It is in obsessional neuroses that the survival of the omnipotence of thoughts is most clearly visible and that the consequences of this primitive mode of thinking come closest to consciousness. But we must not be misled into supposing that it is a distinguishing feature of this particular neurosis, for analytic investigation reveals the same thing in the other neuroses as well. In all of them what determines the formation of symptoms is the reality not of experience but of thought. Neurotics live in a world apart, where, as I have said elsewhere, only 'neurotic currency' is legal tender; that is to say, they are only affected by what is thought with intensity and pictured with emotion, whereas agreement with external reality is a matter of no importance. What hysterics repeat in their attacks and fix by means of their symptoms are experiences which have occurred in that form only in their imagination though it is true that in the last resort those imagined experiences go back to actual events or are based upon them. To attribute the neurotic sense of guilt to real misdeeds would show an equal misunderstanding. An obsessional neurotic may be weighed down by a sense of guilt that would be appropriate in a mass-murderer, while in fact, from his childhood onwards, he has behaved to his fellow-men as the most considerate and scrupulous member of society. Nevertheless, his sense of guilt has a justification: it is founded on the intense and frequent death wishes against his fellows which are unconsciously at work in him. It has a justification if what we take into account are unconscious thoughts and not intentional deeds. Thus the omnipotence of thoughts, the overvaluation of mental processes as compared with reality, is seen to have unrestricted play in the emotional life of neurotic patients and in everything that derives from it. If one of them undergoes psycho-analytic treatment, which makes what is unconscious in him conscious, he will be unable to believe that thoughts are free and will constantly be afraid of expressing evil wishes, as though their expression would lead inevitably to their fulfilment. This behaviour, as well as the superstitions which he practises in ordinary life, reveals his resemblance to the savages who believe they can alter the external world by mere thinking.

[1912-1913, 2729]
If we are prepared to accept the account given above of the evolution of human views of the universe - an animistic phase followed by a religious phase and this in turn by a scientific one - it will not be difficult to follow the vicissitudes of the 'omnipotence of thoughts' through these different phases. At the animistic stage men ascribe omnipotence to themselves. At the religious stage they transfer it to the gods but do not seriously abandon it themselves, for they reserve the power of influencing the gods in a variety of ways according to their wishes. The scientific view of the universe no longer affords any room for human omnipotence; men have acknowledged their smallness and submitted resignedly to death and to the other necessities of nature. None the less some of the primitive belief in omnipotence still survives in men's faith in the power of the human mind, which grapples with the laws of reality.

[1912-1913, 2731]

Primitive men and neurotics, as we have seen, attach a high valuation - in our eyes an over-valuation - to psychical acts. This attitude may plausibly be brought into relation with narcissism and regarded as an essential component of it. It may be said that in primitive men the process of thinking is still to a great extent sexualized. This is the origin of their belief in the omnipotence of thoughts, their unshakable confidence in the possibility of controlling the world and their inaccessibility to the experiences, so easily obtainable, which could teach them man's true position in the universe. As regards neurotics, we find that on the one hand a considerable part of this primitive attitude has survived in their constitution, and on the other hand that the sexual repression that has occurred in them has brought about a further sexualization of their thinking processes. The psychological results must be the same in both cases, whether the libidinal hypercatexsis of thinking is an original one or has been produced by regression: intellectual narcissism and the omnipotence of thoughts.¹

[1912-1913, 2732]

If we may regard the existence among primitive races of the omnipotence of thoughts as evidence in favour of narcissism, we are encouraged to attempt a comparison between the phases in the development of men's view of the universe and the stages of an individual's libidinal development. The animistic phase would correspond to narcissism both chronologically and in its content; the religious phase would correspond to the stage of object-choice of which the characteristic is a child's attachment to his parents; while the scientific phase would have an exact counterpart in the stage at which an individual has reached maturity, has renounced the pleasure principle, adjusted himself to reality and turned to the external world for the object of his desires.¹

[1912-1913, 2733]

In only a single field of our civilization has the omnipotence of thoughts been retained, and that is in the field of art. Only in art does it still happen that a man who is consumed by desires performs something resembling the accomplishment of those desires and that what he does in play produces emotional effects - thanks to artistic illusion - just as though it were something real. People speak with justice of the 'magic of art' and compare artists to magicians. But the comparison is perhaps more significant than it claims to be. There can be no doubt that art did not begin as art for art's sake. It worked originally in the service of impulses which are for the most part extinct to-day. And among them we may suspect the presence of many magical purposes.²

[1912-1913, 2733]

Whereas magic still reserves omnipotence solely for thoughts, animism hands some of it over to spirits and so prepares the way for the construction of a religion. What, we may ask, can have induced a primitive man to make this first act of renunciation? It can scarcely have been a recognition of the falseness of his premises, for he continued to practise the magical technique.

[1912-1913, 2734]
I propose to avoid (as I have already done elsewhere³) entering into the general problem of the origin of the tendency to project mental processes into the outside. It is, however, safe to assume that that tendency will be intensified when projection promises to bring with it the advantage of mental relief. Such an advantage may be expected with certainty where a conflict has arisen between different impulses all of which are striving towards omnipotence - for they clearly cannot all become omnipotent. The pathological process in paranoia in fact makes use of the mechanism of projection in order to deal with mental conflicts of this kind. The typical case of such a conflict is one between the two members of a pair of opposites - the case of an ambivalent attitude, which we have examined in detail as it appears in someone mourning the death of a loved relative. This kind of case must seem particularly likely to provide a motive for the creation of projections. Here again we are in agreement with the writers who maintain that the first born spirits were evil spirits, and who derive the idea of a soul from the impression made by death upon the survivors. The only difference is that we do not lay stress on the intellectual problem with which death confronts the living; in our view the force which gives the impetus to research is rather to be attributed to the emotional conflict into which the survivors are plunged.

[1912-1913, 2735]

May not the same have been true of primitive men? We are justified in believing that, as one of the phenomena of their narcissistic organization, they overvalued their psychical acts to an extraordinary degree.² Accordingly the mere hostile impulse against the father, the mere existence of a wishful phantasy of killing and devouring him, would have been enough to produce the moral reaction that created totemism and taboo. In this way we should avoid the necessity for deriving the origin of our cultural legacy, of which we justly feel so proud, from a hideous crime, revolting to all our feelings. No damage would thus be done to the causal chain stretching from the beginning to the present day, for psychical reality would be strong enough to bear the weight of these consequences. To this it may be objected that an alteration in the form of society from a patriarchal horde to a fraternal clan did actually take place. This is a powerful argument, but not a conclusive one. The alteration might have been effected in a less violent fashion and none the less have been capable of determining the appearance of the moral reaction. So long as the pressure exercised by the primal father could be felt, the hostile feelings towards him were justified, and remorse on their account would have to await a later day. And if it is further argued that everything derived from the ambivalent relation to the father - taboo and the sacrificial ordinance - is characterized by the deepest seriousness and the most complete reality, this further objection carries just as little weight. For the ceremonials and inhibitions of obsessional neurotics show these same characteristics and are nevertheless derived only from psychical reality - from intentions and not from their execution. We must avoid transplanting a contempt for what is merely thought or wished from our commonplace world, with its wealth of material values, into the world of primitive men and neurotics, of which the wealth lies only within themselves.

[1912-1913, 2798]

An investigation of primitive peoples shows mankind caught up, to begin with, in a childish belief in its own omnipotence.¹ A whole number of mental structures can thus be understood as attempts to deny whatever might disturb this feeling of omnipotence and so to prevent emotional life from being affected by reality until the latter could be better controlled and used for purposes of satisfaction. The principle of avoiding unpleasure dominates human actions until it is replaced by the better one of adaptation to the external world. Pari passu with men's progressive control over the world goes a development in their Weltanschauung, their view of the universe as a whole. They turn away more and more from their original belief in their own omnipotence, rising from an animistic phase through a religious to a scientific one. Myths, religion and morality find their place in this scheme as attempts to seek a compensation for the lack of satisfaction of human wishes.

[1913], 2822]
What I have been trying to describe in this outline is the *libido theory* of the neuroses, upon which are founded all our conceptions of the nature of these morbid states, together with our therapeutic measures for relieving them. We naturally regard the premises of the libido theory as valid for normal behaviour as well. We speak of the narcissism of small children, and it is to the excessive narcissism of primitive man that we ascribe his belief in the omnipotence of his thoughts and his consequent attempts to influence the course of events in the external world by the technique of magic. [1917a, 3610]

These last examples of the uncanny are to be referred to the principle which I have called 'omnipotence of thoughts', taking the name from an expression used by one of my patients. And now we find ourselves on familiar ground. Our analysis of instances of the uncanny has led us back to the old, animistic conception of the universe. This was characterized by the idea that the world was peopled with the spirits of human beings; by the subject's narcissistic overvaluation of his own mental processes; by the belief in the omnipotence of thoughts and the technique of magic based on that belief; by the attribution to various outside persons and things of carefully graded magical powers, or *mana*; as well as by all the other creations with the help of which man, in the unrestricted narcissism of that stage of development, strove to fend off the manifest prohibitions of reality. It seems as if each one of us has been through a phase of individual development corresponding to this animistic stage in primitive men, that none of us has passed through it without preserving certain residues and traces of it which are still capable of manifesting themselves, and that everything which now strikes us as 'uncanny' fulfils the condition of touching those residues of animistic mental activity within us and bringing them to expression.¹ [1919h, 3691]

There is one more point of general application which I should like to add, though, strictly speaking, it has been included in what has already been said about animism and modes of working of the mental apparatus that have been surmounted; for I think it deserves special emphasis. This is that an uncanny effect is often and easily produced when the distinction between imagination and reality is effaced, as when something that we have hitherto regarded as imaginary appears before us in reality, or when a symbol takes over the full functions of the thing it symbolizes, and so on. It is this factor which contributes not a little to the uncanny effect attaching to magical practices. The infantile element in this, which also dominates the minds of neurotics, is the over-accentuation of psychical reality in comparison with material reality - a feature closely allied to the belief in the omnipotence of thoughts. In the middle of the isolation of war-time a number of the English *Strand Magazine* fell into my hands; and, among other somewhat redundant matter, I read a story about a young married couple who move into a furnished house in which there is a curiously shaped table with carvings of crocodiles on it. Towards evening an intolerable and very specific smell begins to pervade the house; they stumble over something in the dark; they seem to see a vague form gliding over the stairs - in short, we are given to understand that the presence of the table causes ghostly crocodiles to haunt the place, or that the wooden monsters come to life in the dark, or something of the sort. It was a naïve enough story, but the uncanny feeling it produced was quite remarkable. [1919h, 3694]
I myself set a higher value on my contributions to the psychology of religion, which began with the establishment of a remarkable similarity between obsessive actions and religious practices or ritual (1907b). Without as yet understanding the deeper connections, I described the obsessional neurosis as a distorted private religion and religion as a kind of universal obsessional neurosis. Later on, in 1912, Jung's forcible indication of the far-reaching analogies between the mental products of neurotics and of primitive peoples led me to turn my attention to that subject. In four essays, which were collected into a book with the title of Totem and Taboo, I showed that the horror of incest was even more marked among primitive than among civilized races and had given rise to very special measures of defence against it. I examined the relations between taboo-prohibitions (the earliest form in which moral restrictions make their appearance) and emotional ambivalence; and I discovered under the primitive scheme of the universe known as 'animism' the principle of the over-estimation of the importance of psychical reality - the belief in 'the omnipotence of thoughts' - which lies at the root of magic as well. I developed the comparison with the obsessional neurosis at every point, and showed how many of the postulates of primitive mental life are still in force in that remarkable illness. Above all, however, I was attracted by totemism, the first system of organization in primitive tribes, a system in which the beginnings of social order are united with a rudimentary religion and the implacable domination of a small number of taboo-prohibitions. The being that is revered is ultimately always an animal, from which the clan also claims to be descended. Many indications pointed to the conclusion that every race, even the most highly developed, had once passed through the stage of totemism.

[1925d, 4239]

Now that the Director of this journal has broken the silence to which he is condemned - or to which he has a right - owing to his age, in order to greet his friend, he may be permitted to conclude - not with a wish, for we do not believe in the omnipotence of thoughts - but with the admission that he cannot think of Ernest Jones, even after his fiftieth birthday, as other than before: zealous and energetic, combative and devoted to the cause.

[1929a, 4609]
I feel sure that while you have been listening to me you have been bothered by a number of questions which you would be glad to hear answered. I cannot undertake to do so here and now, but I feel confident that none of these detailed enquiries would upset our thesis that the religious Weltanschauung is determined by the situation of our childhood. That being so, it is all the more remarkable that, in spite of its infantile nature, it nevertheless had a precursor. There is no doubt that there was a time without religion, without gods. This is known as the stage of animism. At that time, too, the world was peopled with spiritual beings resembling men - we call them demons. All the objects in the external world were their habitation, or perhaps were identical with them; but there was no superior power which had created them all and afterwards ruled them and to which one could turn for protection and help. The demons of animism were for the most part hostile in their attitude to human beings, but it appears that human beings had more self-confidence then than later on. They were certainly in a constant state of the most acute fear of these evil spirits; but they defended themselves against them by certain actions to which they ascribed the power to drive them away. Nor apart from this did they regard themselves as defenceless. If they desired something from Nature - if they wished for rain, for instance - they did not direct a prayer to the weather-god, but they performed a magical act which they expected to influence Nature directly: they themselves did something which resembled rain. In their struggle against the powers of the world around them their first weapon was magic, the earliest fore-runner of the technology of to-day. Their reliance on magic was, as we suppose, derived from their overvaluation of their own intellectual operations, from their belief in the ‘omnipotence of thoughts’, which, incidentally, we come upon again in our obsessional neurotic patients. We may suppose that human beings at that period were particularly proud of their acquisitions in the way of language, which must have been accompanied by a great facilitation of thinking. They attributed magical power to words. This feature was later taken over by religion. 'And God said "Let there be light!" and there was light.' Moreover the fact of their magical actions shows that animistic men did not simply rely on the power of their wishes. They expected results, rather, from the performance of an action which would induce Nature to imitate it. If they wanted rain, they themselves poured out water; if they wanted to encourage the earth to be fruitful, they demonstrated a dramatic performance of sexual intercourse to it in the fields.

