start at puberty will take. Not only will the early aggressive impulses be re-awakened; but a greater or lesser proportion of the new libidinal impulses - in bad cases the whole of them - will have to follow the course prescribed for them by regression and will emerge as aggressive and destructive tendencies. In consequence of the erotic trends being disguised in this way and owing to the powerful reaction- formations in the ego, the struggle against sexuality will henceforward be carried on under the banner of ethical principles. The ego will recoil with astonishment from promptings to cruelty and violence which enter consciousness from the id, and it has no notion that in them it is combating erotic wishes, including some to which it would not otherwise have taken exception. The overstrict super-ego insists all the more strongly on the suppression of sexuality, since this has assumed such repellent forms. Thus in obsessional neurosis the conflict is aggravated in two directions: the defensive forces become more intolerant and the forces that are to be fended off become more intolerable. Both effects are due to a single factor, namely, regression of the libido.

[1926d, 4275]

But in thus endeavouring to prevent associations and connections of thought, the ego is obeying one of the oldest and most fundamental commands of obsessional neurosis, the taboo on touching. If we ask ourselves why the avoidance of touching, contact or contagion should play such a large part in this neurosis and should become the subject-matter of complicated systems, the answer is that touching and physical contact are the immediate aim of the aggressive as well as the loving object-cathexes. Eros desires contact because it strives to make the ego and the loved object one, to abolish all spatial barriers between them. But destructiveness, too, which (before the invention of long-range weapons) could only take effect at close quarters, must presuppose physical contact, a coming to grips. To 'touch' a woman has become a euphemism for using her as a sexual object. Not to 'touch' one's genitals is the phrase employed for forbidding auto-erotic satisfaction. Since obsessional neurosis begins by persecuting erotic touching and then, after regression has taken place, goes on to persecute touching in the guise of aggressiveness, it follows that nothing is so strongly proscribed in that illness as touching nor so well suited to become the central point of a system of prohibitions. But isolating is removing the possibility of contact; it is a method of withdrawing a thing from being touched in any way. And when a neurotic isolates an impression or an activity by interpolating an interval, he is letting it be understood symbolically that he will not allow his thoughts about that impression or activity to come into associative contact with other thoughts.

[1926d, 4280]
Furthermore, by a sort of regression, preparatory acts become substituted for the final decision, thinking replaces acting, and, instead of the substitutive act, some thought preliminary to it asserts itself with all the force of compulsion. According as this regression from acting to thinking is more or less marked, a case of obsessional neurosis will exhibit the characteristics of obsessive thinking (that is, of obsessional ideas) or of obsessive acting in the narrower sense of the word. True obsessional acts such as these, however, are only made possible because they constitute a kind of reconciliation, in the shape of a compromise, between the two antagonistic impulses. For obsessional acts tend to approximate more and more - and the longer the disorder lasts the more evident does this become - to infantile sexual acts of a masturbatory character. Thus in this form of the neurosis acts of love are carried out in spite of everything, but only by the aid of a new kind of regression; for such acts no longer relate to another person, the object of love and hatred, but are auto-erotic acts such as occur in infancy.

The first kind of regression, that from acting to thinking, is facilitated by another factor concerned in the production of the neurosis. The histories of obsessional patients almost invariably reveal an early development and premature repression of the sexual instinct of looking and knowing; and, as we know, a part of the infantile sexual activity of our present patient was governed by that instinct.¹

The content of her obsessional neurosis was a compulsion for scrupulous washing and cleanliness and extremely energetic protective measures against severe injuries which she thought other people had reason to fear from her - that is to say, reaction-formations against her own anal-erotic and sadistic impulses. Her sexual need was obliged to find expression in these shapes after her genital life had lost all its value owing to the impotence of the only man of whom there could be any question for her.

At this point a portion of our case history fits in, which I have so far kept back. The patient's sexual life began in her earliest childhood with beating-phantasies. After they were suppressed, an unusually long period of latency set in, during which the girl passed through a period of exalted moral growth, without any awakening of female sexual feelings. Her marriage, which took place at an early age, opened a time of normal sexual activity. This period, during which she was a happy wife, continued for a number of years, until her first great frustration brought on the hysterical neurosis. When this was followed by her genital life losing all its value, her sexual life, as I have said, returned to the infantile stage of sadism.

It is not difficult to determine the characteristic which distinguishes this case of obsessional neurosis from those more frequent ones which start at an early age and thereafter run a chronic course with exacerbations of a more or less striking kind. In these other cases, once the sexual organization which contains the disposition to obsessional neurosis is established it is never afterwards completely surmounted; in our case it was replaced to begin with by the higher stage of development, and was then re-activated by regression from the latter.
But it is precisely in the field of character-development that we come across a good analogy with the case we have been describing - a confirmation, that is, of the occurrence of the pregenital sadistic anal-erotic sexual organization. It is a well-known fact, and one that has given much ground for complaint, that after women have lost their genital function their character often undergoes a peculiar alteration. They become quarrelsome, vexatious and overbearing, petty and stingy; that is to say, they exhibit typically sadistic and anal-erotic traits which they did not possess earlier, during their period of womanliness. Writers of comedy and satirists have in all ages directed their invectives against the 'old dragon' into which the charming girl, the loving wife and the tender mother have been transformed. We can see that this alteration of character corresponds to a regression of sexual life to the pregenital sadistic and anal-erotic stage, in which we have discovered the disposition to obsessional neurosis. It seems, then, to be not only the precursor of the genital phase but often enough its successor as well, its termination after the genitals have fulfilled their function.

[1913i, 2629]

A comparison between such a change of character and obsessional neurosis is very impressive. In both cases the work of regression is apparent. But whereas in the former we find complete regression following repression (or suppression) that has occurred smoothly, in the neurosis there are conflict, an effort to prevent regression from occurring, reaction-formations against it and symptom-formations produced by compromises between the two opposing sides, and a splitting of the psychical activities into some that are admissible to consciousness and others that are unconscious.

[1913i, 2629]
A totally different picture of repression is shown, once more, in the third disorder which we shall consider for the purposes of our illustration - in obsessional neurosis. Here we are at first in doubt what it is that we have to regard as the instinctual representative that is subjected to repression - whether it is a libidinal or a hostile trend. This uncertainty arises because obsessional neurosis has as its basis a regression owing to which a sadistic trend has been substituted for an affectionate one. It is this hostile impulsion against someone who is loved which is subjected to repression. The effect at an early stage of the work of repression is quite different from what it is at a later one. At first the repression is completely successful; the ideational content is rejected and the affect made to disappear. As a substitutive formation there arises an alteration in the ego in the shape of an increased conscientiousness, and this can hardly be called a symptom. Here, substitute and symptom do not coincide. From this we learn something, too, about the mechanism of repression. In this instance, as in all others, repression has brought about a withdrawal of libido; but here it has made use of reaction-formation for this purpose, by intensifying an opposite. Thus in this case the formation of a substitute has the same mechanism as repression and at bottom coincides with it, while conceptually, as well as conceptually, it is distinct from the formation of a symptom. It is very probable that the whole process is made possible by the ambivalent relationship into which the sadistic impulsion that has to be repressed has been introduced. But the repression, which was at first successful, does not hold firm; in the further course of things its failure becomes increasingly marked. The ambivalence which has enabled repression through reaction-formation to take place is also the point at which the repressed succeeds in returning. The vanished affect comes back in its transformed shape as social anxiety, moral anxiety and unlimited self-reproaches; the rejected idea is replaced by a substitute by displacement, often a displacement on to something very small or indifferent. A tendency to a complete re-establishment of the repressed idea is as a rule unmistakably present. The failure in the repression of the quantitative, affective factor brings into play the same mechanism of flight, by means of avoidance and prohibitions, as we have seen at work in the formation of hysterical phobias. The rejection of the idea from the conscious is, however, obstinately maintained, because it entails abstention from action, a motor fettering of the impulsion. Thus in obsessional neurosis the work of repression is prolonged in a sterile and interminable struggle.

[1915d, 2987]

It will help to explain this more than usually absurd symptom if I mention that the patient, who was a man of fully developed intellect and high moral ideals, manifested a very lively anal erotism in the most various ways until after his tenth year. After this had been got over, his sexual life was once again forced back to the preliminary anal stage by his later struggle against genital erotism. He loved and respected his father greatly, and also feared him not a little; judged by his own high standards in regard to asceticism and the suppression of the instincts, however, his father seemed to him a person who stood for debauchery and the pursuit of enjoyment in material things.

[1916b, 3120]
In obsessional neurosis, on the contrary, it is the regression of the libido to the preliminary stage of the sadistic-anal organization that is the most striking fact and the one which is decisive for what is manifested in symptoms. The love-impulse is obliged, when this has happened, to disguise itself as a sadistic impulse. The obsessional idea 'I should like to kill you', when it has been freed from certain additions which are not a matter of chance but are indispensable, means at bottom nothing other than 'I should like to enjoy you in love'. If you consider further that there has been a simultaneous regression in regard to the object, so that these impulses apply only to those who are nearest and dearest to the patient, you can form some idea of the horror which these obsessions arouse in him and at the same time of the alien appearance which they present to his conscious perception. But repression, too, plays a great part in the mechanism of these neuroses, though in a cursory introduction like ours this is not easily demonstrated. A regression of the libido without repression would never produce a neurosis but would lead to a perversion. From this you can see that repression is the process which is most peculiar to neuroses and is most characteristic of them. Perhaps I may have an opportunity later of telling you what we know of the mechanism of the perversions, and you will see that in their case too things are not so simple as we should be glad to make them out.

[1916-1917, 3407]

One of the patient's pieces of information will make it easier for us to understand the alteration in his character which appeared during his parents' absence as a somewhat indirect consequence of his seduction. He said that he gave up masturbating very soon after his Nanya's refusal and threat. His sexual life, therefore, which was beginning to come under the sway of the genital zone, gave way before an external obstacle, and was thrown back by its influence into an earlier phase of pregenital organization. As a result of the suppression of his masturbation, the boy's sexual life took on a sadistic-anal character. He became irritable and a tormentor, and gratified himself in this way at the expense of animals and humans. His principal object was his beloved Nanya, and he knew how to torment her till she burst into tears. In this way he revenged himself on her for the refusal he had met with, and at the same time gratified his sexual lust in the form which corresponded to his present regressive phase. He began to be cruel to small animals, to catch flies and pull off their wings, to crush beetles underfoot; in his imagination he liked beating large animals (horses) as well. All of these, then, were active and sadistic proceedings; we shall discuss his anal impulses at this period in a later connection.

[1918b, 3516]
We shall be in a better position to understand these ruminations if we return to a piece of his sexual development which we have already mentioned. We know that, after the rebuff from his Nanya and the consequent suppression of the beginnings of genital activity, his sexual life developed in the direction of sadism and masochism. He tormented and ill-treated small animals, imagined himself beating horses, and on the other hand imagined the heir to the throne being beaten.¹ In his sadism he maintained his ancient identification with his father; but in his masochism he chose him as a sexual object. He was deep in a phase of the pregenital organization which I regard as the predisposition to obsessional neurosis. The operation of the dream, which brought him under the influence of the primal scene, could have led him to make the advance to the genital organization, and to transform his masochism towards his father into a feminine attitude towards him - into homosexuality. But the dream did not bring about this advance; it ended in a state of anxiety. His relation to his father might have been expected to proceed from the sexual aim of being beaten by him to the next aim, namely, that of being copulated with by him like a woman; but in fact, owing to the opposition of his narcissistic masculinity, this relation was thrown back to an even more primitive stage. It was displaced on to a father-surrogate, and at the same time split off in the shape of a fear of being eaten by the wolf. But this by no means disposed of it. On the contrary, we can only do justice to the apparent complexity of the state of affairs by bearing firmly in mind the co-existence of the three sexual trends which were directed by the boy towards his father. From the time of the dream onwards, in his unconscious he was homosexual, and in his neurosis he was at the level of cannibalism; while the earlier masochistic attitude remained the dominant one. All three currents had passive sexual aims; there was the same object, and the same sexual impulse, but that impulse had become split up along three different levels.

[1918b, 3548]

Thus the interest in faeces is continued partly as interest in money, partly as a wish for a baby, in which latter an anal-erotic and a genital impulse ('envy for a penis') converge. But the penis has another anal-erotic significance apart from its relation to the interest in a baby. The relationship between the penis and the passage lined with mucous membrane which it fills and excites already has its prototype in the pregenital, anal-sadistic phase. The faecal mass, or as one patient called it, the faecal 'stick', represents as it were the first penis, and the stimulated mucous membrane of the rectum represents that of the vagina. There are people whose anal erotism remains vigorous and unmodified up to the age preceding puberty (ten to twelve years); we learn from them that during the pregenital phase they had already developed in phantasy and in perverse play an organization analogous to the genital one, in which penis and vagina were represented by the faecal stick and the rectum. In other people - obsessional neurotics - we can observe the result of a regressive debasement of the genital organization. This is expressed in the fact that every phantasy originally conceived on the genital level is transposed to the anal level - the penis being replaced by the faecal mass and the vagina by the rectum.

[1917c, 3603]
The reproaches of conscience in certain forms of obsessional neurosis are as distressing and tormenting, but here the situation is less perspicuous. It is noteworthy that the obsessional neurotic, in contrast to the melancholic, never in fact takes the step of self-destruction; it is as though he were immune against the danger of suicide, and he is far better protected from it than the hysterics. We can see that what guarantees the safety of the ego is the fact that the object has been retained. In obsessional neurosis it has become possible, through a regression to the pregenital organization, for the love-impulses to transform themselves into impulses of aggression against the object. Here again the instinct of destruction has been set free and it seeks to destroy the object, or at least it appears to have that intention. These purposes have not been adopted by the ego and it struggles against them with reaction-formations and precautionary measures; they remain in the id. The super-ego, however, behaves as if the ego were responsible for them and shows at the same time by the seriousness with which it chastises these destructive intentions that they are no mere semblance evoked by regression but an actual substitution of hate for love. Helpless in both directions, the ego defends itself vainly, alike against the instigations of the murderous id and against the reproaches of the punishing conscience. It succeeds in holding in check at least the most brutal actions of both sides; the first outcome is interminable self-torment, and eventually there follows a systematic torturing of the object, in so far as it is within reach.

Obsessional neurosis is unquestionably the most interesting and repaying subject of analytic research. But as a problem it has not yet been mastered. It must be confessed that, if we endeavour to penetrate more deeply into its nature, we still have to rely upon doubtful assumptions and unconfirmed suppositions. Obsessional neurosis originates, no doubt, in the same situation as hysteria, namely, the necessity of fending off the libidinal demands of the Oedipus complex. Indeed, every obsessional neurosis seems to have a substratum of hysterical symptoms that have been formed at a very early stage. But it is subsequently shaped along quite different lines owing to a constitutional factor. The genital organization of the libido turns out to be feeble and insufficiently resistant, so that when the ego begins its defensive efforts the first thing it succeeds in doing is to throw back the genital organization (of the phallic phase), in whole or in part, to the earlier sadistic-anal level. This fact of regression is decisive for all that follows.

Another possibility has to be considered. Perhaps regression is the result not of a constitutional factor but of a time-factor. It may be that regression is rendered possible not because the genital organization of the libido is too feeble but because the opposition of the ego begins too early, while the sadistic phase is at its height. I am not prepared to express a definite opinion on this point, but I may say that analytic observation does not speak in favour of such an assumption. It shows rather that, by the time an obsessional neurosis is entered upon, the phallic stage has already been reached. Moreover, the onset of this neurosis belongs to a later time of life than that of hysteria - to the second period of childhood, after the latency period has set in. In a woman patient whose case I was able to study and who was overtaken by this disorder at a very late date, it became clear that the determining cause of her regression and of the emergence of her obsessional neurosis was a real occurrence through which her genital life, which had up till then been intact, lost all its value.¹

¹ [1926d, 4272]
In enforcing regression, the ego scores its first success in its defensive struggle against the demands of the libido. (In this connection it is of advantage to distinguish the more general notion of 'defence' from 'repression'. Repression is only one of the mechanisms which defence makes use of.) It is perhaps in obsessional cases more than in normal or hysterical ones that we can most clearly recognize that the motive force of defence is the castration complex and that what is being fended off are the trends of the Oedipus complex. We are at present dealing with the beginning of the latency period, a period which is characterized by the dissolution of the Oedipus complex, the creation or consolidation of the super-ego and the erection of ethical and aesthetic barriers in the ego. In obsessional neuroses these processes are carried further than is normal. In addition to the destruction of the Oedipus complex a regressive degradation of the libido takes place, the super-ego becomes exceptionally severe and unkind, and the ego, in obedience to the super-ego, produces strong reaction-formations in the shape of conscientiousness, pity and cleanliness. Implacable, though not always on that account successful, severity is shown in condemning the temptation to continue early infantile masturbation, which now attaches itself to regressive (sadistic-anal) ideas but which nevertheless represents the unsubjugated part of the phallic organization. There is an inherent contradiction about this state of affairs, in which, precisely in the interests of masculinity (that is to say, from fear of castration), every activity belonging to masculinity is stopped. But here, too, obsessional neurosis is only overdoing the normal method of getting rid of the Oedipus complex. We once more find here an illustration of the truth that every exaggeration contains the seed of its own undoing. For, under the guise of obsessional acts, the masturbation that has been suppressed approaches ever more closely to satisfaction.

We can either simply accept it as a fact that in obsessional neurosis a super-ego of this severe kind emerges, or we can take the regression of the libido as the fundamental characteristic of the affection and attempt to relate the severity of the super-ego to it. And indeed the super-ego, originating as it does from the id, cannot dissociate itself from the regression and defusion of instinct which have taken place there. We cannot be surprised if it becomes harsher, unkind and more tormenting than where development has been normal.

The advent of puberty opens a decisive chapter in the history of an obsessional neurosis. The genital organization which has been broken off in childhood starts again with great vigour. But, as we know, the sexual development in childhood determines what direction this new start at puberty will take. Not only will the early aggressive impulses be re-awakened; but a greater or lesser proportion of the new libidinal impulses - in bad cases the whole of them - will have to follow the course prescribed for them by regression and will emerge as aggressive and destructive tendencies. In consequence of the erotic trends being disguised in this way and owing to the powerful reaction-formations in the ego, the struggle against sexuality will henceforward be carried on under the banner of ethical principles. The ego will recoil with astonishment from promptings to cruelty and violence which enter consciousness from the id, and it has no notion that in them it is combating erotic wishes, including some to which it would not otherwise have taken exception. The overstrict super-ego insists all the more strongly on the suppression of sexuality, since this has assumed such repellent forms. Thus in obsessional neurosis the conflict is aggravated in two directions: the defensive forces become more intolerant and the forces that are to be fended off become more intolerable. Both effects are due to a single factor, namely, regression of the libido.
A good deal of what has been said may be objected to on the ground that the unpleasant obsessive ideas are themselves quite conscious. But there is no doubt that before becoming conscious they have been though the process of repression. In most of them the actual wording of the aggressive instinctual impulse is altogether unknown to the ego, and it requires a good deal of analytic work to make it conscious. What does penetrate into consciousness is usually only a distorted substitute which is either of a vague, dream-like and indeterminate nature or so travestied as to be unrecognizable. Even where repression has not encroached upon the content of the aggressive impulse it has certainly got rid of its accompanying affective character.

As a result, the aggressiveness appears to the ego not to be an impulsion but, as the patients themselves say, merely a 'thought' which awakens no feeling. But the remarkable thing is that this is not the case. What happens is that the affect left out when the obsessional idea is perceived appears in a different place. The super-ego behaves as though repression had not occurred and as though it knew the real wording and full affective character of the aggressive impulse, and it treats the ego accordingly. The ego which, on the one hand, knows that it is innocent is obliged, on the other hand, to be aware of a sense of guilt and to carry a responsibility which it cannot account for. This state of affairs is, however, not so puzzling as it would seem at first sight. The behaviour of the super-ego is perfectly intelligible, and the contradiction in the ego merely shows that it has shut out the id by means of repression while remaining fully accessible to the influence of the super-ego.1 If it is asked why the ego does not also attempt to withdraw from the tormenting criticism of the super-ego, the answer is that it does manage to do so in a great number of instances. There are obsessional neuroses in which no sense of guilt whatever is present. In them, as far as can be seen, the ego has avoided becoming aware of it by instituting a fresh set of symptoms, penances or restrictions of a self-punishing kind. These symptoms, however, represent at the same time a satisfaction of masochistic impulses which, in their turn, have been reinforced by regression.

[1926d, 4276]
Even a purely terminological innovation ought to justify its adoption; it ought to reflect some new point of view or some extension of knowledge. The revival of the concept of defence and the restriction of that of repression takes into account a fact which has long since been known but which has received added importance owing to some new discoveries. Our first observations of repression and of the formation of symptoms were made in connection with hysteria. We found that the perceptual content of exciting experiences and the ideational content of pathogenic structures of thought were forgotten and debarred from being reproduced in memory, and we therefore concluded that the keeping away from consciousness was a main characteristic of hysterical repression. Later on, when we came to study the obsessional neuroses, we found that in that illness pathogenic occurrences are not forgotten. They remain conscious but they are 'isolated' in some way that we cannot as yet grasp, so that much the same result is obtained as in hysterical amnesia. Nevertheless the difference is great enough to justify the belief that the process by which instinctual demands are set aside in obsessional neurosis cannot be the same as in hysteria. Further investigations have shown that in obsessional neurosis a regression of the instinctual impulses to an earlier libidinal stage is brought about through the opposition of the ego, and that this regression, although it does not make repression unnecessary, clearly works in the same sense as repression. We have seen, too, that in obsessional neurosis ant cathexis, which is also presumably present in hysteria, plays a specially large part in protecting the ego by effecting a reactive alteration in it. Our attention has, moreover, been drawn to a process of 'isolation' (whose technique cannot as yet be elucidated) which finds direct symptomatic manifestation, and to a procedure, that may be called magical, of 'undoing' what has been done - a procedure about whose defensive purpose there can be no doubt, but which has no longer any resemblance to the process of 'repression'. These observations provide good enough grounds for re-introducing the old concept of defence, which can cover all these processes that have the same purpose - namely, the protection of the ego against instinctual demands - and for subsuming repression under it as a special case. The importance of this nomenclature is heightened if we consider the possibility that further investigations may show that there is an intimate connection between special forms of defence and particular illnesses, as, for instance, between repression and hysteria. In addition we may look forward to the possible discovery of yet another important correlation. It may well be that before its sharp cleavage into an ego and an id, and before the formation of a super-ego, the mental apparatus makes use of different methods of defence from those which it employs after it has reached these stages of organization.

[1926d, 4316]
Now let us go back and turn to the id. It is not so easy to guess what occurs during repression in connection with the instinctual impulse that is being fought against. The main question which our interest raises is as to what happens to the energy, to the libidinal charge, of that excitation - how is it employed? You recollect that the earlier hypothesis was that it is precisely this that is transformed by repression into anxiety. We no longer feel able to say that. The modest reply will rather be that what happens to it is probably not always the same thing. There is probably an intimate correspondence which we ought to get to know about between what is occurring at the time in the ego and in the id in connection with the repressed impulse. For since we have decided that the pleasure-unpleasure principle, which is set in action by the signal of anxiety, plays a part in repression, we must alter our expectations. That principle exercises an entirely unrestricted dominance over what happens in the id. We can rely on its bringing about quite profound changes in the instinctual impulse in question. We are prepared to find that repression will have very various consequences, more or less far-reaching. In some cases the repressed instinctual impulse may retain its libidinal cathexis, and may persist in the id unchanged, although subject to constant pressure from the ego. In other cases what seems to happen is that it is totally destroyed, while its libido is permanently diverted along other paths. I expressed the view that this is what happens when the Oedipus complex is dealt with normally - in this desirable case, therefore, being not simply repressed but destroyed in the id. Clinical experience has further shown us that in many cases, instead of the customary result of repression, a degradation of the libido takes place - a regression of the libidinal organization to an earlier stage. This can, of course, only occur in the id, and if it occurs it will be under the influence of the same conflict which was introduced by the signal of anxiety. The most striking example of this kind is provided by the obsessional neurosis, in which libidinal regression and repression operate together.

[1933a, 4698]

So far all this is trite repetition. And you must not suppose that the many things I have not mentioned this time no longer hold good. This repetition was necessary so that I might use it as the starting-point for a report on the advances in our knowledge. We can boast of having learnt much that is new, particularly about the early organizations of the libido, and of having obtained a clearer grasp of the significance of what is old; and I will give you at least a few examples to demonstrate this. Abraham showed in 1924 that two stages can be distinguished in the sadistic-anal phase. The earlier of these is dominated by the destructive trends of destroying and losing, the later one by trends friendly towards objects - those of keeping and possessing. It is in the middle of this phase, therefore, that consideration for the object makes its first appearance as a precursor of a later erotic cathexis. We are equally justified in making a similar subdivision in the first, oral phase. In the first sub-stage what is in question is only oral incorporation, there is no ambivalence at all in the relation to the object - the mother's breast. The second stage, characterized by the emergence of the biting activity, may be described as the 'oral-sadistic' one; it exhibits for the first time the phenomena of ambivalence, which become so much clearer afterwards, in the following sadistic-anal phase. The value of these new distinctions is to be seen especially if we look for the dispositional points in the development of the libido in the case of particular neuroses, such as obsessional neurosis or melancholia. You must here recall to mind what we have learnt about the connection between fixation of the libido, disposition and regression.

[1933a, 4704]
The retention of the faecal mass, which is thus carried out intentionally by the child to begin with, in order to serve, as it were, as a masturbatory stimulus upon the anal zone or to be employed in his relation to the people looking after him, is also one of the roots of the constipation which is so common among neuropaths. Further, the whole significance of the anal zone is reflected in the fact that few neurotics are to be found without their special scatological practices, ceremonies, and so on, which they carefully keep secret.¹

¹ [Footnote added 1920: Lou Andreas-Salomé (1916), in a paper which has given us a very much deeper understanding of the significance of anal erotism, has shown how the history of the first prohibition which a child comes across - the prohibition against getting pleasure from anal activity and its products - has a decisive effect on his whole development. This must be the first occasion on which the infant has a glimpse of an environment hostile to his instinctual impulses, on which he learns to separate his own entity from this alien one and on which he carries out the first 'repression' of his possibilities for pleasure. From that time on, what is 'anal' remains the symbol of everything that is to be repudiated and excluded from life. The clear-cut distinction between anal and genital processes which is later insisted upon is contradicted by the close anatomical and functional analogies and relations which hold between them. The genital apparatus remains the neighbour of the cloaca, and actually 'in the case of women is only taken from it on lease'.
[1905d, 1507]

In elucidating the effects produced by the captain's rat story we must follow the course of the analysis more closely. The patient began by producing an enormous mass of associative material, which at first, however, threw no light upon the circumstances in which the formation of his obsession had taken place. The idea of the punishment carried out by means of rats had acted as a stimulus to a number of his instincts and had called up a whole quantity of recollections; so that, in the short interval between the captain's story and his request to him to pay back the money, rats had acquired a series of symbolic meanings, to which, during the period which followed, fresh ones were continually being added. I must confess that I can only give a very incomplete account of the whole business. What the rat punishment stirred up more than anything else was his anal erotism, which had played an important part in his childhood and had been kept in activity for many years by a constant irritation due to worms. In this way rats came to have the meaning of 'money'.¹ The patient gave an indication of this connection by reacting to the word 'Ratten' ['rats'] with the association 'Raten' ['instalments']. In his obsessional deliria he had coined himself a regular rat currency. When, for instance, in reply to a question, I told him the amount of my fee for an hour's treatment, he said to himself (as I learned six months later): 'So many florins, so many rats'. Little by little he translated into this language the whole complex of money interests which centred round his father's legacy to him, that is to say, all his ideas connected with that subject were, by way of the verbal bridge 'Raten - Ratten', carried over into his obsessional life and brought under the dominion of his unconscious. Moreover, the captain's request to him to pay back the charges due upon the packet served to strengthen the money significance of rats, by way of another verbal bridge 'Spielrattle', which led back to his father's gambling debt.
[1909d, 2166]
But the patient was also familiar with the fact that rats are carriers of dangerous infectious diseases; he could therefore employ them as symbols of his dread (justifiable enough in the army) of syphilitic infection. This dread concealed all sorts of doubts as to the kind of life his father had led during his term of military service. Again, in another sense, the penis itself is a carrier of syphilitic infection; and in this way he could consider the rat as a male organ of sex. It had a further title to be so regarded; for a penis (especially a child's penis) can easily be compared to a worm, and the captain's story had been about rats burrowing in some one's anus, just as the large round-worms had in his when he was a child. Thus the penis significance of rats was based, once more, upon anal erotism. And apart from this, the rat is a dirty animal, feeding upon excrement and living in sewers.¹ It is perhaps unnecessary to point out how great an extension of the rat delirium became possible owing to this new meaning. For instance, 'So many rats, so many florins' could serve as an excellent characterization of a certain female profession which he particularly detested. On the other hand, it is certainly not a matter of indifference that the substitution of a penis for a rat in the captain's story resulted in a situation of intercourse per anum, which could not fail to be especially revolting to him when brought into connection with his father and the woman he loved. And when we consider that the same situation was reproduced in the compulsive threat which had formed in his mind after the captain had made his request, we shall be forcibly reminded of certain curses in use among the Southern Slavs.² Moreover, all of this material, and more besides, was woven into the fabric of the rat discussions behind the screen-association 'heiraten' ['to marry'].

¹ I may add that in his childhood he had been subject to strong coprophilic propensities. In this connection his anal erotism has already been noticed (p. 2166).  
² [1909d, 2193]

The content of her obsessional neurosis was a compulsion for scrupulous washing and cleanliness and extremely energetic protective measures against severe injuries which she thought other people had reason to fear from her - that is to say, reaction-formations against her own anal-erotic and sadistic impulses. Her sexual need was obliged to find expression in these shapes after her genital life had lost all its value owing to the impotence of the only man of whom there could be any question for her.  
[1913i, 2626]

(a) The extraordinary part played by impulses of hatred and anal erotism in the symptomatology of obsessional neurosis has already struck many observers and has recently been emphasized with particular clarity by Ernest Jones (1913). This follows directly from our hypothesis if we suppose that in that neurosis the component instincts in question have once more taken over the representation of the genital instincts, whose forerunners they were in the process of development.  
[1913i, 2627]
But it is precisely in the field of character-development that we come across a good analogy with the case we have been describing - a confirmation, that is, of the occurrence of the pregenital sadistic anal-erotic sexual organization. It is a well-known fact, and one that has given much ground for complaint, that after women have lost their genital function their character often undergoes a peculiar alteration. They become quarrelsome, vexatious and overbearing, petty and stingy; that is to say, they exhibit typically sadistic and anal-erotic traits which they did not possess earlier, during their period of womanliness. Writers of comedy and satirists have in all ages directed their invectives against the 'old dragon' into which the charming girl, the loving wife and the tender mother have been transformed. We can see that this alteration of character corresponds to a regression of sexual life to the pregenital sadistic and anal-erotic stage, in which we have discovered the disposition to obsessional neurosis. It seems, then, to be not only the precursor of the genital phase but often enough its successor as well, its termination after the genitals have fulfilled their function.
[1913i, 2629]

It will help to explain this more than usually absurd symptom if I mention that the patient, who was a man of fully developed intellect and high moral ideals, manifested a very lively anal erotism in the most various ways until after his tenth year. After this had been got over, his sexual life was once again forced back to the preliminary anal stage by his later struggle against genital erotism. He loved and respected his father greatly, and also feared him not a little; judged by his own high standards in regard to asceticism and the suppression of the instincts, however, his father seemed to him a person who stood for debauchery and the pursuit of enjoyment in material things.
[1916b, 3120]

We shall not be able to dismiss a second objection so easily. If you survey a fairly long series of interpretations of symptoms, you will probably start by judging that the concept of a substitutive sexual satisfaction has been stretched to its extreme limits in them. You will not fail to emphasize the fact that these symptoms offer nothing real in the way of satisfaction, that often enough they are restricted to the revival of a sensation or the representation of a phantasy derived from a sexual complex. And you will further point out that these supposed sexual satisfactions often take on a childish and discreditable form, approximate to an act of masturbation perhaps, or recall dirty kinds of naughtiness which are forbidden even to children - habits of which they have been broken. And, going on from this, you will also express surprise that we are representing as a sexual satisfaction what would rather have to be described as the satisfaction of lusts that are cruel or horrible or would even have to be called unnatural. We shall come to no agreement, Gentlemen, on this latter point till we have made a thorough investigation of the sexual life of human beings and till, in doing so, we have decided what it is that we are justified in calling 'sexual'.
[1916-1917, 3374]
Of the many symptomatic pictures in which obsessional neurosis appears, the most important turn out to be those provoked by the pressure of excessively strong sadistic sexual impulses (perverse, therefore, in their aim). The symptoms, indeed, in accordance with the structure of an obsessional neurosis, serve predominantly as a defence against these wishes or give expression to the struggle between satisfaction and defence. But satisfaction does not come off too badly either; it succeeds in roundabout ways in putting itself into effect in the patients' behaviour and is preferably directed against themselves and makes them into self-tormentors. Other forms of the neurosis, the brooding kinds, correspond to an excessive sexualization of actions which ordinarily have their place on the path to normal sexual satisfaction - an excessive sexualization of wanting to look or to touch or to explore. Here we have the explanation of the great importance of the fear of touching and of the obsession for washing. An unsuspectedly large proportion of obsessional actions may be traced back to masturbation, of which they are disguised repetitions and modifications; it is a familiar fact that masturbation, though a single and uniform action, accompanies the most various forms of sexual phantasying. [1916-1917, 3380]

One of the patient's pieces of information will make it easier for us to understand the alteration in his character which appeared during his parents' absence as a somewhat indirect consequence of his seduction. He said that he gave up masturbing very soon after his Nanya's refusal and threat. His sexual life, therefore, which was beginning to come under the sway of the genital zone, gave way before an external obstacle, and was thrown back by its influence into an earlier phase of pregenital organization. As a result of the suppression of his masturbation, the boy's sexual life took on a sadistic-anal character. He became irritable and a tormentor, and gratified himself in this way at the expense of animals and humans. His principal object was his beloved Nanya, and he knew how to torment her till she burst into tears. In this way he revenged himself on her for the refusal he had met with, and at the same time gratified his sexual lust in the form which corresponded to his present regressive phase. He began to be cruel to small animals, to catch flies and pull off their wings, to crush beetles underfoot; in his imagination he liked beating large animals (horses) as well. All of these, then, were active and sadistic proceedings; we shall discuss his anal impulses at this period in a later connection. [1918b, 3516]

No doubt was left in the analysis that these passive trends had made their appearance at the same time as the active-sadistic ones, or very soon after them.¹ This is in accordance with the unusually clear, intense, and constant ambivalence of the patient, which was shown here for the first time in the even development of both members of the pairs of contrary component instincts. Such behaviour was also characteristic of his later life, and so was this further trait: no position of the libido which had once been established was ever completely replaced by a later one. It was rather left in existence side by side with all the others, and this allowed him to maintain an incessant vacillation which proved to be incompatible with the acquisition of a stable character. [1918b, 3517]
The boy's masochistic trends lead on to another point, which I have so far avoided mentioning, because it can only be confirmed by means of the analysis of the subsequent phase of his development. I have already mentioned that after his refusal by his Nanya his libidinal expectation detached itself from her and began to contemplate another person as a sexual object. This person was his father, at that time away from home. He was no doubt led to this choice by a number of convergent factors, including such fortuitous ones as the recollection of the snake being cut to pieces; but above all he was in this way able to renew his first and most primitive object-choice, which, in conformity with a small child's narcissism, had taken place along the path of identification. We have heard already that his father had been his admired model, and that when he was asked what he wanted to be he used to reply: a gentleman like his father. This object of identification of his active current became the sexual object of a passive current in his present anal-sadistic phase. It looks as though his seduction by his sister had forced him into a passive role, and had given him a passive sexual aim. Under the persisting influence of this experience he pursued a path from his sister via his Nanya to his father - from a passive attitude towards women to the same attitude towards men - and had, nevertheless, by this means found a link with his earlier and spontaneous phase of development. His father was now his object once more; in conformity with his higher stage of development, identification was replaced by object-choice; while the transformation of his active attitude into a passive one was the consequence and the record of the seduction which had occurred meanwhile. It would naturally not have been so easy to achieve an active attitude in the sadistic phase towards his all-powerful father. When his father came home in the late summer or autumn the patient's fits of rage and scenes of fury were put to a new use. They had served for active sadistic ends in relation to his Nanya; in relation to his father their purpose was masochistic. By bringing his naughtiness forward he was trying to force punishments and beatings out of his father, and in that way to obtain from him the masochistic sexual satisfaction that he desired. His screaming fits were therefore simply attempts at seduction. In accordance, moreover, with the motives which underlie masochism, this beating would also have satisfied his sense of guilt. He had preserved a memory of how, during one of these scenes of naughtiness, he had redoubled his screams as soon as his father came towards him. His father did not beat him, however, but tried to pacify him by playing ball in front of him with the pillows of his cot.
[1918b, 3518]
The wolf that he was afraid of was undoubtedly his father; but his fear of the wolf was conditional upon the creature being in an upright posture. His recollection asserted most definitely that he had not been terrified by pictures of wolves going on all fours or, as in the story of 'Little Red Riding-Hood', lying in bed. The posture which, according to our construction of the primal scene, he had seen the woman assume, was of no less significance; though in this case the significance was limited to the sexual sphere. The most striking phenomenon of his erotic life after maturity was his liability to compulsive attacks of falling physically in love which came on and disappeared again in the most puzzling succession. These attacks released a tremendous energy in him even at times when he was otherwise inhibited, and they were quite beyond his control. I must, for a specially important reason, postpone a full consideration of this compulsive love; but I may mention here that it was subject to a definite condition, which was concealed from his consciousness and was discovered only during the treatment. It was necessary that the woman should have assumed the posture which we have ascribed to his mother in the primal scene. From his puberty he had felt large and conspicuous buttocks as the most powerful attraction in a woman; to copulate except from behind gave him scarcely any enjoyment. At this point a criticism may justly be raised: it may be objected that a sexual preference of this kind for the hind parts of the body is a general characteristic of people who are inclined to an obsessional neurosis, and that its presence does not justify us in referring it back to a special impression in childhood. It is part of the fabric of the anal-erotic disposition and is one of the archaic traits which distinguish that constitution. Indeed, copulation from behind - *more ferrarum* [in the fashion of animals] - may, after all, be regarded as phyllogenetically the older form. We shall return to this point too in a later discussion, when we have brought forward the supplementary material which showed the basis of the unconscious condition upon which his falling in love depended.

[1918b, 3531]

We shall be in a better position to understand these ruminations if we return to a piece of his sexual development which we have already mentioned. We know that, after the rebuff from his Nanya and the consequent suppression of the beginnings of genital activity, his sexual life developed in the direction of sadism and masochism. He tormented and ill-treated small animals, imagined himself beating horses, and on the other hand imagined the heir to the throne being beaten.¹ In his sadism he maintained his ancient identification with his father; but in his masochism he chose him as a sexual object. He was deep in a phase of the pregenital organization which I regard as the predisposition to obsessional neurosis. The operation of the dream, which brought him under the influence of the primal scene, could have led him to make the advance to the genital organization, and to transform his masochism towards his father into a feminine attitude towards him - into homosexuality. But the dream did not bring about this advance; it ended in a state of anxiety. His relation to his father might have been expected to proceed from the sexual aim of being beaten by him to the next aim, namely, that of being copulated with by him like a woman; but in fact, owing to the opposition of his narcissistic masculinity, this relation was thrown back to an even more primitive stage. It was displaced on to a father-surrogate, and at the same time split off in the shape of a fear of being eaten by the wolf. But this by no means disposed of it. On the contrary, we can only do justice to the apparent complexity of the state of affairs by bearing firmly in mind the co-existence of the three sexual trends which were directed by the boy towards his father. From the time of the dream onwards, in his unconscious he was homosexual, and in his neurosis he was at the level of cannibalism; while the earlier masochistic attitude remained the dominant one. All three currents had passive sexual aims; there was the same object, and the same sexual impulse, but that impulse had become split up along three different levels.

[1918b, 3548]
I must beg the reader to bear in mind that I obtained this history of an infantile neurosis as a by-product, so to speak, during the analysis of an illness in mature years. I have therefore been obliged to put it together from even smaller fragments than are usually at one's disposal for purposes of synthesis. This task, which is not difficult in other respects, finds a natural limit when it is a question of forcing a structure which is itself in many dimensions on to the two-dimensional descriptive plane. I must therefore content myself with bringing forward fragmentary portions, which the reader can then put together into a living whole. The obsessional neurosis that has been described grew up, as has been repeatedly emphasized, on the basis of a sadistic-anal constitution. But we have hitherto discussed only one of the two chief factors - the patient's sadism and its transformations. Everything that concerns his anal erotism has intentionally been left on one side so that it might be brought together and discussed at this later stage.

The origin of this obsessional neurosis on the basis of the sadistic-anal organization confirms on the whole what I have said elsewhere on the predisposition to obsessional neurosis (1913). The previous existence, however, of a severe hysteria in the present case makes it more obscure in this respect.

If the sexual component which has broken loose prematurely is the sadistic one, then we may expect, on the basis of knowledge derived from other sources, that its subsequent repression will result in a disposition to an obsessional neurosis. This expectation cannot be said to be contradicted by the results of enquiry. The present short paper is based on the exhaustive study of six cases (four female and two male). Of these, two were cases of obsessional neurosis; one extremely severe and incapacitating, the other of moderate severity and quite well accessible to influence. There was also a third case which at all events exhibited clearly marked individual traits of obsessional neurosis. The fourth case, it must be admitted, was one of straightforward hysteria, with pains and inhibitions; and the fifth patient, who had come to be analysed merely on account of indecisiveness in life, would not have been classified at all by coarse clinical diagnosis, or would have been dismissed as 'psychasthenic'. There is no need for feeling disappointed over these statistics. In the first place, we know that not every disposition is necessarily developed into a disorder; in the second place, we ought to be content to explain the facts before us, and ought as a rule to avoid the additional task of making it clear why something has not taken place.

Another possibility has to be considered. Perhaps regression is the result not of a constitutional factor but of a time-factor. It may be that regression is rendered possible not because the genital organization of the libido is too feeble but because the opposition of the ego begins too early, while the sadistic phase is at its height. I am not prepared to express a definite opinion on this point, but I may say that analytic observation does not speak in favour of such an assumption. It shows rather that, by the time an obsessional neurosis is entered upon, the phallic stage has already been reached. Moreover, the onset of this neurosis belongs to a later time of life than that of hysteria - to the second period of childhood, after the latency period has set in. In a woman patient whose case I was able to study and who was overtaken by this disorder at a very late date, it became clear that the determining cause of her regression and of the emergence of her obsessional neurosis was a real occurrence through which her genital life, which had up till then been intact, lost all its value.
The chief task during the latency period seems to be the fending-off of the temptation to masturbate. This struggle produces a series of symptoms which appear in a typical fashion in the most different individuals and which in general have the character of a ceremonial. It is a great pity that no one has as yet collected them and systematically analysed them. Being the earliest products of the neurosis they should best be able to shed light on the mechanisms employed in its symptom-formation. They already exhibit the features which will emerge so disastrously if a serious illness follows. They tend to become attached to activities (which would later be carried out almost automatically) such as going to sleep, washing, dressing and walking about; and they tend also to repetition and waste of time. Why this should be so is at present not at all clear; but the sublimation of anal-erotic components plays an unmistakable part in it. [1926d, 4275]

The advent of puberty opens a decisive chapter in the history of an obsessional neurosis. The genital organization which has been broken off in childhood starts again with great vigour. But, as we know, the sexual development in childhood determines what direction this new start at puberty will take. Not only will the early aggressive impulses be re-awakened; but a greater or lesser proportion of the new libidinal impulses - in bad cases the whole of them - will have to follow the course prescribed for them by regression and will emerge as aggressive and destructive tendencies. In consequence of the erotic trends being disguised in this way and owing to the powerful reaction-formations in the ego, the struggle against sexuality will henceforward be carried on under the banner of ethical principles. The ego will recoil with astonishment from promptings to cruelty and violence which enter consciousness from the id, and it has no notion that in them it is combating erotic wishes, including some to which it would not otherwise have taken exception. The overstrict super-ego insists all the more strongly on the suppression of sexuality, since this has assumed such repellant forms. Thus in obsessional neurosis the conflict is aggravated in two directions: the defensive forces become more intolerant and the forces that are to be fended off become more intolerable. Both effects are due to a single factor, namely, regression of the libido. [1926d, 4275]

There is another kind of anticathexis, however, which seems more suited to the peculiar character of hysteria. A repressed instinctual impulse can be activated (newly cathected) from two directions: from within, through reinforcement from its internal sources of excitation, and from without, through the perception of an object that it desires. The hysterical anticathexis is mainly directed outwards, against dangerous perceptions. It takes the form of a special kind of vigilance which, by means of restrictions of the ego, causes situations to be avoided that would entail such perceptions, or, if they do occur, manages to withdraw the subject's attention from them. Some French analysts, in particular Laforgue, have recently given this action of hysteria the special name of 'scotomization'. This technique of anticathexis is still more noticeable in the phobias, whose interest is concentrated on removing the subject ever further from the possibility of the occurrence of the feared perception. The fact that anticathexis has an opposite direction in hysteria and the phobias from what it has in obsessional neurosis - though the distinction is not an absolute one - seems to be significant. It suggests that there is an intimate connection between repression and external anticathexis on the one hand and between regression and internal anticathexis (i.e. alteration in the ego through reaction-formation) on the other. The task of defence against a dangerous perception is, incidentally, common to all neuroses. Various commands and prohibitions in obsessional neurosis have the same end in view. [1926d, 4311]
So far all this is trite repetition. And you must not suppose that the many things I have not mentioned this time no longer hold good. This repetition was necessary so that I might use it as the starting-point for a report on the advances in our knowledge. We can boast of having learnt much that is new, particularly about the early organizations of the libido, and of having obtained a clearer grasp of the significance of what is old; and I will give you at least a few examples to demonstrate this. Abraham showed in 1924 that two stages can be distinguished in the sadistic-anal phase. The earlier of these is dominated by the destructive trends of destroying and losing, the later one by trends friendly towards objects - those of keeping and possessing. It is in the middle of this phase, therefore, that consideration for the object makes its first appearance as a precursor of a later erotic cathexis. We are equally justified in making a similar subdivision in the first, oral phase. In the first sub-stage what is in question is only oral incorporation, there is no ambivalence at all in the relation to the object - the mother's breast. The second stage, characterized by the emergence of the biting activity, may be described as the 'oral-sadistic' one; it exhibits for the first time the phenomena of ambivalence, which become so much clearer afterwards, in the following sadistic-anal phase. The value of these new distinctions is to be seen especially if we look for the dispositional points in the development of the libido in the case of particular neuroses, such as obsessional neurosis or melancholia. You must here recall to mind what we have learnt about the connection between fixation of the libido, disposition and regression.

[1933a, 4704]
The other conflict, that between love and hatred, strikes us more strangely. We know that incipient love is often perceived as hatred, and that love, if it is denied satisfaction, may easily be partly converted into hatred, and poets tell us that in the more tempestuous stages of love the two opposed feelings may subsist side by side for a while as though in rivalry with each other. But the chronic co-existence of love and hatred, both directed towards the same person and both of the highest degree of intensity, cannot fail to astonish us. We should have expected that the passionate love would long ago have conquered the hatred or been devoured by it. And in fact such a protracted survival of two opposites is only possible under quite peculiar psychological conditions and with the co-operation of the state of affairs in the unconscious. The love has not succeeded in extinguishing the hatred but only in driving it down into the unconscious; and in the unconscious the hatred, safe from the danger of being destroyed by the operations of consciousness, is able to persist and even to grow. In such circumstances the conscious love attains as a rule, by way of reaction, an especially high degree of intensity, so as to be strong enough for the perpetual task of keeping its opponent under repression. The necessary condition for the occurrence of such a strange state of affairs in a person's erotic life appears to be that at a very early age, somewhere in the prehistoric period of his infancy, the two opposites should have been split apart and one of them, usually the hatred, have been repressed.¹

Once we have admitted the idea of a fusion of the two classes of instincts with each other, the possibility of a - more or less complete - 'defusion' of them forces itself upon us. The sadistic component of the sexual instinct would be a classical example of a serviceable instinctual fusion; and the sadism which has made itself independent as a perversion would be typical of a defusion, though not of one carried to extremes. From this point we obtain a view of a great domain of facts which has not before been considered in this light. We perceive that for purposes of discharge the instinct of destruction is habitually brought into the service of Eros; we suspect that the epileptic fit is a product and indication of an instinctual defusion; and we come to understand that instinctual defusion and the marked emergence of the death instinct call for particular consideration among the effects of some severe neuroses - for instance, the obsessional neuroses. Making a swift generalization, we might conjecture that the essence of a regression of libido (e. g. from the genital to the sadistic-anal phase) lies in a defusion of instincts, just as, conversely, the advance from the earlier phase to the definitive genital one would be conditioned by an accession of erotic components. The question also arises whether ordinary ambivalence, which is so often unusually strong in the constitutional disposition to neurosis, should not be regarded as the product of a defusion; ambivalence, however, is such a fundamental phenomenon that it more probably represents an instinctual fusion that has not been completed.

Let us again consider obsessional neurosis for a moment. The state of affairs is different here. The defusion of love into aggressiveness has not been effected by the work of the ego, but is the result of a regression which has come about in the id. But this process has extended beyond the id to the super-ego, which now increases its severity towards the innocent ego. It would seem, however, that in this case, no less than in that of melancholia, the ego, having gained control over the libido by means of identification, is punished for doing so by the super-ego through the instrumentality of the aggressiveness which was mixed with the libido.
In enforcing regression, the ego scores its first success in its defensive struggle against the demands of the libido. (In this connection it is of advantage to distinguish the more general notion of 'defence' from 'repression'. Repression is only one of the mechanisms which defence makes use of.) It is perhaps in obsessional cases more than in normal or hysterical ones that we can most clearly recognize that the motive force of defence is the castration complex and that what is being fended off are the trends of the Oedipus complex. We are at present dealing with the beginning of the latency period, a period which is characterized by the dissolution of the Oedipus complex, the creation or consolidation of the super-ego and the erection of ethical and aesthetic barriers in the ego. In obsessional neuroses these processes are carried further than is normal. In addition to the destruction of the Oedipus complex a regressive degradation of the libido takes place, the super-ego becomes exceptionally severe and unkind, and the ego, in obedience to the super-ego, produces strong reaction-formations in the shape of conscientiousness, pity and cleanliness. Implacable, though not always on that account successful, severity is shown in condemning the temptation to continue early infantile masturbation, which now attaches itself to regressive (sadistic-anal) ideas but which nevertheless represents the unsubjugated part of the phallic organization. There is an inherent contradiction about this state of affairs, in which, precisely in the interests of masculinity (that is to say, from fear of castration), every activity belonging to masculinity is stopped. But here, too, obsessional neurosis is only overdoing the normal method of getting rid of the Oedipus complex. We once more find here an illustration of the truth that every exaggeration contains the seed of its own undoing. For, under the guise of obsessional acts, the masturbation that has been suppressed approaches ever more closely to satisfaction.

[1926d, 4273]

We can either simply accept it as a fact that in obsessional neurosis a super-ego of this severe kind emerges, or we can take the regression of the libido as the fundamental characteristic of the affection and attempt to relate the severity of the super-ego to it. And indeed the super-ego, originating as it does from the id, cannot dissociate itself from the regression and defusion of instinct which have taken place there. We cannot be surprised if it becomes harsher, unkind, and more tormenting than where development has been normal.

[1926d, 4274]
(c) An especially prominent part is played as factors in the formation of symptoms in psychoneuroses by the component instincts, which emerge for the most part as pairs of opposites and which we have met with as introducing new sexual aims - the scopophilic instinct and exhibitionism and the active and passive forms of the instinct for cruelty. The contribution made by the last of these is essential to the understanding of the fact that symptoms involve suffering, and it almost invariably dominates a part of the patient's social behaviour. It is also through the medium of this connection between libido and cruelty that the transformation of love into hate takes place, the transformation of affectionate into hostile impulses, which is characteristic of a great number of cases of neurosis, and indeed, it would seem, of paranoia in general.

[1905d, 1491]

The other conflict, that between love and hatred, strikes us more strangely. We know that incipient love is often perceived as hatred, and that love, if it is denied satisfaction, may easily be partly converted into hatred, and poets tell us that in the more tempestuous stages of love the two opposed feelings may subsist side by side for a while as though in rivalry with each other. But the chronic co-existence of love and hatred, both directed towards the same person and both of the highest degree of intensity, cannot fail to astonish us. We should have expected that the passionate love would long ago have conquered the hatred or been devoured by it. And in fact such a protracted survival of two opposites is only possible under quite peculiar psychological conditions and with the co-operation of the state of affairs in the unconscious. The love has not succeeded in extinguishing the hatred but only in driving it down into the unconscious; and in the unconscious the hatred, safe from the danger of being destroyed by the operations of consciousness, is able to persist and even to grow. In such circumstances the conscious love attains as a rule, by way of reaction, an especially high degree of intensity, so as to be strong enough for the perpetual task of keeping its opponent under repression. The necessary condition for the occurrence of such a strange state of affairs in a person's erotic life appears to be that at a very early age, somewhere in the prehistoric period of his infancy, the two opposites should have been split apart and one of them, usually the hatred, have been repressed.¹

[1909d, 2186]

Examples of the first process are met with in the two pairs of opposites: sadism-masochism and scopophilia-exhibitionism. The reversal affects only the aims of the instincts. The active aim (to torture, to look at) is replaced by the passive aim (to be tortured, to be looked at). Reversal of content is found in the single instance of the transformation of love into hate.

[1915c, 2964]

The change of the content of an instinct into its opposite is observed in a single instance only - the transformation of love into hate. Since it is particularly common to find both these directed simultaneously towards the same object, their co-existence furnishes the most important example of ambivalence of feeling.

[1915c, 2969]

The case of love and hate acquires a special interest from the circumstance that it refuses to be fitted into our scheme of the instincts. It is impossible to doubt that there is the most intimate relation between these two opposite feelings and sexual life, but we are naturally unwilling to think of love as being some kind of special component instinct of sexuality in the same way as the others we have been discussing. We should prefer to regard loving as the expression of the whole sexual current of feeling; but this idea does not clear up our difficulties, and we cannot see what meaning to attach to an opposite content of this current.

[1915c, 2969]
Loving admits not merely of one, but of three opposites. In addition to the antithesis 'loving-hating', there is the other one of 'loving-being loved'; and, in addition to these, loving and hating taken together are the opposite of the condition of unconcern or indifference. The second of these three antitheses, loving-being loved, corresponds exactly to the transformation from activity to passivity and may be traced to an underlying situation in the same way as in the case of the scopophilic instinct. This situation is that of loving oneself which we regard as the characteristic feature of narcissism. Then, according as the object or the subject is replaced by an extraneous one, what results is the active aim of loving or the passive one of being loved - the latter remaining near to narcissism.

[1915c, 2969]

The history of the origins and relations of love makes us understand how it is that love so frequently manifests itself as 'ambivalent' - i.e. as accompanied by impulses of hate against the same object. The hate which is admixed with the love is in part derived from the preliminary stages of loving which have not been wholly surmounted; it is also in part based on reactions of repudiation by the ego-instincts, which, in view of the frequent conflicts between the interests of the ego and those of love, can find grounds in real and contemporary motives. In both cases, therefore, the admixed hate has as its source the self-preservative instincts. If a love-relation with a given object is broken off, hate not infrequently emerges in its place, so that we get the impression of a transformation of love into hate. This account of what happens leads on to the view that the hate, which has its real motives, is here reinforced by a regression of the love to the sadistic preliminary stage; so that the hate acquires an erotic character and the continuity of a love relation is ensured.

[1915c, 2974]

The reproaches of conscience in certain forms of obsessional neurosis are as distressing and tormenting, but here the situation is less perspicuous. It is noteworthy that the obsessional neurotic, in contrast to the melancholic, never in fact takes the step of self-destruction; it is as though he were immune against the danger of suicide, and he is far better protected from it than the hysteric. We can see that what guarantees the safety of the ego is the fact that the object has been retained. In obsessional neurosis it has become possible, through a regression to the pregeminal organization, for the love-impulses to transform themselves into impulses of aggression against the object. Here again the instinct of destruction has been set free and it seeks to destroy the object, or at least it appears to have that intention. These purposes have not been adopted by the ego and it struggles against them with reaction-formations and precautionary measures; they remain in the id. The super-ego, however, behaves as if the ego were responsible for them and shows at the same time by the seriousness with which it chastises these destructive intentions that they are no mere semblance evoked by regression but an actual substitution of hate for love. Helpless in both directions, the ego defends itself vainly, alike against the instigations of the murderous id and against the reproaches of the punishing conscience. It succeeds in holding in check at least the most brutal actions of both sides; the first outcome is interminable self-torment, and eventually there follows a systematic torturing of the object, in so far as it is within reach.

[1923b, 3987]
On another occasion I had an opportunity of obtaining a deep insight into the unconscious mind of a young man whose life was made almost impossible by an obsessional neurosis. He was unable to go out into the street because he was tortured by the fear that he would kill everyone he met. He spent his days in preparing his alibi in case he might be charged with one of the murders committed in the town. It is unnecessary to add that he was a man of equally high morals and education. The analysis (which, incidentally, led to his recovery) showed that the basis of this distressing obsession was an impulse to murder his somewhat over-severe father. This impulse, to his astonishment, had been consciously expressed when he was seven years old, but it had, of course, originated much earlier in his childhood. After his father's painful illness and death, the patient's obsessional self-reproaches appeared - he was in his thirty-first year at the time - taking the shape of a phobia transferred on to strangers. A person, he felt, who was capable of wanting to push his own father over a precipice from the top of a mountain was not to be trusted to respect the lives of those less closely related to him; he was quite right to shut himself up in his room.

In some instances, indeed, it is only possible to arrive at the meaning of a dream after one has carried out quite a number of reversals of its content in various respects. For instance, in the case of a young obsessional neurotic, there lay concealed behind one of his dreams the memory of a death-wish dating from his childhood and directed against his father, of whom he had been afraid. Here is the text of the dream: *His father was scolding him for coming home so late.* The context in which the dream occurred in the psycho-analytic treatment and the dreamer's associations showed, however, that the original wording must have been that he was angry with his father, and that in his view his father always came home too early (i.e. too soon). He would have preferred it if his father had not come home at all, and this was the same thing as a death-wish against his father. (See p. 733 f.) For as a small boy, during his father's temporary absence, he had been guilty of an act of sexual aggression against someone, and as a punishment had been threatened in these words: 'Just you wait till your father comes back!' For as a small boy, during his father's temporary absence, he had been guilty of an act of sexual aggression against someone, and as a punishment had been threatened in these words: 'Just you wait till your father comes back!'

Analysis made it possible to find another solution. The attempt at an explanation, which seemed so striking when I was obliged to ascribe it to the dream-work, was not an original one of my own, but was copied from the neurosis of one of my patients. I have already spoken elsewhere of a highly educated and, in real life, soft-hearted man who, shortly after the death of his parents, began to reproach himself with having murderous inclinations, and then fell a victim to the precautionary measures which he was obliged to adopt as a safeguard. It was a case of severe obsessions accompanied by complete insight. To begin with, walking through the streets was made a burden to him by a compulsion to make certain where every single person he met disappeared to; if anyone suddenly escaped his watchful eye, he was left with a distressing feeling and the idea that he might possibly have got rid of him. What lay behind this was, among other things, a 'Cain' phantasy - for 'all men are brothers.' Owing to the impossibility of carrying out this task, he gave up going for walks and spent his life incarcerated between his own four walls. But reports of murders which had been committed outside were constantly being brought into his room by the newspapers, and his conscience suggested to him, in the form of a doubt, that he might be the wanted murderer. The certainty that he had in fact not left his house for weeks protected him from these charges for a while, till one day the possibility came into his head that he might have left his house while he was in an unconscious state and have thus been able to commit the murder without knowing anything about it. From that time onwards he locked the front door of the house and gave the key to his old housekeeper with strict instructions never to let it fall into his hands even if he asked for it.
This, then, was the origin of my attempted explanation to the effect that I had changed carriages while I was in an unconscious state; it had been carried over ready-made into the dream from the material of the dream-thoughts, and was evidently intended in the dream to serve the purpose of identifying me with the figure of this patient. My recollection of him had been aroused by an easy association. My last night-journey, a few weeks earlier, had been made in the company of this very man. He was cured, and was travelling with me into the provinces to visit his relatives, who had sent for me. We had a compartment to ourselves; we left all the windows open all through the night and had a most entertaining time for as long as I stayed awake. I knew that the root of his illness had been hostile impulses against his father, dating from his childhood and involving a sexual situation. In so far, therefore, as I was identifying myself with him, I was seeking to confess to something analogous. And in fact the second scene of the dream ended in a somewhat extravagant phantasy that my two elderly travelling companions had treated me in such a stand-offish way because my arrival had prevented the affectionate exchanges which they had planned for the night. This phantasy went back, however, to a scene of early childhood in which the child, probably driven by sexual curiosity, had forced his way into his parents' bedroom and been turned out of it by his father's orders.
[1900a, 902]
If a furious raging against one's own integrity and one's own life can be hidden in this way behind apparently accidental clumsiness and motor inefficiency, it is not a very large step to find it possible to transfer the same view to mistakes that seriously endanger the lives and health of other people. What evidence I have to show that this view is a valid one is drawn from my experience with neurotics, and thus does not wholly meet the demands of the situation. I will give an account of a case in which something that was not strictly a faulty action but that rather deserves the name of a symptomatic or chance action gave me the clue which subsequently made it possible to resolve the patient's conflict. I once undertook the task of bringing an improvement to the marriage of a very intelligent man, whose disagreements with his fondly attached young wife could undoubtedly be shown to have a real basis, but could not, as he himself admitted, be completely accounted for in that way. He was continually occupied with the thought of a divorce, which he then dismissed once more because of his warm love for his two small children. In spite of this he constantly returned to his intention and made no attempt to find a way of making the situation tolerable to himself. Such inability to deal with a conflict is taken by me as proof that unconscious and repressed motives have lent a hand in strengthening the conscious ones which are struggling against each other, and I undertake in such cases to end the conflict by psychical analysis. One day the man told me of a small incident which had frightened him extremely. He was romping with his elder child, who was by far his favourite; he was swinging him high in the air and down again, and once he swung him so high while he was standing at a particular spot that the top of the child's head almost struck the heavy gas chandelier that was hanging there. Almost, but not quite - or perhaps just! No harm came to the child, but it was made giddy with fright. The father stood horrified with the child in his arms, and the mother had a hysterical attack. The peculiar adroitness of this imprudent movement and the violence of the parents' reaction prompted me to look for a symptomatic act in this accident - one which aimed at expressing an evil intention directed against the beloved child. I was able to remove the contradiction between this and the father's contemporary affection for his child by shifting the impulse to injure it back to the time when this child had been the only one and had been so small that its father had not yet had any reason to take an affectionate interest in it. It was then easy for me to suppose that, as he was getting little satisfaction from his wife, he may at that time have had a thought or formed a decision of this kind: 'If this little creature that means nothing at all to me dies, I shall be free and able to get a divorce.' A wish for the death of the creature that he now loved so dearly must therefore have persisted unconsciously. From this point it was easy to find the path by which this wish had become unconsciously fixated. A powerful determinant was in fact provided by a memory from the patient's childhood: namely that the death of a small brother, for which his mother blamed his father's negligence, had led to violent quarrels between the parents and threats of a divorce. The subsequent course of my patient's marriage, as well as my therapeutic success, confirmed my conjecture.
At the next session he began by saying that he must tell me an event in his childhood. From the age of seven, as he had already told me, he had had a fear that his parents guessed his thoughts, and this fear had in fact persisted all through his life. When he was twelve years old he had been in love with a little girl, the sister of a friend of his. (In answer to a question he said that his love had not been sensual; he had not wanted to see her naked for she was too small.) But she had not shown him as much affection as he had desired. And thereupon the idea had come to him that she would be kind to him if some misfortune were to befall him; and as an instance of such a misfortune his father's death had forced itself upon his mind. He had at once rejected the idea with energy. And even now he could not admit the possibility that what had arisen in this way could have been a 'wish'; it had clearly been no more than a 'train of thought'.

By way of objection I asked him why, if it had not been a wish, he had repudiated it. - Merely, he replied, on account of the content of the idea, the notion that his father might die. - I remarked that he was treating the phrase as though it were one that involved lèse-majesté; it was well known, of course, that it was equally punishable to say 'The Emperor is an ass' or to disguise the forbidden words by saying 'If any one says, etc., . . . then he will have me to reckon with.' I added that I could easily insert the idea which he had so energetically repudiated into a context which would exclude the possibility of any such repudiation: for instance, 'If my father dies, I shall kill myself upon his grave.' - He was shaken, but did not abandon his objection. I therefore broke off the argument with the remark that I felt sure this had not been the first occurrence of his idea of his father's dying; it had evidently originated at an earlier date, and some day we should have to trace back its history. - He then proceeded to tell me that a precisely similar thought had flashed through his mind a second time, six months before his father's death. At that time² he had already been in love with his lady, but financial obstacles made it impossible to think of an alliance with her. The idea had then occurred to him that his father's death might make him rich enough to marry her. In defending himself against this idea he had gone to the length of wishing that his father might leave him nothing at all, so that he might have no compensation for his terrible loss. The same idea, though in a much milder form, had come to him for a third time, on the day before his father's death. He had then thought: 'Now I may be going to lose what I love most'; and then had come the contradiction: 'No, there is some one else whose loss would be even more painful to you.'³ These thoughts surprised him very much, for he was quite certain that his father's death could never have been an object of his desire but only of his fear. - After his forcible enunciation of these words I thought it advisable to bring a fresh piece of theory to his notice. According to psycho-analytic theory, I told him, every fear corresponded to a former wish which was now repressed; we were therefore obliged to believe the exact contrary of what he had asserted. This would also fit in with another theoretical requirement, namely, that the unconscious must be the precise contrary of the conscious. - He was much agitated at this and very incredulous. He wondered how he could possibly have had such a wish, considering that he loved his father more than any one else in the world; there could be no doubt that he would have renounced all his own prospects of happiness if by so doing he could have saved his father's life.

[1909d, 2144]
- I answered that it was precisely such intense love as his that was the necessary precondition of the repressed hatred. In the case of people to whom he felt indifferent he would certainly have no difficulty in maintaining side by side inclinations to a moderate liking and to an equally moderate dislike: supposing, for instance, that he were an official, he might think that his chief was agreeable as a superior, but at the same time pettifogging as a lawyer and inhuman as a judge. (Shakespeare makes Brutus speak in a similar way of Julius Caesar: ‘As Caesar loved me, I weep for him; as he was fortunate, I rejoice at it; as he was valiant, I honour him; but, as he was ambitious, I slew him.’ But these words already strike us as rather strange, and for the very reason that we had imagined Brutus's feeling for Caesar as something deeper.) In the case of some one who was closer to him, of his wife for instance, he would wish his feelings to be unmixed, and consequently, as was only human, he would overlook her faults, since they might make him dislike her - he would ignore them as though he were blind to them. So it was precisely the intensity of his love that would not allow his hatred - though to give it such a name was to caricature the feeling - to remain conscious. To be sure, the hatred must have a source, and to discover that source was certainly a problem; his own statements pointed to the time when he was afraid that his parents guessed his thoughts. On the other hand, too, it might be asked why this intense love of his had not succeeded in extinguishing his hatred, as usually happened where there were two opposing impulses. We could only presume that the hatred must flow from some source, must be connected with some particular cause, which made it indestructible. On the one hand, then, some connection of this sort must be keeping his hatred for his father alive, while on the other hand, his intense love prevented it from becoming conscious. Therefore nothing remained for it but to exist in the unconscious, though it was able from time to time to flash out for a moment into consciousness.

[1909d, 2144]
He then went on to say that he would like to speak of a criminal act, whose author he did not recognize as himself, though he quite clearly recollected committing it. He quoted a saying of Nietzsche’s:² "I did this," says my Memory. "I cannot have done this," says my Pride and remains inexorable. In the end - Memory yields. 'Well,' he continued, 'my memory has not yielded on this point.' - 'That is because you derive pleasure from your self-reproaches as a means of self-punishment.' - 'My younger brother - I am really very fond of him now, and he is causing me a great deal of worry just at present, for he wants to make what I consider a preposterous match; I have thought before now of going and killing the person concerned so as to prevent his marrying her - well, my younger brother and I used to fight a lot when we were children. We were very fond of each other at the same time, and were inseparable; but I was plainly filled with jealousy, as he was the stronger and better-looking of the two and consequently the favourite.¹ - 'Yes. You have already given me a description of a scene of jealousy in connection with Fräulein Lina.' - 'Very well then, on some such occasion (it was certainly before I was eight years old, for I was not going to school yet, which I began to do when I was eight) - on some such occasion, this is what I did. We both had toy guns of the usual make. I loaded mine with the ram rod and told him that if he looked up the barrel he would see something. Then, while he was looking in, I pulled the trigger. He was hit on the forehead and not hurt; but I had meant to hurt him very much indeed. Afterwards I was quite beside myself, and threw myself on the ground and asked myself however I could have done such a thing. But I did do it.' - I took the opportunity of urging my case. If he had preserved the recollection of an action so foreign to him as this, he could not, I maintained, deny the possibility of something similar, which he had now forgotten entirely, having happened at a still earlier age in relation to his father. - He then told me he was aware of having felt other vindictive impulses, this time towards the lady he admired so much, of whose character he painted a glowing picture. It might be true, he said, that she could not love easily; but she was reserving her whole self for the one man to whom she would some day belong. She did not love him. When he had become certain of that, a conscious phantasy had taken shape in his mind of how he should grow very rich and marry some one else, and should then take her to call on the lady in order to hurt her feelings. But at that point the phantasy had broken down, for he had been obliged to own to himself that the other woman, his wife, was completely indifferent to him; then his thoughts had become confused, till finally it had been clearly borne in upon him that this other woman would have to die. In this phantasy, just as in his attempt upon his brother, he recognized the quality of cowardice which was so particularly horrible to him.³ - In the further course of our conversation I pointed out to him that he ought logically to consider himself as in no way responsible for any of these traits in his character; for all of these reprehensible impulses originated from his infancy, and were only derivatives of his infantile character surviving in his unconscious; and he must know that moral responsibility could not be applied to children. It was only by a process of development, I added, that a man, with his moral responsibility, grew up out of the sum of his infantile predispositions.⁴ He expressed a doubt, however, whether all his evil impulses had originated from that source. But I promised to prove it to him in the course of the treatment.

[1909d, 2146]

¹ This sense of guilt involves the most glaring contradiction of his opening denial that he had ever entertained such an evil wish against his father. This is a common type of reaction to repressed material which has become conscious: the 'No' with which the fact is first denied is immediately followed by a confirmation of it, though, to begin with, only an indirect one.

[1909d, 2146]
The mutual antagonism between his feelings for his lady was too marked to have escaped his conscious perception entirely, although we may conclude from the obsessions in which it was manifested that he did not rightly appreciate the depth of his negative impulses. The lady had refused his first proposal, ten years earlier. Since then he had to his own knowledge passed through alternating periods, in which he either believed that he loved her intensely, or felt indifferent to her. Whenever in the course of the treatment he was faced by the necessity of taking some step which would bring him nearer the successful end of his courtship, his resistance usually began by taking the form of a conviction that after all he did not very much care for her - though this resistance, it is true, used soon to break down. Once when she was lying seriously ill in bed and he was most deeply concerned about her, there crossed his mind as he looked at her a wish that she might lie like that for ever. He explained this idea by an ingenious piece of sophistry: maintaining that he had only wished her to be permanently ill so that he might be relieved of his intolerable fear that she would have a repeated succession of attacks!¹ Now and then he used to occupy his imagination with day-dreams, which he himself recognized as ‘phantasies of revenge’ and felt ashamed of. Believing, for instance, that the lady set great store by the social standing of a suitor, he made up a phantasy in which she was married to a man of that kind, who was in some government office. He himself then entered the same department, and rose much more rapidly than her husband, who eventually became his subordinate. One day, his phantasy proceeded, this man committed some act of dishonesty. The lady threw herself at his feet and implored him to save her husband. He promised to do so, and informed her that it had only been for love of her that he had entered the service, because he had foreseen that such a moment would occur; and now that her husband was saved, his own mission was fulfilled and he would resign his post.

[1909d, 2153]

He produced other phantasies in which he did the lady some great service without her knowing that it was he who was doing it. In these he only recognized his affection, without sufficiently appreciating the origin and aim of his magnanimity, which was designed to repress his thirst for revenge, after the manner of Dumas’ Count of Monte-Cristo. Moreover he admitted that occasionally he was overcome by quite distinct impulses to do some mischief to the lady he admired. These impulses were mostly in abeyance when she was there, and only appeared in her absence.

[1909d, 2153]

¹ It cannot be doubted that another contributory motive to this compulsive idea was a wish to know that she was powerless against his designs.

[1909d, 2153]
By all accounts our patient's father was a most excellent man. Before his marriage he had been a non-commissioned officer, and, as relics of that period of his life, he had retained a straightforward soldierly manner and a *penchant* for using downright language. Apart from those virtues which are celebrated upon every tombstone, he was distinguished by a hearty sense of humour and a kindly tolerance towards his fellow-men. That he could be hasty and violent was certainly not inconsistent with his other qualities, but was rather a necessary complement to them; but it occasionally brought down the most severe castigations upon the children, while they were young and naughty. When they grew up, however, he differed from other fathers in not attempting to exalt himself into a sacrosanct authority, but in sharing with them a knowledge of the little failures and misfortunes of his life with good-natured candour. His son was certainly not exaggerating when he declared that they had lived together like the best of friends, except upon a single point (p. 2145). And it must no doubt have been in connection with that very point that thoughts about his father's death had occupied his mind when he was a small boy with unusual and undue intensity (p. 2133), and that those thoughts made their appearance in the wording of the obsessional ideas of his childhood; and it can only have been in that same connection that he was able to wish for his father's death, in order that a certain little girl's sympathy might be aroused and that she might behave more kindly towards him (p. 2144).

[1909d, 2158]

Our patient had a quite peculiar attitude towards the question of death. He showed the deepest sympathy whenever any one died, and religiously attended the funeral; so that among his brothers and sisters he earned the nickname of 'carrion crow'. In his imagination, too, he was constantly making away with people so as to show his heartfelt sympathy for their bereaved relatives. The death of an elder sister, which took place when he was between three and four years old, played a great part in his phantasies, and was brought into intimate connection with his childish misdemeanours during the same period. We know, moreover, at what an early age thoughts about his father's death had occupied his mind, and we may regard his illness itself as a reaction to that event, for which he had felt an obsessional wish fifteen years earlier. The strange extension of his obsessional fears to the 'next world' was nothing else than a compensation for these death-wishes which he had felt against his father. It was introduced eighteen months after his father had died, at a time when there had been a revival of his sorrow at the loss, and it was designed - in defiance of reality, and in deference to the wish which had previously been showing itself in phantasies of every kind - were intended to undo the fact of his father's death. We have had occasion in several places (pp. 2173, and 2176) to translate the phrase 'in the next world' by the words 'if my father were still alive'.

[1909d, 2184]
But the behaviour of other obsessional neurotics does not differ greatly from that of our present patient, even though it has not been their fate to come face to face with the phenomenon of death at such an early age. Their thoughts are unceasingly occupied with other people's length of life and possibility of death; their superstitious propensities have had no other content to begin with, and have perhaps no other source whatever. But these neurotics need the help of the possibility of death chiefly in order that it may act as a solution of conflicts they have left unsolved. Their essential characteristic is that they are incapable of coming to a decision, especially in matters of love; they endeavour to postpone every decision, and, in their doubt which person they shall decide for or what measures they shall take against a person, they are obliged to choose as their model the old German courts of justice, in which the suits were usually brought to an end, before judgement had been given, by the death of the parties to the dispute. Thus in every conflict which enters their lives they are on the look out for the death of some one who is of importance to them, usually of some one they love - such as one of their parents, or a rival, or one of the objects of their love between which their inclinations are wavering. But at this point our discussion of the death-complex in obsessional neuroses touches upon the problem of the instinctual life of obsessional neurotics. And to this problem we must now turn.

[1909d, 2184]

The second gap in our hypothesis is far more important. As we know, the developmental disposition to a neurosis is only complete if the phase of the development of the ego at which fixation occurs is taken into account as well as that of the libido. But our hypothesis has only related to the latter, and therefore does not include all the knowledge that we should demand. The stages of development of the ego-instincts are at present very little known to us; I know of only one attempt - the highly promising one made by Ferenczi (1913) - to approach these questions. I cannot tell if it may seem too rash if, on the basis of such indications as we possess, I suggest the possibility that a chronological outstripping of libidinal development by ego development should be included in the disposition to obsessional neurosis. A precocity of this kind would necessitate the choice of an object under the influence of the ego-instincts, at a time at which the sexual instincts had not yet assumed their final shape, and a fixation at the stage of the pregenital sexual organization would thus be left. If we consider that obsessional neurotics have to develop a super-morality in order to protect their object-love from the hostility lurking behind it, we shall be inclined to regard some degree of this precocity of ego development as typical of human nature and to derive the capacity for the origin of morality from the fact that in the order of development hate is the precursor of love. This is perhaps the meaning of an assertion by Stekel (1911a, 536), which at the time I found incomprehensible, to the effect that hate and not love is the primary emotional relation between men.

[1913i, 2630]

Suppose, on the other hand, that we were to take into account the finding arrived at by psycho-analysis from the dreams of normal people, to the effect that we ourselves are subject, more strongly and more often than we suspect, to a temptation to kill someone and that that temptation produces psychical effects even though it remains out of sight of our consciousness. Suppose, again, that we were to recognize the compulsive observances of certain neurotics as being guarantees against an intensified impulse to murder or as being self-punishments on account of it. In that case we should have to attach still greater importance to our thesis that where there is a prohibition there must be an underlying desire. We should have to suppose that the desire to murder is actually present in the unconscious and that neither taboos nor moral prohibitions are psychologically superfluous but that on the contrary they are explained and justified by the existence of an ambivalent attitude towards the impulse to murder.

[1912-1913, 2714]
How, then, are we to account for the unexpected nobility of mind of the neurotic, who fears nothing on his own account but everything for someone he loves? Analytical inquiry shows that this attitude is not primary. Originally, that is to say at the beginning of the illness, the threat of punishment applied, as in the case of savages, to the patient himself; he was invariably in fear for his own life; it was not until later that the mortal fear was displaced on to another and a loved person. The process is a little complicated, but we can follow it perfectly. At the root of the prohibition there is invariably a hostile impulse against someone the patient loves - a wish that that person should die. This impulse is repressed by a prohibition and the prohibition is attached to some particular act, which, by displacement, represents, it may be, a hostile act against the loved person. There is a threat of death if this act is performed. But the process goes further, and the original wish that the loved person may die is replaced by fear that he may die. So that when the neurosis appears to be so tenderly altruistic, it is merely compensating for an underlying contrary attitude of brutal egoism. We may describe as 'social' the emotions which are determined by showing consideration for another person without taking him as a sexual object. The receding into the background of these social factors may be stressed as a fundamental characteristic of the neurosis, though one which is later disguised by overcompensation.

[1912-1913, 2716]

It is in obsessional neuroses that the survival of the omnipotence of thoughts is most clearly visible and that the consequences of this primitive mode of thinking come closest to consciousness. But we must not be misled into supposing that it is a distinguishing feature of this particular neurosis, for analytic investigation reveals the same thing in the other neuroses as well. In all of them what determines the formation of symptoms is the reality not of experience but of thought. Neurotics live in a world apart, where, as I have said elsewhere, only 'neurotic currency' is legal tender; that is to say, they are only affected by what is thought with intensity and pictured with emotion, whereas agreement with external reality is a matter of no importance. What hysterics repeat in their attacks and fix by means of their symptoms are experiences which have occurred in that form only in their imagination though it is true that in the last resort those imagined experiences go back to actual events or are based upon them. To attribute the neurotic sense of guilt to real misdeeds would show an equal misunderstanding. An obsessional neurotic may be weighed down by a sense of guilt that would be appropriate in a mass-murderer, while in fact, from his childhood onwards, he has behaved to his fellow-men as the most considerate and scrupulous member of society. Nevertheless, his sense of guilt has a justification: it is founded on the intense and frequent death wishes against his fellows which are unconsciously at work in him. It has a justification if what we take into account are unconscious thoughts and not intentional deeds. Thus the omnipotence of thoughts, the overvaluation of mental processes as compared with reality, is seen to have unrestricted play in the emotional life of neurotic patients and in everything that derives from it. If one of them undergoes psychoanalytic treatment, which makes what is unconscious in him conscious, he will be unable to believe that thoughts are free and will constantly be afraid of expressing evil wishes, as though their expression would lead inevitably to their fulfilment. This behaviour, as well as the superstitions which he practises in ordinary life, reveals his resemblance to the savages who believe they can alter the external world by mere thinking.

[1912-1913, 2729]
This may be illustrated by an example from a neurosis. In my essay on taboo I mentioned a
woman patient of mine whose obsessional prohibitions showed the most perfect agreement with
a Maori taboo (p. 267). This woman’s neurosis was aimed at her husband and culminated in
her defense against an unconscious wish that he should die. Her manifest, systematic phobia,
however, related to the mention of death in general, while her husband was entirely excluded
from it and was never an object of her conscious solicitude. One day she heard her husband
giving instructions that his razors, which had lost their edge, were to be taken to a particular
shop to be re-set. Driven by a strange uneasiness, she herself set off for the shop. After
reconnoitring the ground, she came back and insisted that her husband should get rid of the
razors for good and all, since she had discovered that next door to the shop he had named
there was an undertaker’s establishment: owing to the plan he had made, she said, the razors
had become inextricably involved with thoughts of death. This, then, was the systematic
reason for her prohibition. We may be quite sure that, even without her discovery of the next-door shop,
the patient would have come home with a prohibition against the razors. It would have been
enough if she had met a hearse on her way to the shop, or someone dressed in mourning or
carrying a funeral wreath. The net of possible determinants for the prohibition was spread wide
enough to catch the quarry in any event; it merely depended on her decision whether to draw it
together or not. It could be shown that on other occasions she would not put the determinants
into operation, and she would explain this by saying it had been ‘a better day’. The real cause of
her prohibition upon the razors was, of course, as it was easy to discover, her repugnance to
attaching any pleasurable feeling to the idea that her husband might cut his throat with the
newly ground razors.
[1912-1913, 2738]

Just as for primaeval man, so also for our unconscious, there is one case in which the two
opposing attitudes towards death, the one which acknowledges it as the annihilation of life and
the other which denies it as unreal, collide and come into conflict. This case is the same as in
primal ages: the death, or the risk of death, of someone we love, a parent or a partner in
marriage, a brother or sister, a child or a dear friend. These loved ones are on the one hand an
inner possession, components of our own ego; but on the other hand they are partly strangers,
even enemies. With the exception of only a very few situations, there adheres to the tenderest
and most intimate of our love-relations a small portion of hostility which can excite an
unconscious death-wish. But this conflict due to ambivalence does not now, as it did then, lead
to the doctrine of the soul and to ethics, but to neurosis, which affords us deep insight into
normal mental life as well. How often have physicians who practise psycho-analysis had to deal
with the symptom of an exaggerated worry over the well-being of relatives, or with entirely
unfounded self-reproaches after the death of a loved person. The study of such phenomena has
left them in no doubt about the extent and importance of unconscious death-wishes.
[1915b, 3090]

The layman feels an extraordinary horror at the possibility of such feelings, and takes this
aversion as a legitimate ground for disbelief in the assertions of psycho-analysis. Mistakenly, I
think. No depreciation of feelings of love is intended, and there is in fact none. It is indeed
foreign to our intelligence as well as to our feelings thus to couple love and hate; but Nature, by
making use of this pair of opposites, contrives to keep love ever vigilant and fresh, so as to
guard it against the hate which lurks behind it. It might be said that we owe the fairest flowerings
of our love to the reaction against the hostile impulse which we sense within us.
[1915b, 3091]
The second gap in our hypothesis is far more important. As we know, the developmental disposition to a neurosis is only complete if the phase of the development of the ego at which fixation occurs is taken into account as well as that of the libido. But our hypothesis has only related to the latter, and therefore does not include all the knowledge that we should demand. The stages of development of the ego-instincts are at present very little known to us; I know of only one attempt - the highly promising one made by Ferenczi (1913) - to approach these questions. I cannot tell if it may seem too rash if, on the basis of such indications as we possess, I suggest the possibility that a chronological outstripping of libidinal development by ego development should be included in the disposition to obsessional neurosis. A precocity of this kind would necessitate the choice of an object under the influence of the ego-instincts, at a time at which the sexual instincts had not yet assumed their final shape, and a fixation at the stage of the pregenital sexual organization would thus be left. If we consider that obsessional neurotics have to develop a super-morality in order to protect their object-love from the hostility lurking behind it, we shall be inclined to regard some degree of this precocity of ego development as typical of human nature and to derive the capacity for the origin of morality from the fact that in the order of development hate is the precursor of love. This is perhaps the meaning of an assertion by Stekel (1911a, 536), which at the time I found incomprehensible, to the effect that hate and not love is the primary emotional relation between men. [1913i, 2630]

An interpretation of the normal, conscious sense of guilt (conscience) presents no difficulties; it is based on the tension between the ego and the ego ideal and is the expression of a condemnation of the ego by its critical agency. The feelings of inferiority so well known in neurotics are presumably not far removed from it. In two very familiar maladies the sense of guilt is over-strongly conscious; in them the ego ideal displays particular severity and often rages against the ego in a cruel fashion. The attitude of the ego ideal in these two conditions, obsessional neurosis and melancholia, presents, alongside of this similarity, differences that are no less significant. [1923b, 3985]

In certain forms of obsessional neurosis the sense of guilt is over-noisy but cannot justify itself to the ego. Consequently the patient's ego rebels against the imputation of guilt and seeks the physician's support in repudiating it. It would be folly to acquiesce in this, for to do so would have no effect. Analysis eventually shows that the super-ego is being influenced by processes that have remained unknown to the ego. It is possible to discover the repressed impulses which are really at the bottom of the sense of guilt. Thus in this case the super-ego knew more than the ego about the unconscious id. [1923b, 3985]

In melancholia the impression that the super-ego has obtained a hold upon consciousness is even stronger. But here the ego ventures no objection; it admits its guilt and submits to the punishment. We understand the difference. In obsessional neurosis what were in question were objectionable impulses which remained outside the ego, while in melancholic the object to which the super-ego's wrath applies has been taken into the ego through identification. [1923b, 3985]
The reproaches of conscience in certain forms of obsessional neurosis are as distressing and tormenting, but here the situation is less perspicuous. It is noteworthy that the obsessional neurotic, in contrast to the melancholic, never in fact takes the step of self-destruction; it is as though he were immune against the danger of suicide, and he is far better protected from it than the hysterical. We can see that what guarantees the safety of the ego is the fact that the object has been retained. In obsessional neurosis it has become possible, through a regression to the pregenital organization, for the love-impulses to transform themselves into impulses of aggression against the object. Here again the instinct of destruction has been set free and it seeks to destroy the object, or at least it appears to have that intention. These purposes have not been adopted by the ego and it struggles against them with reaction-formations and precautionary measures; they remain in the id. The super-ego, however, behaves as if the ego were responsible for them and shows at the same time by the seriousness with which it chastises these destructive intentions that they are no mere semblance evoked by regression but an actual substitution of hate for love. Helpless in both directions, the ego defends itself vainly, alike against the instigations of the murderous id and against the reproaches of the punishing conscience. It succeeds in holding in check at least the most brutal actions of both sides; the first outcome is interminable self-tortment, and eventually there follows a systematic torturing of the object, in so far as it is within reach.

Let us again consider obsessional neurosis for a moment. The state of affairs is different here. The defusion of love into aggressiveness has not been effected by the work of the ego, but is the result of a regression which has come about in the id. But this process has extended beyond the id to the super-ego, which now increases its severity towards the innocent ego. It would seem, however, that in this case, no less than in that of melancholia, the ego, having gained control over the libido by means of identification, is punished for doing so by the super-ego through the instrumentality of the aggressiveness which was mixed with the libido.

Two impressions at once emerge from this brief survey of obsessional symptoms. The first is that a ceaseless struggle is being waged against the repressed, in which the repressing forces steadily lose ground; the second is that the ego and the super-ego have a specially large share in the formation of the symptoms.
In enforcing regression, the ego scores its first success in its defensive struggle against the demands of the libido. (In this connection it is of advantage to distinguish the more general notion of 'defence' from 'repression'. Repression is only one of the mechanisms which defence makes use of.) It is perhaps in obsessional cases more than in normal or hysterical ones that we can most clearly recognize that the motive force of defence is the castration complex and that what is being fended off are the trends of the Oedipus complex. We are at present dealing with the beginning of the latency period, a period which is characterized by the dissolution of the Oedipus complex, the creation or consolidation of the super-ego and the erection of ethical and aesthetic barriers in the ego. In obsessional neuroses these processes are carried further than is normal. In addition to the destruction of the Oedipus complex a regressive degradation of the libido takes place, the super-ego becomes exceptionally severe and unkind, and the ego, in obedience to the super-ego, produces strong reaction-formations in the shape of conscientiousness, pity and cleanliness. Implacable, though not always on that account successful, severity is shown in condemning the temptation to continue early infantile masturbation, which now attaches itself to regressive (sadistic-anal) ideas but which nevertheless represents the unsubjugated part of the phallic organization. There is an inherent contradiction about this state of affairs, in which, precisely in the interests of masculinity (that is to say, from fear of castration), every activity belonging to masculinity is stopped. But here, too, obsessional neurosis is only overdoing the normal method of getting rid of the Oedipus complex. We once more find here an illustration of the truth that every exaggeration contains the seed of its own undoing. For, under the guise of obsessional acts, the masturbation that has been suppressed approaches ever more closely to satisfaction.

We can either simply accept it as a fact that in obsessional neurosis a super-ego of this severe kind emerges, or we can take the regression of the libido as the fundamental characteristic of the affection and attempt to relate the severity of the super-ego to it. And indeed the super-ego, originating as it does from the id, cannot dissociate itself from the regression and defusion of instinct which have taken place there. We cannot be surprised if it becomes harsher, unkind and more tormenting than where development has been normal.

The advent of puberty opens a decisive chapter in the history of an obsessional neurosis. The genital organization which has been broken off in childhood starts again with great vigour. But, as we know, the sexual development in childhood determines what direction this new start at puberty will take. Not only will the early aggressive impulses be re-awakened; but a greater or lesser proportion of the new libidinal impulses - in bad cases the whole of them - will have to follow the course prescribed for them by regression and will emerge as aggressive and destructive tendencies. In consequence of the erotic trends being disguised in this way and owing to the powerful reaction-formations in the ego, the struggle against sexuality will henceforward be carried on under the banner of ethical principles. The ego will recoil with astonishment from promptings to cruelty and violence which enter consciousness from the id, and it has no notion that in them it is combating erotic wishes, including some to which it would not otherwise have taken exception. The overstrict super-ego insists all the more strongly on the suppression of sexuality, since this has assumed such repellent forms. Thus in obsessional neurosis the conflict is aggravated in two directions: the defensive forces become more intolerant and the forces that are to be fended off become more intolerable. Both effects are due to a single factor, namely, regression of the libido.
A good deal of what has been said may be objected to on the ground that the unpleasant obsessive ideas are themselves quite conscious. But there is no doubt that before becoming conscious they have been though the process of repression. In most of them the actual wording of the aggressive instinctual impulse is altogether unknown to the ego, and it requires a good deal of analytic work to make it conscious. What does penetrate into consciousness is usually only a distorted substitute which is either of a vague, dream-like and indeterminate nature or so travestied as to be unrecognizable. Even where repression has not encroached upon the content of the aggressive impulse it has certainly got rid of its accompanying affective character. As a result, the aggressiveness appears to the ego not to be an impulsion but, as the patients themselves say, merely a 'thought' which awakens no feeling. But the remarkable thing is that this is not the case. What happens is that the affect left out when the obsessional idea is perceived appears in a different place. The super-ego behaves as though repression had not occurred and as though it knew the real wording and full affective character of the aggressive impulse, and it treats the ego accordingly. The ego which, on the one hand, knows that it is innocent is obliged, on the other hand, to be aware of a sense of guilt and to carry a responsibility which it cannot account for. This state of affairs is, however, not so puzzling as it would seem at first sight. The behaviour of the super-ego is perfectly intelligible, and the contradiction in the ego merely shows that it has shut out the id by means of repression while remaining fully accessible to the influence of the super-ego. If it is asked why the ego does not also attempt to withdraw from the tormenting criticism of the super-ego, the answer is that it does manage to do so in a great number of instances. There are obsessional neuroses in which no sense of guilt whatever is present. In them, as far as can be seen, the ego has avoided becoming aware of it by instituting a fresh set of symptoms, penances or restrictions of a self-punishing kind. These symptoms, however, represent at the same time a satisfaction of masochistic impulses which, in their turn, have been reinforced by regression.

I have already described the general tendency of symptom-formation in obsessional neurosis. It is to give ever greater room to substitutive satisfaction at the expense of frustration. Symptoms which once stood for a restriction of the ego come later on to represent satisfactions as well, thanks to the ego's inclination to synthesis, and it is quite clear that this second meaning gradually becomes the more important of the two. The result of this process, which approximates more and more to a complete failure of the original purpose of defence, is an extremely restricted ego which is reduced to seeking satisfaction in the symptoms. The displacement of the distribution of forces in favour of satisfaction may have the dreaded final outcome of paralysing the will of the ego, which in every decision it has to make is almost as strongly impelled from the one side as from the other. The over-acute conflict between id and super-ego which has dominated the illness from the very beginning may assume such extensive proportions that the ego, unable to carry out its office of mediator, can undertake nothing which is not drawn into the sphere of that conflict.

We have all found by experience that it is especially difficult for an obsessional neurotic to carry out the fundamental rule of psycho-analysis. His ego is more watchful and makes sharper isolations, probably because of the high degree of tension due to conflict that exists between his super-ego and his id. While he is engaged in thinking, his ego has to keep off too much - the intrusion of unconscious phantasies and the manifestation of ambivalent trends. It must not relax, but is constantly prepared for a struggle. It fortifies this compulsion to concentrate and to isolate by the help of the magical acts of isolation which, in the form of symptoms, grow to be so noticeable and to have so much practical importance for the patient, but which are, of course, useless in themselves and are in the nature of ceremonials.
What we have learnt about anxiety in phobias is applicable to obsessional neuroses as well. In this respect it is not difficult for us to put obsessional neuroses on all fours with phobias. In the former, the mainspring of all later symptom-formation is clearly the ego's fear of its super-ego. The danger-situation from which the ego must get away is the hostility of the super-ego. There is no trace of projection here; the danger is completely internalized. But if we ask ourselves what it is that the ego fears from the super-ego, we cannot but think that the punishment threatened by the latter must be an extension of the punishment of castration. Just as the father has become depersonalized in the shape of the super-ego, so has the fear of castration at his hands become transformed into an undefined social or moral anxiety. But this anxiety is concealed. The ego escapes it by obediently carrying out the commands, precautions and penances that have been enjoined on it. If it is impeded in doing so, it is at once overtaken by an extremely distressing feeling of discomfort which may be regarded as an equivalent of anxiety and which the patients themselves liken to anxiety.

[1926d, 4285]

When, in an earlier part of this discussion, we found that the danger of castration was of importance in more than one neurotic illness, we put ourselves on guard against overestimating that factor, since it could not be a decisive one for the female sex, who are undoubtedly more subject to neuroses than men. We now see that there is no danger of our regarding castration anxiety as the sole motive force of the defensive processes which lead to neurosis. I have shown elsewhere how little girls, in the course of their development, are led into making a tender object-cathexis by their castration complex. It is precisely in women that the danger situation of loss of object seems to have remained the most effective. All we need to do is to make a slight modification in our description of their determinant of anxiety, in the sense that it is no longer a matter of feeling the want of, or actually losing the object itself, but of losing the object's love. Since there is no doubt that hysteria has a strong affinity with femininity, just as obsessional neurosis has with masculinity, it appears probable that, as a determinant of anxiety, loss of love plays much the same part in hysteria as the threat of castration does in phobias and fear of the super-ego in obsessional neurosis.

[1926d, 4298]

One objection to it is that loss of an object (or loss of love on the part of the object) and the threat of castration are just as much dangers coming from outside as, let us say, a ferocious animal would be; they are not instinctual dangers. Nevertheless, the two cases are not the same. A wolf would probably attack us irrespectively of our behaviour towards it; but the loved person would not cease to love us nor should we be threatened with castration if we did not entertain certain feelings and intentions within us. Thus such instinctual impulses are determinants of external dangers and so become dangerous in themselves; and we can now proceed against the external danger by taking measures against the internal ones. In phobias of animals the danger seems to be still felt entirely as an external one, just as it has undergone an external displacement in the symptom. In obsessional neuroses the danger is much more internalized. That portion of anxiety in regard to the super-ego which constitutes social anxiety still represents an internal substitute for an external danger, while the other portion - moral anxiety - is already completely endopsychic.

[1926d, 4300]
The obsessional neurosis (Zwangsneurose) arises from a specific cause very analogous to that of hysteria. Here too we find a precocious sexual event, occurring before puberty, the memory of which becomes active during or after that period; and the same remarks and arguments which I put forward in connection with hysteria will apply to my observations of the other neurosis (six cases, three of which were pure ones). There is only one difference which seems capital. At the basis of the aetiology of hysteria we found an event of passive sexuality, an experience submitted to with indifference or with a small degree of annoyance or fright. In obsessional neurosis it is a question on the other hand, of an event which has given pleasure, of an act of aggression inspired by desire (in the case of a boy) or of a participation in sexual relations accompanied by enjoyment (in the case of a little girl). The obsessional ideas, when their intimate meaning has been recognized by analysis, when they have been reduced, as it were, to their simplest expression, are nothing other than reproaches addressed by the subject himself on account of this anticipated sexual enjoyment, but reproaches distorted by an unconscious psychical work of transformation and substitution.

Analysis of obsessive actions has already given us some sort of an insight into their causes and into the chain of motives which bring them into effect. We may say that the sufferer from compulsions and prohibitions behaves as if he were dominated by a sense of guilt, of which, however, he knows nothing, so that we must call it an unconscious sense of guilt, in spite of the apparent contradiction in terms. This sense of guilt has its source in certain early mental events, but it is constantly being revived by renewed temptations which arise whenever there is a contemporary provocation. Moreover, it occasions a lurking sense of expectant anxiety, an expectation of misfortune, which is linked, through the idea of punishment, with the internal perception of the temptation. When the ceremonial is first being constructed, the patient is still conscious that he must do this or that lest some ill should befall, and as a rule the nature of the ill that is to be expected is still known to his consciousness. But what is already hidden from him is the connection - which is always demonstrable - between the occasion on which this expectant anxiety arises and the danger which it conjures up. Thus a ceremonial starts as an action for defence or insurance, a protective measure.

The sense of guilt of obsessional neurotics finds its counterpart in the protestations of pious people that they know that at heart they are miserable sinners; and the pious observances (such as prayers, invocations, etc.) with which such people preface every daily act, and in especial every unusual undertaking, seem to have the value of defensive or protective measures.

He had a friend, he told me, of whom he had an extraordinarily high opinion. He used always to go to him when he was tormented by some criminal impulse, and ask him whether he despised him as a criminal. His friend used then to give him moral support by assuring him that he was a man of irreproachable conduct, and had probably been in the habit, from his youth onwards, of taking a dark view of his own life. At an earlier date, he went on, another person had exercised a similar influence over him. This was a nineteen-year-old student (he himself had been fourteen or fifteen at the time) who had taken a liking to him, and had raised his self-esteem to an extraordinary degree, so that he appeared to himself to be a genius. This student had subsequently become his tutor, and had suddenly altered his behaviour and begun treating him as though he were an idiot. At length he had noticed that the student was interested in one of his sisters, and had realized that he had only taken him up in order to gain admission into the house. This had been the first great blow of his life.
At the next session, which was the seventh, he took up the same subject once more. He could not believe, he said, that he had ever entertained such a wish against his father. He remembered a story of Sudermann's, he went on, that had made a deep impression upon him. In this story there was a woman who, as she sat by her sister's sick-bed, felt a wish that her sister should die so that she herself might marry her husband. The woman thereupon committed suicide, thinking she was not fit to live after being guilty of such baseness. He could understand this, he said, and it would be only right if his thoughts were the death of him, for he deserved nothing less.¹ - I remarked that it was well known to us that patients derived a certain satisfaction from their sufferings, so that in reality they all resisted their own recovery to some extent. He must never lose sight of the fact that a treatment like ours proceeded to the accompaniment of a constant resistance; I should be repeatedly reminding him of this fact.

¹ This sense of guilt involves the most glaring contradiction of his opening denial that he had ever entertained such an evil wish against his father. This is a common type of reaction to repressed material which has become conscious: the 'No' with which the fact is first denied is immediately followed by a confirmation of it, though, to begin with, only an indirect one. [1909d, 2146]

The second gap in our hypothesis is far more important. As we know, the developmental disposition to a neurosis is only complete if the phase of the development of the ego at which fixation occurs is taken into account as well as that of the libido. But our hypothesis has only related to the latter, and therefore does not include all the knowledge that we should demand. The stages of development of the ego-instincts are at present very little known to us; I know of only one attempt - the highly promising one made by Ferenczi (1913) - to approach these questions. I cannot tell if it may seem too rash if, on the basis of such indications as we possess, I suggest the possibility that a chronological outstripping of libidinal development by ego development should be included in the disposition to obsessional neurosis. A precocity of this kind would necessitate the choice of an object under the influence of the ego-instincts, at a time at which the sexual instincts had not yet assumed their final shape, and a fixation at the stage of the pregenital sexual organization would thus be left. If we consider that obsessional neurotics have to develop a super-morality in order to protect their object-love from the hostility lurking behind it, we shall be inclined to regard some degree of this precocity of ego development as typical of human nature and to derive the capacity for the origin of morality from the fact that in the order of development hate is the precursor of love. This is perhaps the meaning of an assertion by Stekel (1911a, 536), which at the time I found incomprehensible, to the effect that hate and not love is the primary emotional relation between men. [1913i, 2630]
It is in obsessional neuroses that the survival of the omnipotence of thoughts is most clearly visible and that the consequences of this primitive mode of thinking come closest to consciousness. But we must not be misled into supposing that it is a distinguishing feature of this particular neurosis, for analytic investigation reveals the same thing in the other neuroses as well. In all of them what determines the formation of symptoms is the reality not of experience but of thought. Neurotics live in a world apart, where, as I have said elsewhere, only 'neurotic currency' is legal tender; that is to say, they are only affected by what is thought with intensity and pictured with emotion, whereas agreement with external reality is a matter of no importance. What hysterics repeat in their attacks and fix by means of their symptoms are experiences which have occurred in that form only in their imagination though it is true that in the last resort those imagined experiences go back to actual events or are based upon them. To attribute the neurotic sense of guilt to real misdeeds would show an equal misunderstanding. An obsessional neurotic may be weighed down by a sense of guilt that would be appropriate in a mass-murderer, while in fact, from his childhood onwards, he has behaved to his fellow-men as the most considerate and scrupulous member of society. Nevertheless, his sense of guilt has a justification: it is founded on the intense and frequent death wishes against his fellows which are unconsciously at work in him. It has a justification if what we take into account are unconscious thoughts and not intentional deeds. Thus the omnipotence of thoughts, the overvaluation of mental processes as compared with reality, is seen to have unrestricted play in the emotional life of neurotic patients and in everything that derives from it. If one of them undergoes psychoanalytic treatment, which makes what is unconscious in him conscious, he will be unable to believe that thoughts are free and will constantly be afraid of expressing evil wishes, as though their expression would lead inevitably to their fulfilment. This behaviour, as well as the superstitions which he practises in ordinary life, reveals his resemblance to the savages who believe they can alter the external world by mere thinking.

Another difficulty might actually be brought forward from psycho-analytic quarters. The earliest moral precepts and restrictions in primitive society have been explained by us as reactions to a deed which gave those who performed it the concept of 'crime'. They felt remorse for the deed and decided that it should never be repeated and that its performance should bring no advantage. This creative sense of guilt still persists among us. We find it operating in an asocial manner in neurotics, and producing new moral precepts and persistent restrictions, as an atonement for crimes that have been committed and as a precaution against the committing of new ones.¹ If, however, we inquire among these neurotics to discover what were the deeds which provoked these reactions, we shall be disappointed. We find no deeds, but only impulses and emotions, set upon evil ends but held back from their achievement. What lie behind the sense of guilt of neurotics are always psychical realities and never factual ones. What characterizes neurotics is that they prefer psychical to factual reality and react just as seriously to thoughts as normal people do to realities.

It is true that psycho-analysis has taken the individual mind as its subject, but in investigating the individual it could not avoid dealing with the emotional basis of the relation of the individual to society. It has found that the social feelings invariably contain an erotic element - an element which, if it is over-emphasized and then repressed, becomes one of the marks of a particular group of mental disorders. Psycho-analysis has recognized that in general the neuroses are asocial in their nature and that they always aim at driving the individual out of society and at replacing the safe monastic seclusion of earlier days by the isolation of illness. The intense feeling of guilt which dominates so many neuroses has been shown to be a social modification of neurotic anxiety.

¹ [1912-1913, 2729]

[1912-1913, 2798]
Melancholia, therefore, borrows some of its features from mourning, and the others from the process of regression from narcissistic object-choice to narcissism. It is on the one hand, like mourning, a reaction to the real loss of a loved object; but over and above this, it is marked by a determinant which is absent in normal mourning or which, if it is present, transforms the latter into pathological mourning. The loss of a love-object is an excellent opportunity for the ambivalence in love-relationships to make itself effective and come into the open. Where there is a disposition to obsessional neurosis the conflict due to ambivalence gives a pathological cast to mourning and forces it to express itself in the form of self-reproaches to the effect that the mourner himself is to blame for the loss of the loved object, i.e. that he has willed it. These obsessional states of depression following upon the death of a loved person show us what the conflict due to ambivalence can achieve by itself when there is no regressive drawing-in of libido as well. In melancholia, the occasions which give rise to the illness extend for the most part beyond the clear case of a loss by death, and include all those situations of being slighted, neglected or disappointed, which can import opposed feelings of love and hate into the relationship or reinforce an already existing ambivalence. This conflict due to ambivalence, which sometimes arises more from real experiences, sometimes more from constitutional factors, must not be overlooked among the preconditions of melancholia. If the love for the object - a love which cannot be given up though the object itself is given up - takes refuge in narcissistic identification, then the hate comes into operation on this substitutive object, abusing it, debasing it, making it suffer and deriving sadistic satisfaction from its suffering. The self-tormenting in melancholia, which is without doubt enjoyable, signifies, just like the corresponding phenomenon in obsessional neurosis, a satisfaction of trends of sadism and hate which relate to an object, and which have been turned round upon the subject's own self in the ways we have been discussing. In both disorders the patients usually still succeed, by the circuitous path of self-punishment, in taking revenge on the original object and in tormenting their loved one through their illness, having resorted to it in order to avoid the need to express their hostility to him openly. After all, the person who has occasioned the patient's emotional disorder, and on whom his illness is centred, is usually to be found in his immediate environment. The melancholic's erotic cathexis in regard to his object has thus undergone a double vicissitude: part of it has regressed to identification, but the other part, under the influence of the conflict due to ambivalence, has been carried back to the stage of sadism which is nearer to that conflict.

[1917e, 3048]

It is a most important fact that some contemporary phantasies of quite another kind came up as well in the patient's memory. The content of these was of boys being chastised and beaten, and especially being beaten on the penis. And from other phantasies, which represented the heir to the throne being shut up in a narrow room and beaten, it was easy to guess for whom it was that the anonymous figures served as whipping-boys. The heir to the throne was evidently he himself; his sadism had therefore turned round in phantasy against himself, and had been converted into masochism. The detail of the sexual organ itself receiving the beating justified the conclusion that a sense of guilt, which related to his masturbation, was already concerned in this transformation.

[1918b, 3517]
The boy's masochistic trends lead on to another point, which I have so far avoided mentioning, because it can only be confirmed by means of the analysis of the subsequent phase of his development. I have already mentioned that after his refusal by his Nanya his libidinal expectation detached itself from her and began to contemplate another person as a sexual object. This person was his father, at that time away from home. He was no doubt led to this choice by a number of convergent factors, including such fortuitous ones as the recollection of the snake being cut to pieces; but above all he was in this way able to renew his first and most primitive object-choice, which, in conformity with a small child's narcissism, had taken place along the path of identification. We have heard already that his father had been his admired model, and that when he was asked what he wanted to be he used to reply: a gentleman like his father. This object of identification of his active current became the sexual object of a passive current in his present anal-sadistic phase. It looks as though his seduction by his sister had forced him into a passive role, and had given him a passive sexual aim. Under the persisting influence of this experience he pursued a path from his sister via his Nanya to his father - from a passive attitude towards women to the same attitude towards men - and had, nevertheless, by this means found a link with his earlier and spontaneous phase of development. His father was now his object once more; in conformity with his higher stage of development, identification was replaced by object-choice; while the transformation of his active attitude into a passive one was the consequence and the record of the seduction which had occurred meanwhile. It would naturally not have been so easy to achieve an active attitude in the sadistic phase towards his all-powerful father. When his father came home in the late summer or autumn the patient's fits of rage and scenes of fury were put to a new use. They had served for active sadistic ends in relation to his Nanya; in relation to his father their purpose was masochistic. By bringing his naughtiness forward he was trying to force punishments and beatings out of his father, and in that way to obtain from him the masochistic sexual satisfaction that he desired. His screaming fits were therefore simply attempts at seduction. In accordance, moreover, with the motives which underlie masochism, this beating would also have satisfied his sense of guilt. He had preserved a memory of how, during one of these scenes of naughtiness, he had redoubled his screams as soon as his father came towards him. His father did not beat him, however, but tried to pacify him by playing ball in front of him with the pillows of his cot.

We have pointed out that this predominance of the life of phantasy and of the illusion born of an unfulfilled wish is the ruling factor in the psychology of neuroses. We have found that what neurotics are guided by is not ordinary objective reality but psychological reality. A hysterical symptom is based upon phantasy instead of upon the repetition of real experience, and the sense of guilt in an obsessional neurosis is based upon the fact of an evil intention which was never carried out. Indeed, just as in dreams and in hypnosis, in the mental operations of a group the function for testing the reality of things falls into the background in comparison with the strength of wishful impulses with their affective cathexis.

An interpretation of the normal, conscious sense of guilt (conscience) presents no difficulties; it is based on the tension between the ego and the ego ideal and is the expression of a condemnation of the ego by its critical agency. The feelings of inferiority so well known in neurotics are presumably not far removed from it. In two very familiar maladies the sense of guilt is over-strongly conscious; in them the ego ideal displays particular severity and often rages against the ego in a cruel fashion. The attitude of the ego ideal in these two conditions, obsessional neurosis and melancholia, presents, alongside of this similarity, differences that are no less significant.
In certain forms of obsessional neurosis the sense of guilt is over-noisy but cannot justify itself to the ego. Consequently the patient's ego rebels against the imputation of guilt and seeks the physician's support in repudiating it. It would be folly to acquiesce in this, for to do so would have no effect. Analysis eventually shows that the super-ego is being influenced by processes that have remained unknown to the ego. It is possible to discover the repressed impulses which are really at the bottom of the sense of guilt. Thus in this case the super-ego knew more than the ego about the unconscious id.

[1923b, 3985]

In melancholia the impression that the super-ego has obtained a hold upon consciousness is even stronger. But here the ego ventures no objection; it admits its guilt and submits to the punishment. We understand the difference. In obsessional neurosis what were in question were objectionable impulses which remained outside the ego, while in melancholic the object to which the super-ego's wrath applies has been taken into the ego through identification.

[1923b, 3985]

It is certainly not clear why the sense of guilt reaches such an extraordinary strength in these two neurotic disorders; but the main problem presented in this state of affairs lies in another direction. We shall postpone discussion of it until we have dealt with the other cases in which the sense of guilt remains unconscious.

[1923b, 3985]

The reproaches of conscience in certain forms of obsessional neurosis are as distressing and tormenting, but here the situation is less perspicuous. It is noteworthy that the obsessional neurotic, in contrast to the melancholic, never in fact takes the step of self-destruction; it is as though he were immune against the danger of suicide, and he is far better protected from it than the hysteric. We can see that what guarantees the safety of the ego is the fact that the object has been retained. In obsessional neurosis it has become possible, through a regression to the pregenital organization, for the love-impulses to transform themselves into impulses of aggression against the object. Here again the instinct of destruction has been set free and it seeks to destroy the object, or at least it appears to have that intention. These purposes have not been adopted by the ego and it struggles against them with reaction-formations and precautionary measures; they remain in the id. The super-ego, however, behaves as if the ego were responsible for them and shows at the same time by the seriousness with which it chastises these destructive intentions that they are no mere semblance evoked by regression but an actual substitution of hate for love. Helpless in both directions, the ego defends itself vainly, alike against the instigations of the murderous id and against the reproaches of the punishing conscience. It succeeds in holding in check at least the most brutal actions of both sides; the first outcome is interminable self-torment, and eventually there follows a systematic torturing of the object, in so far as it is within reach.

[1923b, 3987]
A good deal of what has been said may be objected to on the ground that the unpleasant obsessive ideas are themselves quite conscious. But there is no doubt that before becoming conscious they have been though the process of repression. In most of them the actual wording of the aggressive instinctual impulse is altogether unknown to the ego, and it requires a good deal of analytic work to make it conscious. What does penetrate into consciousness is usually only a distorted substitute which is either of a vague, dream-like and indeterminate nature or so travestied as to be unrecognizable. Even where repression has not encroached upon the content of the aggressive impulse it has certainly got rid of its accompanying affective character.

As a result, the aggressiveness appears to the ego not to be an impulsion but, as the patients themselves say, merely a 'thought' which awakens no feeling. But the remarkable thing is that this is not the case. What happens is that the affect left out when the obsessional idea is perceived appears in a different place. The super-ego behaves as though repression had not occurred and as though it knew the real wording and full affective character of the aggressive impulse, and it treats the ego accordingly. The ego which, on the one hand, knows that it is innocent is obliged, on the other hand, to be aware of a sense of guilt and to carry a responsibility which it cannot account for. This state of affairs is, however, not so puzzling as it would seem at first sight. The behaviour of the super-ego is perfectly intelligible, and the contradiction in the ego merely shows that it has shut out the id by means of repression while remaining fully accessible to the influence of the super-ego. If it is asked why the ego does not also attempt to withdraw from the tormenting criticism of the super-ego, the answer is that it does manage to do so in a great number of instances. There are obsessional neuroses in which no sense of guilt whatever is present. In them, as far as can be seen, the ego has avoided becoming aware of it by instituting a fresh set of symptoms, penances or restrictions of a self-punishing kind. These symptoms, however, represent at the same time a satisfaction of masochistic impulses which, in their turn, have been reinforced by regression.

A patient, then, may be suffering from fluctuations in his moods which he cannot control, or from a sense of despondency by which his energy feels paralysed because he thinks he is incapable of doing anything properly, or from a nervous embarrassment among strangers. He may perceive, without understanding the reason for it, that he has difficulties in carrying out his professional work, or indeed any comparatively important decision or any undertaking. He may one day have suffered from a distressing attack - unknown in its origin - of feelings of anxiety, and since then have been unable, without a struggle, to walk along the street alone, or to travel by train; he may perhaps have had to give up both entirely. Or, a very remarkable thing, his thoughts may go their own way and refuse to be directed by his will. They pursue problems that are quite indifferent to him, but from which he cannot get free. Quite ludicrous tasks, too, are imposed on him, such as counting up the windows on the fronts of houses. And when he has performed simple actions such as posting a letter or turning off a gas-jet, he finds himself a moment later doubting whether he has really done so. This may be no more than an annoyance and a nuisance. But his state becomes intolerable if he suddenly finds he is unable to fend off the idea that he has pushed a child under the wheels of a car or has thrown a stranger off the bridge into the water, or if he has to ask himself whether he is not the murderer whom the police are looking for in connection with a crime that was discovered that day. It is obvious nonsense, as he himself knows; he has never done any harm to anyone; but if he were really the murderer who is being looked for, his feeling - his sense of guilt - could not be stronger.
In the first place, I suspect that the reader has the impression that our discussions on the sense of guilt disrupt the framework of this essay: that they take up too much space, so that the rest of its subject-matter, with which they are not always closely connected, is pushed to one side. This may have spoilt the structure of my paper; but it corresponds faithfully to my intention to represent the sense of guilt as the most important problem in the development of civilization and to show that the price we pay for our advance in civilization is a loss of happiness through the heightening of the sense of guilt. Anything that still sounds strange about this statement, which is the final conclusion of our investigation, can probably be traced to the quite peculiar relationship - as yet completely unexplained - which the sense of guilt has to our consciousness. In the common case of remorse, which we regard as normal, this feeling makes itself clearly enough perceptible to consciousness. Indeed, we are accustomed to speak of a 'consciousness of guilt' instead of a 'sense of guilt'. Our study of the neuroses, to which, after all we owe the most valuable pointers to an understanding of normal conditions, brings us up against some contradictions. In one of those affections, obsessional neurosis, the sense of guilt makes itself noisily heard in consciousness; it dominates the clinical picture and the patient's life as well, and it hardly allows anything else to appear alongside of it. But in most other cases and forms of neurosis it remains completely unconscious, without on that account producing any less important effects. Our patients do not believe us when we attribute an 'unconscious sense of guilt' to them. In order to make ourselves at all intelligible to them, we tell them of an unconscious need for punishment, in which the sense of guilt finds expression. But its connection with a particular form of neurosis must not be over-estimated. Even in obsessional neurosis there are types of patients who are not aware of their sense of guilt, or who only feel it as a tormenting uneasiness, a kind of anxiety, if they are prevented from carrying out certain actions. It ought to be possible eventually to understand these things; but as yet we cannot. Here perhaps we may be glad to have it pointed out that the sense of guilt is at bottom nothing else but a topographical variety of anxiety; in its later phases it coincides completely with fear of the super-ego. And the relations of anxiety to consciousness exhibit the same extraordinary variations. Anxiety is always present somewhere or other behind every symptom; but at one time it takes noisy possession of the whole of consciousness, while at another it conceals itself so completely that we are obliged to speak of unconscious anxiety or, if we want to have a clearer psychological conscience, since anxiety is in the first instance simply a feeling, of possibilities of anxiety. Consequently it is very conceivable that the sense of guilt produced by civilization is not perceived as such either, and remains to a large extent unconscious, or appears as a sort of malaise, a dissatisfaction, for which people seek other motivations. Religions, at any rate, have never overlooked the part played in civilization by a sense of guilt. Furthermore - a point which I failed to appreciate elsewhere² - they claim to redeem mankind from this sense of guilt, which they call sin. From the manner in which, in Christianity, this redemption is achieved - by the sacrificial death of a single person, who in this manner takes upon himself a guilt that is common to everyone - we have been able to infer what the first occasion may have been on which this primal guilt, which was also the beginning of civilization, was acquired.³

[1930a, 4523]
Nor will it do any harm if we once more review the contradictions which have for a while perplexed us during our enquiry. Thus, at one point the sense of guilt was the consequence of acts of aggression that had been abstained from; but at another point - and precisely at its historical beginning, the killing of the father - it was the consequence of an act of aggression that had been carried out. But a way out of this difficulty was found. For the institution of the internal authority, the super-ego, altered the situation radically. Before this, the sense of guilt coincided with remorse. (We may remark, incidentally, that the term 'remorse' should be reserved for the reaction after an act of aggression has actually been carried out.) After this, owing to the omniscience of the super-ego, the difference between an aggression intended and an aggression carried out lost its force. Henceforward a sense of guilt could be produced not only by an act of violence that is actually carried out (as all the world knows), but also by one that is merely intended (as psycho-analysis has discovered). Irrespectively of this alteration in the psychological situation, the conflict arising from ambivalence - the conflict between the two primal instincts - leaves the same result behind. We are tempted to look here for the solution of the problem of the varying relation in which the sense of guilt stands to consciousness. It might be thought that a sense of guilt arising from remorse for an evil deed must always be conscious, whereas a sense of guilt arising from the perception of an evil impulse may remain unconscious. But the answer is not so simple as that. Obsessional neurosis speaks energetically against it.

[1930a, 4525]
Other symptoms of my case of paranoia are to be described as symptoms of the return of the repressed, and they, too, like those of obsessional neurosis, bear the traces of the compromise which alone allows them to enter consciousness. Such are, for instance, my patient's delusional idea of being watched while she was undressing, her visual hallucinations, her hallucinations of sensation and her hearing of voices. In the delusional idea which I have just mentioned there is a mnemonic content which is almost unaltered and has only been made indefinite through omission. The return of the repressed in visual images approaches the character of hysteria rather than of obsessional neurosis; but hysteria is in the habit of repeating its mnemonic symbols without modification, whereas mnemonic hallucinations in paranoia undergo a distortion similar to that in obsessional neurosis: an analogous modern image takes the place of the repressed one. (E.g., the abdomen of an adult woman appears instead of a child's, and an abdomen on which the hairs are especially distinct, because they were absent in the original impression.) A thing which is quite peculiar to paranoia and on which no further light can be shed by this comparison, is that the repressed self-reproaches return in the form of thoughts spoken aloud. In the course of this process, they are obliged to submit to twofold distortion: they are subjected to a censorship, which leads to their being replaced by other, associated, thoughts or to their being concealed by an indefinite mode of expression, and they are referred to recent experiences which are no more than analogous to the old ones.

¹ He said 'idea' - the stronger and more significant term 'wish', or rather 'fear', having evidently been censored. Unfortunately I am not able to reproduce the peculiar indeterminateness of all his remarks.

² Secondly, in the course of the analytic examination of a case history, one becomes convinced that if a number of obsessions succeed one another they are often - even though their wording is not identical - ultimately one and the same. The obsession may have been successfully shaken off on its first appearance, but it comes back a second time in a distorted form and without being recognized, and may then perhaps be able to hold its own in the defensive struggle more effectively, precisely because of its distortion. But the original form is the correct one, and often displays its meaning quite openly. When we have at great pains elucidated an unintelligible obsessional idea, it often happens that the patient informs us that just such a notion, wish, or temptation as the one we have constructed did in fact make its appearance on one occasion before the obsessional idea had arisen, but that it did not persist. It would unfortunately involve us in too lengthy a digression if we were to give instances of this from the history of our present patient.

What is officially described as an 'obsessional idea' exhibits, therefore, in its distortion from its original wording, traces of the primary defensive struggle. Its distortion enables it to persist, since conscious thought is thus compelled to misapprehend it, just as though it were a dream; for dreams also are a product of compromise and distortion, and are also misapprehended by waking thought.
I have already asserted that obsessional thoughts have undergone a distortion similar to that undergone by dream-thoughts before they become the manifest content of a dream. The technique of this distortion may therefore be of interest to us, and there should be nothing to prevent our exhibiting its various modes by means of a series of obsessions which have been translated and made clear. But here again the conditions governing the publication of this case make it impossible for me to give more than a few specimens. Not all of the patient's obsessions were so complicated in their structure and so difficult to solve as the great rat idea. In some of the others a very simple technique was employed - namely, that of distortion by omission or ellipsis. This technique is pre-eminently applicable to jokes, but in our present case, too, it did useful work as a means of protecting things from being understood.

For instance, one of the patient's oldest and favourite obsessions (which corresponded to an admonition or warning) ran as follows: 'If I marry the lady, some misfortune will befall my father (in the next world). If we insert the intermediate steps, which had been skipped but were known to us from the analysis, we get the following train of thought: 'If my father were alive, he would be as furious over my design of marrying the lady as he was in the scene in my childhood; so that I should fly into a rage with him once more and wish him every possible evil; and thanks to the omnipotence of my wishes¹ these evils would be bound to come upon him.'

The obsessive thought which has forced its way into consciousness with such excessive violence has next to be secured against the efforts made by conscious thought to resolve it. As we already know, this protection is afforded by the distortion which the obsessive thought has undergone before becoming conscious. But this is not the only means employed. In addition, each separate obsessional idea is almost invariably removed from the situation in which it originated and in which, in spite of its distortion, it would be most easily comprehensible. With this end in view, in the first place an interval of time is inserted between the pathogenic situation and the obsession that arises from it, so as to lead astray any conscious investigation of its causal connections, and in the second place the content of the obsession is taken out of its particular setting by being generalized. Our patient's 'obsession for understanding' is an example of this (p. 2150). But perhaps a better one is afforded by another patient. This was a woman who prohibited herself from wearing any sort of personal adornment, though the exciting cause of the prohibition related only to one particular piece of jewellery: she had envied her mother the possession of it and had had hopes that one day she would inherit it. Finally, if we care to distinguish verbal distortion from distortion of content, there is yet another means by which the obsession is protected against conscious attempts at solution. And that is the choice of an indefinite or ambiguous wording. After being misunderstood, the wording may find its way into the patient's 'deliria', and whatever further processes of development or substitution his obsession undergoes will then be based upon the misunderstanding and not upon the proper sense of the text. Observation will show, however, that the deliria constantly tend to form new connections with that part of the matter and wording of the obsession which is not present in consciousness.
Besides these compromise symptoms, which signify the return of the repressed and consequently a collapse of the defence that had been originally achieved, the obsessional neurosis constructs a set of further symptoms, whose origin is quite different. For the ego seeks to fend off the derivatives of the initially repressed memory, and in this defensive struggle it creates symptoms which might be classed together as 'secondary defence'. These are all of them 'protective measures', which have already done good service in the fight against obsessional ideas and obsessional affects. If these aids in the defensive struggle genuinely succeed in once more repressing the symptoms of the return which have forced themselves on the ego, then the obsession is transferred to the protective measures themselves and creates a third form of 'obsessional neurosis'- obsessional actions. These actions are never primary; they never contain anything but a defence - never an aggression. A psychical analysis of them shows that, in spite of their peculiarity, they can always be fully explained by being traced back to the obsessional memories which they are fighting against.¹

Secondary defence against the obsessional ideas may be effected by a forcible diversion on to other thoughts with a content as contrary as possible. This is why obsessional brooding, if it succeeds, regularly deals with abstract and suprasensual things; because the ideas that have been repressed are always concerned with sensuality. Or else the patient tries to make himself master of each of his obsessional ideas singly by logical work and by having recourse to his conscious memories. This leads to obsessional thinking, to a compulsion to test things and to doubting mania. The advantage which perception has over memory in such tests at first causes the patient, and later compels him, to collect and store up all the objects with which he has come into contact. Secondary defence against obsessional affects leads to a still wider set of protective measures which are capable of being transformed into obsessional acts. These may be grouped according to their purpose: penitential measures (burdensome ceremonials, the observation of numbers), precautionary measures (all sorts of phobias, superstition, pedantry, increase of the primary symptom of conscientiousness); measures to do with fear of betrayal (collecting scraps of paper, seclusiveness), or to ensure numbing (dipsomania). Among these obsessional acts and obsessional impulses, phobias, since they circumscribe the patient's existence, play the greatest part.

The third group of symptoms that are found in obsessional neurosis, the symptoms of secondary defence, cannot be present as such in paranoia, because no defence can avail against the returning symptoms to which, as we know, belief is attached. In place of this, we find in paranoia another source for the formation of symptoms. The delusional ideas which have arrived in consciousness by means of a compromise (the symptoms of the return) make demands on the thought-activity of the ego until they can be accepted without contradiction. Since they are not themselves open to influence, the ego must adapt itself to them; and thus what corresponds here to the symptoms of secondary defence in obsessional neurosis is a combinatory delusional formation - interpretative delusions which end in an alteration of the ego. In this respect, the case under discussion was not complete; at that time my patient did not as yet exhibit any signs of the attempts at interpretation which appeared later. But I have no doubt that if we apply psycho-analysis to this stage of paranoia as well, we shall be able to arrive at a further important result. It should then turn out that the so-called weakness of memory of paranoics is also a tendentious one - that is to say, that it is based on repression and serves the ends of repression. A subsequent repression and replacement takes place of memories which are not in the least pathogenic, but which are in contradiction to the alteration of the ego which the symptoms of the return of the repressed so insistently demand.

[1896b, 392]

[1896b, 393]

[1896b, 404]
We find, accordingly: an erotic instinct and a revolt against it; a wish which has not yet become compulsive and, struggling against it, a fear which is already compulsive; a distressing affect and an impulsion towards the performance of defensive acts. The inventory of the neurosis has reached its full muster. Indeed, something more is present, namely, a kind of delusion or delirium with the strange content that his parents knew his thoughts because he spoke them out loud without his hearing himself do it. We shall not go far astray if we suppose that in making this attempt at an explanation the child had some inkling of those remarkable mental processes which we describe as unconscious and which we cannot dispense with if we are to throw any scientific light upon this obscure subject. 'I speak my thoughts out loud, without hearing them' sounds like a projection into the external world of our own hypothesis that he had thoughts without knowing anything about them; it sounds like an endopsychic perception of what has been repressed.

He broke off his story in order to assure me that these thoughts were entirely foreign and repugnant to him, and to tell me that everything which had followed in their train had passed through his mind with the most extraordinary rapidity. Simultaneously with the idea there always appeared a 'sanction', that is to say, the defensive measure which he was obliged to adopt in order to prevent the phantasy from being fulfilled. When the captain had spoken of this ghastly punishment, he went on, and these ideas had come into his head, by employing his usual formulas (a 'but' accompanied by a gesture of repudiation, and the phrase 'whatever are you thinking of?') he had just succeeded in warding off both of them.

The other compulsive commands that have been mentioned put us upon the track of this other element. His obsession for protecting can only have been a reaction - as an expression of remorse and penitence - to a contrary, that is a hostile, impulse which he must have felt towards his lady before they had their éclaircissement. His obsession for counting during the thunderstorm can be interpreted, with the help of some material which he produced, as having been a defensive measure against fears that some one was in danger of death. The analysis of the obsessions which we first considered has already warned us to regard our patient's hostile impulses as particularly violent and as being in the nature of senseless rage; and now we find that even after their reconciliation his rage against the lady continued to play a part in the formation of his obsessions. His doubting mania as to whether he had heard correctly was an expression of the doubt still lurking in his mind, whether he had really understood his lady correctly this time and whether he had been justified in taking her words as a proof of her affection for him. The doubt implied in his obsession for understanding was a doubt of her love. A battle between love and hate was raging in the lover's breast, and the object of both these feelings was one and the same person. The battle was represented in a plastic form by his compulsive and symbolic act of removing the stone from the road along which she was to drive, and then of undoing this deed of love by replacing the stone where it had lain, so that her carriage might come to grief against it and she herself be hurt. We shall not be forming a correct judgement of this second part of the compulsive act if we take it at its face value as having merely been a critical repudiation of a pathological action. The fact that it was accompanied by a sense of compulsion betrays it as having itself been a part of the pathological action, though a part which was determined by a motive contrary to that which produced the first part.
It must be confessed, moreover, that even the phenomenology of obsessional thinking has not yet had sufficient attention paid to it. During the secondary defensive struggle, which the patient carries on against the 'obsessional ideas' that have forced their way into his consciousness, psychical structures make their appearance which deserve to be given a special name. (Such, for example, were the sequences of thoughts that occupied our patient's mind on his journey back from the manoeuvres.) They are not purely reasonable considerations arising in opposition to the obsessional thoughts, but, as it were, hybrids between the two species of thinking; they accept certain of the premises of the obsession they are combating, and thus, while using the weapons of reason, are established upon a basis of pathological thought. I think such structures as these deserve to be given the name of 'deliria'. To make the distinction clear, I will give an instance, which should be inserted into its proper context in the patient's case history. I have already described the crazy conduct to which he gave way at one time when he was preparing for an examination - how, after working till far into the night, he used to go and open the front door to his father's ghost, and then look at his genitals in the looking-glass (p. 2160). He tried to bring himself to his senses by asking himself what his father would say to it all if he were really still alive. But the argument had no effect so long as it was put forward in this rational shape. The spectre was not laid until he had transformed the same idea into a 'delirious' threat to the effect that if he ever went through this nonsense again some evil would befall his father in the next world.

The distinction between a primary and a secondary defensive struggle is no doubt well founded, but we find its value unexpectedly diminished when we discover that the patients themselves do not know the wording of their own obsessional ideas. This may sound paradoxical, but it is perfectly good sense. During the progress of a psycho-analysis it is not only the patient who plucks up courage, but his disease as well; it grows bold enough to speak more plainly than before. To drop the metaphor, what happens is that the patient, who his hitherto turned his eyes away in terror from his own pathological productions, begins to attend to them and obtains a clearer and more detailed view of them.¹

There are, besides this, two special ways in which a more precise knowledge of obsessional structures can be gained. In the first place, experience shows that an obsessional command (or whatever it may be), which in waking life is known only in a truncated and distorted form, like a mutilated telegraph message, may have its actual text brought to light in a dream. Such texts appear in dreams in the shape of speeches, and are thus an exception to the rule that speeches in dreams are derived from speeches in real life.² Secondly, in the course of the analytic examination of a case history, one becomes convinced that if a number of obsessions succeed one another they are often - even though their wording is not identical - ultimately one and the same. The obsession may have been successfully shaken off on its first appearance, but it comes back a second time in a distorted form and without being recognized, and may then perhaps be able to hold its own in the defensive struggle more effectively, precisely because of its distortion. But the original form is the correct one, and often displays its meaning quite openly. When we have at great pains elucidated an unintelligible obsessional idea, it often happens that the patient informs us that just such a notion, wish, or temptation as the one we have constructed did in fact make its appearance on one occasion before the obsessional idea had arisen, but that it did not persist. It would unfortunately involve us in too lengthy a digression if we were to give instances of this from the history of our present patient.

¹ [1909d, 2173]
² [1909d, 2174]
What is officially described as an 'obsessional idea' exhibits, therefore, in its distortion from its original wording, traces of the primary defensive struggle. Its distortion enables it to persist, since conscious thought is thus compelled to misapprehend it, just as though it were a dream; for dreams also are a product of compromise and distortion, and are also misapprehended by waking thought.

[1909d, 2175]

This misapprehension on the part of consciousness can be seen at work not only in reference to the obsessional ideas themselves, but also in reference to the products of the secondary defensive struggle, such, for instance, as the protective formulas. I can produce two good examples of this. Our patient used to employ as a defensive formula a rapidly pronounced 'aber' ['but'] accompanied by a gesture of repudiation. He told me on one occasion that this formula had become altered recently; he now no longer said 'áber' but 'abér'. When he was asked to give the reason for this new departure, he declared that the mute 'e' of the second syllable gave him no sense of security against the intrusion, which he so much dreaded, of some foreign and contradictory element, and that he had therefore decided to accent the 'e'. This explanation (an excellent sample of the obsessional neurotic style) was, however, clearly inadequate; the most that it could claim to be was a rationalization. The truth was that 'abér' was an approximation towards the similar-sounding 'abwehr' ['defence'], a term which he had learnt in the course of our theoretical discussions of psycho-analysis. He had thus put the treatment to an illegitimate and 'delirious' use in order to strengthen a defensive formula. Another time he told me about his principal magic word, which was an apotropaic against every evil; he had put it together out of the initial letters of the most powerfully beneficent of his prayers and had clapped on an 'amen' at the end of it. I cannot reproduce the word itself, for reasons which will become apparent immediately. For, when he told me, I could not help noticing that the word was in fact an anagram of the name of his lady. Her name contained an 's', and this he had put last, that is, immediately before the 'amen' at the end. We may say, therefore, that by this process he had brought his 'Samen' ['semen'] into contact with the woman he loved; in imagination, that is to say, he had masturbated with her. He himself, however, had never noticed this very obvious connection; his defensive forces had allowed themselves to be fooled by the repressed ones. This is also a good example of the rule that in time the thing which is meant to be warded off invariably finds its way into the very means which is being used for warding it off.

[1909d, 2175]
It is this same doubt that leads the patient to uncertainty about his protective measures, and to his continual repetition of them in order to banish that uncertainty; and it is this doubt, too, that eventually brings it about that the patient's protective acts themselves become as impossible to carry out as his original inhibited decision in connection with his love. At the beginning of my investigations I was led to assume another and more general origin for the uncertainty of obsessional neurotics and one which seemed to be nearer the normal. If, for instance, while I am writing a letter some one interrupts me with questions, I afterwards feel a quite justifiable uncertainty as to what I may not have written under the influence of the disturbance, and, to make sure, I am obliged to read the letter over after I have finished it. In the same way I might suppose that the uncertainty of obsessional neurotics, when they are praying, for instance, is due to unconscious phantasies constantly mingling with their prayers and disturbing them. This hypothesis is correct, but it may be easily reconciled with what I have just said. It is true that the patient's uncertainty whether he has carried through a protective measure is due to the disturbing effect of unconscious phantasies; but the content of these phantasies is precisely the contrary impulse - which it was the very aim of the prayer to ward off. This became clearly evident in our patient on one occasion, for the disturbing element did not remain unconscious but made its appearance openly. The words he wanted to use in his prayer were, 'May God protect her', but a hostile 'not' suddenly darted out of his unconscious and inserted itself into the sentence; and he understood that this was an attempt at a curse (p. 2152). If the 'not' had remained mute, he would have found himself in a state of uncertainty and would have kept on prolonging his prayers indefinitely. But since it became articulate he eventually gave up praying. Before doing so, however, he, like other obsessional patients, tried every kind of method for preventing the opposite feeling from insinuating itself. He shortened his prayers, for instance, or said them more rapidly. And similarly other patients will endeavour to 'isolate' all such protective acts from other things. But none of these technical procedures are of any avail in the long run. If the impulse of love achieves any success by displacing itself on to some trivial act, the impulse of hostility will very soon follow it on to its new ground and once more proceed to undo all that it has done.

There is also another path open to us. We can start an inquiry as to whether some of the hypotheses which we have carried over from neuroses to taboo or some of the results to which that procedure has led us may not be directly verifiable in the phenomena of taboo. But we must decide what we are to look for. Our assertion that taboo originated in a primaeval prohibition imposed at one time or other by some external authority is obviously incapable of demonstration. What we shall rather endeavour to confirm, therefore, are the psychological determinants of taboo, which we have learnt to know from obsessional neurosis. How did we arrive at our knowledge of these psychological factors in the case of the neurosis? Through the analytical study of its symptoms, and particularly of obsessional acts, defensive measures and obsessional commands. We found that they showed every sign of being derived from ambivalent impulses, either corresponding simultaneously to both a wish and a counter-wish or operating predominantly on behalf of one of the two opposing trends. If, now, we could succeed in demonstrating that ambivalence, that is, the dominance of opposing trends, is also to be found in the observances of taboo, or if we could point to some of them which, like obsessional acts, give simultaneous expression to both currents, we should have established the psychological agreement between taboo and obsessional neurosis in what is perhaps their most important feature.

[1909d, 2189]

[1912-1913, 2683]
This, then, is what I wanted to tell you about the formation of symptoms in the neuroses. But I must not fail to lay emphasis expressly once again on the fact that everything I have said here applies only to the formation of symptoms in hysteria. Even in obsessional neurosis there is much - apart from fundamentals, which remain unaltered - that will be found different. The anticathexes opposing the demands of the instincts (which we have already spoken of in the case of hysteria as well) become prominent in obsessional neurosis and dominate the clinical picture in the form of what are known as ‘reaction formations’. We discover similar and even more far-reaching divergences in the other neuroses, where our researches into the mechanisms of symptom-formation are not yet concluded at any point.

[1916-1917, 3430]

*The Theory of Repression.* - These theoretical considerations, taken together with the immediate impressions derived from analytic work, lead to a view of the neuroses which may be described in the roughest outline as follows. The neuroses are the expression of conflicts between the ego and such of the sexual impulses as seem to the ego incompatible with its integrity or with its ethical standards. Since these impulses are not *ego-syntonic*, the ego has *repressed* them: that is to say, it has withdrawn its interest from them and has shut them off from becoming conscious as well as from obtaining satisfaction by motor discharge. If in the course of analytic work one attempts to make these repressed impulses conscious, one becomes aware of the repressive forces in the form of *resistance*. But the achievement of repression fails particularly readily in the case of the sexual instincts. Their dammed-up libido finds other ways out from the unconscious: for it *regresses* to earlier phases of development and earlier attitudes towards objects, and, at weak points in the libidinal development where there are infantile fixations, it breaks through into consciousness and obtains discharge. What results is a *symptom* and consequently in its essence a substitutive sexual satisfaction. Nevertheless the symptom cannot entirely escape from the repressive forces of the ego and must therefore submit to modifications and displacements exactly as happens with dreams - by means of which its characteristic of being a sexual satisfaction becomes unrecognizable. Consequently symptoms are in the nature of compromises between the repressed sexual instincts and the repressing ego-instincts; they represent a wish-fulfilment for both partners to the conflict simultaneously, but one which is incomplete for each of them. This is quite strictly true of the symptoms of hysteria, while in the symptoms of obsessional neurosis there is often a stronger emphasis upon the side of the repressing function owing to the erection of reaction-formations, which are assurances against sexual satisfaction.

[1923a, 3923]

Let us turn to the obsessional neuroses in the hope of learning more about the formation of symptoms. The symptoms belonging to this neurosis fall, in general, into two groups, each having an opposite trend. They are either prohibitions, precautions and expiations - that is, negative in character - or they are, on the contrary, substitutive satisfactions which often appear in symbolic disguise. The negative, defensive group of symptoms is the older of the two; but as illness is prolonged, the satisfactions, which scoff at all defensive measures, gain the upper hand. The symptom-formation scores a triumph if it succeeds in combining the prohibition with satisfaction so that what was originally a defensive command or prohibition acquires the significance of a satisfaction as well; and in order to achieve this end it will often make use of the most ingenious associative paths. Such an achievement demonstrates the tendency of the ego to synthesize, which we have already observed. In extreme cases the patient manages to make most of his symptoms acquire, in addition to their original meaning, a directly contrary one. This is a tribute to the power of ambivalence, which, for some unknown reason, plays such a large part in obsessional neuroses. In the crudest instance the symptom is diphasic: an action which carries out a certain injunction is immediately succeeded by another action which stops or undoes the first one even if it does not go quite so far as to carry out its opposite.

[1926d, 4271]
Let us first consider the relation of children to their brothers and sisters. I do not know why we presuppose that that relation must be a loving one; for instances of hostility between adult brothers and sisters force themselves upon everyone's experience and we can often establish the fact that the disunity originated in childhood or has always existed. But it is further true that a great many adults, who are on affectionate terms with their brothers and sisters and are ready to stand by them to-day, passed their childhood on almost unbroken terms of enmity with them. The elder child ill-treats the younger, maligns him and robs him of his toys; while the younger is consumed with impotent rage against the elder, envies and fears him, or meets his oppressor with the first stirrings of a love of liberty and a sense of justice. Their parents complain that the children do not get on with one another, but cannot discover why. It is easy to see that the character of even a good child is not what we should wish to find it in an adult. Children are completely egoistic; they feel their needs intensely and strive ruthlessly to satisfy them - especially as against the rivals, other children, and first and foremost as against their brothers and sisters. But we do not on that account call a child 'bad', we call him 'naughty'; he is no more answerable for his evil deeds in our judgement than in the eyes of the law. And it is right that this should be so; for we may expect that, before the end of the period which we count as childhood, altruistic impulses and morality will awaken in the little egoist and (to use Meynert's terms) a secondary ego will overlay and inhibit the primary one. It is true, no doubt, that morality does not set in simultaneously all along the line and that the length of non-moral childhood varies in different individuals. If this morality fails to develop, we like to talk of 'degeneracy', though what in fact faces us is an inhibition in development. After the primary character has already been overlay by later development, it can still be laid bare again, at all events in part, in cases of hysterical illness. There is a really striking resemblance between what is known as the hysterical character and that of a naughty child. Obsessional neurosis, on the contrary, corresponds to a super-morality imposed as a reinforcing weight upon fresh stirrings of the primary character.

[1900a, 729]

Now what is one to do in the face of a supervalent thought like this, after one has heard what its conscious grounds are and listened to the ineffectual protests made against it? Reflection will suggest that this excessively intense train of thought must owe its reinforcement to the unconscious. It cannot be resolved by any effort of thought, either because it itself reaches with its root down into unconscious, repressed material, or because another unconscious thought lies concealed behind it. In the latter case, the concealed thought is usually the direct contrary of the supervalent one. Contrary thoughts are always closely connected with each other and are often paired off in such a way that the one thought is excessively intensely conscious while its counterpart is repressed and unconscious. This relation between the two thoughts is an effect of the process of repression. For repression is often achieved by means of an excessive reinforcement of the thought contrary to the one which is to be repressed. This process I call reactive reinforcement, and the thought which asserts itself with excessive intensity in consciousness and (in the same way as a prejudice) cannot be removed I call a reactive thought. The two thoughts then act towards each other much like the two needles of an astatic galvanometer. The reactive thought keeps the objectionable one under repression by means of a certain surplus of intensity; but for that reason it itself is 'damped' and proof against conscious efforts of thought. So that the way to deprive the excessively intense thought of its reinforcement is by bringing its repressed contrary into consciousness.

[1905e, 1391]
A deeper insight into the mechanism of obsessional neurosis is gained if we take into account the primary fact which lies at the bottom of it. This is always the repression of an instinctual impulse (a component of the sexual instinct) which was present in the subject's constitution and which was allowed to find expression for a while during his childhood but later succumbed to suppression. In the course of the repression of this instinct a special conscientiousness is created which is directed against the instinct's aims; but this psychical reaction-formation feels insecure and constantly threatened by the instinct which is lurking in the unconscious. The influence of the repressed instinct is felt as a temptation, and during the process of repression itself anxiety is generated, which gains control over the future in the form of expectant anxiety. The process of repression which leads to obsessional neurosis must be considered as one which is only partly successful and which increasingly threatens to fail. It may thus be compared to an unending conflict; fresh psychical efforts are continually required to counterbalance the forward pressure of the instinct. Thus the ceremonial and obsessive actions arise partly as a defence against the temptation and partly as a protection against the ill which is expected. Against the temptation the protective measures seem soon to become inadequate; then the prohibitions come into play, with the purpose of keeping at a distance situations that give rise to temptation. Prohibitions take the place of obsessive actions, it will be seen, just as a phobia is designed to avert a hysterical attack. Again, a ceremonial represents the sum of the conditions subject to which something that is not yet absolutely forbidden is permitted, just as the Church's marriage ceremony signifies for the believer a sanctioning of sexual enjoyment which would otherwise be sinful. A further characteristic of obsessional neurosis, as of all similar affections, is that its manifestations (its symptoms, including the obsessive actions) fulfil the condition of being a compromise between the warring forces of the mind. They thus always reproduce something of the pleasure which they are designed to prevent; they serve the repressed instinct no less than the agencies which are repressing it. As the illness progresses, indeed, actions which were originally mostly concerned with maintaining the defence come to approximate more and more to the proscribed actions through which the instinct was able to find expression in childhood.

[1907b, 1907]

'I think I will begin to-day with the experience which was the immediate occasion of my coming to you. It was in August, during the manoeuvres in ---. I had been suffering before, and tormenting myself with all kinds of obsessional thoughts, but they had quickly passed off during the manoeuvres. I was keen to show the regular officers that people like me had not only learnt a good deal but could stand a good deal too. One day we started from --- on a short march. During a halt I lost my pince-nez, and, although I could easily have found them, I did not want to delay our start, so I gave them up. But I wired to my opticians in Vienna to send me another pair by the next post. During that same halt I sat between two officers, one of whom, a captain with a Czech name, was to be of no small importance to me. I had a kind of dread of him, for he was obviously fond of cruelty. I do not say he was a bad man, but at the officers' mess he had repeatedly defended the introduction of corporal punishment, so that I had been obliged to disagree with him very sharply. Well, during this halt we got into conversation, and the captain told me he had read of a specially horrible punishment used in the East . . .'  

[1909d, 2135]
At the next session he began by saying that he must tell me an event in his childhood. From
the age of seven, as he had already told me, he had had a fear that his parents guessed his
thoughts, and this fear had in fact persisted all through his life. When he was twelve years old
he had been in love with a little girl, the sister of a friend of his. (In answer to a question he said
that his love had not been sensual; he had not wanted to see her naked for she was too small.)
But she had not shown him as much affection as he had desired. And thereupon the idea had
come to him that she would be kind to him if some misfortune were to befall him; and as an
instance of such a misfortune his father's death had forced itself upon his mind. He had at once
rejected the idea with energy. And even now he could not admit the possibility that what had
arisen in this way could have been a 'wish'; it had clearly been no more than a 'train of thought'¹
- By way of objection I asked him why, if it had not been a wish, he had repudiated it. - Merely,
he replied, on account of the content of the idea, the notion that his father might die. - I
reminded him that he was treating the phrase as though it were one that involved lèse-majesté; it
was well known, of course, that it was equally punishable to say 'The Emperor is an ass' or to
disguise the forbidden words by saying 'If any one says, etc., . . . then he will have me to reckon
with.' I added that I could easily insert the idea which he had so energetically repudiated into a
context which would exclude the possibility of any such repudiation: for instance, 'If my father
dies, I shall kill myself upon his grave.' - He was shaken, but did not abandon his objection. I
therefore broke off the argument with the remark that I felt sure this had not been the first
occurrence of his idea of his father's dying; it had evidently originated at an earlier date, and
some day we should have to trace back its history. - He then proceeded to tell me that a
precisely similar thought had flashed through his mind a second time, six months before his
father's death. At that time² he had already been in love with his lady, but financial obstacles
made it impossible to think of an alliance with her. The idea had then occurred to him that his
father's death might make him rich enough to marry her. In defending himself against this idea
he had gone to the length of wishing that his father might leave him nothing at all, so that he
might have no compensation for his terrible loss. The same idea, though in a much milder form,
had come to him for a third time, on the day before his father's death. He had then thought:
'Now I may be going to lose what I love most'; and then had come the contradiction: 'No, there
is some one else whose loss would be even more painful to you.'³ These thoughts surprised
him very much, for he was quite certain that his father's death could never have been an object
of his desire but only of his fear. - After his forcible enunciation of these words I thought it
advisable to bring a fresh piece of theory to his notice. According to psycho-analytic theory, I
told him, every fear corresponded to a former wish which was now repressed; we were
therefore obliged to believe the exact contrary of what he had asserted. This would also fit in
with another theoretical requirement, namely, that the unconscious must be the precise contrary
of the conscious. - He was much agitated at this and very incredulous. He wondered how he
could possibly have had such a wish, considering that he loved his father more than any one
else in the world; there could be no doubt that he would have renounced all his own prospects
of happiness if by so doing he could have saved his father's life. - I answered that it was
precisely such intense love as his that was the necessary precondition of the repressed hatred.
In the case of people to whom he felt indifferent he would certainly have no difficulty in
maintaining side by side inclinations to a moderate liking and to an equally moderate dislike:
supposing, for instance, that he were an official, he might think that his chief was agreeable as a
superior, but at the same time pettifogging as a lawyer and inhuman as a judge. (Shakespeare
makes Brutus speak in a similar way of Julius Caesar: 'As Caesar loved me, I weep for him; as
he was fortunate, I rejoice at it; as he was valiant, I honour him; but, as he was ambitious, I slew
him.' But these words already strike us as rather strange, and for the very reason that we had
imagined Brutus's feeling for Caesar as something deeper.) In the case of some one who was
closer to him, of his wife for instance, he would wish his feelings to be unmixed, and
consequently, as was only human, he would overlook her faults, since they might make him
dislike her - he would ignore them as though he were blind to them.