[1933a, 4763]

My Dear Thomas Mann, Accept as a friend my affectionate greetings on your sixtieth birthday. I am one of your 'oldest' readers and admirers and I might wish you a very long and happy life as is the custom on such occasions. But I shall not do so. Wishing is cheap and strikes me as a relapse into the days when people believed in the magical omnipotence of thoughts. I think, too, from my most personal experience, that it is well if a compassionate fate sets a timely end to the length of our life.

[1935c, 4835]
This may not seem obvious at first sight, and before it can carry conviction we must recall other processes of the same character in the development of human civilization. The earliest of these and perhaps the most important is merged in the obscurity of primaeval ages. Its astonishing effects compel us to assert its occurrence. In our children, in adults who are neurotic, as well as in primitive peoples, we meet with the mental phenomenon which we describe as a belief in the 'omnipotence of thoughts'. In our judgement this lies in an over-estimation of the influence which our mental (in this case, intellectual) acts can exercise in altering the external world. At bottom, all magic, the precursor of our technology, rests on this premiss. All the magic of words, too, has its place here, and the conviction of the power which is bound up with the knowledge and pronouncing of a name. The 'omnipotence of thoughts' was, we suppose, an expression of the pride of mankind in the development of speech, which resulted in such an extraordinary advancement of intellectual activities. The new realm of intellectuality was opened up, in which ideas, memories and inferences became decisive in contrast to the lower psychical activity which had direct perceptions by the sense-organs as its content. This was unquestionably one of the most important stages on the path to hominization. [1939a, 4934]
Some features of this state of affairs may be seen in the sphere of religious life as well. The
formation of a religion, too, seems to be based on the suppression, the renunciation, of certain
instinctual impulses. These impulses, however, are not, as in the neuroses, exclusively
components of the sexual instinct; they are self-seeking, socially harmful instincts, though, even
so, they are usually not without a sexual component. A sense of guilt following upon continual
temptation and an expectant anxiety in the form of fear of divine punishment have, after all,
been familiar to us in the field of religion longer than in that of neurosis. Perhaps because of the
admixture of sexual components, perhaps because of some general characteristics of the
instincts, the suppression of instinct proves to be an inadequate and interminable process in
religious life also. Indeed, complete backslidings into sin are more common among pious people
than among neurotics and these give rise to a new form of religious activity, namely acts of
penance, which have their counterpart in obsessional neurosis.
[1907b, 1908]

Obsessional prohibitions involve just as extensive renunciations and restrictions in the lives of
those who are subject to them as do taboo prohibitions; but some of them can be lifted if certain
actions are performed. Thereafter, these actions must be performed: they become compulsive
or obsessive acts, and there can be no doubt that they are in the nature of expiation, penance,
defensive measures and purification. The commonest of these obsessive acts is washing in
water (‘washing mania’). Some taboo prohibitions can be replaced in just the same way; or
rather their violation can be made good by a similar ‘ceremonial’; and here again lustration with
water is the preferred method.
[1912-1913, 2676]

A good deal of what has been said may be objected to on the ground that the unpleasant
obsessive ideas are themselves quite conscious. But there is no doubt that before becoming
conscious they have been though the process of repression. In most of them the actual wording
of the aggressive instinctual impulse is altogether unknown to the ego, and it requires a good
deal of analytic work to make it conscious. What does penetrate into consciousness is usually
only a distorted substitute which is either of a vague, dream-like and indeterminate nature or so
travestied as to be unrecognizable. Even where repression has not encroached upon the
content of the aggressive impulse it has certainly got rid of its accompanying affective character.
As a result, the aggressiveness appears to the ego not to be an impulsion but, as the patients
themselves say, merely a ‘thought’ which awakens no feeling. But the remarkable thing is that
this is not the case. What happens is that the affect left out when the obsessional idea is
perceived appears in a different place. The super-ego behaves as though repression had not
occurred and as though it knew the real wording and full affective character of the aggressive
impulse, and it treats the ego accordingly. The ego which, on the one hand, knows that it is
innocent is obliged, on the other hand, to be aware of a sense of guilt and to carry a
responsibility which it cannot account for. This state of affairs is, however, not so puzzling as it
would seem at first sight. The behaviour of the super-ego is perfectly intelligible, and the
contradiction in the ego merely shows that it has shut out the id by means of repression while
remaining fully accessible to the influence of the super-ego.¹ If it is asked why the ego does not
also attempt to withdraw from the tormenting criticism of the super-ego, the answer is that it
does manage to do so in a great number of instances. There are obsessional neuroses in which
no sense of guilt whatever is present. In them, as far as can be seen, the ego has avoided
becoming aware of it by instituting a fresh set of symptoms, penances or restrictions of a self-
punishing kind. These symptoms, however, represent at the same time a satisfaction of
masochistic impulses which, in their turn, have been reinforced by regression.
[1926d, 4276]
What we have learnt about anxiety in phobias is applicable to obsessional neuroses as well. In this respect it is not difficult for us to put obsessional neuroses on all fours with phobias. In the former, the mainspring of all later symptom-formation is clearly the ego's fear of its super-ego. The danger-situation from which the ego must get away is the hostility of the super-ego. There is no trace of projection here; the danger is completely internalized. But if we ask ourselves what it is that the ego fears from the super-ego, we cannot but think that the punishment threatened by the latter must be an extension of the punishment of castration. Just as the father has become depersonalized in the shape of the super-ego, so has the fear of castration at his hands become transformed into an undefined social or moral anxiety. But this anxiety is concealed. The ego escapes it by obediently carrying out the commands, precautions and penances that have been enjoined on it. If it is impeded in doing so, it is at once overtaken by an extremely distressing feeling of discomfort which may be regarded as an equivalent of anxiety and which the patients themselves liken to anxiety.
[1926d, 4285]
Secondary defence against the obsessional ideas may be effected by a forcible diversion on to other thoughts with a content as contrary as possible. This is why *obsessional brooding*, if it succeeds, regularly deals with abstract and *suprasensual* things; because the ideas that have been repressed are always concerned with *sensuality*. Or else the patient tries to make himself master of each of his obsessional ideas singly by logical work and by having recourse to his conscious memories. This leads to *obsessional thinking*, to a *compulsion to test things* and to *doubting mania*. The advantage which perception has over memory in such tests at first causes the patient, and later compels him, to collect and store up all the objects with which he has come into contact. Secondary defence against obsessional *affects* leads to a still wider set of protective measures which are capable of being transformed into obsessional acts. These may be grouped according to their purpose: *penitential* measures (burdensome ceremonials, the observation of numbers), *precautionary* measures (all sorts of phobias, superstition, pedantry, increase of the primary symptom of conscientiousness); measures to do with *fear of betrayal* (collecting scraps of paper, seclusiveness), or to ensure *numbing* (dipsomania). Among these obsessional acts and obsessional impulses, phobias, since they circumscribe the patient's existence, play the greatest part.

[1896b, 393]
Secondary defence against the obsessional ideas may be effected by a forcible diversion on to other thoughts with a content as contrary as possible. Among these obsessional acts and obsessional impulses, phobias, since they circumscribe the patient's existence, play the greatest part.

[1896b, 393]

There are cases in which one can observe how the obsession is transferred from the idea or from the affect on to the protective measure; others in which the obsession oscillates periodically between the symptom of the return of the repressed and the symptom of the secondary defence; and yet other cases in which no obsessional idea is constructed at all, but, instead, the repressed memory is at once represented by what is apparently a primary measure of defence. Here we reach at one bound the stage which elsewhere only completes the course run by the obsessional neurosis after the defensive struggle has taken place. Severe cases of this disorder end in the ceremonial actions becoming fixated, or in a general state of doubting mania, or in a life of eccentricity conditioned by phobias.

[1896b, 393]

This may be illustrated by an example from a neurosis. In my essay on taboo I mentioned a woman patient of mine whose obsessional prohibitions showed the most perfect agreement with a Maori taboo (p. 2676). This woman's neurosis was aimed at her husband and culminated in her defence against an unconscious wish that he should die. Her manifest, systematic phobia, however, related to the mention of death in general, while her husband was entirely excluded from it and was never an object of her conscious solicitude. One day she heard her husband giving instructions that his razors, which had lost their edge, were to be taken to a particular shop to be re-set. Driven by a strange uneasiness, she herself set off for the shop. After reconnoitring the ground, she came back and insisted that her husband should get rid of the razors for good and all, since she had discovered that next door to the shop he had named there was an undertaker's establishment: owing to the plan he had made, she said, the razors had become inextricably involved with thoughts of death. This, then, was the *systematic* reason for her prohibition. We may be quite sure that, even without her discovery of the next-door shop, the patient would have come home with a prohibition against the razors. It would have been enough if she had met a hearse on her way to the shop, or someone dressed in mourning or carrying a funeral wreath. The net of possible determinants for the prohibition was spread wide enough to catch the quarry in any event; it merely depended on her decision whether to draw it together or not. It could be shown that on other occasions she would not put the determinants into operation, and she would explain this by saying it had been 'a better day'. The *real* cause of her prohibition upon the razors was, of course, as it was easy to discover, her repugnance to attaching any pleasurable feeling to the idea that her husband might cut his throat with the newly ground razors.

[1912-1913, 2738]
Secondary defence against the obsessional ideas may be effected by a forcible diversion on to other thoughts with a content as contrary as possible. This is why *obsessional brooding*, if it succeeds, regularly deals with abstract and *suprasensual* things; because the ideas that have been repressed are always concerned with *sensuality*. Or else the patient tries to make himself master of each of his obsessional ideas singly by logical work and by having recourse to his conscious memories. This leads to *obsessional thinking*, to a *compulsion to test things* and to *doubting mania*. The advantage which perception has over memory in such tests at first causes the patient, and later compels him, to collect and store up all the objects with which he has come into contact. Secondary defence against obsessional *affects* leads to a still wider set of protective measures which are capable of being transformed into obsessional acts. These may be grouped according to their purpose: *penitential* measures (burdensome ceremonials, the observation of numbers), *precautionary* measures (all sorts of phobias, superstition, pedantry, increase of the primary symptom of conscientiousness); measures to do with *fear of betrayal* (collecting scraps of paper, seclusiveness), or to ensure *numbing* (dipsomania). Among these obsessional acts and obsessional impulses, phobias, since they circumscribe the patient's existence, play the greatest part.

[1896b, 393]

Analysis made it possible to find another solution. The attempt at an explanation, which seemed so striking when I was obliged to ascribe it to the dream-work, was not an original one of my own, but was copied from the neurosis of one of my patients. I have already spoken elsewhere of a highly educated and, in real life, soft-hearted man who, shortly after the death of his parents, began to reproach himself with having murderous inclinations, and then fell a victim to the precautionary measures which he was obliged to adopt as a safeguard. It was a case of severe obsessions accompanied by complete insight. To begin with, walking through the streets was made a burden to him by a compulsion to make certain where every single person he met disappeared to; if anyone suddenly escaped his watchful eye, he was left with a distressing feeling and the idea that he might possibly have got rid of him. What lay behind this was, among other things, a 'Cain' phantasy - for 'all men are brothers.' Owing to the impossibility of carrying out this task, he gave up going for walks and spent his life incarcerated between his own four walls. But reports of murders which had been committed outside were constantly being brought into his room by the newspapers, and his conscience suggested to him, in the form of a doubt, that he might be the wanted murderer. The certainty that he had in fact not left his house for weeks protected him from these charges for a while, till one day the possibility came into his head that *he might have left his house while he was in an unconscious state* and have thus been able to commit the murder without knowing anything about it. From that time onwards he locked the front door of the house and gave the key to his old housekeeper with strict instructions never to let it fall into his hands even if he asked for it.

[1900a, 902]
In place of a single sick person let us put society - suffering as a whole from neuroses, though composed of sick and healthy members; and in place of individual acceptance in the one case let us put general recognition in the other. A little reflection will then show you that this substitution cannot in any way alter the outcome. The success which the treatment can have with the individual must occur equally with the community. Sick people will not be able to let their various neuroses become known - their anxious over-tenderness which is meant to conceal their hatred, their agoraphobia which tells of disappointed ambition, their obsessive actions which represent self-reproaches for evil intentions and precautions against them - if all their relatives and every stranger from whom they wish to conceal their mental processes know the general meaning of such symptoms, and if they themselves know that in the manifestations of their illness they are producing nothing that other people cannot instantly interpret. The effect, however, will not be limited to the concealment of the symptoms which, incidentally, it is often impossible to carry out; for this necessity for concealment destroys the use of being ill. Disclosure of the secret will have attacked, at its most sensitive point, the 'aetiological equation' from which neuroses arise - it will have made the gain from the illness illusory; and consequently the final outcome of the changed situation brought about by the physician's indiscretion can only be that the production of the illness will be brought to a stop. [1910d, 2312]

In certain diseases - including the very neuroses of which we have made special study - things are different. The ego feels uneasy; it comes up against limits to its power in its own house, the mind. Thoughts emerge suddenly without one's knowing where they come from, nor can one do anything to drive them away. These alien guests even seem to be more powerful than those which are at the ego's command. They resist all the well-proved measures of enforcement used by the will, remain unmoved by logical refutation, and are unaffected by the contradictory assertions of reality. Or else impulses appear which seem like those of a stranger, so that the ego disowns them; yet it has to fear them and take precautions against them. The ego says to itself: 'This is an illness, a foreign invasion.' It increases its vigilance, but cannot understand why it feels so strangely paralysed. [1917a, 3612]

The reproaches of conscience in certain forms of obsessional neurosis are as distressing and tormenting, but here the situation is less perspicuous. It is noteworthy that the obsessional neurotic, in contrast to the melancholic, never in fact takes the step of self-destruction; it is as though he were immune against the danger of suicide, and he is far better protected from it than the hysterical. We can see that what guarantees the safety of the ego is the fact that the object has been retained. In obsessional neurosis it has become possible, through a regression to the pregenital organization, for the love-impulses to transform themselves into impulses of aggression against the object. Here again the instinct of destruction has been set free and it seeks to destroy the object, or at least it appears to have that intention. These purposes have not been adopted by the ego and it struggles against them with reaction-formations and precautionary measures; they remain in the id. The super-ego, however, behaves as if the ego were responsible for them and shows at the same time by the seriousness with which it chastises these destructive intentions that they are no mere semblance evoked by regression but an actual substitution of hate for love. Helpless in both directions, the ego defends itself vainly, alike against the instigations of the murderous id and against the reproaches of the punishing conscience. It succeeds in holding in check at least the most brutal actions of both sides; the first outcome is interminable self-torment, and eventually there follows a systematic torturing of the object, in so far as it is within reach. [1923b, 3987]
That there is a relationship between inhibition and anxiety is pretty evident. Some inhibitions obviously represent a relinquishment of a function because its exercise would produce anxiety. Many women are openly afraid of the sexual function. We class this anxiety under hysteria, just as we do the defensive symptom of disgust which, arising originally as a deferred reaction to the experiencing of a passive sexual act, appears later whenever the idea of such an act is presented. Furthermore, many obsessional acts turn out to be measures of precaution and security against sexual experiences and are thus of a phobic character.