[1909d, 2144]
So it was precisely the intensity of his love that would not allow his hatred - though to give it such a name was to caricature the feeling - to remain conscious. To be sure, the hatred must have a source, and to discover that source was certainly a problem; his own statements pointed to the time when he was afraid that his parents guessed his thoughts. On the other hand, too, it might be asked why this intense love of his had not succeeded in extinguishing his hatred, as usually happened where there were two opposing impulses. We could only presume that the hatred must flow from some source, must be connected with some particular cause, which made it indestructible. On the one hand, then, some connection of this sort must be keeping his hatred for his father alive, while on the other hand, his intense love prevented it from becoming conscious. Therefore nothing remained for it but to exist in the unconscious, though it was able from time to time to flash out for a moment into consciousness.

The other conflict, that between love and hatred, strikes us more strangely. We know that incipient love is often perceived as hatred, and that love, if it is denied satisfaction, may easily be partly converted into hatred, and poets tell us that in the more tempestuous stages of love the two opposed feelings may subsist side by side for a while as though in rivalry with each other. But the chronic co-existence of love and hatred, both directed towards the same person and both of the highest degree of intensity, cannot fail to astonish us. We should have expected that the passionate love would long ago have conquered the hatred or been devoured by it. And in fact such a protracted survival of two opposites is only possible under quite peculiar psychological conditions and with the co-operation of the state of affairs in the unconscious. The love has not succeeded in extinguishing the hatred but only in driving it down into the unconscious; and in the unconscious the hatred, safe from the danger of being destroyed by the operations of consciousness, is able to persist and even to grow. In such circumstances the conscious love attains as a rule, by way of reaction, an especially high degree of intensity, so as to be strong enough for the perpetual task of keeping its opponent under repression. The necessary condition for the occurrence of such a strange state of affairs in a person's erotic life appears to be that at a very early age, somewhere in the prehistoric period of his infancy, the two opposites should have been split apart and one of them, usually the hatred, have been repressed.

If we consider a number of analyses of obsessional neurotics we shall find it impossible to escape the impression that a relation between love and hatred such as we have found in our present patient is among the most frequent, the most marked, and probably, therefore, the most important characteristics of obsessional neurosis. But however tempting it may be to bring the problem of the 'choice of neurosis' into connection with instinctual life, there are reasons enough for avoiding such a course. For we must remember that in every neurosis we come upon the same suppressed instincts behind the symptoms. After all, hatred, kept suppressed in the unconscious by love, plays a great part in the pathogenesis of hysteria and paranoia. We know too little of the nature of love to be able to arrive at any definite conclusion here; and, in particular, the relation between the negative factor in love and the sadistic components of the libido remains completely obscure. What follows is therefore to be regarded as no more than a provisional explanation. We may suppose, then, that in the cases of unconscious hatred with which we are concerned the sadistic components of love have, from constitutional causes, been exceptionally strongly developed, and have consequently undergone a premature and all too thorough suppression, and that the neurotic phenomena we have observed arise on the one hand from conscious feelings of affection which have become exaggerated as a reaction, and on the other hand from sadism persisting in the unconscious in the form of hatred.
Furthermore, by a sort of regression, preparatory acts become substituted for the final decision, thinking replaces acting, and, instead of the substitutive act, some thought preliminary to it asserts itself with all the force of compulsion. According as this regression from acting to thinking is more or less marked, a case of obsessional neurosis will exhibit the characteristics of obsessive thinking (that is, of obsessional ideas) or of obsessive acting in the narrower sense of the word. True obsessional acts such as these, however, are only made possible because they constitute a kind of reconciliation, in the shape of a compromise, between the two antagonistic impulses. For obsessional acts tend to approximate more and more - and the longer the disorder lasts the more evident does this become - to infantile sexual acts of a masturbatory character. Thus in this form of the neurosis acts of love are carried out in spite of everything, but only by the aid of a new kind of regression; for such acts no longer relate to another person, the object of love and hatred, but are auto-erotic acts such as occur in infancy.

In bringing this paper to a close I may express a hope that, though my communication is incomplete in every sense, it may at least stimulate other workers to throw more light upon the obsessional neurosis by a deeper investigation of the subject. What is characteristic of this neurosis - what differentiates it from hysteria - is not, in my opinion, to be found in instinctual life but in the psychological field. I cannot take leave of my patient without putting on paper my impression that he had, as it were, disintegrated into three personalities: into one unconscious personality, that is to say, and into two preconscious ones between which his consciousness could oscillate. His unconscious comprised those of his impulses which had been suppressed at an early age and which might be described as passionate and evil impulses. In his normal state he was kind, cheerful, and sensible - an enlightened and superior kind of person - while in his third psychological organization he paid homage to superstition and asceticism. Thus he was able to have two different creeds and two different outlooks upon life. This second preconscious personality comprised chiefly the reaction-formations against his repressed wishes, and it was easy to foresee that it would have swallowed up the normal personality if the illness had lasted much longer. I have at present an opportunity of studying a lady suffering severely from obsessional acts. She has become similarly disintegrated into an easy-going and lively personality and into an exceedingly gloomy and ascetic one. She puts forward the first of them as her official ego, while in fact she is dominated by the second. Both of these psychical organizations have access to her consciousness, but behind her ascetic personality may be discerned the unconscious part of her being - quite unknown to her and composed of ancient and long-repressed wishful impulses.¹

We have no information about the circumstances of his heredity; on the other hand we have seen that the accidental conditions of his childhood had a profound and disturbing effect on him. His illegitimate birth deprived him of his father's influence until perhaps his fifth year, and left him open to the tender seductions of a mother whose only solace he was. After being kissed by her into precocious sexual maturity, he must no doubt have embarked on a phase of infantile sexual activity of which only one single manifestation is definitely attested - the intensity of his infantile sexual researches. The instinct to look and the instinct to know were those most strongly excited by the impressions of his early childhood; the erotogenic zone of the mouth was given an emphasis which it never afterwards surrendered. From his later behaviour in the contrary direction, such as his exaggerated sympathy for animals, we can conclude that there was no lack of strong sadistic traits in this period of his childhood.

¹[1909d, 2191]
In place of a single sick person let us put society - suffering as a whole from neuroses, though composed of sick and healthy members; and in place of individual acceptance in the one case let us put general recognition in the other. A little reflection will then show you that this substitution cannot in any way alter the outcome. The success which the treatment can have with the individual must occur equally with the community. Sick people will not be able to let their various neuroses become known - their anxious over-tenderness which is meant to conceal their hatred, their agoraphobia which tells of disappointed ambition, their obsessive actions which represent self-reproaches for evil intentions and precautions against them - if all their relatives and every stranger from whom they wish to conceal their mental processes know the general meaning of such symptoms, and if they themselves know that in the manifestations of their illness they are producing nothing that other people cannot instantly interpret. The effect, however, will not be limited to the concealment of the symptoms which, incidentally, it is often impossible to carry out; for this necessity for concealment destroys the use of being ill. Disclosure of the secret will have attacked, at its most sensitive point, the 'aetiological equation' from which neuroses arise - it will have made the gain from the illness illusory; and consequently the final outcome of the changed situation brought about by the physician's indiscretion can only be that the production of the illness will be brought to a stop.

[1910d, 2312]

The content of her obsessional neurosis was a compulsion for scrupulous washing and cleanliness and extremely energetic protective measures against severe injuries which she thought other people had reason to fear from her - that is to say, reaction-formations against her own anal-erotic and sadistic impulses. Her sexual need was obliged to find expression in these shapes after her genital life had lost all its value owing to the impotence of the only man of whom there could be any question for her.

[1913i, 2626]

A comparison between such a change of character and obsessional neurosis is very impressive. In both cases the work of regression is apparent. But whereas in the former we find complete regression following repression (or suppression) that has occurred smoothly, in the neurosis there are conflict, an effort to prevent regression from occurring, reaction-formations against it and symptom-formations produced by compromises between the two opposing sides, and a splitting of the psychological activities into some that are admissible to consciousness and others that are unconscious.

[1913i, 2629]

The lesson that bodily cleanliness is far more readily associated with vice than with virtue often occurred to me later on, when psycho-analytic work made me acquainted with the way in which civilized men to-day deal with the problem of their physical nature. They are clearly embarrassed by anything that reminds them too much of their animal origin. They are trying to emulate the 'more perfected angels' in the last scene of Faust, who complain:

[1913k, 2639]

In the first place, we have found that a feature in the character of obsessional neurotics is a scrupulous conscientiousness which is a symptom reacting against the temptation lurking in their unconscious. If their illness becomes more acute, they develop a sense of guilt of the most intense degree. In fact, one may venture to say that if we cannot trace the origin of the sense of guilt in obsessional neurotics, there can be no hope of our ever tracing it. This task can be directly achieved in the case of individual neurotic patients, and we may rely upon reaching a similar solution by inference in the case of primitive peoples.

[1912-1913, 2712]
It is in obsessional neuroses that the survival of the omnipotence of thoughts is most clearly visible and that the consequences of this primitive mode of thinking come closest to consciousness. But we must not be misled into supposing that it is a distinguishing feature of this particular neurosis, for analytic investigation reveals the same thing in the other neuroses as well. In all of them what determines the formation of symptoms is the reality not of experience but of thought. Neurotics live in a world apart, where, as I have said elsewhere, only 'neurotic currency' is legal tender; that is to say, they are only affected by what is thought with intensity and pictured with emotion, whereas agreement with external reality is a matter of no importance. What hysterics repeat in their attacks and fix by means of their symptoms are experiences which have occurred in that form only in their imagination though it is true that in the last resort those imagined experiences go back to actual events or are based upon them. To attribute the neurotic sense of guilt to real misdeeds would show an equal misunderstanding. An obsessional neurotic may be weighed down by a sense of guilt that would be appropriate in a mass-murderer, while in fact, from his childhood onwards, he has behaved to his fellow-men as the most considerate and scrupulous member of society. Nevertheless, his sense of guilt has a justification: it is founded on the intense and frequent death wishes against his fellows which are unconsciously at work in him. It has a justification if what we take into account are unconscious thoughts and not intentional deeds. Thus the omnipotence of thoughts, the overvaluation of mental processes as compared with reality, is seen to have unrestricted play in the emotional life of neurotic patients and in everything that derives from it. If one of them undergoes psychoanalytic treatment, which makes what is unconscious in him conscious, he will be unable to believe that thoughts are free and will constantly be afraid of expressing evil wishes, as though their expression would lead inevitably to their fulfilment. This behaviour, as well as the superstitions which he practises in ordinary life, reveals his resemblance to the savages who believe they can alter the external world by mere thinking.

Here we are faced by a decision which is indeed no easy one. First, however, it must be confessed that the distinction, which may seem fundamental to other people, does not in our judgement affect the heart of the matter. If wishes and impulses have the full value of facts for primitive men, it is our business to give their attitude our understanding attention instead of correcting it in accordance with our own standards. Let us, then, examine more closely the case of neurosis - comparison with which led us into our present uncertainty. It is not accurate to say that obsessional neurotics, weighed down under the burden of an excessive morality, are defending themselves only against psychical reality and are punishing themselves for impulses which were merely felt. Historical reality has a share in the matter as well. In their childhood they had these evil impulses pure and simple, and turned them into acts so far as the impotence of childhood allowed. Each of these excessively virtuous individuals passed though an evil period in his infancy - a phase of perversion which was the forerunner and precondition of the later period of excessive morality. The analogy between primitive men and neurotics will therefore be far more fully established if we suppose that in the former instance, too, psychical reality - as to the form taken by which we are in no doubt - coincided at the beginning with factual reality: that primitive men actually did what all the evidence shows that they intended to do.
I shall try here to penetrate a little further into the mechanism of paraphrenia and shall bring together those views which already seem to me to deserve consideration. The difference between paraphrenic affections and the transference neuroses appears to me to lie in the circumstance that, in the former, the libido that is liberated by frustration does not remain attached to objects in phantasy, but withdraws on to the ego. Megalomania would accordingly correspond to the psychical mastering of this latter amount of libido, and would thus be the counterpart of the introversion on to phantasies that is found in the transference neuroses; a failure of this psychical function gives rise to the hypochondria of paraphrenia and this is homologous to the anxiety of the transference neuroses. We know that this anxiety can be resolved by further psychical working over, i.e. by conversion, reaction-formation or the construction of protections (phobias). The corresponding process in paraphrenics is an attempt at restoration, to which the striking manifestations of the disease are due. Since paraphrenia frequently, if not usually, brings about only a partial detachment of the libido from objects, we can distinguish three groups of phenomena in the clinical picture: (1) those representing what remains of a normal state or of neurosis (residual phenomena); (2) those representing the morbid process (detachment of libido from its objects and, further, megalomania, hypochondria, affective disturbance and every kind of regression); (3) those representing restoration, in which the libido is once more attached to objects, after the manner of a hysteria (in dementia praecox or paraphrenia proper), or of an obsessional neurosis (in paranoia). This fresh libidinal cathexis differs from the primary one in that it starts from another level and under other conditions. The difference between the transference neuroses brought about in the case of this fresh kind of libidinal cathexis and the corresponding formations where the ego is normal should be able to afford us the deepest insight into the structure of our mental apparatus.
[1914c, 2941]
A totally different picture of repression is shown, once more, in the third disorder which we shall consider for the purposes of our illustration - in obsessional neurosis. Here we are at first in doubt what it is that we have to regard as the instinctual representative that is subjected to repression - whether it is a libidinal or a hostile trend. This uncertainty arises because obsessional neurosis has as its basis a regression owing to which a sadistic trend has been substituted for an affectionate one. It is this hostile impulsion against someone who is loved which is subjected to repression. The effect at an early stage of the work of repression is quite different from what it is at a later one. At first the repression is completely successful; the ideational content is rejected and the affect made to disappear. As a substitutive formation there arises an alteration in the ego in the shape of an increased conscientiousness, and this can hardly be called a symptom. Here, substitute and symptom do not coincide. From this we learn something, too, about the mechanism of repression. In this instance, as in all others, repression has brought about a withdrawal of libido; but here it has made use of reaction-formation for this purpose, by intensifying an opposite. Thus in this case the formation of a substitute has the same mechanism as repression and at bottom coincides with it, while chronologically, as well as conceptually, it is distinct from the formation of a symptom. It is very probable that the whole process is made possible by the ambivalent relationship into which the sadistic impulsion that has to be repressed has been introduced. But the repression, which was at first successful, does not hold firm; in the further course of things its failure becomes increasingly marked. The ambivalence which has enabled repression through reaction-formation to take place is also the point at which the repressed succeeds in returning. The vanished affect comes back in its transformed shape as social anxiety, moral anxiety and unlimited self-reproaches; the rejected idea is replaced by a substitute by displacement, often a displacement on to something very small or indifferent. A tendency to a complete re-establishment of the repressed idea is as a rule unmistakably present. The failure in the repression of the quantitative, affective factor brings into play the same mechanism of flight, by means of avoidance and prohibitions, as we have seen at work in the formation of hysterical phobias. The rejection of the idea from the conscious is, however, obstinately maintained, because it entails abstention from action, a motor fettering of the impulsion. Thus in obsessional neurosis the work of repression is prolonged in a sterile and interminable struggle.

As regards obsessional neurosis, we need only add to the observations brought forward in the preceding paper that it is here that the anticathexis from the system Cs. comes most noticeably into the foreground. It is this which, organized as a reaction-formation, brings about the first repression, and which is later the point at which the repressed idea breaks through. We may venture the supposition that it is because of the predominance of the anticathexis and the absence of discharge that the work of repression seems far less successful in anxiety hysteria and in obsessional neurosis than in conversion hysteria.

The layman feels an extraordinary horror at the possibility of such feelings, and takes this aversion as a legitimate ground for disbelief in the assertions of psycho-analysis. Mistakenly, I think. No depreciation of feelings of love is intended, and there is in fact none. It is indeed foreign to our intelligence as well as to our feelings thus to couple love and hate; but Nature, by making use of this pair of opposites, contrives to keep love ever vigilant and fresh, so as to guard it against the hate which lurks behind it. It might be said that we owe the fairest flowerings of our love to the reaction against the hostile impulse which we sense within us.
This, then, is what I wanted to tell you about the formation of symptoms in the neuroses. But I must not fail to lay emphasis expressly once again on the fact that everything I have said here applies only to the formation of symptoms in hysteria. Even in obsessional neurosis there is much - apart from fundamentals, which remain unaltered - that will be found different. The anticathexes opposing the demands of the instincts (which we have already spoken of in the case of hysteria as well) become prominent in obsessional neurosis and dominate the clinical picture in the form of what are known as 'reaction formations'. We discover similar and even more far-reaching divergences in the other neuroses, where our researches into the mechanisms of symptom-formation are not yet concluded at any point.

[1916-1917, 3430]

One of the ways in which the ego is related to its neuroses is, however, so obvious that it was possible to take it into account from the first. It seems never to be absent; but it is most clearly recognizable in a disorder which we are even to-day far from understanding - traumatic neurosis. For you must know that the same factors always come into operation in the causation and mechanism of every possible form of neurosis; but the chief importance in the construction of the symptoms falls now upon one and now upon another of these factors. The position is like that among the members of a theatrical company. Each of them is regularly cast for his own stock role - hero, confidant, villain, and so on; but each of them will choose a different piece for his benefit performance. In the same way phantasies which turn into symptoms are nowhere more obvious than in hysteria; the anticathexes or reaction-formations of the ego dominate the picture in obsessional neurosis; what in the case of dreams we have termed 'secondary revision' stands in the forefront in paranoia in the shape of delusions, and so on.

[1916-1917, 3434]

*The Theory of Repression*. - These theoretical considerations, taken together with the immediate impressions derived from analytic work, lead to a view of the neuroses which may be described in the roughest outline as follows. The neuroses are the expression of conflicts between the ego and such of the sexual impulses as seem to the ego incompatible with its integrity or with its ethical standards. Since these impulses are not ego-syntonic, the ego has repressed them: that is to say, it has withdrawn its interest from them and has shut them off from becoming conscious as well as from obtaining satisfaction by motor discharge. If in the course of analytic work one attempts to make these repressed impulses conscious, one becomes aware of the repressive forces in the form of resistance. But the achievement of repression fails particularly readily in the case of the sexual instincts. Their dammed-up libido finds other ways out from the unconscious: for it regresses to earlier phases of development and earlier attitudes towards objects, and, at weak points in the libidinal development where there are infantile fixations, it breaks through into consciousness and obtains discharge. What results is a symptom and consequently in its essence a substitutive sexual satisfaction. Nevertheless the symptom cannot entirely escape from the repressive forces of the ego and must therefore submit to modifications and displacements exactly as happens with dreams - by means of which its characteristic of being a sexual satisfaction becomes unrecognizable. Consequently symptoms are in the nature of compromises between the repressed sexual instincts and the repressing ego-ininsticts; they represent a wish-fulfilment for both partners to the conflict simultaneously, but one which is incomplete for each of them. This is quite strictly true of the symptoms of hysteria, while in the symptoms of obsessional neurosis there is often a stronger emphasis upon the side of the repressing function owing to the erection of reaction-formations, which are assurances against sexual satisfaction.

[1923a, 3923]
It is essentially in hysteria and in states of a hysterical type that this is found. Here the mechanism by which the sense of guilt remains unconscious is easy to discover. The hysterical ego fends off a distressing perception with which the criticisms of its super-ego threaten it, in the same way in which it is in the habit of fending off an unendurable object-cathexis - by an act of repression. It is the ego, therefore, that is responsible for the sense of guilt remaining unconscious. We know that as a rule the ego carries out repressions in the service and at the behest of its super-ego; but this is a case in which it has turned the same weapon against its harsh taskmaster. In obsessional neurosis, as we know, the phenomena of reaction-formation predominate; but here the ego succeeds only in keeping at a distance the material to which the sense of guilt refers.

[1923b, 3985]

The reproaches of conscience in certain forms of obsessional neurosis are as distressing and tormenting, but here the situation is less perspicuous. It is noteworthy that the obsessional neurotic, in contrast to the melancholic, never in fact takes the step of self-destruction; it is as though he were immune against the danger of suicide, and he is far better protected from it than the hysteric. We can see that what guarantees the safety of the ego is the fact that the object has been retained. In obsessional neurosis it has become possible, through a regression to the pregenital organization, for the love-impulses to transform themselves into impulses of aggression against the object. Here again the instinct of destruction has been set free and it seeks to destroy the object, or at least it appears to have that intention. These purposes have not been adopted by the ego and it struggles against them with reaction-formations and precautionary measures; they remain in the id. The super-ego, however, behaves as if the ego were responsible for them and shows at the same time by the seriousness with which it chastises these destructive intentions that they are no mere semblance evoked by regression but an actual substitution of hate for love. Helpless in both directions, the ego defends itself vainly, alike against the instigations of the murderous id and against the reproaches of the punishing conscience. It succeeds in holding in check at least the most brutal actions of both sides; the first outcome is interminable self-torment, and eventually there follows a systematic torturing of the object, in so far as it is within reach.

[1923b, 3987]
In enforcing regression, the ego scores its first success in its defensive struggle against the demands of the libido. (In this connection it is of advantage to distinguish the more general notion of 'defence' from 'repression'. Repression is only one of the mechanisms which defence makes use of.) It is perhaps in obsessional cases more than in normal or hysterical ones that we can most clearly recognize that the motive force of defence is the castration complex and that what is being fended off are the trends of the Oedipus complex. We are at present dealing with the beginning of the latency period, a period which is characterized by the dissolution of the Oedipus complex, the creation or consolidation of the super-ego and the erection of ethical and aesthetic barriers in the ego. In obsessional neuroses these processes are carried further than is normal. In addition to the destruction of the Oedipus complex a regressive degradation of the libido takes place, the super-ego becomes exceptionally severe and unkind, and the ego, in obedience to the super-ego, produces strong reaction-formations in the shape of conscientiousness, pity and cleanliness. Implacable, though not always on that account successful, severity is shown in condemning the temptation to continue early infantile masturbation, which now attaches itself to regressive (sadistic-anal) ideas but which nevertheless represents the unsubjugated part of the phallic organization. There is an inherent contradiction about this state of affairs, in which, precisely in the interests of masculinity (that is to say, from fear of castration), every activity belonging to masculinity is stopped. But here, too, obsessional neurosis is only overdoing the normal method of getting rid of the Oedipus complex. We once more find here an illustration of the truth that every exaggeration contains the seed of its own undoing. For, under the guise of obsessional acts, the masturbation that has been suppressed approaches ever more closely to satisfaction.

The reaction-formations in the ego of the obsessional neurotic, which we recognize as exaggerations of normal character-formation, should be regarded, I think, as yet another mechanism of defence and placed alongside of regression and repression. They seem to be absent or very much weaker in hysteria. Looking back, we can now get an idea of what is peculiar to the defensive process in hysteria. It seems that in it the process is limited to repression alone. The ego turns away from the disagreeable instinctual impulse, leaves it to pursue its course in the unconscious, and takes no further part in its fortunes. This view cannot be absolutely correct, for we are acquainted with the case in which a hysterical symptom is at the same time a fulfilment of a penalty imposed by the super-ego; but it may describe a general characteristic of the behaviour of the ego in hysteria.

The advent of puberty opens a decisive chapter in the history of an obsessional neurosis. The genital organization which has been broken off in childhood starts again with great vigour. But, as we know, the sexual development in childhood determines what direction this new start at puberty will take. Not only will the early aggressive impulses be re-awakened; but a greater or lesser proportion of the new libidinal impulses - in bad cases the whole of them - will have to follow the course prescribed for them by regression and will emerge as aggressive and destructive tendencies. In consequence of the erotic trends being disguised in this way and owing to the powerful reaction-formations in the ego, the struggle against sexuality will henceforward be carried on under the banner of ethical principles. The ego will recoil with astonishment from promptings to cruelty and violence which enter consciousness from the id, and it has no notion that in them it is combating erotic wishes, including some to which it would not otherwise have taken exception. The overstrict super-ego insists all the more strongly on the suppression of sexuality, since this has assumed such repellent forms. Thus in obsessional neurosis the conflict is aggravated in two directions: the defensive forces become more intolerant and the forces that are to be fended off become more intolerable. Both effects are due to a single factor, namely, regression of the libido.
An important element in the theory of repression is the view that repression is not an event that occurs once but that it requires a permanent expenditure. If this expenditure were to cease, the repressed impulse, which is being fed all the time from its sources, would on the next occasion flow along the channels from which it had been forced away, and the repression would either fail in its purpose or would have to be repeated an indefinite number of times. Thus it is because instincts are continuous in their nature that the ego has to make its defensive action secure by a permanent expenditure. This action undertaken to protect repression is observable in analytic treatment as resistance. Resistance presupposes the existence of what I have called anticathexis. An anticathexis of this kind is clearly seen in obsessional neurosis. It appears there in the form of an alteration of the ego, as a reaction-formation in the ego, and is effected by the reinforcement of the attitude which is the opposite of the instinctual trend that has to be repressed - as, for instance, in pity, conscientiousness and cleanliness. These reaction-formations of obsessional neurosis are essentially exaggerations of the normal traits of character which develop during the latency period. The presence of an anticathexis in hysteria is much more difficult to detect, though theoretically it is equally indispensable. In hysteria, too, a certain amount of alteration of the ego through reaction-formation is unmistakable and in some circumstances becomes so marked that it forces itself on our attention as the principal symptom. The conflict due to ambivalence, for instance, is resolved in hysteria by this means. The subject's hatred of a person whom he loves is kept down by an exaggerated amount of tenderness for him and apprehensiveness about him. But the difference between reaction-formations in obsessional neurosis and in hysteria is that in the latter they do not have the universality of a character-trait but are confined to particular relationships. A hysterical woman, for instance, may be specially affectionate with her own children whom at bottom she hates; but she will not on that account be more loving in general than other women or even more affectionate to other children. The reaction-formation of hysteria clings tenaciously to a particular object and never spreads over into a general disposition of the ego, whereas what is characteristic of obsessional neurosis is precisely a spreading-over of this kind - a loosening of relations to the object and a facilitation of displacement in the choice of object.

There is another kind of anticathexis, however, which seems more suited to the peculiar character of hysteria. A repressed instinctual impulse can be activated (newly cathected) from two directions: from within, through reinforcement from its internal sources of excitation, and from without, through the perception of an object that it desires. The hysterical anticathexis is mainly directed outwards, against dangerous perceptions. It takes the form of a special kind of vigilance which, by means of restrictions of the ego, causes situations to be avoided that would entail such perceptions, or, if they do occur, manages to withdraw the subject's attention from them. Some French analysts, in particular Laforgue, have recently given this action of hysteria the special name of 'scotomization'. This technique of anticathexis is still more noticeable in the phobias, whose interest is concentrated on removing the subject ever further from the possibility of the occurrence of the feared perception. The fact that anticathexis has an opposite direction in hysteria and the phobias from what it has in obsessional neurosis - though the distinction is not an absolute one - seems to be significant. It suggests that there is an intimate connection between repression and external anticathexis on the one hand and between regression and internal anticathexis (i.e. alteration in the ego through reaction-formation) on the other. The task of defence against a dangerous perception is, incidentally, common to all neuroses. Various commands and prohibitions in obsessional neurosis have the same end in view.
Even a purely terminological innovation ought to justify its adoption; it ought to reflect some new point of view or some extension of knowledge. The revival of the concept of defence and the restriction of that of repression takes into account a fact which has long since been known but which has received added importance owing to some new discoveries. Our first observations of repression and of the formation of symptoms were made in connection with hysteria. We found that the perceptual content of exciting experiences and the ideational content of pathogenic structures of thought were forgotten and debarred from being reproduced in memory, and we therefore concluded that the keeping away from consciousness was a main characteristic of hysterical repression. Later on, when we came to study the obsessional neuroses, we found that in that illness pathogenic occurrences are not forgotten. They remain conscious but they are 'isolated' in some way that we cannot as yet grasp, so that much the same result is obtained as in hysterical amnesia. Nevertheless the difference is great enough to justify the belief that the process by which instinctual demands are set aside in obsessional neurosis cannot be the same as in hysteria. Further investigations have shown that in obsessional neurosis a regression of the instinctual impulses to an earlier libidinal stage is brought about through the opposition of the ego, and that this regression, although it does not make repression unnecessary, clearly works in the same sense as repression. We have seen, too, that in obsessional neurosis anticathexis, which is also presumably present in hysteria, plays a specially large part in protecting the ego by effecting a reactive alteration in it. Our attention has, moreover, been drawn to a process of 'isolation' (whose technique cannot as yet be elucidated) which finds direct symptomatic manifestation, and to a procedure, that may be called magical, of 'undoing' what has been done - a procedure about whose defensive purpose there can be no doubt, but which has no longer any resemblance to the process of 'repression'. These observations provide good enough grounds for re-introducing the old concept of defence, which can cover all these processes that have the same purpose - namely, the protection of the ego against instinctual demands - and for subsuming repression under it as a special case. The importance of this nomenclature is heightened if we consider the possibility that further investigations may show that there is an intimate connection between special forms of defence and particular illnesses, as, for instance, between repression and hysteria. In addition we may look forward to the possible discovery of yet another important correlation. It may well be that before its sharp cleavage into an ego and an id, and before the formation of a super-ego, the mental apparatus makes use of different methods of defence from those which it employs after it has reached these stages of organization.

[1926d, 4316]
The direction to be taken by this father-religion was in this way laid down for all time. Yet this
did not bring its development to an end. Ambivalence is a part of the essence of the relation to
the father: in the course of time the hostility too could not fail to stir, which had once driven the
sons into killing their admired and dreaded father. There was no place in the framework of the
religion of Moses for a direct expression of the murderous hatred of the father. All that could
come to light was a mighty reaction against it - a sense of guilt on account of that hostility, a bad
conscience for having sinned against God and for not ceasing to sin. This sense of guilt, which
was uninterruptedly kept awake by the Prophets, and which soon formed an essential part of
the religious system, had yet another superficial motivation, which neatly disguised its true
origin. Things were going badly for the people; the hopes resting on the favour of God failed in
fulfilment; it was not easy to maintain the illusion, loved above all else, of being God's chosen
people. If they wished to avoid renouncing that happiness, a sense of guilt on account of their
own sinfulness offered a welcome means of exculpating God: they deserved no better than to
be punished by him since they had not obeyed his commandments. And, driven by the need to
satisfy this sense of guilt, which was insatiable and came from sources so much deeper, they
must make those commandments grow ever stricter, more meticulous and even more trivial. In
a fresh rapture of moral asceticism they imposed more and more new instinctual renunciations
on themselves and in that way reached - in doctrine and precept, at least - ethical heights which
had remained inaccessible to the other peoples of antiquity. Many Jews regard this attainment
of ethical heights as the second main characteristic and the second great achievement of their
religion. The way in which it was connected with the first one - the idea of a single god - should
be plain from our remarks. These ethical ideas cannot, however, disavow their origin from the
sense of guilt felt on account of a suppressed hostility to God. They possess the characteristic
- uncompleted and incapable of completion - of obsessional neurotic reaction-formations; we can
guess, too, that they serve the secret purposes of punishment.
[1939a, 4951]
A second form of obsessional neurosis comes about if what has forced its way to representation in conscious psychical life is not the repressed mnemic content but the likewise repressed self-reproach. The affect of self-reproach can, by means of some mental addition, be transformed into any other unpleasurable affect. When this has happened there is no longer anything to prevent the substituted affect from becoming conscious. Thus self-reproach (for having carried out the sexual act in childhood) can easily turn into shame (in case someone else should find out about it), into hypochondriacal anxiety (fear of the physical injuries resulting from the act involving the self-reproach), into social anxiety (fear of being punished by society for the misdeed), into religious anxiety, into delusions of being noticed (fear of betraying the act to other people), or into fear of temptation (a justified mistrust of one's own moral powers of resistance), and so on. In addition, the mnemic content of the act involving self-reproach may be represented in consciousness as well, or it may remain completely in the background - which makes diagnosis much more difficult. Many cases which, on a superficial examination, seem to be common (neurasthenic hypochondria, belong to this group of obsessional affects; what is known as 'periodic neurasthenia' or 'periodic melancholia' seems in particular to resolve itself with unexpected frequency into obsessional affects and obsessional ideas - a discovery which is not a matter of indifference therapeutically.

In the case of a psychical complex which has come under the influence of the censorship imposed by resistance, the affects are the constituent which is least influenced and which alone can give us a pointer as to how we should fill in the missing thoughts. This is seen even more clearly in the psychoneuroses than in dreams. Their affects are always appropriate, at least in their quality though we must allow for their intensity being increased owing to displacements of neurotic attention. If a hysterical is surprised at having to be so frightened of something trivial or if a man suffering from obsessions is surprised at such distressing self-reproaches arising out of a mere nothing, they have both gone astray, because they regard the ideational content - the triviality or the mere nothing - as what is essential; and they put up an unsuccessful fight because they take this ideational content as the starting-point of their thought-activity. Psychoanalysis can put them upon the right path by recognizing the affect as being, on the contrary, justified and by seeking out the idea which belongs to it but has been repressed and replaced by a substitute. A necessary premise to all this is that the release of affect and the ideational content do not constitute the indissoluble organic unity as which we are in the habit of treating them, but that these two separate entities may be merely soldered together and can thus be detached from each other by analysis. Dream-interpretation shows that this is in fact the case.

¹ Yet attempts have been made to explain obsessions without taking the affects into account!

[1896b, 391]

[1900a, 905]
In another neurotic disorder, obsessional neurosis, the patients become the victims of distressing and apparently senseless ceremonials which take the form of the rhythmical repetition of the most trivial acts (such as washing or dressing) or of carrying out meaningless injunctions or of obeying mysterious prohibitions. It was nothing less than a triumph of psycho-analytic research when it succeeded in showing that all these obsessive acts, even the most insignificant and trivial of them, have a meaning, and that they are reflections, translated into indifferent terms, of conflicts in the patients' lives, of the struggle between temptations and moral restraints - reflections of the proscribed wish itself and of the punishment and atonement which that wish incurs. In another form of the same disorder the victim suffers from tormenting ideas (obsessions) which force themselves upon him and are accompanied by affects whose character and intensity are often only quite inadequately accounted for by the terms of the obsessive ideas themselves. Analytic investigation has shown in their case that the affects are entirely justified, since they correspond to self-reproaches which are based on something that is at least psychically real. But the ideas to which these affects are attached are not the original ones, but have found their way into their present position by a process of displacement - by being substituted for something that has been repressed. If these displacements can be reversed, the way is open to the discovery of the repressed ideas, and the relation between affect and idea is found to be perfectly appropriate.

A good deal of what has been said may be objected to on the ground that the unpleasant obsessive ideas are themselves quite conscious. But there is no doubt that before becoming conscious they have been through the process of repression. In most of them the actual wording of the aggressive instinctual impulse is altogether unknown to the ego, and it requires a good deal of analytic work to make it conscious. What does penetrate into consciousness is usually only a distorted substitute which is either of a vague, dream-like and indeterminate nature or so travestied as to be unrecognizable. Even where repression has not encroached upon the content of the aggressive impulse it has certainly got rid of its accompanying affective character. As a result, the aggressiveness appears to the ego not to be an impulsion but, as the patients themselves say, merely a 'thought' which awakens no feeling. But the remarkable thing is that this is not the case. What happens is that the affect left out when the obsessional idea is perceived appears in a different place. The super-ego behaves as though repression had not occurred and as though it knew the real wording and full affective character of the aggressive impulse, and it treats the ego accordingly. The ego which, on the one hand, knows that it is innocent is obliged, on the other hand, to be aware of a sense of guilt and to carry a responsibility which it cannot account for. This state of affairs is, however, not so puzzling as it would seem at first sight. The behaviour of the super-ego is perfectly intelligible, and the contradiction in the ego merely shows that it has shut out the id by means of repression while remaining fully accessible to the influence of the super-ego. If it is asked why the ego does not also attempt to withdraw from the tormenting criticism of the super-ego, the answer is that it does manage to do so in a great number of instances. There are obsessional neuroses in which no sense of guilt whatever is present. In them, as far as can be seen, the ego has avoided becoming aware of it by instituting a fresh set of symptoms, penances or restrictions of a self-punishing kind. These symptoms, however, represent at the same time a satisfaction of masochistic impulses which, in their turn, have been reinforced by regression.

[1913j, 2810]

[1926d, 4276]
The second of these techniques which we are setting out to describe for the first time, that of isolation, is peculiar to obsessional neurosis. It, too, takes place in the motor sphere. When something unpleasant has happened to the subject or when he himself has done something which has a significance for his neurosis, he interpolates an interval during which nothing further must happen - during which he must perceive nothing and do nothing. This behaviour, which seems strange at first sight, is soon seen to have a relation to repression. We know that in hysteria it is possible to cause a traumatic experience to be overtaken by amnesia. In obsessional neurosis this can often not be achieved: the experience is not forgotten, but, instead, it is deprived of its affect, and its associative connections are suppressed or interrupted so that it remains as though isolated and is not reproduced in the ordinary processes of thought. The effect of this isolation is the same as the effect of repression with amnesia. This technique, then, is reproduced in the isolations of obsessional neurosis; and it is at the same time given motor reinforcement for magical purposes. The elements that are held apart in this way are precisely those which belong together associatively. The motor isolation is meant to ensure an interruption of the connection in thought. The normal phenomenon of concentration provides a pretext for this kind of neurotic procedure: what seems to us important in the way of an impression or a piece of work must not be interfered with by the simultaneous claims of any other mental processes or activities. But even a normal person uses concentration to keep away not only what is irrelevant or unimportant, but, above all, what is unsuitable because it is contradictory. He is most disturbed by those elements which once belonged together but which have been torn apart in the course of his development - as, for instance, by manifestations of the ambivalence of his father-complex in his relation to God, or by impulses attached to his excretory organs in his emotions of love. Thus, in the normal course of things, the ego has a great deal of isolating work to do in its function of directing the current of thought. And, as we know, we are obliged, in carrying out our analytic technique, to train it to relinquish that function for the time being, eminently justified as it usually is.

[1926d, 4279]
A second form of obsessional neurosis comes about if what has forced its way to representation in conscious psychical life is not the repressed mnemic content but the likewise repressed self-reproach. The effect of self-reproach can, by means of some mental addition, be transformed into any other unpleasurable affect. When this has happened there is no longer anything to prevent the substituted affect from becoming conscious. Thus self-reproach (for having carried out the sexual act in childhood) can easily turn into shame (in case someone else should find out about it), into hypochondriacal anxiety (fear of the physical injuries resulting from the act involving the self-reproach), into social anxiety (fear of being punished by society for the misdeed), into religious anxiety, into delusions of being noticed (fear of betraying the act to other people), or into fear of temptation (a justified mistrust of one's own moral powers of resistance), and so on. In addition, the mnemic content of the act involving self-reproach may be represented in consciousness as well, or it may remain completely in the background - which makes diagnosis much more difficult. Many cases which, on a superficial examination, seem to be common (neurasthenic hypochondria, belong to this group of obsessional affects; what is known as 'periodic neurasthenia' or 'periodic melancholia' seems in particular to resolve itself with unexpected frequency into obsessional affects and obsessional ideas - a discovery which is not a matter of indifference therapeutically.

In this scene - second in order of mention, but first in order of time - the behaviour of this child of fourteen was already entirely and completely hysterical. I should without question consider a person hysterical in whom an occasion for sexual excitement elicited feelings that were preponderantly or exclusively unpleasurable; and I should do so whether or not the person were capable of producing somatic symptoms. The elucidation of the mechanism of this reversal of affect is one of the most important and at the same time one of the most difficult problems in the psychology of the neuroses. In my own judgement I am still some way from having achieved this end; and I may add that within the limits of the present paper I shall be able to bring forward only a part of such knowledge on the subject as I do possess.

But Hans was not by any means a bad character; he was not even one of those children who at his age still give free play to the propensity towards cruelty and violence which is a constituent of human nature. On the contrary, he had an unusually kind-hearted and affectionate disposition; his father reported that the transformation of aggressive tendencies into feelings of pity took place in him at a very early age. Long before the phobia he had become uneasy when he saw the horses in a merry-go-round being beaten; and he was never unmoved if any one wept in his presence. At one stage in the analysis a piece of suppressed sadism made its appearance in a particular context:¹ but it was suppressed sadism, and we shall presently have to discover from the content what it stood for and what it was meant to replace. And Hans deeply loved the father against whom he cherished these death-wishes; and while his intellect demurred to such a contradiction,² he could not help demonstrating the fact of its existence, by hitting his father and immediately afterwards kissing the place he had hit. We ourselves, too, must guard against making a difficulty of such a contradiction. The emotional life of man is in general made up of pairs of contraries such as these.³ Indeed, if it were not so, repressions and neuroses would perhaps never come about. In the adult these pairs of contrary emotions do not as a rule become simultaneously conscious except at the climaxes of passionate love; at other times they usually go on suppressing each other until one of them succeeds in keeping the other altogether out of sight. But in children they can exist peaceably side by side for quite a considerable time.
Quite unexpectedly, and certainly without any prompting from his father, Hans now began to be occupied with the 'lumf' complex, and to show disgust at things that reminded him of evacuating his bowels. His father, who was reluctant to go with him along that line, pushed on with the analysis through thick and thin in the direction in which he wanted to go. He elicited from Hans the recollection of an event at Gmunden, the impression of which lay concealed behind that of the falling bus-horse. While they were playing at horses, Fritzl, the playmate of whom he was so fond, but at the same time, perhaps, his rival with his many girl friends, had hit his foot against a stone and had fallen down, and his foot had bled. Seeing the bus-horse fall had reminded him of this accident. It deserves to be noticed that Hans, who was at the moment concerned with other things, began by denying that Fritzl had fallen down (though this, was the event which formed the connection between the two scenes) and only admitted it at a later stage of the analysis. It is especially interesting, however, to observe the way in which the transformation of Hans's libido into anxiety was projected on to the principal object of his phobia, on to horses. Horses interested him the most of all the large animals; playing at horses was his favourite game with the other children. I had a suspicion - and this was confirmed by Hans's father when I asked him - that the first person who had served Hans as a horse must have been his father; and it was this that had enabled him to regard Fritzl as a substitute for his father when the accident happened at Gmunden. When repression had set in and brought a revulsion of feeling along with it, horses, which had till then been associated with so much pleasure, were necessarily turned into objects of fear.

[1909b, 2108]

Nevertheless, the neurosis took its start directly from this chance event and preserved a trace of it in the circumstance of the horse being exalted into the object of his anxiety. In itself the impression of the accident which he happened to witness carried no 'traumatic force'; it acquired its great effectiveness only from the fact that horses had formerly been of importance to him as objects of his predilection and interest, from the fact that he associated the event in his mind with an earlier event at Gmunden which had more claim to be regarded as traumatic, namely, with Fritzl's falling down while he was playing at horses, and lastly from the fact that there was an easy path of association from Fritzl to his father. Indeed, even these connections would probably not have been sufficient if it had not been that, thanks to the pliability and ambiguity of associative chains, the same event showed itself capable of stirring the second of the complexes that lurked in Hans's unconscious, the complex of his pregnant mother's confinement. From that moment the way was clear for the return of the repressed; and it returned in such a manner that the pathogenic material was remodelled and transposed on to the horse-complex, while the accompanying affects were uniformly transformed into anxiety.

[1909b, 2115]
The other conflict, that between love and hatred, strikes us more strangely. We know that incipient love is often perceived as hatred, and that love, if it is denied satisfaction, may easily be partly converted into hatred, and poets tell us that in the more tempestuous stages of love the two opposed feelings may subsist side by side for a while as though in rivalry with each other. But the *chronic* co-existence of love and hatred, both directed towards the same person and both of the highest degree of intensity, cannot fail to astonish us. We should have expected that the passionate love would long ago have conquered the hatred or been devoured by it. And in fact such a protracted survival of two opposites is only possible under quite peculiar psychological conditions and with the co-operation of the state of affairs in the unconscious. The love has not succeeded in extinguishing the hatred but only in driving it down into the unconscious; and in the unconscious the hatred, safe from the danger of being destroyed by the operations of consciousness, is able to persist and even to grow. In such circumstances the conscious love attains as a rule, by way of reaction, an especially high degree of intensity, so as to be strong enough for the perpetual task of keeping its opponent under repression. The necessary condition for the occurrence of such a strange state of affairs in a person's erotic life appears to be that at a very early age, somewhere in the prehistoric period of his infancy, the two opposites should have been split apart and one of them, usually the hatred, have been repressed.¹

If we consider a number of analyses of obsessional neurotics we shall find it impossible to escape the impression that a relation between love and hatred such as we have found in our present patient is among the most frequent, the most marked, and probably, therefore, the most important characteristics of obsessional neurosis. But however tempting it may be to bring the problem of the 'choice of neurosis' into connection with instinctual life, there are reasons enough for avoiding such a course. For we must remember that in every neurosis we come upon the same suppressed instincts behind the symptoms. After all, hatred, kept suppressed in the unconscious by love, plays a great part in the pathogenesis of hysteria and paranoia. We know too little of the nature of love to be able to arrive at any definite conclusion here; and, in particular, the relation between the *negative* factor¹ in love and the sadistic components of the libido remains completely obscure. What follows is therefore to be regarded as no more than a provisional explanation. We may suppose, then, that in the cases of unconscious hatred with which we are concerned the sadistic components of love have, from constitutional causes, been exceptionally strongly developed, and have consequently undergone a premature and all too thorough suppression, and that the neurotic phenomena we have observed arise on the one hand from conscious feelings of affection which have become exaggerated as a reaction, and on the other hand from sadism persisting in the unconscious in the form of hatred.

But in whatever way this remarkable relation of love and hatred is to be explained, its occurrence is established beyond any possibility of doubt by the observations made in the present case; and it is gratifying to find how easily we can now follow the puzzling processes of an obsessional neurosis by bringing them into relation with this one factor. If an intense love is opposed by an almost equally powerful hatred, and is at the same time inseparably bound up with it, the immediate consequence is certain to be a partial paralysis of the will and an incapacity for coming to a decision upon any of those actions for which love ought to provide the motive power. But this indecision will not confine itself for long to a single group of actions. For, in the first place, what actions of a lover are not brought into relation with his one principal motive? And secondly a man's attitude in sexual things has the force of a model to which the rest of his reactions tend to conform. And Thirdly, it is an inherent characteristic in the psychology of an obsessional neurotic to make the fullest possible use of the mechanism of *displacement*. So the paralysis of his powers of decision gradually extends itself over the entire field of the patient's behaviour.
The two cases are in fact not on all fours. In the first place, it may happen that an affective or emotional impulse is perceived but misconstrued. Owing to the repression of its proper representative it has been forced to become connected with another idea, and is now regarded by consciousness as the manifestation of that idea. If we restore the true connection, we call the original affective impulse an 'unconscious' one. Yet its affect was never unconscious; all that had happened was that its idea had undergone repression. In general, the use of the terms 'unconscious affect' and 'unconscious emotion' has reference to the vicissitudes undergone, in consequence of repression, by the quantitative factor in the instinctual impulse. We know that three such vicissitudes are possible:¹ either the affect remains, wholly or in part, as it is; or it is transformed into a qualitatively different quota of affect, above all into anxiety; or it is suppressed, i.e. it is prevented from developing at all. (These possibilities may perhaps be studied even more easily in the dream-work than in neuroses.) We know, too, that to suppress the development of affect is the true aim of repression and that its work is incomplete if this aim is not achieved. In every instance where repression has succeeded in inhibiting the development of affects, we term those affects (which we restore when we undo the work of repression) 'unconscious'. Thus it cannot be denied that the use of the terms in question is consistent; but in comparison with unconscious ideas there is the important difference that unconscious ideas continue to exist after repression as actual structures in the system Ucs., whereas all that corresponds in that system to unconscious affects is a potential beginning which is prevented from developing. Strictly speaking, then, and although no fault can be found with the linguistic usage, there are no unconscious affects as there are unconscious ideas. But there may very well be in the system Ucs. affective structures which, like others, become conscious. The whole difference arises from the fact that ideas are catheces - basically of memory-traces - whilst affects and feelings correspond to processes of discharge, the final manifestations of which are perceived as feelings. In the present state of our knowledge of affects and feelings we cannot express this difference more clearly.

[1915e, 3001]
It is true that dreams of dead people whom the dreamer has loved raise difficult problems in dream-interpretation and that these cannot always be satisfactorily solved. The reason for this is to be found in the particularly strongly marked emotional ambivalence which dominates the dreamer's relation to the dead person. It very commonly happens that in dreams of this kind the dead person is treated to begin with as though he were alive, that he then suddenly turns out to be dead and that in a subsequent part of the dream he is alive once more. This has a confusing effect. It eventually occurred to me that this alternation between death and life is intended to represent indifference on the part of the dreamer. ('It's all the same to me whether he's alive or dead.') This indifference is, of course, not real but merely desired; it is intended to help the dreamer to repudiate his very intense and often contradictory emotional attitudes and it thus becomes a dream-representation of his ambivalence.

-In other dreams in which the dreamer associates with dead people, the following rule often helps to give us our bearings. If there is no mention in the dream of the fact that the dead man is dead, the dreamer is equating himself with him: he is dreaming of his own death. If, in the course of the dream, the dreamer suddenly says to himself in astonishment, 'why, he died ever so long ago', he is repudiating this equation and is denying that the dream signifies his own death. -But I willingly confess to a feeling that dream-interpretation is far from having revealed all the secrets of dreams of this character.

[1900a, 880]

But Hans was not by any means a bad character; he was not even one of those children who at his age still give free play to the propensity towards cruelty and violence which is a constituent of human nature. On the contrary, he had an unusually kind-hearted and affectionate disposition; his father reported that the transformation of aggressive tendencies into feelings of pity took place in him at a very early age. Long before the phobia he had become uneasy when he saw the horses in a merry-go-round being beaten; and he was never unmoved if any one wept in his presence. At one stage in the analysis a piece of suppressed sadism made its appearance in a particular context:¹ but it was suppressed sadism, and we shall presently have to discover from the content what it stood for and what it was meant to replace. And Hans deeply loved the father against whom he cherished these death-wishes; and while his intellect demurred to such a contradiction,² he could not help demonstrating the fact of its existence, by hitting his father and immediately afterwards kissing the place he had hit. We ourselves, too, must guard against making a difficulty of such a contradiction. The emotional life of man is in general made up of pairs of contraries such as these.³ Indeed, if it were not so, repressions and neuroses would perhaps never come about. In the adult these pairs of contrary emotions do not as a rule become simultaneously conscious except at the climaxes of passionate love; at other times they usually go on suppressing each other until one of them succeeds in keeping the other altogether out of sight. But in children they can exist peaceably side by side for quite a considerable time.

[1909b, 2097]
At the next session he began by saying that he must tell me an event in his childhood. From
the age of seven, as he had already told me, he had had a fear that his parents guessed his
thoughts, and this fear had in fact persisted all through his life. When he was twelve years old
he had been in love with a little girl, the sister of a friend of his. (In answer to a question he said
that his love had not been sensual; he had not wanted to see her naked for she was too small.)
But she had not shown him as much affection as he had desired. And thereupon the idea had
come to him that she would be kind to him if some misfortune were to befall him; and as an
instance of such a misfortune his father's death had forced itself upon his mind. He had at once
rejected the idea with energy. And even now he could not admit the possibility that what had
arisen in this way could have been a 'wish'; it had clearly been no more than a 'train of thought'
- By way of objection I asked him why, if it had not been a wish, he had repudiated it. - Merely,
he replied, on account of the content of the idea, the notion that his father might die. - I
remarked that he was treating the phrase as though it were one that involved lèse-majesté; it
was well known, of course, that it was equally punishable to say 'The Emperor is an ass' or to
disguise the forbidden words by saying 'If any one says, etc., . . . then he will have me to reckon
with.' I added that I could easily insert the idea which he had so energetically repudiated into a
context which would exclude the possibility of any such repudiation: for instance, 'If my father
dies, I shall kill myself upon his grave.' - He was shaken, but did not abandon his objection. I
therefore broke off the argument with the remark that I felt sure this had not been the first
occurrence of his idea of his father's dying; it had evidently originated at an earlier date, and
some day we should have to trace back its history. - He then proceeded to tell me that a
precisely similar thought had flashed through his mind a second time, six months before his
father's death. At that time² he had already been in love with his lady, but financial obstacles
made it impossible to think of an alliance with her. The idea had then occurred to him that his
father's death might make him rich enough to marry her. In defending himself against this idea
he had gone to the length of wishing that his father might leave him nothing at all, so that he
might have no compensation for his terrible loss. The same idea, though in a much milder form,
had come to him for a third time, on the day before his father's death. He had then thought:
'Now I may be going to lose what I love most'; and then had come the contradiction: 'No, there
is some one else whose loss would be even more painful to you.'³ These thoughts surprised
him very much, for he was quite certain that his father's death could never have been an object
of his desire but only of his fear. - After his forcible enunciation of these words I thought it
advisable to bring a fresh piece of theory to his notice. According to psycho-analytic theory, I
told him, every fear corresponded to a former wish which was now repressed; we were
therefore obliged to believe the exact contrary of what he had asserted. This would also fit in
with another theoretical requirement, namely, that the unconscious must be the precise contrary
of the conscious. - He was much agitated at this and very incredulous. He wondered how he
could possibly have had such a wish, considering that he loved his father more than any one
else in the world; there could be no doubt that he would have renounced all his own prospects
of happiness if by so doing he could have saved his father's life. - I answered that it was
precisely such intense love as his that was the necessary precondition of the repressed hatred.
In the case of people to whom he felt indifferent he would certainly have no difficulty in
maintaining side by side inclinations to a moderate liking and to an equally moderate dislike:
supposing, for instance, that he were an official, he might think that his chief was agreeable as a
superior, but at the same time pettifogging as a lawyer and inhuman as a judge. (Shakespeare
makes Brutus speak in a similar way of Julius Caesar: 'As Caesar loved me, I weep for him; as
he was fortunate, I rejoice at it; as he was valiant, I honour him; but, as he was ambitious, I slew
him.' But these words already strike us as rather strange, and for the very reason that we had
imagined Brutus's feeling for Caesar as something deeper.) In the case of some one who was
closer to him, of his wife for instance, he would wish his feelings to be unmixed, and
consequently, as was only human, he would overlook her faults, since they might make him
dislike her - he would ignore them as though he were blind to them.

[1909d, 2144]
So it was precisely the intensity of his love that would not allow his hatred - though to give it such a name was to caricature the feeling - to remain conscious. To be sure, the hatred must have a source, and to discover that source was certainly a problem; his own statements pointed to the time when he was afraid that his parents guessed his thoughts. On the other hand, too, it might be asked why this intense love of his had not succeeded in extinguishing his hatred, as usually happened where there were two opposing impulses. We could only presume that the hatred must flow from some source, must be connected with some particular cause, which made it indestructible. On the one hand, then, some connection of this sort must be keeping his hatred for his father alive, while on the other hand, his intense love prevented it from becoming conscious. Therefore nothing remained for it but to exist in the unconscious, though it was able from time to time to flash out for a moment into consciousness.

The other compulsive commands that have been mentioned put us upon the track of this other element. His obsession for protecting can only have been a reaction - as an expression of remorse and penitence - to a contrary, that is a hostile, impulse which he must have felt towards his lady before they had their éclaircissement. His obsession for counting during the thunderstorm can be interpreted, with the help of some material which he produced, as having been a defensive measure against fears that some one was in danger of death. The analysis of the obsessions which we first considered has already warned us to regard our patient's hostile impulses as particularly violent and as being in the nature of senseless rage; and now we find that even after their reconciliation his rage against the lady continued to play a part in the formation of his obsessions. His doubting mania as to whether he had heard correctly was an expression of the doubt still lurking in his mind, whether he had really understood his lady correctly this time and whether he had been justified in taking her words as a proof of her affection for him. A battle between love and hate was raging in the lover's breast, and the object of both these feelings was one and the same person. The battle was represented in a plastic form by his compulsive and symbolic act of removing the stone from the road along which she was to drive, and then of undoing this deed of love by replacing the stone where it had lain, so that her carriage might come to grief against it and she herself be hurt. We shall not be forming a correct judgement of this second part of the compulsive act if we take it at its face value as having merely been a critical repudiation of a pathological action. The fact that it was accompanied by a sense of compulsion betrays it as having itself been a part of the pathological action, though a part which was determined by a motive contrary to that which produced the first part.

Compulsive acts like this, in two successive stages, of which the second neutralizes the first, are a typical occurrence in obsessional neuroses. The patient's consciousness naturally misunderstands them and puts forward a set of secondary motives to account for them - rationalizes them, in short. (Cf. Jones, 1908.) But their true significance lies in their being a representation of a conflict between two opposing impulses of approximately equal strength: and hitherto I have invariably found that this opposition has been one between love and hate. Compulsive acts of this sort are theoretically of special interest, for they show us a new type of method of constructing symptoms. What regularly occurs in hysteria is that a compromise is arrived at which enables both the opposing tendencies to find expression simultaneously - which kills two birds with one stone;¹ whereas here each of the two opposing tendencies finds satisfaction singly, first one and then the other, though naturally an attempt is made to establish some sort of logical connection (often in defiance of all logic) between the antagonists.²
The conflict between love and hatred showed itself in our patient by other signs as well. At the
time of the revival of his piety he made up prayers for himself, which took up more and more
and eventually lasted for an hour and a half. The reason for this was that he found, like an
inverted Balaam, that something always inserted itself into his pious phrases and turned them
into their opposite. E.g., if he said, 'May God protect him', an evil spirit would hurriedly insinuate
a 'not'.¹ On one such occasion the idea occurred to him of cursing instead, for in that case, he
thought, the contrary words would be sure to creep in. His original intention, which had been
repressed by his praying, was forcing its way through in this last idea of his. In the end he found
his way out of his embarrassment by giving up the prayers and replacing them by a short
formula concocted out of the initial letters or syllables of various prayers. He then recited this
formula so quickly that nothing could slip into it.
[1909d, 2152]

He once brought me a dream which represented the same conflict in relation to his
transference on to the physician. He dreamt that my mother was dead; he was anxious to offer
me his condolences, but was afraid that in doing so he might break into an impertinent laugh
as he had repeatedly done on similar occasions in the past. He preferred, therefore, to leave a
card on me with 'p. c.' written on it; but as he was writing them the letters turned into 'p. f.'²
[1909d, 2152]

² [The customary abbreviations for 'pour condoler' and 'pour féliciter' respectively.] This dream provides
the explanation of the compulsive laughter which so often occurs on mournful occasions and which is
regarded as such an unaccountable phenomenon.
[1909d, 2152]

The mutual antagonism between his feelings for his lady was too marked to have escaped his
conscious perception entirely, although we may conclude from the obsessions in which it was
manifested that he did not rightly appreciate the depth of his negative impulses. The lady had
refused his first proposal, ten years earlier. Since then he had to his own knowledge passed
through alternating periods, in which he either believed that he loved her intensely, or felt
indifferent to her. Whenever in the course of the treatment he was faced by the necessity of
taking some step which would bring him nearer the successful end of his courtship, his
resistance usually began by taking the form of a conviction that after all he did not very much
care for her - though this resistance, it is true, used soon to break down. Once when she was
lying seriously ill in bed and he was most deeply concerned about her, there crossed his mind
as he looked at her a wish that she might lie like that for ever. He explained this idea by an
ingenious piece of sophistry: maintaining that he had only wished her to be permanently ill so
that he might be relieved of his intolerable fear that she would have a repeated succession of
attacks!¹ Now and then he used to occupy his imagination with day-dreams, which he himself
recognized as 'phantasies of revenge' and felt ashamed of. Believing, for instance, that the lady
set great store by the social standing of a suitor, he made up a phantasy in which she was
married to a man of that kind, who was in some government office. He himself then entered the
same department, and rose much more rapidly than her husband, who eventually became his
subordinate. One day, his phantasy proceeded, this man committed some act of dishonesty.
The lady threw herself at his feet and implored him to save her husband. He promised to do so,
and informed her that it had only been for love of her that he had entered the service, because
he had foreseen that such a moment would occur; and now that her husband was saved, his
own mission was fulfilled and he would resign his post.
[1909d, 2153]
He produced other phantasies in which he did the lady some great service without her knowing that it was he who was doing it. In these he only recognized his affection, without sufficiently appreciating the origin and aim of his magnanimity, which was designed to repress his thirst for revenge, after the manner of Dumas' Count of Monte-Cristo. Moreover he admitted that occasionally he was overcome by quite distinct impulses to do some mischief to the lady he admired. These impulses were mostly in abeyance when she was there, and only appeared in her absence.

¹ It cannot be doubted that another contributory motive to this compulsive idea was a wish to know that she was powerless against his designs.

If we wish to obtain a grasp of the psychical forces whose interplay built up this neurosis, we must turn back to what we have learnt from the patient on the subject of the precipitating causes of his falling ill as a grown-up man and as a child. He fell ill when he was in his twenties on being faced with a temptation to marry another woman instead of the one whom he had loved so long; and he avoided a decision of this conflict by postponing all the necessary preliminary actions. The means for doing this was given him by his neurosis. His hesitation between the lady he loved and the other girl can be reduced to a conflict between his father's influence and his love for his lady, or, in other words, to a conflicting choice between his father and his sexual object, such as had already subsisted (judging from his recollections and obsessional ideas) in his remote childhood. All through his life, moreover, he was unmistakably victim to a conflict between love and hatred, in regard both to his lady and to his father. His phantasies of revenge and such obsessional phenomena as his obsession for understanding and his exploit with the stone in the road bore witness to his divided feelings; and they were to a certain degree comprehensible and normal, for the lady by her original refusal and subsequently by her coolness had given him some excuse for hostility. But his relations with his father were dominated by a similar division of feeling, as we have seen from our translation of his obsessional thoughts; and his father, too, must have given him an excuse for hostility in his childhood, as indeed we have been able to establish almost beyond question. His attitude towards the lady - a compound of tenderness and hostility - came to a great extent within the scope of his conscious knowledge; at most he deceived himself over the degree and violence of his negative feelings. But his hostility towards his father, on the contrary, though he had once been acutely conscious of it, had long since vanished from his ken, and it was only in the teeth of the most violent resistance that it could be brought back into his consciousness. We may regard the repression of his infantile hatred of his father as the event which brought his whole subsequent career under the dominion of the neurosis.
The conflicts of feeling in our patient which we have here enumerated separately were not independent of each other, but were bound together in pairs. His hatred of his lady was inevitably coupled with his attachment to his father, and inversely his hatred of his father with his attachment to his lady. But the two conflicts of feeling which result from this simplification - namely, the opposition between his relation to his father and to his lady, and the contradiction between his love and his hatred within each of these relations - had no connection whatever with each other, either in their content or in their origin. The first of these two conflicts corresponds to the normal vacillation between male and female which characterizes every one's choice of a love-object. It is first brought to the child's notice by the time-honoured question: 'Which do you love most, Daddy or Mummy?' and it accompanies him through his whole life, whatever may be the relative intensity of his feelings to the two sexes or whatever may be the sexual aim upon which he finally becomes fixed. But normally this opposition soon loses the character of a hard-and-fast contradiction, of an inexorable 'either-or'. Room is found for satisfying the unequal demands of both sides, although even in a normal person the higher estimation of one sex is always thrown into relief by a depreciation of the other.

[1909d, 2186]

The other conflict, that between love and hatred, strikes us more strangely. We know that incipient love is often perceived as hatred, and that love, if it is denied satisfaction, may easily be partly converted into hatred, and poets tell us that in the more tempestuous stages of love the two opposed feelings may subsist side by side for a while as though in rivalry with each other. But the chronic co-existence of love and hatred, both directed towards the same person and both of the highest degree of intensity, cannot fail to astonish us. We should have expected that the passionate love would long ago have conquered the hatred or been devoured by it. And in fact such a protracted survival of two opposites is only possible under quite peculiar psychological conditions and with the co-operation of the state of affairs in the unconscious. The love has not succeeded in extinguishing the hatred but only in driving it down into the unconscious; and in the unconscious the hatred, safe from the danger of being destroyed by the operations of consciousness, is able to persist and even to grow. In such circumstances the conscious love attains as a rule, by way of reaction, an especially high degree of intensity, so as to be strong enough for the perpetual task of keeping its opponent under repression. The necessary condition for the occurrence of such a strange state of affairs in a person's erotic life appears to be that at a very early age, somewhere in the prehistoric period of his infancy, the two opposites should have been split apart and one of them, usually the hatred, have been repressed.¹

[1909d, 2186]

¹ Compare the discussion on this point during one of the first sessions. - (Added 1923:) Bleuler subsequently introduced the appropriate term 'ambivalence' to describe this emotional constellation. See also a further development of this line of thought in my paper 'The Predisposition to Obsessional Neurosis' (1913/).

[1909d, 2186]
If we consider a number of analyses of obsessional neurotics we shall find it impossible to escape the impression that a relation between love and hatred such as we have found in our present patient is among the most frequent, the most marked, and probably, therefore, the most important characteristics of obsessional neurosis. But however tempting it may be to bring the problem of the 'choice of neurosis' into connection with instinctual life, there are reasons enough for avoiding such a course. For we must remember that in every neurosis we come upon the same suppressed instincts behind the symptoms. After all, hatred, kept suppressed in the unconscious by love, plays a great part in the pathogenesis of hysteria and paranoia. We know too little of the nature of love to be able to arrive at any definite conclusion here; and, in particular, the relation between the negative factor\(^1\) in love and the sadistic components of the libido remains completely obscure. What follows is therefore to be regarded as no more than a provisional explanation. We may suppose, then, that in the cases of unconscious hatred with which we are concerned the sadistic components of love have, from constitutional causes, been exceptionally strongly developed, and have consequently undergone a premature and all too thorough suppression, and that the neurotic phenomena we have observed arise on the one hand from conscious feelings of affection which have become exaggerated as a reaction, and on the other hand from sadism persisting in the unconscious in the form of hatred.

[1909d, 2187]

But in whatever way this remarkable relation of love and hatred is to be explained, its occurrence is established beyond any possibility of doubt by the observations made in the present case; and it is gratifying to find how easily we can now follow the puzzling processes of an obsessional neurosis by bringing them into relation with this one factor. If an intense love is opposed by an almost equally powerful hatred, and is at the same time inseparably bound up with it, the immediate consequence is certain to be a partial paralysis of the will and an incapacity for coming to a decision upon any of those actions for which love ought to provide the motive power. But this indecision will not confine itself for long to a single group of actions. For, in the first place, what actions of a lover are not brought into relation with his one principal motive? And secondly a man's attitude in sexual things has the force of a model to which the rest of his reactions tend to conform. And thirdly, it is an inherent characteristic in the psychology of an obsessional neurotic to make the fullest possible use of the mechanism of displacement. So the paralysis of his powers of decision gradually extends itself over the entire field of the patient's behaviour.

[1909d, 2188]

The doubt corresponds to the patient's internal perception of his own indecision, which, in consequence of the inhibition of his love by his hatred, takes possession of him in the face of every intended action. The doubt is in reality a doubt of his own love - which ought to be the most certain thing in his whole mind; and it becomes diffused over everything else, and is especially apt to become displaced on to what is most insignificant and small.\(^1\) A man who doubts his own love may, or rather must, doubt every lesser thing.\(^2\)

[1909d, 2188]
The negative transference deserves a detailed examination, which it cannot be given within the limits of the present paper. In the curable forms of psychoneurosis it is found side by side with the affectionate transference, often directed simultaneously towards the same person. Bleuler has coined the excellent term 'ambivalence' to describe this phenomenon.¹ Up to a point, ambivalence of feeling of this sort seems to be normal; but a high degree of it is certainly a special peculiarity of neurotic people. In obsessional neurotics an early separation of the 'pairs of opposites' seems to be characteristic of their instinctual life and to be one of their constitutional preconditions. Ambivalence in the emotional trends of neurotics is the best explanation of their ability to enlist their transferences in the service of resistance. Where the capacity for transference has become essentially limited to a negative one, as is the case with paranoics, there ceases to be any possibility of influence or cure.

[1912b, 2463]

I shall discuss on another occasion the explanation of these animal phobias and the significance attaching to them. I will only remark in anticipation that this explanation is in complete harmony with the principal characteristic shown by the neurosis from which the present dreamer suffered later in his life. His fear of his father was the strongest motive for his falling ill, and his ambivalent attitude towards every father-surrogate was the dominating feature of his life as well as of his behaviour during the treatment.

[1913d, 2601]

The principal characteristic of the psychological constellation which becomes fixed in this way is what might be described as the subject's ambivalent³ attitude towards a single object, or rather towards one act in connection with that object. He is constantly wishing to perform this act (the touching), and detests it as well. The conflict between these two currents cannot be promptly settled because - there is no other way of putting it - they are localized in the subject's mind in such a manner that they cannot come up against each other. The prohibition is noisily conscious, while the persistent desire to touch is unconscious and the subject knows nothing of it. If it were not for this psychological factor, an ambivalence like this could neither last so long nor lead to such consequences.

[1912-1913, 2677]

We have heard, though without understanding it, that anyone who does what is forbidden, that is, who violates a taboo, becomes taboo himself. How is this to be brought into line with the fact that taboo attaches not only to a person who has done what is forbidden but also to persons in particular states, to the states themselves, as well as to impersonal objects? What can the dangerous attribute be which remains the same under all these different conditions? There is only one thing it can be: the quality of exciting men's ambivalence and tempting them to transgress the prohibition.

[1912-1913, 2680]

I will now sum up the respects in which light has been thrown on the nature of taboo by comparing it with the obsessional prohibitions of neurotics. Taboo is a primaeval prohibition forcibly imposed (by some authority) from outside, and directed against the most powerful longings to which human beings are subject. The desire to violate it persists in their unconscious; those who obey the taboo have an ambivalent attitude to what the taboo prohibits. The magical power that is attributed to taboo is based on the capacity for arousing temptation; and it acts like a contagion because examples are contagious and because the prohibited desire in the unconscious shifts from one thing to another. The fact that the violation of a taboo can be atoned for by a renunciation shows that renunciation lies at the basis of obedience to taboo.

[1912-1913, 2682]
There is also another path open to us. We can start an inquiry as to whether some of the hypotheses which we have carried over from neuroses to taboo or some of the results to which that procedure has led us may not be directly verifiable in the phenomena of taboo. But we must decide what we are to look for. Our assertion that taboo originated in a primaeval prohibition imposed at one time or other by some external authority is obviously incapable of demonstration. What we shall rather endeavour to confirm, therefore, are the psychological determinants of taboo, which we have learnt to know from obsessional neurosis. How did we arrive at our knowledge of these psychological factors in the case of the neurosis? Through the analytical study of its symptoms, and particularly of obsessional acts, defensive measures and obsessional commands. We found that they showed every sign of being derived from ambivalent impulses, either corresponding simultaneously to both a wish and a counter-wish or operating predominantly on behalf of one of the two opposing trends. If, now, we could succeed in demonstrating that ambivalence, that is, the dominance of opposing trends, is also to be found in the observances of taboo, or if we could point to some of them which, like obsessional acts, give simultaneous expression to both currents, we should have established the psychological agreement between taboo and obsessional neurosis in what is perhaps their most important feature.

[1912-1913, 2683]

Before considering the remaining classes of taboo usages in connection with enemies, we must deal with an obvious objection. It will be argued against us, with Frazer and others, that the grounds for such rites of appeasement are simple enough and have nothing to do with any such thing as 'ambivalence'. These peoples are dominated by a superstitious fear of the ghosts of the slain - a fear which was not unknown in classical antiquity and which was put upon the stage by the great English dramatist in the hallucinations of Macbeth and Richard III. All the rites of appeasement follow logically from this superstition, as well as the restrictions and acts of expiation which will be discussed presently. This view is also supported by the fourth group of these observances, which can only be explained as attempts at driving away the ghosts of the victims that are pursuing their murderers.¹ In addition to this, the savages openly admit their fear of the ghosts of dead enemies and themselves attribute to it the taboo usages which we are discussing.

[1912-1913, 2686]

In the accepted explanation of all these observances of appeasement, restriction, expiation and purification, two principles are combined: the extension of the taboo from the slain man on to everything that has come in contact with him, and the fear of the slain man's ghost. How these two factors are to be combined with each other to explain the ceremonials, whether they are to be regarded as of equal weight, whether one is primary and the other secondary, and if so which - none of these questions receives an answer, and indeed it would be hard to find one. We, on the other hand, can lay stress on the unity of our view, which derives all of these observances from emotional ambivalence towards the enemy.

[1912-1913, 2688]
So far so good; but the technique of psycho-analysis allows us to go into the question further and to enter more into the details of these various impulses. If we submit the recorded facts to analysis, as though they formed part of the symptoms presented by a neurosis, our starting-point must be the excessive apprehensiveness and solicitude which is put forward as the reason for the taboo ceremonials. The occurrence of excessive solicitude of this kind is very common in neuroses, and especially in obsessional neuroses, with which our comparison is chiefly drawn. We have come to understand its origin quite clearly. It appears wherever, in addition to a predominant feeling of affection, there is also a contrary, but unconscious, current of hostility - a state of affairs which represents a typical instance of an ambivalent emotional attitude. The hostility is then shouted down, as it were, by an excessive intensification of the affection, which is expressed as solicitude and becomes compulsive, because it might otherwise be inadequate to perform its task of keeping the unconscious contrary current of feeling under repression. Every psycho-analyst knows from experience with what certainty this explanation of solicitous over-affection is found to apply even in the most unlikely circumstances - in cases, for instance, of attachments between a mother and child or between a devoted married couple. If we now apply this to the case of privileged persons, we shall realize that alongside the veneration, and indeed idolization, felt towards them, there is in the unconscious an opposing current of intense hostility; that, in fact, as we expected, we are faced by a situation of emotional ambivalence. The distrust which provides one of the unmistakable elements in kingly taboos would thus be another, more direct, expression of the same unconscious hostility. Indeed, owing to the variety of outcomes of a conflict of this kind which are reached among different peoples, we are not at a loss for examples in which the existence of this hostility is still more obviously shown. 'The savage Timmes of Sierra Leone', we learn from Frazer, 'who elect their king, reserve to themselves the right of beating him on the eve of his coronation; and they avail themselves of this constitutional privilege with such hearty goodwill that sometimes the unhappy monarch does not long survive his elevation to the throne. Hence when the leading chiefs have a spite at a man and wish to rid themselves of him, they elect him king.' Even in glaring instances like this, however, the hostility is not admitted as such, but masquerades as a ceremonial.

[1912-1913, 2695]

But the strongest support for our effort to equate taboo prohibitions with neurotic symptoms is to be found in the taboo ceremonials themselves, the effect of which upon the position of royalty has already been discussed. These ceremonials unmistakably reveal their double meaning and their derivation from ambivalent impulses, as soon as we are ready to allow that the results which they bring about were intended from the first. The taboo does not only pick out the king and exalt him above all common mortals, it also makes his existence a torment and an intolerable burden and reduces him to a bondage far worse than that of his subjects. Here, then, we have an exact counterpart of the obsessional act in the neurosis, in which the suppressed impulse and the impulse that suppresses it find simultaneous and common satisfaction. The obsessional act is ostensively a protection against the prohibited act; but actually, in our view, it is a repetition of it. The 'ostensibly' applies to the conscious part of the mind, and the 'actually' to the unconscious part. In exactly the same way, the ceremonial taboo of kings is ostensively the highest honour and protection for them, while actually it is a punishment for their exaltation, a revenge taken on them by their subjects. The experiences of Sancho Panza (as described by Cervantes) when he was Governor of his island convinced him that this view of court ceremonial was the only one that met the case. If we could hear the views of modern kings and rulers on the subject, we might find that there were many others who agreed with him.