As regards inhibitions, then, we may say in conclusion that they are restrictions of the functions of the ego which have been either imposed as a measure of precaution or brought about as a result of an impoverishment of energy; and we can see without difficulty in what respect an inhibition differs from a symptom: for a symptom cannot any longer be described as a process that takes place within, or acts upon, the ego.

Let us turn to the obsessional neuroses in the hope of learning more about the formation of symptoms. The symptoms belonging to this neurosis fall, in general, into two groups, each having an opposite trend. They are either prohibitions, precautions and expiations - that is, negative in character - or they are, on the contrary, substitutive satisfactions which often appear in symbolic disguise. The negative, defensive group of symptoms is the older of the two; but as illness is prolonged, the satisfactions, which scoff at all defensive measures, gain the upper hand. The symptom-formation scores a triumph if it succeeds in combining the prohibition with satisfaction so that what was originally a defensive command or prohibition acquires the significance of a satisfaction as well; and in order to achieve this end it will often make use of the most ingenious associative paths. Such an achievement demonstrates the tendency of the ego to synthesize, which we have already observed. In extreme cases the patient manages to make most of his symptoms acquire, in addition to their original meaning, a directly contrary one. This is a tribute to the power of ambivalence, which, for some unknown reason, plays such a large part in obsessional neuroses. In the crudest instance the symptom is diphasic: an action which carries out a certain injunction is immediately succeeded by another action which stops or undoes the first one even if it does not go quite so far as to carry out its opposite.
The two techniques I refer to are undoing what has been done and isolating. The first of these has a wide range of application and goes back very far. It is, as it were, negative magic, and endeavours, by means of motor symbolism, to 'blow away' not merely the consequences of some event (or experience or impression) but the event itself. I choose the term 'blow away' advisedly, so as to remind the reader of the part played by this technique not only in neuroses but in magical acts, popular customs and religious ceremonies as well. In obsessional neurosis the technique of undoing what has been done is first met with in the 'diphasic' symptoms, in which one action is cancelled out by a second, so that it is as though neither action had taken place, whereas, in reality, both have. This aim of undoing is the second underlying motive of obsessional ceremonials, the first being to take precautions in order to prevent the occurrence or recurrence of some particular event. The difference between the two is easily seen: the precautionary measures are rational, while trying to get rid of something by 'making it not to have happened' is irrational and in the nature of magic. It is of course to be suspected that the latter is the earlier motive of the two and proceeds from the animistic attitude towards the environment. This endeavour to undo shades off into normal behaviour in the case in which a person decides to regard an event as not having happened. But whereas he will take no direct steps against the event, and will simply pay no further attention to it or its consequences, the neurotic person will try to make the past itself non-existent. He will try to repress it by motor means. The same purpose may perhaps account for the obsession for repeating which is so frequently met with in this neurosis and the carrying out of which serves a number of contradictory intentions at once. When anything has not happened in the desired way it is undone by being repeated in a different way; and thereupon all the motives that exist for lingering over such repetitions come into play as well. As the neurosis proceeds, we often find that the endeavour to undo a traumatic experience is a motive of first-rate importance in the formation of symptoms. We thus unexpectedly discover a new, motor technique of defence, or (as we may say in this case with less inaccuracy) of repression.

What we have learnt about anxiety in phobias is applicable to obsessional neuroses as well. In this respect it is not difficult for us to put obsessional neuroses on all fours with phobias. In the former, the mainspring of all later symptom-formation is clearly the ego's fear of its super-ego. The danger-situation from which the ego must get away is the hostility of the super-ego. There is no trace of projection here; the danger is completely internalized. But if we ask ourselves what it is that the ego fears from the super-ego, we cannot but think that the punishment threatened by the latter must be an extension of the punishment of castration. Just as the father has become depersonalized in the shape of the super-ego, so has the fear of castration at his hands become transformed into an undefined social or moral anxiety. But this anxiety is concealed. The ego escapes it by obediently carrying out the commands, precautions and penances that have been enjoined on it. If it is impeded in doing so, it is at once overtaken by an extremely distressing feeling of discomfort which may be regarded as an equivalent of anxiety and which the patients themselves liken to anxiety.
The two techniques I refer to are undoing what has been done and isolating. The first of these has a wide range of application and goes back very far. It is, as it were, negative magic, and endeavours, by means of motor symbolism, to 'blow away' not merely the consequences of some event (or experience or impression) but the event itself. I choose the term 'blow away' advisedly, so as to remind the reader of the part played by this technique not only in neuroses but in magical acts, popular customs and religious ceremonies as well. In obsessional neurosis the technique of undoing what has been done is first met with in the 'diphasic' symptoms, in which one action is cancelled out by a second, so that it is as though neither action had taken place, whereas, in reality, both have. This aim of undoing is the second underlying motive of obsessional ceremonials, the first being to take precautions in order to prevent the occurrence or recurrence of some particular event. The difference between the two is easily seen: the precautionary measures are rational, while trying to get rid of something by 'making it not to have happened' is irrational and in the nature of magic. It is of course to be suspected that the latter is the earlier motive of the two and proceeds from the animistic attitude towards the environment. This endeavour to undo shades off into normal behaviour in the case in which a person decides to regard an event as not having happened. But whereas he will take no direct steps against the event, and will simply pay no further attention to it or its consequences, the neurotic person will try to make the past itself non-existent. He will try to repress it by motor means. The same purpose may perhaps account for the obsession for repeating which is so frequently met with in this neurosis and the carrying out of which serves a number of contradictory intentions at once. When anything has not happened in the desired way it is undone by being repeated in a different way; and thereupon all the motives that exist for lingering over such repetitions come into play as well. As the neurosis proceeds, we often find that the endeavour to undo a traumatic experience is a motive of first-rate importance in the formation of symptoms. We thus unexpectedly discover a new, motor technique of defence, or (as we may say in this case with less inaccuracy) of repression.

[1926d, 4278]
What she told me was perfectly coherent and revealed an unusual degree of education and intelligence. This made it seem all the more strange when every two or three minutes she suddenly broke off, contorted her face into an expression of horror and disgust, stretched out her hand towards me, spreading and crooking her fingers, and exclaimed, in a changed voice, charged with anxiety: 'Keep still! - Don't say anything! - Don't touch me!' She was probably under the influence of some recurrent hallucination of a horrifying kind and was keeping the intruding material at bay with this formula.¹ These interpolations came to an end with equal suddenness and the patient took up what she had been saying, without pursuing her momentary excitement any further, and without explaining or apologizing for her behaviour - probably, therefore, without herself having noticed the interpolation.²

¹ These words did in fact represent a protective formula, and this will be explained later on. Since then I have come across similar protective formulas in a melancholic woman who endeavoured by their means to control her tormenting thoughts - wishes that something bad might happen to her husband and her mother, blasphemies, etc.

² Although the cases I have enumerated show varying degrees of complexity, they have this in common: the original (incompatible) idea has been replaced by another idea, the substituted idea. In the cases which I now append, the original idea has been replaced, but not by another idea; it has been replaced by acts or impulses which originally served as measures of relief or as protective procedures, and are now grotesquely associated with an emotional state which does not fit them, but which has persisted unchanged, and which has remained as justifiable as it was at its origin.

In conclusion I may point out that combinations of a phobia and an obsession proper may co-exist, and that indeed this is a very frequent occurrence. We may find that a phobia had developed at the beginning of the disease as a symptom of anxiety neurosis. The idea which constitutes the phobia and which is associated with the state of fear may be replaced by another idea or rather by the protective procedure that seemed to relieve the fear. Case 7 (obsessive speculating) presents a neat example of this group: a phobia along with a true substitutive obsession.

Both kinds of phobias (and also obsessions) often appear side by side; although the atypical phobias, which are based on obsessions, need not necessarily spring from the soil of anxiety neurosis. A very frequent and apparently complicated mechanism makes its appearance if, in what was originally a simple phobia belonging to an anxiety neurosis, the content of the phobia is replaced by another idea, so that the substitute is subsequent to the phobia. What are most often employed as substitutes are the 'protective measures' that were originally used to combat the phobia. Thus, for instance, 'brooding mania' arises from the subject's endeavours to disprove that he is mad, as his hypochondriacal phobia maintains; the hesitations and doubt, and still more the repetitions, of folie du doute arise from a justifiable doubt about the certainty of one's own train of thought, since one is conscious of its persistent disturbance by ideas of an obsessional sort, and so on. We can therefore assert that many syndromes, too, of obsessional neurosis, such as folie du doute and the like, are also to be reckoned, clinically if not conceptually, as belonging to anxiety neurosis.²
Besides these compromise symptoms, which signify the return of the repressed and consequently a collapse of the defence that had been originally achieved, the obsessional neurosis constructs a set of further symptoms, whose origin is quite different. For the ego seeks to fend off the derivatives of the initially repressed memory, and in this defensive struggle it creates symptoms which might be classed together as ‘secondary defence’. These are all of them ‘protective measures’, which have already done good service in the fight against obsessional ideas and obsessional affects. If these aids in the defensive struggle genuinely succeed in once more repressing the symptoms of the return which have forced themselves on the ego, then the obsession is transferred to the protective measures themselves and creates a third form of ‘obsessional neurosis’ - obsessional actions. These actions are never primary; they never contain anything but a defence - never an aggression. A psychical analysis of them shows that, in spite of their peculiarity, they can always be fully explained by being traced back to the obsessional memories which they are fighting against.¹

Analysis of obsessive actions has already given us some sort of an insight into their causes and into the chain of motives which bring them into effect. We may say that the sufferer from compulsions and prohibitions behaves as if he were dominated by a sense of guilt, of which, however, he knows nothing, so that we must call it an unconscious sense of guilt, in spite of the apparent contradiction in terms. This sense of guilt has its source in certain early mental events, but it is constantly being revived by renewed temptations which arise whenever there is a contemporary provocation. Moreover, it occasions a lurking sense of expectant anxiety, an expectation of misfortune, which is linked, through the idea of punishment, with the internal perception of the temptation. When the ceremonial is first being constructed, the patient is still conscious that he must do this or that lest some ill should befall, and as a rule the nature of the ill that is to be expected is still known to his consciousness. But what is already hidden from him is the connection - which is always demonstrable - between the occasion on which this expectant anxiety arises and the danger which it conjures up. Thus a ceremonial starts as an action for defence or insurance, a protective measure.

The sense of guilt of obsessional neurotics finds its counterpart in the protestations of pious people that they know that at heart they are miserable sinners; and the pious observances (such as prayers, invocations, etc.) with which such people preface every daily act, and in especial every unusual undertaking, seem to have the value of defensive or protective measures.

¹[1896b, 392]
The events in his sixth or seventh year which the patient described in the first hour of his treatment were not merely, as he supposed, the beginning of his illness, but were already the illness itself. It was a complete obsessional neurosis, wanting in no essential element, at once the nucleus and the prototype of the later disorder, - an elementary organism, as it were, the study of which could alone enable us to obtain a grasp of the complicated organization of his subsequent illness. The child, as we have seen, was under the domination of a component of the sexual instinct, the desire to look, as a result of which there was a constant recurrence in him of a very intense wish connected with persons of the female sex who pleased him - the wish, that is, to see them naked. This wish corresponds to the later obsessional or compulsive idea; and if the quality of compulsion was not yet present in the wish, this was because the ego had not yet placed itself in complete opposition to it and did not yet regard it as something foreign to itself. Nevertheless, opposition to this wish from some source or other was already in activity, for its occurrence was regularly accompanied by a distressing affect.¹ A conflict was evidently in progress in the mind of this young libertine. Side by side with the obsessive wish, and intimately associated with it, was an obsessive fear: every time he had a wish of this kind he could not help fearing that something dreadful would happen. This something dreadful was already clothed in a characteristic indeterminateness which was thenceforward to be an invariable feature of every manifestation of the neurosis. But in a child it is not hard to discover what it is that is veiled behind an indeterminateness of this kind. If the patient can once be induced to give a particular instance in place of the vague generalities which characterize an obsessional neurosis, it may be confidently assumed that the instance is the original and actual thing which has tried to hide itself behind the generalization. Our present patient's obsessive fear, therefore, when restored to its original meaning, would run as follows: 'If I have this wish to see a woman naked, my father will be bound to die.' The distressing affect was distinctly coloured with a tinge of uncanniness and superstition, and was already beginning to give rise to impulses to do something to ward off the impending evil. These impulses were subsequently to develop into the protective measures which the patient adopted.

[1909d, 2133]
This misapprehension on the part of consciousness can be seen at work not only in reference to the obsessional ideas themselves, but also in reference to the products of the secondary defensive struggle, such, for instance, as the protective formulas. I can produce two good examples of this. Our patient used to employ as a defensive formula a rapidly pronounced ‘aber’ ['but'] accompanied by a gesture of repudiation. He told me on one occasion that this formula had become altered recently; he now no longer said ‘áber’ but ‘abéř’. When he was asked to give the reason for this new departure, he declared that the mute ‘e’ of the second syllable gave him no sense of security against the intrusion, which he so much dreaded, of some foreign and contradictory element, and that he had therefore decided to accent the ‘e’. This explanation (an excellent sample of the obsessional neurotic style) was, however, clearly inadequate; the most that it could claim to be was a rationalization. The truth was that ‘abéř’ was an approximation towards the similar-sounding ‘abwehr’ ['defence'], a term which he had learnt in the course of our theoretical discussions of psycho-analysis. He had thus put the treatment to an illegitimate and ‘delirious’ use in order to strengthen a defensive formula. Another time he told me about his principal magic word, which was an apotropaic against every evil; he had put it together out of the initial letters of the most powerfully beneficent of his prayers and had clapped on an ‘amen’ at the end of it. I cannot reproduce the word itself, for reasons which will become apparent immediately. For, when he told it me, I could not help noticing that the word was in fact an anagram of the name of his lady. Her name contained an ‘s’, and this he had put last, that is, immediately before the ‘amen’ at the end. We may say, therefore, that by this process he had brought his ‘Samen’ ['semen'] into contact with the woman he loved; in imagination, that is to say, he had masturbated with her. He himself, however, had never noticed this very obvious connection; his defensive forces had allowed themselves to be fooled by the repressed ones. This is also a good example of the rule that in time the thing which is meant to be warded off invariably finds its way into the very means which is being used for warding it off.

[1909d, 2175]
It is this same doubt that leads the patient to uncertainty about his protective measures, and to his continual repetition of them in order to banish that uncertainty; and it is this doubt, too, that eventually brings it about that the patient's protective acts themselves become as impossible to carry out as his original inhibited decision in connection with his love. At the beginning of my investigations I was led to assume another and more general origin for the uncertainty of obsessional neurotics and one which seemed to be nearer the normal. If, for instance, while I am writing a letter some one interrupts me with questions, I afterwards feel a quite justifiable uncertainty as to what I may not have written under the influence of the disturbance, and, to make sure, I am obliged to read the letter over after I have finished it. In the same way I might suppose that the uncertainty of obsessional neurotics, when they are praying, for instance, is due to unconscious phantasies constantly mingling with their prayers and disturbing them. This hypothesis is correct, but it may be easily reconciled with what I have just said. It is true that the patient's uncertainty whether he has carried through a protective measure is due to the disturbing effect of unconscious phantasies; but the content of these phantasies is precisely the contrary impulse - which it was the very aim of the prayer to ward off. This became clearly evident in our patient on one occasion, for the disturbing element did not remain unconscious but made its appearance openly. The words he wanted to use in his prayer were, 'May God protect her', but a hostile 'not' suddenly darted out of his unconscious and inserted itself into the sentence; and he understood that this was an attempt at a curse (p. 2152). If the 'not' had remained mute, he would have found himself in a state of uncertainty and would have kept on prolonging his prayers indefinitely. But since it became articulate he eventually gave up praying. Before doing so, however, he, like other obsessional patients, tried every kind of method for preventing the opposite feeling from insinuating itself. He shortened his prayers, for instance, or said them more rapidly. And similarly other patients will endeavour to 'isolate' all such protective acts from other things. But none of these technical procedures are of any avail in the long run. If the impulse of love achieves any success by displacing itself on to some trivial act, the impulse of hostility will very soon follow it on to its new ground and once more proceed to undo all that it has done.

The compulsion on the other hand is an attempt at a compensation for the doubt and at a correction of the intolerable conditions of inhibition to which the doubt bears witness. If the patient, by the help of displacement, succeeds at last in bringing one of his inhibited intentions to a decision, then the intention must be carried out. It is true that this intention is not his original one, but the energy dammed up in the latter cannot let slip the opportunity of finding an outlet for its discharge in the substitutive act. Thus this energy makes itself felt now in commands and now in prohibitions, according as the affectionate impulse or the hostile one snatches control of the pathway leading to discharge. If it happens that a compulsive command cannot be obeyed, the tension becomes intolerable and is perceived by the patient in the form of extreme anxiety. But the pathway leading to a substitutive act, even where the displacement has been on to something very small, is so hotly contested, that such an act can as a rule be carried out only in the shape of a protective measure intimately associated with the very impulse which it is designed to ward off.

The content of her obsessional neurosis was a compulsion for scrupulous washing and cleanliness and extremely energetic protective measures against severe injuries which she thought other people had reason to fear from her - that is to say, reaction-formations against her own anal-erotic and sadistic impulses. Her sexual need was obliged to find expression in these shapes after her genital life had lost all its value owing to the impotence of the only man of whom there could be any question for her.
The primary obsessive acts of these neurotics are of an entirely magical character. If they are not charms, they are at all events counter-charms, designed to ward off the expectations of disaster with which the neurosis usually starts. Whenever I have succeeded in penetrating the mystery, I have found that the expected disaster was death. Schopenhauer has said that the problem of death stands at the outset of every philosophy; and we have already seen that the origin of the belief in souls and in demons, which is the essence of animism, goes back to the impression which is made upon men by death. It is difficult to judge whether the obsessive or protective acts performed by obsessional neurotics follow the law of similarity (or, as the case may be, of contrast); for as a rule, owing to the prevailing conditions of the neurosis, they have been distorted by being displaced on to something very small, some action in itself of the greatest triviality.¹ The protective formulas of obsessional neuroses, too, have their counterpart in the formulas of magic. It is possible, however, to describe the course of development of obsessive acts: we can show how they begin by being as remote as possible from anything sexual - magical defences against evil wishes - and how they end by being substitutes for the forbidden sexual act and the closest possible imitations of it.

[1912-1913, 2730]

The language of dreams may be looked upon as the method by which unconscious mental activity expresses itself. But the unconscious speaks more than one dialect. According to the differing psychological conditions governing and distinguishing the various forms of neurosis, we find regular modifications in the way in which unconscious mental impulses are expressed. While the gesture-language of hysteria agrees on the whole with the picture-language of dreams and visions, etc., the thought-language of obsessional neurosis and of the paraphrenias (dementia praecox and paranoia) exhibits special idiomatic peculiarities which, in a number of instances, we have been able to understand and interrelate. For instance, what a hysteric expresses by vomiting an obsessional will express by painstaking protective measures against infection, while a paraphrenic will be led to complaints or suspicions that he is being poisoned. These are all of them different representations of the patient's wish to become pregnant which have been repressed into the unconscious, or of his defensive reaction against that wish.

[1913j, 2814]

Psycho-analysis is obliged to give its backing to the second constituent of Adler's theory as it would to something of its own. And in fact it is nothing else than psycho-analytic knowledge, which that author extracted from sources open to everyone during ten years of work in common and which he has now labelled as his own by a change in nomenclature. I myself consider 'safeguarding [Sicherung]', for instance, a better term than 'protective measure [Schutzmassregeln]' which is the one I employ; but I cannot discover any difference in their meaning. Again, a host of familiar features come to light in Adler's propositions when one restores the earlier 'phantasied' and 'phantasy' in place of 'fingiert', 'fictive' and 'fiction'. The identity of these terms would be insisted upon by psycho-analysis even if their author had not taken part in our common work over a period of many years.

[1914d, 2916]
Obsessional prohibitions involve just as extensive renunciations and restrictions in the lives of those who are subject to them as do taboo prohibitions; but some of them can be lifted if certain actions are performed. Thereafter, these actions must be performed: they become compulsive or obsessive acts, and there can be no doubt that they are in the nature of expiation, penance, defensive measures and purification. The commonest of these obsessive acts is washing in water (‘washing mania’). Some taboo prohibitions can be replaced in just the same way; or rather their violation can be made good by a similar ‘ceremonial’; and here again lustration with water is the preferred method.
[1912-1913, 2676]

If the violation of a taboo can be made good by atonement or expiation, which involve the renunciation of some possession or some freedom, this proves that obedience to the taboo injunction meant in itself the renunciation of something desirable. Emancipation from one renunciation is made up for by the imposition of another one elsewhere. This leads us to conclude that atonement is a more fundamental factor than purification in the ceremonials of taboo.
[1912-1913, 2682]

I will now sum up the respects in which light has been thrown on the nature of taboo by comparing it with the obsessional prohibitions of neurotics. Taboo is a primaeval prohibition forcibly imposed (by some authority) from outside, and directed against the most powerful longings to which human beings are subject. The desire to violate it persists in their unconscious; those who obey the taboo have an ambivalent attitude to what the taboo prohibits. The magical power that is attributed to taboo is based on the capacity for arousing temptation; and it acts like a contagion because examples are contagious and because the prohibited desire in the unconscious shifts from one thing to another. The fact that the violation of a taboo can be atoned for by a renunciation shows that renunciation lies at the basis of obedience to taboo.
[1912-1913, 2682]
If we take instinctual repression as a measure of the level of civilization that has been reached, we shall have to admit that even under the animistic system advances and developments took place which are unjustly despised on account of their superstitious basis. When we are told that the warriors in a savage tribe practise the greatest continence and cleanliness when they go on the war-path, the explanation is put forward that their motive is ‘a fear lest the enemy should obtain the refuse of their persons, and thus be enabled to work their destruction by magic’ (Frazer, 1911b, 157); and an analogous superstitious reason could be suggested for their continence. None the less the fact remains that they have made an instinctual renunciation; and we can understand the position better if we suppose that the savage warrior submits to these restrictions as a counter-measure because he is on the point of yielding completely to the satisfaction of cruel and hostile impulses which are as a rule prohibited to him. The same is true of the numerous cases of sexual restrictions being imposed on anyone who is engaged on difficult or responsible work (ibid., 200 f.). Though the grounds alleged for these prohibitions may belong to a magical context, yet the fundamental idea of gaining greater strength by renouncing some instinctual satisfaction remains unmistakable; and the hygienic root of the prohibition which lies alongside its magical rationalization must not be overlooked. When the men of a savage tribe go out on an expedition to hunt, to fish, to fight or to gather precious plants, their wives left at home are subjected to many oppressive restrictions, to which the savages themselves ascribe a favourable influence, operating at a distance upon the success of the expedition. But it requires very little penetration to see that this factor which operates at a distance is nothing other than the absent men's longing thoughts of home, and that behind these disguises lies a sound piece of psychological insight that the men will only do their best if they feel completely secure about the women whom they have left behind them unguarded. Sometimes they will even themselves declare, without alleging any magical reasons, that a wife's infidelity in marriage will bring to nothing the efforts of an absent husband engaged on some responsible work.