[1912-1913, 2696]
When a wife has lost her husband or a daughter her mother, it not infrequently happens that
the survivor is overwhelmed by tormenting doubts (to which we give the name of 'obsessive
self-reproaches') as to whether she may not herself have been responsible for the death of this
cherished being through some act of carelessness or neglect. No amount of recollection of the
care she lavished on the sufferer, no amount of objective disproof of the accusation, serves to
bring the torment to an end. It may be regarded as a pathological form of mourning, and with
the passage of time it gradually dies away. The psycho-analytic investigation of such cases has
revealed the secret motives of the disorder. We find that in a certain sense these obsessive
self-reproaches are justified, and that this is why they are proof against contradictions and
protests. It is not that the mourner was really responsible for the death or was really guilty of
neglect, as the self-reproaches declare to be the case. None the less there was something in
her - a wish that was unconscious to herself - which would not have been dissatisfied by the
occurrence of death and which might actually have brought it about if it had had the power. And
after death has occurred, it is against this unconscious wish that the reproaches are a reaction.
In almost every case where there is an intense emotional attachment to a particular person we
find that behind the tender love there is a concealed hostility in the unconscious. This is the
classical example, the prototype, of the ambivalence of human emotions. This ambivalence is
present to a greater or less amount in the innate disposition of everyone; normally, there is not
so much of it as to produce the obsessive self-reproaches we are considering. Where, however,
it is copiously present in the disposition, it will manifest itself precisely in the subject's relation to
those of whom he is most fond, in the place, in fact, where one would least expect to find it. It
must be supposed that the presence of a particularly large amount of this original emotional
ambivalence is characteristic of the disposition of obsessional neurotics - whom I have so often
brought up for comparison in this discussion upon taboo.

We have now discovered a motive which can explain the idea that the souls of those who
have just died are transformed into demons and the necessity felt by survivors to protect
themselves by taboos against their hostility. Let us suppose that the emotional life of primitive
peoples is characterized by an amount of ambivalence as great as that which we are led by the
findings of psycho-analysis to attribute to obsessional patients. It then becomes easy to
understand how after a painful bereavement savages should be obliged to produce a reaction
against the hostility latent in their unconscious similar to that expressed as obsessive self-
reproach in the case of neurotics. But this hostility, distressingly felt in the unconscious as
satisfaction over the death, is differently dealt with among primitive peoples. The defence
against it takes the form of displacing it on to the object of the hostility, on to the dead
themselves. This defensive procedure, which is a common one both in normal and in
pathological mental life, is known as a 'projection'. The survivor thus denies that he has ever
harboured any hostile feelings against the dead loved one; the soul of the dead harbours them
instead and seeks to put them into action during the whole period of mourning. In spite of the
successful defence which the survivor achieves by means of projection, his emotional reaction
shows the characteristics of punishment and remorse, for he is the subject of fears and submits
to renunciations and restrictions, though these are in part disguised as measures of protection
against the hostile demon. Once again, therefore, we find that the taboo has grown up on the
basis of an ambivalent emotional attitude. The taboo upon the dead arises, like the others, from
the contrast between conscious pain and unconscious satisfaction over the death that has
occurred. Since such is the origin of the ghost's resentment, it follows naturally that the
survivors who have the most to fear will be those who were formerly its nearest and dearest.
Westermarck is right in insisting that savages draw no distinction between violent and natural death. In the view of unconscious thinking, a man who has died a natural death is a murdered man: evil wishes have killed him. Anyone who investigates the origin and significance of dreams of the death of loved relatives (of parents or brothers or sisters) will be able to convince himself that dreamers, children and savages are at one in their attitude towards the dead - an attitude based upon emotional ambivalence.

Both of the two sets of feelings (the affectionate and the hostile), which, as we have good reason to believe, exist towards the dead person, seek to take effect at the time of the bereavement, as mourning and as satisfaction. There is bound to be a conflict between these two contrary feelings; and, since one of the two, the hostility, is wholly or for the greater part unconscious, the outcome of the conflict cannot be to subtract, as it were, the feeling with the lesser intensity from that with the greater and to establish the remainder in consciousness - as occurs, for instance, when one forgives a slight that one has received from someone of whom one is fond. The process is dealt with instead by the special psychical mechanism known in psycho-analysis, as I have said, by the name of 'projection'. The hostility, of which the survivors know nothing and moreover wish to know nothing, is ejected from internal perception into the external world, and thus detached from them and pushed on to someone else. It is no longer true that they are rejoicing to be rid of the dead man; on the contrary, they are mourning for him; but, strange to say, he has turned into a wicked demon ready to gloat over their misfortunes and eager to kill them. It then becomes necessary for them, the survivors, to defend themselves against this evil enemy; they are relieved of pressure from within, but have only exchanged it for oppression from without.

Wundt (1906, 129) remarks that 'among the activities attributed by myths all over the world to demons, the harmful predominate, so that in popular belief bad demons are clearly older than good ones'. It is quite possible that the whole concept of demons was derived from the important relation of the living to the dead. The ambivalence inherent in that relation was expressed in the subsequent course of human development by the fact that, from the same root, it gave rise to two completely opposed psychical structures: on the one hand fear of demons and ghosts and on the other hand veneration of ancestors. The fact that demons are always regarded as the spirits of those who have died recently shows better than anything the influence of mourning on the origin of the belief in demons. Mourning has a quite specific psychical task to perform: its function is to detach the survivors' memories and hopes from the dead. When this has been achieved, the pain grows less and with it the remorse and self-reproaches and consequently the fear of the demon as well. And the same spirits who to begin with were feared as demons may now expect to meet with friendlier treatment; they are revered as ancestors and appeals are made to them for help.
If we follow the changing relations between survivors and the dead through the course of ages, it becomes obvious that there has been an extraordinary diminution in ambivalence. It is now quite easy to keep down the unconscious hostility to the dead (though its existence can still be traced) without any particular expenditure of psychical energy. Where, in earlier times, satisfied hatred and pained affection fought each other, we now find that a kind of scar has been formed in the shape of piety, which declares 'de mortuis nil nisi bonum'. It is only neurotics whose mourning for the loss of those dear to them is still troubled by obsessive self-reproaches - the secret of which is revealed by psycho-analysis as the old emotional ambivalence. We need not discuss here how this alteration came about or how much share in it is due to a constitutional modification and how much to a real improvement in family relations. But this example suggests the probability that the psychical impulses of primitive peoples were characterized by a higher amount of ambivalence than is to be found in modern civilized man. It is to be supposed that as this ambivalence diminished, taboo (a symptom of the ambivalence and a compromise between two conflicting impulses) slowly disappeared Neurotics, who are obliged to reproduce the struggle and the taboo resulting from it, may be said to have inherited an archaic constitution as an atavistic vestige; the need to compensate for this at the behest of civilization is what drives them to their immense expenditure of mental energy.

Our discussions, on the contrary, lead us to the simple conclusion that the word 'taboo' had a double meaning from the very first and that it was used to designate a particular kind of ambivalence and whatever arose from it. 'Taboo' is itself an ambivalent word; and one feels on looking back that the well-attested meaning of the word should alone have made it possible to infer - what has actually been arrived at as a result of extensive researches - that the prohibitions of taboo are to be understood as consequences of an emotional ambivalence. Study of the earliest languages has taught us that there were once many such words, which expressed contrary ideas and in a sense (though not in quite the same sense as the word 'taboo') were ambivalent.¹ Slight modifications in the pronunciation of the antithetical 'primal word' made it possible subsequently to give separate verbal expression to the two contrary ideas which were originally combined in it.

Thus it seems probable that conscience too arose, on a basis of emotional ambivalence, from quite specific human relations to which this ambivalence was attached; and that it arose under the conditions which we have shown to apply in the case of taboo and of obsessional neurosis - namely, that one of the opposing feelings involved shall be unconscious and kept under repression by the compulsive domination of the other one. This conclusion is supported by several things we have learnt from the analysis of neuroses.

Suppose, on the other hand, that we were to take into account the finding arrived at by psycho-analysis from the dreams of normal people, to the effect that we ourselves are subject, more strongly and more often than we suspect, to a temptation to kill someone and that that temptation produces psychical effects even though it remains out of sight of our consciousness. Suppose, again, that we were to recognize the compulsive observances of certain neurotics as being guarantees against an intensified impulse to murder or as being self-punishments on account of it. In that case we should have to attach still greater importance to our thesis that where there is a prohibition there must be an underlying desire. We should have to suppose that the desire to murder is actually present in the unconscious and that neither taboos nor moral prohibitions are psychologically superfluous but that on the contrary they are explained and justified by the existence of an ambivalent attitude towards the impulse to murder.
One of the characteristics of this ambivalent relation which I have repeatedly stressed as fundamental - the fact that the positive current of desire is an unconscious one - opens the way to further considerations and to further possible explanations. Psychical processes in the unconscious are not in every respect identical with those with which our conscious mind is familiar; they enjoy some remarkable liberties that are forbidden to the latter. An unconscious impulse need not have arisen at the point where it makes its appearance; it may arise from some quite other region and have applied originally to quite other persons and connections; it may have reached the place at which it attracts our attention though the mechanism of 'displacement'. Owing, moreover, to the indestructibility and insusceptibility to correction which are attributes of unconscious processes, it may have survived from very early times to which it was appropriate into later times and circumstances in which its manifestations are bound to seem strange. These are no more than hints, but if they were attentively developed their importance for our understanding of the growth of civilization would become apparent.

[1912-1913, 2714]

I propose to avoid (as I have already done elsewhere³) entering into the general problem of the origin of the tendency to project mental processes into the outside. It is, however, safe to assume that that tendency will be intensified when projection promises to bring with it the advantage of mental relief. Such an advantage may be expected with certainty where a conflict has arisen between different impulses all of which are striving towards omnipotence - for they clearly cannot all become omnipotent. The pathological process in paranoia in fact makes use of the mechanism of projection in order to deal with mental conflicts of this kind. The typical case of such a conflict is one between the two members of a pair of opposites - the case of an ambivalent attitude, which we have examined in detail as it appears in someone mourning the death of a loved relative. This kind of case must seem particularly likely to provide a motive for the creation of projections. Here again we are in agreement with the writers who maintain that the first born spirits were evil spirits, and who derive the idea of a soul from the impression made by death upon the survivors. The only difference is that we do not lay stress on the intellectual problem with which death confronts the living; in our view the force which gives the impetus to research is rather to be attributed to the emotional conflict into which the survivors are plunged.

[1912-1913, 2735]

Analysis is able to trace the associative paths along which this displacement passes - both the fortuitous paths and those with a significant content. Analysis also enables us to discover the motives for the displacement. The hatred of his father that arises in a boy from rivalry for his mother is not able to achieve uninhibited sway over his mind; it has to contend against his old-established affection and admiration for the very same person. The child finds relief from the conflict arising out of this double-sided, this ambivalent emotional attitude towards his father by displacing his hostile and fearful feelings on to a substitute for his father. The displacement cannot, however, bring the conflict to an end, it cannot effect a clear-cut severance between the affectionate and the hostile feelings. On the contrary, the conflict is resumed in relation to the object on to which the displacement has been made: the ambivalence is extended to it. There could be no doubt that little Hans was not only frightened of horses; he also approached them with admiration and interest. As soon as his anxiety began to diminish, he identified himself with the dreaded creature: he began to jump about like a horse and in his turn bit his father.¹ At another stage in the resolution of his phobia he did not hesitate to identify his parents with some other large animals.²

[1912-1913, 2769]
Later on we shall be able to assess the worth of this observation more completely. At the moment I will only emphasize two features in it which offer valuable points of agreement with totemism: the boy’s complete identification with his totem animal¹ and his ambivalent emotional attitude to it. These observations justify us, in my opinion, in substituting the father for the totem animal in the formula for totemism (in the case of males). It will be observed that there is nothing new or particularly daring in this step forward. Indeed, primitive men say the very same thing themselves, and, where the totemic system is still in force to-day, they describe the totem as their common ancestor and primal father. All we have done is to take at its literal value an expression used by these people, of which the anthropologists have been able to make very little and which they have therefore been glad to keep in the background. Psycho-analysis, on the contrary, leads us to put special stress upon this same point and to take it as the starting-point of our attempt at explaining totemism.²

Psycho-analysis has revealed that the totem animal is in reality a substitute for the father; and this tallies with the contradictory fact that, though the killing of the animal is as a rule forbidden, yet its killing is a festive occasion - with the fact that it is killed and yet mourned. The ambivalent emotional attitude, which to this day characterizes the father-complex in our children and which often persists into adult life, seems to extend to the totem animal in its capacity as substitute for the father.

In order that these latter consequences may seem plausible, leaving their premises on one side, we need only suppose that the tumultuous mob of brothers were filled with the same contradictory feelings which we can see at work in the ambivalent father-complexes of our children and of our neurotic patients. They hated their father, who presented such a formidable obstacle to their craving for power and their sexual desires; but they loved and admired him too. After they had got rid of him, had satisfied their hatred and had put into effect their wish to identify themselves with him, the affection which had all this time been pushed under was bound to make itself felt.¹ It did so in the form of remorse. A sense of guilt made its appearance, which in this instance coincided with the remorse felt by the whole group. The dead father became stronger than the living one had been - for events took the course we so often see them follow in human affairs to this day. What had up to then been prevented by his actual existence was thenceforward prohibited by the sons themselves, in accordance with the psychological procedure so familiar to us in psycho-analyses under the name of ‘deferred obedience’. They revoked their deed by forbidding the killing of the totem, the substitute for their father; and they renounced its fruits by resigning their claim to the women who had now been set free. They thus created out of their filial sense of guilt the two fundamental taboos of totemism, which for that very reason inevitably corresponded to the two repressed wishes of the Oedipus complex. Whoever contravened those taboos be came guilty of the only two crimes with which primitive society concerned itself.²
There is another feature which was already present in totemism and which has been preserved unaltered in religion. The tension of ambivalence was evidently too great for any contrivance to be able to counteract it; or it is possible that psychological conditions in general are unfavourable to getting rid of these antithetical emotions. However that may be, we find that the ambivalence implicit in the father-complex persists in totemism and in religions generally. Totemic religion not only comprised expressions of remorse and attempts at atonement, it also served as a remembrance of the triumph over the father. Satisfaction over that triumph led to the institution of the memorial festival of the totem meal, in which the restrictions of deferred obedience no longer held. Thus it became a duty to repeat the crime of parricide again and again in the sacrifice of the totem animal, whenever, as a result of the changing conditions of life, the cherished fruit of the crime - appropriation of the paternal attributes - threatened to disappear. We shall not be surprised to find that the element of filial rebelliousness also emerges, in the later products of religion, often in the strangest disguises and transformations. [1912-1913, 2785]

Hitherto we have followed the developments of the affectionate current of feeling towards the father, transformed into remorse, as we find them in religion and in moral ordinances (which are not sharply distinguished in totemism). But we must not overlook the fact that it was in the main with the impulses that led to parricide that the victory lay. For a long time afterwards, the social fraternal feelings, which were the basis of the whole transformation, continued to exercise a profound influence on the development of society. They found expression in the sanctification of the blood tie, in the emphasis upon the solidarity of all life within the same clan. In thus guaranteeing one another's lives, the brothers were declaring that no one of them must be treated by another as their father was treated by them all jointly. They were precluding the possibility of a repetition of their father's fate. To the religiously-based prohibition against killing the totem was now added the socially-based prohibition against fratricide. It was not until long afterwards that the prohibition ceased to be limited to members of the clan and assumed the simple form: 'Thou shalt do no murder.' The patriarchal horde was replaced in the first instance by the fraternal clan, whose existence was assured by the blood tie. Society was now based on complicity in the common crime; religion was based on the sense of guilt and the remorse attaching to it; while morality was based partly on the exigencies of this society and partly on the penance demanded by the sense of guilt. [1912-1913, 2786]

We see, then, that in the scene of sacrifice before the god of the clan the father is in fact represented twice over - as the god and as the totemic animal victim. But in our attempts at understanding this situation we must beware of interpretations which seek to translate it in a two-dimensional fashion as though it were an allegory, and which in so doing forget its historical stratification. The two-fold presence of the father corresponds to the two chronologically successive meanings of the scene. The ambivalent attitude towards the father has found a plastic expression in it, and so, too, has the victory of the son's affectionate emotions over his hostile ones. The scene of the father's vanquishment, of his greatest defeat, has become the stuff for the representation of his supreme triumph. The importance which is everywhere, without exception, ascribed to sacrifice lies in the fact that it offers satisfaction to the father for the outrage inflicted on him in the same act in which that deed is commemorated. [1912-1913, 2789]
In the Christian doctrine, therefore, men were acknowledging in the most undisguised manner the guilty primaeval deed, since they found the fullest atonement for it in the sacrifice of this one son. Atonement with the father was all the more complete since the sacrifice was accompanied by a total renunciation of the women on whose account the rebellion against the father was started. But at that point the inexorable psychological law of ambivalence stepped in. The very deed in which the son offered the greatest possible atonement to the father brought him at the same time to the attainment of his wishes against the father. He himself became God, beside, or, more correctly, in place of, the father. A son-religion displaced the father-religion. As a sign of this substitution the ancient totem meal was revived in the form of communion, in which the company of brothers consumed the flesh and blood of the son - no longer the father - obtained sanctity thereby and identified themselves with him. Thus we can trace through the ages the identity of the totem meal with animal sacrifice, with theanthropic human sacrifice and with the Christian Eucharist, and we can recognize in all these rituals the effect of the crime by which men were so deeply weighed down but of which they must none the less feel so proud. The Christian communion, however, is essentially a fresh elimination of the father, a repetition of the guilty deed. We can see the full justice of Frazer's pronouncement that 'the Christian communion has absorbed within itself a sacrament which is doubtless far older than Christianity'.²

[1912-1913, 2794]

At the conclusion, then, of this exceedingly condensed inquiry, I should like to insist that its outcome shows that the beginnings of religion, morals, society and art converge in the Oedipus complex. This is in complete agreement with the psycho-analytic finding that the same complex constitutes the nucleus of all neuroses, so far as our present knowledge goes. It seems to me a most surprising discovery that the problems of social psychology, too, should prove soluble on the basis of one single concrete point - man's relation to his father. It is even possible that yet another psychological problem belongs in this same connection. I have often had occasion to point out that emotional ambivalence in the proper sense of the term - that is, the simultaneous existence of love and hate towards the same object - lies at the root of many important cultural institutions. We know nothing of the origin of this ambivalence. One possible assumption is that it is a fundamental phenomenon of our emotional life. But it seems to me quite worth considering another possibility, namely that originally it formed no part of our emotional life but was acquired by the human race in connection with their father-complex,¹ precisely where the psycho-analytic examination of modern individuals still finds it revealed at its strongest.²

[1912-1913, 2796]
May not the same have been true of primitive men? We are justified in believing that, as one of the phenomena of their narcissistic organization, they overvalued their psychical acts to an extraordinary degree.² Accordingly the mere hostile impulse against the father, the mere existence of a wishful phantasy of killing and devouring him, would have been enough to produce the moral reaction that created totemism and taboo. In this way we should avoid the necessity for deriving the origin of our cultural legacy, of which we justly feel so proud, from a hideous crime, revolting to all our feelings. No damage would thus be done to the causal chain stretching from the beginning to the present day, for psychical reality would be strong enough to bear the weight of these consequences. To this it may be objected that an alteration in the form of society from a patriarchal horde to a fraternal clan did actually take place. This is a powerful argument, but not a conclusive one. The alteration might have been effected in a less violent fashion and none the less have been capable of determining the appearance of the moral reaction. So long as the pressure exercised by the primal father could be felt, the hostile feelings towards him were justified, and remorse on their account would have to await a later day. And if it is further argued that everything derived from the ambivalent relation to the father - taboo and the sacrificial ordinance - is characterized by the deepest seriousness and the most complete reality, this further objection carries just as little weight. For the ceremonials and inhibitions of obsessional neurotics show these same characteristics and are nevertheless derived only from psychical reality - from intentions and not from their execution. We must avoid transplanting a contempt for what is merely thought or wished from our commonplace world, with its wealth of material values, into the world of primitive men and neurotics, of which the wealth lies only within themselves.

[1912-1913, 2798]

We courted them or turned our backs on them, we imagined sympathies and antipathies in them which probably had no existence, we studied their characters and on theirs we formed or misformed our own. They called up our fiercest opposition and forced us to complete submission; we peered into their little weaknesses, and took pride in their excellences, their knowledge and their justice. At bottom we felt a great affection for them if they gave us any ground for it, though I cannot tell how many of them were aware of this. But it cannot be denied that our position in regard to them was a quite remarkable one and one which may well have had its inconvenience for those concerned. We were from the very first equally inclined to love and to hate them, to criticize and respect them. Psycho-analysis has given the name of 'ambivalence' to this readiness to contradictory attitudes, and it has no difficulty in pointing to the source of ambivalent feelings of such a kind.

[1914f, 2872]

Of all the imagos of a childhood which, as a rule, is no longer remembered, none is more important for a youth or a man than that of his father. Organic necessity introduces into a man's relation to his father an emotional ambivalence which we have found most strikingly expressed in the Greek myth of King Oedipus. A little boy is bound to love and admire his father, who seems to him the most powerful, the kindest and the wisest creature in the world. God himself is after all only an exaltation of this picture of a father as he is represented in the mind of early childhood. But soon the other side of this emotional relationship emerges. One's father is recognized as the paramount disturber of one's instinctual life; he becomes a model not only to imitate but also to get rid of, in order to take his place. Thenceforward affectionate and hostile impulses towards him persist side by side, often to the end of one's life, without either of them being able to do away with the other. It is in this existence of contrary feelings side by side that lies the essential character of what we call emotional ambivalence.

[1914f, 2873]
It is in this phase of a youth's development that he comes into contact with his teachers. So that we can now understand our relation to our schoolmasters. These men, not all of whom were in fact fathers themselves, became our substitute fathers. That was why, even though they were still quite young, they struck us as so mature and so unattainably adult. We transferred on to them the respect and expectations attaching to the omniscient father of our childhood, and we then began to treat them as we treated our fathers at home. We confronted them with the ambivalence that we had acquired in our own families and with its help we struggled with them as we had been in the habit of struggling with our fathers in the flesh. Unless we take into account our nurseries and our family homes, our behaviour to our schoolmasters would be not only incomprehensible but inexcusable.

The fact that, at this later period of development of an instinctual impulse, its (passive) opposite may be observed alongside of it deserves to be marked by the very apt term introduced by Bleuler - 'ambivalence'.

This reference to the developmental history of instincts and the permanence of their intermediate stages should make the development of instincts fairly intelligible to us. Experience shows that the amount of demonstrable ambivalence varies greatly between individuals, groups and races. Marked instinctual ambivalence in a human being living at the present day may be regarded as an archaic inheritance, for we have reason to suppose that the part played in instinctual life by the active impulses in their unmodified form was greater in primaeval times than it is on an average to-day.

The change of the content of an instinct into its opposite is observed in a single instance only - the transformation of love into hate. Since it is particularly common to find both these directed simultaneously towards the same object, their co-existence furnishes the most important example of ambivalence of feeling.

The history of the origins and relations of love makes us understand how it is that love so frequently manifests itself as 'ambivalent' - i.e. as accompanied by impulses of hate against the same object. The hate which is admixed with the love is in part derived from the preliminary stages of loving which have not been wholly surmounted; it is also in part based on reactions of repudiation by the ego-instincts, which, in view of the frequent conflicts between the interests of the ego and those of love, can find grounds in real and contemporary motives. In both cases, therefore, the admixed hate has as its source the self-preservative instincts. If a love-relation with a given object is broken off, hate not infrequently emerges in its place, so that we get the impression of a transformation of love into hate. This account of what happens leads on to the view that the hate, which has its real motives, is here reinforced by a regression of the love to the sadistic preliminary stage; so that the hate acquires an erotic character and the continuity of a love relation is ensured.
A totally different picture of repression is shown, once more, in the third disorder which we shall consider for the purposes of our illustration - in obsessional neurosis. Here we are at first in doubt what it is that we have to regard as the instinctual representative that is subjected to repression - whether it is a libidinal or a hostile trend. This uncertainty arises because obsessional neurosis has as its basis a regression owing to which a sadistic trend has been substituted for an affectionate one. It is this hostile impulsion against someone who is loved which is subjected to repression. The effect at an early stage of the work of repression is quite different from what it is at a later one. At first the repression is completely successful; the ideational content is rejected and the affect made to disappear. As a substitutive formation there arises an alteration in the ego in the shape of an increased conscientiousness, and this can hardly be called a symptom. Here, substitute and symptom do not coincide. From this we learn something, too, about the mechanism of repression. In this instance, as in all others, repression has brought about a withdrawal of libido; but here it has made use of reaction-formation for this purpose, by intensifying an opposite. Thus in this case the formation of a substitute has the same mechanism as repression and at bottom coincides with it, while chronologically, as well as conceptually, it is distinct from the formation of a symptom. It is very probable that the whole process is made possible by the ambivalent relationship into which the sadistic impulsion that has to be repressed has been introduced. But the repression, which was at first successful, does not hold firm; in the further course of things its failure becomes increasingly marked. The ambivalence which has enabled repression through reaction-formation to take place is also the point at which the repressed succeeds in returning. The vanished affect comes back in its transformed shape as social anxiety, moral anxiety and unlimited self-reproaches; the rejected idea is replaced by a substitute by displacement, often a displacement on to something very small or indifferent. A tendency to a complete re-establishment of the repressed idea is as a rule unmistakably present. The failure in the repression of the quantitative, affective factor brings into play the same mechanism of flight, by means of avoidance and prohibitions, as we have seen at work in the formation of hysterical phobias. The rejection of the idea from the conscious is, however, obstinately maintained, because it entails abstention from action, a motor fettering of the impulsion. Thus in obsessional neurosis the work of repression is prolonged in a sterile and interminable struggle.

[1915d, 2987]
Melancholia, therefore, borrows some of its features from mourning, and the others from the process of regression from narcissistic object-choice to narcissism. It is on the one hand, like mourning, a reaction to the real loss of a loved object; but over and above this, it is marked by a determinant which is absent in normal mourning or which, if it is present, transforms the latter into pathological mourning. The loss of a love-object is an excellent opportunity for the ambivalence in love-relationships to make itself effective and come into the open. Where there is a disposition to obsessional neurosis the conflict due to ambivalence gives a pathological cast to mourning and forces it to express itself in the form of self-reproaches to the effect that the mourner himself is to blame for the loss of the loved object, i.e. that he has willed it. These obsessional states of depression following upon the death of a loved person show us what the conflict due to ambivalence can achieve by itself when there is no regressive drawing-in of libido as well. In melancholia, the occasions which give rise to the illness extend for the most part beyond the clear case of a loss by death, and include all those situations of being slighted, neglected or disappointed, which can import opposed feelings of love and hate into the relationship or reinforce an already existing ambivalence. This conflict due to ambivalence, which sometimes arises more from real experiences, sometimes more from constitutional factors, must not be overlooked among the preconditions of melancholia. If the love for the object - a love which cannot be given up though the object itself is given up - takes refuge in narcissistic identification, then the hate comes into operation on this substitutive object, abusing it, debasing it, making it suffer and deriving sadistic satisfaction from its suffering. The self-tormenting in melancholia, which is without doubt enjoyable, signifies, just like the corresponding phenomenon in obsessional neurosis, a satisfaction of trends of sadism and hate which relate to an object, and which have been turned round upon the subject's own self in the ways we have been discussing. In both disorders the patients usually still succeed, by the circuitous path of self-punishment, in taking revenge on the original object and in tormenting their loved one through their illness, having resorted to it in order to avoid the need to express their hostility to him openly. After all, the person who has occasioned the patient's emotional disorder, and on whom his illness is centred, is usually to be found in his immediate environment. The melancholic's erotic cathexis in regard to his object has thus undergone a double vicissitude: part of it has regressed to identification, but the other part, under the influence of the conflict due to 'ambivalence, has been carried back to the stage of sadism which is nearer to that conflict.

[1917e, 3048]
As we have seen, however, melancholia contains something more than normal mourning. In melancholia the relation to the object is no simple one; it is complicated by the conflict due to ambivalence. The ambivalence is either constitutional, i.e. is an element of every love-relation formed by this particular ego, or else it proceeds precisely from those experiences that involved the threat of losing the object. For this reason the exciting causes of melancholia have a much wider range than those of mourning, which is for the most part occasioned only by a real loss of the object, by its death. In melancholia, accordingly, countless separate struggles are carried on over the object, in which hate and love contend with each other; the one seeks to detach the libido from the object, the other to maintain this position of the libido against the assault. The location of these separate struggles cannot be assigned to any system but the Ucs., the region of the memory-traces of things (as contrasted with word-cathexes). In mourning, too, the efforts to detach the libido are made in this same system; but in it nothing hinders these processes from proceeding along the normal path through the Pcs. to consciousness. This path is blocked for the work of melancholia, owing perhaps to a number of causes or a combination of them. Constitutional ambivalence belongs by its nature to the repressed; traumatic experiences in connection with the object may have activated other repressed material. Thus everything to do with these struggles due to ambivalence remains withdrawn from consciousness, until the outcome characteristic of melancholia has set in. This, as we know, consists in the threatened libidinal cathexis at length abandoning the object, only, however, to draw back to the place in the ego from which it had proceeded. So by taking flight into the ego love escapes extinction. After this regression of the libido the process can become conscious, and it is represented to consciousness as a conflict between one part of the ego and the critical agency.

[1917e, 3052]

These primitive impulses undergo a lengthy process of development before they are allowed to become active in the adult. They are inhibited, directed towards other aims and fields, become commingled, alter their objects, and are to some extent turned back upon their possessor. Reaction-formations against certain instincts take the deceptive form of a change in their content, as though egoism had changed into altruism, or cruelty into pity. These reaction-formations are facilitated by the circumstance that some instinctual impulses make their appearance almost from the first in pairs of opposites - a very remarkable phenomenon, and one strange to the lay public, which is termed 'ambivalence of feeling'. The most easily observed and comprehensible instance of this is the fact that intense love and intense hatred are so often to be found together in the same person. Psycho-analysis adds that the two opposed feelings not infrequently have the same person for their object.

[1915b, 3073]

His own death was certainly just as unimaginable and unreal for primaeval man as it is for any one of us to-day. But there was for him one case in which the two opposite attitudes towards death collided and came into conflict with each other; and this case became highly important and productive of far-reaching consequences. It occurred when primaeval man saw someone who belonged to him die - his wife, his child, his friend - whom he undoubtedly loved as we love ours, for love cannot be much younger than the lust to kill. Then, in his pain, he was forced to learn that one can die, too, oneself, and his whole being revolted against the admission; for each of these loved ones was, after all, a part of his own beloved ego. But, on the other hand, deaths such as these pleased him as well, since in each of the loved persons there was also something of the stranger. The law of ambivalence of feeling, which to this day governs our emotional relations with those whom we love most, certainly had a very much wider validity in primaeval times. Thus these beloved dead had also been enemies and strangers who had aroused in him some degree of hostile feeling.¹

[1915b, 3085]
Just as for primaeval man, so also for our unconscious, there is one case in which the two opposing attitudes towards death, the one which acknowledges it as the annihilation of life and the other which denies it as unreal, collide and come into conflict. This case is the same as in primal ages: the death, or the risk of death, of someone we love, a parent or a partner in marriage, a brother or sister, a child or a dear friend. These loved ones are on the one hand an inner possession, components of our own ego; but on the other hand they are partly strangers, even enemies. With the exception of only a very few situations, there adheres to the tenderest and most intimate of our love-relations a small portion of hostility which can excite an unconscious death-wish. But this conflict due to ambivalence does not now, as it did then, lead to the doctrine of the soul and to ethics, but to neurosis, which affords us deep insight into normal mental life as well. How often have physicians who practise psycho-analysis had to deal with the symptom of an exaggerated worry over the well-being of relatives, or with entirely unfounded self-reproaches after the death of a loved person. The study of such phenomena has left them in no doubt about the extent and importance of unconscious death-wishes.

[1915b, 3090]

The layman feels an extraordinary horror at the possibility of such feelings, and takes this aversion as a legitimate ground for disbelief in the assertions of psycho-analysis. Mistakenly, I think. No depreciation of feelings of love is intended, and there is in fact none. It is indeed foreign to our intelligence as well as to our feelings thus to couple love and hate; but Nature, by making use of this pair of opposites, contrives to keep love ever vigilant and fresh, so as to guard it against the hate which lurks behind it. It might be said that we owe the fairest flowerings of our love to the reaction against the hostile impulse which we sense within us.

[1915b, 3091]

To sum up: our unconscious is just as inaccessible to the idea of our own death, just as murderously inclined towards strangers, just as divided (that is, ambivalent) towards those we love, as was primaeval man. But how far we have moved from this primal state in our conventional and cultural attitude towards death!

[1915b, 3091]
Certainly this is a crazy illness. The most extravagant psychiatric imagination would not, I think, have succeeded in constructing anything like it; and if one did not see it before one every day one would never bring oneself to believe in it. Do not suppose, however, that you will help the patient in the least by calling on him to take a new line, to cease to occupy himself with such foolish thoughts and to do something sensible instead of his childish pranks. He would like to do so himself, for he is completely clear in his head, shares your opinion of his obsessional symptoms and even puts it forward to you spontaneously. Only he cannot help himself. What is carried into action in an obsessional neurosis is sustained by an energy to which we probably know nothing comparable in normal mental life. There is only one thing he can do: he can make displacements, and exchanges, he can replace one foolish idea by another somewhat milder, he can proceed from one precaution or prohibition to another, instead of one ceremonial he can perform another. He can displace the obsession but not remove it. The ability to displace any symptom into something far removed from its original conformation is a main characteristic of his illness. Moreover it is a striking fact that in his condition the contradictions (polarties) with which mental life is interlaced emerge especially sharply differentiated. Alongside of obsessions with a positive and negative content, doubt makes itself felt in the intellectual field and little by little it begins to gnaw even at what is usually most certain. The whole position ends up in an ever-increasing degree of indecision, loss of energy and restriction of freedom. At the same time, the obsessional neurotic starts off with a very energetic disposition, he is often extraordinarily self-willed and as a rule he has intellectual gifts above the average. He has usually reached a satisfactorily high level of ethical development; he exhibits over-conscientiousness, and is more than ordinarily correct in his behaviour. You can imagine that no small amount of work is needed before one can make one's way any distance into this contradictory hotch-potch of character-traits and symptoms. And to begin with we aim at nothing whatever else than understanding a few of the symptoms and being able to interpret them. [1916-1917, 3340]

Wild thoughts, you will say, to be running through an unmarried girl's head. I admit that is so. But you must not forget that I did not make these things but only interpreted them. A sleep-ceremonial like this is a strange thing too, and you will not fail to see how the ceremonial corresponds to the phantasies which are revealed by the interpretation. But I attach more importance to your noticing that what was seen in the ceremonial was a precipitate not of a single phantasy but of a number of them, though they had a nodal point somewhere, and, further, that the rules laid down by the ceremonial reproduced the patient's sexual wishes at one point positively and at another negatively - in part they represented them, but in part they served as a defence against them. [1916-1917, 3347]
No doubt all kinds of objections can still be raised to the assertion that neurotic symptoms are substitutes for sexual satisfactions. I will mention two of them to-day. When you yourselves have carried out analytic examinations of a considerable number of neurotics, you will perhaps tell me, shaking your head, that in a lot of cases my assertion is simply not true; the symptoms seem rather to have the contrary purpose of excluding or of stopping sexual satisfaction. I will not dispute the correctness of your interpretation. The facts in psycho-analysis have a habit of being rather more complicated than we like. If they were as simple as all that, perhaps it might not have needed psycho-analysis to bring them to light. Indeed, some of the features of our second patient's ceremonial show signs of this ascetic character with its hostility to sexual satisfaction: when, for instance, she got rid of the clocks and watches, which had the magical meaning of avoiding erections during the night, or when she tried to guard against flower-pots falling and breaking, which was equivalent to protecting her virginity. In some other cases of bed ceremonials, which I have been able to analyse, this negative character was far more outspoken; the ceremonial might consist exclusively of defensive measures against sexual memories and temptations. However, we have already found often enough that in psycho-analysis opposites imply no contradiction. We might extend our thesis and say that symptoms aim either at a sexual satisfaction or at fending it off, and that on the whole the positive, wish-fulfilling character prevails in hysteria and the negative, ascetic one in obsessional neurosis. If symptoms can serve the purpose both of sexual satisfaction and of its opposite, there is an excellent basis for this double-sidedness or polarity in a part of their mechanism which I have so far not been able to mention. For, as we shall hear, they are the products of a compromise and arise from the mutual interference between two opposing currents; they represent not only the repressed but also the repressing force which had a share in their origin. One side or the other may be more strongly represented; but it is rarely that one influence is entirely absent. In hysteria a convergence of both intentions in the same symptom is usually achieved. In obsessional neurosis the two portions are often separated; the symptom then becomes diphasic and consists in two actions, one after the other, which cancel each other out.

[1916-1917, 3373]

No doubt was left in the analysis that these passive trends had made their appearance at the same time as the active-sadistic ones, or very soon after them.¹ This is in accordance with the unusually clear, intense, and constant ambivalence of the patient, which was shown here for the first time in the even development of both members of the pairs of contrary component instincts. Such behaviour was also characteristic of his later life, and so was this further trait: no position of the libido which had once been established was ever completely replaced by a later one. It was rather left in existence side by side with all the others, and this allowed him to maintain an incessant vacillation which proved to be incompatible with the acquisition of a stable character.

[1918b, 3517]

His old love for his father, which had been manifest in his earliest period, was therefore the source of his energy in struggling against God and of his acuteness in criticizing religion. But on the other hand this hostility to the new God was not an original reaction either; it had its prototype in a hostile impulse against his father, which had come into existence under the influence of the anxiety-dream, and it was at bottom only a revival of that impulse. The two opposing currents of feeling, which were to rule the whole of his later life, met here in the ambivalent struggle over the question of religion. It followed, moreover, that what this struggle produced in the shape of symptoms (the blasphemous ideas, the compulsion which came over him of thinking 'God-shit', 'God-swine') were genuine compromise-products, as we shall see from the analysis of these ideas in connection with his anal erotism.

[1918b, 3550]
An analogy of this kind can of course have no meaning for a patient while the work of analysis is still uncompleted. At this point I recall a discussion which I was led into with a patient whose exceptionally ambivalent attitude was expressed in the most intense compulsive doubt. He did not dispute my interpretations of his dreams and was very much struck by their agreement with the hypotheses which I put forward. But he asked whether these corroborative dreams might not be an expression of his compliance towards me. I pointed out that the dreams had also brought up a quantity of details of which I could have had no suspicion and that his behaviour in the treatment apart from this had not been precisely characterized by compliance. Whereupon he switched over to another theory and asked whether his narcissistic wish to be cured might not have caused him to produce these dreams, since, after all, I had held out to him a prospect of recovery if he were able to accept my constructions. I could only reply that I had not yet come across any such mechanism of dream-formation. But a decision was reached by another road. He recollected some dreams which he had had before starting analysis and indeed before he had known anything about it; and the analysis of these dreams, which were free from all suspicion of suggestion, led to the same interpretations as the later ones. It is true that his obsession for contradiction once more found a way out in the idea that the earlier dreams had been less clear than those that occurred during the treatment; but I was satisfied with their similarity. I think that in general it is a good plan occasionally to bear in mind the fact that people were in the habit of dreaming before there was such a thing as psycho-analysis.

[1923c, 4037]

I myself set a higher value on my contributions to the psychology of religion, which began with the establishment of a remarkable similarity between obsessive actions and religious practices or ritual (1907b). Without as yet understanding the deeper connections, I described the obsessional neurosis as a distorted private religion and religion as a kind of universal obsessional neurosis. Later on, in 1912, Jung’s forcible indication of the far-reaching analogies between the mental products of neurotics and of primitive peoples led me to turn my attention to that subject. In four essays, which were collected into a book with the title of Totem and Taboo, I showed that the horror of incest was even more marked among primitive than among civilized races and had given rise to very special measures of defence against it. I examined the relations between taboo-prohibitions (the earliest form in which moral restrictions make their appearance) and emotional ambivalence; and I discovered under the primitive scheme of the universe known as ‘animism’ the principle of the over-estimation of the importance of psychical reality - the belief in ‘the omnipotence of thoughts’ - which lies at the root of magic as well. I developed the comparison with the obsessional neurosis at every point, and showed how many of the postulates of primitive mental life are still in force in that remarkable illness. Above all, however, I was attracted by totemism, the first system of organization in primitive tribes, a system in which the beginnings of social order are united with a rudimentary religion and the implacable domination of a small number of taboo-prohibitions. The being that is revered is ultimately always an animal, from which the clan also claims to be descended. Many indications pointed to the conclusion that every race, even the most highly developed, had once passed through the stage of totemism.

[1925d, 4239]
Let us turn to the obsessional neuroses in the hope of learning more about the formation of symptoms. The symptoms belonging to this neurosis fall, in general, into two groups, each having an opposite trend. They are either prohibitions, precautions and expiations - that is, negative in character - or they are, on the contrary, substitutive satisfactions which often appear in symbolic disguise. The negative, defensive group of symptoms is the older of the two; but as illness is prolonged, the satisfactions, which scoff at all defensive measures, gain the upper hand. The symptom-formation scores a triumph if it succeeds in combining the prohibition with satisfaction so that what was originally a defensive command or prohibition acquires the significance of a satisfaction as well; and in order to achieve this end it will often make use of the most ingenious associative paths. Such an achievement demonstrates the tendency of the ego to synthesize, which we have already observed. In extreme cases the patient manages to make most of his symptoms acquire, in addition to their original meaning, a directly contrary one. This is a tribute to the power of ambivalence, which, for some unknown reason, plays such a large part in obsessional neuroses. In the crudest instance the symptom is diphasic: an action which carries out a certain injunction is immediately succeeded by another action which stops or undoes the first one even if it does not go quite so far as to carry out its opposite. [1926d, 4271]

We cannot go so far as to assert that the ambivalence of emotional cathexes is a universally valid law, and that it is absolutely impossible to feel great love for a person without its being accompanied by a hatred that is perhaps equally great, or vice versa. Normal adults do undoubtedly succeed in separating those two attitudes from each other, and do not find themselves obliged to hate their love-objects and to love their enemy as well as hate him. But this seems to be the result of later developments. In the first phases of erotic life, ambivalence is evidently the rule. Many people retain this archaic trait all through their lives. It is characteristic of obsessional neurotics that in their object-relationships love and hate counterbalance each other. In primitive races, too, we may say that ambivalence predominates. We shall conclude, then, that the little girl's intense attachment to her mother is strongly ambivalent, and that it is in consequence precisely of this ambivalence that (with the assistance of the other factors we have adduced) her attachment is forced away from her mother - once again, that is to say, in consequence of a general characteristic of infantile sexuality. [1931b, 4599]
In conclusion I may point out that combinations of a phobia and an obsession proper may co-exist, and that indeed this is a very frequent occurrence. We may find that a phobia had developed at the beginning of the disease as a symptom of anxiety neurosis. The idea which constitutes the phobia and which is associated with the state of fear may be replaced by another idea or rather by the protective procedure that seemed to relieve the fear. Case 7 (obsessive speculating) presents a neat example of this group: a phobia along with a true substitutive obsession.
[1895c, 324]

Both kinds of phobias (and also obsessions) often appear side by side; although the atypical phobias, which are based on obsessions, need not necessarily spring from the soil of anxiety neurosis. A very frequent and apparently complicated mechanism makes its appearance if, in what was originally a simple phobia belonging to an anxiety neurosis, the content of the phobia is replaced by another idea, so that the substitute is subsequent to the phobia. What are most often employed as substitutes are the 'protective measures' that were originally used to combat the phobia. Thus, for instance, 'brooding mania' arises from the subject's endeavours to disprove that he is mad, as his hypochondriacal phobia maintains; the hesitations and doubt, and still more the repetitions, of folie du doute arise from a justifiable doubt about the certainty of one's own train of thought, since one is conscious of its persistent disturbance by ideas of an obsessional sort, and so on. We can therefore assert that many syndromes, too, of obsessional neurosis, such as folie du doute and the like, are also to be reckoned, clinically if not conceptually, as belonging to anxiety neurosis.²
[1895b, 334]

Neurotic ceremonials consist in making small adjustments to particular everyday actions, small additions or restrictions or arrangements, which have always to be carried out in the same, or in a methodically varied, manner. These activities give the impression of being mere formalities, and they seem quite meaningless to us. Nor do they appear otherwise to the patient himself; yet he is incapable of giving them up, for any deviation from the ceremonial is visited by intolerable anxiety, which obliges him at once to make his omission good. Just as trivial as the ceremonial actions themselves are the occasions and activities which are embellished, encumbered and in any case prolonged by the ceremonial - for instance, dressing and undressing, going to bed or satisfying bodily needs. The performance of a ceremonial can be described by replacing it, as it were, by a series of unwritten laws. For instance, to take the case of the bed ceremonial: the chair must stand in a particular place beside the bed; the clothes must lie upon it folded in a particular order; the blanket must be tucked in at the bottom and the sheet smoothed out; the pillows must be arranged in such and such a manner, and the subject's own body must lie in a precisely defined position. Only after all this may he go to sleep. Thus in slight cases the ceremonial seems to be no more than an exaggeration of an orderly procedure that is customary and justifiable; but the special conscientiousness with which it is carried out and the anxiety which follows upon its neglect stamp the ceremonial as a 'sacred act'. Any interruption of it is for the most part badly tolerated, and the presence of other people during its performance is almost always ruled out.
[1907b, 1902]
Analysis of obsessive actions has already given us some sort of an insight into their causes and into the chain of motives which bring them into effect. We may say that the sufferer from compulsions and prohibitions behaves as if he were dominated by a sense of guilt, of which, however, he knows nothing, so that we must call it an unconscious sense of guilt, in spite of the apparent contradiction in terms. This sense of guilt has its source in certain early mental events, but it is constantly being revived by renewed temptations which arise whenever there is a contemporary provocation. Moreover, it occasions a lurking sense of expectant anxiety, an expectation of misfortune, which is linked, through the idea of punishment, with the internal perception of the temptation. When the ceremonial is first being constructed, the patient is still conscious that he must do this or that lest some ill should befall, and as a rule the nature of the ill that is to be expected is still known to his consciousness. But what is already hidden from him is the connection - which is always demonstrable - between the occasion on which this expectant anxiety arises and the danger which it conjures up. Thus a ceremonial starts as an action for defence or insurance, a protective measure.

A deeper insight into the mechanism of obsessional neurosis is gained if we take into account the primary fact which lies at the bottom of it. This is always the repression of an instinctual impulse (a component of the sexual instinct) which was present in the subject's constitution and which was allowed to find expression for a while during his childhood but later succumbed to suppression. In the course of the repression of this instinct a special conscientiousness is created which is directed against the instinct's aims; but this psychical reaction-formation feels insecure and constantly threatened by the instinct which is lurking in the unconscious. The influence of the repressed instinct is felt as a temptation, and during the process of repression itself anxiety is generated, which gains control over the future in the form of expectant anxiety. The process of repression which leads to obsessional neurosis must be considered as one which is only partly successful and which increasingly threatens to fail. It may thus be compared to an unending conflict; fresh psychical efforts are continually required to counterbalance the forward pressure of the instinct. Thus the ceremonial and obsessive actions arise partly as a defence against the temptation and partly as a protection against the ill which is expected. Against the temptation the protective measures seem soon to become inadequate; then the prohibitions come into play, with the purpose of keeping at a distance situations that give rise to temptation. Prohibitions take the place of obsessive actions, it will be seen, just as a phobia is designed to avert a hysterical attack. Again, a ceremonial represents the sum of the conditions subject to which something that is not yet absolutely forbidden is permitted, just as the Church's marriage ceremony signifies for the believer a sanctioning of sexual enjoyment which would otherwise be sinful. A further characteristic of obsessional neurosis, as of all similar affections, is that its manifestations (its symptoms, including the obsessive actions) fulfil the condition of being a compromise between the warring forces of the mind. They thus always reproduce something of the pleasure which they are designed to prevent; they serve the repressed instinct no less than the agencies which are repressing it. As the illness progresses, indeed, actions which were originally mostly concerned with maintaining the defence come to approximate more and more to the proscribed actions through which the instinct was able to find expression in childhood.

[1907b, 1906]

[1907b, 1907]
The compulsion on the other hand is an attempt at a compensation for the doubt and at a correction of the intolerable conditions of inhibition to which the doubt bears witness. If the patient, by the help of displacement, succeeds at last in bringing one of his inhibited intentions to a decision, then the intention must be carried out. It is true that this intention is not his original one, but the energy dammed up in the latter cannot let slip the opportunity of finding an outlet for its discharge in the substitutive act. Thus this energy makes itself felt now in commands and now in prohibitions, according as the affectionate impulse or the hostile one snatches control of the pathway leading to discharge. If it happens that a compulsive command cannot be obeyed, the tension becomes intolerable and is perceived by the patient in the form of extreme anxiety. (But the pathway leading to a substitutive act, even where the displacement has been on to something very small, is so hotly contested, that such an act can as a rule be carried out only in the shape of a protective measure intimately associated with the very impulse which it is designed to ward off.
[1909d, 2190]

The primary obsessive acts of these neurotics are of an entirely magical character. If they are not charms, they are at all events counter-charms, designed to ward off the expectations of disaster with which the neurosis usually starts. Whenever I have succeeded in penetrating the mystery, I have found that the expected disaster was death. Schopenhauer has said that the problem of death stands at the outset of every philosophy; and we have already seen that the origin of the belief in souls and in demons, which is the essence of animism, goes back to the impression which is made upon men by death. It is difficult to judge whether the obsessive or protective acts performed by obsessional neurotics follow the law of similarity (or, as the case may be, of contrast); for as a rule, owing to the prevailing conditions of the neurosis, they have been distorted by being displaced on to something very small, some action in itself of the greatest triviality.¹ The protective formulas of obsessional neuroses, too, have their counterpart in the formulas of magic. It is possible, however, to describe the course of development of obsessive acts: we can show how they begin by being as remote as possible from anything sexual - magical defences against evil wishes - and how they end by being substitutes for the forbidden sexual act and the closest possible imitations of it.
[1912-1913, 2730]

(c) We make a third discovery when we come to patients suffering from obsessional actions, who seem in a remarkable way exempt from anxiety. If we try to hinder their carrying out of their obsessional action - their washing or their ceremonial - or if they themselves venture upon an attempt to give up one of their compulsions, they are forced by the most terrible anxiety to yield to the compulsion. We can see that the anxiety was screened by the obsessional action, and that the latter was only performed in order to avoid the anxiety. In an obsessional neurosis, therefore, anxiety which would otherwise inevitably set in is replaced by the formation of a symptom, and if we turn to hysteria we find a similar relation: the result of the process of repression is either a generating of anxiety pure and simple, or anxiety accompanied by the formation of a symptom, or a more complete formation of a symptom without anxiety. It would thus seem not to be wrong in an abstract sense to assert that in general symptoms are only formed to escape an otherwise unavoidable generating of anxiety. If we adopt this view, anxiety is placed, as it were, in the very centre of our interest in the problems of neurosis.
[1916-1917, 3451]
What we have learnt about anxiety in phobias is applicable to obsessional neuroses as well. In this respect it is not difficult for us to put obsessional neuroses on all fours with phobias. In the former, the mainspring of all later symptom-formation is clearly the ego's fear of its super-ego. The danger-situation from which the ego must get away is the hostility of the super-ego. There is no trace of projection here; the danger is completely internalized. But if we ask ourselves what it is that the ego fears from the super-ego, we cannot but think that the punishment threatened by the latter must be an extension of the punishment of castration. Just as the father has become depersonalized in the shape of the super-ego, so has the fear of castration at his hands become transformed into an undefined social or moral anxiety. But this anxiety is concealed. The ego escapes it by obediently carrying out the commands, precautions and penances that have been enjoined on it. If it is impeded in doing so, it is at once overtaken by an extremely distressing feeling of discomfort which may be regarded as an equivalent of anxiety and which the patients themselves liken to anxiety.

That this latter opinion is at least in part true is shown by some striking examples. If an agoraphobic patient who has been accompanied into the street is left alone there, he will produce an anxiety attack. Or if an obsessional neurotic is prevented from washing his hands after having touched something, he will become a prey to almost unbearable anxiety. It is plain, then, that the purpose and the result of the imposed condition of being accompanied in the street and the obsessional act of washing the hands were to obviate outbreaks of anxiety of this kind. In this sense every inhibition which the ego imposes on itself can be called a symptom.

One objection to it is that loss of an object (or loss of love on the part of the object) and the threat of castration are just as much dangers coming from outside as, let us say, a ferocious animal would be; they are not instinctual dangers. Nevertheless, the two cases are not the same. A wolf would probably attack us irrespectively of our behaviour towards it; but the loved person would not cease to love us nor should we be threatened with castration if we did not entertain certain feelings and intentions within us. Thus such instinctual impulses are determinants of external dangers and so become dangerous in themselves; and we can now proceed against the external danger by taking measures against the internal ones. In phobias of animals the danger seems to be still felt entirely as an external one, just as it has undergone an external displacement in the symptom. In obsessional neuroses the danger is much more internalized. That portion of anxiety in regard to the super-ego which constitutes social anxiety still represents an internal substitute for an external danger, while the other portion - moral anxiety - is already completely endopsychic.
In the course of these investigations our attention was drawn to a highly significant relation between the generation of anxiety and the formation of symptoms - namely, that these two represent and replace each other. For instance, an agoraphobic patient may start his illness with an attack of anxiety in the street. This would be repeated every time he went into the street again. He will now develop the symptom of agoraphobia; this may also be described as an inhibition, a restriction of the ego's functioning, and by means of it he spares himself anxiety attacks. We can witness the converse of this if we interfere in the formation of symptoms, as is possible, for instance, with obsessions. If we prevent a patient from carrying out a washing ceremonial, he falls into a state of anxiety which he finds hard to tolerate and from which he had evidently been protected by his symptom. And it seems, indeed, that the generation of anxiety is the earlier and the formation of symptoms the later of the two, as though the symptoms are created in order to avoid the outbreak of the anxiety state. This is confirmed too by the fact that the first neuroses of childhood are phobias - states in which we see so clearly how an initial generation of anxiety is replaced by the later formation of a symptom; we get an impression that it is from these interrelations that we shall best obtain access to an understanding of neurotic anxiety. And at the same time we have also succeeded in answering the question of what it is that a person is afraid of in neurotic anxiety and so in establishing the connection between neurotic and realistic anxiety. What he is afraid of is evidently his own libido. The difference between this situation and that of realistic anxiety lies in two points: that the danger is an internal instead of an external one and that it is not consciously recognized.

[1933a, 4690]
(b) A student who is now suffering from a severe obsessional neurosis remembers having repeatedly had the following dream during his sixth year: *He went to the hairdresser's to have his hair cut. A big, severe-looking woman came up to him and cut his head off. He recognized the woman as his mother.*

[1900a, 828]

I shall discuss on another occasion the explanation of these animal phobias and the significance attaching to them. I will only remark in anticipation that this explanation is in complete harmony with the principal characteristic shown by the neurosis from which the present dreamer suffered later in his life. His fear of his father was the strongest motive for his falling ill, and his ambivalent attitude towards every father-surrogate was the dominating feature of his life as well as of his behaviour during the treatment.

[1913d, 2601]

If in my patient's case the wolf was merely a first father-surrogate, the question arises whether the hidden content in the fairy tales of the wolf that ate up the little goats and of 'Little Red Riding-Hood' may not simply be infantile fear of the father.¹ Moreover, my patient's father had the characteristic, shown by so many people in relation to their children, of indulging in 'affectionate abuse'; and it is possible that during the patient's earlier years his father (though he grew severe later on) may more than once, as he caressed the little boy or played with him, have threatened in fun to 'gobble him up'. One of my patients told me that her two children could never get to be fond of their grandfather, because in the course of his affectionate romping with them he used to frighten them by saying he would cut open their tummies.

[1913d, 2601]

Experience in the analysis of dreams has sufficiently well established the hat as a symbol of the genital organ, most frequently of the male organ. It cannot be said, however, that the symbol is an intelligible one. In phantasies and in numerous symptoms the head too appears as a symbol of the male genitals, or, if one prefers to put it so, as something standing for them. It will sometimes have been noticed that patients suffering from obsessions express an amount of abhorrence of and indignation against punishment by beheading far greater than they do in the case of any other form of death; and in such cases the analyst may be led to explain to them that they are treating being beheaded as a substitute for being castrated. Instances have often been analysed and published of dreams dreamt by young people or reported as having occurred in youth, which concerned the subject of castration, and in which a round ball was mentioned which could only be interpreted as the head of the dreamer's father. I was recently able to solve a ceremonial performed by a woman patient before going to sleep, in which she had to lay her small top pillow diamond-wise on the other ones and to rest her head exactly in the long diameter of the diamond-shape. The diamond had the meaning that is familiar to us from drawings on walls [graffiti]; the head was supposed to represent a male organ.

[1916c, 3122]
It may be that the symbolic meaning of the hat is derived from that of the head, in so far as a hat can be regarded as a prolonged, though detachable head. In this connection I am reminded of a symptom by means of which obsessional neurotics succeed in causing themselves continual torments. When they are in the street they are constantly on the look-out to see whether some acquaintance will greet them first by taking of his hat, or whether he seems to be waiting for their salutation; and they give up a number of their acquaintances after discovering that they no longer greet them or do not return their own salutation properly. There is no end to their difficulties in this connection; they find them everywhere as their mood and fancy dictate. It makes no difference to their behaviour when we tell them, what they all know already, that a salutation by taking off the hat has the meaning of an abasement before the person saluted - that a Spanish grandee, for example, enjoyed the privilege of remaining covered in the king's presence - and that their own sensitiveness on the subject of greeting therefore means that they are unwilling to show themselves less important than the other person thinks he is. The resistance of their sensitiveness to explanations such as this suggests that a motive less familiar to consciousness is at work; and the source of this excess of feeling might easily be found in its relation to the castration complex.

[1916c, 3122]

Though I am anxious to cut short this discussion still further, I must nevertheless tell you a little about the sexual researches of children: they are too characteristic of infantile sexuality and of too great significance for the symptomatology of the neuroses to be passed over. Infantile sexual researches begin very early, sometimes before the third year of life. They do not relate to the distinction between the sexes, for this means nothing to children, since they (or at any rate boys) attribute the same male genital to both sexes. If, afterwards, a boy makes the discovery of the vagina from seeing his little sister or a girl playmate, he tries, to begin with, to disavow the evidence of his senses, for he cannot imagine a human creature like himself who is without such a precious portion. Later on, he takes fright at the possibility thus presented to him; and any threats that may have been made to him earlier, because he took too intense an interest in his little organ, now produce a deferred effect. He comes under the sway of the castration complex, the form taken by which plays a great part in the construction of his character if he remains normal, in his neurosis if he falls ill, and in his resistances if he comes into analytic treatment. As regards little girls, we can say of them that they feel greatly at a disadvantage owing to their lack of a big, visible penis, that they envy boys for possessing one and that, in the main for this reason, they develop a wish to be a man - a wish that re-emerges later on, in any neurosis that may arise if they meet with a mishap in playing a feminine part. In her childhood, moreover, a girl's clitoris takes on the role of a penis entirely: it is characterized by special excitability and is the area in which auto-erotic satisfaction is obtained. The process of a girl's becoming a woman depends very much on the clitoris passing on this sensitivity to the vaginal orifice in good time and completely. In cases of what is known as sexual anaesthesia in women the clitoris has obstinately retained its sensitivity.

[1916-1917, 3387]
It is easy to understand that the first suspicion fell upon the English governess, for the change in
the boy made its appearance while she was there. Two screen memories had persisted, which
were incomprehensible in themselves, and which related to her. On one occasion, as she was
walking along in front of them, she said: 'Do look at my little tail!' Another time, when they were
on a drive, her hat flew away, to the two children's great satisfaction. This pointed to the
castration complex, and might permit of a construction being made to the effect that a threat
uttered by her against the boy had been largely responsible for originating his abnormal
conduct. There is no danger at all in communicating constructions of this kind to the person
under analysis; they never do any damage to the analysis if they are mistaken; but at the same
time they are not put forward unless there is some prospect of reaching a nearer approximation
to the truth by means of them. The first effect of this supposition was the appearance of some
dreams, which it was not possible to interpret completely, but all of which seemed to centre
around the same material. As far as they could be understood, they were concerned with
aggressive actions on the boy's part against his sister or against the governess and with
energetic reproofs and punishments on account of them. It was as though . . . after her bath . . .
he had tried . . . to undress his sister . . . to tear off her coverings . . . or veils - and so on. But it
was not possible to get at any firm content from the interpretation; and since these dreams gave
an impression of always working over the same material in various different ways, the correct
reading of these ostensible reminiscences became assured: it could only be a question of
phantasies, which the dreamer had made on the subject of his childhood at some time or other,
probably at the age of puberty, and which had now come to the surface again in this
unrecognizable form.
[1918b, 3512]

The transformation did not occur spontaneously, through internal development, but through an
outside influence. Its visible effect was that the patient's relation to his father, which stood in the
foreground, and which had so far found expression in the wolf phobia, was now manifested in
obsessional piety. I cannot refrain from pointing out that the course of events in this part of the
patient's history affords an unmistakable confirmation of an assertion which I made in Totem
and Taboo upon the relation of the totem animal to the deity.¹ I there decided in favour of the
view that the idea of God was not a development from the totem, but replaced it after arising
independently from a root common to both ideas. The totem, I maintained, was the first father-
surrogate, and the god was a later one, in which the father had regained his human shape. And
we find the same thing with our patient. In his wolf phobia he had gone through the stage of the
totemic father-surrogate; but that stage was now broken off, and, as a result of new relations
between him and his father, was replaced by a phase of religious piety.
[1918b, 3590]
This revolt against castration or a feminine attitude has been torn out of its organic context by Alfred Adler. He has linked it superficially or falsely with the longing for power, and has postulated it as an independent 'masculine protest'. Since a neurosis can only arise from a conflict between two trends, it is as justifiable to see the cause of 'every' neurosis in the masculine protest as it is to see it in the feminine attitude against which the protest is being made. It is quite true that this masculine protest plays a regular part in the formation of character - in some types of people a very large part - and that we meet it in the analysis of neurotic men as a vigorous resistance. Psycho-analysis has attached due importance to the masculine protest in connection with the castration complex, without being able to accept its omnipotence or its omnipresence in neuroses. The most marked case of a masculine protest with all its manifest reactions and character-traits that I have met with in analysis was that of a patient who came to me for treatment on account of an obsessional neurosis in whose symptoms the unresolved conflict between a masculine and a feminine attitude (fear of castration and desire for castration) found clear expression. In addition, the patient had developed masochistic phantasies which were wholly derived from a wish to accept castration; and he had even gone beyond these phantasies to real satisfaction in perverse situations. The whole of his state rested - like Adler's theory itself - on the repression and denial of early infantile fixations of love. [1923d, 4016]

In enforcing regression, the ego scores its first success in its defensive struggle against the demands of the libido. (In this connection it is of advantage to distinguish the more general notion of 'defence' from 'repression'. Repression is only one of the mechanisms which defence makes use of.) It is perhaps in obsessional cases more than in normal or hysterical ones that we can most clearly recognize that the motive force of defence is the castration complex and that what is being fended off are the trends of the Oedipus complex. We are at present dealing with the beginning of the latency period, a period which is characterized by the dissolution of the Oedipus complex, the creation or consolidation of the super-ego and the erection of ethical and aesthetic barriers in the ego. In obsessional neuroses these processes are carried further than is normal. In addition to the destruction of the Oedipus complex a regressive degradation of the libido takes place, the super-ego becomes exceptionally severe and unkind, and the ego, in obedience to the super-ego, produces strong reaction-formations in the shape of conscientiousness, pity and cleanliness. Implacable, though not always on that account successful, severity is shown in condemning the temptation to continue early infantile masturbation, which now attaches itself to regressive (sadistic-anal) ideas but which nevertheless represents the unsubjugated part of the phallic organization. There is an inherent contradiction about this state of affairs, in which, precisely in the interests of masculinity (that is to say, from fear of castration), every activity belonging to masculinity is stopped. But here, too, obsessional neurosis is only overdoing the normal method of getting rid of the Oedipus complex. We once more find here an illustration of the truth that every exaggeration contains the seed of its own undoing. For, under the guise of obsessional acts, the masturbation that has been suppressed approaches ever more closely to satisfaction. [1926d, 4273]
This is as far as our investigations into the formation of symptoms take us. It is hardly worth while summing them up, for the results they have yielded are scanty and incomplete and tell us scarcely anything that we do not already know. It would be fruitless to turn our attention to symptom-formation in other disorders besides phobias, conversion hysteria and obsessional neurosis, for too little is known about them. But in reviewing those three neuroses together we are brought up against a very serious problem the consideration of which can no longer be put off. All three have as their outcome the destruction of the Oedipus complex; and in all three the motive force of the ego's opposition is, we believe, the fear of castration. Yet it is only in the phobias that this fear comes to the surface and is acknowledged. What has become of it in the other two neuroses? How has the ego spared itself this fear? The problem becomes accentuated when we recall the possibility, already referred to, that anxiety arises directly, by a kind of fermentation, from a libidinal cathexis whose processes have been disturbed. Furthermore, is it absolutely certain that fear of castration is the only motive force of repression (or defence)? If we think of neuroses in women we are bound to doubt it. For though we can with certainty establish in them the presence of a castration complex, we can hardly speak with propriety of castration anxiety where castration has already taken place.

[1926d, 4281]

What we have learnt about anxiety in phobias is applicable to obsessional neuroses as well. In this respect it is not difficult for us to put obsessional neuroses on all fours with phobias. In the former, the mainspring of all later symptom-formation is clearly the ego's fear of its super-ego. The danger-situation from which the ego must get away is the hostility of the super-ego. There is no trace of projection here; the danger is completely internalized. But if we ask ourselves what it is that the ego fears from the super-ego, we cannot but think that the punishment threatened by the latter must be an extension of the punishment of castration. Just as the father has become depersonalized in the shape of the super-ego, so has the fear of castration at his hands become transformed into an undefined social or moral anxiety. But this anxiety is concealed. The ego escapes it by obediently carrying out the commands, precautions and penances that have been enjoined on it. If it is impeded in doing so, it is at once overtaken by an extremely distressing feeling of discomfort which may be regarded as an equivalent of anxiety and which the patients themselves liken to anxiety.

[1926d, 4285]

The conclusion we have come to, then, is this. Anxiety is a reaction to a situation of danger. It is obviated by the ego's doing something to avoid that situation or to withdraw from it. It might be said that symptoms are created so as to avoid the generating of anxiety. But this does not go deep enough. It would be truer to say that symptoms are created so as to avoid a danger-situation whose presence has been signalled by the generation of anxiety. In the cases that we have discussed, the danger concerned was the danger of castration or of something traceable back to castration.

[1926d, 4285]
He then went on to say that he would like to speak of a criminal act, whose author he did not recognize as himself, though he quite clearly recollected committing it. He quoted a saying of Nietzsche's:² "I did this," says my Memory. "I cannot have done this," says my Pride and remains inexorable. In the end - Memory yields. 'Well,' he continued, 'my memory has not yielded on this point.' - 'That is because you derive pleasure from your self-reproaches as a means of self-punishment.' - 'My younger brother - I am really very fond of him now, and he is causing me a great deal of worry just at present, for he wants to make what I consider a preposterous match; I have thought before now of going and killing the person concerned so as to prevent his marrying her -well, my younger brother and I used to fight a lot when we were children. We were very fond of each other at the same time, and were inseparable; but I was plainly filled with jealousy, as he was the stronger and better-looking of the two and consequently the favourite.' - 'Yes. You have already given me a description of a scene of jealousy in connection with Fräulein Lina.' - 'Very well then, on some such occasion (it was certainly before I was eight years old, for I was not going to school yet, which I began to do when I was eight) - on some such occasion, this is what I did. We both had toy guns of the usual make. I loaded mine with the ram rod and told him that if he looked up the barrel he would see something. Then, while he was looking in, I pulled the trigger. He was hit on the forehead and not hurt; but I had meant to hurt him very much indeed. Afterwards I was quite beside myself, and threw myself on the ground and asked myself however I could have done such a thing. But I did do it.' - I took the opportunity of urging my case. If he had preserved the recollection of an action so foreign to him as this, he could not, I maintained, deny the possibility of something similar, which he had now forgotten entirely, having happened at a still earlier age in relation to his father. - He then told me he was aware of having felt other vindictive impulses, this time towards the lady he admired so much, of whose character he painted a glowing picture. It might be true, he said, that she could not love easily; but she was reserving her whole self for the one man to whom she would some day belong. She did not love him. When he had become certain of that, a conscious phantasy had taken shape in his mind of how he should grow very rich and marry some one else, and should then take her to call on the lady in order to hurt her feelings. But at that point the phantasy had broken down, for he had been obliged to own to himself that the other woman, his wife, was completely indifferent to him; then his thoughts had become confused, till finally it had been clearly borne in upon him that this other woman would have to die. In this phantasy, just as in his attempt upon his brother, he recognized the quality of cowardice which was so particularly horrible to him.³ - In the further course of our conversation I pointed out to him that he ought logically to consider himself as in no way responsible for any of these traits in his character; for all of these reprehensible impulses originated from his infancy, and were only derivatives of his infantile character surviving in his unconscious; and he must know that moral responsibility could not be applied to children. It was only by a process of development, I added, that a man, with his moral responsibility, grew up out of the sum of his infantile predispositions.⁴ He expressed a doubt, however, whether all his evil impulses had originated from that source. But I promised to prove it to him in the course of the treatment.

[1909d, 2146]
As was to be expected, the patient did not, to begin with, accept my elucidation of the matter. He could not imagine, he said, that the plan of marriage could have had any such effects: it had not made the slightest impression on him at the time. But in the further course of treatment he was forcibly brought to believe in the truth of my suspicion, and in a most singular manner. With the help of a transference phantasy, he experienced, as though it were new and belonged to the present, the very episode from the past which he had forgotten, or which had only passed though his mind unconsciously. There came an obscure and difficult period in the treatment; eventually it turned out that he had once met a young girl on the stairs in my house and had on the spot promoted her into being my daughter. She had pleased him, and he pictured to himself that the only reason I was so kind and incredibly patient with him was that I wanted to have him for a son-in-law. At the same time he raised the wealth and position of my family to a level which agreed with the model he had in mind. But his undying love for his lady fought against the temptation. After we had gone though a series of the severest resistances and bitterest vituperations on his part, he could no longer remain blind to the overwhelming effect of the perfect analogy between the transference phantasy and the actual state of affairs in the past. I will repeat one of the dreams which he had at this period, so as to give an example of his manner of treating the subject. He dreamt that he saw my daughter in front of him; she had two patches of dung instead of eyes. No one who understands the language of dreams will find much difficulty in translating this one: it declared that he was marrying my daughter not for her 'beaux yeux' but for her money.

[1909d, 2157]

If we wish to obtain a grasp of the psychical forces whose interplay built up this neurosis, we must turn back to what we have learnt from the patient on the subject of the precipitating causes of his falling ill as a grown-up man and as a child. He fell ill when he was in his twenties on being faced with a temptation to marry another woman instead of the one whom he had loved so long; and he avoided a decision of this conflict by postponing all the necessary preliminary actions. The means for doing this was given him by his neurosis. His hesitation between the lady he loved and the other girl can be reduced to a conflict between his father's influence and his love for his lady, or, in other words, to a conflicting choice between his father and his sexual object, such as had already subsisted (judging from his recollections and obsessional ideas) in his remote childhood. All through his life, moreover, he was unmistakably victim to a conflict between love and hatred, in regard both to his lady and to his father. His phantasies of revenge and such obsessional phenomena as his obsession for understanding and his exploit with the stone in the road bore witness to his divided feelings; and they were to a certain degree comprehensible and normal, for the lady by her original refusal and subsequently by her coolness had given him some excuse for hostility. But his relations with his father were dominated by a similar division of feeling, as we have seen from our translation of his obsessional thoughts; and his father, too, must have given him an excuse for hostility in his childhood, as indeed we have been able to establish almost beyond question. His attitude towards the lady - a compound of tenderness and hostility - came to a great extent within the scope of his conscious knowledge; at most he deceived himself over the degree and violence of his negative feelings. But his hostility towards his father, on the contrary, though he had once been acutely conscious of it, had long since vanished from his ken, and it was only in the teeth of the most violent resistance that it could be brought back into his consciousness. We may regard the repression of his infantile hatred of his father as the event which brought his whole subsequent career under the dominion of the neurosis.

[1909d, 2185]
In just the same way, an inhibition upon movement (an abasia or an agoraphobia) will gradually become more complete and more detailed, when once that system has succeeded in installing itself as a representative of an unconscious wish and of the defence against the wish. Whatever other unconscious phantasies and operative reminiscences may be present in the patient force their way to expression as symptoms along this same path, once it has been opened, and group themselves into an appropriate new arrangement within the framework of the inhibition upon movement. Thus it would be a vain and indeed a foolish task to attempt to understand the complexities and details of the symptoms of (for example) an agoraphobia on the basis of its underlying premises; for the whole consistency and strictness of the combination are merely apparent. Just as with the façades of dreams, if we look more attentively we find the most blatant inconsistency and arbitrariness in the structure of symptoms. The real reason for the details of a systematic phobia of this kind lies in concealed determinants, which need have nothing to do with an inhibition upon movement; and that, too, is why these phobias take such various and contradictory shapes in different people.

[1912-1913, 2738]

Wild thoughts, you will say, to be running through an unmarried girl's head. I admit that is so. But you must not forget that I did not make these things but only interpreted them. A sleep-ceremonial like this is a strange thing too, and you will not fail to see how the ceremonial corresponds to the phantasies which are revealed by the interpretation. But I attach more importance to your noticing that what was seen in the ceremonial was a precipitate not of a single phantasy but of a number of them, though they had a nodal point somewhere, and, further, that the rules laid down by the ceremonial reproduced the patient's sexual wishes at one point positively and at another negatively - in part they represented them, but in part they served as a defence against them.

[1916-1917, 3347]

It is a most important fact that some contemporary phantasies of quite another kind came up as well in the patient's memory. The content of these was of boys being chastised and beaten, and especially being beaten on the penis. And from other phantasies, which represented the heir to the throne being shut up in a narrow room and beaten, it was easy to guess for whom it was that the anonymous figures served as whipping-boys. The heir to the throne was evidently he himself; his sadism had therefore turned round in phantasy against himself, and had been converted into masochism. The detail of the sexual organ itself receiving the beating justified the conclusion that a sense of guilt, which related to his masturbation, was already concerned in this transformation.