[1912-1913, 2739]
The other members of this class of wish-fulfilments - hysterical symptoms, for instance - possess one essential characteristic, however, which I cannot discover in dreams. I have learnt from the researches which I have mentioned so often in the course of this work that in order to bring about the formation of a hysterical symptom both currents of our mind must converge. A symptom is not merely the expression of a realized unconscious wish; a wish from the preconscious which is fulfilled by the same symptom must also be present. So that the symptom will have of at least two determinants, one arising from each of the systems involved in the conflict. As in the case of dreams, there are no limits to the further determinants that may be present - to the 'overdetermination' of the symptoms. The determinant which does not arise from the Ucs. is invariably, so far as I know, a train of thought reacting against the unconscious wish - a self-punishment, for instance. I can therefore make the quite general assertion that a hysterical symptom develops only where the fulfilments of two opposing wishes, arising each from a different psychical system, are able to converge in a single expression. (Compare in this connection my most recent formulations on the origin of hysterical symptoms in my paper on hysterical phantasies and their relation to bisexuality.) Examples would serve very little purpose here, since nothing but an exhaustive elucidation of the complications involved could carry conviction. I will therefore leave my assertion to stand for itself and only quote an example in order to make the point clear, and not to carry conviction. In one of my women patients, then, hysterical vomiting turned out to be on the one hand the fulfilment of an unconscious phantasy dating from her puberty - of a wish, that is, that she might be continuously pregnant and have innumerable children, with a further wish, added later, that she might have them by as many men as possible. A powerful defensive impulse had sprung up against this unbridled wish. And, since the patient might lose her figure and her good looks as a result of her vomiting, and so might cease to be attractive to anyone, the symptom was acceptable to the punitive train of thought as well; and since it was permitted by both sides it could become a reality. This was the same method of treating a wish-fulfilment as was adopted by the Parthian queen towards the Roman triumvir Crassus. Believing that he had embarked on his expedition out of love of gold, she ordered molten gold to be poured down his throat when he was dead: 'Now', she said, 'you have what you wanted.' But all that we so far know about dreams is that they express the fulfilment of a wish from the unconscious; it seems as though the dominant, preconscious system acquiesces in this after insisting upon a certain number of distortions. Nor is it possible as a general rule to find a train of thought opposed to the dream-wish and, like its counterpart, realized in the dream. Only here and there in dream-analyses do we come upon signs of reactive creations, like, for instance, my affectionate feelings for my friend R. in the dream of my uncle (cf. p. 637 ff.). But we can find the missing ingredient from the preconscious elsewhere. Whereas the wish from the Ucs. is able to find expression in the dream after undergoing distortions of every kind, the dominant system withdraws into a wish to sleep, realizes that wish by bringing about the modifications which it is able to produce in the cathexes within the psychical apparatus, and persists in that wish throughout the whole duration of sleep.¹ [1900a, 999]
¹ The proof of infantile masturbation in other cases is established in a precisely similar way. The evidence for it is mostly of a similar nature: indications of the presence of leucorrhoea, bed-wetting, hand-ceremonials (obsessional washing), and such things. It is always possible to discover with certainty from the nature of the symptoms of the case whether the habit was discovered by the person in charge of the child or not, or whether this sexual activity was brought to an end by long efforts on the child's part to break itself of the habit, or by a sudden change. In Dora's case the masturbation had remained undiscovered, and had come to an end at a single blow (cf. her secret, her fear of doctors, and the replacement by dyspnoea). The patients, it is true, invariably dispute the conclusiveness of circumstantial evidence such as this, and they do so even when they have retained a conscious recollection of the catarrh or of their mother's warning (e.g. 'That makes people stupid; it's dangerous'). But some time later the memory, which has been so long repressed, of this piece of infantile sexual life emerges with certainty, and it does so in every instance. I am reminded of the case of a patient of mine suffering from obsessions, which were direct derivatives of infantile masturbation. Her peculiarities, such as self-prohibitions and self-punishments, the feeling that if she had done this she must not do that, the idea that she must not be interrupted, the introduction of pauses between one procedure (with her hands) and the next, her hand-washing, etc., - all of these turned out to be unaltered fragments of her nurse's efforts to break her of the habit. The only thing which had remained permanently in her memory were the words of warning: 'Ugh! That's dangerous!' Compare also in this connection my Three Essays on the Theory of Sexuality, 1905d. [1905e, 1416]
He then went on to say that he would like to speak of a criminal act, whose author he did not recognize as himself, though he quite clearly recollected committing it. He quoted a saying of Nietzsche's:² "I did this," says my Memory. "I cannot have done this," says my Pride and remains inexorable. In the end - Memory yields.' 'Well,' he continued, 'my memory has not yielded on this point.' - 'That is because you derive pleasure from your self-reproaches as a means of self-punishment.' - 'My younger brother - I am really very fond of him now, and he is causing me a great deal of worry just at present, for he wants to make what I consider a preposterous match; I have thought before now of going and killing the person concerned so as to prevent his marrying her -well, my younger brother and I used to fight a lot when we were children. We were very fond of each other at the same time, and were inseparable; but I was plainly filled with jealousy, as he was the stronger and better-looking of the two and consequently the favourite.' - 'Yes. You have already given me a description of a scene of jealousy in connection with Fräulein Lina.' - 'Very well then, on some such occasion (it was certainly before I was eight years old, for I was not going to school yet, which I began to do when I was eight) - on some such occasion, this is what I did. We both had toy guns of the usual make. I loaded mine with the ram rod and told him that if he looked up the barrel he would see something. Then, while he was looking in, I pulled the trigger. He was hit on the forehead and not hurt; but I had meant to hurt him very much indeed. Afterwards I was quite beside myself, and threw myself on the ground and asked myself however I could have done such a thing. But I did do it.' - I took the opportunity of urging my case. If he had preserved the recollection of an action so foreign to him as this, he could not, I maintained, deny the possibility of something similar, which he had now forgotten entirely, having happened at a still earlier age in relation to his father. - He then told me he was aware of having felt other vindictive impulses, this time towards the lady he admired so much, of whose character he painted a glowing picture. It might be true, he said, that she could not love easily; but she was reserving her whole self for the one man to whom she would some day belong. She did not love him. When he had become certain of that, a conscious phantasy had taken shape in his mind of how he should grow very rich and marry some one else, and should then take her to call on the lady in order to hurt her feelings. But at that point the phantasy had broken down, for he had been obliged to own to himself that the other woman, his wife, was completely indifferent to him; then his thoughts had become confused, till finally it had been clearly borne in upon him that this other woman would have to die. In this phantasy, just as in his attempt upon his brother, he recognized the quality of cowardice which was so particularly horrible to him.³ - In the further course of our conversation I pointed out to him that he ought logically to consider himself as in no way responsible for any of these traits in his character; for all of these reprehensible impulses originated from his infancy, and were only derivatives of his infantile character surviving in his unconscious; and he must know that moral responsibility could not be applied to children. It was only by a process of development, I added, that a man, with his moral responsibility, grew up out of the sum of his infantile predispositions.⁴ He expressed a doubt, however, whether all his evil impulses had originated from that source. But I promised to prove it to him in the course of the treatment. [1909d, 2146]
Suppose, on the other hand, that we were to take into account the finding arrived at by psycho-analysis from the dreams of normal people, to the effect that we ourselves are subject, more strongly and more often than we suspect, to a temptation to kill someone and that that temptation produces psychical effects even though it remains out of sight of our consciousness. Suppose, again, that we were to recognize the compulsive observances of certain neurotics as being guarantees against an intensified impulse to murder or as being self-punishments on account of it. In that case we should have to attach still greater importance to our thesis that where there is a prohibition there must be an underlying desire. We should have to suppose that the desire to murder is actually present in the unconscious and that neither taboos nor moral prohibitions are psychologically superfluous but that on the contrary they are explained and justified by the existence of an ambivalent attitude towards the impulse to murder.

[1912-1913, 2714]

In another neurotic disorder, obsessional neurosis, the patients become the victims of distressing and apparently senseless ceremonials which take the form of the rhythmical repetition of the most trivial acts (such as washing or dressing) or of carrying out meaningless injunctions or of obeying mysterious prohibitions. It was nothing less than a triumph of psycho-analytic research when it succeeded in showing that all these obsessive acts, even the most insignificant and trivial of them, have a meaning, and that they are reflections, translated into indifferent terms, of conflicts in the patients' lives, of the struggle between temptations and moral restraints - reflections of the proscribed wish itself and of the punishment and atonement which that wish incurs. In another form of the same disorder the victim suffers from tormenting ideas (obsessions) which force themselves upon him and are accompanied by affects whose character and intensity are often only quite inadequately accounted for by the terms of the obsessive ideas themselves. Analytic investigation has shown in their case that the affects are entirely justified, since they correspond to self-reproaches which are based on something that is at least psychically real. But the ideas to which these affects are attached are not the original ones, but have found their way into their present position by a process of displacement - by being substituted for something that has been repressed. If these displacements can be reversed, the way is open to the discovery of the repressed ideas, and the relation between affect and idea is found to be perfectly appropriate.

[1913], 2810

If, in the third place, you will recall our idea that the dreamer fighting against his own wishes is to be compared with a summation of two separate, though in some way intimately connected, people, you will understand another possibility. For there is a possibility that the fulfilment of a wish may bring about something very far from pleasant - namely, a punishment. Here we can once more use the fairy tale of the three wishes as an illustration. The fried sausages on a plate were the direct fulfilment of the wish of the first person, the woman, The sausages on her nose were the fulfilment of the wish of the second person, the man, but were at the same time a punishment for the woman's foolish wish. (We shall discover in neuroses the motive for the third wish, the last remaining one in the fairy tale.) There are many such punitive trends in the mental life of human beings; they are very powerful, and we may hold them responsible for some of the distressing dreams. Perhaps you will now say that this leaves very little over of the famous wish-fulfilment. But if you look more closely you will admit that you are wrong. Compared with the multiplicity (which I shall mention later) of the things that dreams might be and according to many authorities actually are, our solution - wish-fulfilment, anxiety-fulfilment, punishment-fulfilment - is a very restricted one. We may add that the anxiety is the direct opposite of the wish, that opposites are especially close to one another in associations and that in the unconscious they coalesce; and further, that the punishment is also the fulfilment of a wish - of the wish of the other, censoring person.

[1916-1917, 3307]
We are led into quite another realm of explanation by the analysis of the attempt at suicide, which I must regard as seriously intended, and which, incidentally, considerably improved her position both with her parents and with the lady she loved. She went for a walk with her one day in a part of the town and at an hour at which she was not unlikely to meet her father on his way from his office. So it turned out. Her father passed them in the street and cast a furious look at her and her companion, about whom he had by that time come to know. A few moments later she flung herself into the railway cutting. The explanation she gave of the immediate reasons determining her decision sounded quite plausible. She had confessed to the lady that the man who had given them such an irate glance was her father, and that he had absolutely forbidden their friendship. The lady became incensed at this and ordered the girl to leave her then and there, and never again to wait for her or to address her - the affair must now come to an end. In her despair at having thus lost her loved one for ever, she wanted to put an end to herself. The analysis, however, was able to disclose another and deeper interpretation behind the one she gave, which was confirmed by the evidence of her own dreams. The attempted suicide was, as might have been expected, determined by two other motives besides the one she gave: it was the fulfilment of a punishment (self-punishment), and the fulfilment of a wish. As the latter it meant the attainment of the very wish which, when frustrated, had driven her into homosexuality - namely, the wish to have a child by her father, for now she 'fell' through her father's fault.¹ The fact that at that moment the lady had spoken in just the same terms as her father, and had uttered the same prohibition, forms the connecting link between this deep interpretation and the superficial one of which the girl herself was conscious. From the point of view of self-punishment the girl's action shows us that she had developed in her unconscious strong death-wishes against one or other of her parents - perhaps against her father, out of revenge for impeding her love, but more probably against her mother too, when she was pregnant with the little brother. For analysis has explained the enigma of suicide in the following way: probably no one finds the mental energy required to kill himself unless, in the first place, in doing so he is at the same time killing an object with whom he has identified himself, and, in the second place, is turning against himself a death-wish which had been directed against someone else. Nor need the regular discovery of these unconscious death-wishes in those who have attempted suicide surprise us (any more than it ought to make us think that it confirms our deductions), since the unconscious of all human beings is full enough of such death-wishes, even against those they love.² Since the girl identified herself with her mother, who should have died at the birth of the child denied to herself, this punishment-fulfilment itself was once again a wish-fulfilment. Finally, the discovery that several quite different motives, all of great strength, must have co-operated to make such a deed possible is only in accordance with what we should expect.

¹ That the various methods of suicide can represent sexual wish-fulfilments has long been known to all analysts. (To poison oneself = to become pregnant; to drown - to bear a child; to throw oneself from a height = to be delivered of a child.)

² There are clearly also inhibitions which serve the purpose of self-punishment. This is often the case in inhibitions of professional activities. The ego is not allowed to carry on those activities, because they would bring success and gain, and these are things which the severe super-ego has forbidden. So the ego gives them up too, in order to avoid coming into conflict with the super-ego.

[1920a, 3851]

[1926d, 4251]
A good deal of what has been said may be objected to on the ground that the unpleasant obsessive ideas are themselves quite conscious. But there is no doubt that before becoming conscious they have been though the process of repression. In most of them the actual wording of the aggressive instinctual impulse is altogether unknown to the ego, and it requires a good deal of analytic work to make it conscious. What does penetrate into consciousness is usually only a distorted substitute which is either of a vague, dream-like and indeterminate nature or so travestied as to be unrecognizable. Even where repression has not encroached upon the content of the aggressive impulse it has certainly got rid of its accompanying affective character. As a result, the aggressiveness appears to the ego not to be an impulsion but, as the patients themselves say, merely a 'thought' which awakens no feeling. But the remarkable thing is that this is not the case. What happens is that the affect left out when the obsessional idea is perceived appears in a different place. The super-ego behaves as though repression had not occurred and as though it knew the real wording and full affective character of the aggressive impulse, and it treats the ego accordingly. The ego which, on the one hand, knows that it is innocent is obliged, on the other hand, to be aware of a sense of guilt and to carry a responsibility which it cannot account for. This state of affairs is, however, not so puzzling as it would seem at first sight. The behaviour of the super-ego is perfectly intelligible, and the contradiction in the ego merely shows that it has shut out the id by means of repression while remaining fully accessible to the influence of the super-ego. If it is asked why the ego does not also attempt to withdraw from the tormenting criticism of the super-ego, the answer is that it does manage to do so in a great number of instances. There are obsessional neuroses in which no sense of guilt whatever is present. In them, as far as can be seen, the ego has avoided becoming aware of it by instituting a fresh set of symptoms, penances or restrictions of a self-punishing kind. These symptoms, however, represent at the same time a satisfaction of masochistic impulses which, in their turn, have been reinforced by regression.

The direction to be taken by this father-religion was in this way laid down for all time. Yet this did not bring its development to an end. Ambivalence is a part of the essence of the relation to the father: in the course of time the hostility too could not fail to stir, which had once driven the sons into killing their admired and dreaded father. There was no place in the framework of the religion of Moses for a direct expression of the murderous hatred of the father. All that could come to light was a mighty reaction against it - a sense of guilt on account of that hostility, a bad conscience for having sinned against God and for not ceasing to sin. This sense of guilt, which was uninterruptedly kept awake by the Prophets, and which soon formed an essential part of the religious system, had yet another superficial motivation, which neatly disguised its true origin. Things were going badly for the people; the hopes resting on the favour of God failed in fulfilment; it was not easy to maintain the illusion, loved above all else, of being God's chosen people. If they wished to avoid renouncing that happiness, a sense of guilt on account of their own sinfulness offered a welcome means of exculpating God: they deserved no better than to be punished by him since they had not obeyed his commandments. And, driven by the need to satisfy this sense of guilt, which was insatiable and came from sources so much deeper, they must make those commandments grow ever stricter, more meticulous and even more trivial. In a fresh rapture of moral asceticism they imposed more and more new instinctual renunciations on themselves and in that way reached - in doctrine and precept, at least - ethical heights which had remained inaccessible to the other peoples of antiquity. Many Jews regard this attainment of ethical heights as the second main characteristic and the second great achievement of their religion. The way in which it was connected with the first one - the idea of a single god - should be plain from our remarks. These ethical ideas cannot, however, disavow their origin from the sense of guilt felt on account of a suppressed hostility to God. They possess the characteristic - uncompleted and incapable of completion - of obsessional neurotic reaction-formations; we can guess, too, that they serve the secret purposes of punishment.
It is not at all rare for both of the two children to fall ill later on of a defence neurosis - the brother with obsessions and the sister with hysteria. This naturally gives the appearance of a familial neurotic disposition. Occasionally, however, this pseudo-heredity is resolved in a surprising fashion. In one of my cases a brother, a sister, and a somewhat older male cousin were all of them ill. From the analysis which I carried out on the brother, I learnt that he was suffering from self-reproaches for being the cause of his sister's illness. He himself had been seduced by his cousin, and the latter, it was known in the family, had been the victim of his nursemaid.