[1918b, 3517]
Reinstatement of the replaced idea: She reproached herself with the masturbation she had been practising in secret without being able to renounce it. She was cured by careful surveillance which prevented her from masturbating.
[1895c, 319]

Reinstatement: He had been much affected by reading in a quasi-medical book that masturbation, to which he was addicted, destroyed one's morale.
[1895c, 319]

¹ The proof of infantile masturbation in other cases is established in a precisely similar way. The evidence for it is mostly of a similar nature: indications of the presence of leucorrhoea, bed-wetting, hand-ceremonials (obsessional washing), and such things. It is always possible to discover with certainty from the nature of the symptoms of the case whether the habit was discovered by the person in charge of the child or not, or whether this sexual activity was brought to an end by long efforts on the child's part to break itself of the habit, or by a sudden change. In Dora's case the masturbation had remained undiscovered, and had come to an end at a single blow (cf. her secret, her fear of doctors, and the replacement by dyspnoea). The patients, it is true, invariably dispute the conclusiveness of circumstantial evidence such as this, and they do so even when they have retained a conscious recollection of the catarrh or of their mother's warning (e.g. 'That makes people stupid; it's dangerous'). But some time later the memory, which has been so long repressed, of this piece of infantile sexual life emerges with certainty, and it does so in every instance. I am reminded of the case of a patient of mine suffering from obsessions, which were direct derivatives of infantile masturbation. Her peculiarities, such as self-prohibitions and self-punishments, the feeling that if she had done this she must not do that, the idea that she must not be interrupted, the introduction of pauses between one procedure (with her hands) and the next, her hand-washing, etc, - all of these turned out to be unaltered fragments of her nurse's efforts to break her of the habit. The only thing which had remained permanently in her memory were the words of warning: 'Ugh! That's dangerous!' Compare also in this connection my Three Essays on the Theory of Sexuality, 1905d. [1905e, 1416]

¹ [Footnote added 1915:] The problem of why the sense of guilt of neurotics is, as Bleuler recently recognized, regularly attached to the memory of some masturbatory activity, usually at puberty, still awaits an exhaustive analytic explanation. [Added 1920:] The most general and most important factor concerned must no doubt be that masturbation represents the executive agency of the whole of infantile sexuality and is, therefore, able to take over the sense of guilt attaching to it.
[1905d, 1509]
To this unimpeachable body of evidence we shall be able to add fresh material, if we turn to the history of the masturbatory side of our patient's sexual activities. There is a conflict between the opinions of doctors and patients on this subject which has not hitherto been properly appreciated. The patients are unanimous in their belief that masturbation, by which they mean masturbation during puberty, is the root and origin of all their troubles. The doctors are, upon the whole, unable to decide what line to take; but, influenced by the knowledge that not only neurotics but most normal people pass through a period of masturbation during their puberty, the majority of them are inclined to dismiss the patients' assertions as gross exaggerations. In my opinion the patients are once again nearer to a correct view than the doctors; for the patients have some glimmering notion of the truth, while the doctors are in danger of overlooking an essential point. The thesis propounded by the patients certainly does not correspond to the facts in the sense in which they themselves construe it, namely, that masturbation during puberty (which may almost be described as a typical occurrence) is responsible for all neurotic disturbances. Their thesis requires interpretation. The masturbation of puberty is in fact no more than a revival of the masturbation of infancy, a subject which has hitherto invariably been neglected. Infantile masturbation reaches a kind of climax, as a rule, between the ages of three and four or five; and it is the clearest expression of a child's sexual constitution, in which the aetiology of subsequent neuroses must be sought. In this disguised way, therefore, the patients are putting the blame for their illnesses upon their infantile sexuality; and they are perfectly right in doing so. On the other hand, the problem of masturbation becomes insoluble if we attempt to treat it as a clinical unit, and forget that it can represent the discharge of every variety of sexual component and of every sort of phantasy to which such components can give rise. The injurious effects of masturbation are only in a very small degree autonomous - that is to say, determined by its own nature. They are in substance merely part and parcel of the pathogenic significance of the subject's sexual life as a whole. The fact that so many people can tolerate masturbation - that is, a certain amount of it - without injury merely shows that their sexual constitution and the course of development of their sexual life have been such as to allow them to exercise the sexual function within the limits of what is culturally permissible; whereas other people, because their sexual constitution has been less favourable or their development has been disturbed, fall ill as a result of their sexuality - they cannot, that is, achieve the necessary suppression or sublimation of their sexual components without having recourse to inhibitions or substitutes.¹

Our present patient's behaviour in the matter of masturbation was most remarkable. He did not practise it during puberty and therefore, according to one set of views, he might have expected to be exempt from neurosis. On the other hand, an impulsion towards masturbatory activities came over him in his twenty-first year, shortly after his father's death. He felt very much ashamed of himself each time he gave way to this kind of gratification, and soon foresaw the habit. From that time onwards it reappeared only upon rare and extraordinary occasions. It was provoked, he told me, when he experienced especially fine moments, or when he read especially fine passages. It occurred once, for instance, on a lovely summer's afternoon when, in the middle of Vienna, he heard a postilion blowing his horn in the most wonderful way - until a policeman stopped him, because blowing horns is not allowed in the centre of the town. And another time it happened when he read in Dichtung und Wahrheit how the young Goethe had freed himself in a burst of tenderness from the effects of a curse which a jealous mistress had pronounced upon the next woman who should kiss his lips after her; he had long, almost superstitiously, suffered the curse to hold him back, but now he broke his bonds and kissed his love joyfully again and again.

¹[1909d, 2159]
It seemed to the patient not a little strange that he should be impelled to masturbate precisely upon such beautiful and uplifting occasions as these. But I could not help pointing out that these two occasions had something in common - a prohibition, and the defiance of a command.

Starting from these indications and from other data of a similar kind, I ventured to put forward a construction to the effect that when he was a child of under six he had been guilty of some sexual misdemeanour connected with masturbation and had been soundly castigated for it by his father. This punishment, according to my hypothesis, had, it was true, put an end to his masturbations, but on the other hand it had left behind it an ineradicable grudge against his father and had established him for all time in his role of an interferer with the patient's sexual enjoyment.¹ To my great astonishment the patient then informed me that his mother had repeatedly described to him an occurrence of this kind which dated from his earliest childhood and had evidently escaped being forgotten by her on account of its remarkable consequences.

He himself, however, had no recollection of it whatever. The tale was as follows. When he was very small - it became possible to establish the date more exactly owing to its having coincided with the fatal illness of an elder sister - he had done something naughty, for which his father had given him a beating. The little boy had flown into a terrible rage and had hurled abuse at his father even while he was under his blows. But as he knew no bad language, he had called him all the names of common objects that he could think of, and had screamed: 'You lamp! You towel! You plate!' and so on. His father, shaken by such an outburst of elemental fury, had stopped beating him, and had declared: 'The child will be either a great man or a great criminal!'² The patient believed that the scene made a permanent impression upon himself as well as upon his father. His father, he said, never beat him again; and he also attributed to this experience a part of the change which came over his own character. From that time forward he was a coward - out of fear of the violence of his own rage. His whole life long, moreover, he was terribly afraid of blows, and used to creep away and hide, filled with terror and indignation, when one of his brothers or sisters was beaten.

Furthermore, by a sort of regression, preparatory acts become substituted for the final decision, thinking replaces acting, and, instead of the substitutive act, some thought preliminary to it asserts itself with all the force of compulsion. According as this regression from acting to thinking is more or less marked, a case of obsessional neurosis will exhibit the characteristics of obsessive thinking (that is, of obsessional ideas) or of obsessive acting in the narrower sense of the word. True obsessional acts such as these, however, are only made possible because they constitute a kind of reconciliation, in the shape of a compromise, between the two antagonistic impulses. For obsessional acts tend to approximate more and more - and the longer the disorder lasts the more evident does this become - to infantile sexual acts of a masturbatory character. Thus in this form of the neurosis acts of love are carried out in spite of everything, but only by the aid of a new kind of regression; for such acts no longer relate to another person, the object of love and hatred, but are auto-erotic acts such as occur in infancy.
There is another question that I might draw your attention to, which has been dealt with too little in our discussions: that of 'unconscious' masturbation. I mean masturbation during sleep, during abnormal states, or fits. You will recall the many hysterical fits in which masturbatory acts recur in a disguised or unrecognizable way, after the subject has renounced that form of satisfaction, and the many symptoms in obsessional neurosis which seek to replace and repeat this kind of sexual activity, which has formerly been forbidden. We may also speak of a therapeutic return of masturbation. A number of you will have found on occasion, as I have, that it represents a great advance if during the treatment the patient ventures to take up masturbation once more, though he may have no intention of making a permanent stop at that infantile halting-place. In this connection I may remind you that a considerable number of precisely the most severe sufferers from neurosis have avoided all recollection of masturbation during historic times, while psycho-analysis is able to prove that that species of sexual activity had by no means been strange to them during the forgotten earliest period of their lives. [1912f, 2574]

¹ Both the desire and the prohibition relate to the child’s touching his own genitals. [1912-1913, 2677]

It is equally clear why it is that the violation of certain taboo prohibitions constitutes a social danger which must be punished or atoned for by all the members of the community if they are not all to suffer injury. If we replace the unconscious desires by conscious impulses we shall see that the danger is a real one. It lies in the risk of imitation, which would quickly lead to the dissolution of the community. If the violation were not avenged by the other members they would become aware that they wanted to act in the same way as the transgressor. We cannot be surprised at the fact that, in the restrictions of taboo, touching plays a part similar to the one which it plays in ‘touching phobias’, though the secret meaning of the prohibition cannot be of such a specialized nature in taboo as it is in the neurosis. Touching is the first step towards obtaining any sort of control over, or attempting to make use of, a person or object. [1912-1913, 2681]

Of the many symptomatic pictures in which obsessional neurosis appears, the most important turn out to be those provoked by the pressure of excessively strong sadistic sexual impulses (perverse, therefore, in their aim). The symptoms, indeed, in accordance with the structure of an obsessional neurosis, serve predominantly as a defence against these wishes or give expression to the struggle between satisfaction and defence. But satisfaction does not come off too badly either; it succeeds in roundabout ways in putting itself into effect in the patients’ behaviour and is preferably directed against themselves and makes them into self-tormentors. Other forms of the neurosis, the brooding kinds, correspond to an excessive sexualization of actions which ordinarily have their place on the path to normal sexual satisfaction - an excessive sexualization of wanting to look or to touch or to explore. Here we have the explanation of the great importance of the fear of touching and of the obsession for washing. An unsuspectedly large proportion of obsessional actions may be traced back to masturbation, of which they are disguised repetitions and modifications; it is a familiar fact that masturbation, though a single and uniform action, accompanies the most various forms of sexual phantasying. [1916-1917, 3380]
In enforcing regression, the ego scores its first success in its defensive struggle against the demands of the libido. (In this connection it is of advantage to distinguish the more general notion of 'defence' from 'repression'. Repression is only one of the mechanisms which defence makes use of.) It is perhaps in obsessional cases more than in normal or hysterical ones that we can most clearly recognize that the motive force of defence is the castration complex and that what is being fended off are the trends of the Oedipus complex. We are at present dealing with the beginning of the latency period, a period which is characterized by the dissolution of the Oedipus complex, the creation or consolidation of the super-ego and the erection of ethical and aesthetic barriers in the ego. In obsessional neuroses these processes are carried further than is normal. In addition to the destruction of the Oedipus complex a regressive degradation of the libido takes place, the super-ego becomes exceptionally severe and unkind, and the ego, in obedience to the super-ego, produces strong reaction-formations in the shape of conscientiousness, pity and cleanliness. Implacable, though not always on that account successful, severity is shown in condemning the temptation to continue early infantile masturbation, which now attaches itself to regressive (sadistic-anal) ideas but which nevertheless represents the unsubjugated part of the phallic organization. There is an inherent contradiction about this state of affairs, in which, precisely in the interests of masculinity (that is to say, from fear of castration), every activity belonging to masculinity is stopped. But here, too, obsessional neurosis is only overdoing the normal method of getting rid of the Oedipus complex. We once more find here an illustration of the truth that every exaggeration contains the seed of its own undoing. For, under the guise of obsessional acts, the masturbation that has been suppressed approaches ever more closely to satisfaction.

[1926d, 4273]

The chief task during the latency period seems to be the fending-off of the temptation to masturbate. This struggle produces a series of symptoms which appear in a typical fashion in the most different individuals and which in general have the character of a ceremonial. It is a great pity that no one has as yet collected them and systematically analysed them. Being the earliest products of the neurosis they should best be able to shed light on the mechanisms employed in its symptom-formation. They already exhibit the features which will emerge so disastrously if a serious illness follows. They tend to become attached to activities (which would later be carried out almost automatically) such as going to sleep, washing, dressing and walking about; and they tend also to repetition and waste of time. Why this should be so is at present not at all clear; but the sublimation of anal-erotic components plays an unmistakable part in it.

[1926d, 4275]
In a few instances a change of expression of this kind assists dream-condensation even more directly, by finding a form of words which owing to its ambiguity is able to give expression to more than one of the dream-thoughts. In this way the whole domain of verbal wit is put at the disposal of the dream-work. There is no need to be astonished at the part played by words in dream-formation. Words, since they are the nodal point of numerous ideas, may be regarded as predestined to ambiguity; and the neuroses (e.g. in framing obsessions and phobias), no less than dreams, make unashamed use of the advantages thus offered by words for purposes of condensation and disguise.¹ It is easy to show that dream-distortion too profits from displacement of expression. If one ambiguous word is used instead of two unambiguous ones the result is misleading; and if our everyday, sober method of expression is replaced by a pictorial one, our understanding is brought to a halt, particularly since a dream never tells us whether its elements are to be interpreted literally or in a figurative sense or whether they are to be connected with the material of the dream-thoughts directly or through the intermediary of some interpolated phraseology. In interpreting any dream-element it is in general doubtful

Another impulse, which might be described as indirectly suicidal and which was of longer duration, was not so easily explicable. For its relation to the patient's experiences succeeded in concealing itself behind one of those purely external associations which are so obnoxious to our consciousness. One day while he was away on his summer holidays the idea suddenly occurred to him that he was too fat [German 'dick'] and that he must make himself slimmer. So he began getting up from table before the pudding came round and tearing along the road without a hat in the blazing heat of an August sun. Then he would dash up a mountain at the double, till, dripping with perspiration, he was forced to come to a stop. On one occasion his suicidal intentions actually emerged without any disguise from behind this mania for slimming: as he was standing on the edge of a steep precipice he suddenly received a command to jump over, which would have been certain death. Our patient could think of no explanation of this senseless obsessional behaviour until it suddenly occurred to him that at that time his lady had also been stopping at the same resort; but she had been in the company of an English cousin, who was very attentive to her and of whom the patient had been very jealous. This cousin's name was Richard, and, according to the usual practice in England, he was known as Dick. Our patient, then, had wanted to kill this Dick; he had been far more jealous of him and enraged with him than he could admit to himself, and that was why he had imposed on himself this course of slimming by way of a punishment. This obsessional impulse may seem very different from the directly suicidal command which was discussed above, but they have nevertheless one important feature in common. For they both arose as reactions to a tremendous feeling of rage, which was inaccessible to the patient's consciousness and was directed against some one who had cropped up as an interference with the course of his love.¹

¹ Names and words are not nearly so frequently or so recklessly employed in obsessional neuroses as in hysteria for the purpose of establishing a connection between unconscious thoughts (whether they are impulses or phantasies) and symptoms. I happen, however, to recollect another instance in which the very same name, Richard, was similarly used by a patient whom I analysed a long time since. After a quarrel with his brother he began brooding over the best means of getting rid of his fortune, and declaring that he did not want to have anything more to do with money, and so on. His brother was called Richard, and 'richard' is the French for 'a rich man'.

¹ [1900a, 810]

¹ [1909d, 2148]
In elucidating the effects produced by the captain's rat story we must follow the course of the analysis more closely. The patient began by producing an enormous mass of associative material, which at first, however, threw no light upon the circumstances in which the formation of his obsession had taken place. The idea of the punishment carried out by means of rats had acted as a stimulus to a number of his instincts and had called up a whole quantity of recollections; so that, in the short interval between the captain's story and his request to him to pay back the money, rats had acquired a series of symbolic meanings, to which, during the period which followed, fresh ones were continually being added. I must confess that I can only give a very incomplete account of the whole business. What the rat punishment stirred up more than anything else was his anal erotism, which had played an important part in his childhood and had been kept in activity for many years by a constant irritation due to worms. In this way rats came to have the meaning of 'money'.¹ The patient gave an indication of this connection by reacting to the word 'Ratten' ['rats'] with the association 'Raten' ['instalments']. In his obsessional deliria he had coined himself a regular rat currency. When, for instance, in reply to a question, I told him the amount of my fee for an hour's treatment, he said to himself (as I learned six months later): 'So many florins, so many rats'. Little by little he translated into this language the whole complex of money interests which centred round his father's legacy to him, that is to say, all his ideas connected with that subject were, by way of the verbal bridge 'Raten - Ratten', carried over into his obsessional life and brought under the dominion of his unconscious. Moreover, the captain's request to him to pay back the charges due upon the packet served to strengthen the money significance of rats, by way of another verbal bridge 'Spielratte', which led back to his father's gambling debt.

[1909d, 2166]

But the patient was also familiar with the fact that rats are carriers of dangerous infectious diseases; he could therefore employ them as symbols of his dread (justifiable enough in the army) of syphilitic infection. This dread concealed all sorts of doubts as to the kind of life his father had led during his term of military service. Again, in another sense, the penis itself is a carrier of syphilitic infection; and in this way he could consider the rat as a male organ of sex. It had a further title to be so regarded; for a penis (especially a child's penis) can easily be compared to a worm, and the captain's story had been about rats burrowing in some one's anus, just as the large round-worms had in his when he was a child. Thus the penis significance of rats was based, once more, upon anal erotism. And apart from this, the rat is a dirty animal, feeding upon excrement and living in sewers.¹ It is perhaps unnecessary to point out how great an extension of the rat delirium became possible owing to this new meaning. For instance, 'So many rats, so many florins' could serve as an excellent characterization of a certain female profession which he particularly detested. On the other hand, it is certainly not a matter of indifference that the substitution of a penis for a rat in the captain's story resulted in a situation of intercourse per anum, which could not fail to be especially revolting to him when brought into connection with his father and the woman he loved. And when we consider that the same situation was reproduced in the compulsive threat which had formed in his mind after the captain had made his request, we shall be forcibly reminded of certain curses in use among the Southern Slavs.² Moreover, all of this material, and more besides, was woven into the fabric of the rat discussions behind the screen-association 'heiraten' ['to marry'].

[1909d, 2167]
The obsessive thought which has forced its way into consciousness with such excessive violence has next to be secured against the efforts made by conscious thought to resolve it. As we already know, this protection is afforded by the distortion which the obsessive thought has undergone before becoming conscious. But this is not the only means employed. In addition, each separate obsessional idea is almost invariably removed from the situation in which it originated and in which, in spite of its distortion, it would be most easily comprehensible. With this end in view, in the first place an interval of time is inserted between the pathogenic situation and the obsession that arises from it, so as to lead astray any conscious investigation of its causal connections, and in the second place the content of the obsession is taken out of its particular setting by being generalized. Our patient’s ‘obsession for understanding’ is an example of this (p. 2150). But perhaps a better one is afforded by another patient. This was a woman who prohibited herself from wearing any sort of personal adornment, though the exciting cause of the prohibition related only to one particular piece of jewellery: she had envied her mother the possession of it and had had hopes that one day she would inherit it. Finally, if we care to distinguish verbal distortion from distortion of content, there is yet another means by which the obsession is protected against conscious attempts at solution. And that is the choice of an indefinite or ambiguous wording. After being misunderstood, the wording may find its way into the patient’s ‘deliria’, and whatever further processes of development or substitution his obsession undergoes will then be based upon the misunderstanding and not upon the proper sense of the text. Observation will show, however, that the deliria constantly tend to form new connections with that part of the matter and wording of the obsession which is not present in consciousness.

[1909d, 2192]
Another impulse, which might be described as indirectly suicidal and which was of longer duration, was not so easily explicable. For its relation to the patient's experiences succeeded in concealing itself behind one of those purely external associations which are so obnoxious to our consciousness. One day while he was away on his summer holidays the idea suddenly occurred to him that he was too fat [German 'dick'] and that he must make himself slimmer. So he began getting up from table before the pudding came round and tearing along the road without a hat in the blazing heat of an August sun. Then he would dash up a mountain at the double, till, dripping with perspiration, he was forced to come to a stop. On one occasion his suicidal intentions actually emerged without any disguise from behind this mania for slimming: as he was standing on the edge of a steep precipice he suddenly received a command to jump over, which would have been certain death. Our patient could think of no explanation of this senseless obsessional behaviour until it suddenly occurred to him that at that time his lady had also been stopping at the same resort; but she had been in the company of an English cousin, who was very attentive to her and of whom the patient had been very jealous. This cousin's name was Richard, and, according to the usual practice in England, he was known as Dick. Our patient, then, had wanted to kill this Dick; he had been far more jealous of him and enraged with him than he could admit to himself, and that was why he had imposed on himself this course of slimming by way of a punishment. This obsessional impulse may seem very different from the directly suicidal command which was discussed above, but they have nevertheless one important feature in common. For they both arose as reactions to a tremendous feeling of rage, which was inaccessible to the patient's consciousness and was directed against some one who had cropped up as an interference with the course of his love.¹
It is easy to see where the resemblances lie between neurotic ceremonials and the sacred acts of religious ritual: in the qualms of conscience brought on by their neglect, in their complete isolation from all other actions (shown in the prohibition against interruption) and in the conscientiousness with which they are carried out in every detail. But the differences are equally obvious, and a few of them are so glaring that they make the comparison a sacrilege: the greater individual variability of ceremonial actions in contrast to the stereotyped character of rituals (prayer, turning to the East, etc.), their private nature as opposed to the public and communal character of religious observances, above all, however, the fact that, while the minutiae of religious ceremonial are full of significance and have a symbolic meaning, those of neurotics seem foolish and senseless. In this respect an obsessional neurosis presents a travesty, half comic and half tragic, of a private religion. But it is precisely this sharpest difference between neurotic and religious ceremonial which disappears when, with the help of the psycho-analytic technique of investigation, one penetrates to the true meaning of obsessive actions.¹ In the course of such an investigation the appearance which obsessive actions afford of being foolish and senseless is completely effaced, and the reason for their having that appearance is explained. It is found that the obsessive actions are perfectly significant in every detail, that they serve important interests of the personality and that they give expression to experiences that are still operative and to thoughts that are cathected with affect. They do this in two ways, either by direct or by symbolic representation; and they are consequently to be interpreted either historically or symbolically.

(c) The same patient could only sit on one particular chair and could only get up from it with difficulty. In regard to certain details of her married life, the chair symbolized her husband, to whom she remained faithful. She found an explanation of her compulsion in this sentence: 'It is so hard to part from anything (a husband, a chair) upon which one has once settled.'

We have noted as a curious and derogatory characteristic of obsessional neurosis that its ceremonials are concerned with the small actions of daily life and are expressed in foolish regulations and restrictions in connection with them. We cannot understand this remarkable feature of the clinical picture until we have realized that the mechanism of psychical displacement, which was first discovered by me in the construction of dreams,¹ dominates the mental processes of obsessional neurosis. It is already clear from the few examples of obsessive actions given above that their symbolism and the detail of their execution are brought about by a displacement from the actual, important thing on to a small one which takes its place - for instance, from a husband on to a chair. It is this tendency to displacement which progressively changes the clinical picture and eventually succeeds in turning what is apparently the most trivial matter into something of the utmost importance and urgency. It cannot be denied that in the religious field as well there is a similar tendency to a displacement of psychical values, and in the same direction, so that the petty ceremonials of religious practice gradually become the essential thing and push aside the underlying thoughts. That is why religions are subject to reforms which work retroactively and aim at a re-establishment of the original balance of values.

[1907b, 1908]
But the patient was also familiar with the fact that rats are carriers of dangerous infectious diseases; he could therefore employ them as symbols of his dread (justifiable enough in the army) of syphilitic infection. This dread concealed all sorts of doubts as to the kind of life his father had led during his term of military service. Again, in another sense, the penis itself is a carrier of syphilitic infection; and in this way he could consider the rat as a male organ of sex. It had a further title to be so regarded; for a penis (especially a child's penis) can easily be compared to a worm, and the captain's story had been about rats burrowing in some one's anus, just as the large round-worms had in his when he was a child. Thus the penis significance of rats was based, once more, upon anal erotism. And apart from this, the rat is a dirty animal, feeding upon excrement and living in sewers.¹ It is perhaps unnecessary to point out how great an extension of the rat delirium became possible owing to this new meaning. For instance, 'So many rats, so many florins' could serve as an excellent characterization of a certain female profession which he particularly detested. On the other hand, it is certainly not a matter of indifference that the substitution of a penis for a rat in the captain's story resulted in a situation of intercourse per anum, which could not fail to be especially revolting to him when brought into connection with his father and the woman he loved. And when we consider that the same situation was reproduced in the compulsive threat which had formed in his mind after the captain had made his request, we shall be forcibly reminded of certain curses in use among the Southern Slavs.² Moreover, all of this material, and more besides, was woven into the fabric of the rat discussions behind the screen-association 'heiraten' ['to marry'].

¹ [1909d, 2167]

² The story of the rat punishment, as was shown by the patient's own account of the matter and by his facial expression as he repeated the story to me, had fanned into a flame all his prematurely suppressed impulses of cruelty, egoistic and sexual alike. Yet, in spite of all this wealth of material, no light was thrown upon the meaning of his obsessional idea until one day the Rat-Wife in Ibsen's Little Eyolf came up in the analysis, and it became impossible to escape the inference that in many of the shapes assumed by his obsessional deliria rats had another meaning still - namely, that of children.¹ Enquiry into the origin of this new meaning at once brought me up against some of the earliest and most important roots. Once when the patient was visiting his father's grave he had seen a big beast, which he had taken to be a rat, gliding along over the grave.² He assumed that it had actually come out of his father's grave, and had just been having a meal off his corpse. The notion of a rat is inseparably bound up with the fact that it has sharp teeth with which it gnaws and bites.³ But rats cannot be sharp-toothed, greedy and dirty with impunity: they are cruelly persecuted and mercilessly put to death by man, as the patient had often observed with horror. He had often pitied the poor creatures. But he himself had been just such a nasty, dirty little wretch, who was apt to bite people when he was in a rage, and had been fearfully punished for doing so (p. 2162). He could truly be said to find 'a living likeness of himself' in the rat. It was almost as though Fate, when the captain told him his story, had been putting him through an association test: she had called out a 'complex stimulus-word', and he had reacted to it with his obsessional idea.

³ [1909d, 2168]
It was only then that it became possible to understand the inexplicable process by which his
obsessional idea had been formed. With the assistance of our knowledge of infantile sexual
theories and of symbolism (as learnt from the interpretation of dreams) the whole thing could be
translated and given a meaning. When, at the afternoon halt (during which he had lost his
prise-nez), the captain had told him about the rat punishment, the patient had only been struck
at first by the combined cruelty and lasciviousness of the situation depicted. But immediately
afterwards a connection had been set up with the scene from his childhood in which he himself
had bitten some one. The captain - a man who could defend such punishments - had become a
substitute for his father, and had thus drawn down upon himself a part of the reviving animosity
which had burst out, on the original occasion, against his cruel father. The idea which came into
his consciousness for a moment, to the effect that something of the sort might happen to some
one he was fond of, is probably to be translated into a wish such as 'You ought to have the
same thing done to you!' aimed at the teller of the story, but through him at his father. A day and
a half later,¹ when the captain had handed him the packet upon which the charges were due
and had requested him to pay back the 3.80 kronen to Lieutenant A., he had already been
aware that his 'cruel superior' was making a mistake, and that the only person he owed anything
to was the young lady at the post office. It might easily, therefore, have occurred to him to think
of some derisive reply, such as, 'Will I, though?' or 'Pay your grandmother!' or 'Yes! You bet I'll
pay him back the money!' - answers which would have been subject to no compulsive force. But
instead, out of the stirrings of his father-complex and out of his memory of the scene from his
childhood, there formed in his mind some such answer as: 'Yes! I'll pay back the money to A.
when my father and the lady have children!' or 'As sure as my father and the lady can have
children, I'll pay him back the money!' In short, a derisive affirmation attached to an absurd
condition which could never be fulfilled.²

Experience in the analysis of dreams has sufficiently well established the hat as a symbol of
the genital organ, most frequently of the male organ. It cannot be said, however, that the symbol
is an intelligible one. In phantasies and in numerous symptoms the head too appears as a
symbol of the male genitals, or, if one prefers to put it so, as something standing for them. It will
sometimes have been noticed that patients suffering from obsessions express an amount of
abhorrence of and indignation against punishment by beheading far greater than they do in the
case of any other form of death; and in such cases the analyst may be led to explain to them
that they are treating being beheaded as a substitute for being castrated. Instances have often
been analysed and published of dreams dreamt by young people or reported as having
occurred in youth, which concerned the subject of castration, and in which a round ball was
mentioned which could only be interpreted as the head of the dreamer's father. I was recently
able to solve a ceremonial performed by a woman patient before going to sleep, in which she
had to lay her small top pillow diamond-wise on the other ones and to rest her head exactly in
the long diameter of the diamond-shape. The diamond had the meaning that is familiar to us
from drawings on walls [graffiti]; the head was supposed to represent a male organ.

³[1909d, 2169]

¹[1916c, 3122]
It may be that the symbolic meaning of the hat is derived from that of the head, in so far as a hat can be regarded as a prolonged, though detachable head. In this connection I am reminded of a symptom by means of which obsessional neurotics succeed in causing themselves continual torments. When they are in the street they are constantly on the look-out to see whether some acquaintance will greet them first by taking of his hat, or whether he seems to be waiting for their salutation; and they give up a number of their acquaintances after discovering that they no longer greet them or do not return their own salutation properly. There is no end to their difficulties in this connection; they find them everywhere as their mood and fancy dictate. It makes no difference to their behaviour when we tell them, what they all know already, that a salutation by taking off the hat has the meaning of an abasement before the person saluted - that a Spanish grandee, for example, enjoyed the privilege of remaining covered in the king's presence - and that their own sensitiveness on the subject of greeting therefore means that they are unwilling to show themselves less important than the other person thinks he is. The resistance of their sensitiveness to explanations such as this suggests that a motive less familiar to consciousness is at work; and the source of this excess of feeling might easily be found in its relation to the castration complex.

[1916c, 3122]

Our patient gradually came to learn that it was as symbols of the female genitals that clocks were banished from her equipment for the night. Clocks and watches - though elsewhere we have found other symbolic interpretations for them - have arrived at a genital role owing to their relation to periodic processes and equal intervals of time. A woman may boast that her menstruation behaves with the regularity of clockwork. Our patient's anxiety, however, was directed in particular against being disturbed in her sleep by the ticking of a clock. The ticking of a clock may be compared with the knocking or throbbing in the clitoris during sexual excitement. She had in fact been repeatedly woken from her sleep by this sensation, which had now become distressing to her; and she gave expression to this fear of an erection in the rule that all clocks and watches that were going should be removed from her neighbourhood at night. Flower-pots and vases, like all vessels, are also female symbols. Taking precautions against their falling and being broken at night was thus not without its good sense. We know the widespread custom of breaking a vessel or plate at betrothal ceremonies. Each man present gets hold of a fragment, and we may regard this as a sign of his resigning the claims he had upon the bride in virtue of a marriage-regulation dating from before the establishment of monogamy. In connection with this part of her ceremonial the girl produced a recollection and several associations. Once when she was a child she had fallen down while she was carrying a glass or china vase and had cut her finger and bled profusely. When she grew up and came to know the facts about sexual intercourse she formed an anxious idea that on her wedding-night she would not bleed and would thus fail to show that she was a virgin. Her precautions against vases being broken thus meant a repudiation of the whole complex concerned with virginity and bleeding at the first intercourse - a repudiation equally of the fear of bleeding and of the contrary fear of not bleeding. These precautions, which she subsumed under her avoidance of noise, had only a remote connection with it.

[1916-1917, 3346]
She found out the central meaning of her ceremonial one day when she suddenly understood the meaning of the rule that the pillow must not touch the back of the bedstead. The pillow, she said, had always been a woman to her and the upright wooden back a man. Thus she wanted - by magic, we must interpolate - to keep the man and woman apart - that is, to separate her parents from each other, not to allow them to have sexual intercourse. In earlier years, before she had established the ceremonial, she had tried to achieve the same aim in a more direct way. She had simulated fear (or had exploited a tendency to fear which was already present) in order that the connecting doors between her parents' bedroom and the nursery should not be shut. This rule had, indeed, been retained in her present ceremonial. In that way she gave herself the opportunity of listening to her parents, but in making use of it she brought on an insomnia which lasted for months. Not satisfied with disturbing her parents by this means, she contrived to be allowed from time to time to sleep in her parents' bed between them. The 'pillow' and the 'wooden back' were thus really unable to come together. Finally, when she was so big that it became physically uncomfortable for her to find room in the bed between her parents, she managed, by a conscious simulation of anxiety, to arrange for her mother to exchange places with her for the night and to leave her own place so that the patient could sleep beside her father. This situation no doubt became the starting-point of phantasies whose after-effect was to be seen in the ceremonial.

[1916-1917, 3347]

If a pillow was a woman, then the shaking of the eiderdown till all the feathers were at the bottom and caused a swelling there had a sense as well. It meant making a woman pregnant; but she never failed to smooth away the pregnancy again, for she had for years been afraid that her parents' intercourse would result in another child and so present her with a competitor. On the other hand, if the big pillow was a woman, the mother, then the small top-pillow could only stand for the daughter. Why did this pillow have to be placed diamond-wise and her head precisely along its centre line? It was easy to recall to her that this diamond shape is the inscription scribbled on every wall to represent the open female genitals. If so, she herself was playing the man and replacing the male organ by her head. (Cf. the symbolism of beheading for castrating.)

[1916-1917, 3347]
No doubt all kinds of objections can still be raised to the assertion that neurotic symptoms are substitutes for sexual satisfactions. I will mention two of them to-day. When you yourselves have carried out analytic examinations of a considerable number of neurotics, you will perhaps tell me, shaking your head, that in a lot of cases my assertion is simply not true; the symptoms seem rather to have the contrary purpose of excluding or of stopping sexual satisfaction. I will not dispute the correctness of your interpretation. The facts in psycho-analysis have a habit of being rather more complicated than we like. If they were as simple as all that, perhaps it might not have needed psycho-analysis to bring them to light. Indeed, some of the features of our second patient's ceremonial show signs of this ascetic character with its hostility to sexual satisfaction: when, for instance, she got rid of the clocks and watches, which had the magical meaning of avoiding erections during the night, or when she tried to guard against flower-pots falling and breaking, which was equivalent to protecting her virginity. In some other cases of bed ceremonials, which I have been able to analyse, this negative character was far more outspoken; the ceremonial might consist exclusively of defensive measures against sexual memories and temptations. However, we have already found often enough that in psycho-analysis opposites imply no contradiction. We might extend our thesis and say that symptoms aim either at a sexual satisfaction or at fending it off, and that on the whole the positive, wish-fulfilling character prevails in hysteria and the negative, ascetic one in obsessional neurosis. If symptoms can serve the purpose both of sexual satisfaction and of its opposite, there is an excellent basis for this double-sidedness or polarity in a part of their mechanism which I have so far not been able to mention. For, as we shall hear, they are the products of a compromise and arise from the mutual interference between two opposing currents; they represent not only the repressed but also the repressing force which had a share in their origin. One side or the other may be more strongly represented; but it is rarely that one influence is entirely absent. In hysteria a convergence of both intentions in the same symptom is usually achieved. In obsessional neurosis the two portions are often separated; the symptom then becomes diphasic and consists in two actions, one after the other, which cancel each other out.

Let us turn to the obsessional neuroses in the hope of learning more about the formation of symptoms. The symptoms belonging to this neurosis fall, in general, into two groups, each having an opposite trend. They are either prohibitions, precautions and expiations - that is, negative in character - or they are, on the contrary, substitutive satisfactions which often appear in symbolic disguise. The negative, defensive group of symptoms is the older of the two; but as illness is prolonged, the satisfactions, which scoff at all defensive measures, gain the upper hand. The symptom-formation scores a triumph if it succeeds in combining the prohibition with satisfaction so that what was originally a defensive command or prohibition acquires the significance of a satisfaction as well; and in order to achieve this end it will often make use of the most ingenious associative paths. Such an achievement demonstrates the tendency of the ego to synthesize, which we have already observed. In extreme cases the patient manages to make most of his symptoms acquire, in addition to their original meaning, a directly contrary one. This is a tribute to the power of ambivalence, which, for some unknown reason, plays such a large part in obsessional neuroses. In the crudest instance the symptom is diphasic: an action which carries out a certain injunction is immediately succeeded by another action which stops or undoes the first one even if it does not go quite so far as to carry out its opposite.
Compulsive acts like this, in two successive stages, of which the second neutralizes the first, are a typical occurrence in obsessional neuroses. The patient's consciousness naturally misunderstands them and puts forward a set of secondary motives to account for them - rationalizes them, in short. (Cf. Jones, 1908.) But their true significance lies in their being a representation of a conflict between two opposing impulses of approximately equal strength: and hitherto I have invariably found that this opposition has been one between love and hate. Compulsive acts of this sort are theoretically of special interest, for they show us a new type of method of constructing symptoms. What regularly occurs in hysteria is that a compromise is arrived at which enables both the opposing tendencies to find expression simultaneously - which kills two birds with one stone;¹ whereas here each of the two opposing tendencies finds satisfaction singly, first one and then the other, though naturally an attempt is made to establish some sort of logical connection (often in defiance of all logic) between the antagonists.² [1909d, 2151]

² Another obsessional patient once told me the following story. He was walking one day in the park at Schönbrunn when he kicked his foot against a branch that was lying on the ground. He picked it up and flung it into the hedge that bordered the path. On his way home he was suddenly seized with uneasiness that the branch in its new position might perhaps be projecting a little from the hedge and might cause an injury to some one passing by the same place after him. He was obliged to jump off his tram, hurry back to the park, find the place again, and put the branch back in its former position - although any one else but the patient would have seen that, on the contrary, it was bound to be more dangerous to passers-by in its original position than where he had put it in the hedge. The second and hostile act, which he carried out under compulsion, had clothed itself to his conscious view with the motives that really belonged to the first and philanthropic one. [1909d, 2151]

I do not want to introduce at this point the attempts - which are so frequent - to take flight from the first occasion of sexual intercourse, because they are open to several interpretations and are in the main, although not altogether, to be understood as an expression of the general female tendency to take a defensive line. As against this, I do believe that light is thrown on the riddle of female frigidity by certain pathological cases in which, after the first and indeed after each repeated instance of sexual intercourse, the woman gives uncleaned expression to her hostility towards the man by abusing him, raising her hand against him or actually striking him. In one very clear case of this kind, which I was able to submit to a thorough analysis, this happened although the woman loved the man very much, used to demand intercourse herself and unmistakably found great satisfaction in it. I think that this strange, contradictory reaction is the result of the very same impulses which ordinarily can only find expression as frigidity - which, that is, can hold back the tender reaction without at the same time being able to put themselves into effect. In the pathological case we find separated so to speak into its two components what in the far more common instance of frigidity is united to produce an inhibiting effect, just like the process we have long recognized in the so-called 'diphasic symptoms' of obsessional neurosis. The danger which is thus aroused through the defloration of a woman would consist in drawing her hostility down upon oneself, and the prospective husband is just the person who would have every reason to avoid such enmity. [1918a, 2357]
No doubt all kinds of objections can still be raised to the assertion that neurotic symptoms are substitutes for sexual satisfactions. I will mention two of them to-day. When you yourselves have carried out analytic examinations of a considerable number of neurotics, you will perhaps tell me, shaking your head, that in a lot of cases my assertion is simply not true; the symptoms seem rather to have the contrary purpose of excluding or of stopping sexual satisfaction. I will not dispute the correctness of your interpretation. The facts in psycho-analysis have a habit of being rather more complicated than we like. If they were as simple as all that, perhaps it might not have needed psycho-analysis to bring them to light. Indeed, some of the features of our second patient’s ceremonial show signs of this ascetic character with its hostility to sexual satisfaction: when, for instance, she got rid of the clocks and watches, which had the magical meaning of avoiding erections during the night, or when she tried to guard against flower-pots falling and breaking, which was equivalent to protecting her virginity. In some other cases of bed ceremonials, which I have been able to analyse, this negative character was far more outspoken; the ceremonial might consist exclusively of defensive measures against sexual memories and temptations. However, we have already found often enough that in psycho-analysis opposites imply no contradiction. We might extend our thesis and say that symptoms aim either at a sexual satisfaction or at fending it off, and that on the whole the positive, wish-fulfilling character prevails in hysteria and the negative, ascetic one in obsessional neurosis. If symptoms can serve the purpose both of sexual satisfaction and of its opposite, there is an excellent basis for this double-sidedness or polarity in a part of their mechanism which I have so far not been able to mention. For, as we shall hear, they are the products of a compromise and arise from the mutual interference between two opposing currents; they represent not only the repressed but also the repressing force which had a share in their origin. One side or the other may be more strongly represented; but it is rarely that one influence is entirely absent. In hysteria a convergence of both intentions in the same symptom is usually achieved. In obsessional neurosis the two portions are often separated; the symptom then becomes diphasic and consists in two actions, one after the other, which cancel each other out.

Let us turn to the obsessional neuroses in the hope of learning more about the formation of symptoms. The symptoms belonging to this neurosis fall, in general, into two groups, each having an opposite trend. They are either prohibitions, precautions and expiations - that is, negative in character - or they are, on the contrary, substitutive satisfactions which often appear in symbolic disguise. The negative, defensive group of symptoms is the older of the two; but as illness is prolonged, the satisfactions, which scoff at all defensive measures, gain the upper hand. The symptom-formation scores a triumph if it succeeds in combining the prohibition with satisfaction so that what was originally a defensive command or prohibition acquires the significance of a satisfaction as well; and in order to achieve this end it will often make use of the most ingenious associative paths. Such an achievement demonstrates the tendency of the ego to synthesize, which we have already observed. In extreme cases the patient manages to make most of his symptoms acquire, in addition to their original meaning, a directly contrary one. This is a tribute to the power of ambivalence, which, for some unknown reason, plays such a large part in obsessional neuroses. In the crudest instance the symptom is diphasic: an action which carries out a certain injunction is immediately succeeded by another action which stops or undoes the first one even if it does not go quite so far as to carry out its opposite.
The two techniques I refer to are undoing what has been done and isolating. The first of these has a wide range of application and goes back very far. It is, as it were, negative magic, and endeavours, by means of motor symbolism, to 'blow away' not merely the consequences of some event (or experience or impression) but the event itself. I choose the term 'blow away' advisedly, so as to remind the reader of the part played by this technique not only in neuroses but in magical acts, popular customs and religious ceremonies as well. In obsessional neurosis the technique of undoing what has been done is first met with in the 'diphasic' symptoms, in which one action is cancelled out by a second, so that it is as though neither action had taken place, whereas, in reality, both have. This aim of undoing is the second underlying motive of obsessional ceremonials, the first being to take precautions in order to prevent the occurrence or recurrence of some particular event. The difference between the two is easily seen: the precautionary measures are rational, while trying to get rid of something by 'making it not to have happened' is irrational and in the nature of magic. It is of course to be suspected that the latter is the earlier motive of the two and proceeds from the animistic attitude towards the environment. This endeavour to undo shades off into normal behaviour in the case in which a person decides to regard an event as not having happened. But whereas he will take no direct steps against the event, and will simply pay no further attention to it or its consequences, the neurotic person will try to make the past itself non-existent. He will try to repress it by motor means. The same purpose may perhaps account for the obsession for repeating which is so frequently met with in this neurosis and the carrying out of which serves a number of contradictory intentions at once. When anything has not happened in the desired way it is undone by being repeated in a different way; and thereupon all the motives that exist for lingering over such repetitions come into play as well. As the neurosis proceeds, we often find that the endeavour to undo a traumatic experience is a motive of first-rate importance in the formation of symptoms. We thus unexpectedly discover a new, motor technique of defence, or (as we may say in this case with less inaccuracy) of repression.

[1926d, 4278]
One day the patient mentioned quite casually an event which I could not fail to recognize as the precipitating cause of his illness, or at least as the immediate occasion of the attack which had begun some six years previously and had persisted to that day. He himself had no notion that he had brought forward anything of importance; he could not remember that he had ever attached any importance to the event; and moreover he had never forgotten it. Such an attitude on his part calls for some theoretical consideration.

[1909d, 2154]

In hysteria it is the rule that the precipitating causes of the illness are overtaken by amnesia no less than the infantile experiences by whose help the precipitating causes are able to transform their affective energy into symptoms. And where the amnesia cannot be complete, it nevertheless subjects the recent traumatic precipitating cause to a process of erosion and robs it at least of its most important components. In this amnesia we see the evidence of the repression which has taken place. The case is different in obsessional neuroses. The infantile preconditions of the neurosis may be overtaken by amnesia, though this is often an incomplete one; but the immediate occasions of the illness are, on the contrary, retained in the memory. Repression makes use of another, and in reality a simpler, mechanism. The trauma, instead of being forgotten, is deprived of its affective cathexis; so that what remains in consciousness is nothing but its ideational content, which is perfectly colourless and is judged to be unimportant. The distinction between what occurs in hysteria and in an obsessional neurosis lies in the psychological processes which we can reconstruct behind the phenomena; the result is almost always the same, for the colourless mnemic content is rarely reproduced and plays no part in the patient's mental activity. In order to differentiate between the two kinds of repression we have on the surface nothing to rely upon but the patient's assurance that he has a feeling in the one case of having always known the thing and in the other of having long ago forgotten it.¹

[1909d, 2154]

But I must now return to a more detailed examination of the precipitating cause of our present patient's illness. His mother was brought up in a wealthy family with which she was distantly connected. This family carried on a large industrial concern. His father, at the time of his marriage, had been taken into the business, and had thus by his marriage made himself a fairly comfortable position. The patient had learnt from some chaff exchanged between his parents (whose marriage was an extremely happy one) that his father, some time before making his mother's acquaintance, had made advances to a pretty but penniless girl of humble birth. So much by way of introduction. After his father's death the patient's mother told him one day that she had been discussing his future with her rich relations, and that one of her cousins had declared himself ready to let him marry one of his daughters when his education was completed; a business connection with the firm would offer him a brilliant opening in his profession. This family plan stirred up in him a conflict as to whether he should remain faithful to the lady he loved in spite of her poverty, or whether he should follow in his father's footsteps and marry the lovely, rich, and well-connected girl who had been assigned to him. And he resolved this conflict, which was in fact one between his love and the persisting influence of his father's wishes, by falling ill; or, to put it more correctly, by falling ill he avoided the task of resolving it in real life.¹

[1909d, 2156]
From the precipitating cause of the patient's illness in his adult years there was a thread leading back to his childhood. He had found himself in a situation similar to that in which, as he knew or suspected, his father had been before his marriage; and he had thus been able to identify himself with his father. But his dead father was involved in his recent attack in yet another way. The conflict at the root of his illness was in essentials a struggle between the persisting influence of his father's wishes and his own amatory predilections. If we take into consideration what the patient reported in the course of the first hours of his treatment, we shall not be able to avoid a suspicion that this struggle was a very ancient one and had arisen as far back as in his childhood.

If we wish to obtain a grasp of the psychical forces whose interplay built up this neurosis, we must turn back to what we have learnt from the patient on the subject of the precipitating causes of his falling ill as a grown-up man and as a child. He fell ill when he was in his twenties on being faced with a temptation to marry another woman instead of the one whom he had loved so long; and he avoided a decision of this conflict by postponing all the necessary preliminary actions. The means for doing this was given him by his neurosis. His hesitation between the lady he loved and the other girl can be reduced to a conflict between his father's influence and his love for his lady, or, in other words, to a conflicting choice between his father and his sexual object, such as had already subsisted (judging from his recollections and obsessional ideas) in his remote childhood. All through his life, moreover, he was unmistakably victim to a conflict between love and hatred, in regard both to his lady and to his father. His phantasies of revenge and such obsessional phenomena as his obsession for understanding and his exploit with the stone in the road bore witness to his divided feelings; and they were to a certain degree comprehensible and normal, for the lady by her original refusal and subsequently by her coolness had given him some excuse for hostility. But his relations with his father were dominated by a similar division of feeling, as we have seen from our translation of his obsessional thoughts; and his father, too, must have given him an excuse for hostility in his childhood, as indeed we have been able to establish almost beyond question. His attitude towards the lady - a compound of tenderness and hostility - came to a great extent within the scope of his conscious knowledge; at most he deceived himself over the degree and violence of his negative feelings. But his hostility towards his father, on the contrary, though he had once been acutely conscious of it, had long since vanished from his ken, and it was only in the teeth of the most violent resistance that it could be brought back into his consciousness. We may regard the repression of his infantile hatred of his father as the event which brought his whole subsequent career under the dominion of the neurosis.

Another possibility has to be considered. Perhaps regression is the result not of a constitutional factor but of a time-factor. It may be that regression is rendered possible not because the genital organization of the libido is too feeble but because the opposition of the ego begins too early, while the sadistic phase is at its height. I am not prepared to express a definite opinion on this point, but I may say that analytic observation does not speak in favour of such an assumption. It shows rather that, by the time an obsessional neurosis is entered upon, the phallic stage has already been reached. Moreover, the onset of this neurosis belongs to a later time of life than that of hysteria - to the second period of childhood, after the latency period has set in. In a woman patient whose case I was able to study and who was overtaken by this disorder at a very late date, it became clear that the determining cause of her regression and of the emergence of her obsessional neurosis was a real occurrence through which her genital life, which had up till then been intact, lost all its value.
In addition to these two groups of true obsessions there is the class of 'phobias', which must now be considered. I have already mentioned the great difference between obsessions and phobias: that in the latter the emotion is always one of anxiety, fear. I might add that obsessions are varied and more specialized, phobias are more monotonous and typical. But this distinction is not of capital importance.

[1895c, 323]

Besides these compromise symptoms, which signify the return of the repressed and consequently a collapse of the defence that had been originally achieved, the obsessional neurosis constructs a set of further symptoms, whose origin is quite different. For the ego seeks to fend off the derivatives of the initially repressed memory, and in this defensive struggle it creates symptoms which might be classed together as 'secondary defence'. These are all of them 'protective measures', which have already done good service in the fight against obsessional ideas and obsessional affects. If these aids in the defensive struggle genuinely succeed in once more repressing the symptoms of the return which have forced themselves on the ego, then the obsession is transferred to the protective measures themselves and creates a third form of 'obsessional neurosis'- obsessional actions. These actions are never primary; they never contain anything but a defence - never an aggression. A psychical analysis of them shows that, in spite of their peculiarity, they can always be fully explained by being traced back to the obsessional memories which they are fighting against.¹

[1896b, 392]

Let us turn to the obsessional neuroses in the hope of learning more about the formation of symptoms. The symptoms belonging to this neurosis fall, in general, into two groups, each having an opposite trend. They are either prohibitions, precautions and expiations - that is, negative in character - or they are, on the contrary, substitutive satisfactions which often appear in symbolic disguise. The negative, defensive group of symptoms is the older of the two; but as illness is prolonged, the satisfactions, which scoff at all defensive measures, gain the upper hand. The symptom-formation scores a triumph if it succeeds in combining the prohibition with satisfaction so that what was originally a defensive command or prohibition acquires the significance of a satisfaction as well; and in order to achieve this end it will often make use of the most ingenious associative paths. Such an achievement demonstrates the tendency of the ego to synthesize, which we have already observed. In extreme cases the patient manages to make most of his symptoms acquire, in addition to their original meaning, a directly contrary one. This is a tribute to the power of ambivalence, which, for some unknown reason, plays such a large part in obsessional neuroses. In the crudest instance the symptom is diphasic: an action which carries out a certain injunction is immediately succeeded by another action which stops or undoes the first one even if it does not go quite so far as to carry out its opposite.

[1926d, 4271]
Everything I could tell you about this woman fits in with this. Or, more correctly speaking, everything else we know about her points the way to this interpretation of what was in itself an unintelligible obsessional action. The woman had been living apart from her husband for years and was struggling with an intention to obtain a legal divorce. But there was no question of her being free of him; she was forced to remain faithful to him; she withdrew from the world so as not to be tempted; she exculpated and magnified his nature in her imagination. Indeed, the deepest secret of her illness was that by means of it she protected her husband from malicious gossip, justified her separation from him and enabled him to lead a comfortable separate life. Thus the analysis of a harmless obsessional action led directly to the inmost core of an illness, but at the same time betrayed to us no small part of the secret of obsessional neurosis in general. I am glad to let you dwell a little on this example because it combines conditions which we could not fairly expect to find in every case. Here the interpretation of the symptom was discovered by the patient herself at a single blow, without any prompting or intervention on the analyst's part; and it resulted from a connection with an event which did not (as is usually the case) belong to a forgotten period of childhood, but which had happened in the patient's adult life and had remained undimmed in her memory. All the objections which criticism is normally in the habit of raising against our interpretation of symptoms fall to the ground in this particular case. We cannot hope always to have such good luck.

[1916-1917, 3344]

The negative reactions follow the opposite aim: that nothing of the forgotten traumas shall be remembered and nothing repeated. We can summarize them as 'defensive reactions'. Their principal expression are what are called 'avoidances', which may be intensified into 'inhibitions' and 'phobias'. These negative reactions too make the most powerful contributions to the stamping of character. Fundamentally they are just as much fixations to the trauma as their opposites, except that they are fixations with a contrary purpose. The symptoms of neurosis in the narrower sense are compromises in which both the trends proceeding from traumas come together, so that the share, now of one and now of the other tendency, finds preponderant expression in them. This opposition between the reactions sets up conflicts which in the ordinary course of events can reach no conclusion.

[1939a, 4901]
Secondary defence against the obsessional ideas may be effected by a forcible diversion on to other thoughts with a content as contrary as possible. This is why obsessional brooding, if it succeeds, regularly deals with abstract and suprasensual things; because the ideas that have been repressed are always concerned with sensuallity. Or else the patient tries to make himself master of each of his obsessional ideas singly by logical work and by having recourse to his conscious memories. This leads to obsessional thinking, to a compulsion to test things and to doubting mania. The advantage which perception has over memory in such tests at first causes the patient, and later compels him, to collect and store up all the objects with which he has come into contact. Secondary defence against obsessional affects leads to a still wider set of protective measures which are capable of being transformed into obsessional acts. These may be grouped according to their purpose: penitential measures (burdensome ceremonials, the observation of numbers), precautionary measures (all sorts of phobias, superstition, pedantry, increase of the primary symptom of conscientiousness); measures to do with fear of betrayal (collecting scraps of paper, seclusiveness), or to ensure numbing (dipsomania). Among these obsessional acts and obsessional impulses, phobias, since they circumscribe the patient's existence, play the greatest part.

[1896b, 393]
The fact that the obsessional ideas and everything derived from them meet with no belief is no doubt because at their first repression the defensive symptom of conscientiousness has been formed and that that symptom, too, acquires an obsessional force. The subject's certainty of having lived a moral life throughout the whole period of his successful defence makes it impossible for him to believe the self-reproach which his obsessional idea involves. Only transitarily, too, on the appearance of a new obsessional idea and occasionally in melancholic states of exhaustion of the ego, do the pathological symptoms of the return of the repressed compel belief. The 'obsessional' character of the psychical formations which I have described here has quite generally nothing to do with attaching belief to them. Nor is it to be confused with the factor which is described as the 'strength' or 'intensity' of an idea. Its essence is rather indissolubility by psychical activity that is capable of being conscious; and this attribute undergoes no change, whether the idea to which the obsession attaches is stronger or weaker, or less or more intensely 'illuminated', or 'cathcted with energy' and so on.

It only remains for me now to employ what has been learned from this case of paranoia for making a comparison between paranoia and obsessional neurosis. In each of them, repression has been shown to be the nucleus of the psychical mechanism, and in each what has been repressed is a sexual experience in childhood. In this case of paranoia, too, every obsession sprang from repression; the symptoms of paranoia allow of a classification similar to the one which has proved justified for obsessional neurosis. Part of the symptoms, once again, arise from primary defence - namely, all the delusional ideas which are characterized by distrust and suspicion and which are concerned with ideas of being persecuted by others. In obsessional neurosis the initial self-reproach has been repressed by the formation of the primary symptom of defence: self-distrust. With this, the self-reproach is acknowledged as justified; and, to weigh against this, the conscientiousness which the subject has acquired during his healthy interval now protects him from giving credence to the self-reproaches which return in the form of obsessional ideas. In paranoia, the self-reproach is repressed in a manner which may be described as projection. It is repressed by erecting the defensive symptom of distrust of other people. In this way the subject withdraws his acknowledgement of the self-reproach; and, as if to make up for this, he is deprived of a protection against the self-reproaches which return in his delusional ideas.
A deeper insight into the mechanism of obsessional neurosis is gained if we take into account the primary fact which lies at the bottom of it. This is always the repression of an instinctual impulse (a component of the sexual instinct) which was present in the subject's constitution and which was allowed to find expression for a while during his childhood but later succumbed to suppression. In the course of the repression of this instinct a special conscientiousness is created which is directed against the instinct's aims; but this psychical reaction-formation feels insecure and constantly threatened by the instinct which is lurking in the unconscious. The influence of the repressed instinct is felt as a temptation, and during the process of repression itself anxiety is generated, which gains control over the future in the form of expectant anxiety. The process of repression which leads to obsessional neurosis must be considered as one which is only partly successful and which increasingly threatens to fail. It may thus be compared to an unending conflict; fresh psychical efforts are continually required to counterbalance the forward pressure of the instinct. Thus the ceremonial and obsessive actions arise partly as a defence against the temptation and partly as a protection against the ill which is expected. Against the temptation the protective measures seem soon to become inadequate; then the prohibitions come into play, with the purpose of keeping at a distance situations that give rise to temptation. Prohibitions take the place of obsessive actions, it will be seen, just as a phobia is designed to avert a hysterical attack. Again, a ceremonial represents the sum of the conditions subject to which something that is not yet absolutely forbidden is permitted, just as the Church's marriage ceremony signifies for the believer a sanctioning of sexual enjoyment which would otherwise be sinful. A further characteristic of obsessional neurosis, as of all similar affections, is that its manifestations (its symptoms, including the obsessive actions) fulfil the condition of being a compromise between the warring forces of the mind. They thus always reproduce something of the pleasure which they are designed to prevent; they serve the repressed instinct no less than the agencies which are repressing it. As the illness progresses, indeed, actions which were originally mostly concerned with maintaining the defence come to approximate more and more to the proscribed actions through which the instinct was able to find expression in childhood.

[1907b, 1907]
For this reason it not uncommonly happens that obsessional neurotics, who are troubled with self-reproaches but have connected their affects with the wrong causes, will also tell the physician the true causes, without any suspicion that their self-reproaches have simply become detached from them. In relating such an incident they will sometimes add with astonishment or even with an air of pride: 'But I think nothing of that.' This happened in the first case of obsessional neurosis which gave me an insight many years ago into the nature of the malady. The patient, who was a government official, was troubled by innumerable scruples. He was the man whose compulsive act in connection with the branch in the park at Schönbrunn I have already described. I was struck by the fact that the florin notes with which he paid his consultation fees were invariably clean and smooth. (This was before we had a silver coinage in Austria.) I once remarked to him that one could always tell a government official by the brand-new florins that he drew from the State treasury, and he then informed me that his florins were by no means new, but that he had them ironed out at home. It was a matter of conscience with him, he explained, not to hand any one dirty paper florins; for they harboured all sorts of dangerous bacteria and might do some harm to the recipient. At that time I already had a vague suspicion of the connection between neuroses and sexual life, so on another occasion I ventured to ask the patient how he stood in regard to that matter. 'Oh, that's quite all right,' he answered airily, 'I'm not at all badly off in that respect. I play the part of a dear old uncle in a number of respectable families, and now and then I make use of my position to invite some young girl to go out with me for a day's excursion in the country. Then I arrange that we shall miss the train home and be obliged to spend the night out of town. I always engage two rooms - I do things most handsomely; but when the girl has gone to bed I go in to her and masturbate her with my fingers.' - 'But aren't you afraid of doing her some harm, fiddling about in her genitals with your dirty hand?' - At this he flared up: 'Harm? Why, what harm should it do her? It hasn't done a single one of them any harm yet, and they've all of them enjoyed it. Some of them are married now, and it hasn't done them any harm at all.' - He took my remonstrance in very bad part, and never appeared again. But I could only account for the contrast between his fastidiousness with the paper florins and his unscrupulousness in abusing the girls entrusted to him by supposing that the self-reproachful affect had become displaced. The aim of this displacement was obvious enough: if his self-reproaches had been allowed to remain where they belonged he would have had to abandon a form of sexual gratification to which he was probably impelled by some powerful infantile determinants. The displacement therefore ensured his deriving a considerable advantage from his illness.

[1909d, 2155]

In the first place, we have found that a feature in the character of obsessional neurotics is a scrupulous conscientiousness which is a symptom reacting against the temptation lurking in their unconscious. If their illness becomes more acute, they develop a sense of guilt of the most intense degree. In fact, one may venture to say that if we cannot trace the origin of the sense of guilt in obsessional neurotics, there can be no hope of our ever tracing it. This task can be directly achieved in the case of individual neurotic patients, and we may rely upon reaching a similar solution by inference in the case of primitive peoples.

[1912-1913, 2712]
Certainly this is a crazy illness. The most extravagant psychiatric imagination would not, I think, have succeeded in constructing anything like it; and if one did not see it before one every day one would never bring oneself to believe in it. Do not suppose, however, that you will help the patient in the least by calling on him to take a new line, to cease to occupy himself with such foolish thoughts and to do something sensible instead of his childish pranks. He would like to do so himself, for he is completely clear in his head, shares your opinion of his obsessional symptoms and even puts it forward to you spontaneously. Only he cannot help himself. What is carried into action in an obsessional neurosis is sustained by an energy to which we probably know nothing comparable in normal mental life. There is only one thing he can do: he can make displacements, and exchanges, he can replace one foolish idea by another somewhat milder, he can proceed from one precaution or prohibition to another, instead of one ceremonial he can perform another. He can displace the obsession but not remove it. The ability to displace any symptom into something far removed from its original conformation is a main characteristic of his illness. Moreover it is a striking fact that in his condition the contradictions (polarities) with which mental life is interlaced emerge especially sharply differentiated. Alongside of obsessions with a positive and negative content, doubt makes itself felt in the intellectual field and little by little it begins to gnaw even at what is usually most certain. The whole position ends up in an ever-increasing degree of indecision, loss of energy and restriction of freedom. At the same time, the obsessional neurotic starts off with a very energetic disposition, he is often extraordinarily self-willed and as a rule he has intellectual gifts above the average. He has usually reached a satisfactorily high level of ethical development; he exhibits over-conscientiousness, and is more than ordinarily correct in his behaviour. You can imagine that no small amount of work is needed before one can make one's way into this contradictory hotch-potch of character-traits and symptoms. And to begin with we aim at nothing whatever else than understanding a few of the symptoms and being able to interpret them.

[1916-1917, 3340]

In obsessional neurosis and paranoia the forms which the symptoms assume become very valuable to the ego because they obtain for it, not certain advantages, but a narcissistic satisfaction which it would otherwise be without. The systems which the obsessional neurotic constructs flatter his self-love by making him feel that he is better than other people because he is specially cleanly or specially conscientious. The delusional constructions of the paranoic offer to his acute perceptive and imaginative powers a field of activity which he could not easily find elsewhere.

[1926d, 4260]
An important element in the theory of repression is the view that repression is not an event that occurs once but that it requires a permanent expenditure. If this expenditure were to cease, the repressed impulse, which is being fed all the time from its sources, would on the next occasion flow along the channels from which it had been forced away, and the repression would either fail in its purpose or would have to be repeated an indefinite number of times. Thus it is because instincts are continuous in their nature that the ego has to make its defensive action secure by a permanent expenditure. This action undertaken to protect repression is observable in analytic treatment as resistance. Resistance presupposes the existence of what I have called anticathexis. An anticathexis of this kind is clearly seen in obsessional neurosis. It appears there in the form of an alteration of the ego, as a reaction-formation in the ego, and is effected by the reinforcement of the attitude which is the opposite of the instinctual trend that has to be repressed - as, for instance, in pity, conscientiousness and cleanliness. These reaction-formations of obsessional neurosis are essentially exaggerations of the normal traits of character which develop during the latency period. The presence of an anticathexis in hysteria is much more difficult to detect, though theoretically it is equally indispensable. In hysteria, too, a certain amount of alteration of the ego through reaction-formation is unmistakable and in some circumstances becomes so marked that it forces itself on our attention as the principal symptom. The conflict due to ambivalence, for instance, is resolved in hysteria by this means. The subject's hatred of a person whom he loves is kept down by an exaggerated amount of tenderness for him and apprehensiveness about him. But the difference between reaction-formations in obsessional neurosis and in hysteria is that in the latter they do not have the universality of a character-trait but are confined to particular relationships. A hysterical woman, for instance, may be specially affectionate with her own children whom at bottom she hates; but she will not on that account be more loving in general than other women or even more affectionate to other children. The reaction-formation of hysteria clings tenaciously to a particular object and never spreads over into a general disposition of the ego, whereas what is characteristic of obsessional neurosis is precisely a spreading-over of this kind - a loosening of relations to the object and a facilitation of displacement in the choice of object.

[1926d, 4310]
A train of thought such as this may be described as excessively intense, or better reinforced, or 'supervalent' ['überwertig'] in Wernicke's sense. It shows its pathological character in spite of its apparently reasonable content, by the single peculiarity that no amount of conscious and voluntary effort of thought on the patient's part is able to dissipate or remove it. A normal train of thought, however intense it may be, can eventually be disposed of. Dora felt quite rightly that her thoughts about her father required to be judged in a special way. 'I can think of nothing else', she complained again and again. 'I know my brother says we children have no right to criticize this behaviour of Father's. He declares that we ought not to trouble ourselves about it, and ought even to be glad, perhaps, that he has found a woman he can love, since Mother understands him so little. I can quite see that, and I should like to think the same as my brother, but I can't. I can't forgive him for it.'¹

Now what is one to do in the face of a supervalent thought like this, after one has heard what its conscious grounds are and listened to the ineffectual protests made against it? Reflection will suggest that this excessively intense train of thought must owe its reinforcement to the unconscious. It cannot be resolved by any effort of thought, either because it itself reaches with its root down into unconscious, repressed material, or because another unconscious thought lies concealed behind it. In the latter case, the concealed thought is usually the direct contrary of the supervalent one. Contrary thoughts are always closely connected with each other and are often paired off in such a way that the one thought is excessively intensely conscious while its counterpart is repressed and unconscious. This relation between the two thoughts is an effect of the process of repression. For repression is often achieved by means of an excessive reinforcement of the thought contrary to the one which is to be repressed. This process I call reactive reinforcement, and the thought which asserts itself with excessive intensity in consciousness and (in the same way as a prejudice) cannot be removed I call a reactive thought. The two thoughts then act towards each other much like the two needles of an astatic galvanometer. The reactive thought keeps the objectionable one under repression by means of a certain surplus of intensity; but for that reason it itself is 'damped' and proof against conscious efforts of thought. So that the way to deprive the excessively intense thought of its reinforcement is by bringing its repressed contrary into consciousness.

We must also be prepared to meet with instances in which the supervalence of a thought is due not to the presence of one only of these two causes but to a concurrence of both of them. Other complications, too, may arise, but they can easily be fitted into the general scheme.

Let us now apply our theory to the instance provided by Dora's case. We will begin with the first hypothesis, namely, that her preoccupation with her father's relations to Frau K, owed its obsessive character to the fact that its root was unknown to her and lay in the unconscious. It is not difficult to divine the nature of that root from her circumstances and her conduct. Her behaviour obviously went far beyond what would have been appropriate to filial concern. She felt and acted more like a jealous wife - in a way which would have been comprehensible in her mother. By her ultimatum to her father ('either her or me'), by the scenes she used to make, by the suicidal intentions she allowed to transpire, - by all this she was clearly putting herself in her mother's place. If we have rightly guessed the nature of the imaginary sexual situation which underlay her cough, in that phantasy she must have been putting herself in Frau K.'s place. She was therefore identifying herself both with the woman her father had once loved and with the woman he loved now. The inference is obvious that her affection for her father was a much stronger one than she knew or than she would have cared to admit: in fact, that she was in love with him.
For years on end she had given no expression to this passion for her father. On the contrary, she had for a long time been on the closest terms with the woman who had supplanted her with her father, and she had actually, as we know from her self-reproaches, facilitated this woman's relations with her father. Her own love for her father had therefore been recently revived; and, if so, the question arises to what end this had happened. Clearly as a reactive symptom, so as to suppress something else - something, that is, that still exercised power in the unconscious. Considering how things stood, I could not help supposing in the first instance that what was suppressed in this manner was her love of Herr K. I could not avoid the assumption that she was still in love with him, but that, for unknown reasons, since the scene by the lake her love had aroused in her violent feelings of opposition, and that the girl had brought forward and reinforced her old affection for her father in order to avoid and further necessity for paying conscious attention to the love which she had felt in the first years of her girlhood and which had now become distressing to her. In this way I gained an insight into a conflict which was well calculated to unhinge the girl's mind. On the one hand she was filled with regret at having rejected the man's proposal, and with longing for his company and all the little signs of his affection; while on the other hand these feelings of tenderness and longing were combated by powerful forces, amongst which her pride was one of the most obvious. Thus she had succeeded in persuading herself that she had done with Herr K. - that was the advantage she derived from this typical process of repression; and yet she was obliged to summon up her infantile affection for her father and to exaggerate it, in order to protect herself against the feelings of love which were constantly pressing forward into consciousness. The further fact that she was almost incessantly a prey to the most embittered jealousy seemed to admit of still another determination.¹

The dream does in fact contain infantile material, though it is impossible at a first glance to discover any connections between that material and Dora's intention of flying from Herr K.'s house and the temptation of his presence. Why should a recollection have emerged of her bed-wetting when she was a child and of the trouble her father used to take to teach the child clean habits? We may answer this by saying that it was only by the help of this train of thought that it was possible to suppress the other thoughts which were so intensely occupied with the temptation to yield or that it was possible to secure the dominance of the intention which had been formed of combating those other thoughts. The child decided to fly with her father; in reality she fled to her father because she was afraid of the man who was pursuing her; she summoned up an infantile affection for her father so that it might protect her against her present affection for a stranger. Her father was himself partly responsible for her present danger, for he had handed her over to this strange man in the interests of his own love-affair. And how much better it had been when that same father of hers had loved no one more than her, and had exerted all his strength to save her from the dangers that had then threatened her! The infantile, and now unconscious, wish to put her father in the strange man's place had the potency necessary for the formation of a dream. If there were a past situation similar to a present one, and differing from it only in being concerned with one instead of with the other of the two persons mentioned in the wish, that situation would become the main one in the dream. But there had been such a situation. Her father had once stood beside her bed, just as Herr K. had the day before, and had woken her up, with a kiss perhaps, as Herr K. may have meant to do. Thus her intention of flying from the house was not in itself capable of producing a dream; but it became so by being associated with another intention which was founded upon infantile wishes. The wish to replace Herr K. by her father provided the necessary motive power for the dream. Let me recall the interpretation I was led to adopt of Dora's reinforced train of thought about her father's relations with Frau K. My interpretation was that she had at that point summoned up an infantile affection for her father so as to be able to keep her repressed love for Herr K. in its state of repression. This same sudden revulsion in the patient's mental life was reflected in the dream.

¹[1905e, 1395]
²[1905e, 1422]
A patient, then, may be suffering from fluctuations in his moods which he cannot control, or from a sense of despondency by which his energy feels paralysed because he thinks he is incapable of doing anything properly, or from a nervous embarrassment among strangers. He may perceive, without understanding the reason for it, that he has difficulties in carrying out his professional work, or indeed any comparatively important decision or any undertaking. He may one day have suffered from a distressing attack - unknown in its origin - of feelings of anxiety, and since then have been unable, without a struggle, to walk along the street alone, or to travel by train; he may perhaps have had to give up both entirely. Or, a very remarkable thing, his thoughts may go their own way and refuse to be directed by his will. They pursue problems that are quite indifferent to him, but from which he cannot get free. Quite ludicrous tasks, too, are imposed on him, such as counting up the windows on the fronts of houses. And when he has performed simple actions such as posting a letter or turning off a gas-jet, he finds himself a moment later doubting whether he has really done so. This may be no more than an annoyance and a nuisance. But his state becomes intolerable if he suddenly finds he is unable to fend off the idea that he has pushed a child under the wheels of a car or has thrown a stranger off the bridge into the water, or if he has to ask himself whether he is not the murderer whom the police are looking for in connection with a crime that was discovered that day. It is obvious nonsense, as he himself knows; he has never done any harm to anyone; but if he were really the murderer who is being looked for, his feeling - his sense of guilt - could not be stronger.
[1926e, 4328]
Any activities whatever may become obsessive actions in the wider sense of the term if they are elaborated by small additions or given a rhythmic character by means of pauses and repetitions. We shall not expect to find a sharp distinction between 'ceremonials' and 'obsessive actions'. As a rule obsessive actions have grown out of ceremonials. Besides these two, prohibitions and hindrances (abulias) make up the content of the disorder; these, in fact, only continue the work of the obsessive actions, inasmuch as some things are completely forbidden to the patient and others only allowed subject to his following a prescribed ceremonial.

[1907b, 1902]

We must expressly insist that we have never reckoned Leonardo as a neurotic or a 'nerve case', as the awkward phrase goes. Anyone who protests at our so much as daring to examine him in the light of discoveries gained in the field of pathology is still clinging to prejudices which we have to-day rightly abandoned. We no longer think that health and illness, normal and neurotic people, are to be sharply distinguished from each other, and that neurotic traits must necessarily be taken as proofs of a general inferiority. To-day we know that neurotic symptoms are structures which are substitutes for certain achievements of repression that we have to carry out in the course of our development from a child to a civilized human being. We know too that we all produce such substitutive structures, and that it is only their number, intensity and distribution which justify us in using the practical concept of illness and in inferring the presence of constitutional inferiority. From the slight indications we have about Leonardo's personality we should be inclined to place him close to the type of neurotic that we describe as 'obsessional'; and we may compare his researches to the 'obsessive brooding' of neurotics, and his inhibitions to what are known as their 'abulias'.

[1910c, 2300]

The aim of our work has been to explain the inhibitions in Leonardo's sexual life and in his artistic activity. With this in view we may be allowed to summarize what we have been able to discover about the course of his psychical development.

[1910c, 2300]

This relation of an organ with a double claim on it - its relation to the conscious ego and to repressed sexuality - is to be seen even more clearly in motor organs than in the eye: as when, for instance, a hand which has tried to carry out an act of sexual aggression, and has become paralysed hysterically, is unable, after that act has been inhibited, to do anything else as though it were obstinately insisting on carrying out a repressed innervation; or as when the fingers of people who have given up masturbation refuse to learn the delicate movements required for playing the piano or the violin. As regards the eye, we are in the habit of translating the obscure psychical processes concerned in the repression of sexual scopophilia and in the development of the psychogenic disturbance of vision as though a punishing voice was speaking from within the subject, and saying: 'Because you sought to misuse your organ of sight for evil sensual pleasures, it is fitting that you should not see anything at all any more', and as though it was in this way approving the outcome of the process. The idea of talion punishment is involved in this, and in fact our explanation of psychogenic visual disturbance coincides with what is suggested by myths and legends. The beautiful legend of Lady Godiva tells how all the town's inhabitants hid behind their shuttered windows, so as to make easier the lady's task of riding naked through the streets in broad daylight, and how the only man who peeped through the shutters at her revealed loveliness was punished by going blind. Nor is this the only example which suggests that neurotic illness holds the hidden key to mythology as well.

[1910i, 2370]
In just the same way, an inhibition upon movement (an abasia or an agoraphobia) will gradually become more complete and more detailed, when once that system has succeeded in installing itself as a representative of an unconscious wish and of the defence against the wish. Whatever other unconscious phantasies and operative reminiscences may be present in the patient force their way to expression as symptoms along this same path, once it has been opened, and group themselves into an appropriate new arrangement within the framework of the inhibition upon movement. Thus it would be a vain and indeed a foolish task to attempt to understand the complexities and details of the symptoms of (for example) an agoraphobia on the basis of its underlying premises; for the whole consistency and strictness of the combination are merely apparent. Just as with the façades of dreams, if we look more attentively we find the most blatant inconsistency and arbitrariness in the structure of symptoms. The real reason for the details of a systematic phobia of this kind lies in concealed determinants, which need have nothing to do with an inhibition upon movement; and that, too, is why these phobias take such various and contradictory shapes in different people.