[1896b, 386]

The nature of obsessional neurosis can be expressed in a simple formula. Obsessional ideas are invariably transformed self-reproaches which have re-emerged from repression and which always relate to some sexual act that was performed with pleasure in childhood. In order to elucidate this statement it is necessary to describe the typical course taken by an obsessional neurosis.

[1896b, 389]
He admitted that all of this sounded quite plausible, but he was naturally not in the very least convinced by it. He would venture to ask, he said, how it was that an idea of this kind could have remissions, how it could appear for a moment when he was twelve years old, and again when he was twenty, and then once more two years later, this time for good. He could not believe that his hostility had been extinguished in the intervals, and yet during them there had been no sign of self-reproaches. To this I replied that whenever any one asked a question like that, he was already prepared with an answer; he needed only to be encouraged to go on talking. He then proceeded, somewhat disconnectedly as it seemed, to say that he had been his father's best friend, and that his father had been his. Except on a few subjects, upon which fathers and sons usually hold aloof from one another — (What could he mean by that?) —, there had been a greater intimacy between them than there now was between him and his best friend. As regards the lady for whose sake he had sacrificed his father in that idea of his, it was true that he had loved her very much, but he had never felt really sensual wishes towards her, such as he had constantly had in his childhood. Altogether, in his childhood his sensual impulses had been much stronger than during his puberty. At this I told him I thought he had now produced the answer we were waiting for, and had at the same time discovered the third great characteristic of the unconscious. The source from which his hostility to his father derived its indestructibility was evidently something in the nature of sensual desires, and in that connection he must have felt his father as in some way or other an interference. A conflict of this kind, I added, between sensuality and childish love was entirely typical. The remissions he had spoken of had occurred because the premature explosion of his sensual feelings had had as its immediate consequence a considerable diminution of their violence. It was not until he was once more seized with intense erotic desires that his hostility reappeared again owing to the revival of the old situation. I then got him to agree that I had not led him on to the subject either of childhood or of sex, but that he had raised them both of his own free will. He then went on to ask why he had not simply come to a decision, at the time he was in love with the lady, that his father's interference with that love could not for a moment weigh against his love of his father. I replied that it was scarcely possible to destroy a person in absentia. Such a decision would only have been possible if the wish that he took objection to had made its first appearance on that occasion; whereas, as a matter of fact, it was a long-repressed wish, towards which he could not behave otherwise than he had formerly done, and which was consequently immune from destruction. This wish (to get rid of his father as being an interference) must have originated at a time when circumstances had been very different — at a time, perhaps, when he had not loved his father more than the person whom he desired sensually, or when he was incapable of making a clear decision. It must have been in his very early childhood, therefore, before he had reached the age of six, and before the date at which his memory became continuous; and things must have remained in the same state ever since. With this piece of construction our discussion was broken off for the time being.

[1909d, 2145]
He then went on to say that he would like to speak of a criminal act, whose author he did not recognize as himself, though he quite clearly recollected committing it. He quoted a saying of Nietzsche's:² "I did this," says my Memory. "I cannot have done this," says my Pride and remains inexorable. In the end - Memory yields. 'Well,' he continued, 'my memory has not yielded on this point.' - 'That is because you derive pleasure from your self-reproaches as a means of self-punishment.' - 'My younger brother - I am really very fond of him now, and he is causing me a great deal of worry just at present, for he wants to make what I consider a preposterous match; I have thought before now of going and killing the person concerned so as to prevent his marrying her - well, my younger brother and I used to fight a lot when we were children. We were very fond of each other at the same time, and were inseparable; but I was plainly filled with jealousy, as he was the stronger and better-looking of the two and consequently the favourite.' - 'Yes. You have already given me a description of a scene of jealousy in connection with Fräulein Lina.' - 'Very well then, on some such occasion (it was certainly before I was eight years old, for I was not going to school yet, which I began to do when I was eight) - on some such occasion, this is what I did. We both had toy guns of the usual make. I loaded mine with the ram rod and told him that if he looked up the barrel he would see something. Then, while he was looking in, I pulled the trigger. He was hit on the forehead and not hurt; but I had meant to hurt him very much indeed. Afterwards I was quite beside myself, and threw myself on the ground and asked myself however I could have done such a thing. But I did do it.' - I took the opportunity of urging my case. If he had preserved the recollection of an action so foreign to him as this, he could not, I maintained, deny the possibility of something similar, which he had now forgotten entirely, having happened at a still earlier age in relation to his father. - He then told me he was aware of having felt other vindictive impulses, this time towards the lady he admired so much, of whose character he painted a glowing picture. It might be true, he said, that she could not love easily; but she was reserving her whole self for the one man to whom she would some day belong. She did not love him. When he had become certain of that, a conscious phantasy had taken shape in his mind of how he should grow very rich and marry some one else, and should then take her to call on the lady in order to hurt her feelings. But at that point the phantasy had broken down, for he had been obliged to own to himself that the other woman, his wife, was completely indifferent to him; then his thoughts had become confused, till finally it had been clearly borne in upon him that this other woman would have to die. In this phantasy, just as in his attempt upon his brother, he recognized the quality of cowardice which was so particularly horrible to him.³ - In the further course of our conversation I pointed out to him that he ought logically to consider himself as in no way responsible for any of these traits in his character; for all of these reprehensible impulses originated from his infancy, and were only derivatives of his infantile character surviving in his unconscious; and he must know that moral responsibility could not be applied to children. It was only by a process of development, I added, that a man, with his moral responsibility, grew up out of the sum of his infantile predispositions.⁴ He expressed a doubt, however, whether all his evil impulses had originated from that source. But I promised to prove it to him in the course of the treatment.

[1909d, 2146]
For this reason it not uncommonly happens that obsessional neurotics, who are troubled with self-reproaches but have connected their affects with the wrong causes, will also tell the physician the true causes, without any suspicion that their self-reproaches have simply become detached from them. In relating such an incident they will sometimes add with astonishment or even with an air of pride: 'But I think nothing of that.' This happened in the first case of obsessional neurosis which gave me an insight many years ago into the nature of the malady. The patient, who was a government official, was troubled by innumerable scruples. He was the man whose compulsive act in connection with the branch in the park at Schönbrunn I have already described. I was struck by the fact that the florin notes with which he paid his consultation fees were invariably clean and smooth. (This was before we had a silver coinage in Austria.) I once remarked to him that one could always tell a government official by the brand-new florins that he drew from the State treasury, and he then informed me that his florins were by no means new, but that he had them ironed out at home. It was a matter of conscience with him, he explained, not to hand any one dirty paper florins; for they harboured all sorts of dangerous bacteria and might do some harm to the recipient. At that time I already had a vague suspicion of the connection between neuroses and sexual life, so on another occasion I ventured to ask the patient how he stood in regard to that matter. 'Oh, that's quite all right,' he answered airily, 'I'm not at all badly off in that respect. I play the part of a dear old uncle in a number of respectable families, and now and then I make use of my position to invite some young girl to go out with me for a day's excursion in the country. Then I arrange that we shall miss the train home and be obliged to spend the night out of town. I always engage two rooms - I do things most handsomely; but when the girl has gone to bed I go in to her and masturbate her with my fingers.' - 'But aren't you afraid of doing her some harm, fiddling about in her genitals with your dirty hand?' - At this he flared up: 'Harm? Why, what harm should it do her? It hasn't done a single one of them any harm yet, and they've all of them enjoyed it. Some of them are married now, and it hasn't done them any harm at all.' - He took my remonstrance in very bad part, and never appeared again. But I could only account for the contrast between his fastidiousness with the paper florins and his unscrupulousness in abusing the girls entrusted to him by supposing that the self-reproachful affect had become displaced. The aim of this displacement was obvious enough: if his self-reproaches had been allowed to remain where they belonged he would have had to abandon a form of sexual gratification to which he was probably impelled by some powerful infantile determinants. The displacement therefore ensured his deriving a considerable advantage from his illness.

[1909d, 2155]

In place of a single sick person let us put society - suffering as a whole from neuroses, though composed of sick and healthy members; and in place of individual acceptance in the one case let us put general recognition in the other. A little reflection will then show you that this substitution cannot in any way alter the outcome. The success which the treatment can have with the individual must occur equally with the community. Sick people will not be able to let their various neuroses become known - their anxious over-tenderness which is meant to conceal their hatred, their agoraphobia which tells of disappointed ambition, their obsessive actions which represent self-reproaches for evil intentions and precautions against them - if all their relatives and every stranger from whom they wish to conceal their mental processes know the general meaning of such symptoms, and if they themselves know that in the manifestations of their illness they are producing nothing that other people cannot instantly interpret. The effect, however, will not be limited to the concealment of the symptoms which, incidentally, it is often impossible to carry out; for this necessity for concealment destroys the use of being ill. Disclosure of the secret will have attacked, at its most sensitive point, the 'aetiological equation' from which neuroses arise - it will have made the gain from the illness illusory; and consequently the final outcome of the changed situation brought about by the physician's indiscretion can only be that the production of the illness will be brought to a stop.

[1910d, 2312]
We are perfectly familiar with the infantile attitude of boys towards their father; it is composed of the same mixture of reverent submission and mutinous insubordination that we have found in Schreber's relation to his God, and is the unmistakable prototype of that relation, which is faithfully copied from it. But the circumstance that Schreber's father was a physician, and a most eminent physician, and one who was no doubt highly respected by his patients, is what explains the most striking characteristics of his God and those upon which he dwells in such a critical fashion. Could more bitter scorn be shown for such a physician than by declaring that he understands nothing about living men and only knows how to deal with corpses? No doubt it is an essential attribute of God to perform miracles; but a physician performs miracles too; he effects miraculous cures, as his enthusiastic clients proclaim. So that when we see that these very miracles (the material for which was provided by the patient's hypochondria) turn out to be incredible, absurd, and to some extent positively silly, we are reminded of the assertion in my Interpretation of Dreams that absurdity in dreams expresses ridicule and derision.¹ Evidently, therefore, it is used for the same purposes in paranoia. As regards some of the other reproaches which he levelled against God, such, for instance, as that He learned nothing by experience, it is natural to suppose that they are examples of the *tu quoque* mechanism used by children,² which, when they receive a reproof, flings it back unchanged upon the person who originated it. Similarly, the voices give us grounds for suspecting that the accusation of soul-murder brought against Flechsig was in the first instance a self-accusation.³

It is always a striking thing and deserves special notice when a neurotic is in the habit of speaking ill of himself, expressing a low opinion of himself, and so on. As in the case of self-reproaches, it is often possible to explain it by supposing that he is identifying himself with someone else. But in one patient the attendant circumstances during the session necessitated another explanation of behaviour of this kind. A young lady, who was never tired of declaring that she had very little intelligence, was without gifts, etc., was only trying to indicate by this that she had great physical beauty, and was concealing this boast behind her self-criticism. Nor was a reference to the harmful effects of masturbation - a reference which is to be expected in all such cases - absent in this one.

The reproaches of conscience in certain forms of obsessional neurosis are as distressing and tormenting, but here the situation is less perspicuous. It is noteworthy that the obsessional neurotic, in contrast to the melancholic, never in fact takes the step of self-destruction; it is as though he were immune against the danger of suicide, and he is far better protected from it than the hysteric. We can see that what guarantees the safety of the ego is the fact that the object has been retained. In obsessional neurosis it has become possible, through a regression to the pregenital organization, for the love-impulses to transform themselves into impulses of aggression against the object. Here again the instinct of destruction has been set free and it seeks to destroy the object, or at least it appears to have that intention. These purposes have not been adopted by the ego and it struggles against them with reaction-formations and precautionary measures; they remain in the id. The super-ego, however, behaves as if the ego were responsible for them and shows at the same time by the seriousness with which it chastises these destructive intentions that they are no mere semblance evoked by regression but an actual substitution of hate for love. Helpless in both directions, the ego defends itself vainly, alike against the instigations of the murderous id and against the reproaches of the punishing conscience. It succeeds in holding in check at least the most brutal actions of both sides; the first outcome is interminable self-torment, and eventually there follows a systematic torturing of the object, in so far as it is within reach.

---

³ [1923b, 3987]
What we had here was a hysterical delirium which alternated with normal consciousness, just as a true tic intrudes into a voluntary movement without interfering with it and without being mixed up with it.
[1895d, 47]
No doubt all kinds of objections can still be raised to the assertion that neurotic symptoms are substitutes for sexual satisfactions. I will mention two of them to-day. When you yourselves have carried out analytic examinations of a considerable number of neurotics, you will perhaps tell me, shaking your head, that in a lot of cases my assertion is simply not true; the symptoms seem rather to have the contrary purpose of excluding or of stopping sexual satisfaction. I will not dispute the correctness of your interpretation. The facts in psycho-analysis have a habit of being rather more complicated than we like. If they were as simple as all that, perhaps it might not have needed psycho-analysis to bring them to light. Indeed, some of the features of our second patient’s ceremonial show signs of this ascetic character with its hostility to sexual satisfaction: when, for instance, she got rid of the clocks and watches, which had the magical meaning of avoiding erections during the night, or when she tried to guard against flower-pots falling and breaking, which was equivalent to protecting her virginity. In some other cases of bed ceremonials, which I have been able to analyse, this negative character was far more outspoken; the ceremonial might consist exclusively of defensive measures against sexual memories and temptations. However, we have already found often enough that in psycho-analysis opposites imply no contradiction. We might extend our thesis and say that symptoms aim either at a sexual satisfaction or at fending it off, and that on the whole the positive, wish-fulfilling character prevails in hysteria and the negative, ascetic one in obsessional neurosis. If symptoms can serve the purpose both of sexual satisfaction and of its opposite, there is an excellent basis for this double-sidedness or polarity in a part of their mechanism which I have so far not been able to mention. For, as we shall hear, they are the products of a compromise and arise from the mutual interference between two opposing currents; they represent not only the repressed but also the repressing force which had a share in their origin. One side or the other may be more strongly represented; but it is rarely that one influence is entirely absent. In hysteria a convergence of both intentions in the same symptom is usually achieved. In obsessional neurosis the two portions are often separated; the symptom then becomes diphasic and consists in two actions, one after the other, which cancel each other out.