[1912-1913, 2738]

May not the same have been true of primitive men? We are justified in believing that, as one of the phenomena of their narcissistic organization, they overvalued their psychical acts to an extraordinary degree.² Accordingly the mere hostile impulse against the father, the mere existence of a wishful phantasy of killing and devouring him, would have been enough to produce the moral reaction that created totemism and taboo. In this way we should avoid the necessity for deriving the origin of our cultural legacy, of which we justly feel so proud, from a hideous crime, revolting to all our feelings. No damage would thus be done to the causal chain stretching from the beginning to the present day, for psychical reality would be strong enough to bear the weight of these consequences. To this it may be objected that an alteration in the form of society from a patriarchal horde to a fraternal clan did actually take place. This is a powerful argument, but not a conclusive one. The alteration might have been effected in a less violent fashion and none the less have been capable of determining the appearance of the moral reaction. So long as the pressure exercised by the primal father could be felt, the hostile feelings towards him were justified, and remorse on their account would have to await a later day. And if it is further argued that everything derived from the ambivalent relation to the father - taboo and the sacrificial ordinance - is characterized by the deepest seriousness and the most complete reality, this further objection carries just as little weight. For the ceremonials and inhibitions of obsessional neurotics show these same characteristics and are nevertheless derived only from psychical reality - from intentions and not from their execution. We must avoid transplanting a contempt for what is merely thought or wished from our commonplace world, with its wealth of material values, into the world of primitive men and neurotics, of which the wealth lies only within themselves.

[1912-1913, 2798]

Nor must we let ourselves be influenced too far in our judgement of primitive men by the analogy of neurotics. There are distinctions, too, which must be borne in mind. It is no doubt true that the sharp contrast that we make between thinking and doing is absent in both of them. But neurotics are above all inhibited in their actions: with them the thought is a complete substitute for the deed. Primitive men, on the other hand, are uninhibited: thought passes directly into action. With them it is rather the deed that is a substitute for the thought. And that is why, without laying claim to any finality of judgement, I think that in the case before us it may safely be assumed that 'in the beginning was the Deed'.
In inhibition in work - a thing which we so often have to deal with as an isolated symptom in our therapeutic work - the subject feels a decrease in his pleasure in it or becomes less able to do it well; or he has certain reactions to it, like fatigue, giddiness or sickness, if he is obliged to go on with it. If he is a hysteric he will have to give up his work owing to the appearance of organic and functional paralyses which make it impossible for him to carry it on. If he is an obsessional neurotic he will be perpetually being distracted from his work or losing time over it through the introduction of delays and repetitions.

The prohibition against thought issued by religion to assist in its self-preservation is also far from being free from danger either for the individual or for human society. Analytic experience has taught us that a prohibition like this, even if it is originally limited to a particular field, tends to widen out and thereafter to become the cause of severe inhibitions in the subject's conduct of life. This result may be observed, too, in the female sex, following from their being forbidden to have anything to do with their sexuality even in thought. Biography is able to point to the damage done by the religious inhibition of thought in the life stories of nearly all eminent individuals in the past. On the other hand intellect - or let us call it by the name that is familiar to us, reason - is among the powers which we may most expect to exercise a unifying influence on men - on men who are held together with such difficulty and whom it is therefore scarcely possible to rule. It may be imagined how impossible human society would be, merely if everyone had his own multiplication table and his own private units of length and weight. Our best hope for the future is that intellect - the scientific spirit, reason - may in process of time establish a dictatorship in the mental life of man. The nature of reason is a guarantee that afterwards it will not fail to give man's emotional impulses and what is determined by them the position they deserve. But the common compulsion exercised by such a dominance of reason will prove to be the strongest uniting bond among men and lead the way to further unions. Whatever, like religion's prohibition against thought, opposes such a development, is a danger for the future of mankind.

The negative reactions follow the opposite aim: that nothing of the forgotten traumas shall be remembered and nothing repeated. We can summarize them as 'defensive reactions'. Their principal expression are what are called 'avoidances', which may be intensified into 'inhibitions' and 'phobias'. These negative reactions too make the most powerful contributions to the stamping of character. Fundamentally they are just as much fixations to the trauma as their opposites, except that they are fixations with a contrary purpose. The symptoms of neurosis in the narrower sense are compromises in which both the trends proceeding from traumas come together, so that the share, now of one and now of the other tendency, finds preponderant expression in them. This opposition between the reactions sets up conflicts which in the ordinary course of events can reach no conclusion.
It is this same doubt that leads the patient to uncertainty about his protective measures, and to his continual repetition of them in order to banish that uncertainty; and it is this doubt, too, that eventually brings it about that the patient's protective acts themselves become as impossible to carry out as his original inhibited decision in connection with his love. At the beginning of my investigations I was led to assume another and more general origin for the uncertainty of obsessional neurotics and one which seemed to be nearer the normal. If, for instance, while I am writing a letter some one interrupts me with questions, I afterwards feel a quite justifiable uncertainty as to what I may not have written under the influence of the disturbance, and, to make sure, I am obliged to read the letter over after I have finished it. In the same way I might suppose that the uncertainty of obsessional neurotics, when they are praying, for instance, is due to unconscious phantasies constantly mingling with their prayers and disturbing them. This hypothesis is correct, but it may be easily reconciled with what I have just said. It is true that the patient's uncertainty whether he has carried through a protective measure is due to the disturbing effect of unconscious phantasies; but the content of these phantasies is precisely the contrary impulse - which it was the very aim of the prayer to ward off. This became clearly evident in our patient on one occasion, for the disturbing element did not remain unconscious but made its appearance openly. The words he wanted to use in his prayer were, *May God protect her*, but a hostile *not* suddenly darted out of his unconscious and inserted itself into the sentence; and he understood that this was an attempt at a curse (p. 2152). If the *not* had remained mute, he would have found himself in a state of uncertainty and would have kept on prolonging his prayers indefinitely. But since it became articulate he eventually gave up praying. Before doing so, however, he, like other obsessional patients, tried every kind of method for preventing the opposite feeling from insinuating itself. He shortened his prayers, for instance, or said them more rapidly. And similarly other patients will endeavour to *isolate* all such protective acts from other things. But none of these technical procedures are of any avail in the long run. If the impulse of love achieves any success by displacing itself on to some trivial act, the impulse of hostility will very soon follow it on to its new ground and once more proceed to undo all that it has done.

[1909d, 2189]
The two techniques I refer to are undoing what has been done and isolating. The first of these has a wide range of application and goes back very far. It is, as it were, negative magic, and endeavours, by means of motor symbolism, to 'blow away' not merely the consequences of some event (or experience or impression) but the event itself. I choose the term 'blow away' advisedly, so as to remind the reader of the part played by this technique not only in neuroses but in magical acts, popular customs and religious ceremonies as well. In obsessional neurosis the technique of undoing what has been done is first met with in the 'diphasic' symptoms, in which one action is cancelled out by a second, so that it is as though neither action had taken place, whereas, in reality, both have. This aim of undoing is the second underlying motive of obsessional ceremonials, the first being to take precautions in order to prevent the occurrence or recurrence of some particular event. The difference between the two is easily seen: the precautionary measures are rational, while trying to get rid of something by 'making it not to have happened' is irrational and in the nature of magic. It is of course to be suspected that the latter is the earlier motive of the two and proceeds from the animistic attitude towards the environment. This endeavour to undo shades off into normal behaviour in the case in which a person decides to regard an event as not having happened. But whereas he will take no direct steps against the event, and will simply pay no further attention to it or its consequences, the neurotic person will try to make the past itself non-existent. He will try to repress it by motor means. The same purpose may perhaps account for the obsession for repeating which is so frequently met with in this neurosis and the carrying out of which serves a number of contradictory intentions at once. When anything has not happened in the desired way it is undone by being repeated in a different way; and thereupon all the motives that exist for lingering over such repetitions come into play as well. As the neurosis proceeds, we often find that the endeavour to undo a traumatic experience is a motive of first-rate importance in the formation of symptoms. We thus unexpectedly discover a new, motor technique of defence, or (as we may say in this case with less inaccuracy) of repression.

[1926d, 4278]
The second of these techniques which we are setting out to describe for the first time, that of isolation, is peculiar to obsessional neurosis. It, too, takes place in the motor sphere. When something unpleasant has happened to the subject or when he himself has done something which has a significance for his neurosis, he interpolates an interval during which nothing further must happen - during which he must perceive nothing and do nothing. This behaviour, which seems strange at first sight, is soon seen to have a relation to repression. We know that in hysteria it is possible to cause a traumatic experience to be overtaken by amnesia. In obsessional neurosis this can often not be achieved: the experience is not forgotten, but, instead, it is deprived of its affect, and its associative connections are suppressed or interrupted so that it remains as though isolated and is not reproduced in the ordinary processes of thought. The effect of this isolation is the same as the effect of repression with amnesia. This technique, then, is reproduced in the isolations of obsessional neurosis; and it is at the same time given motor reinforcement for magical purposes. The elements that are held apart in this way are precisely those which belong together associatively. The motor isolation is meant to ensure an interruption of the connection in thought. The normal phenomenon of concentration provides a pretext for this kind of neurotic procedure: what seems to us important in the way of an impression or a piece of work must not be interfered with by the simultaneous claims of any other mental processes or activities. But even a normal person uses concentration to keep away not only what is irrelevant or unimportant, but, above all, what is unsuitable because it is contradictory. He is most disturbed by those elements which once belonged together but which have been torn apart in the course of his development - as, for instance, by manifestations of the ambivalence of his father-complex in his relation to God, or by impulses attached to his excretory organs in his emotions of love. Thus, in the normal course of things, the ego has a great deal of isolating work to do in its function of directing the current of thought. And, as we know, we are obliged, in carrying out our analytic technique, to train it to relinquish that function for the time being, eminently justified as it usually is.

[1926d, 4279]

We have all found by experience that it is especially difficult for an obsessional neurotic to carry out the fundamental rule of psycho-analysis. His ego is more watchful and makes sharper isolations, probably because of the high degree of tension due to conflict that exists between his super-ego and his id. While he is engaged in thinking, his ego has to keep off too much - the intrusion of unconscious phantasies and the manifestation of ambivalent trends. It must not relax, but is constantly prepared for a struggle. It fortifies this compulsion to concentrate and to isolate by the help of the magical acts of isolation which, in the form of symptoms, grow to be so noticeable and to have so much practical importance for the patient, but which are, of course, useless in themselves and are in the nature of ceremonials.

[1926d, 4280]
But in thus endeavouring to prevent associations and connections of thought, the ego is obeying one of the oldest and most fundamental commands of obsessional neurosis, the taboo on touching. If we ask ourselves why the avoidance of touching, contact or contagion should play such a large part in this neurosis and should become the subject-matter of complicated systems, the answer is that touching and physical contact are the immediate aim of the aggressive as well as the loving object-catheces. Eros desires contact because it strives to make the ego and the loved object one, to abolish all spatial barriers between them. But destructiveness, too, which (before the invention of long-range weapons) could only take effect at close quarters, must presuppose physical contact, a coming to grips. To 'touch' a woman has become a euphemism for using her as a sexual object. Not to 'touch' one's genitals is the phrase employed for forbidding auto-erotic satisfaction. Since obsessional neurosis begins by persecuting erotic touching and then, after regression has taken place, goes on to persecute touching in the guise of aggressiveness, it follows that nothing is so strongly proscribed in that illness as touching nor so well suited to become the central point of a system of prohibitions. But isolating is removing the possibility of contact; it is a method of withdrawing a thing from being touched in any way. And when a neurotic isolates an impression or an activity by interpolating an interval, he is letting it be understood symbolically that he will not allow his thoughts about that impression or activity to come into associative contact with other thoughts.

Even a purely terminological innovation ought to justify its adoption; it ought to reflect some new point of view or some extension of knowledge. The revival of the concept of defence and the restriction of that of repression takes into account a fact which has long since been known but which has received added importance owing to some new discoveries. Our first observations of repression and of the formation of symptoms were made in connection with hysteria. We found that the perceptual content of exciting experiences and the ideational content of pathogenic structures of thought were forgotten and debarred from being reproduced in memory, and we therefore concluded that the keeping away from consciousness was a main characteristic of hysterical repression. Later on, when we came to study the obsessional neuroses, we found that in that illness pathogenic occurrences are not forgotten. They remain conscious but they are 'isolated' in some way that we cannot as yet grasp, so that much the same result is obtained as in hysterical amnesia. Nevertheless the difference is great enough to justify the belief that the process by which instinctual demands are set aside in obsessional neurosis cannot be the same as in hysteria. Further investigations have shown that in obsessional neurosis a regression of the instinctual impulses to an earlier libidinal stage is brought about through the opposition of the ego, and that this regression, although it does not make repression unnecessary, clearly works in the same sense as repression. We have seen, too, that in obsessional neurosis anticathexis, which is also presumably present in hysteria, plays a specially large part in protecting the ego by effecting a reactive alteration in it. Our attention has, moreover, been drawn to a process of 'isolation' (whose technique cannot as yet be elucidated) which finds direct symptomatic manifestation, and to a procedure, that may be called magical, of 'undoing' what has been done - a procedure about whose defensive purpose there can be no doubt, but which has no longer any resemblance to the process of 'repression'. These observations provide good enough grounds for re-introducing the old concept of defence, which can cover all these processes that have the same purpose - namely, the protection of the ego against instinctual demands - and for subsuming repression under it as a special case. The importance of this nomenclature is heightened if we consider the possibility that further investigations may show that there is an intimate connection between special forms of defence and particular illnesses, as, for instance, between repression and hysteria. In addition we may look forward to the possible discovery of yet another important correlation. It may well be that before its sharp cleavage into an ego and an id, and before the formation of a super-ego, the mental apparatus makes use of different methods of defence from those which it employs after it has reached these stages of organization.

[1926d, 4280]

[1926d, 4316]
Secondary defence against the obsessional ideas may be effected by a forcible diversion on to other thoughts with a content as contrary as possible. This is why *obsessional brooding*, if it succeeds, regularly deals with abstract and *suprasensual* things; because the ideas that have been repressed are always concerned with *sensuality*. Or else the patient tries to make himself master of each of his obsessional ideas singly by logical work and by having recourse to his conscious memories. This leads to *obsessional thinking*, to a *compulsion to test things* and to *doubting mania*. The advantage which perception has over memory in such tests at first causes the patient, and later compels him, to collect and store up all the objects with which he has come into contact. Secondary defence against obsessional *affects* leads to a still wider set of protective measures which are capable of being transformed into obsessional acts. These may be grouped according to their purpose: *penitential* measures (burdensome ceremonials, the observation of numbers), *precautionary* measures (all sorts of phobias, superstition, pedantry, increase of the primary symptom of conscientiousness); measures to do with *fear of betrayal* (collecting scraps of paper, seclusiveness), or to ensure *numbing* (dipsomania). Among these obsessional acts and obsessional impulses, phobias, since they circumscribe the patient's existence, play the greatest part.

[1896b, 393]
Some other of the patient's obsessions, however, though they too were centred upon his lady, exhibited a different mechanism and owed their origin to a different instinct. Besides his slimming mania he produced a whole series of other obsessional activities at the period during which the lady was stopping at his summer resort; and, in part at least, these directly related to her. One day, when he was out with her in a boat and there was a stiff breeze blowing, he was obliged to make her put on his cap, because a command had been formulated in his mind that *nothing must happen to her.*¹ This was a kind of *obsession for protecting,* and it bore other fruit besides this. Another time, as they were sitting together during a thunderstorm, he was obsessed, he could not tell why, with the *necessity for counting* up to forty or fifty between each flash of lightning and its accompanying thunder-clap. On the day of her departure he knocked his foot against a stone lying in the road, and was *obliged* to put it out of the way by the side of the road, because the idea struck him that her carriage would be driving along the same road in a few hours' time and might come to grief against this stone. But a few minutes later it occurred to him that this was absurd, and he was *obliged* to go back and replace the stone in its original position in the middle of the road. After her departure he became a prey to an *obsession for understanding,* which made him a curse to all his companions. He forced himself to understand the precise meaning of every syllable that was addressed to him, as though he might otherwise be missing some priceless treasure. Accordingly he kept asking: 'What was it you said just then?' And after it had been repeated to him he could not help thinking it had sounded different the first time, so he remained dissatisfied.

[1909d, 2149]

The other compulsive commands that have been mentioned put us upon the track of this other element. His obsession for protecting can only have been a reaction - as an expression of remorse and penitence - to a contrary, that is a hostile, impulse which he must have felt towards his lady before they had their *éclaircissement.* His obsession for counting during the thunderstorm can be interpreted, with the help of some material which he produced, as having been a defensive measure against fears that some one was in danger of death. The analysis of the obsessions which we first considered has already warned us to regard our patient's hostile impulses as particularly violent and as being in the nature of senseless rage; and now we find that even after their reconciliation his rage against the lady continued to play a part in the formation of his obsessions. His doubting mania as to whether he had heard correctly was an expression of the doubt still lurking in his mind, whether he had really understood his lady correctly this time and whether he had been justified in taking her words as a proof of her affection for him. The doubt implied in his obsession for understanding was a doubt of her love. A battle between love and hate was raging in the lover's breast, and the object of both these feelings was one and the same person. The battle was represented in a plastic form by his compulsive and symbolic act of removing the stone from the road along which she was to drive, and then of undoing this deed of love by replacing the stone where it had lain, so that her carriage might come to grief against it and she herself be hurt. We shall not be forming a correct judgement of this second part of the compulsive act if we take it at its face value as having merely been a critical repudiation of a pathological action. The fact that it was accompanied by a sense of compulsion betrays it as having itself been a part of the pathological action, though a part which was determined by a motive contrary to that which produced the first part.

[1909d, 2150]
Some other of the patient's obsessions, however, though they too were centred upon his lady, exhibited a different mechanism and owed their origin to a different instinct. Besides his slimming mania he produced a whole series of other obsessional activities at the period during which the lady was stopping at his summer resort; and, in part at least, these directly related to her. One day, when he was out with her in a boat and there was a stiff breeze blowing, he was obliged to make her put on his cap, because a command had been formulated in his mind that nothing must happen to her.¹ This was a kind of obsession for protecting, and it bore other fruit besides this. Another time, as they were sitting together during a thunderstorm, he was obsessed, he could not tell why, with the necessity for counting up to forty or fifty between each flash of lightning and its accompanying thunder-clap. On the day of her departure he knocked his foot against a stone lying in the road, and was obliged to put it out of the way by the side of the road, because the idea struck him that her carriage would be driving along the same road in a few hours' time and might come to grief against this stone. But a few minutes later it occurred to him that this was absurd, and he was obliged to go back and replace the stone in its original position in the middle of the road. After her departure he became a prey to an obsession for understanding, which made him a curse to all his companions. He forced himself to understand the precise meaning of every syllable that was addressed to him, as though he might otherwise be missing some priceless treasure. Accordingly he kept asking: 'What was it you said just then?' And after it had been repeated to him he could not help thinking it had sounded different the first time, so he remained dissatisfied.

All of these products of his illness depended upon a certain circumstance which at that time dominated his relations to his lady. When he had been taking leave of her in Vienna before the summer holidays, she had said something which he had construed into a desire on her part to disown him before the rest of the company; and this had made him very unhappy. During her stay at the holiday resort there had been an opportunity for discussing the question, and the lady had been able to prove to him that these words of hers which he had misunderstood had on the contrary been intended to save him from looking ridiculous. This made him very happy again. The clearest allusion to this incident was contained in the obsession for understanding. It was constructed as though he were saying to himself: 'After such an experience you must never misunderstand any one again, if you want to spare yourself unnecessary distress.' This resolution was not merely a generalization from a single occasion, but it was also displaced - perhaps on account of the lady's absence - from a single highly valued individual on to all the remaining inferior ones. And the obsession cannot have arisen solely from his satisfaction at the explanation she had given him; it must have expressed something else besides, for it ended in an unsatisfying doubt as to whether what he had heard had been correctly repeated.
The other compulsive commands that have been mentioned put us upon the track of this other element. His obsession for protecting can only have been a reaction - as an expression of remorse and penitence - to a contrary, that is a hostile, impulse which he must have felt towards his lady before they had their éclaircissement. His obsession for counting during the thunderstorm can be interpreted, with the help of some material which he produced, as having been a defensive measure against fears that some one was in danger of death. The analysis of the obsessions which we first considered has already warned us to regard our patient's hostile impulses as particularly violent and as being in the nature of senseless rage; and now we find that even after their reconciliation his rage against the lady continued to play a part in the formation of his obsessions. His doubting mania as to whether he had heard correctly was an expression of the doubt still lurking in his mind, whether he had really understood his lady correctly this time and whether he had been justified in taking her words as a proof of her affection for him. The doubt implied in his obsession for understanding was a doubt of her love. A battle between love and hate was raging in the lover's breast, and the object of both these feelings was one and the same person. The battle was represented in a plastic form by his compulsive and symbolic act of removing the stone from the road along which she was to drive, and then of undoing this deed of love by replacing the stone where it had lain, so that her carriage might come to grief against it and she herself be hurt. We shall not be forming a correct judgement of this second part of the compulsive act if we take it at its face value as having merely been a critical repudiation of a pathological action. The fact that it was accompanied by a sense of compulsion betrays it as having itself been a part of the pathological action, though a part which was determined by a motive contrary to that which produced the first part.

[1909d, 2150]

If we wish to obtain a grasp of the psychical forces whose interplay built up this neurosis, we must turn back to what we have learnt from the patient on the subject of the precipitating causes of his falling ill as a grown-up man and as a child. He fell ill when he was in his twenties on being faced with a temptation to marry another woman instead of the one whom he had loved so long; and he avoided a decision of this conflict by postponing all the necessary preliminary actions. The means for doing this was given him by his neurosis. His hesitation between the lady he loved and the other girl can be reduced to a conflict between his father's influence and his love for his lady, or, in other words, to a conflicting choice between his father and his sexual object, such as had already subsisted (judging from his recollections and obsessional ideas) in his remote childhood. All through his life, moreover, he was unmistakably victim to a conflict between love and hatred, in regard both to his lady and to his father. His phantasies of revenge and such obsessional phenomena as his obsession for understanding and his exploit with the stone in the road bore witness to his divided feelings; and they were to a certain degree comprehensible and normal, for the lady by her original refusal and subsequently by her coolness had given him some excuse for hostility. But his relations with his father were dominated by a similar division of feeling, as we have seen from our translation of his obsessional thoughts; and his father, too, must have given him an excuse for hostility in his childhood, as indeed we have been able to establish almost beyond question. His attitude towards the lady - a compound of tenderness and hostility - came to a great extent within the scope of his conscious knowledge; at most he deceived himself over the degree and violence of his negative feelings. But his hostility towards his father, on the contrary, though he had once been acutely conscious of it, had long since vanished from his ken, and it was only in the teeth of the most violent resistance that it could be brought back into his consciousness. We may regard the repression of his infantile hatred of his father as the event which brought his whole subsequent career under the dominion of the neurosis.

[1909d, 2185]
The obsessive thought which has forced its way into consciousness with such excessive violence has next to be secured against the efforts made by conscious thought to resolve it. As we already know, this protection is afforded by the distortion which the obsessive thought has undergone before becoming conscious. But this is not the only means employed. In addition, each separate obsessional idea is almost invariably removed from the situation in which it originated and in which, in spite of its distortion, it would be most easily comprehensible. With this end in view, in the first place an interval of time is inserted between the pathogenic situation and the obsession that arises from it, so as to lead astray any conscious investigation of its causal connections, and in the second place the content of the obsession is taken out of its particular setting by being generalized. Our patient's 'obsession for understanding' is an example of this (p. 2150). But perhaps a better one is afforded by another patient. This was a woman who prohibited herself from wearing any sort of personal adornment, though the exciting cause of the prohibition related only to one particular piece of jewellery: she had envied her mother the possession of it and had had hopes that one day she would inherit it. Finally, if we care to distinguish verbal distortion from distortion of content, there is yet another means by which the obsession is protected against conscious attempts at solution. And that is the choice of an indefinite or ambiguous wording. After being misunderstood, the wording may find its way into the patient's 'deliria', and whatever further processes of development or substitution his obsession undergoes will then be based upon the misunderstanding and not upon the proper sense of the text. Observation will show, however, that the deliria constantly tend to form new connections with that part of the matter and wording of the obsession which is not present in consciousness.

[1909d, 2192]
The proof of infantile masturbation in other cases is established in a precisely similar way. The evidence for it is mostly of a similar nature: indications of the presence of leucorrhoea, bed-wetting, hand-ceremonials (obsessional washing), and such things. It is always possible to discover with certainty from the nature of the symptoms of the case whether the habit was discovered by the person in charge of the child or not, or whether this sexual activity was brought to an end by long efforts on the child's part to break itself of the habit, or by a sudden change. In Dora's case the masturbation had remained undiscovered, and had come to an end at a single blow (cf. her secret, her fear of doctors, and the replacement by dyspnoea). The patients, it is true, invariably dispute the conclusiveness of circumstantial evidence such as this, and they do so even when they have retained a conscious recollection of the catarrh or of their mother's warning (e.g. 'That makes people stupid; it's dangerous'). But some time later the memory, which has been so long repressed, of this piece of infantile sexual life emerges with certainty, and it does so in every instance. I am reminded of the case of a patient of mine suffering from obsessions, which were direct derivatives of infantile masturbation. Her peculiarities, such as self-prohibitions and self-punishments, the feeling that if she had done this she must not do that, the idea that she must not be interrupted, the introduction of pauses between one procedure (with her hands) and the next, her hand-washing, etc. - all of these turned out to be unaltered fragments of her nurse's efforts to break her of the habit. The only thing which had remained permanently in her memory were the words of warning: 'Ugh! That's dangerous!' Compare also in this connection my *Three Essays on the Theory of Sexuality*, 1905d.

Any activities whatever may become obsessive actions in the wider sense of the term if they are elaborated by small additions or given a rhythmic character by means of pauses and repetitions. We shall not expect to find a sharp distinction between 'ceremonials' and 'obsessive actions'. As a rule obsessive actions have grown out of ceremonials. Besides these two, prohibitions and hindrances (abulias) make up the content of the disorder; these, in fact, only continue the work of the obsessive actions, inasmuch as some things are completely forbidden to the patient and others only allowed subject to his following a prescribed ceremonial.

It is remarkable that both compulsions and prohibitions (having to do something and having *not* to do something) apply in the first instance only to the subject's solitary activities and for a long time leave his social behaviour unaffected. Sufferers from this illness are consequently able to treat their affliction as a private matter and keep it concealed for many years. And, indeed, many more people suffer from these forms of obsessional neurosis than doctors hear of. For many sufferers, too, concealment is made easier from the fact that they are quite well able to fulfil their social duties during a part of the day, once they have devoted a number of hours to their secret doings, hidden from view like Mélusine.

---

¹ The proof of infantile masturbation in other cases is established in a precisely similar way.
Analysis of obsessive actions has already given us some sort of an insight into their causes and into the chain of motives which bring them into effect. We may say that the sufferer from compulsions and prohibitions behaves as if he were dominated by a sense of guilt, of which, however, he knows nothing, so that we must call it an unconscious sense of guilt, in spite of the apparent contradiction in terms. This sense of guilt has its source in certain early mental events, but it is constantly being revived by renewed temptations which arise whenever there is a contemporary provocation. Moreover, it occasions a lurking sense of expectant anxiety, an expectation of misfortune, which is linked, through the idea of punishment, with the internal perception of the temptation. When the ceremonial is first being constructed, the patient is still conscious that he must do this or that lest some ill should befall, and as a rule the nature of the ill that is to be expected is still known to his consciousness. But what is already hidden from him is the connection - which is always demonstrable - between the occasion on which this expectant anxiety arises and the danger which it conjures up. Thus a ceremonial starts as an action for defence or insurance, a protective measure.

[1907b, 1906]

A deeper insight into the mechanism of obsessional neurosis is gained if we take into account the primary fact which lies at the bottom of it. This is always the repression of an instinctual impulse (a component of the sexual instinct) which was present in the subject's constitution and which was allowed to find expression for a while during his childhood but later succumbed to suppression. In the course of the repression of this instinct a special conscientiousness is created which is directed against the instinct's aims; but this psychical reaction-formation feels insecure and constantly threatened by the instinct which is lurking in the unconscious. The influence of the repressed instinct is felt as a temptation, and during the process of repression itself anxiety is generated, which gains control over the future in the form of expectant anxiety. The process of repression which leads to obsessional neurosis must be considered as one which is only partly successful and which increasingly threatens to fail. It may thus be compared to an unending conflict; fresh psychical efforts are continually required to counterbalance the forward pressure of the instinct. Thus the ceremonial and obsessive actions arise partly as a defence against the temptation and partly as a protection against the ill which is expected. Against the temptation the protective measures seem soon to become inadequate; then the prohibitions come into play, with the purpose of keeping at a distance situations that give rise to temptation. Prohibitions take the place of obsessive actions, it will be seen, just as a phobia is designed to avert a hysterical attack. Again, a ceremonial represents the sum of the conditions subject to which something that is not yet absolutely forbidden is permitted, just as the Church's marriage ceremony signifies for the believer a sanctioning of sexual enjoyment which would otherwise be sinful. A further characteristic of obsessional neurosis, as of all similar affections, is that its manifestations (its symptoms, including the obsessive actions) fulfil the condition of being a compromise between the warring forces of the mind. They thus always reproduce something of the pleasure which they are designed to prevent; they serve the repressed instinct no less than the agencies which are repressing it. As the illness progresses, indeed, actions which were originally mostly concerned with maintaining the defence come to approximate more and more to the proscribed actions through which the instinct was able to find expression in childhood.

[1907b, 1907]
A youngish man of university education introduced himself to me with the statement that he had suffered from obsessions ever since his childhood, but with particular intensity for the last four years. The chief features of his disorder were fears that something might happen to two people of whom he was very fond - his father and a lady whom he admired. Besides this he was aware of compulsive impulses - such as an impulse, for instance, to cut his throat with a razor; and further he produced prohibitions, sometimes in connection with quite unimportant things. He had wasted years, he told me, in fighting against these ideas of his, and in this way had lost much ground in the course of his life. He had tried various treatments, but none had been of any use to him except a course of hydrotherapy at a sanatorium near ----; and this, he thought, had probably only been because he had made an acquaintance there which had led to regular sexual intercourse. Here he had no opportunities of the sort, and he seldom had intercourse and only at irregular intervals. He felt disgust at prostitutes. Altogether, he said, his sexual life had been stunted; masturbation had played only a small part in it, in his sixteenth or seventeenth year. His potency was normal; he had first had intercourse at the age of twenty-six.

[1909d, 2129]

In the year 1896 I defined obsessional ideas as 'transformed self-reproaches which have re-emerged from repression and which always relate to some sexual act that was performed with pleasure in childhood'. This definition now seems to me to be open to criticism upon formal grounds, though its component elements are unobjectionable. It was aiming too much at unification, and took as its model the practice of obsessional neurotics themselves, when, with their characteristic liking for indeterminateness, they heap together under the name of 'obsessional ideas' the most heterogeneous psychical structures.² In point of fact, it would be more correct to speak of 'obsessive thinking', and to make it clear that obsessional structures can correspond to every sort of psychical act. They can be classed as wishes, temptations, impulses, reflections, doubts, commands, or prohibitions. Patients endeavour in general to tone down such distinctions and to regard what remains of these psychical acts after they have been deprived of their affective index simply as 'obsessional ideas'. Our present patient gave an example of this type of behaviour in one of his first sessions, when he attempted to reduce a wish to the level of a mere 'train of thought' (p. 2144).

[1909d, 2172]

Here is another instance in which a solution can be reached by filling out an ellipsis. It is once more in the nature of a warning or an ascetic prohibition. The patient had a charming little niece of whom he was very fond. One day this idea came into his head: 'If you indulge in intercourse, something will happen to Ella' (i.e. she will die). When the omissions have been made good, we have: 'Every time you copulate, even with a stranger, you will not be able to avoid the reflection that in your married life sexual intercourse can never bring you a child (on account of the lady's sterility). This will grieve you so much that you will become envious of your sister on account of little Ella, and you will grudge her the child. These envious impulses will inevitably lead to the child's death.'²

[1909d, 2176]
The compulsion on the other hand is an attempt at a compensation for the doubt and at a correction of the intolerable conditions of inhibition to which the doubt bears witness. If the patient, by the help of displacement, succeeds at last in bringing one of his inhibited intentions to a decision, then the intention must be carried out. It is true that this intention is not his original one, but the energy dammed up in the latter cannot let slip the opportunity of finding an outlet for its discharge in the substitutive act. Thus this energy makes itself felt now in commands and now in prohibitions, according as the affectionate impulse or the hostile one snatches control of the pathway leading to discharge. If it happens that a compulsive command cannot be obeyed, the tension becomes intolerable and is perceived by the patient in the form of extreme anxiety. (But the pathway leading to a substitutive act, even where the displacement has been on to something very small, is so hotly contested, that such an act can as a rule be carried out only in the shape of a protective measure intimately associated with the very impulse which it is designed to ward off.

[1909d, 2190]

The most obvious and striking point of agreement between the obsessional prohibitions of neurotics and taboos is that these prohibitions are equally lacking in motive and equally puzzling in their origin. Having made their appearance at some unspecified moment, they are forcibly maintained by an irresistible fear. No external threat of punishment is required, for there is an internal certainty, a moral conviction, that any violation will lead to intolerable disaster. The most that an obsessional patient can say on this point is that he has an undefined feeling that some particular person in his environment will be injured as result of the violation. Nothing is known of the nature of the injury; and indeed even this wretchedly small amount of information is more often obtained in connection with the expiatory and defensive actions which we shall have to discuss later than with the prohibitions themselves.

[1912-1913, 2674]

The purpose of some of the prohibitions is immediately obvious. Others, on the contrary, strike us as incomprehensible, senseless and silly, and prohibitions of this latter sort are described as 'ceremonial'. This distinction, too, is found in the observances of taboo.

[1912-1913, 2675]

Obsessional prohibitions involve just as extensive renunciations and restrictions in the lives of those who are subject to them as do taboo prohibitions; but some of them can be lifted if certain actions are performed. Thereafter, these actions must be performed: they become compulsive or obsessive acts, and there can be no doubt that they are in the nature of expiation, penance, defensive measures and purification. The commonest of these obsessive acts is washing in water ('washing mania'). Some taboo prohibitions can be replaced in just the same way; or rather their violation can be made good by a similar 'ceremonial'; and here again lustration with water is the preferred method.

[1912-1913, 2676]
In our clinical history of a case we have insisted that the imposition of the prohibition in very early childhood is the determining point; a similar importance attaches in the subsequent developments to the mechanism of repression at the same early age. As a result of the repression which has been enforced and which involves a loss of memory - an amnesia - the motives for the prohibition (which is conscious) remain unknown; and all attempts at disposing of it by intellectual processes must fail, since they cannot find any base of attack. The prohibition owes its strength and its obsessive character precisely to its unconscious opponent, the concealed and undiminished desire - that is to say, to an internal necessity inaccessible to conscious inspection. The ease with which the prohibition can be transferred and extended reflects a process which falls in with the unconscious desire and is greatly facilitated by the psychological conditions that prevail in the unconscious. The instinctual desire is constantly shifting in order to escape from the impasse and endeavours to find substitutes - substitute objects and substitute acts - in place of the prohibited ones. In consequence of this, the prohibition itself shifts about as well, and extends to any new aims which the forbidden impulse may adopt. Any fresh advance made by the repressed libido is answered by a fresh sharpening of the prohibition. The mutual inhibition of the two conflicting forces produces a need for discharge, for reducing the prevailing tension; and to this may be attributed the reason for the performance of obsessive acts. In the case of a neurosis these are clearly compromise actions: from one point of view they are evidences of remorse, efforts at expiation, and so on, while on the other hand they are at the same time substitutive acts to compensate the instinct for what has been prohibited. It is a law of neurotic illness that these obsessive acts fall more and more under the sway of the instinct and approach nearer and nearer to the activity which was originally prohibited.

Let us now make the experiment of treating taboo as though it were of the same nature as an obsessional prohibition in one of our patients. We must make it clear beforehand, however, that many of the taboo prohibitions that come under our notice are of a secondary, displaced and distorted kind, and that we shall have to be satisfied if we can throw only a little light on the most fundamental and significant taboos. Moreover, the differences between the situation of a savage and of a neurotic are no doubt of sufficient importance to make any exact agreement impossible and to prevent our carrying the comparison to the point of identity in every detail.

Suppose, on the other hand, that we were to take into account the finding arrived at by psycho-analysis from the dreams of normal people, to the effect that we ourselves are subject, more strongly and more often than we suspect, to a temptation to kill someone and that that temptation produces psychical effects even though it remains out of sight of our consciousness. Suppose, again, that we were to recognize the compulsive observances of certain neurotics as being guarantees against an intensified impulse to murder or as being self-punishments on account of it. In that case we should have to attach still greater importance to our thesis that where there is a prohibition there must be an underlying desire. We should have to suppose that the desire to murder is actually present in the unconscious and that neither taboos nor moral prohibitions are psychologically superfluous but that on the contrary they are explained and justified by the existence of an ambivalent attitude towards the impulse to murder.
Once again I will take a single fact as my starting-point. It is feared among primitive peoples that the violation of a taboo will be followed by a punishment, as a rule by some serious illness or by death. The punishment threatens to fall on whoever was responsible for violating the taboo. In obsessional neuroses the case is different. What the patient fears if he performs some forbidden action is that a punishment will fall not on himself but on someone else. This person's identity is as a rule left unstated, but can usually be shown without difficulty by analysis to be one of those closest and most dear to the patient. Here, then, the neurotic seems to be behaving altruistically and the primitive man egoistically. Only if the violation of a taboo is not automatically avenged upon the wrong-doer does a collective feeling arise among savages that they are all threatened by the outrage; and they thereupon hasten to carry out the omitted punishment themselves. There is no difficulty in explaining the mechanism of this solidarity. What is in question is fear of an infectious example, of the temptation to imitate - that is, of the contagious character of taboo. If one person succeeds in gratifying the repressed desire, the same desire is bound to be kindled in all the other members of the community. In order to keep the temptation down, the envied transgressor must be deprived of the fruit of his enterprise; and the punishment will not infrequently give those who carry it out an opportunity of committing the same outrage under colour of an act of expiation. This is indeed one of the foundations of the human penal system and it is based, no doubt correctly, on the assumption that the prohibited impulses are present alike in the criminal and in the avenging community. In this, psycho-analysis is no more than confirming the habitual pronouncement of the pious: we are all miserable sinners.

This may be illustrated by an example from a neurosis. In my essay on taboo I mentioned a woman patient of mine whose obsessional prohibitions showed the most perfect agreement with a Maori taboo (p. 2676). This woman's neurosis was aimed at her husband and culminated in her defence against an unconscious wish that he should die. Her manifest, systematic phobia, however, related to the mention of death in general, while her husband was entirely excluded from it and was never an object of her conscious solicitude. One day she heard her husband giving instructions that his razors, which had lost their edge, were to be taken to a particular shop to be re-set. Driven by a strange uneasiness, she herself set off for the shop. After reconnoitring the ground, she came back and insisted that her husband should get rid of the razors for good and all, since she had discovered that next door to the shop he had named there was an undertaker's establishment: owing to the plan he had made, she said, the razors had become inextricably involved with thoughts of death. This, then, was the systematic reason for her prohibition. We may be quite sure that, even without her discovery of the next-door shop, the patient would have come home with a prohibition against the razors. It would have been enough if she had met a hearse on her way to the shop, or someone dressed in mourning or carrying a funeral wreath. The net of possible determinants for the prohibition was spread wide enough to catch the quarry in any event; it merely depended on her decision whether to draw it together or not. It could be shown that on other occasions she would not put the determinants into operation, and she would explain this by saying it had been 'a better day'. The real cause of her prohibition upon the razors was, of course, as it was easy to discover, her repugnance to attaching any pleasurable feeling to the idea that her husband might cut his throat with the newly ground razors.
If we take instinctual repression as a measure of the level of civilization that has been reached, we shall have to admit that even under the animistic system advances and developments took place which are unjustly despised on account of their superstitious basis. When we are told that the warriors in a savage tribe practise the greatest continence and cleanliness when they go on the war-path, the explanation is put forward that their motive is ‘a fear lest the enemy should obtain the refuse of their persons, and thus be enabled to work their destruction by magic’ (Frazer, 1911b, 157); and an analogous superstitious reason could be suggested for their continence. None the less the fact remains that they have made an instinctual renunciation; and we can understand the position better if we suppose that the savage warrior submits to these restrictions as a counter-measure because he is on the point of yielding completely to the satisfaction of cruel and hostile impulses which are as a rule prohibited to him. The same is true of the numerous cases of sexual restrictions being imposed on anyone who is engaged on difficult or responsible work (ibid., 200 f.). Though the grounds alleged for these prohibitions may belong to a magical context, yet the fundamental idea of gaining greater strength by renouncing some instinctual satisfaction remains unmistakable; and the hygienic root of the prohibition which lies alongside its magical rationalization must not be overlooked. When the men of a savage tribe go out on an expedition to hunt, to fish, to fight or to gather precious plants, their wives left at home are subjected to many oppressive restrictions, to which the savages themselves ascribe a favourable influence, operating at a distance upon the success of the expedition. But it requires very little penetration to see that this factor which operates at a distance is nothing other than the absent men’s longing thoughts of home, and that behind these disguises lies a sound piece of psychological insight that the men will only do their best if they feel completely secure about the women whom they have left behind them unguarded. Sometimes they will even themselves declare, without alleging any magical reasons, that a wife’s infidelity in marriage will bring to nothing the efforts of an absent husband engaged on some responsible work. 

[1912-1913, 2739]

One further group of taboo observances, which have not hitherto been accounted for, deserve mention, since they admit of an explanation which is familiar to psycho-analysts. Among many savage peoples there is a prohibition against keeping sharp weapons or cutting instruments in a house. Frazer (1911b, 238) quotes a German superstition to the effect that a knife should not be left edge upwards, for fear that God and the angels might be injured on it. May we not recognize in this taboo a premonitory warning against possible ‘symptomatic acts’ in the execution of which a sharp weapon might be employed by unconscious evil impulses?

[1912-1913, 2740]
In another neurotic disorder, obsessional neurosis, the patients become the victims of distressing and apparently senseless ceremonials which take the form of the rhythmical repetition of the most trivial acts (such as washing or dressing) or of carrying out meaningless injunctions or of obeying mysterious prohibitions. It was nothing less than a triumph of psychoanalytic research when it succeeded in showing that all these obsessive acts, even the most insignificant and trivial of them, have a meaning, and that they are reflections, translated into indifferent terms, of conflicts in the patients' lives, of the struggle between temptations and moral restraints - reflections of the proscribed wish itself and of the punishment and atonement which that wish incurs. In another form of the same disorder the victim suffers from tormenting ideas (obsessions) which force themselves upon him and are accompanied by affects whose character and intensity are often only quite inadequately accounted for by the terms of the obsessive ideas themselves. Analytic investigation has shown in their case that the affects are entirely justified, since they correspond to self-reproaches which are based on something that is at least psychically real. But the ideas to which these affects are attached are not the original ones, but have found their way into their present position by a process of displacement - by being substituted for something that has been repressed. If these displacements can be reversed, the way is open to the discovery of the repressed ideas, and the relation between affect and idea is found to be perfectly appropriate.

[1913j, 2810]

Let us turn to the obsessional neuroses in the hope of learning more about the formation of symptoms. The symptoms belonging to this neurosis fall, in general, into two groups, each having an opposite trend. They are either prohibitions, precautions and expiations - that is, negative in character - or they are, on the contrary, substitutive satisfactions which often appear in symbolic disguise. The negative, defensive group of symptoms is the older of the two; but as illness is prolonged, the satisfactions, which scoff at all defensive measures, gain the upper hand. The symptom-formation scores a triumph if it succeeds in combining the prohibition with satisfaction so that what was originally a defensive command or prohibition acquires the significance of a satisfaction as well; and in order to achieve this end it will often make use of the most ingenious associative paths. Such an achievement demonstrates the tendency of the ego to synthesize, which we have already observed. In extreme cases the patient manages to make most of his symptoms acquire, in addition to their original meaning, a directly contrary one. This is a tribute to the power of ambivalence, which, for some unknown reason, plays such a large part in obsessional neuroses. In the crudest instance the symptom is diphasic: an action which carries out a certain injunction is immediately succeeded by another action which stops or undoes the first one even if it does not go quite so far as to carry out its opposite.

[1926d, 4271]
But in thus endeavouring to prevent associations and connections of thought, the ego is
obeying one of the oldest and most fundamental commands of obsessional neurosis, the taboo
on touching. If we ask ourselves why the avoidance of touching, contact or contagion should
play such a large part in this neurosis and should become the subject-matter of complicated
systems, the answer is that touching and physical contact are the immediate aim of the
aggressive as well as the loving object-cathexes. Eros desires contact because it strives to
make the ego and the loved object one, to abolish all spatial barriers between them. But
destructiveness, too, which (before the invention of long-range weapons) could only take effect
at close quarters, must presuppose physical contact, a coming to grips. To ‘touch’ a woman has
become a euphemism for using her as a sexual object. Not to ‘touch’ one’s genitals is the
phrase employed for forbidding auto-erotic satisfaction. Since obsessional neurosis begins by
persecuting erotic touching and then, after regression has taken place, goes on to persecute
touching in the guise of aggressiveness, it follows that nothing is so strongly proscribed in that
illness as touching nor so well suited to become the central point of a system of prohibitions. But
isolating is removing the possibility of contact; it is a method of withdrawing a thing from being
touched in any way. And when a neurotic isolates an impression or an activity by interpolating
an interval, he is letting it be understood symbolically that he will not allow his thoughts about
that impression or activity to come into associative contact with other thoughts.

There is another kind of anticathexis, however, which seems more suited to the peculiar
character of hysteria. A repressed instinctual impulse can be activated (newly cathexed) from
two directions: from within, through reinforcement from its internal sources of excitation, and
from without, through the perception of an object that it desires. The hysterical anticathexis is
mainly directed outwards, against dangerous perceptions. It takes the form of a special kind of
vigilance which, by means of restrictions of the ego, causes situations to be avoided that would
entail such perceptions, or, if they do occur, manages to withdraw the subject’s attention from
them. Some French analysts, in particular Laforgue, have recently given this action of hysteria
the special name of ‘scotomization’. This technique of anticathexis is still more noticeable in the
phobias, whose interest is concentrated on removing the subject ever further from the possibility
of the occurrence of the feared perception. The fact that anticathexis has an opposite direction
in hysteria and the phobias from what it has in obsessional neurosis - though the distinction is
not an absolute one - seems to be significant. It suggests that there is an intimate connection
between repression and external anticathexis on the one hand and between regression and
internal anticathexis (i.e. alteration in the ego through reaction-formation) on the other. The task
of defence against a dangerous perception is, incidentally, common to all neuroses. Various
commands and prohibitions in obsessional neurosis have the same end in view.

[1926d, 4280]

[1926d, 4311]
The prohibition against thought issued by religion to assist in its self-preservation is also far from being free from danger either for the individual or for human society. Analytic experience has taught us that a prohibition like this, even if it is originally limited to a particular field, tends to widen out and thereafter to become the cause of severe inhibitions in the subject's conduct of life. This result may be observed, too, in the female sex, following from their being forbidden to have anything to do with their sexuality even in thought. Biography is able to point to the damage done by the religious inhibition of thought in the life stories of nearly all eminent individuals in the past. On the other hand intellect - or let us call it by the name that is familiar to us, reason - is among the powers which we may most expect to exercise a unifying influence on men - on men who are held together with such difficulty and whom it is therefore scarcely possible to rule. It may be imagined how impossible human society would be, merely if everyone had his own multiplication table and his own private units of length and weight. Our best hope for the future is that intellect - the scientific spirit, reason - may in process of time establish a dictatorship in the mental life of man. The nature of reason is a guarantee that afterwards it will not fail to give man's emotional impulses and what is determined by them the position they deserve. But the common compulsion exercised by such a dominance of reason will prove to be the strongest uniting bond among men and lead the way to further unions. Whatever, like religion's prohibition against thought, opposes such a development, is a danger for the future of mankind.
[1933a, 4769]
Besides these compromise symptoms, which signify the return of the repressed and consequently a collapse of the defence that had been originally achieved, the obsessional neurosis constructs a set of further symptoms, whose origin is quite different. For the ego seeks to fend off the derivatives of the initially repressed memory, and in this defensive struggle it creates symptoms which might be classed together as ‘secondary defence’. These are all of them ‘protective measures’, which have already done good service in the fight against obsessional ideas and obsessional affects. If these aids in the defensive struggle genuinely succeed in once more repressing the symptoms of the return which have forced themselves on the ego, then the obsession is transferred to the protective measures themselves and creates a third form of ‘obsessional neurosis’ - *obsessional actions*. These actions are never primary; they never contain anything but a defence - never an aggression. A psychical analysis of them shows that, in spite of their peculiarity, they can always be fully explained by being traced back to the obsessional memories which they are fighting against.¹

People who carry out obsessive actions or ceremonials belong to the same class as those who suffer from obsessive thinking, obsessive ideas, obsessive impulses and the like. Taken together, these form a particular clinical entity, to which the name of ‘obsessional neurosis’ ['*Zwangsneurose*'] is customarily applied.¹ But one should not attempt to deduce the character of the illness from its name; for, strictly speaking, other kinds of morbid mental phenomena have an equal claim to possessing what are spoken of as ‘obsessional’ characteristics. In place of a definition we must for the time being be content with obtaining a detailed knowledge of these states, since we have not yet been able to arrive at a criterion of obsessional neuroses; it probably lies very deep, although we seem to sense its presence everywhere in the manifestations of the illness.

Any activities whatever may become obsessive actions in the wider sense of the term if they are elaborated by small additions or given a rhythmic character by means of pauses and repetitions. We shall not expect to find a sharp distinction between ‘ceremonials’ and ‘obsessive actions’. As a rule obsessive actions have grown out of ceremonials. Besides these two, prohibitions and hindrances (abulias) make up the content of the disorder; these, in fact, only continue the work of the obsessive actions, inasmuch as some things are completely forbidden to the patient and others only allowed subject to his following a prescribed ceremonial.

It is remarkable that both compulsions and prohibitions (having to do something and having *not* to do something) apply in the first instance only to the subject's solitary activities and for a long time leave his social behaviour unaffected. Sufferers from this illness are consequently able to treat their affliction as a private matter and keep it concealed for many years. And, indeed, many more people suffer from these forms of obsessional neurosis than doctors hear of. For many sufferers, too, concealment is made easier from the fact that they are quite well able to fulfil their social duties during a part of the day, once they have devoted a number of hours to their secret doings, hidden from view like Mélusine.

I must give a few examples to illustrate my point. Those who are familiar with the findings of psycho-analytic investigation into the psychoneuroses will not be surprised to learn that what is being represented in obsessive actions or in ceremonials is derived from the most intimate, and for the most part from the sexual, experiences of the patient.
These few examples, selected from the great number I have met with, are merely intended to illustrate my assertion that in obsessive actions everything has its meaning and can be interpreted. The same is true of ceremonials in the strict sense, only that the evidence for this would require a more circumstantial presentation. I am quite aware of how far our explanations of obsessive actions are apparently taking us from the sphere of religious thought.

[1907b, 1906]

It is one of the conditions of the illness that the person who is obeying a compulsion carries it out without understanding its meaning - or at any rate its chief meaning. It is only thanks to the efforts of psycho-analytic treatment that he becomes conscious of the meaning of his obsessive action and, with it, of the motives that are impelling him to it. We express this important fact by saying that the obsessive action serves to express unconscious motives and ideas. In this, we seem to find a further departure from religious practices; but we must remember that as a rule the ordinary pious individual, too, performs a ceremonial without concerning himself with its significance, although priests and scientific investigators may be familiar with the - mostly symbolic - meaning of the ritual. In all believers, however, the motives which impel them to religious practices are unknown to them or are represented in consciousness by others which are advanced in their place.

[1907b, 1906]

Analysis of obsessive actions has already given us some sort of an insight into their causes and into the chain of motives which bring them into effect. We may say that the sufferer from compulsions and prohibitions behaves as if he were dominated by a sense of guilt, of which, however, he knows nothing, so that we must call it an unconscious sense of guilt, in spite of the apparent contradiction in terms. This sense of guilt has its source in certain early mental events, but it is constantly being revived by renewed temptations which arise whenever there is a contemporary provocation. Moreover, it occasions a lurking sense of expectant anxiety, an expectation of misfortune, which is linked, through the idea of punishment, with the internal perception of the temptation. When the ceremonial is first being constructed, the patient is still conscious that he must do this or that lest some ill should befall, and as a rule the nature of the ill that is to be expected is still known to his consciousness. But what is already hidden from him is the connection - which is always demonstrable - between the occasion on which this expectant anxiety arises and the danger which it conjures up. Thus a ceremonial starts as an action for defence or insurance, a protective measure.

[1907b, 1906]
A deeper insight into the mechanism of obsessional neurosis is gained if we take into account the primary fact which lies at the bottom of it. This is always the repression of an instinctual impulse (a component of the sexual instinct) which was present in the subject's constitution and which was allowed to find expression for a while during his childhood but later succumbed to suppression. In the course of the repression of this instinct a special conscientiousness is created which is directed against the instinct's aims; but this psychical reaction-formation feels insecure and constantly threatened by the instinct which is lurking in the unconscious. The influence of the repressed instinct is felt as a temptation, and during the process of repression itself anxiety is generated, which gains control over the future in the form of expectant anxiety. The process of repression which leads to obsessional neurosis must be considered as one which is only partly successful and which increasingly threatens to fail. It may thus be compared to an unending conflict; fresh psychical efforts are continually required to counterbalance the forward pressure of the instinct. Thus the ceremonial and obsessive actions arise partly as a defence against the temptation and partly as a protection against the ill which is expected. Against the temptation the protective measures seem soon to become inadequate; then the prohibitions come into play, with the purpose of keeping at a distance situations that give rise to temptation. Prohibitions take the place of obsessive actions, it will be seen, just as a phobia is designed to avert a hysterical attack. Again, a ceremonial represents the sum of the conditions subject to which something that is not yet absolutely forbidden is permitted, just as the Church's marriage ceremony signifies for the believer a sanctioning of sexual enjoyment which would otherwise be sinful. A further characteristic of obsessional neurosis, as of all similar affections, is that its manifestations (its symptoms, including the obsessive actions) fulfil the condition of being a compromise between the warring forces of the mind. They thus always reproduce something of the pleasure which they are designed to prevent; they serve the repressed instinct no less than the agencies which are repressing it. As the illness progresses, indeed, actions which were originally mostly concerned with maintaining the defence come to approximate more and more to the proscribed actions through which the instinct was able to find expression in childhood.

We have noted as a curious and derogatory characteristic of obsessional neurosis that its ceremonials are concerned with the small actions of daily life and are expressed in foolish regulations and restrictions in connection with them. We cannot understand this remarkable feature of the clinical picture until we have realized that the mechanism of psychical displacement, which was first discovered by me in the construction of dreams, dominates the mental processes of obsessional neurosis. It is already clear from the few examples of obsessive actions given above that their symbolism and the detail of their execution are brought about by a displacement from the actual, important thing on to a small one which takes its place - for instance, from a husband on to a chair. It is this tendency to displacement which progressively changes the clinical picture and eventually succeeds in turning what is apparently the most trivial matter into something of the utmost importance and urgency. It cannot be denied that in the religious field as well there is a similar tendency to a displacement of psychical values, and in the same direction, so that the petty ceremonials of religious practice gradually become the essential thing and push aside the underlying thoughts. That is why religions are subject to reforms which work retroactively and aim at a re-establishment of the original balance of values.

The character of compromise which obsessive actions possess in their capacity as neurotic symptoms is the character least easily detected in corresponding religious observances. Yet here, too, one is reminded of this feature of neuroses when one remembers how commonly all the acts which religion forbids - the expressions of the instincts it has suppressed - are committed precisely in the name of, and ostensibly for the sake of, religion.
The other compulsive commands that have been mentioned put us upon the track of this other element. His obsession for protecting can only have been a reaction - as an expression of remorse and penitence - to a contrary, that is a hostile, impulse which he must have felt towards his lady before they had their **éclaircissement**. His obsession for counting during the thunderstorm can be interpreted, with the help of some material which he produced, as having been a defensive measure against fears that some one was in danger of death. The analysis of the obsessions which we first considered has already warned us to regard our patient's hostile impulses as particularly violent and as being in the nature of senseless rage; and now we find that even after their reconciliation his rage against the lady continued to play a part in the formation of his obsessions. His doubting mania as to whether he had heard correctly was an expression of the doubt still lurking in his mind, whether he had really understood his lady correctly this time and whether he had been justified in taking her words as a proof of her affection for him. The doubt implied in his obsession for understanding was a doubt of her love. A battle between love and hate was raging in the lover's breast, and the object of both these feelings was one and the same person. The battle was represented in a plastic form by his compulsive and symbolic act of removing the stone from the road along which she was to drive, and then of undoing this deed of love by replacing the stone where it had lain, so that her carriage might come to grief against it and she herself be hurt. We shall not be forming a correct judgement of this second part of the compulsive act if we take it at its face value as having merely been a critical repudiation of a pathological action. The fact that it was accompanied by a sense of compulsion betrays it as having itself been a part of the pathological action, though a part which was determined by a motive contrary to that which produced the first part.

Compulsive acts like this, in two successive stages, of which the second neutralizes the first, are a typical occurrence in obsessional neuroses. The patient's consciousness naturally misunderstands them and puts forward a set of secondary motives to account for them - rationalizes them, in short. (Cf. Jones, 1908.) But their true significance lies in their being a representation of a conflict between two opposing impulses of approximately equal strength: and hitherto I have invariably found that this opposition has been one between love and hate. Compulsive acts of this sort are theoretically of special interest, for they show us a new type of method of constructing symptoms. What regularly occurs in hysteria is that a compromise is arrived at which enables both the opposing tendencies to find expression simultaneously - which kills two birds with one stone;¹ whereas here each of the two opposing tendencies finds satisfaction singly, first one and then the other, though naturally an attempt is made to establish some sort of logical connection (often in defiance of all logic) between the antagonists.²

¹ Some patients carry the diversion of their attention to such lengths that they are totally unable to give the content of an obsessional idea or to describe an obsessional act though they have performed it over and over again.

² [1909d, 2174]
The technique of distortion by ellipsis seems to be typical of obsessional neuroses; I have come across it in the obsessional thoughts of other patients as well. One example, a particularly transparent one, is of especial interest on account of a certain structural similarity with the rat idea. It was a case of doubting, and occurred in a lady who suffers principally from obsessional acts. This lady was going for a walk with her husband in Nuremberg, and made him take her into a shop, where she purchased various objects for her child and amongst them a comb. Her husband, finding that the shopping was too long a business for his taste, said that he had noticed some coins in an antique shop on the way which he was anxious to secure, adding that after he had made his purchase he would come and fetch her in the shop in which they at present were. But he stayed away, as she thought, far too long. When he came back she accordingly asked him where he had been. 'Why,' he replied, 'at the antique shop I told you about.' At the same instant she was seized by a tormenting doubt whether she had not as a matter of fact always possessed the comb which she had just bought for her child. She was naturally quite unable to discover the simple mental link that was involved. There is nothing for it but to regard the doubt as having become displaced, and to reconstruct the complete chain of unconscious thoughts as follows: 'If it is true that you were only at the antique shop, if I am really to believe that, then I may just as well believe that this comb that I bought a moment ago has been in my possession for years.' Here, therefore, the lady was drawing a derisive and ironical parallel, just as when our patient thought: 'Oh yes, as sure as those two' (his father and the lady) 'will have children, I shall pay back the money to A.' In the lady's case the doubt was dependent upon her unconscious jealousy, which led her to suppose that her husband had spent the interval of his absence in paying a visit of gallantry.

The compulsion on the other hand is an attempt at a compensation for the doubt and at a correction of the intolerable conditions of inhibition to which the doubt bears witness. If the patient, by the help of displacement, succeeds at last in bringing one of his inhibited intentions to a decision, then the intention must be carried out. It is true that this intention is not his original one, but the energy dammed up in the latter cannot let slip the opportunity of finding an outlet for its discharge in the substitutive act. Thus this energy makes itself felt now in commands and now in prohibitions, according as the affectionate impulse or the hostile one snatches control of the pathway leading to discharge. If it happens that a compulsive command cannot be obeyed, the tension becomes intolerable and is perceived by the patient in the form of extreme anxiety. (But the pathway leading to a substitutive act, even where the displacement has been on to something very small, is so hotly contested, that such an act can as a rule be carried out only in the shape of a protective measure intimately associated with the very impulse which it is designed to ward off.

Furthermore, by a sort of regression, preparatory acts become substituted for the final decision, thinking replaces acting, and, instead of the substitutive act, some thought preliminary to it asserts itself with all the force of compulsion. According as this regression from acting to thinking is more or less marked, a case of obsessional neurosis will exhibit the characteristics of obsessive thinking (that is, of obsessional ideas) or of obsessive acting in the narrower sense of the word. True obsessional acts such as these, however, are only made possible because they constitute a kind of reconciliation, in the shape of a compromise, between the two antagonistic impulses. For obsessional acts tend to approximate more and more - and the longer the disorder lasts the more evident does this become - to infantile sexual acts of a masturbatory character. Thus in this form of the neurosis acts of love are carried out in spite of everything, but only by the aid of a new kind of regression; for such acts no longer relate to another person, the object of love and hatred, but are auto-erotic acts such as occur in infancy.
In bringing this paper to a close I may express a hope that, though my communication is incomplete in every sense, it may at least stimulate other workers to throw more light upon the obsessional neurosis by a deeper investigation of the subject. What is characteristic of this neurosis - what differentiates it from hysteria - is not, in my opinion, to be found in instinctual life but in the psychological field. I cannot take leave of my patient without putting on paper my impression that he had, as it were, disintegrated into three personalities: into one unconscious personality, that is to say, and into two preconscious ones between which his consciousness could oscillate. His unconscious comprised those of his impulses which had been suppressed at an early age and which might be described as passionate and evil impulses. In his normal state he was kind, cheerful, and sensible - an enlightened and superior kind of person - while in his third psychological organization he paid homage to superstition and asceticism. Thus he was able to have two different creeds and two different outlooks upon life. This second preconscious personality comprised chiefly the reaction-formations against his repressed wishes, and it was easy to foresee that it would have swallowed up the normal personality if the illness had lasted much longer. I have at present an opportunity of studying a lady suffering severely from obsessional acts. She has become similarly disintegrated into an easy-going and lively personality and into an exceedingly gloomy and ascetic one. She puts forward the first of them as her official ego, while in fact she is dominated by the second. Both of these psychical organizations have access to her consciousness, but behind her ascetic personality may be discerned the unconscious part of her being - quite unknown to her and composed of ancient and long-repressed wishful impulses.¹

¹[1909d, 2194]

In place of a single sick person let us put society - suffering as a whole from neuroses, though composed of sick and healthy members; and in place of individual acceptance in the one case let us put general recognition in the other. A little reflection will then show you that this substitution cannot in any way alter the outcome. The success which the treatment can have with the individual must occur equally with the community. Sick people will not be able to let their various neuroses become known - their anxious over-tenderness which is meant to conceal their hatred, their agoraphobia which tells of disappointed ambition, their obsessive actions which represent self-reproaches for evil intentions and precautions against them - if all their relatives and every stranger from whom they wish to conceal their mental processes know the general meaning of such symptoms, and if they themselves know that in the manifestations of their illness they are producing nothing that other people cannot instantly interpret. The effect, however, will not be limited to the concealment of the symptoms which, incidentally, it is often impossible to carry out; for this necessity for concealment destroys the use of being ill. Disclosure of the secret will have attacked, at its most sensitive point, the 'aetiological equation' from which neuroses arise - it will have made the gain from the illness illusory; and consequently the final outcome of the changed situation brought about by the physician's indiscretion can only be that the production of the illness will be brought to a stop.

[1910d, 2312]
There is also another path open to us. We can start an inquiry as to whether some of the hypotheses which we have carried over from neuroses to taboo or some of the results to which that procedure has led us may not be directly verifiable in the phenomena of taboo. But we must decide what we are to look for. Our assertion that taboo originated in a primaeval prohibition imposed at one time or other by some external authority is obviously incapable of demonstration. What we shall rather endeavour to confirm, therefore, are the psychological determinants of taboo, which we have learnt to know from obsessional neurosis. How did we arrive at our knowledge of these psychological factors in the case of the neurosis? Through the analytical study of its symptoms, and particularly of obsessional acts, defensive measures and obsessional commands. We found that they showed every sign of being derived from ambivalent impulses, either corresponding simultaneously to both a wish and a counter-wish or operating predominantly on behalf of one of the two opposing trends. If, now, we could succeed in demonstrating that ambivalence, that is, the dominance of opposing trends, is also to be found in the observances of taboo, or if we could point to some of them which, like obsessional acts, give simultaneous expression to both currents, we should have established the psychological agreement between taboo and obsessional neurosis in what is perhaps their most important feature.

The primary obsessive acts of these neurotics are of an entirely magical character. If they are not charms, they are at all events counter-charms, designed to ward off the expectations of disaster with which the neurosis usually starts. Whenever I have succeeded in penetrating the mystery, I have found that the expected disaster was death. Schopenhauer has said that the problem of death stands at the outset of every philosophy; and we have already seen that the origin of the belief in souls and in demons, which is the essence of animism, goes back to the impression which is made upon men by death. It is difficult to judge whether the obsessive or protective acts performed by obsessional neurotics follow the law of similarity (or, as the case may be, of contrast); for as a rule, owing to the prevailing conditions of the neurosis, they have been distorted by being displaced on to something very small, some action in itself of the greatest triviality.¹ The protective formulas of obsessional neuroses, too, have their counterpart in the formulas of magic. It is possible, however, to describe the course of development of obsessive acts: we can show how they begin by being as remote as possible from anything sexual - magical defences against evil wishes - and how they end by being substitutes for the forbidden sexual act and the closest possible imitations of it.

¹
In another neurotic disorder, obsessional neurosis, the patients become the victims of distressing and apparently senseless ceremonials which take the form of the rhythmical repetition of the most trivial acts (such as washing or dressing) or of carrying out meaningless injunctions or of obeying mysterious prohibitions. It was nothing less than a triumph of psychoanalytic research when it succeeded in showing that all these obsessive acts, even the most insignificant and trivial of them, have a meaning, and that they are reflections, translated into indifferent terms, of conflicts in the patients' lives, of the struggle between temptations and moral restraints - reflections of the proscribed wish itself and of the punishment and atonement which that wish incurs. In another form of the same disorder the victim suffers from tormenting ideas (obsessions) which force themselves upon him and are accompanied by affects whose character and intensity are often only quite inadequately accounted for by the terms of the obsessive ideas themselves. Analytic investigation has shown in their case that the affects are entirely justified, since they correspond to self-reproaches which are based on something that is at least psychically real. But the ideas to which these affects are attached are not the original ones, but have found their way into their present position by a process of displacement - by being substituted for something that has been repressed. If these displacements can be reversed, the way is open to the discovery of the repressed ideas, and the relation between affect and idea is found to be perfectly appropriate.

[1913], 2810

In enforcing regression, the ego scores its first success in its defensive struggle against the demands of the libido. (In this connection it is of advantage to distinguish the more general notion of 'defence' from 'repression'. Repression is only one of the mechanisms which defence makes use of.) It is perhaps in obsessional cases more than in normal or hysterical ones that we can most clearly recognize that the motive force of defence is the castration complex and that what is being fended off are the trends of the Oedipus complex. We are at present dealing with the beginning of the latency period, a period which is characterized by the dissolution of the Oedipus complex, the creation or consolidation of the super-ego and the erection of ethical and aesthetic barriers in the ego. In obsessional neuroses these processes are carried further than is normal. In addition to the destruction of the Oedipus complex a regressive degradation of the libido takes place, the super-ego becomes exceptionally severe and unkind, and the ego, in obedience to the super-ego, produces strong reaction-formations in the shape of conscientiousness, pity and cleanliness. Implacable, though not always on that account successful, severity is shown in condemning the temptation to continue early infantile masturbation, which now attaches itself to regressive (sadistic-anal) ideas but which nevertheless represents the unsubjugated part of the phallic organization. There is an inherent contradiction about this state of affairs, in which, precisely in the interests of masculinity (that is to say, from fear of castration), every activity belonging to masculinity is stopped. But here, too, obsessional neurosis is only overdoing the normal method of getting rid of the Oedipus complex. We once more find here an illustration of the truth that every exaggeration contains the seed of its own undoing. For, under the guise of obsessional acts, the masturbation that has been suppressed approaches ever more closely to satisfaction.

[1926d, 4273]
Case 7. Obsessional brooding and speculating. - A woman suffered from attacks of this obsession which ceased only when she was ill, and then gave place to hypochondriacal fears. The theme of her worry was always a part or function of her body; for example, respiration: 'Why must I breathe? Suppose I didn't want to breathe?' etc.

Both kinds of phobias (and also obsessions) often appear side by side; although the atypical phobias, which are based on obsessions, need not necessarily spring from the soil of anxiety neurosis. A very frequent and apparently complicated mechanism makes its appearance if, in what was originally a simple phobia belonging to an anxiety neurosis, the content of the phobia is replaced by another idea, so that the substitute is subsequent to the phobia. What are most often employed as substitutes are the 'protective measures' that were originally used to combat the phobia. Thus, for instance, 'brooding mania' arises from the subject's endeavours to disprove that he is mad, as his hypochondriacal phobia maintains; the hesitations and doubt, and still more the repetitions, of folie du doute arise from a justifiable doubt about the certainty of one's own train of thought, since one is conscious of its persistent disturbance by ideas of an obsessional sort, and so on. We can therefore assert that many syndromes, too, of obsessional neurosis, such as folie du doute and the like, are also to be reckoned, clinically if not conceptually, as belonging to anxiety neurosis.

Secondary defence against the obsessional ideas may be effected by a forcible diversion on to other thoughts with a content as contrary as possible. This is why obsessional brooding, if it succeeds, regularly deals with abstract and suprasensual things; because the ideas that have been repressed are always concerned with sensuality. Or else the patient tries to make himself master of each of his obsessional ideas singly by logical work and by having recourse to his conscious memories. This leads to obsessional thinking, to a compulsion to test things and to doubting mania. The advantage which perception has over memory in such tests at first causes the patient, and later compels him, to collect and store up all the objects with which he has come into contact. Secondary defence against obsessional affects leads to a still wider set of protective measures which are capable of being transformed into obsessional acts. These may be grouped according to their purpose: penitential measures (burdensome ceremonials, the observation of numbers), precautionary measures (all sorts of phobias, superstition, pedantry, increase of the primary symptom of conscientiousness); measures to do with fear of betrayal (collecting scraps of paper, seclusiveness), or to ensure numbing (dipsomania). Among these obsessional acts and obsessional impulses, phobias, since they circumscribe the patient's existence, play the greatest part.

I do not believe that this touching letter brought the two sisters the enlightenment they wanted. Later on the writer of it fell ill of the neurosis that arises from unanswered unconscious questions - of obsessional brooding.

¹ [1895c, 321]
² [1896b, 393]
If children could follow the hints given by the excitation of the penis they would get a little nearer to the solution of their problem. That the baby grows inside the mother's body is obviously not a sufficient explanation. How does it get inside? What starts its development? That the father has something to do with it seems likely; he says that the baby is his baby as well.¹ Again, the penis certainly has a share, too, in these mysterious happenings; the excitation in it which accompanies all these activities of the child's thoughts bears witness to this. Attached to this excitation are impulses which the child cannot account for - obscure urges to do something violent, to press in, to knock to pieces, to tear open a hole somewhere. But when the child thus seems to be well on the way to postulating the existence of the vagina and to concluding that an incursion of this kind by his father's penis into his mother is the act by means of which the baby is created in his mother's body - at this juncture his enquiry is broken off in helpless perplexity. For standing in its way is his theory that his mother possesses a penis just as a man does, and the existence of the cavity which receives the penis remains undiscovered by him. It is not hard to guess that the lack of success of his intellectual efforts makes it easier for him to reject and forget them. This brooding and doubting, however, becomes the prototype of all later intellectual work directed towards the solution of problems, and the first failure has a crippling effect on the child's whole future.

[1908c, 1972]

We have already mentioned the important part played by the sadistic instinctual components in the genesis of obsessional neuroses. Where the epistemophilic instinct is a preponderant feature in the constitution of an obsessional patient, brooding becomes the principal symptom of the neurosis. The thought-process itself becomes sexualized, for the sexual pleasure which is normally attached to the content of thought becomes shifted on to the act of thinking itself, and the satisfaction derived from reaching the conclusion of a line of thought is experienced as a sexual satisfaction. In the various forms of obsessional neurosis in which the epistemophilic instinct plays a part, its relation to thought-processes makes it particularly well adapted to attract the energy which is vainly endeavouring to make its way forward into action, and divert it into the sphere of thought, where there is a possibility of its obtaining pleasurable satisfaction of another sort. In this way, with the help of the epistemophilic instinct, the substitutive act may in its turn be replaced by preparatory acts of thought. But procrastination in action is soon replaced by lingering over thoughts, and eventually the whole process, together with all its peculiarities, is transferred into the new sphere, just as in America an entire house will sometimes be shifted from one site to another.

[1909d, 2191]
When the period of infantile sexual researches has been terminated by a wave of energetic sexual repression, the instinct for research has three distinct possible vicissitudes open to it owing to its early connection with sexual interests. In the first of these, research shares the fate of sexuality; thenceforward curiosity remains inhibited and the free activity of intelligence may be limited for the whole of the subject's lifetime, especially as shortly after this the powerful religious inhibition of thought is brought into play by education. This is the type characterized by neurotic inhibition. We know very well that the intellectual weakness which has been acquired in this way gives an effective impetus to the outbreak of a neurotic illness. In a second type the intellectual development is sufficiently strong to resist the sexual repression which has hold of it. Some time after the infantile sexual researches have come to an end, the intelligence, having grown stronger, recalls the old association and offers its help in evading sexual repression, and the suppressed sexual activities of research return from the unconscious in the form of compulsive brooding, naturally in a distorted and unfree form, but sufficiently powerful to sexualize thinking itself and to colour intellectual operations with the pleasure and anxiety that belong to sexual processes proper. Here investigation becomes a sexual activity, often the exclusive one, and the feeling that comes from settling things in one's mind and explaining them replaces sexual satisfaction; but the interminable character of the child's researches is also repeated in the fact that this brooding never ends and that the intellectual feeling, so much desired, of having found a solution recedes more and more into the distance.

In virtue of a special disposition, the third type, which is the rarest and most perfect, escapes both inhibition of thought and neurotic compulsive thinking. It is true that here too sexual repression comes about, but it does not succeed in relegating a component instinct of sexual desire to the unconscious. Instead, the libido evades the fate of repression by being sublimated from the very beginning into curiosity and by becoming attached to the powerful instinct for research as a reinforcement. Here, too, the research becomes to some extent compulsive and a substitute for sexual activity; but owing to the complete difference in the underlying psychical processes (sublimation instead of an irruption from the unconscious) the quality of neurosis is absent; there is no attachment to the original complexes of infantile sexual research, and the instinct can operate freely in the service of intellectual interest. Sexual repression, which has made the instinct so strong through the addition to it of sublimated libido, is still taken into account by the instinct, in that it avoids any concern with sexual themes.

We must expressly insist that we have never reckoned Leonardo as a neurotic or a 'nerve case', as the awkward phrase goes. Anyone who protests at our so much as daring to examine him in the light of discoveries gained in the field of pathology is still clinging to prejudices which we have to-day rightly abandoned. We no longer think that health and illness, normal and neurotic people, are to be sharply distinguished from each other, and that neurotic traits must necessarily be taken as proofs of a general inferiority. To-day we know that neurotic symptoms are structures which are substitutes for certain achievements of repression that we have to carry out in the course of our development from a child to a civilized human being. We know too that we all produce such substitutive structures, and that it is only their number, intensity and distribution which justify us in using the practical concept of illness and in inferring the presence of constitutional inferiority. From the slight indications we have about Leonardo's personality we should be inclined to place him close to the type of neurotic that we describe as 'obsessional'; and we may compare his researches to the 'obsessive brooding' of neurotics, and his inhibitions to what are known as their 'abulias'.

[1910c, 2256]

[1910c, 2257]

[1910c, 2300]
Obsessional neurosis is shown in the patient's being occupied with thoughts in which he is in fact not interested, in his being aware of impulses in himself which appear very strange to him and in his being led to actions the performance of which give him no enjoyment, but which it is quite impossible for him to omit. The thoughts (obsessions) may be senseless in themselves, or merely a matter of indifference to the subject; often they are completely silly, and invariably they are the starting-point of a strenuous mental activity, which exhausts the patient and to which he only surrenders himself most unwillingly. He is obliged against his will to brood and speculate as though it were a question of his most important vital problems. The impulses which the patient is aware of in himself may also make a childish and senseless impression; but as a rule they have a content of the most frightful kind, tempting him, for instance, to commit serious crimes, so that he not merely disavows them as alien to himself, but flies from them in horror and protects himself from carrying them out by prohibitions, renunciations and restrictions upon his freedom. At the same time, these impulse never - literally never - force their way through to performance; the outcome lies always in victory for the flight and the precautions. What the patient actually carries out - his so called obsessional actions - are very harmless and certainly trivial things, for the most part repetitions or ceremonial elaborations of the activities of ordinary life. But these necessary activities (such as going to bed, washing, dressing or going for a walk) become extremely tedious and almost insoluble tasks. In different forms and cases of obsessional neurosis the pathological ideas, impulses and actions are not combined in equal proportions; it is the rule, rather, that one or other of these factors dominates the picture and gives its name to the illness, but the common element in all these forms is sufficiently unmistakable.

[1916-1917, 3339]
Case 11. *Mysophobia*. - A woman kept washing her hands constantly and touched door-handles only with her elbow.

[1895c, 322]

The sympathies of the girl herself, who, as I have said, became my patient at the age of eighteen, had always been with the father's side of the family, and ever since she had fallen ill she had taken as her model the aunt who has just been mentioned. There could be no doubt, too, that it was from her father's family that she had derived not only her natural gifts and her intellectual precocity but also the predisposition to her illness. I never made her mother's acquaintance. From the accounts given me by the girl and her father I was led to imagine her as an uncultivated woman and above all as a foolish one, who had concentrated all her interests upon domestic affairs, especially since her husband's illness and the estrangement to which it led. She presented the picture, in fact, of what might be called the 'housewife's psychosis'. She had no understanding of her children's more active interests, and was occupied all day long in cleaning the house with its furniture and utensils and in keeping them clean - to such an extent as to make it almost impossible to use or enjoy them. This condition, traces of which are to be found often enough in normal housewives, inevitably reminds one of forms of obsessional washing and other kinds of obsessional cleanliness. But such women (and this applied to the patient's mother) are entirely without insight into their illness, so that one essential characteristic of an 'obsessional neurosis' is lacking. The relations between the girl and her mother had been unfriendly for years. The daughter looked down on her mother and used to criticize her mercilessly, and she had withdrawn completely from her influence.¹

[1905e, 1361]

¹ The proof of infantile masturbation in other cases is established in a precisely similar way. The evidence for it is mostly of a similar nature: indications of the presence of leucorrhoea, bed-wetting, hand-ceremonials (obsessional washing), and such things. It is always possible to discover with certainty from the nature of the symptoms of the case whether the habit was discovered by the person in charge of the child or not, or whether this sexual activity was brought to an end by long efforts on the child's part to break itself of the habit, or by a sudden change. In Dora's case the masturbation had remained undiscovered, and had come to an end at a single blow (cf. her secret, her fear of doctors, and the replacement by dyspnoea). The patients, it is true, invariably dispute the conclusiveness of circumstantial evidence such as this, and they do so even when they have retained a conscious recollection of the catarrh or of their mother's warning (e.g. 'That makes people stupid; it's dangerous'). But some time later the memory, which has been so long repressed, of this piece of infantile sexual life emerges with certainty, and it does so in every instance. I am reminded of the case of a patient of mine suffering from obsessions, which were direct derivatives of infantile masturbation. Her peculiarities, such as self-prohibitions and self-punishments, the feeling that if she had done this she must not do that, the idea that she must not be interrupted, the introduction of pauses between one procedure (with her hands) and the next, her hand-washing, etc, - all of these turned out to be unaltered fragments of her nurse's efforts to break her of the habit. The only thing which had remained permanently in her memory were the words of warning: 'Ugh! That's dangerous!' Compare also in this connection my *Three Essays on the Theory of Sexuality*, 1905d.

[1905e, 1416]

'Wet' and 'drops' at the same time opened the way to the other group of associations - the group relating to the disgusting catarrh, which in her later years had no doubt possessed the same mortifying significance for her as the bed-wetting had in her childhood. 'Wet' in this connection had the same meaning as 'dirtied'. Her genitals, which ought to have been kept clean, had been dirtied already by the catarrh - and this applied to her mother no less than to herself (p. 1412). She seemed to understand that her mother's mania for cleanliness was a reaction against this dirtying.

[1905e, 1426]
A recollection of this sort was furnished by the episode of the 'drops' - the jewellery ['Schmuck'] that Dora's mother wanted to have. In appearance the connection between this reminiscence and the two groups of thoughts relating to sexual wetness and to being dirtied was a purely external and superficial one, of a verbal character. For 'drops' was used ambiguously as a 'switch-word', while 'jewellery' ['Schmuck'] was taken as an equivalent to 'clean', and thus as a rather forced contrary of 'dirtied'.¹ But in reality the most substantial connections can be shown to have existed between the things denoted themselves. The recollection originated from the material connected with Dora's jealousy of her mother, which, though its roots were infantile, had persisted far beyond that period. By means of these two verbal bridges it was possible to transfer on to the single reminiscence of the 'jewel-drops' the whole of the significance attaching to the ideas of her parents' sexual intercourse, and of her mother's gonorrhoea and tormenting passion for cleanliness.

¹[1905e, 1426]

For this reason it not uncommonly happens that obsessional neurotics, who are troubled with self-reproaches but have connected their affects with the wrong causes, will also tell the physician the true causes, without any suspicion that their self-reproaches have simply become detached from them. In relating such an incident they will sometimes add with astonishment or even with an air of pride: 'But I think nothing of that.' This happened in the first case of obsessional neurosis which gave me an insight many years ago into the nature of the malady. The patient, who was a government official, was troubled by innumerable scruples. He was the man whose compulsive act in connection with the branch in the park at Schönbrunn I have already described. I was struck by the fact that the florin notes with which he paid his consultation fees were invariably clean and smooth. (This was before we had a silver coinage in Austria.) I once remarked to him that one could always tell a government official by the brand-new florins that he drew from the State treasury, and he then informed me that his florins were by no means new, but that he had them ironed out at home. It was a matter of conscience with him, he explained, not to hand any one dirty paper florins; for they harboured all sorts of dangerous bacteria and might do some harm to the recipient. At that time I already had a vague suspicion of the connection between neuroses and sexual life, so on another occasion I ventured to ask the patient how he stood in regard to that matter. 'Oh, that's quite all right,' he answered airily, 'I'm not at all badly off in that respect. I play the part of a dear old uncle in a number of respectable families, and now and then I make use of my position to invite some young girl to go out with me for a day's excursion in the country. Then I arrange that we shall miss the train home and be obliged to spend the night out of town. I always engage two rooms - I do things most handsomely; but when the girl has gone to bed I go in to her and masturbate her with my fingers.' - 'But aren't you afraid of doing her some harm, fiddling about in her genitals with your dirty hand?' - At this he flared up: 'Harm? Why, what harm should it do her? It hasn't done a single one of them any harm yet, and they've all of them enjoyed it. Some of them are married now, and it hasn't done them any harm at all.' - He took my remonstrance in very bad part, and never appeared again. But I could only account for the contrast between his fastidiousness with the paper florins and his unscrupulousness in abusing the girls entrusted to him by supposing that the self-reproachful affect had become displaced. The aim of this displacement was obvious enough: if his self-reproaches had been allowed to remain where they belonged he would have had to abandon a form of sexual gratification to which he was probably impelled by some powerful infantile determinants. The displacement therefore ensured his deriving a considerable advantage from his illness.

¹[1909d, 2155]
The content of her obsessional neurosis was a compulsion for scrupulous washing and cleanliness and extremely energetic protective measures against severe injuries which she thought other people had reason to fear from her - that is to say, reaction-formation against her own anal-erotic and sadistic impulses. Her sexual need was obliged to find expression in these shapes after her genital life had lost all its value owing to the impotence of the only man of whom there could be any question for her.

[1913i, 2626]

Obsessional prohibitions involve just as extensive renunciations and restrictions in the lives of those who are subject to them as do taboo prohibitions; but some of them can be lifted if certain actions are performed. Thereafter, these actions must be performed: they become compulsive or obsessive acts, and there can be no doubt that they are in the nature of expiation, penance, defensive measures and purification. The commonest of these obsessive acts is washing in water ('washing mania'). Some taboo prohibitions can be replaced in just the same way; or rather their violation can be made good by a similar 'ceremonial'; and here again lustration with water is the preferred method.

[1912-1913, 2676]

In another neurotic disorder, obsessional neurosis, the patients become the victims of distressing and apparently senseless ceremonials which take the form of the rhythmical repetition of the most trivial acts (such as washing or dressing) or of carrying out meaningless injunctions or of obeying mysterious prohibitions. It was nothing less than a triumph of psycho-analytic research when it succeeded in showing that all these obsessive acts, even the most insignificant and trivial of them, have a meaning, and that they are reflections, translated into indifferent terms, of conflicts in the patients' lives, of the struggle between temptations and moral restraints - reflections of the proscribed wish itself and of the punishment and atonement which that wish incurs. In another form of the same disorder the victim suffers from tormenting ideas (obsessions) which force themselves upon him and are accompanied by affects whose character and intensity are often only quite inadequately accounted for by the terms of the obsessive ideas themselves. Analytic investigation has shown in their case that the affects are entirely justified, since they correspond to self-reproaches which are based on something that is at least psychically real. But the ideas to which these affects are attached are not the original ones, but have found their way into their present position by a process of displacement - by being substituted for something that has been repressed. If these displacements can be reversed, the way is open to the discovery of the repressed ideas, and the relation between affect and idea is found to be perfectly appropriate.

[1913j, 2810]

The language of dreams may be looked upon as the method by which unconscious mental activity expresses itself. But the unconscious speaks more than one dialect. According to the differing psychological conditions governing and distinguishing the various forms of neurosis, we find regular modifications in the way in which unconscious mental impulses are expressed. While the gesture-language of hysteria agrees on the whole with the picture-language of dreams and visions, etc., the thought-language of obsessional neurosis and of the paraphrenias (dementia praecox and paranoia) exhibits special idiomatic peculiarities which, in a number of instances, we have been able to understand and interrelate. For instance, what a hysteric expresses by vomiting an obsessional will express by painstaking protective measures against infection, while a paraphrenic will be led to complaints or suspicions that he is being poisoned. These are all of them different representations of the patient's wish to become pregnant which have been repressed into the unconscious, or of his defensive reaction against that wish.

[1913j, 2814]
In obsessional neurosis and paranoia the forms which the symptoms assume become very valuable to the ego because they obtain for it, not certain advantages, but a narcissistic satisfaction which it would otherwise be without. The systems which the obsessional neurotic constructs flatter his self-love by making him feel that he is better than other people because he is specially cleanly or specially conscientious. The delusional constructions of the paranoic offer to his acute perceptive and imaginative powers a field of activity which he could not easily find elsewhere.

[1926d, 4260]

The chief task during the latency period seems to be the fending-off of the temptation to masturbate. This struggle produces a series of symptoms which appear in a typical fashion in the most different individuals and which in general have the character of a ceremonial. It is a great pity that no one has as yet collected them and systematically analysed them. Being the earliest products of the neurosis they should best be able to shed light on the mechanisms employed in its symptom-formation. They already exhibit the features which will emerge so disastrously if a serious illness follows. They tend to become attached to activities (which would later be carried out almost automatically) such as going to sleep, washing, dressing and walking about; and they tend also to repetition and waste of time. Why this should be so is at present not at all clear; but the sublimation of anal-erotic components plays an unmistakable part in it.

[1926d, 4275]

That this latter opinion is at least in part true is shown by some striking examples. If an agoraphobic patient who has been accompanied into the street is left alone there, he will produce an anxiety attack. Or if an obsessional neurotic is prevented from washing his hands after having touched something, he will become a prey to almost unbearable anxiety. It is plain, then, that the purpose and the result of the imposed condition of being accompanied in the street and the obsessional act of washing the hands were to obviate outbreaks of anxiety of this kind. In this sense every inhibition which the ego imposes on itself can be called a symptom.

[1926d, 4299]
An important element in the theory of repression is the view that repression is not an event that occurs once but that it requires a permanent expenditure. If this expenditure were to cease, the repressed impulse, which is being fed all the time from its sources, would on the next occasion flow along the channels from which it had been forced away, and the repression would either fail in its purpose or would have to be repeated an indefinite number of times. Thus it is because instincts are continuous in their nature that the ego has to make its defensive action secure by a permanent expenditure. This action undertaken to protect repression is observable in analytic treatment as resistance. Resistance presupposes the existence of what I have called anticathexis. An anticathexis of this kind is clearly seen in obsessional neurosis. It appears there in the form of an alteration of the ego, as a reaction-formation in the ego, and is effected by the reinforcement of the attitude which is the opposite of the instinctual trend that has to be repressed - as, for instance, in pity, conscientiousness and cleanliness. These reaction-formations of obsessional neurosis are essentially exaggerations of the normal traits of character which develop during the latency period. The presence of an anticathexis in hysteria is much more difficult to detect, though theoretically it is equally indispensable. In hysteria, too, a certain amount of alteration of the ego through reaction-formation is unmistakable and in some circumstances becomes so marked that it forces itself on our attention as the principal symptom. The conflict due to ambivalence, for instance, is resolved in hysteria by this means. The subject's hatred of a person whom he loves is kept down by an exaggerated amount of tenderness for him and apprehensiveness about him. But the difference between reaction-formations in obsessional neurosis and in hysteria is that in the latter they do not have the universality of a character-trait but are confined to particular relationships. A hysterical woman, for instance, may be specially affectionate with her own children whom at bottom she hates; but she will not on that account be more loving in general than other women or even more affectionate to other children. The reaction-formation of hysteria clings tenaciously to a particular object and never spreads over into a general disposition of the ego, whereas what is characteristic of obsessional neurosis is precisely a spreading-over of this kind - a loosening of relations to the object and a facilitation of displacement in the choice of object.

In the course of these investigations our attention was drawn to a highly significant relation between the generation of anxiety and the formation of symptoms - namely, that these two represent and replace each other. For instance, an agoraphobic patient may start his illness with an attack of anxiety in the street. This would be repeated every time he went into the street again. He will now develop the symptom of agoraphobia; this may also be described as an inhibition, a restriction of the ego's functioning, and by means of it he spares himself anxiety attacks. We can witness the converse of this if we interfere in the formation of symptoms, as is possible, for instance, with obsessions. If we prevent a patient from carrying out a washing ceremonial, he falls into a state of anxiety which he finds hard to tolerate and from which he had evidently been protected by his symptom. And it seems, indeed, that the generation of anxiety is the earlier and the formation of symptoms the later of the two, as though the symptoms are created in order to avoid the outbreak of the anxiety state. This is confirmed too by the fact that the first neuroses of childhood are phobias - states in which we see so clearly how an initial generation of anxiety is replaced by the later formation of a symptom; we get an impression that it is from these interrelations that we shall best obtain access to an understanding of neurotic anxiety. And at the same time we have also succeeded in answering the question of what it is that a person is afraid of in neurotic anxiety and so in establishing the connection between neurotic and realistic anxiety. What he is afraid of is evidently his own libido. The difference between this situation and that of realistic anxiety lies in two points: that the danger is an internal instead of an external one and that it is not consciously recognized.

[1926d, 4310] [1933a, 4690]
In the year 1896 I defined obsessional ideas as 'transformed self-reproaches which have re-emerged from repression and which always relate to some sexual act that was performed with pleasure in childhood'. This definition now seems to me to be open to criticism upon formal grounds, though its component elements are unobjectionable. It was aiming too much at unification, and took as its model the practice of obsessional neurotics themselves, when, with their characteristic liking for indeterminateness, they heap together under the name of 'obsessional ideas' the most heterogeneous psychical structures.² In point of fact, it would be more correct to speak of 'obsessive thinking', and to make it clear that obsessional structures can correspond to every sort of psychical act. They can be classed as wishes, temptations, impulses, reflections, doubts, commands, or prohibitions. Patients endeavour in general to tone down such distinctions and to regard what remains of these psychical acts after they have been deprived of their affective index simply as 'obsessional ideas'. Our present patient gave an example of this type of behaviour in one of his first sessions, when he attempted to reduce a wish to the level of a mere 'train of thought' (p. 2144).

There are, besides this, two special ways in which a more precise knowledge of obsessional structures can be gained. In the first place, experience shows that an obsessional command (or whatever it may be), which in waking life is known only in a truncated and distorted form, like a mutilated telegraph message, may have its actual text brought to light in a dream. Such texts appear in dreams in the shape of speeches, and are thus an exception to the rule that speeches in dreams are derived from speeches in real life.² Secondly, in the course of the analytic examination of a case history, one becomes convinced that if a number of obsessions succeed one another they are often - even though their wording is not identical - ultimately one and the same. The obsession may have been successfully shaken off on its first appearance, but it comes back a second time in a distorted form and without being recognized, and may then perhaps be able to hold its own in the defensive struggle more effectively, precisely because of its distortion. But the original form is the correct one, and often displays its meaning quite openly. When we have at great pains elucidated an unintelligible obsessional idea, it often happens that the patient informs us that just such a notion, wish, or temptation as the one we have constructed did in fact make its appearance on one occasion before the obsessional idea had arisen, but that it did not persist. It would unfortunately involve us in too lengthy a digression if we were to give instances of this from the history of our present patient.

The compulsion on the other hand is an attempt at a compensation for the doubt and at a correction of the intolerable conditions of inhibition to which the doubt bears witness. If the patient, by the help of displacement, succeeds at last in bringing one of his inhibited intentions to a decision, then the intention must be carried out. It is true that this intention is not his original one, but the energy dammed up in the latter cannot let slip the opportunity of finding an outlet for its discharge in the substitutive act. Thus this energy makes itself felt now in commands and now in prohibitions, according as the affectionate impulse or the hostile one snatches control of the pathway leading to discharge. If it happens that a compulsive command cannot be obeyed, the tension becomes intolerable and is perceived by the patient in the form of extreme anxiety. But the pathway leading to a substitutive act, even where the displacement has been on to something very small, is so hotly contested, that such an act can as a rule be carried out only in the shape of a protective measure intimately associated with the very impulse which it is designed to ward off.
There is also another path open to us. We can start an inquiry as to whether some of the hypotheses which we have carried over from neuroses to taboo or some of the results to which that procedure has led us may not be directly verifiable in the phenomena of taboo. But we must decide what we are to look for. Our assertion that taboo originated in a primaeval prohibition imposed at one time or other by some external authority is obviously incapable of demonstration. What we shall rather endeavour to confirm, therefore, are the psychological determinants of taboo, which we have learnt to know from obsessional neurosis. How did we arrive at our knowledge of these psychological factors in the case of the neurosis? Through the analytical study of its symptoms, and particularly of obsessional acts, defensive measures and obsessional commands. We found that they showed every sign of being derived from ambivalent impulses, either corresponding simultaneously to both a wish and a counter-wish or operating predominantly on behalf of one of the two opposing trends. If, now, we could succeed in demonstrating that ambivalence, that is, the dominance of opposing trends, is also to be found in the observances of taboo, or if we could point to some of them which, like obsessional acts, give simultaneous expression to both currents, we should have established the psychological agreement between taboo and obsessional neurosis in what is perhaps their most important feature.

[1912-1913, 2683]

In another neurotic disorder, obsessional neurosis, the patients become the victims of distressing and apparently senseless ceremonials which take the form of the rhythmical repetition of the most trivial acts (such as washing or dressing) or of carrying out meaningless injunctions or of obeying mysterious prohibitions. It was nothing less than a triumph of psycho-analytic research when it succeeded in showing that all these obsessive acts, even the most insignificant and trivial of them, have a meaning, and that they are reflections, translated into indifferent terms, of conflicts in the patients' lives, of the struggle between temptations and moral restraints - reflections of the proscribed wish itself and of the punishment and atonement which that wish incurs. In another form of the same disorder the victim suffers from tormenting ideas (obsessions) which force themselves upon him and are accompanied by affects whose character and intensity are often only quite inadequately accounted for by the terms of the obsessive ideas themselves. Analytic investigation has shown in their case that the affects are entirely justified, since they correspond to self-reproaches which are based on something that is at least psychically real. But the ideas to which these affects are attached are not the original ones, but have found their way into their present position by a process of displacement - by being substituted for something that has been repressed. If these displacements can be reversed, the way is open to the discovery of the repressed ideas, and the relation between affect and idea is found to be perfectly appropriate.

[1913j, 2810]
There is another kind of anticathexis, however, which seems more suited to the peculiar character of hysteria. A repressed instinctual impulse can be activated (newly cathected) from two directions: from within, through reinforcement from its internal sources of excitation, and from without, through the perception of an object that it desires. The hysterical anticathexis is mainly directed outwards, against dangerous perceptions. It takes the form of a special kind of vigilance which, by means of restrictions of the ego, causes situations to be avoided that would entail such perceptions, or, if they do occur, manages to withdraw the subject's attention from them. Some French analysts, in particular Laforgue, have recently given this action of hysteria the special name of 'scotomization'. This technique of anticathexis is still more noticeable in the phobias, whose interest is concentrated on removing the subject ever further from the possibility of the occurrence of the feared perception. The fact that anticathexis has an opposite direction in hysteria and the phobias from what it has in obsessional neurosis - though the distinction is not an absolute one - seems to be significant. It suggests that there is an intimate connection between repression and external anticathexis on the one hand and between regression and internal anticathexis (i.e. alteration in the ego through reaction-formation) on the other. The task of defence against a dangerous perception is, incidentally, common to all neuroses. Various commands and prohibitions in obsessional neurosis have the same end in view.

[1926d, 4311]
Some other of the patient's obsessions, however, though they too were centred upon his lady, exhibited a different mechanism and owed their origin to a different instinct. Besides his slimming mania he produced a whole series of other obsessional activities at the period during which the lady was stopping at his summer resort; and, in part at least, these directly related to her. One day, when he was out with her in a boat and there was a stiff breeze blowing, he was obliged to make her put on his cap, because a command had been formulated in his mind that nothing must happen to her.¹ This was a kind of obsession for protecting, and it bore other fruit besides this. Another time, as they were sitting together during a thunderstorm, he was obsessed, he could not tell why, with the necessity for counting up to forty or fifty between each flash of lightning and its accompanying thunder-clap. On the day of her departure he knocked his foot against a stone lying in the road, and was obliged to put it out of the way by the side of the road, because the idea struck him that her carriage would be driving along the same road in a few hours' time and might come to grief against this stone. But a few minutes later it occurred to him that this was absurd, and he was obliged to go back and replace the stone in its original position in the middle of the road. After her departure he became a prey to an obsession for understanding, which made him a curse to all his companions. He forced himself to understand the precise meaning of every syllable that was addressed to him, as though he might otherwise be missing some priceless treasure. Accordingly he kept asking: 'What was it you said just then?' And after it had been repeated to him he could not help thinking it had sounded different the first time, so he remained dissatisfied.

¹[1909d, 2149]

The other compulsive commands that have been mentioned put us upon the track of this other element. His obsession for protecting can only have been a reaction - as an expression of remorse and penitence - to a contrary, that is a hostile, impulse which he must have felt towards his lady before they had their éclaircissement. His obsession for counting during the thunderstorm can be interpreted, with the help of some material which he produced, as having been a defensive measure against fears that some one was in danger of death. The analysis of the obsessions which we first considered has already warned us to regard our patient's hostile impulses as particularly violent and as being in the nature of senseless rage; and now we find that even after their reconciliation his rage against the lady continued to play a part in the formation of his obsessions. His doubting mania as to whether he had heard correctly was an expression of the doubt still lurking in his mind, whether he had really understood his lady correctly this time and whether he had been justified in taking her words as a proof of her affection for him. The doubt implied in his obsession for understanding was a doubt of her love. A battle between love and hate was raging in the lover's breast, and the object of both these feelings was one and the same person. The battle was represented in a plastic form by his compulsive and symbolic act of removing the stone from the road along which she was to drive, and then of undoing this deed of love by replacing the stone where it had lain, so that her carriage might come to grief against it and she herself be hurt. We shall not be forming a correct judgement of this second part of the compulsive act if we take it at its face value as having merely been a critical repudiation of a pathological action. The fact that it was accompanied by a sense of compulsion betrays it as having itself been a part of the pathological action, though a part which was determined by a motive contrary to that which produced the first part.

[1909d, 2150]
A patient, then, may be suffering from fluctuations in his moods which he cannot control, or from a sense of despondency by which his energy feels paralysed because he thinks he is incapable of doing anything properly, or from a nervous embarrassment among strangers. He may perceive, without understanding the reason for it, that he has difficulties in carrying out his professional work, or indeed any comparatively important decision or any undertaking. He may one day have suffered from a distressing attack - unknown in its origin - of feelings of anxiety, and since then have been unable, without a struggle, to walk along the street alone, or to travel by train; he may perhaps have had to give up both entirely. Or, a very remarkable thing, his thoughts may go their own way and refuse to be directed by his will. They pursue problems that are quite indifferent to him, but from which he cannot get free. Quite ludicrous tasks, too, are imposed on him, such as counting up the windows on the fronts of houses. And when he has performed simple actions such as posting a letter or turning off a gas-jet, he finds himself a moment later doubting whether he has really done so. This may be no more than an annoyance and a nuisance. But his state becomes intolerable if he suddenly finds he is unable to fend off the idea that he has pushed a child under the wheels of a car or has thrown a stranger off the bridge into the water, or if he has to ask himself whether he is not the murderer whom the police are looking for in connection with a crime that was discovered that day. It is obvious nonsense, as he himself knows; he has never done any harm to anyone; but if he were really the murderer who is being looked for, his feeling - his sense of guilt - could not be stronger.

[1926e, 4328]
It must be confessed, moreover, that even the phenomenology of obsessional thinking has not yet had sufficient attention paid to it. During the secondary defensive struggle, which the patient carries on against the 'obsessional ideas' that have forced their way into his consciousness, psychical structures make their appearance which deserve to be given a special name. (Such, for example, were the sequences of thoughts that occupied our patient's mind on his journey back from the manoeuvres.) They are not purely reasonable considerations arising in opposition to the obsessional thoughts, but, as it were, hybrids between the two species of thinking; they accept certain of the premises of the obsession they are combating, and thus, while using the weapons of reason, are established upon a basis of pathological thought. I think such structures as these deserve to be given the name of 'deliria'. To make the distinction clear, I will give an instance, which should be inserted into its proper context in the patient's case history. I have already described the crazy conduct to which he gave way at one time when he was preparing for an examination - how, after working till far into the night, he used to go and open the front door to his father's ghost, and then look at his genitals in the looking-glass (p. 2160). He tried to bring himself to his senses by asking himself what his father would say to it all if he were really still alive. But the argument had no effect so long as it was put forward in this rational shape. The spectre was not laid until he had transformed the same idea into a 'delirious' threat to the effect that if he ever went through this nonsense again some evil would befall his father in the next world.

I hope the reader will restrain himself and not allow a surge of indignation to prevent his following psycho-analysis any further because it leads to an unpardonable aspersion on the memory of a great and pure man the very first time it is applied to his case. Such indignation, it is clear, will never be able to tell us the significance of Leonardo's childhood phantasy; at the same time Leonardo has acknowledged the phantasy in the most unambiguous fashion, and we cannot abandon our expectation - or, if it sounds better, our prejudice - that a phantasy of this kind must have some meaning, in the same way as any other psychical creation: a dream, a vision or a delirium. Let us rather therefore give a fair hearing for a while to the work of analysis, which indeed has not yet spoken its last word.

[1909d, 2173]

[1910c, 2262]
Case 8. Folie du doute. - Several cases showed the typical symptoms of this obsession but were explained very simply. These persons had suffered or were still suffering from various obsessions, and the knowledge that the obsessions had disturbed all their acts and had many times interrupted their train of thought provoked a legitimate doubt about the reliability of their memory. The confidence of each one of us is shaken, and we all of us have to re-read a letter or repeat a calculation if our attention has been distracted several times during the performance of the act. Doubt is a quite logical result when obsessions are present.

A further expression of anxious expectation is no doubt to be found in the inclination to moral anxiety, to scrupulousness and pedantry - an inclination which is so often present in people with more than the usual amount of moral sensitiveness and which likewise varies from the normal to an exaggerated form in doubting mania.

Both kinds of phobias (and also obsessions) often appear side by side; although the atypical phobias, which are based on obsessions, need not necessarily spring from the soil of anxiety neurosis. A very frequent and apparently complicated mechanism makes its appearance if, in what was originally a simple phobia belonging to an anxiety neurosis, the content of the phobia is replaced by another idea, so that the substitute is subsequent to the phobia. What are most often employed as substitutes are the 'protective measures' that were originally used to combat the phobia. Thus, for instance, 'brooding mania' arises from the subject's endeavours to disprove that he is mad, as his hypochondriacal phobia maintains; the hesitations and doubt, and still more the repetitions, of folie du doute arise from a justifiable doubt about the certainty of one's own train of thought, since one is conscious of its persistent disturbance by ideas of an obsessional sort, and so on. We can therefore assert that many syndromes, too, of obsessional neurosis, such as folie du doute and the like, are also to be reckoned, clinically if not conceptually, as belonging to anxiety neurosis.²

Secondary defence against the obsessional ideas may be effected by a forcible diversion on to other thoughts with a content as contrary as possible. This is why obsessional brooding, if it succeeds, regularly deals with abstract and suprasensual things; because the ideas that have been repressed are always concerned with sensuality. Or else the patient tries to make himself master of each of his obsessional ideas singly by logical work and by having recourse to his conscious memories. This leads to obsessional thinking, to a compulsion to test things and to doubting mania. The advantage which perception has over memory in such tests at first causes the patient, and later compels him, to collect and store up all the objects with which he has come into contact. Secondary defence against obsessional affects leads to a still wider set of protective measures which are capable of being transformed into obsessional acts. These may be grouped according to their purpose: penitential measures (burdensome ceremonials, the observation of numbers), precautionary measures (all sorts of phobias, superstition, pedantry, increase of the primary symptom of conscientiousness); measures to do with fear of betrayal (collecting scraps of paper, seclusiveness), or to ensure numbing (dipsomania). Among these obsessional acts and obsessional impulses, phobias, since they circumscribe the patient's existence, play the greatest part.
There are cases in which one can observe how the obsession is transferred from the idea or from the affect on to the protective measure; others in which the obsession oscillates periodically between the symptom of the return of the repressed and the symptom of the secondary defence; and yet other cases in which no obsessional idea is constructed at all, but, instead, the repressed memory is at once represented by what is apparently a primary measure of defence. Here we reach at one bound the stage which elsewhere only completes the course run by the obsessional neurosis after the defensive struggle has taken place. Severe cases of this disorder end in the ceremonial actions becoming fixated, or in a general state of doubting mania, or in a life of eccentricity conditioned by phobias.

Previous writers have had less justification in devoting so much space to the doubt with which our judgement receives accounts of dreams. For this doubt has no intellectual warrant. There is in general no guarantee of the correctness of our memory; and yet we yield to the compulsion to attach belief to its data far more often than is objectively justified. Doubt whether a dream or certain of its details have been correctly reported is once more a derivative of the dream-censorship, of resistance to the penetration of the dream-thoughts into consciousness. This resistance has not been exhausted even by the displacements and substitutions it has brought about; it persists in the form of doubt attaching to the material which has been allowed through. We are especially inclined to misunderstand this doubt since it is careful never to attack the more intense elements of a dream but only the weak and indistinct ones. As we already know, however, a complete reversal of all psychical values takes place between the dream-thoughts and the dream. Distortion is only made possible by a withdrawal of psychical value; it habitually expresses itself by that means and is occasionally content to require nothing more. If, then, an indistinct element of a dream's content is in addition attacked by doubt, we have a sure indication that we are dealing with a comparatively direct derivative of one of the proscribed dream-thoughts. The state of things is what it was after some sweeping revolution in one of the republics of antiquity or the Renaissance. The noble and powerful families which had previously dominated the scene were sent into exile and all the high offices were filled by newcomers. Only the most impoverished and powerless members of the vanquished families, or their remote dependants, were allowed to remain in the city; and even so they did not enjoy full civic rights and were viewed with distrust. The distrust in this analogy corresponds to the doubt in the case we are considering. That is why in analysing a dream I insist that the whole scale of estimates of certainty shall be abandoned and that the faintest possibility that something of this or that sort may have occurred in the dream shall be treated as complete certainty. In tracing any element of a dream it will be found that unless this attitude is firmly adopted the analysis will come to a standstill. If any doubt is thrown upon the value of the element in question, the psychical result in the patient is that none of the involuntary ideas underlying that element comes into his head. This result is not a self-evident one. It would not make nonsense if someone were to say: 'I don't know for certain whether such and such a thing came into the dream, but here is what occurs to me in connection with it.' But in fact no one ever does say this; and it is precisely the fact that doubt produces this interrupting effect upon an analysis that reveals it as a derivative and tool of psychical resistance. Psycho-analysis is justly suspicious. One of its rules is that whatever interrupts the progress of analytic work is a resistance.
If children could follow the hints given by the excitation of the penis they would get a little nearer to the solution of their problem. That the baby grows inside the mother's body is obviously not a sufficient explanation. How does it get inside? What starts its development? That the father has something to do with it seems likely; he says that the baby is his baby as well.¹ Again, the penis certainly has a share; too, in these mysterious happenings; the excitation in it which accompanies all these activities of the child's thoughts bears witness to this. Attached to this excitation are impulsions which the child cannot account for - obscure urges to do something violent, to press in, to knock to pieces, to tear open a hole somewhere. But when the child thus seems to be well on the way to postulating the existence of the vagina and to concluding that an incursion of this kind by his father's penis into his mother is the act by means of which the baby is created in his mother's body - at this juncture his enquiry is broken off in helpless perplexity. For standing in its way is his theory that his mother possesses a penis just as a man does, and the existence of the cavity which receives the penis remains undiscovered by him. It is not hard to guess that the lack of success of his intellectual efforts makes it easier for him to reject and forget them. This brooding and doubting, however, becomes the prototype of all later intellectual work directed towards the solution of problems, and the first failure has a crippling effect on the child's whole future.

[1908c, 1972]

All of these products of his illness depended upon a certain circumstance which at that time dominated his relations to his lady. When he had been taking leave of her in Vienna before the summer holidays, she had said something which he had construed into a desire on her part to disown him before the rest of the company; and this had made him very unhappy. During her stay at the holiday resort there had been an opportunity for discussing the question, and the lady had been able to prove to him that these words of hers which he had misunderstood had on the contrary been intended to save him from looking ridiculous. This made him very happy again. The clearest allusion to this incident was contained in the obsession for understanding. It was constructed as though he were saying to himself: 'After such an experience you must never misunderstand any one again, if you want to spare yourself unnecessary distress.' This resolution was not merely a generalization from a single occasion, but it was also displaced - perhaps on account of the lady's absence - from a single highly valued individual on to all the remaining inferior ones. And the obsession cannot have arisen solely from his satisfaction at the explanation she had given him; it must have expressed something else besides, for it ended in an unsatisfying doubt as to whether what he had heard had been correctly repeated.

[1909d, 2150]
The other compulsive commands that have been mentioned put us upon the track of this other element. His obsession for protecting can only have been a reaction - as an expression of remorse and penitence - to a contrary, that is a hostile, impulse which he must have felt towards his lady before they had their éclaircissement. His obsession for counting during the thunderstorm can be interpreted, with the help of some material which he produced, as having been a defensive measure against fears that some one was in danger of death. The analysis of the obsessions which we first considered has already warned us to regard our patient's hostile impulses as particularly violent and as being in the nature of senseless rage; and now we find that even after their reconciliation his rage against the lady continued to play a part in the formation of his obsessions. His doubting mania as to whether he had heard correctly was an expression of the doubt still lurking in his mind, whether he had really understood his lady correctly this time and whether he had been justified in taking her words as a proof of her affection for him. The doubt implied in his obsession for understanding was a doubt of her love. A battle between love and hate was raging in the lover's breast, and the object of both these feelings was one and the same person. The battle was represented in a plastic form by his compulsive and symbolic act of removing the stone from the road along which she was to drive, and then of undoing this deed of love by replacing the stone where it had lain, so that her carriage might come to grief against it and she herself be hurt. We shall not be forming a correct judgement of this second part of the compulsive act if we take it at its face value as having merely been a critical repudiation of a pathological action. The fact that it was accompanied by a sense of compulsion betrays it as having itself been a part of the pathological action, though a part which was determined by a motive contrary to that which produced the first part.

[1909d, 2150]

The technique of distortion by ellipsis seems to be typical of obsessional neuroses; I have come across it in the obsessional thoughts of other patients as well. One example, a particularly transparent one, is of especial interest on account of a certain structural similarity with the rat idea. It was a case of doubting, and occurred in a lady who suffers principally from obsessional acts. This lady was going for a walk with her husband in Nuremberg, and made him take her into a shop, where she purchased various objects for her child and amongst them a comb. Her husband, finding that the shopping was too long a business for his taste, said that he had noticed some coins in an antique shop on the way which he was anxious to secure, adding that after he had made his purchase he would come and fetch her in the shop in which they at present were. But he stayed away, as she thought, far too long. When he came back she accordingly asked him where he had been. 'Why,' he replied, 'at the antique shop I told you about.' At the same instant she was seized by a tormenting doubt whether she had not as a matter of fact always possessed the comb which she had just bought for her child. She was naturally quite unable to discover the simple mental link that was involved. There is nothing for it but to regard the doubt as having become displaced, and to reconstruct the complete chain of unconscious thoughts as follows: 'If it is true that you were only at the antique shop, if I am really to believe that, then I may just as well believe that this comb that I bought a moment ago has been in my possession for years.' Here, therefore, the lady was drawing a derisive and ironical parallel, just as when our patient thought: 'Oh yes, as sure as those two' (his father and the lady) 'will have children, I shall pay back the money to A.' In the lady's case the doubt was dependent upon her unconscious jealousy, which led her to suppose that her husband had spent the interval of his absence in paying a visit of gallantry.

[1909d, 2177]
Another mental need, which is also shared by obsessional neurotics and which is in some respects related to the one just mentioned, is the need for uncertainty in their life, or for doubt. An enquiry into this characteristic leads deep into the investigation of instinct. The creation of uncertainty is one of the methods employed by the neurosis for drawing the patient away from reality and isolating him from the world - which is among the objects of every psychoneurotic disorder. Again, it is only too obvious what efforts are made by the patients themselves in order to avoid certainty and remain in doubt. Some of them, indeed, give a vivid expression to this tendency in a dislike of clocks and watches (for these at least make the time of day certain), and in the unconscious artifices which they employ in order to render these doubt removing instruments innocuous. Our present patient had developed a peculiar talent for avoiding a knowledge of any facts which would have helped him in deciding his conflict. Thus he was in ignorance upon those matters relating to his lady which were the most relevant to the question of his marriage: he was ostensibly unable to say who had operated upon her and whether the operation had been unilateral or bilateral. He had to be forced into remembering what he had forgotten and into finding out what he had overlooked.

[1909d, 2182]

The predilection felt by obsessional neurotics for uncertainty and doubt leads them to turn their thoughts by preference to those subjects upon which all mankind are uncertain and upon which our knowledge and judgements must necessarily remain open to doubt. The chief subjects of this kind are paternity, length of life, life after death, and memory - in the last of which we are all in the habit of believing, without having the slightest guarantee of its trustworthiness.

[1909d, 2182]

But the behaviour of other obsessional neurotics does not differ greatly from that of our present patient, even though it has not been their fate to come face to face with the phenomenon of death at such an early age. Their thoughts are unceasingly occupied with other people's length of life and possibility of death; their superstitious propensities have had no other content to begin with, and have perhaps no other source whatever. But these neurotics need the help of the possibility of death chiefly in order that it may act as a solution of conflicts they have left unsolved. Their essential characteristic is that they are incapable of coming to a decision, especially in matters of love; they endeavour to postpone every decision, and, in their doubt which person they shall decide for or what measures they shall take against a person, they are obliged to choose as their model the old German courts of justice, in which the suits were usually brought to an end, before judgement had been given, by the death of the parties to the dispute. Thus in every conflict which enters their lives they are on the look out for the death of some one who is of importance to them, usually of some one they love - such as one of their parents, or a rival, or one of the objects of their love between which their inclinations are wavering. But at this point our discussion of the death-complex in obsessional neuroses touches upon the problem of the instinctual life of obsessional neurotics. And to this problem we must now turn.

[1909d, 2184]
But in whatever way this remarkable relation of love and hatred is to be explained, its occurrence is established beyond any possibility of doubt by the observations made in the present case; and it is gratifying to find how easily we can now follow the puzzling processes of an obsessional neurosis by bringing them into relation with this one factor. If an intense love is opposed by an almost equally powerful hatred, and is at the same time inseparably bound up with it, the immediate consequence is certain to be a partial paralysis of the will and an incapacity for coming to a decision upon any of those actions for which love ought to provide the motive power. But this indecision will not confine itself for long to a single group of actions. For, in the first place, what actions of a lover are not brought into relation with his one principal motive? And secondly a man's attitude in sexual things has the force of a model to which the rest of his reactions tend to conform. And thirdly, it is an inherent characteristic in the psychology of an obsessional neurotic to make the fullest possible use of the mechanism of displacement. So the paralysis of his powers of decision gradually extends itself over the entire field of the patient's behaviour.

And here we have the domination of compulsion and doubt such as we meet with in the mental life of obsessional neurotics.

The doubt corresponds to the patient's internal perception of his own indecision, which, in consequence of the inhibition of his love by his hatred, takes possession of him in the face of every intended action. The doubt is in reality a doubt of his own love - which ought to be the most certain thing in his whole mind; and it becomes diffused over everything else, and is especially apt to become displaced on to what is most insignificant and small. A man who doubts his own love may, or rather must, doubt every lesser thing.
It is this same doubt that leads the patient to uncertainty about his protective measures, and to his continual repetition of them in order to banish that uncertainty; and it is this doubt, too, that eventually brings it about that the patient's protective acts themselves become as impossible to carry out as his original inhibited decision in connection with his love. At the beginning of my investigations I was led to assume another and more general origin for the uncertainty of obsessional neurotics and one which seemed to be nearer the normal. If, for instance, while I am writing a letter some one interrupts me with questions, I afterwards feel a quite justifiable uncertainty as to what I may not have written under the influence of the disturbance, and, to make sure, I am obliged to read the letter over after I have finished it. In the same way I might suppose that the uncertainty of obsessional neurotics, when they are praying, for instance, is due to unconscious phantasies constantly mingling with their prayers and disturbing them. This hypothesis is correct, but it may be easily reconciled with what I have just said. It is true that the patient's uncertainty whether he has carried through a protective measure is due to the disturbing effect of unconscious phantasies; but the content of these phantasies is precisely the contrary impulse - which it was the very aim of the prayer to ward off. This became clearly evident in our patient on one occasion, for the disturbing element did not remain unconscious but made its appearance openly. The words he wanted to use in his prayer were, 'May God protect her', but a hostile 'not' suddenly darted out of his unconscious and inserted itself into the sentence; and he understood that this was an attempt at a curse (p. 2152). If the 'not' had remained mute, he would have found himself in a state of uncertainty and would have kept on prolonging his prayers indefinitely. But since it became articulate he eventually gave up praying. Before doing so, however, he, like other obsessional patients, tried every kind of method for preventing the opposite feeling from insinuating itself. He shortened his prayers, for instance, or said them more rapidly. And similarly other patients will endeavour to 'isolate' all such protective acts from other things. But none of these technical procedures are of any avail in the long run. If the impulse of love achieves any success by displacing itself on to some trivial act, the impulse of hostility will very soon follow it on to its new ground and once more proceed to undo all that it has done.

And when the obsessional patient lays his finger on the weak spot in the security of our mental life - on the untrustworthiness of our memory - the discovery enables him to extend his doubt over everything, even over actions which have already been performed and which have so far had no connection with the love-hatred complex, and over the entire past. I may recall the instance of the woman who had just bought a comb for her little daughter in a shop, and, becoming suspicious of her husband, began to doubt whether she had not as a matter of fact been in possession of the comb for a long time. Was not this woman saying point-blank: 'If I can doubt your love' (and this was only a projection of her doubt of her own love for him), 'then I can doubt this too, then I can doubt everything' - thus revealing to us the hidden meaning of neurotic doubt?
The compulsion on the other hand is an attempt at a compensation for the doubt and at a correction of the intolerable conditions of inhibition to which the doubt bears witness. If the patient, by the help of displacement, succeeds at last in bringing one of his inhibited intentions to a decision, then the intention must be carried out. It is true that this intention is not his original one, but the energy dammed up in the latter cannot let slip the opportunity of finding an outlet for its discharge in the substitutive act. Thus this energy makes itself felt now in commands and now in prohibitions, according as the affectionate impulse or the hostile one snatches control of the pathway leading to discharge. If it happens that a compulsive command cannot be obeyed, the tension becomes intolerable and is perceived by the patient in the form of extreme anxiety. (But the pathway leading to a substitutive act, even where the displacement has been on to something very small, is so hotly contested, that such an act can as a rule be carried out only in the shape of a protective measure intimately associated with the very impulse which it is designed to ward off.

Certainly this is a crazy illness. The most extravagant psychiatric imagination would not, I think, have succeeded in constructing anything like it; and if one did not see it before one every day one would never bring oneself to believe in it. Do not suppose, however, that you will help the patient in the least by calling on him to take a new line, to cease to occupy himself with such foolish thoughts and to do something sensible instead of his childish pranks. He would like to do so himself, for he is completely clear in his head, shares your opinion of his obsessional symptoms and even puts it forward to you spontaneously. Only he cannot help himself. What is carried into action in an obsessional neurosis is sustained by an energy to which we probably know nothing comparable in normal mental life. There is only one thing he can do: he can make displacements, and exchanges, he can replace one foolish idea by another somewhat milder, he can proceed from one precaution or prohibition to another, instead of one ceremonial he can perform another. He can displace the obsession but not remove it. The ability to displace any symptom into something far removed from its original conformation is a main characteristic of his illness. Moreover it is a striking fact that in his condition the contradictions (polarities) with which mental life is interlaced emerge especially sharply differentiated. Alongside of obsessions with a positive and negative content, doubt makes itself felt in the intellectual field and little by little it begins to gnaw even at what is usually most certain. The whole position ends up in an ever-increasing degree of indecision, loss of energy and restriction of freedom. At the same time, the obsessional neurotic starts off with a very energetic disposition, he is often extraordinarily self-willed and as a rule he has intellectual gifts above the average. He has usually reached a satisfactorily high level of ethical development; he exhibits over-conscientiousness, and is more than ordinarily correct in his behaviour. You can imagine that no small amount of work is needed before one can make one's way any distance into this contradictory hotch-potch of character-trails and symptoms. And to begin with we aim at nothing whatever else than understanding a few of the symptoms and being able to interpret them.

With your leave I will pass over the remaining, often very trivial, details of the ceremonial; they would teach us nothing new, and would lead us too far afield from our aims. But you must not overlook the fact that all this was not carried out smoothly. There was always an apprehension that things might not have been done properly. Everything must be checked and repeated, doubts assailed first one and then another of the safety measures, and the result was that one or two hours were spent, during which the girl herself could not sleep and would not allow her intimidated parents to sleep either.
We know how important doubt is to the physician who is analysing an obsessional neurosis. It is the patient's strongest weapon, the favourite expedient of his resistance. This same doubt enabled our patient to lie entrenched behind a respectful indifference and to allow the efforts of the treatment to slip past him for years together. Nothing changed, and there was no way of convincing him. At last I recognized the importance of the intestinal trouble for my purposes; it represented the small trait of hysteria which is regularly to be found at the root of an obsessional neurosis. I promised the patient a complete recovery of his intestinal activity, and by means of this promise made his incredulity manifest. I then had the satisfaction of seeing his doubt dwindle away, as in the course of the work his bowel began, like a hysterically affected organ, to 'join in the conversation', and in a few week's time recovered its normal functions after their long impairment.

[1918b, 3557]

An analogy of this kind can of course have no meaning for a patient while the work of analysis is still uncompleted. At this point I recall a discussion which I was led into with a patient whose exceptionally ambivalent attitude was expressed in the most intense compulsive doubt. He did not dispute my interpretations of his dreams and was very much struck by their agreement with the hypotheses which I put forward. But he asked whether these corroborative dreams might not be an expression of his compliance towards me. I pointed out that the dreams had also brought up a quantity of details of which I could have had no suspicion and that his behaviour in the treatment apart from this had not been precisely characterized by compliance. Whereupon he switched over to another theory and asked whether his narcissistic wish to be cured might not have caused him to produce these dreams, since, after all, I had held out to him a prospect of recovery if he were able to accept my constructions. I could only reply that I had not yet come across any such mechanism of dream-formation. But a decision was reached by another road. He recollected some dreams which he had had before starting analysis and indeed before he had known anything about it; and the analysis of these dreams, which were free from all suspicion of suggestion, led to the same interpretations as the later ones. It is true that his obsession for contradiction once more found a way out in the idea that the earlier dreams had been less clear than those that occurred during the treatment; but I was satisfied with their similarity. I think that in general it is a good plan occasionally to bear in mind the fact that people were in the habit of dreaming before there was such a thing as psycho-analysis.

[1923c, 4037]

I have already described the general tendency of symptom-formation in obsessional neurosis. It is to give ever greater room to substitutive satisfaction at the expense of frustration. Symptoms which once stood for a restriction of the ego come later on to represent satisfactions as well, thanks to the ego's inclination to synthesis, and it is quite clear that this second meaning gradually becomes the more important of the two. The result of this process, which approximates more and more to a complete failure of the original purpose of defence, is an extremely restricted ego which is reduced to seeking satisfaction in the symptoms. The displacement of the distribution of forces in favour of satisfaction may have the dreaded final outcome of paralysing the will of the ego, which in every decision it has to make is almost as strongly impelled from the one side as from the other. The over-acute conflict between id and super-ego which has dominated the illness from the very beginning may assume such extensive proportions that the ego, unable to carry out its office of mediator, can undertake nothing which is not drawn into the sphere of that conflict.

[1926d, 4277]
The two techniques I refer to are undoing what has been done and isolating. The first of these has a wide range of application and goes back very far. It is, as it were, negative magic, and endeavours, by means of motor symbolism, to 'blow away' not merely the consequences of some event (or experience or impression) but the event itself. I choose the term 'blow away' advisedly, so as to remind the reader of the part played by this technique not only in neuroses but in magical acts, popular customs and religious ceremonies as well. In obsessional neurosis the technique of undoing what has been done is first met with in the 'diphasic' symptoms, in which one action is cancelled out by a second, so that it is as though neither action had taken place, whereas, in reality, both have. This aim of undoing is the second underlying motive of obsessional ceremonials, the first being to take precautions in order to prevent the occurrence or recurrence of some particular event. The difference between the two is easily seen: the precautionary measures are rational, while trying to get rid of something by 'making it not to have happened' is irrational and in the nature of magic. It is of course to be suspected that the latter is the earlier motive of the two and proceeds from the animistic attitude towards the environment. This endeavour to undo shades off into normal behaviour in the case in which a person decides to regard an event as not having happened. But whereas he will take no direct steps against the event, and will simply pay no further attention to it or its consequences, the neurotic person will try to make the past itself non-existent. He will try to repress it by motor means. The same purpose may perhaps account for the obsession for repeating which is so frequently met with in this neurosis and the carrying out of which serves a number of contradictory intentions at once. When anything has not happened in the desired way it is undone by being repeated in a different way; and thereupon all the motives that exist for lingering over such repetitions come into play as well. As the neurosis proceeds, we often find that the endeavour to undo a traumatic experience is a motive of first-rate importance in the formation of symptoms. We thus unexpectedly discover a new, motor technique of defence, or (as we may say in this case with less inaccuracy) of repression.

[1926d, 4278]

A patient, then, may be suffering from fluctuations in his moods which he cannot control, or from a sense of despondency by which his energy feels paralysed because he thinks he is incapable of doing anything properly, or from a nervous embarrassment among strangers. He may perceive, without understanding the reason for it, that he has difficulties in carrying out his professional work, or indeed any comparatively important decision or any undertaking. He may one day have suffered from a distressing attack - unknown in its origin - of feelings of anxiety, and since then have been unable, without a struggle, to walk along the street alone, or to travel by train; he may perhaps have had to give up both entirely. Or, a very remarkable thing, his thoughts may go their own way and refuse to be directed by his will. They pursue problems that are quite indifferent to him, but from which he cannot get free. Quite ludicrous tasks, too, are imposed on him, such as counting up the windows on the fronts of houses. And when he has performed simple actions such as posting a letter or turning off a gas-jet, he finds himself a moment later doubting whether he has really done so. This may be no more than an annoyance and a nuisance. But his state becomes intolerable if he suddenly finds he is unable to fend off the idea that he has pushed a child under the wheels of a car or has thrown a stranger off the bridge into the water, or if he has to ask himself whether he is not the murderer whom the police are looking for in connection with a crime that was discovered that day. It is obvious nonsense, as he himself knows; he has never done any harm to anyone; but if he were really the murderer who is being looked for, his feeling - his sense of guilt - could not be stronger.

[1926e, 4328]
This 'both' took me aback, and it has no doubt also mystified the reader. For so far we have heard only of one idea - of the rat punishment being carried out upon the lady. He was now obliged to admit that a second idea had occurred to him simultaneously, namely, the idea of the punishment being applied to his father. As his father had died many years previously, this obsessive fear was much more nonsensical even than the first, and accordingly it had attempted to escape being confessed to for a little while longer.

[1909d, 2137]

At the next session he began by saying that he must tell me an event in his childhood. From the age of seven, as he had already told me, he had had a fear that his parents guessed his thoughts, and this fear had in fact persisted all through his life. When he was twelve years old he had been in love with a little girl, the sister of a friend of his. (In answer to a question he said that his love had not been sensual; he had not wanted to see her naked for she was too small.) But she had not shown him as much affection as he had desired. And thereupon the idea had come to him that she would be kind to him if some misfortune were to befall him; and as an instance of such a misfortune his father's death had forced itself upon his mind. He had at once rejected the idea with energy. And even now he could not admit the possibility that what had arisen in this way could have been a 'wish'; it had clearly been no more than a 'train of thought'¹ - By way of objection I asked him why, if it had not been a wish, he had repudiated it. - Merely, he replied, on account of the content of the idea, the notion that his father might die. - I remarked that he was treating the phrase as though it were one that involved lèse-majesté; it was well known, of course, that it was equally punishable to say 'The Emperor is an ass' or to disguise the forbidden words by saying 'If any one says, etc., . . . then he will have me to reckon with.' I added that I could easily insert the idea which he had so energetically repudiated into a context which would exclude the possibility of any such repudiation: for instance, 'If my father dies, I shall kill myself upon his grave.' - He was shaken, but did not abandon his objection. I therefore broke off the argument with the remark that I felt sure this had not been the first occurrence of his idea of his father's dying; it had evidently originated at an earlier date, and some day we should have to trace back its history. - He then proceeded to tell me that a precisely similar thought had flashed through his mind a second time, six months before his father's death. At that time² he had already been in love with his lady, but financial obstacles made it impossible to think of an alliance with her. The idea had then occurred to him that his father's death might make him rich enough to marry her. In defending himself against this idea he had gone to the length of wishing that his father might leave him nothing at all, so that he might have no compensation for his terrible loss. The same idea, though in a much milder form, had come to him for a third time, on the day before his father's death. He had then thought: 'Now I may be going to lose what I love most'; and then had come the contradiction: 'No, there is some one else whose loss would be even more painful to you.'³ These thoughts surprised him very much, for he was quite certain that his father's death could never have been an object of his desire but only of his fear. - After his forcible enunciation of these words I thought it advisable to bring a fresh piece of theory to his notice. According to psycho-analytic theory, I told him, every fear corresponded to a former wish which was now repressed; we were therefore obliged to believe the exact contrary of what he had asserted. This would also fit in with another theoretical requirement, namely, that the unconscious must be the precise contrary of the conscious. - He was much agitated at this and very incredulous. He wondered how he could possibly have had such a wish, considering that he loved his father more than any one else in the world; there could be no doubt that he would have renounced all his own prospects of happiness if by so doing he could have saved his father's life.

[1909d, 2144]
- I answered that it was precisely such intense love as his that was the necessary precondition of the repressed hatred. In the case of people to whom he felt indifferent he would certainly have no difficulty in maintaining side by side inclinations to a moderate liking and to an equally moderate dislike: supposing, for instance, that he were an official, he might think that his chief was agreeable as a superior, but at the same time pettifogging as a lawyer and inhuman as a judge. (Shakespeare makes Brutus speak in a similar way of Julius Caesar: 'As Caesar loved me, I weep for him; as he was fortunate, I rejoice at it; as he was valiant, I honour him; but, as he was ambitious, I slew him.' But these words already strike us as rather strange, and for the very reason that we had imagined Brutus's feeling for Caesar as something deeper.) In the case of some one who was closer to him, of his wife for instance, he would wish his feelings to be unmixed, and consequently, as was only human, he would overlook her faults, since they might make him dislike her - he would ignore them as though he were blind to them. So it was precisely the intensity of his love that would not allow his hatred - though to give it such a name was to caricature the feeling - to remain conscious. To be sure, the hatred must have a source, and to discover that source was certainly a problem; his own statements pointed to the time when he was afraid that his parents guessed his thoughts. On the other hand, too, it might be asked why this intense love of his had not succeeded in extinguishing his hatred, as usually happened where there were two opposing impulses. We could only presume that the hatred must flow from some source, must be connected with some particular cause, which made it indestructible. On the one hand, then, some connection of this sort must be keeping his hatred for his father alive, while on the other hand, his intense love prevented it from becoming conscious. Therefore nothing remained for it but to exist in the unconscious, though it was able from time to time to flash out for a moment into consciousness.

[1909d, 2144]

At the end of this dream, which is clearly charged with anxiety, the dreamer falls out of bed. This is a fresh representation of childbirth. Analytic investigation of the fear of heights, of the dread of an impulse to throw oneself out of the window, has doubtless led you all to the same conclusion.

[1922a, 3892]
But this same person who clung so obstinately to her symptoms in the face of suggestion and would only abandon them in response to psychical analysis or personal conviction, was on the other hand as amenable as the best medium to be found in any hospital, so far as irrelevant suggestions were concerned - so far as it was a question of matters not connected with her illness. I have given instances of her post-hypnotic obedience in the course of the case history. There does not seem to me to be anything contradictory in this behaviour. Here, too, the stronger idea was bound to assert itself. If we go into the mechanism of 'idées fixes', we find that they are based upon and supported by so many experiences operating with such intensity that we cannot be surprised to find that these ideas are able to put up a successful resistance against the opposing idea brought forward by suggestion, which is clothed with only limited powers. It would have to be a truly pathological brain from which it was possible to blow away by mere suggestion such well founded products of intense psychical events.

The first form includes the typical obsessional ideas, in which the content engages the patient's attention and, as an affect, he merely feels an indefinite unpleasure, whereas the only affect which would be suitable to the obsessional idea would be one of self-reproach. The content of the obsessional idea is distorted in two ways in relation to the obsessional act of childhood. First, something contemporary is put in the place of something past; and secondly, something sexual is replaced by something analogous to it that is not sexual. These two alterations are the effect of the inclination to repress, still in force, which we will ascribe to the 'ego'. The influence of the re-activated pathogenic memory is shown by the fact that the content of the obsessional idea is still in part identical with what has been repressed or follows from it by a logical train of thought. If, with the help of the psycho-analytic method, we reconstruct the origin of an individual obsessional idea, we find that from a single current impression two different trains of thought have been set going. The one which has passed by way of the repressed memory proves to be as correctly logical in its structure as the other, although it is incapable of being conscious and insusceptible to correction. If the products of the two psychical operations do not tally, what takes place is not some sort of logical adjustment of the contradiction between them; instead, alongside of the normal intellectual outcome, there comes into consciousness, as a compromise between the resistance and the pathological intellectual product, an obsessional idea which appears absurd. If the two trains of thought lead to the same conclusion, they reinforce each other, so that an intellectual product that has been arrived at normally now behaves, psychologically, like an obsessional idea. Wherever a neurotic obsession emerges in the psychological sphere, it comes from repression. Obsessional ideas have, as it were, a compulsive psychical currency, not on account of their intrinsic value, but on account of the source from which they derive or which has added a contribution to their value.

People who carry out obsessive actions or ceremonials belong to the same class as those who suffer from obsessive thinking, obsessive ideas, obsessive impulses and the like. Taken together, these form a particular clinical entity, to which the name of 'obsessional neurosis' ['Zwangsneurose'] is customarily applied. But one should not attempt to deduce the character of the illness from its name; for, strictly speaking, other kinds of morbid mental phenomena have an equal claim to possessing what are spoken of as 'obsessional' characteristics. In place of a definition we must for the time being be content with obtaining a detailed knowledge of these states, since we have not yet been able to arrive at a criterion of obsessional neuroses; it probably lies very deep, although we seem to sense its presence everywhere in the manifestations of the illness.
Obsessional ideas, as is well known, have an appearance of being either without motive or without meaning, just as dreams have. The first problem is how to give them a sense and a status in the subject's mental life, so as to make them comprehensible and even obvious. The problem of translating them may seem insoluble; but we must never let ourselves be misled by that illusion. The wildest and most eccentric obsessional ideas can be cleared up if they are investigated deeply enough. The solution is effected by bringing the obsessional ideas into temporal relationship with the patient's experiences, that is to say, by enquiring when a particular obsessional idea made its first appearance and in what external circumstances it is apt to recur. When, as so often happens, an obsessional idea has not succeeded in establishing itself permanently, the task of clearing it up is correspondingly simplified. We can easily convince ourselves that, when once the interconnections between an obsessional idea and the patient's experiences have been discovered, there will be no difficulty in obtaining access to whatever else may be puzzling or worth knowing in the pathological structure we are dealing with - its meaning, the mechanism of its origin, and its derivation from the preponderant motive forces of the patient's mind.

In the year 1896 I defined obsessional ideas as 'transformed self-reproaches which have re-emerged from repression and which always relate to some sexual act that was performed with pleasure in childhood'. This definition now seems to me to be open to criticism upon formal grounds, though its component elements are unobjectionable. It was aiming too much at unification, and took as its model the practice of obsessional neurotics themselves, when, with their characteristic liking for indeterminateness, they heap together under the name of 'obsessional ideas' the most heterogeneous psychical structures.² In point of fact, it would be more correct to speak of 'obsessive thinking', and to make it clear that obsessional structures can correspond to every sort of psychical act. They can be classed as wishes, temptations, impulses, reflections, doubts, commands, or prohibitions. Patients endeavour in general to tone down such distinctions and to regard what remains of these psychical acts after they have been deprived of their affective index simply as 'obsessional ideas'. Our present patient gave an example of this type of behaviour in one of his first sessions, when he attempted to reduce a wish to the level of a mere 'train of thought' (p. 2144).

It must be confessed, moreover, that even the phenomenology of obsessional thinking has not yet had sufficient attention paid to it. During the secondary defensive struggle, which the patient carries on against the 'obsessional ideas' that have forced their way into his consciousness, psychical structures make their appearance which deserve to be given a special name. (Such, for example, were the sequences of thoughts that occupied our patient's mind on his journey back from the manoeuvres.) They are not purely reasonable considerations arising in opposition to the obsessional thoughts, but, as it were, hybrids between the two species of thinking; they accept certain of the premises of the obsession they are combating, and thus, while using the weapons of reason, are established upon a basis of pathological thought. I think such structures as these deserve to be given the name of 'deliria'. To make the distinction clear, I will give an instance, which should be inserted into its proper context in the patient's case history. I have already described the crazy conduct to which he gave way at one time when he was preparing for an examination - how, after working till far into the night, he used to go and open the front door to his father's ghost, and then look at his genitals in the looking-glass (p. 2160). He tried to bring himself to his senses by asking himself what his father would say to it all if he were really still alive. But the argument had no effect so long as it was put forward in this rational shape. The spectre was not laid until he had transformed the same idea into a 'delirious' threat to the effect that if he ever went through this nonsense again some evil would befall his father in the next world.
The distinction between a primary and a secondary defensive struggle is no doubt well founded, but we find its value unexpectedly diminished when we discover that the patients themselves do not know the wording of their own obsessional ideas. This may sound paradoxical, but it is perfectly good sense. During the progress of a psycho-analysis it is not only the patient who plucks up courage, but his disease as well; it grows bold enough to speak more plainly than before. To drop the metaphor, what happens is that the patient, who his hitherto turned his eyes away in terror from his own pathological productions, begins to attend to them and obtains a clearer and more detailed view of them.¹

[1909d, 2174]

There are, besides this, two special ways in which a more precise knowledge of obsessional structures can be gained. In the first place, experience shows that an obsessional command (or whatever it may be), which in waking life is known only in a truncated and distorted form, like a mutilated telegraph message, may have its actual text brought to light in a dream. Such texts appear in dreams in the shape of speeches, and are thus an exception to the rule that speeches in dreams are derived from speeches in real life.² Secondly, in the course of the analytic examination of a case history, one becomes convinced that if a number of obsessions succeed one another they are often - even though their wording is not identical - ultimately one and the same. The obsession may have been successfully shaken off on its first appearance, but it comes back a second time in a distorted form and without being recognized, and may then perhaps be able to hold its own in the defensive struggle more effectively, precisely because of its distortion. But the original form is the correct one, and often displays its meaning quite openly. When we have at great pains elucidated an unintelligible obsessional idea, it often happens that the patient informs us that just such a notion, wish, or temptation as the one we have constructed did in fact make its appearance on one occasion before the obsessional idea had arisen, but that it did not persist. It would unfortunately involve us in too lengthy a digression if we were to give instances of this from the history of our present patient.

[1909d, 2174]

¹ Some patients carry the diversion of their attention to such lengths that they are totally unable to give the content of an obsessional idea or to describe an obsessional act though they have performed it over and over again.

[1909d, 2174]

What is officially described as an 'obsessional idea' exhibits, therefore, in its distortion from its original wording, traces of the primary defensive struggle. Its distortion enables it to persist, since conscious thought is thus compelled to misapprehend it, just as though it were a dream; for dreams also are a product of compromise and distortion, and are also misapprehended by waking thought.

[1909d, 2175]
This misapprehension on the part of consciousness can be seen at work not only in reference to the obsessional ideas themselves, but also in reference to the products of the secondary defensive struggle, such, for instance, as the protective formulas. I can produce two good examples of this. Our patient used to employ as a defensive formula a rapidly pronounced 'âber' ["but"] accompanied by a gesture of repudiation. He told me on one occasion that this formula had become altered recently; he now no longer said 'âber' but 'âbër'. When he was asked to give the reason for this new departure, he declared that the mute 'e' of the second syllable gave him no sense of security against the intrusion, which he so much dreaded, of some foreign and contradictory element, and that he had therefore decided to accent the 'e'. This explanation (an excellent sample of the obsessional neurotic style) was, however, clearly inadequate; the most that it could claim to be was a rationalization. The truth was that 'âbër' was an approximation towards the similar-sounding 'abwehr' ['defence'], a term which he had learnt in the course of our theoretical discussions of psycho-analysis. He had thus put the treatment to an illegitimate and 'delirious' use in order to strengthen a defensive formula. Another time he told me about his principal magic word, which was an apotropaic against every evil; he had put it together out of the initial letters of the most powerfully beneficent of his prayers and had clapped on an 'amen' at the end of it. I cannot reproduce the word itself, for reasons which will become apparent immediately. For, when he told it me, I could not help noticing that the word was in fact an anagram of the name of his lady. Her name contained an 's', and this he had put last, that is, immediately before the 'amen' at the end. We may say, therefore, that by this process he had brought his 'Samen' ['semen'] into contact with the woman he loved; in imagination, that is to say, he had masturbated with her. He himself, however, had never noticed this very obvious connection; his defensive forces had allowed themselves to be fooled by the repressed ones. This is also a good example of the rule that in time the thing which is meant to be warded off invariably finds its way into the very means which is being used for warding it off.

[1909d, 2175]

I shall not in the present paper attempt any discussion of the psychological significance of obsessional thinking. Such a discussion would be of extraordinary value in its results, and would do more to clarify our ideas upon the nature of the conscious and the unconscious than any study of hysteria or the phenomena of hypnosis. It would be a most desirable thing if the philosophers and psychologists who develop brilliant theoretical views on the unconscious upon a basis of hearsay knowledge or from their own conventional definitions would first submit to the convincing impressions which may be gained from a first-hand study of the phenomena of obsessional thinking. We might almost go to the length of requiring it of them, if the task were not so far more laborious than the methods of work to which they are accustomed. I will only add here that in obsessional neuroses the unconscious mental processes occasionally break through into consciousness in their pure and undistorted form, that such incursions may take place at every possible stage of the unconscious process of thought, and that at the moment of the incursion the obsessional ideas can, for the most part, be recognized as formations of very long standing. This accounts for the striking circumstance that, when the analyst tries, with the patient's help, to discover the date of the first occurrence of an obsessional idea, the patient is obliged to place it further and further back as the analysis proceeds, and is constantly finding fresh 'first' occasions for the appearance of the obsession.

[1909d, 2178]
Furthermore, by a sort of regression, preparatory acts become substituted for the final decision, thinking replaces acting, and, instead of the substitutive act, some thought preliminary to it asserts itself with all the force of compulsion. According as this regression from acting to thinking is more or less marked, a case of obsessional neurosis will exhibit the characteristics of obsessive thinking (that is, of obsessional ideas) or of obsessive acting in the narrower sense of the word. True obsessional acts such as these, however, are only made possible because they constitute a kind of reconciliation, in the shape of a compromise, between the two antagonistic impulses. For obsessional acts tend to approximate more and more - and the longer the disorder lasts the more evident does this become - to infantile sexual acts of a masturbatory character. Thus in this form of the neurosis acts of love are carried out in spite of everything, but only by the aid of a new kind of regression; for such acts no longer relate to another person, the object of love and hatred, but are auto-erotic acts such as occur in infancy.

[1909d, 2191]

In another neurotic disorder, obsessional neurosis, the patients become the victims of distressing and apparently senseless ceremonials which take the form of the rhythmical repetition of the most trivial acts (such as washing or dressing) or of carrying out meaningless injunctions or of obeying mysterious prohibitions. It was nothing less than a triumph of psycho-analytic research when it succeeded in showing that all these obsessive acts, even the most insignificant and trivial of them, have a meaning, and that they are reflections, translated into indifferent terms, of conflicts in the patients’ lives, of the struggle between temptations and moral restraints - reflections of the proscribed wish itself and of the punishment and atonement which that wish incurs. In another form of the same disorder the victim suffers from tormented ideas (obsessions) which force themselves upon him and are accompanied by affects whose character and intensity are often only quite inadequately accounted for by the terms of the obsessive ideas themselves. Analytic investigation has shown in their case that the affects are entirely justified, since they correspond to self-reproaches which are based on something that is at least psychically real. But the ideas to which these effects are attached are not the original ones, but have found their way into their present position by a process of displacement - by being substituted for something that has been repressed. If these displacements can be reversed, the way is open to the discovery of the repressed ideas, and the relation between affect and idea is found to be perfectly appropriate.

[1913j, 2810]

A patient, then, may be suffering from fluctuations in his moods which he cannot control, or from a sense of despondency by which his energy feels paralysed because he thinks he is incapable of doing anything properly, or from a nervous embarrassment among strangers. He may perceive, without understanding the reason for it, that he has difficulties in carrying out his professional work, or indeed any comparatively important decision or any undertaking. He may one day have suffered from a distressing attack - unknown in its origin - of feelings of anxiety, and since then have been unable, without a struggle, to walk along the street alone, or to travel by train; he may perhaps have had to give up both entirely. Or, a very remarkable thing, his thoughts may go their own way and refuse to be directed by his will. They pursue problems that are quite indifferent to him, but from which he cannot get free. Quite ludicrous tasks, too, are imposed on him, such as counting up the windows on the fronts of houses. And when he has performed simple actions such as posting a letter or turning off a gas-jet, he finds himself a moment later doubting whether he has really done so. This may be no more than an annoyance and a nuisance. But his state becomes intolerable if he suddenly finds he is unable to fend off the idea that he has pushed a child under the wheels of a car or has thrown a stranger off the bridge into the water, or if he has to ask himself whether he is not the murderer whom the police are looking for in connection with a crime that was discovered that day. It is obvious nonsense, as he himself knows; he has never done any harm to anyone; but if he were really the murderer who is being looked for, his feeling - his sense of guilt - could not be stronger.

[1926e, 4328]
People who carry out obsessive actions or ceremonials belong to the same class as those who suffer from obsessive thinking, obsessive ideas, obsessive impulses and the like. Taken together, these form a particular clinical entity, to which the name of 'obsessional neurosis' ['Zwangsneurose'] is customarily applied.¹ But one should not attempt to deduce the character of the illness from its name; for, strictly speaking, other kinds of morbid mental phenomena have an equal claim to possessing what are spoken of as 'obsessional' characteristics. In place of a definition we must for the time being be content with obtaining a detailed knowledge of these states, since we have not yet been able to arrive at a criterion of obsessional neuroses; it probably lies very deep, although we seem to sense its presence everywhere in the manifestations of the illness.

A youngish man of university education introduced himself to me with the statement that he had suffered from obsessions ever since his childhood, but with particular intensity for the last four years. The chief features of his disorder were fears that something might happen to two people of whom he was very fond - his father and a lady whom he admired. Besides this he was aware of compulsive impulses - such as an impulse, for instance, to cut his throat with a razor; and further he produced prohibitions, sometimes in connection with quite unimportant things. He had wasted years, he told me, in fighting against these ideas of his, and in this way had lost much ground in the course of his life. He had tried various treatments, but none had been of any use to him except a course of hydrotherapy at a sanatorium near ---; and this, he thought, had probably only been because he had made an acquaintance there which had led to regular sexual intercourse. Here he had no opportunities of the sort, and he seldom had intercourse and only at irregular intervals. He felt disgust at prostitutes. Altogether, he said, his sexual life had been stunted; masturbation had played only a small part in it, in his sixteenth or seventeenth year. His potency was normal; he had first had intercourse at the age of twenty-six.