This is not very illuminating. We can only note that disturbances of the sexual function are brought about by a great variety of means. (1) The libido may simply be turned away (this seems most readily to produce what we regard as an inhibition pure and simple); (2) the function may be less well carried out; (3) it may be hampered by having conditions attached to it, or modified by being diverted to other aims; (4) it may be prevented by security measures; (5) if it cannot be prevented from starting, it may be immediately interrupted by the appearance of anxiety; and (6), if it is nevertheless carried out, there may be a subsequent reaction of protest against it and an attempt to undo what has been done.
We turn to the obsessional neuroses in the hope of learning more about the formation of symptoms. The symptoms belonging to this neurosis fall, in general, into two groups, each having an opposite trend. They are either prohibitions, precautions and expiations - that is, negative in character - or they are, on the contrary, substitutive satisfactions which often appear in symbolic disguise. The negative, defensive group of symptoms is the older of the two; but as illness is prolonged, the satisfactions, which scoff at all defensive measures, gain the upper hand. The symptom-formation scores a triumph if it succeeds in combining the prohibition with satisfaction so that what was originally a defensive command or prohibition acquires the significance of a satisfaction as well; and in order to achieve this end it will often make use of the most ingenious associative paths. Such an achievement demonstrates the tendency of the ego to synthesize, which we have already observed. In extreme cases the patient manages to make most of his symptoms acquire, in addition to their original meaning, a directly contrary one. This is a tribute to the power of ambivalence, which, for some unknown reason, plays such a large part in obsessional neuroses. In the crudest instance the symptom is diphasic: an action which carries out a certain injunction is immediately succeeded by another action which stops or undoes the first one even if it does not go quite so far as to carry out its opposite.

[1926d, 4271]

The two techniques I refer to are *undoing what has been done* and *isolating*. The first of these has a wide range of application and goes back very far. It is, as it were, negative magic, and endeavours, by means of motor symbolism, to 'blow away' not merely the consequences of some event (or experience or impression) but the event itself. I choose the term 'blow away' advisedly, so as to remind the reader of the part played by this technique not only in neuroses but in magical acts, popular customs and religious ceremonies as well. In obsessional neurosis the technique of undoing what has been done is first met with in the 'diphasic' symptoms, in which one action is cancelled out by a second, so that it is as though neither action had taken place, whereas, in reality, both have. This aim of undoing is the second underlying motive of obsessional ceremonials, the first being to take precautions in order to prevent the occurrence or recurrence of some particular event. The difference between the two is easily seen: the precautionary measures are rational, while trying to get rid of something by 'making it not to have happened' is irrational and in the nature of magic. It is of course to be suspected that the latter is the earlier motive of the two and proceeds from the animistic attitude towards the environment. This endeavour to undo shades off into normal behaviour in the case in which a person decides to regard an event as not having happened. But whereas he will take no direct steps against the event, and will simply pay no further attention to it or its consequences, the neurotic person will try to make the past itself non-existent. He will try to repress it by motor means. The same purpose may perhaps account for the obsession for *repeating* which is so frequently met with in this neurosis and the carrying out of which serves a number of contradictory intentions at once. When anything has not happened in the desired way it is undone by being repeated in a different way; and thereupon all the motives that exist for lingering over such repetitions come into play as well. As the neurosis proceeds, we often find that the endeavour to undo a traumatic experience is a motive of first-rate importance in the formation of symptoms. We thus unexpectedly discover a new, motor technique of defence, or (as we may say in this case with less inaccuracy) of repression.

[1926d, 4278]
Even a purely terminological innovation ought to justify its adoption; it ought to reflect some new point of view or some extension of knowledge. The revival of the concept of defence and the restriction of that of repression takes into account a fact which has long since been known but which has received added importance owing to some new discoveries. Our first observations of repression and of the formation of symptoms were made in connection with hysteria. We found that the perceptual content of exciting experiences and the ideational content of pathogenic structures of thought were forgotten and debarred from being reproduced in memory, and we therefore concluded that the keeping away from consciousness was a main characteristic of hysterical repression. Later on, when we came to study the obsessional neuroses, we found that in that illness pathogenic occurrences are not forgotten. They remain conscious but they are 'isolated' in some way that we cannot as yet grasp, so that much the same result is obtained as in hysterical amnesia. Nevertheless the difference is great enough to justify the belief that the process by which instinctual demands are set aside in obsessional neurosis cannot be the same as in hysteria. Further investigations have shown that in obsessional neurosis a regression of the instinctual impulses to an earlier libidinal stage is brought about through the opposition of the ego, and that this regression, although it does not make repression unnecessary, clearly works in the same sense as repression. We have seen, too, that in obsessional neurosis anticathexis, which is also presumably present in hysteria, plays a specially large part in protecting the ego by effecting a reactive alteration in it. Our attention has, moreover, been drawn to a process of 'isolation' (whose technique cannot as yet be elucidated) which finds direct symptomatic manifestation, and to a procedure, that may be called magical, of 'undoing' what has been done - a procedure about whose defensive purpose there can be no doubt, but which has no longer any resemblance to the process of 'repression'. These observations provide good enough grounds for re-introducing the old concept of defence, which can cover all these processes that have the same purpose - namely, the protection of the ego against instinctual demands - and for subsuming repression under it as a special case. The importance of this nomenclature is heightened if we consider the possibility that further investigations may show that there is an intimate connection between special forms of defence and particular illnesses, as, for instance, between repression and hysteria. In addition we may look forward to the possible discovery of yet another important correlation. It may well be that before its sharp cleavage into an ego and an id, and before the formation of a super-ego, the mental apparatus makes use of different methods of defence from those which it employs after it has reached these stages of organization.

[1926d, 4316]
Secondary defence against the obsessional ideas may be effected by a forcible diversion on to other thoughts with a content as contrary as possible. This is why *obsessional brooding*, if it succeeds, regularly deals with abstract and *suprasensual* things; because the ideas that have been repressed are always concerned with *sensuality*. Or else the patient tries to make himself master of each of his obsessional ideas singly by logical work and by having recourse to his conscious memories. This leads to *obsessional thinking*, to a *compulsion to test things* and to *doubting mania*. The advantage which perception has over memory in such tests at first causes the patient, and later compels him, to collect and store up all the objects with which he has come into contact. Secondary defence against obsessional *affects* leads to a still wider set of protective measures which are capable of being transformed into obsessional acts. These may be grouped according to their purpose: *penitential* measures (burdensome ceremonials, the observation of numbers), *precautionary* measures (all sorts of phobias, superstition, pedantry, increase of the primary symptom of conscientiousness); measures to do with *fear of betrayal* (collecting scraps of paper, seclusiveness), or to ensure *numbing* (dipsomania). Among these obsessional acts and obsessional impulses, phobias, since they circumscribe the patient's existence, play the greatest part. [1896b, 393]

There are cases in which one can observe how the obsession is transferred from the idea or from the affect on to the protective measure; others in which the obsession oscillates periodically between the symptom of the return of the repressed and the symptom of the secondary defence; and yet other cases in which no obsessional idea is constructed at all, but, instead, the repressed memory is at once represented by what is apparently a primary measure of defence. Here we reach at one bound the stage which elsewhere only completes the course run by the obsessional neurosis after the defensive struggle has taken place. Severe cases of this disorder end in the ceremonial actions becoming fixated, or in a general state of doubting mania, or in a life of eccentricity conditioned by phobias. [1896b, 393]
We now observe that the store of religious ideas includes not only wish-fulfilments but important historical recollections. This concurrent influence of past and present must give religion a truly incomparable wealth of power. But perhaps with the help of an analogy yet another discovery may begin to dawn on us. Though it is not a good plan to transplant ideas far from the soil in which they grew up, yet here is a conformity which we cannot avoid pointing out. We know that a human child cannot successfully complete its development to the civilized stage without passing through a phase of neurosis sometimes of greater and sometimes of less distinctness. This is because so many instinctual demands which will later be unserviceable cannot be suppressed by the rational operation of the child's intellect but have to be tamed by acts of repression, behind which, as a rule, lies the motive of anxiety. Most of these infantile neuroses are overcome spontaneously in the course of growing up, and this is especially true of the obsessional neuroses of childhood. The remainder can be cleared up later still by psychoanalytic treatment. In just the same way, one might assume, humanity as a whole, in its development through the ages, fell into states analogous to the neuroses, and for the same reasons - namely because in the times of its ignorance and intellectual weakness the instinctual renunciations indispensable for man's communal existence had only been achieved by it by means of purely affective forces. The precipitates of these processes resembling repression which took place in prehistoric times still remained attached to civilization for long periods. Religion would thus be the universal obsessional neurosis of humanity; like the obsessional neuroses of children, it arose out of the Oedipus complex, out of the relation to the father. If this view is right, it is to be supposed that a turning-away from religion is bound to occur with the fatal inevitability of a process of growth, and that we find ourselves at this very juncture in the middle of that phase of development. Our behaviour should therefore be modelled on that of a sensible teacher who does not oppose an impending new development but seeks to ease its path and mitigate the violence of its irruption. Our analogy does not, to be sure, exhaust the essential nature of religion. If, on the one hand, religion brings with it obsessional restrictions, exactly as an individual obsessional neurosis does, on the other hand it comprises a system of wishful illusions together with a disavowal of reality, such as we find in an isolated form nowhere else but in amentia, in a state of blissful hallucinatory confusion. But these are only analogies, by the help of which we endeavour to understand a social phenomenon; the pathology of the individual does not supply us with a fully valid counterpart.

[1927c, 4452]
It must therefore be admitted that in an obsessional neurosis there are two kinds of knowledge, and it is just as reasonable to hold that the patient 'knows' his traumas as that he does not 'know' them. For he knows them in that he has not forgotten them, and he does not know them in that he is unaware of their significance. It is often the same in ordinary life. The waiters who used to serve Schopenhauer at his regular restaurant 'knew' him in a certain sense, at a time when, apart from that, he was not known either in Frankfurt or outside it; but they did not 'know' him in the sense in which we speak to-day of 'knowing' Schopenhauer.

[1909d, 2154]
The fact that the obsessional ideas and everything derived from them meet with no belief is no
doubt because at their first repression the defensive symptom of conscientiousness has been
formed and that that symptom, too, acquires an obsessional force. The subject's certainty of
having lived a moral life throughout the whole period of his successful defence makes it
impossible for him to believe the self-reproach which his obsessional idea involves. Only
transitorily, too, on the appearance of a new obsessional idea and occasionally in melancholic
states of exhaustion of the ego, do the pathological symptoms of the return of the repressed
compel belief. The 'obsessional' character of the psychical formations which I have described
here has quite generally nothing to do with attaching belief to them. Nor is it to be confused with
the factor which is described as the 'strength' or 'intensity' of an idea. Its essence is rather
indissolubility by psychical activity that is capable of being conscious; and this attribute
undergoes no change, whether the idea to which the obsession attaches is stronger or weaker,
or less or more intensely 'illuminated', or 'cathected with energy' and so on.
[1896b, 394]
The fact that the obsessional ideas and everything derived from them meet with no belief is no doubt because at their first repression the defensive symptom of conscientiousness has been formed and that that symptom, too, acquires an obsessional force. The subject's certainty of having lived a moral life throughout the whole period of his successful defence makes it impossible for him to believe the self-reproach which his obsessional idea involves. Only transitorily, too, on the appearance of a new obsessional idea and occasionally in melancholic states of exhaustion of the ego, do the pathological symptoms of the return of the repressed compel belief. The 'obsessional' character of the psychical formations which I have described here has quite generally nothing to do with attaching belief to them. Nor is it to be confused with the factor which is described as the 'strength' or 'intensity' of an idea. Its essence is rather indissolubility by psychical activity that is capable of being conscious; and this attribute undergoes no change, whether the idea to which the obsession attaches is stronger or weaker, or less or more intensely 'illuminated', or 'cathected with energy' and so on. [1896b, 394]
The first form includes the typical obsessional ideas, in which the content engages the patient's attention and, as an affect, he merely feels an indefinite unpleasure, whereas the only affect which would be suitable to the obsessional idea would be one of self-reproach. The content of the obsessional idea is distorted in two ways in relation to the obsessional act of childhood. First, something contemporary is put in the place of something past; and secondly, something sexual is replaced by something analogous to it that is not sexual. These two alterations are the effect of the inclination to repress, still in force, which we will ascribe to the 'ego'. The influence of the re-activated pathogenic memory is shown by the fact that the content of the obsessional idea is still in part identical with what has been repressed or follows from it by a logical train of thought. If, with the help of the psycho-analytic method, we reconstruct the origin of an individual obsessional idea, we find that from a single current impression two different trains of thought have been set going. The one which has passed by way of the repressed memory proves to be as correctly logical in its structure as the other, although it is incapable of being conscious and insusceptible to correction. If the products of the two psychical operations do not tally, what takes place is not some sort of logical adjustment of the contradiction between them; instead, alongside of the normal intellectual outcome, there comes into consciousness, as a compromise between the resistance and the pathological intellectual product, an obsessional idea which appears absurd. If the two trains of thought lead to the same conclusion, they reinforce each other, so that an intellectual product that has been arrived at normally now behaves, psychologically, like an obsessional idea. Wherever a neurotic obsession emerges in the psychological sphere, it comes from repression. Obsessional ideas have, as it were, a compulsive psychical currency, not on account of their intrinsic value, but on account of the source from which they derive or which has added a contribution to their value.