Another impulse, which might be described as indirectly suicidal and which was of longer duration, was not so easily explicable. For its relation to the patient's experiences succeeded in concealing itself behind one of those purely external associations which are so obnoxious to our consciousness. One day while he was away on his summer holidays the idea suddenly occurred to him that he was too fat [German 'dick'] and that he must make himself slimmer. So he began getting up from table before the pudding came round and tearing along the road without a hat in the blazing heat of an August sun. Then he would dash up a mountain at the double, till, dripping with perspiration, he was forced to come to a stop. On one occasion his suicidal intentions actually emerged without any disguise from behind this mania for slimming: as he was standing on the edge of a steep precipice he suddenly received a command to jump over, which would have been certain death. Our patient could think of no explanation of this senseless obsessional behaviour until it suddenly occurred to him that at that time his lady had also been stopping at the same resort; but she had been in the company of an English cousin, who was very attentive to her and of whom the patient had been very jealous. This cousin's name was Richard, and, according to the usual practice in England, he was known as Dick. Our patient, then, had wanted to kill this Dick; he had been far more jealous of him and enraged with him than he could admit to himself, and that was why he had imposed on himself this course of slimming by way of a punishment. This obsessional impulse may seem very different from the directly suicidal command which was discussed above, but they have nevertheless one important feature in common. For they both arose as reactions to a tremendous feeling of rage, which was inaccessible to the patient's consciousness and was directed against some one who had cropped up as an interference with the course of his love.¹

¹[1909d, 2129]
In the year 1896 I defined obsessional ideas as 'transformed self-reproaches which have re-emerged from repression and which always relate to some sexual act that was performed with pleasure in childhood'. This definition now seems to me to be open to criticism upon formal grounds, though its component elements are unobjectionable. It was aiming too much at unification, and took as its model the practice of obsessional neurotics themselves, when, with their characteristic liking for indeterminateness, they heap together under the name of 'obsessional ideas' the most heterogeneous psychical structures.² In point of fact, it would be more correct to speak of 'obsessive thinking', and to make it clear that obsessional structures can correspond to every sort of psychical act. They can be classed as wishes, temptations, impulses, reflections, doubts, commands, or prohibitions. Patients endeavour in general to tone down such distinctions and to regard what remains of these psychical acts after they have been deprived of their affective index simply as 'obsessional ideas'. Our present patient gave an example of this type of behaviour in one of his first sessions, when he attempted to reduce a wish to the level of a mere 'train of thought' (p. 214).

[1909d, 217]

In certain diseases - including the very neuroses of which we have made special study - things are different. The ego feels uneasy; it comes up against limits to its power in its own house, the mind. Thoughts emerge suddenly without one's knowing where they come from, nor can one do anything to drive them away. These alien guests even seem to be more powerful than those which are at the ego's command. They resist all the well-proved measures of enforcement used by the will, remain unmoved by logical refutation, and are unaffected by the contradictory assertions of reality. Or else impulses appear which seem like those of a stranger, so that the ego disowns them; yet it has to fear them and take precautions against them. The ego says to itself: 'This is an illness, a foreign invasion.' It increases its vigilance, but cannot understand why it feels so strangely paralysed.

[1917a, 3612]
In the year 1896 I defined obsessional ideas as 'transformed self-reproaches which have re-emerged from repression and which always relate to some sexual act that was performed with pleasure in childhood'. This definition now seems to me to be open to criticism upon formal grounds, though its component elements are unobjectionable. It was aiming too much at unification, and took as its model the practice of obsessional neurotics themselves, when, with their characteristic liking for indeterminateness, they heap together under the name of 'obsessional ideas' the most heterogeneous psychical structures.² In point of fact, it would be more correct to speak of 'obsessive thinking', and to make it clear that obsessional structures can correspond to every sort of psychical act. They can be classed as wishes, temptations, impulses, reflections, doubts, commands, or prohibitions. Patients endeavour in general to tone down such distinctions and to regard what remains of these psychical acts after they have been deprived of their affective index simply as 'obsessional ideas'. Our present patient gave an example of this type of behaviour in one of his first sessions, when he attempted to reduce a wish to the level of a mere 'train of thought' (p. 2144).

[1909d, 2172]
There are cases in which one can observe how the obsession is transferred from the idea or from the affect on to the protective measure; others in which the obsession oscillates periodically between the symptom of the return of the repressed and the symptom of the secondary defence; and yet other cases in which no obsessional idea is constructed at all, but, instead, the repressed memory is at once represented by what is apparently a primary measure of defence. Here we reach at one bound the stage which elsewhere only completes the course run by the obsessional neurosis after the defensive struggle has taken place. Severe cases of this disorder end in the ceremonial actions becoming fixated, or in a general state of doubting mania, or in a life of eccentricity conditioned by phobias.

¹ The proof of infantile masturbation in other cases is established in a precisely similar way. The evidence for it is mostly of a similar nature: indications of the presence of leucorrhoea, bed-wetting, hand-ceremonials (obsessional washing), and such things. It is always possible to discover with certainty from the nature of the symptoms of the case whether the habit was discovered by the person in charge of the child or not, or whether this sexual activity was brought to an end by long efforts on the child's part to break itself of the habit, or by a sudden change. In Dora's case the masturbation had remained undiscovered, and had come to an end at a single blow (cf. her secret, her fear of doctors, and the replacement by dyspnoea). The patients, it is true, invariably dispute the conclusiveness of circumstantial evidence such as this, and they do so even when they have retained a conscious recollection of the catarrh or of their mother's warning (e.g. 'That makes people stupid; it's dangerous'). But some time later the memory, which has been so long repressed, of this piece of infantile sexual life emerges with certainty, and it does so in every instance. I am reminded of the case of a patient of mine suffering from obsessions, which were direct derivatives of infantile masturbation. Her peculiarities, such as self-prohibitions and self-punishments, the feeling that if she had done this she must not do that, the idea that she must not be interrupted, the introduction of pauses between one procedure (with her hands) and the next, her hand-washing, etc, - all of these turned out to be unaltered fragments of her nurse's efforts to break her of the habit. The only thing which had remained permanently in her memory were the words of warning: 'Ugh! That's dangerous!' Compare also in this connection my Three Essays on the Theory of Sexuality, 1905d. [1905e, 1416]

People who carry out obsessive actions or ceremonials belong to the same class as those who suffer from obsessive thinking, obsessive ideas, obsessive impulses and the like. Taken together, these form a particular clinical entity, to which the name of 'obsessional neurosis' ['Zwangsneurose'] is customarily applied.¹ But one should not attempt to deduce the character of the illness from its name; for, strictly speaking, other kinds of morbid mental phenomena have an equal claim to possessing what are spoken of as 'obsessional' characteristics. In place of a definition we must for the time being be content with obtaining a detailed knowledge of these states, since we have not yet been able to arrive at a criterion of obsessional neuroses; it probably lies very deep, although we seem to sense its presence everywhere in the manifestations of the illness.

[1896b, 393]

[1907b, 1901]
Neurotic ceremonials consist in making small adjustments to particular everyday actions, small additions or restrictions or arrangements, which have always to be carried out in the same, or in a methodically varied, manner. These activities give the impression of being mere formalities, and they seem quite meaningless to us. Nor do they appear otherwise to the patient himself; yet he is incapable of giving them up, for any deviation from the ceremonial is visited by intolerable anxiety, which obliges him at once to make his omission good. Just as trivial as the ceremonial actions themselves are the occasions and activities which are embellished, encumbered and in any case prolonged by the ceremonial - for instance, dressing and undressing, going to bed or satisfying bodily needs. The performance of a ceremonial can be described by replacing it, as it were, by a series of unwritten laws. For instance, to take the case of the bed ceremonial: the chair must stand in a particular place beside the bed; the clothes must lie upon it folded in a particular order; the blanket must be tucked in at the bottom and the sheet smoothed out; the pillows must be arranged in such and such a manner, and the subject's own body must lie in a precisely defined position. Only after all this may he go to sleep. Thus in slight cases the ceremonial seems to be no more than an exaggeration of an orderly procedure that is customary and justifiable; but the special conscientiousness with which it is carried out and the anxiety which follows upon its neglect stamp the ceremonial as a 'sacred act'. Any interruption of it is for the most part badly tolerated, and the presence of other people during its performance is almost always ruled out.

[1907b, 1902]

Any activities whatever may become obsessive actions in the wider sense of the term if they are elaborated by small additions or given a rhythmic character by means of pauses and repetitions. We shall not expect to find a sharp distinction between 'ceremonials' and 'obsessive actions'. As a rule obsessive actions have grown out of ceremonials. Besides these two, prohibitions and hindrances (abulia) make up the content of the disorder; these, in fact, only continue the work of the obsessive actions, inasmuch as some things are completely forbidden to the patient and others only allowed subject to his following a prescribed ceremonial.

[1907b, 1902]

It is easy to see where the resemblances lie between neurotic ceremonials and the sacred acts of religious ritual: in the qualms of conscience brought on by their neglect, in their complete isolation from all other actions (shown in the prohibition against interruption) and in the conscientiousness with which they are carried out in every detail. But the differences are equally obvious, and a few of them are so glaring that they make the comparison a sacrilege: the greater individual variability of ceremonial actions in contrast to the stereotyped character of rituals (prayer, turning to the East, etc.), their private nature as opposed to the public and communal character of religious observances, above all, however, the fact that, while the minutiae of religious ceremonial are full of significance and have a symbolic meaning, those of neurotics seem foolish and senseless. In this respect an obsessional neurosis presents a travesty, half comic and half tragic, of a private religion. But it is precisely this sharpest difference between neurotic and religious ceremonial which disappears when, with the help of the psycho-analytic technique of investigation, one penetrates to the true meaning of obsessive actions.¹ In the course of such an investigation the appearance which obsessive actions afford of being foolish and senseless is completely effaced, and the reason for their having that appearance is explained. It is found that the obsessive actions are perfectly significant in every detail, that they serve important interests of the personality and that they give expression to experiences that are still operative and to thoughts that are cathexed with affect. They do this in two ways, either by direct or by symbolic representation; and they are consequently to be interpreted either historically or symbolically.

[1907b, 1903]
I must give a few examples to illustrate my point. Those who are familiar with the findings of psycho-analytic investigation into the psychoneuroses will not be surprised to learn that what is being represented in obsessive actions or in ceremonials is derived from the most intimate, and for the most part from the sexual, experiences of the patient.

[1907b, 1904]

These few examples, selected from the great number I have met with, are merely intended to illustrate my assertion that in obsessive actions everything has its meaning and can be interpreted. The same is true of ceremonials in the strict sense, only that the evidence for this would require a more circumstantial presentation. I am quite aware of how far our explanations of obsessive actions are apparently taking us from the sphere of religious thought.

[1907b, 1906]

It is one of the conditions of the illness that the person who is obeying a compulsion carries it out without understanding its meaning - or at any rate its chief meaning. It is only thanks to the efforts of psycho-analytic treatment that he becomes conscious of the meaning of his obsessive action and, with it, of the motives that are impelling him to it. We express this important fact by saying that the obsessive action serves to express unconscious motives and ideas. In this, we seem to find a further departure from religious practices; but we must remember that as a rule the ordinary pious individual, too, performs a ceremonial without concerning himself with its significance, although priests and scientific investigators may be familiar with the - mostly symbolic - meaning of the ritual. In all believers, however, the motives which impel them to religious practices are unknown to them or are represented in consciousness by others which are advanced in their place.

[1907b, 1906]

Analysis of obsessive actions has already given us some sort of an insight into their causes and into the chain of motives which bring them into effect. We may say that the sufferer from compulsions and prohibitions behaves as if he were dominated by a sense of guilt, of which, however, he knows nothing, so that we must call it an unconscious sense of guilt, in spite of the apparent contradiction in terms. This sense of guilt has its source in certain early mental events, but it is constantly being revived by renewed temptations which arise whenever there is a contemporary provocation. Moreover, it occasions a lurking sense of expectant anxiety, an expectation of misfortune, which is linked, through the idea of punishment, with the internal perception of the temptation. When the ceremonial is first being constructed, the patient is still conscious that he must do this or that lest some ill should befall, and as a rule the nature of the ill that is to be expected is still known to his consciousness. But what is already hidden from him is the connection - which is always demonstrable - between the occasion on which this expectant anxiety arises and the danger which it conjures up. Thus a ceremonial starts as an action for defence or insurance, a protective measure.

[1907b, 1906]
A deeper insight into the mechanism of obsessional neurosis is gained if we take into account the primary fact which lies at the bottom of it. This is always the repression of an instinctual impulse (a component of the sexual instinct) which was present in the subject's constitution and which was allowed to find expression for a while during his childhood but later succumbed to suppression. In the course of the repression of this instinct a special conscientiousness is created which is directed against the instinct's aims; but this psychical reaction-formation feels insecure and constantly threatened by the instinct which is lurking in the unconscious. The influence of the repressed instinct is felt as a temptation, and during the process of repression itself anxiety is generated, which gains control over the future in the form of expectant anxiety. The process of repression which leads to obsessional neurosis must be considered as one which is only partly successful and which increasingly threatens to fail. It may thus be compared to an unending conflict; fresh psychical efforts are continually required to counterbalance the forward pressure of the instinct. Thus the ceremonial and obsessive actions arise partly as a defence against the temptation and partly as a protection against the ill which is expected. Against the temptation the protective measures seem soon to become inadequate; then the prohibitions come into play, with the purpose of keeping at a distance situations that give rise to temptation. Prohibitions take the place of obsessive actions, it will be seen, just as a phobia is designed to avert a hysterical attack. Again, a ceremonial represents the sum of the conditions subject to which something that is not yet absolutely forbidden is permitted, just as the Church's marriage ceremony signifies for the believer a sanctioning of sexual enjoyment which would otherwise be sinful. A further characteristic of obsessional neurosis, as of all similar affections, is that its manifestations (its symptoms, including the obsessive actions) fulfil the condition of being a compromise between the warring forces of the mind. They thus always reproduce something of the pleasure which they are designed to prevent; they serve the repressed instinct no less than the agencies which are repressing it. As the illness progresses, indeed, actions which were originally mostly concerned with maintaining the defence come to approximate more and more to the proscribed actions through which the instinct was able to find expression in childhood.

[1907b, 1907]

We have noted as a curious and derogatory characteristic of obsessional neurosis that its ceremonials are concerned with the small actions of daily life and are expressed in foolish regulations and restrictions in connection with them. We cannot understand this remarkable feature of the clinical picture until we have realized that the mechanism of psychical displacement, which was first discovered by me in the construction of dreams,₉ dominates the mental processes of obsessional neurosis. It is already clear from the few examples of obsessive actions given above that their symbolism and the detail of their execution are brought about by a displacement from the actual, important thing on to a small one which takes its place - for instance, from a husband on to a chair. It is this tendency to displacement which progressively changes the clinical picture and eventually succeeds in turning what is apparently the most trivial matter into something of the utmost importance and urgency. It cannot be denied that in the religious field as well there is a similar tendency to a displacement of psychical values, and in the same direction, so that the petty ceremonials of religious practice gradually become the essential thing and push aside the underlying thoughts. That is why religions are subject to reforms which work retroactively and aim at a re-establishment of the original balance of values.

[1907b, 1908]
There is a second explanation, also unconcerned with sexuality, which has, however, a much more general scope than the first. It suggests that primitive man is prey to a perpetual lurking apprehensiveness, just as in the psycho-analytic theory of the neuroses we claim to be the case with people suffering from anxiety neurosis. This apprehensiveness will appear most strongly on all occasions which differ in any way from the usual, which involve something new or unexpected, something not understood or uncanny. This is also the origin of the ceremonial practices, widely adopted in later religions, which are connected with the beginning of every new undertaking, the start of every new period of time, the first-fruits of human, animal and plant life. The dangers which the anxious man believes to be threatening him never appear more vivid in his expectation than on the threshold of a dangerous situation, and then, too, is the only time when protecting himself against them is of any use. The first act of intercourse in marriage can certainly claim, on grounds of importance, to be preceded by such precautionary measures. These two attempts at explanation, based on horror of blood and on fear of first occurrences, do not contradict but rather reinforce each other. The first occasion of sexual intercourse is certainly a critical action, all the more so if it is to involve a flow of blood.

[1918a, 2353]

The purpose of some of the prohibitions is immediately obvious. Others, on the contrary, strike us as incomprehensible, senseless and silly, and prohibitions of this latter sort are described as 'ceremonial'. This distinction, too, is found in the observances of taboo.

[1912-1913, 2675]

Obsessional prohibitions involve just as extensive renunciations and restrictions in the lives of those who are subject to them as do taboo prohibitions; but some of them can be lifted if certain actions are performed. Thereafter, these actions must be performed: they become compulsive or obsessive acts, and there can be no doubt that they are in the nature of expiation, penance, defensive measures and purification. The commonest of these obsessive acts is washing in water ('washing mania'). Some taboo prohibitions can be replaced in just the same way; or rather their violation can be made good by a similar 'ceremonial'; and here again lustration with water is the preferred method.

[1912-1913, 2676]

Let us now summarize the points in which agreement between taboo usages and obsessional symptoms is most clearly shown: (1) the fact that the prohibitions lack any assignable motive; (2) the fact that they are maintained by an internal necessity; (3) the fact that they are easily displaceable and that there is a risk of infection from the prohibited object; and (4) the fact that they give rise to injunctions for the performance of ceremonial acts.

[1912-1913, 2676]

I shall not attempt to give a complete catalogue of the instances quoted by Frazer of restrictions imposed upon victorious manslayers. I will only remark upon a few more such cases in which their taboo character is particularly marked or in which the restrictions are accompanied by expiation, purification and other ceremonials.

[1912-1913, 2687]

However much the details and variations of the ceremonies of expiation and purification after the slaying of enemies might be of interest for deeper research into the subject, I shall break off at this point, since for our present purpose they have nothing more to tell us. I may perhaps suggest that the temporary or permanent isolation of professional executioners, which has persisted to the present day, may belong in this connection. The position of the public hangman in mediaeval society offers a good picture of the workings of taboo among savages.¹

[1912-1913, 2687]
In the accepted explanation of all these observances of appeasement, restriction, expiation and purification, two principles are combined: the extension of the taboo from the slain man on to everything that has come in contact with him, and the fear of the slain man's ghost. How these two factors are to be combined with each other to explain the ceremonials, whether they are to be regarded as of equal weight, whether one is primary and the other secondary, and if so which - none of these questions receives an answer, and indeed it would be hard to find one. We, on the other hand, can lay stress on the unity of our view, which derives all of these observances from emotional ambivalence towards the enemy.

[1912-1913, 2688]

So far so good; but the technique of psycho-analysis allows us to go into the question further and to enter more into the details of these various impulses. If we submit the recorded facts to analysis, as though they formed part of the symptoms presented by a neurosis, our starting-point must be the excessive apprehensiveness and solicitude which is put forward as the reason for the taboo ceremonials. The occurrence of excessive solicitude of this kind is very common in neuroses, and especially in obsessional neuroses, with which our comparison is chiefly drawn. We have come to understand its origin quite clearly. It appears wherever, in addition to a predominant feeling of affection, there is also a contrary, but unconscious, current of hostility - a state of affairs which represents a typical instance of an ambivalent emotional attitude. The hostility is then shouted down, as it were, by an excessive intensification of the affection, which is expressed as solicitude and becomes compulsive, because it might otherwise be inadequate to perform its task of keeping the unconscious contrary current of feeling under repression. Every psycho-analyst knows from experience with what certainty this explanation of solicitous over-affection is found to apply even in the most unlikely circumstances - in cases, for instance, of attachments between a mother and child or between a devoted married couple. If we now apply this to the case of privileged persons, we shall realize that alongside the veneration, and indeed idolization, felt towards them, there is in the unconscious an opposing current of intense hostility; that, in fact, as we expected, we are faced by a situation of emotional ambivalence. The distrust which provides one of the unmistakable elements in kingly taboos would thus be another, more direct, expression of the same unconscious hostility. Indeed, owing to the variety of outcomes of a conflict of this kind which are reached among different peoples, we are not at a loss for examples in which the existence of this hostility is still more obviously shown. 'The savage Timmes of Sierra Leone', we learn from Frazer, 'who elect their king, reserve to themselves the right of beating him on the eve of his coronation; and they avail themselves of this constitutional privilege with such hearty goodwill that sometimes the unhappy monarch does not long survive his elevation to the throne. Hence when the leading chiefs have a spite at a man and wish to rid themselves of him, they elect him king.' Even in glaring instances like this, however, the hostility is not admitted as such, but masquerades as a ceremonial.

[1912-1913, 2695]
May not the same have been true of primitive men? We are justified in believing that, as one of the phenomena of their narcissistic organization, they overvalued their psychical acts to an extraordinary degree. Accordingly the mere hostile impulse against the father, the mere existence of a wishful phantasy of killing and devouring him, would have been enough to produce the moral reaction that created totemism and taboo. In this way we should avoid the necessity for deriving the origin of our cultural legacy, of which we justly feel so proud, from a hideous crime, revolting to all our feelings. No damage would thus be done to the causal chain stretching from the beginning to the present day, for psychical reality would be strong enough to bear the weight of these consequences. To this it may be objected that an alteration in the form of society from a patriarchal horde to a fraternal clan did actually take place. This is a powerful argument, but not a conclusive one. The alteration might have been effected in a less violent fashion and none the less have been capable of determining the appearance of the moral reaction. So long as the pressure exercised by the primal father could be felt, the hostile feelings towards him were justified, and remorse on their account would have to await a later day. And if it is further argued that everything derived from the ambivalent relation to the father - taboo and the sacrificial ordinance - is characterized by the deepest seriousness and the most complete reality, this further objection carries just as little weight. For the ceremonials and inhibitions of obsessional neurotics show these same characteristics and are nevertheless derived only from psychical reality - from intentions and not from their execution. We must avoid transplanting a contempt for what is merely thought or wished from our commonplace world, with its wealth of material values, into the world of primitive men and neurotics, of which the wealth lies only within themselves.

In another neurotic disorder, obsessional neurosis, the patients become the victims of distressing and apparently senseless ceremonials which take the form of the rhythmical repetition of the most trivial acts (such as washing or dressing) or of carrying out meaningless injunctions or of obeying mysterious prohibitions. It was nothing less than a triumph of psychoanalytic research when it succeeded in showing that all these obsessive acts, even the most insignificant and trivial of them, have a meaning, and that they are reflections, translated into indifferent terms, of conflicts in the patients' lives, of the struggle between temptations and moral restraints - reflections of the proscribed wish itself and of the punishment and atonement which that wish incurs. In another form of the same disorder the victim suffers from tormenting ideas (obsessions) which force themselves upon him and are accompanied by affects whose character and intensity are often only quite inadequately accounted for by the terms of the obsessive ideas themselves. Analytic investigation has shown in their case that the affects are entirely justified, since they correspond to self-reproaches which are based on something that is at least psychically real. But the ideas to which these affects are attached are not the original ones, but have found their way into their present position by a process of displacement - by being substituted for something that has been repressed. If these displacements can be reversed, the way is open to the discovery of the repressed ideas, and the relation between affect and idea is found to be perfectly appropriate.
A nineteen-year-old girl, well developed and gifted, was the only child of parents to whom she was superior in education and intellectual liveliness. As a child she had been wild and high spirited, and in the course of the last few years had changed, without any visible cause, into a neurotic. She was very irritable, particularly towards her mother, always dissatisfied and depressed, and inclined to indecisiveness and doubt; finally she admitted that she was no longer able to walk by herself across squares or along comparatively wide streets. We will not concern ourselves much with her complicated illness, which called for at least two diagnoses - agoraphobia and obsessional neurosis - but will dwell only on the fact that she also developed a sleep-ceremonial, with which she tormented her parents. In a certain sense it may be said that every normal person has his sleep-ceremonial or that he has established certain necessary conditions the non-fulfilment of which interferes with his going to sleep; he has imposed certain forms on the transition from the waking to the sleeping state and repeats them in the same manner every evening. But everything that a healthy person requires as a necessary condition for sleep can be understood rationally, and if external circumstances call for a change he will comply easily and without waste of time. A pathological ceremonial, however, is unyielding and insists on being carried through, even at the cost of great sacrifices; it too is screened by having a rational basis and at a superficial glance seems to diverge from the normal only by a certain exaggerated meticulousness. On closer examination, nevertheless, we can see that the screen is insufficient, that the ceremonial comprises some stipulations which go far beyond its rational basis and others which positively run counter to it. Our present patient put forward as a pretext for her nightly precautions that she needed quiet in order to sleep and must exclude every source of noise. With that end in view she did two kinds of things. The big clock in her room was stopped, all the other clocks or watches in the room were removed, and her tiny wrist-watch was not allowed even to be inside her bedside table. Flower-pots and vases were collected on the writing-table so that they might not fall over in the night and break, and disturb her in her sleep. She was aware that these measures could find only an ostensible justification in the rule in favour of quiet: the ticking of the little watch would not have been audible even if it had been left lying on the top of the bedside table, and we have all had experience of the fact that the regular ticking of a pendulum-clock never disturbs sleep but acts, rather, as a soporific. She admitted too that her fear that flower-pots and vases, if they were left in their places, might fall over and break of their own accord lacked all plausibility. In the case of other stipulations made by the ceremonial the need for quiet was dropped as a basis. Indeed, the requirement that the door between her room and her parents' bedroom should stay half-open - the fulfilment of which she ensured by placing various objects in the open doorway - seemed on the contrary to act as a source of disturbing noises. But the most important stipulations related to the bed itself. The pillow at the top end of the bed must not touch the wooden back of the bedstead. The small top pillow must lie on this large pillow in one specific way only - namely, so as to form a diamond shape. Her head had then to lie exactly along the long diameter of the diamond. The eiderdown (or 'Duchent' as we call it in Austria) had to be shaken before being laid on the bed so that its bottom end became very thick; afterwards, however, she never failed to even out this accumulation of feathers by pressing them apart.
She found out the central meaning of her ceremonial one day when she suddenly understood the meaning of the rule that the pillow must not touch the back of the bedstead. The pillow, she said, had always been a woman to her and the upright wooden back a man. Thus she wanted - by magic, we must interpolate - to keep the man and woman apart - that is, to separate her parents from each other, not to allow them to have sexual intercourse. In earlier years, before she had established the ceremonial, she had tried to achieve the same aim in a more direct way. She had simulated fear (or had exploited a tendency to fear which was already present) in order that the connecting doors between her parents' bedroom and the nursery should not be shut. This rule had, indeed, been retained in her present ceremonial. In that way she gave herself the opportunity of listening to her parents, but in making use of it she brought on an insomnia which lasted for months. Not satisfied with disturbing her parents by this means, she contrived to be allowed from time to time to sleep in her parents' bed between them. The 'pillow' and the 'wooden back' were thus really unable to come together. Finally, when she was so big that it became physically uncomfortable for her to find room in the bed between her parents, she managed, by a conscious simulation of anxiety, to arrange for her mother to exchange places with her for the night and to leave her own place so that the patient could sleep beside her father. This situation no doubt became the starting-point of phantasies whose after-effect was to be seen in the ceremonial.

[1916-1917, 3347]

Wild thoughts, you will say, to be running through an unmarried girl's head. I admit that is so. But you must not forget that I did not make these things but only interpreted them. A sleep-ceremonial like this is a strange thing too, and you will not fail to see how the ceremonial corresponds to the phantasies which are revealed by the interpretation. But I attach more importance to your noticing that what was seen in the ceremonial was a precipitate not of a single phantasy but of a number of them, though they had a nodal point somewhere, and, further, that the rules laid down by the ceremonial reproduced the patient's sexual wishes at one point positively and at another negatively - in part they represented them, but in part they served as a defence against them.

[1916-1917, 3347]
No doubt all kinds of objections can still be raised to the assertion that neurotic symptoms are substitutes for sexual satisfactions. I will mention two of them to-day. When you yourselves have carried out analytic examinations of a considerable number of neurotics, you will perhaps tell me, shaking your head, that in a lot of cases my assertion is simply not true; the symptoms seem rather to have the contrary purpose of excluding or of stopping sexual satisfaction. I will not dispute the correctness of your interpretation. The facts in psycho-analysis have a habit of being rather more complicated than we like. If they were as simple as all that, perhaps it might not have needed psycho-analysis to bring them to light. Indeed, some of the features of our second patient's ceremonial show signs of this ascetic character with its hostility to sexual satisfaction: when, for instance, she got rid of the clocks and watches, which had the magical meaning of avoiding erections during the night, or when she tried to guard against flower-pots falling and breaking, which was equivalent to protecting her virginity. In some other cases of bed ceremonies, which I have been able to analyse, this negative character was far more outspoken; the ceremonial might consist exclusively of defensive measures against sexual memories and temptations. However, we have already found often enough that in psycho-analysis opposites imply no contradiction. We might extend our thesis and say that symptoms aim either at a sexual satisfaction or at fending it off, and that on the whole the positive, wish-fulfilling character prevails in hysteria and the negative, ascetic one in obsessional neurosis. If symptoms can serve the purpose both of sexual satisfaction and of its opposite, there is an excellent basis for this double-sidedness or polarity in a part of their mechanism which I have so far not been able to mention. For, as we shall hear, they are the products of a compromise and arise from the mutual interference between two opposing currents; they represent not only the repressed but also the repressing force which had a share in their origin. One side or the other may be more strongly represented; but it is rarely that one influence is entirely absent. In hysteria a convergence of both intentions in the same symptom is usually achieved. In obsessional neurosis the two portions are often separated; the symptom then becomes diphasic and consists in two actions, one after the other, which cancel each other out.

The influence that provoked this transformation was the acquaintance which he obtained through his mother's agency with the doctrines of religion and with the Bible story. This educational measure had the desired effect. The sadistic-masochistic sexual organization came slowly to an end, the wolf phobia quickly vanished, and, instead of sexuality being repudiated with anxiety, a higher method of suppressing it made its appearance. Piety became the dominant force in the child's life. These victories, however, were not won without struggles, of which his blasphemous thoughts were an indication, and of which the establishment of an obsessive exaggeration of religious ceremonial was the result.
A little reflection was bound to show that it would be impossible to restrict to the provinces of dreams and nervous disorders a view such as this of the life of the human mind. If that view has hit upon a truth, it must apply equally to normal mental events, and even the highest achievements of the human spirit must bear a demonstrable relation to the factors found in pathology - to repression, to the efforts at mastering the unconscious and to the possibilities of satisfying the primitive instincts. There was thus an irresistible temptation and, indeed, a scientific duty, to apply the research methods of psycho-analysis, in regions far remote from its native soil, to the various mental sciences. And indeed psycho-analytic work upon patients itself pointed persistently in the direction of this new task, for it was obvious that the forms assumed by the different neuroses echoed the most highly admired productions of our culture. Thus hysterics are undoubtedly imaginative artists, even if they express their phantasies mimaetically in the main and without considering their intelligibility to other people; the ceremonials and prohibitions of obsessional neurotics drive us to suppose that they have created a private religion of their own; and the delusions of paranoics have an unpalatable external similarity and internal kinship to the systems of our philosophers. It is impossible to escape the conclusion that these patients are, in an asocial fashion, making the very attempts at solving their conflicts and appeasing their pressing needs which, when those attempts are carried out in a fashion that is acceptable to the majority, are known as poetry, religion and philosophy.

To take an instance from another field. It is impossible to escape the impression of the perfect correspondence which can be discovered between the obsessive actions of certain obsessional patients and the religious observances of believers all over the world. Some cases of obsessional neurosis actually behave like a caricature of a private religion, so that it is tempting to liken the official religions to an obsessional neurosis that has been mitigated by becoming universalized. This comparison, which is no doubt highly objectionable to all believers, has nevertheless proved most fruitful psychologically. For psycho-analysis soon discovered in the case of obsessional neurosis what the forces are that struggle with one another in it till their conflicts find a remarkable expression in the ceremonial of obsessive actions. Nothing similar was suspected in the case of religious ceremonial until, by tracing back religious feeling to the relation with the father as its deepest root, it became possible to point to an analogous dynamic situation in that case too. This instance, moreover, may warn the reader that even in its application to non-medical fields psycho-analysis cannot avoid wounding cherished prejudices, touching upon deeply-rooted sensibilities and thus provoking enmities which have an essentially emotional basis.

The chief task during the latency period seems to be the fending-off of the temptation to masturbate. This struggle produces a series of symptoms which appear in a typical fashion in the most different individuals and which in general have the character of a ceremonial. It is a great pity that no one has as yet collected them and systematically analysed them. Being the earliest products of the neurosis they should best be able to shed light on the mechanisms employed in its symptom-formation. They already exhibit the features which will emerge so disastrously if a serious illness follows. They tend to become attached to activities (which would later be carried out almost automatically) such as going to sleep, washing, dressing and walking about; and they tend also to repetition and waste of time. Why this should be so is at present not at all clear; but the sublimation of anal-erotic components plays an unmistakable part in it.
The two techniques I refer to are undoing what has been done and isolating. The first of these has a wide range of application and goes back very far. It is, as it were, negative magic, and endeavours, by means of motor symbolism, to 'blow away' not merely the consequences of some event (or experience or impression) but the event itself. I choose the term 'blow away' advisedly, so as to remind the reader of the part played by this technique not only in neuroses but in magical acts, popular customs and religious ceremonies as well. In obsessional neurosis the technique of undoing what has been done is first met with in the 'diphasic' symptoms, in which one action is cancelled out by a second, so that it is as though neither action had taken place, whereas, in reality, both have. This aim of undoing is the second underlying motive of obsessional ceremonials, the first being to take precautions in order to prevent the occurrence or recurrence of some particular event. The difference between the two is easily seen: the precautionary measures are rational, while trying to get rid of something by 'making it not to have happened' is irrational and in the nature of magic. It is of course to be suspected that the latter is the earlier motive of the two and proceeds from the animistic attitude towards the environment. This endeavour to undo shades off into normal behaviour in the case in which a person decides to regard an event as not having happened. But whereas he will take no direct steps against the event, and will simply pay no further attention to it or its consequences, the neurotic person will try to make the past itself non-existent. He will try to repress it by motor means. The same purpose may perhaps account for the obsession for repeating which is so frequently met with in this neurosis and the carrying out of which serves a number of contradictory intentions at once. When anything has not happened in the desired way it is undone by being repeated in a different way; and thereupon all the motives that exist for lingering over such repetitions come into play as well. As the neurosis proceeds, we often find that the endeavour to undo a traumatic experience is a motive of first-rate importance in the formation of symptoms. We thus unexpectedly discover a new, motor technique of defence, or (as we may say in this case with less inaccuracy) of repression.

We have all found by experience that it is especially difficult for an obsessional neurotic to carry out the fundamental rule of psycho-analysis. His ego is more watchful and makes sharper isolations, probably because of the high degree of tension due to conflict that exists between his super-ego and his id. While he is engaged in thinking, his ego has to keep off too much - the intrusion of unconscious phantasies and the manifestation of ambivalent trends. It must not relax, but is constantly prepared for a struggle. It fortifies this compulsion to concentrate and to isolate by the help of the magical acts of isolation which, in the form of symptoms, grow to be so noticeable and to have so much practical importance for the patient, but which are, of course, useless in themselves and are in the nature of ceremonials.
Why this should be so calls for a rather long reply. First of all, we must sift the facts. In a great number of cases the old determinants of anxiety do really lapse, after having produced neurotic reactions. The phobias of very young children, fears of being alone or in the dark or with strangers - phobias which can almost be called normal - usually pass off later on; the child 'grows out of them', as we say about some other disturbances of childhood. Animal phobias, which are of such frequent occurrence, undergo the same fate and many conversion hysterias of early years find no continuation in later life. Ceremonial actions appear extremely often in the latency period, but only a very small percentage of them develop later into a full obsessional neurosis. In general, so far as we can tell from our observations of town children belonging to the white races and living according to fairly high cultural standards, the neuroses of childhood are in the nature of regular episodes in a child's development, although too little attention is still being paid to them. Signs of childhood neuroses can be detected in all adult neurotics without exception; but by no means all children who show those signs become neurotic in later life. It must be, therefore, that certain determinants of anxiety are relinquished and certain danger-situations lose their significance as the individual becomes more mature. Moreover, some of these danger-situations manage to survive into later times by modifying their determinants of anxiety so as to bring them up to date. Thus, for instance, a man may retain his fear of castration in the guise of a syphilidophobia, after he has come to know that it is no longer customary to castrate people for indulging their sexual lusts, but that, on the other hand, severe diseases may overtake anyone who thus gives way to his instincts. Other determinants of anxiety, such as fear of the super-ego, are destined not to disappear at all but to accompany people throughout their lives. In that case the neurotic will differ from the normal person in that his reactions to the dangers in question will be unduly strong. Finally, being grown-up affords no absolute protection against a return of the original traumatic anxiety-situation. Each individual has in all probability a limit beyond which his mental apparatus fails in its function of mastering the quantities of excitation which require to be disposed of.
In the year 1896 I defined obsessional ideas as 'transformed self-reproaches which have re-emerged from repression and which always relate to some sexual act that was performed with pleasure in childhood'. This definition now seems to me to be open to criticism upon formal grounds, though its component elements are unobjectionable. It was aiming too much at unification, and took as its model the practice of obsessional neurotics themselves, when, with their characteristic liking for indeterminateness, they heap together under the name of 'obsessional ideas' the most heterogeneous psychical structures.² In point of fact, it would be more correct to speak of 'obsessive thinking', and to make it clear that obsessional structures can correspond to every sort of psychical act. They can be classed as wishes, temptations, impulses, reflections, doubts, commands, or prohibitions. Patients endeavour in general to tone down such distinctions and to regard what remains of these psychical acts after they have been deprived of their affective index simply as 'obsessional ideas'. Our present patient gave an example of this type of behaviour in one of his first sessions, when he attempted to reduce a wish to the level of a mere 'train of thought' (p. 2144).

[1909d, 2172]

There are, besides this, two special ways in which a more precise knowledge of obsessional structures can be gained. In the first place, experience shows that an obsessional command (or whatever it may be), which in waking life is known only in a truncated and distorted form, like a mutilated telegraph message, may have its actual text brought to light in a dream. Such texts appear in dreams in the shape of speeches, and are thus an exception to the rule that speeches in dreams are derived from speeches in real life.² Secondly, in the course of the analytic examination of a case history, one becomes convinced that if a number of obsessions succeed one another they are often - even though their wording is not identical - ultimately one and the same. The obsession may have been successfully shaken off on its first appearance, but it comes back a second time in a distorted form and without being recognized, and may then perhaps be able to hold its own in the defensive struggle more effectively, precisely because of its distortion. But the original form is the correct one, and often displays its meaning quite openly. When we have at great pains elucidated an unintelligible obsessional idea, it often happens that the patient informs us that just such a notion, wish, or temptation as the one we have constructed did in fact make its appearance on one occasion before the obsessional idea had arisen, but that it did not persist. It would unfortunately involve us in too lengthy a digression if we were to give instances of this from the history of our present patient.

[1909d, 2174]
Secondary defence against the obsessional ideas may be effected by a forcible diversion on to other thoughts with a content as contrary as possible. This is why *obsessional brooding*, if it succeeds, regularly deals with abstract and *suprasensual* things; because the ideas that have been repressed are always concerned with *sensuality*. Or else the patient tries to make himself master of each of his obsessional ideas singly by logical work and by having recourse to his conscious memories. This leads to *obsessional thinking*, to a *compulsion to test things* and to *doubting mania*. The advantage which perception has over memory in such tests at first causes the patient, and later compels him, to collect and store up all the objects with which he has come into contact. Secondary defence against obsessional *affects* leads to a still wider set of protective measures which are capable of being transformed into obsessional acts. These may be grouped according to their purpose: *penitential* measures (burdensome ceremonials, the observation of numbers), *precautionary* measures (all sorts of phobias, superstition, pedantry, increase of the primary symptom of conscientiousness); measures to do with *fear of betrayal* (collecting scraps of paper, seclusiveness), or to ensure *numbing* (dipsomania). Among these obsessional acts and obsessional impulses, phobias, since they circumscribe the patient's existence, play the greatest part.

[1896b, 393]

People who carry out obsessive actions or ceremonials belong to the same class as those who suffer from obsessive thinking, obsessive ideas, obsessive impulses and the like. Taken together, these form a particular clinical entity, to which the name of 'obsessional neurosis' [*Zwangsneurose*] is customarily applied.¹ But one should not attempt to deduce the character of the illness from its name; for, strictly speaking, other kinds of morbid mental phenomena have an equal claim to possessing what are spoken of as 'obsessional' characteristics. In place of a definition we must for the time being be content with obtaining a detailed knowledge of these states, since we have not yet been able to arrive at a criterion of obsessional neuroses; it probably lies very deep, although we seem to sense its presence everywhere in the manifestations of the illness.

[1907b, 1901]

It must be confessed, moreover, that even the phenomenology of obsessional thinking has not yet had sufficient attention paid to it. During the secondary defensive struggle, which the patient carries on against the 'obsessional ideas' that have forced their way into his consciousness, psychical structures make their appearance which deserve to be given a special name. (Such, for example, were the sequences of thoughts that occupied our patient's mind on his journey back from the manoeuvres.) They are not purely reasonable considerations arising in opposition to the obsessional thoughts, but, as it were, hybrids between the two species of thinking; they accept certain of the premises of the obsession they are combating, and thus, while using the weapons of reason, are established upon a basis of pathological thought. I think such structures as these deserve to be given the name of 'deliria'. To make the distinction clear, I will give an instance, which should be inserted into its proper context in the patient's case history. I have already described the crazy conduct to which he gave way at one time when he was preparing for an examination - how, after working till far into the night, he used to go and open the front door to his father's ghost, and then look at his genitals in the looking-glass (p. 2160). He tried to bring himself to his senses by asking himself what his father would say to it all if he were really still alive. But the argument had no effect so long as it was put forward in this rational shape. The spectre was not laid until he had transformed the same idea into a 'delirious' threat to the effect that if he ever went through this nonsense again some evil would befall his father in the next world.

[1909d, 2173]
I shall not in the present paper attempt any discussion of the psychological significance of obsessional thinking. Such a discussion would be of extraordinary value in its results, and would do more to clarify our ideas upon the nature of the conscious and the unconscious than any study of hysteria or the phenomena of hypnosis. It would be a most desirable thing if the philosophers and psychologists who develop brilliant theoretical views on the unconscious upon a basis of hearsay knowledge or from their own conventional definitions would first submit to the convincing impressions which may be gained from a first-hand study of the phenomena of obsessional thinking. We might almost go to the length of requiring it of them, if the task were not so far more laborious than the methods of work to which they are accustomed. I will only add here that in obsessional neuroses the unconscious mental processes occasionally break through into consciousness in their pure and undistorted form, that such incursions may take place at every possible stage of the unconscious process of thought, and that at the moment of the incursion the obsessional ideas can, for the most part, be recognized as formations of very long standing. This accounts for the striking circumstance that, when the analyst tries, with the patient's help, to discover the date of the first occurrence of an obsessional idea, the patient is obliged to place it further and further back as the analysis proceeds, and is constantly finding fresh 'first' occasions for the appearance of the obsession.

Our patient was to a high degree superstitious, and this although he was a highly educated and enlightened man of considerable acumen, and although he was able at times to assure me that he did not believe a word of all this rubbish. Thus he was at once superstitious and not superstitious; and there was a clear distinction between his attitude and the superstition of uneducated people who feel themselves at one with their belief. He seemed to understand that his superstition was dependent upon his obsessional thinking, although at times he gave way to it completely. The meaning of this inconsistent and vacillating behaviour can be most easily grasped if it is regarded in the light of a hypothesis which I shall now proceed to mention. I did not hesitate to assume that the truth was not that the patient still had an open mind upon this subject, but that he had two separate and contradictory convictions upon it. His oscillation between these two views quite obviously depended upon his momentary attitude towards his obsessional disorder. As soon as he had got the better of one of these obsessions, he used to smile in a superior way at his own credulity, and no events then occurred that were calculated to shake his firmness; but the moment he came under the sway of another obsession which had not been cleared up - or, what amounts to the same thing, of a resistance - the strangest coincidences would happen, to support him in his credulous belief.

Furthermore, by a sort of regression, preparatory acts become substituted for the final decision, thinking replaces acting, and, instead of the substitutive act, some thought preliminary to it asserts itself with all the force of compulsion. According as this regression from acting to thinking is more or less marked, a case of obsessional neurosis will exhibit the characteristics of obsessive thinking (that is, of obsessional ideas) or of obsessive acting in the narrower sense of the word. True obsessional acts such as these, however, are only made possible because they constitute a kind of reconciliation, in the shape of a compromise, between the two antagonistic impulses. For obsessional acts tend to approximate more and more - and the longer the disorder lasts the more evident does this become - to infantile sexual acts of a masturbatory character. Thus in this form of the neurosis acts of love are carried out in spite of everything, but only by the aid of a new kind of regression; for such acts no longer relate to another person, the object of love and hatred, but are auto-erotic acts such as occur in infancy.
The first kind of regression, that from acting to thinking, is facilitated by another factor concerned in the production of the neurosis. The histories of obsessional patients almost invariably reveal an early development and premature repression of the sexual instinct of looking and knowing; and, as we know, a part of the infantile sexual activity of our present patient was governed by that instinct.¹

We have already mentioned the important part played by the sadistic instinctual components in the genesis of obsessional neuroses. Where the epistemophilic instinct is a preponderant feature in the constitution of an obsessional patient, brooding becomes the principal symptom of the neurosis. The thought-process itself becomes sexualized, for the sexual pleasure which is normally attached to the content of thought becomes shifted on to the act of thinking itself, and the satisfaction derived from reaching the conclusion of a line of thought is experienced as a sexual satisfaction. In the various forms of obsessional neurosis in which the epistemophilic instinct plays a part, its relation to thought-processes makes it particularly well adapted to attract the energy which is vainly endeavouring to make its way forward into action, and divert it into the sphere of thought, where there is a possibility of its obtaining pleasurable satisfaction of another sort. In this way, with the help of the epistemophilic instinct, the substitutive act may in its turn be replaced by preparatory acts of thought. But procrastination in action is soon replaced by lingering over thoughts, and eventually the whole process, together with all its peculiarities, is transferred into the new sphere, just as in America an entire house will sometimes be shifted from one site to another.

The obsessive thought which has forced its way into consciousness with such excessive violence has next to be secured against the efforts made by conscious thought to resolve it. As we already know, this protection is afforded by the distortion which the obsessive thought has undergone before becoming conscious. But this is not the only means employed. In addition, each separate obsessional idea is almost invariably removed from the situation in which it originated and in which, in spite of its distortion, it would be most easily comprehensible. With this end in view, in the first place an interval of time is inserted between the pathogenic situation and the obsession that arises from it, so as to lead astray any conscious investigation of its causal connections, and in the second place the content of the obsession is taken out of its particular setting by being generalized. Our patient's 'obsession for understanding' is an example of this (p. 2150). But perhaps a better one is afforded by another patient. This was a woman who prohibited herself from wearing any sort of personal adornment, though the exciting cause of the prohibition related only to one particular piece of jewellery: she had envied her mother the possession of it and had had hopes that one day she would inherit it. Finally, if we care to distinguish verbal distortion from distortion of content, there is yet another means by which the obsession is protected against conscious attempts at solution. And that is the choice of an indefinite or ambiguous wording. After being misunderstood, the wording may find its way into the patient's 'deliria', and whatever further processes of development or substitution his obsession undergoes will then be based upon the misunderstanding and not upon the proper sense of the text. Observation will show, however, that the deliria constantly tend to form new connections with that part of the matter and wording of the obsession which is not present in consciousness.

[1909d, 2191, 2192]
Thus in the case of Schreber we find ourselves once again on the familiar ground of the father-complex. The patient's struggle with Flechsig became revealed to him as a conflict with God, and we must therefore construe it as an infantile conflict with the father whom he loved; the details of that conflict (of which we know nothing) are what determined the content of his delusions. None of the material which in other cases of the sort is brought to light by analysis is absent in the present one: every element is hinted at in one way or another. In infantile experiences such as this the father appears as an interferer with the satisfaction which the child is trying to obtain; this is usually of an auto-erotic character, though at a later date it is often replaced in phantasy by some other satisfaction of a less inglorious kind. In the final stage of Schreber's delusion a magnificent victory was scored by the infantile sexual urge; for voluptuousness became God-fearing, and God Himself (his father) never tired of demanding it from him. His father's most dreaded threat, castration, actually provided the material for his wishful phantasy (at first resisted but later accepted) of being transformed into a woman. His allusion to an offence covered by the surrogate idea 'soul-murder' could not be more transparent. The chief attendant was discovered to be identical with his neighbour von W., who, according to the voices, had falsely accused him of masturbation (108). The voices said, as though giving grounds for the threat of castration: 'For you are to be represented as being given over to voluptuous excesses.' Finally, we come to the enforced thinking (47) to which the patient submitted himself because he supposed that God would believe he had become an idiot and would withdraw from him if he ceased thinking for a moment. This is a reaction (with which we are also familiar in other connections) to the threat or fear of losing one's reason as a result of indulging in sexual practices and especially in masturbation. Considering the enormous number of delusional ideas of a hypochondriacal nature which the patient developed, no great importance should perhaps be attached to the fact that some of them coincide word for word with the hypochondriacal fears of masturbators.

The secondary revision of the product of the dream-work is an admirable example of the nature and pretensions of a system. There is an intellectual function in us which demands unity, connection and intelligibility from any material, whether of perception or thought, that comes within its grasp; and if, as a result of special circumstances, it is unable to establish a true connection, it does not hesitate to fabricate a false one. Systems constructed in this way are known to us not only from dreams, but also from phobias, from obsessive thinking and from delusions. The construction of systems is seen most strikingly in delusional disorders (in paranoia), where it dominates the symptomatic picture; but its occurrence in other forms of neuro-psychosis must not be overlooked. In all these cases it can be shown that a rearrangement of the psychical material has been made with a fresh aim in view; and the rearrangement may often have to be a drastic one if the outcome is to be made to appear intelligible from the point of view of the system. Thus a system is best characterized by the fact that at least two reasons can be discovered for each of its products: a reason based upon the premises of the system (a reason, then, which may be delusional) and a concealed reason, which we must judge to be the truly operative and the real one.

In the course of these struggles we come across two activities of the ego which form symptoms and which deserve special attention because they are obviously surrogates of repression and therefore well calculated to illustrate its purpose and technique. The fact that such auxiliary and substitutive techniques emerge may argue that true repression has met with difficulties in its functioning. If one considers how much more the ego is the scene of action of symptom-formation in obsessional neurosis than it is in hysteria and with what tenacity the ego clings to its relations to reality and to consciousness, employing all its intellectual faculties to that end - and indeed how the very process of thinking becomes hypercathexed and erotized - then one may perhaps come to a better understanding of these variations of repression.
A patient, then, may be suffering from fluctuations in his moods which he cannot control, or from a sense of despondency by which his energy feels paralysed because he thinks he is incapable of doing anything properly, or from a nervous embarrassment among strangers. He may perceive, without understanding the reason for it, that he has difficulties in carrying out his professional work, or indeed any comparatively important decision or any undertaking. He may one day have suffered from a distressing attack - unknown in its origin - of feelings of anxiety, and since then have been unable, without a struggle, to walk along the street alone, or to travel by train; he may perhaps have had to give up both entirely. Or, a very remarkable thing, his thoughts may go their own way and refuse to be directed by his will. They pursue problems that are quite indifferent to him, but from which he cannot get free. Quite ludicrous tasks, too, are imposed on him, such as counting up the windows on the fronts of houses. And when he has performed simple actions such as posting a letter or turning off a gas-jet, he finds himself a moment later doubting whether he has really done so. This may be no more than an annoyance and a nuisance. But his state becomes intolerable if he suddenly finds he is unable to fend off the idea that he has pushed a child under the wheels of a car or has thrown a stranger off the bridge into the water, or if he has to ask himself whether he is not the murderer whom the police are looking for in connection with a crime that was discovered that day. It is obvious nonsense, as he himself knows; he has never done any harm to anyone; but if he were really the murderer who is being looked for, his feeling - his sense of guilt - could not be stronger.

The source of our findings does not seem it me to deprive them of their value. Embryology, to take an example, would not deserve to be trusted if it could not give a plain explanation of the origin of innate malformations. I have told you of people whose thoughts go their own way, so that they are obliged to worry over problems to which they are perfectly indifferent. Do you think that academic psychology could ever make the smallest contribution towards explaining an abnormality such as that? And, after all, we all of us have the experience at night-time of our thoughts going their own way and creating things which we do not understand, which puzzle us, and which are suspiciously reminiscent of pathological products. Our dreams, I mean. The common people have always firmly believed that dreams have a sense and a value - that they mean something. Academic psychology has never been able to inform us what this meaning is. It could make nothing of dreams. If it attempted to produce explanations, they were non-psychological - such as tracing them to sensory stimuli, or to an unequal depth of sleep in different portions of the brain, and so on. But it is fair to say that a psychology which cannot explain dreams is also useless for an understanding of normal mental life, that it has no claim to be called a science.
A train of thought such as this may be described as excessively intense, or better reinforced, or 'supervalent' ['überwertig'] in Wernicke's sense. It shows its pathological character in spite of its apparently reasonable content, by the single peculiarity that no amount of conscious and voluntary effort of thought on the patient's part is able to dissipate or remove it. A normal train of thought, however intense it may be, can eventually be disposed of. Dora felt quite rightly that her thoughts about her father required to be judged in a special way. 'I can think of nothing else', she complained again and again. 'I know my brother says we children have no right to criticize this behaviour of Father's. He declares that we ought not to trouble ourselves about it, and ought even to be glad, perhaps, that he has found a woman he can love, since Mother understands him so little. I can quite see that, and I should like to think the same as my brother, but I can't. I can't forgive him for it.'¹

[1905e, 1391]

Now what is one to do in the face of a supervalent thought like this, after one has heard what its conscious grounds are and listened to the ineffectual protests made against it? Reflection will suggest that this excessively intense train of thought must owe its reinforcement to the unconscious. It cannot be resolved by any effort of thought, either because it itself reaches with its root down into unconscious, repressed material, or because another unconscious thought lies concealed behind it. In the latter case, the concealed thought is usually the direct contrary of the supervalent one. Contrary thoughts are always closely connected with each other and are often paired off in such a way that the one thought is excessively intensely conscious while its counterpart is repressed and unconscious. This relation between the two thoughts is an effect of the process of repression. For repression is often achieved by means of an excessive reinforcement of the thought contrary to the one which is to be repressed. This process I call reactive reinforcement, and the thought which asserts itself with excessive intensity in consciousness and (in the same way as a prejudice) cannot be removed I call a reactive thought. The two thoughts then act towards each other much like the two needles of an astatic galvanometer. The reactive thought keeps the objectionable one under repression by means of a certain surplus of intensity; but for that reason it itself is 'damped' and proof against conscious efforts of thought. So that the way to deprive the excessively intense thought of its reinforcement is by bringing its repressed contrary into consciousness.

[1905e, 1391]

We must also be prepared to meet with instances in which the supervalence of a thought is due not to the presence of one only of these two causes but to a concurrence of both of them. Other complications, too, may arise, but they can easily be fitted into the general scheme. [1905e, 1392]
At the next session the patient showed great interest in what I had said, but ventured, so he told me, to bring for ward a few doubts. - How, he asked, could the information that the self-reproach, the sense of guilt, was justified have a therapeutic effect? - I explained that it was not the information that had this effect, but the discovery of the unknown content to which the self-reproach was really attached. - Yes, he said, that was the precise point to which his question had been directed. - I then made some short observations upon the psychological differences between the conscious and the unconscious, and upon the fact that everything conscious was subject to a process of wearing-away, while what was unconscious was relatively unchangeable; and I illustrated my remarks by pointing to the antiques standing about in my room. They were, in fact, I said, only objects found in a tomb, and their burial had been their preservation: the destruction of Pompeii was only beginning now that it had been dug up. - Was there any guarantee, he next enquired, of what one's attitude would be towards what was discovered? One man, he thought, would no doubt behave in such a way as to get the better of his self-reproach, but another would not. - No, I said, it followed from the nature of the circumstances that in every case the affect would be overcome - for the most part during the progress of the work itself. Every effort was made to preserve Pompeii, whereas people were anxious to be rid of tormenting ideas like his. - He had said to himself, he went on, that a self-reproach could only arise from a breach of a person's own inner moral principles and not from that of any external ones. - I agreed, and said that the man who merely breaks an external law often regards himself as a hero. - Such an occurrence, he continued, was thus only possible where a disintegration of the personality was already present. Was there a possibility of his effecting a reintegration of his personality? If this could be done, he thought he would be able to make a success of his life, perhaps more of one than most people. - I replied that I was in complete agreement with this notion of a splitting of his personality. He had only to assimilate this new contrast, between a moral self and an evil one, with the contrast I had already mentioned, between the conscious and the unconscious. The moral self was the conscious, the evil self was the unconscious.¹ - He then said that, though he considered himself a moral person, he could quite definitely remember having done things in his childhood which came from his other self. - I remarked that here he had incidentally hit upon one of the chief characteristics of the unconscious, namely, its relation to the infantile. The unconscious, I explained, was the infantile; it was that part of the self which had become separated off from it in infancy, which had not shared the later stages of its development, and which had in consequence become repressed. It was the derivatives of this repressed unconscious that were responsible for the involuntary thoughts which constituted his illness. He might now, I added, discover yet another characteristic of the unconscious; it was a discovery which I should be glad to let him make for himself. - He found nothing more to say in this immediate connection, but instead he expressed a doubt whether it was possible to undo modifications of such long standing. What, in particular, could be done against his idea about the next world, for it could not be refuted by logic? - I told him I did not dispute the gravity of his case nor the significance of his pathological constructions; but at the same time his youth was very much in his favour as well as the intactness of his personality. In this connection I said a word or two upon the good opinion I had formed of him, and this gave him visible pleasure.

[1909d, 2143]
The technique of distortion by ellipsis seems to be typical of obsessional neuroses; I have come across it in the obsessional thoughts of other patients as well. One example, a particularly transparent one, is of especial interest on account of a certain structural similarity with the rat idea. It was a case of doubting, and occurred in a lady who suffers principally from obsessional acts. This lady was going for a walk with her husband in Nuremberg, and made him take her into a shop, where she purchased various objects for her child and amongst them a comb. Her husband, finding that the shopping was too long a business for his taste, said that he had noticed some coins in an antique shop on the way which he was anxious to secure, adding that after he had made his purchase he would come and fetch her in the shop in which they at present were. But he stayed away, as she thought, far too long. When he came back she accordingly asked him where he had been. 'Why,' he replied, 'at the antique shop I told you about.' At the same instant she was seized by a tormenting doubt whether she had not as a matter of fact always possessed the comb which she had just bought for her child. She was naturally quite unable to discover the simple mental link that was involved. There is nothing for it but to regard the doubt as having become displaced, and to reconstruct the complete chain of unconscious thoughts as follows: 'If it is true that you were only at the antique shop, if I am really to believe that, then I may just as well believe that this comb that I bought a moment ago has been in my possession for years.' Here, therefore, the lady was drawing a derisive and ironical parallel, just as when our patient thought: 'Oh yes, as sure as those two' (his father and the lady) 'will have children, I shall pay back the money to A.' In the lady's case the doubt was dependent upon her unconscious jealousy, which led her to suppose that her husband had spent the interval of his absence in paying a visit of gallantry.

If we wish to obtain a grasp of the psychical forces whose interplay built up this neurosis, we must turn back to what we have learnt from the patient on the subject of the precipitating causes of his falling ill as a grown-up man and as a child. He fell ill when he was in his twenties on being faced with a temptation to marry another woman instead of the one whom he had loved so long; and he avoided a decision of this conflict by postponing all the necessary preliminary actions. The means for doing this was given him by his neurosis. His hesitation between the lady he loved and the other girl can be reduced to a conflict between his father's influence and his love for his lady, or, in other words, to a conflicting choice between his father and his sexual object, such as had already subsisted (judging from his recollections and obsessional ideas) in his remote childhood. All through his life, moreover, he was unmistakably victim to a conflict between love and hatred, in regard both to his lady and to his father. His phantasies of revenge and such obsessional phenomena as his obsession for understanding and his exploit with the stone in the road bore witness to his divided feelings; and they were to a certain degree comprehensible and normal, for the lady by her original refusal and subsequently by her coolness had given him some excuse for hostility. But his relations with his father were dominated by a similar division of feeling, as we have seen from our translation of his obsessional thoughts; and his father, too, must have given him an excuse for hostility in his childhood, as indeed we have been able to establish almost beyond question. His attitude towards the lady - a compound of tenderness and hostility - came to a great extent within the scope of his conscious knowledge; at most he deceived himself over the degree and violence of his negative feelings. But his hostility towards his father, on the contrary, though he had once been acutely conscious of it, had long since vanished from his ken, and it was only in the teeth of the most violent resistance that it could be brought back into his consciousness. We may regard the repression of his infantile hatred of his father as the event which brought his whole subsequent career under the dominion of the neurosis.

[1909d, 2177]

[1909d, 2185]
The obsessive thought which has forced its way into consciousness with such excessive violence has next to be secured against the efforts made by conscious thought to resolve it. As we already know, this protection is afforded by the distortion which the obsessive thought has undergone before becoming conscious. But this is not the only means employed. In addition, each separate obsessional idea is almost invariably removed from the situation in which it originated and in which, in spite of its distortion, it would be most easily comprehensible. With this end in view, in the first place an interval of time is inserted between the pathogenic situation and the obsession that arises from it, so as to lead astray any conscious investigation of its causal connections, and in the second place the content of the obsession is taken out of its particular setting by being generalized. Our patient's 'obsession for understanding' is an example of this (p. 2150). But perhaps a better one is afforded by another patient. This was a woman who prohibited herself from wearing any sort of personal adornment, though the exciting cause of the prohibition related only to one particular piece of jewellery: she had envied her mother the possession of it and had had hopes that one day she would inherit it. Finally, if we care to distinguish verbal distortion from distortion of content, there is yet another means by which the obsession is protected against conscious attempts at solution. And that is the choice of an indefinite or ambiguous wording. After being misunderstood, the wording may find its way into the patient's 'deliria', and whatever further processes of development or substitution his obsession undergoes will then be based upon the misunderstanding and not upon the proper sense of the text. Observation will show, however, that the deliria constantly tend to form new connections with that part of the matter and wording of the obsession which is not present in consciousness.

In certain diseases - including the very neuroses of which we have made special study - things are different. The ego feels uneasy; it comes up against limits to its power in its own house, the mind. Thoughts emerge suddenly without one's knowing where they come from, nor can one do anything to drive them away. These alien guests even seem to be more powerful than those which are at the ego's command. They resist all the well-proved measures of enforcement used by the will, remain unmoved by logical refutation, and are unaffected by the contradictory assertions of reality. Or else impulses appear which seem like those of a stranger, so that the ego disowns them; yet it has to fear them and take precautions against them. The ego says to itself: 'This is an illness, a foreign invasion.' It increases its vigilance, but cannot understand why it feels so strangely paralysed.

The source of our findings does not seem it me to deprive them of their value. Embryology, to take an example, would not deserve to be trusted if it could not give a plain explanation of the origin of innate malformations. I have told you of people whose thoughts go their own way, so that they are obliged to worry over problems to which they are perfectly indifferent. Do you think that academic psychology could ever make the smallest contribution towards explaining an abnormality such as that? And, after all, we all of us have the experience at night-time of our thoughts going their own way and creating things which we do not understand, which puzzle us, and which are suspiciously reminiscent of pathological products. Our dreams, I mean. The common people have always firmly believed that dreams have a sense and a value - that they mean something. Academic psychology has never been able to inform us what this meaning is. It could make nothing of dreams. If it attempted to produce explanations, they were non-psychological - such as tracing them to sensory stimuli, or to an unequal depth of sleep in different portions of the brain, and so on. But it is fair to say that a psychology which cannot explain dreams is also useless for an understanding of normal mental life, that it has no claim to be called a science.
As in the case of taboo, the principal prohibition, the nucleus of the neurosis, is against touching; and thence it is sometimes known as 'touching phobia' or 'délire du toucher'. The prohibition does not merely apply to immediate physical contact but has an extent as wide as the metaphorical use of the phrase 'to come in contact with'. Anything that directs the patient's thoughts to the forbidden object, anything that brings him into intellectual contact with it, is just as much prohibited as direct physical contact. This same extension also occurs in the case of taboo.
[1912-1913, 2675]

The purpose of some of the prohibitions is immediately obvious. Others, on the contrary, strike us as incomprehensible, senseless and silly, and prohibitions of this latter sort are described as 'ceremonial'. This distinction, too, is found in the observances of taboo.
[1912-1913, 2675]

Now both the clinical history and the psychical mechanism of obsessional neurosis have become known to us through psycho-analysis. The clinical history of a typical case of 'touching phobia' is as follows. Right at the beginning, in very early childhood, the patient shows a strong desire to touch, the aim of which is of a far more specialized kind that one would have been inclined to expect. This desire is promptly met by an external prohibition against carrying out that particular kind of touching.¹ The prohibition is accepted, since it finds support from powerful internal forces,² and proves stronger than the instinct which is seeking to express itself in the touching. In consequence, however, of the child's primitive psychical constitution, the prohibition does not succeed in abolishing the instinct. Its only result is to repress the instinct (the desire to touch) and banish it into the unconscious. Both the prohibition and the instinct persist: the instinct because it has only been repressed and not abolished, and the prohibition because, if it ceased, the instinct would force its way through into consciousness and into actual operation. A situation is created which remains undealt with - a psychical fixation - and everything else follows from the continuing conflict between the prohibition and the instinct.
[1912-1913, 2677]

It is equally clear why it is that the violation of certain taboo prohibitions constitutes a social danger which must be punished or atoned for by all the members of the community if they are not all to suffer injury. If we replace the unconscious desires by conscious impulses we shall see that the danger is a real one. It lies in the risk of imitation, which would quickly lead to the dissolution of the community. If the violation were not avenged by the other members they would become aware that they wanted to act in the same way as the transgressor. We cannot be surprised at the fact that, in the restrictions of taboo, touching plays a part similar to the one which it plays in 'touching phobias', though the secret meaning of the prohibition cannot be of such a specialized nature in taboo as it is in the neurosis. Touching is the first step towards obtaining any sort of control over, or attempting to make use of, a person or object.
[1912-1913, 2681]
I do not propose to linger over the origin of these social impulses and their relation to the other basic human instincts but shall proceed to illustrate the second main characteristic of the neurosis by means of another example. In the forms which it assumes, taboo very closely resembles the neurotic's fear of touching, his 'touching phobia'. Now, in the case of the neurosis the prohibition invariably relates to touching of a sexual kind, and psycho-analysis has shown that it is in general true that the instinctual forces that are diverted and displaced in neuroses have a sexual origin. In the case of taboo the prohibited touching is obviously not to be understood in an exclusively sexual sense but in the more general sense of attacking, of getting control, and of asserting oneself. If there is a prohibition against touching a chief or anything that has been in contact with him, this means that an inhibition is to be laid on the same impulse which expresses itself on other occasions in keeping a suspicious watch upon the chief or even in ill-treating him physically before his coronation. (See above.) Thus the fact which is characteristic of the neurosis is the preponderance of the sexual over the social instinctual elements. The social instincts, however, are themselves derived from a combination of egoistic and erotic components into wholes of a special kind.

[1912-1913, 2716]

I am to put before you, then, the psycho-analytic view of the phenomena of neurosis. In doing so, the best plan would seem to be to make a start in connection with the phenomena we have already dealt with, for the sake both of analogy and contrast; and I will begin with a symptomatic action which I have seen many people perform during my consulting hours. We analysts cannot do much for the people who come to us in our consulting-room to lay before us in a quarter of an hour the miseries of a long lifetime. Our deeper knowledge makes it difficult for us to give the kind of opinion another doctor would - 'There's nothing wrong with you' - with the added advice: 'You should arrange for a mild hydropathic treatment.' One of my colleagues who was asked what he did with his consultation patients shrugged his shoulders and replied: 'I fine them so-and-so many Kronen for a frivolous waste of time.' So you will not be surprised to hear that even in the case of busy psycho-analysts their consulting hours are not apt to be very lively. I have had the ordinary door between my waiting-room and my consulting- and treatment-room doubled and given a baize lining. There can be no doubt about the purpose of this arrangement. Now it constantly happens that a person whom I have brought in from the waiting-room omits to shut the door behind him and almost always he leaves both doors open. As soon as I notice this I insist in a rather unfriendly tone on his or her going back and making good the omission even if the person concerned is a well-dressed gentleman or a fashionable lady. This makes an impression of uncalled-for pedantry. Occasionally, too, I have put myself in a foolish position by making this request when it has turned out to be a person who cannot touch a door-handle himself and is glad if someone with him spares him the necessity. But in the majority of cases I have been right; for anyone who behaves like this and leaves the door open between a doctor's waiting-room and consulting-room is ill-mannered and deserves an unfriendly reception. But do not take sides over this till you have heard the sequel. For this carelessness on the part of the patient only occurs when he has been alone in the waiting-room and has therefore left an empty room behind him; it never happens if other people, strangers to him, have been waiting with him. In this latter case he knows quite well that it is in his interest not to be overheard while he is talking to the doctor, and he never fails to shut both the doors carefully.

[1916-1917, 3329]
But in thus endeavouring to prevent associations and connections of thought, the ego is obeying one of the oldest and most fundamental commands of obsessional neurosis, the taboo on touching. If we ask ourselves why the avoidance of touching, contact or contagion should play such a large part in this neurosis and should become the subject-matter of complicated systems, the answer is that touching and physical contact are the immediate aim of the aggressive as well as the loving object-cathexes. Eros desires contact because it strives to make the ego and the loved object one, to abolish all spatial barriers between them. But destructiveness, too, which (before the invention of long-range weapons) could only take effect at close quarters, must presuppose physical contact, a coming to grips. To 'touch' a woman has become a euphemism for using her as a sexual object. Not to 'touch' one’s genitals is the phrase employed for forbidding auto-erotic satisfaction. Since obsessional neurosis begins by persecuting erotic touching and then, after regression has taken place, goes on to persecute touching in the guise of aggressiveness, it follows that nothing is so strongly proscribed in that illness as touching nor so well suited to become the central point of a system of prohibitions. But isolating is removing the possibility of contact; it is a method of withdrawing a thing from being touched in any way. And when a neurotic isolates an impression or an activity by interpolating an interval, he is letting it be understood symbolically that he will not allow his thoughts about that impression or activity to come into associative contact with other thoughts. [1926d, 4280]
In the year 1896 I defined obsessional ideas as 'transformed self-reproaches which have re-emerged from repression and which always relate to some sexual act that was performed with pleasure in childhood'. This definition now seems to me to be open to criticism upon formal grounds, though its component elements are unobjectionable. It was aiming too much at unification, and took as its model the practice of obsessional neurotics themselves, when, with their characteristic liking for indeterminateness, they heap together under the name of 'obsessional ideas' the most heterogeneous psychical structures.² In point of fact, it would be more correct to speak of 'obsessive thinking', and to make it clear that obsessional structures can correspond to every sort of psychical act. They can be classed as wishes, temptations, impulses, reflections, doubts, commands, or prohibitions. Patients endeavour in general to tone down such distinctions and to regard what remains of these psychical acts after they have been deprived of their affective index simply as 'obsessional ideas'. Our present patient gave an example of this type of behaviour in one of his first sessions, when he attempted to reduce a wish to the level of a mere 'train of thought' (p. 2144).
[1909d, 2172]

There are, besides this, two special ways in which a more precise knowledge of obsessional structures can be gained. In the first place, experience shows that an obsessional command (or whatever it may be), which in waking life is known only in a truncated and distorted form, like a mutilated telegraph message, may have its actual text brought to light in a dream. Such texts appear in dreams in the shape of speeches, and are thus an exception to the rule that speeches in dreams are derived from speeches in real life.² Secondly, in the course of the analytic examination of a case history, one becomes convinced that if a number of obsessions succeed one another they are often - even though their wording is not identical - ultimately one and the same. The obsession may have been successfully shaken off on its first appearance, but it comes back a second time in a distorted form and without being recognized, and may then perhaps be able to hold its own in the defensive struggle more effectively, precisely because of its distortion. But the original form is the correct one, and often displays its meaning quite openly. When we have at great pains elucidated an unintelligible obsessional idea, it often happens that the patient informs us that just such a notion, wish, or temptation as the one we have constructed did in fact make its appearance on one occasion before the obsessional idea had arisen, but that it did not persist. It would unfortunately involve us in too lengthy a digression if we were to give instances of this from the history of our present patient.
[1909d, 2174]
For instance, one of the patient's oldest and favourite obsessions (which corresponded to an admonition or warning) ran as follows: 'If I marry the lady, some misfortune will befall my father (in the next world).’ If we insert the intermediate steps, which had been skipped but were known to us from the analysis, we get the following train of thought: 'If my father were alive, he would be as furious over my design of marrying the lady as he was in the scene in my childhood; so that I should fly into a rage with him once more and wish him every possible evil; and thanks to the omnipotence of my wishes¹ these evils would be bound to come upon him.'

[1909d, 2176]

In obsessional neuroses the uncertainty of memory is used to the fullest extent as a help in the formation of symptoms; and we shall learn directly the part played in the actual content of the patients' thoughts by the questions of length of life and life after death. But as an appropriate transition I will first consider one particular superstitious trait in our patient to which I have already alluded (p. 2176) and which will no doubt have puzzled more than one of my readers.

[1909d, 2183]

I refer to the omnipotence which he ascribed to his thoughts and feelings, and to his wishes, whether good or evil. It is, I must admit, decidedly tempting to declare that this idea was a delusion and that it oversteps the limits of obsessional neurosis. I have, however, come across the same conviction in another obsessional patient; and he was long ago restored to health and is leading a normal life. Indeed, all obsessional neurotics behave as though they shared this conviction. It will be our business to throw some light upon these patients' over-estimation of their powers. Assuming, without more ado, that this belief is a frank acknowledgement of a relic of the old megalomania of infancy, we will proceed to ask our patient for the grounds of his conviction. In reply, he adduces two experiences. When he returned for a second visit to the hydropathic establishment at which his disorder had been relieved for the first and only time, he asked to be given his old room, for its position had facilitated his relations with one of the nurses. He was told that the room was already taken and that it was occupied by an old professor. This piece of news considerably diminished his prospects of successful treatment, and he reacted to it with the unamiable thought: 'I wish he may be struck dead for it!' A fortnight later he was woken up from his sleep by the disturbing idea of a corpse; and in the morning he heard that the professor had really had a stroke, and that he had been carried up into his room at about the time he himself had woken up. The second experience related to an unmarried woman, no longer young, though with a great desire to be loved, who had paid him a great deal of attention and had once asked him point blank whether he could not love her. He had given her an evasive answer. A few days afterwards he heard that she had thrown herself out of a window. He then began to reproach himself, and said to himself that it would have been in his power to save her life by giving her his love. In this way he became convinced of the omnipotence of his love and of his hatred. Without denying the omnipotence of love we may point out that both these instances were concerned with death, and we may adopt the obvious explanation that, like other obsessional neurotics, our patient was compelled to overestimate the effects of his hostile feelings upon the external world, because a large part of their internal, mental effects escaped his conscious knowledge. His love - or rather his hatred - was in truth overpowering; it was precisely they that created the obsessional thoughts, of which he could not understand the origin and against which he strove in vain to defend himself.¹

[1909d, 2183]

¹ [Footnote added 1923:] The omnipotence of thoughts, or, more accurately speaking, of wishes, has since been recognized as an essential element in the mental life of primitive people. See Totem and Taboo (1912-13).

[1909d, 2183]
By way of summary, then, it may be said that the principle governing magic, the technique of the animistic mode of thinking, is the principle of the 'omnipotence of thoughts'.

[1912-1913, 2728]

I have adopted the term 'omnipotence of thoughts' from a highly intelligent man who suffered from obsessional ideas and who, after having been set right by psycho-analytic treatment, was able to give evidence of his efficiency and good sense. (Cf. Freud, 1909d.) He had coined the phrase as an explanation of all the strange and uncanny events by which he, like others afflicted with the same illness, seemed to be pursued. If he thought of someone, he would be sure to meet that very person immediately afterwards, as though by magic. If he suddenly asked after the health of an acquaintance whom he had not seen for a long time, he would hear that he had just died, so that it would look as though a telepathic message had arrived from him. If, without any really serious intention, he swore at some stranger, he might be sure that the man would die soon afterwards, so that he would feel responsible for his death. In the course of the treatment he himself was able to tell me how the deceptive appearance arose in most of these cases, and by what contrivances he himself had helped to strengthen his own superstitious beliefs. All obsessional neurotics are superstitious in this way, usually against their better judgement.¹

[1912-1913, 2728]

¹ We appear to attribute an 'uncanny' quality to impressions that seek to confirm the omnipotence of thoughts and the animistic mode of thinking in general, after we have reached a stage at which, in our judgement, we have abandoned such beliefs.

[1912-1913, 2728]