The fact that the obsessional ideas and everything derived from them meet with no belief is no doubt because at their first repression the defensive symptom of conscientiousness has been formed and that that symptom, too, acquires an obsessional force. The subject's certainty of having lived a moral life throughout the whole period of his successful defence makes it impossible for him to believe the self-reproach which his obsessional idea involves. Only transitarily, too, on the appearance of a new obsessional idea and occasionally in melancholic states of exhaustion of the ego, do the pathological symptoms of the return of the repressed compel belief. The 'obsessional' character of the psychical formations which I have described here has quite generally nothing to do with attaching belief to them. Nor is it to be confused with the factor which is described as the 'strength' or 'intensity' of an idea. Its essence is rather indissolubility by psychical activity that is capable of being conscious; and this attribute undergoes no change, whether the idea to which the obsession attaches is stronger or weaker, or less or more intensely 'illuminated', or 'cathected with energy' and so on.

[1896b, 390]
Though the preceding considerations have reduced the importance of the part played by the
day's residues in dreams, it is worth while devoting a little more attention to them. It must be that
they are essential ingredients in the formation of dreams, since experience has revealed the
surprising fact that in the content of every dream some link with a recent daytime impression -
often of the most insignificant sort - is to be detected. We have not hitherto been able to explain
the necessity for this addition to the mixture that constitutes a dream (see p. 669). And it is only
possible to do so if we bear firmly in mind the part played by the unconscious wish and then
seek for information from the psychology of the neuroses. We learn from the latter that an
unconscious idea is as such quite incapable of entering the preconscious and that it can only
exercise any effect there by establishing a connection with an idea which already belongs to the
preconscious, by transferring its intensity on to it and by getting itself 'covered' by it. Here we
have the fact of 'transference', which provides an explanation of so many striking phenomena in
the mental life of neurotics. The preconscious idea, which thus acquires an undeserved degree
of intensity may either be left unaltered by the transference, or it may have a modification forced
upon it, derived from the content of the idea which effects the transference. I hope I may be
forgiven for drawing analogies from everyday life, but I am tempted to say that the position of a
repressed idea resembles that of an American dentist in this country: he is not allowed to set up
in practice unless he can make use of a legally qualified medical practitioner to serve as a
stalking-horse and to act as a 'cover' in the eyes of the law. And just as it is not exactly the
physicians with the largest practices who form alliances of this kind with dentists, so in the same
way preconscious or conscious ideas which have already attracted a sufficient amount of the
attention that is operating in the preconscious will not be the ones to be chosen to act as covers
for a repressed idea. The unconscious prefers to weave its connections round preconscious
impressions and ideas which are either indifferent and have thus had no attention paid to them,
or have been rejected and have thus had attention promptly withdrawn from them. It is a familiar
article in the doctrine of association, and one that is entirely confirmed by experience, that an
idea which is bound by a very intimate tie in one direction, tends, as it were, to repel whole
groups of new ties. I once attempted to base a theory of hysterical paralyses on this proposition.
[1900a, 993]

A train of thought such as this may be described as excessively intense, or better reinforced,
or 'supervalent' ['überwertig'] in Wernicke's sense. It shows its pathological character in spite of
its apparently reasonable content, by the single peculiarity that no amount of conscious and
voluntary effort of thought on the patient's part is able to dissipate or remove it. A normal train of
thought, however intense it may be, can eventually be disposed of. Dora felt quite rightly that
her thoughts about her father required to be judged in a special way. 'I can think of nothing
else', she complained again and again. 'I know my brother says we children have no right to
criticize this behaviour of Father's. He declares that we ought not to trouble ourselves about it,
and ought even to be glad, perhaps, that he has found a woman he can love, since Mother
understands him so little. I can quite see that, and I should like to think the same as my brother,
but I can't. I can't forgive him for it.' [1905e, 1391]
Now what is one to do in the face of a supervalent thought like this, after one has heard what its conscious grounds are and listened to the ineffectual protests made against it? Reflection will suggest that this excessively intense train of thought must owe its reinforcement to the unconscious. It cannot be resolved by any effort of thought, either because it itself reaches with its root down into unconscious, repressed material, or because another unconscious thought lies concealed behind it. In the latter case, the concealed thought is usually the direct contrary of the supervalent one. Contrary thoughts are always closely connected with each other and are often paired off in such a way that the one thought is excessively intensely conscious while its counterpart is repressed and unconscious. This relation between the two thoughts is an effect of the process of repression. For repression is often achieved by means of an excessive reinforcement of the thought contrary to the one which is to be repressed. This process I call reactive reinforcement, and the thought which asserts itself with excessive intensity in consciousness and (in the same way as a prejudice) cannot be removed I call a reactive thought. The two thoughts then act towards each other much like the two needles of an astatic galvanometer. The reactive thought keeps the objectionable one under repression by means of a certain surplus of intensity; but for that reason it itself is ‘damped’ and proof against conscious efforts of thought. So that the way to deprive the excessively intense thought of its reinforcement is by bringing its repressed contrary into consciousness.

SECOND PHASE OF INFANTILE MASTURBATION The masturbation of early infancy seems to disappear after a short time; but it may persist uninterruptedly until puberty, and this would constitute the first great deviation from the course of development laid down for civilized men. At some point of childhood after early infancy, as a rule before the fourth year, the sexual instinct belonging to the genital zone usually revives and persists again for a time until it is once more suppressed, or it may continue without interruption. This second phase of infantile sexual activity may assume a variety of different forms which can only be determined by a precise analysis of individual cases. But all its details leave behind the deepest (unconscious) impressions in the subject's memory, determine the development of his character, if he is to remain healthy, and the symptomatology of his neurosis, if he is to fall ill after puberty.¹ In the latter case we find that this sexual period has been forgotten and that the conscious memories that bear witness to it have been displaced. (I have already mentioned that I am also inclined to relate normal infantile amnesia to this infantile sexual activity.) Psychoanalytic investigation enables us to make what has been forgotten conscious and thus do away with a compulsion that arises from the unconscious psychical material.

[1905e, 1391]

[1905d, 1509]
Moreover, the effects of seduction do not help to reveal the early history of the sexual instinct; they rather confuse our view of it by presenting children prematurely with a sexual object for which the infantile sexual instinct at first shows no need. It must, however, be admitted that infantile sexual life, in spite of the preponderating dominance of erotogenic zones, exhibits components which from the very first involve other people as sexual objects. Such are the instincts of scopophilia, exhibitionism and cruelty, which appear in a sense independently of erotogenic zones; these instincts do not enter into intimate relations with genital life until later, but are already to be observed in childhood as independent impulses, distinct in the first instance from erotogenic sexual activity. Small children are essentially without shame, and at some periods of their earliest years show an unmistakable satisfaction in exposing their bodies, with especial emphasis on the sexual parts. The counterpart of this supposedly perverse inclination, curiosity to see other people’s genitals, probably, does not become manifest until somewhat later in childhood, when the obstacle set up by a sense of shame has already reached a certain degree of development. Under the influence of seduction the scopophilic perversion can attain great importance in the sexual life of a child. But my researches into the early years of normal people, as well as of neurotic patients, force me to the conclusion that scopophilia can also appear in children as a spontaneous manifestation. Small children whose attention has once been drawn - as a rule by masturbation - to their own genitals usually take the further step without help from outside and develop a lively interest in the genitals of their playmates. Since opportunities for satisfying curiosity of this kind usually occur only in the course of satisfying the two kinds of need for excretion, children of this kind turn into voyeurs, eager spectators of the processes of micturition and defaecation. When repression of these inclinations sets in, the desire to see other people’s genitals (whether of their own or the opposite sex) persists as a tormenting compulsion, which in some cases of neurosis later affords the strongest motive force for the formation of symptoms.

(f) Finally, Gentlemen, I must confess that it is hardly fair to take up your attention for so long on the subject of psycho-analytic therapy without telling you in what this treatment consists and on what it is based. Still, as I am forced to be brief, I can only hint at this: This therapy, then, is based on the recognition that unconscious ideas - or better, the unconsciousness of certain mental processes - are the direct cause of the morbid symptoms. We share this opinion with the French school (Janet) who, by the way, owing to excessive schematization, refer the cause of hysterical symptoms to an unconscious idée fixe. Now please do not be afraid that this is going to land us in the depths of philosophical obscurities. Our unconscious is not quite the same thing as that of philosophers and, moreover, the majority of philosophers will hear nothing of ‘unconscious mental processes’. If, however, you will look at the matter from our point of view, you will understand that the transformation of this unconscious material in the mind of the patient into conscious material must have the result of correcting his deviation from normality and of lifting the compulsion to which his mind has been subjected. For conscious will-power governs only conscious mental processes, and every mental compulsion is rooted in the unconscious. Nor need you ever fear that the patient will be harmed by the shock accompanying the introduction of the unconscious into consciousness, for you can convince yourselves theoretically that the somatic and emotional effect of an impulse that has become conscious can never be so powerful as that of an unconscious one. It is only by the application of our highest mental functions, which are bound up with consciousness, that we can control all our impulses.
Neurotic ceremonials consist in making small adjustments to particular everyday actions, small additions or restrictions or arrangements, which have always to be carried out in the same, or in a methodically varied, manner. These activities give the impression of being mere formalities, and they seem quite meaningless to us. Nor do they appear otherwise to the patient himself; yet he is incapable of giving them up, for any deviation from the ceremonial is visited by intolerable anxiety, which obliges him at once to make his omission good. Just as trivial as the ceremonial actions themselves are the occasions and activities which are embellished, encumbered and in any case prolonged by the ceremonial - for instance, dressing and undressing, going to bed or satisfying bodily needs. The performance of a ceremonial can be described by replacing it, as it were, by a series of unwritten laws. For instance, to take the case of the bed ceremonial: the chair must stand in a particular place beside the bed; the clothes must lie upon it folded in a particular order; the blanket must be tucked in at the bottom and the sheet smoothed out; the pillows must be arranged in such and such a manner, and the subject's own body must lie in a precisely defined position. Only after all this may he go to sleep. Thus in slight cases the ceremonial seems to be no more than an exaggeration of an orderly procedure that is customary and justifiable; but the special conscientiousness with which it is carried out and the anxiety which follows upon its neglect stamp the ceremonial as a 'sacred act'. Any interruption of it is for the most part badly tolerated, and the presence of other people during its performance is almost always ruled out.

[1907b, 1902]
'I have decided to tell you something which I consider most important and which has tormented me from the very first.' He then told me at great length the story of the last illness of his father, who had died of emphysema nine years previously. One evening, thinking that the condition was one which would come to a crisis, he had asked the doctor when the danger could be regarded as over. 'The evening of the day after to-morrow', had been the reply. It had never entered his head that his father might not survive that limit. At half-past eleven at night he had lain down for an hour's rest. He had woken up at one o'clock, and had been told by a medical friend that his father had died. He had reproached himself with not having been present at his death; and the reproach had been intensified when the nurse told him that his father had spoken his name once during the last days, and had said to her as she came up to the bed: 'Is that Paul?' He had thought he noticed that his mother and sisters had been inclined to reproach themselves in a similar way; but they had never spoken about it. At first, however, the reproach had not tormented him. For a long time he had not realized the fact of his father's death. It had constantly happened that, when he heard a good joke, he would say to himself: 'I must tell Father that.' His imagination, too, had been occupied with his father, so that often, when there was a knock at the door, he would think: 'Here comes Father', and when he walked into a room he would expect to find his father in it. And although he had never forgotten that his father was dead, the prospect of seeing a ghostly apparition of this kind had had no terrors for him; on the contrary, he had greatly desired it. It had not been until eighteen months later that the recollection of his neglect had recurred to him and begun to torment him terribly, so that he had come to treat himself as a criminal. The occasion of this happening had been the death of an aunt by marriage and of a visit of condolence that he had paid at her house. From that time forward he had extended the structure of his obsessional thoughts so as to include the next world. The immediate consequence of this development had been that he became seriously incapacitated from working.³ He told me that the only thing that had kept him going at that time had been the consolation given him by his friend, who had always brushed his self-reproaches aside on the ground that they were grossly exaggerated. Hearing this, I took the opportunity of giving him a first glance at the underlying principles of psycho-analytic therapy. When there is a mésalliance, I began, between an affect and its ideational content (in this instance, between the intensity of the self-reproach and the occasion for it), a layman will say that the affect is too great for the occasion - that it is exaggerated and that consequently the inference following from the self-reproach (the inference that the patient is a criminal) is false. On the contrary, the physician says: 'No. The affect is justified. The sense of guilt is not in itself open to further criticism. But it belongs to some other content, which is unknown (unconscious), and which requires to be looked for. The known ideational content has only got into its actual position owing to a false connection. We are not used to feeling strong affects without their having any ideational content, and therefore, if the content is missing, we seize as a substitute upon some other content which is in some way or other suitable, much as our police, when they cannot catch the right murderer, arrest a wrong one instead. Moreover, this fact of there being a false connection is the only way of accounting for the powerlessness of logical processes to combat the tormenting idea.' I concluded by admitting that this new way of looking at the matter gave immediate rise to some hard problems; for how could he admit that his self-reproach of being a criminal towards his father was justified, when he must know that as a matter of fact he had never committed any crime against him?

What is officially described as an 'obsessional idea' exhibits, therefore, in its distortion from its original wording, traces of the primary defensive struggle. Its distortion enables it to persist, since conscious thought is thus compelled to misapprehend it, just as though it were a dream; for dreams also are a product of compromise and distortion, and are also misapprehended by waking thought.
And here we have the domination of compulsion and doubt such as we meet with in the mental life of obsessional neurotics.

[1909d, 2188]

The compulsion on the other hand is an attempt at a compensation for the doubt and at a correction of the intolerable conditions of inhibition to which the doubt bears witness. If the patient, by the help of displacement, succeeds at last in bringing one of his inhibited intentions to a decision, then the intention must be carried out. It is true that this intention is not his original one, but the energy dammed up in the latter cannot let slip the opportunity of finding an outlet for its discharge in the substitutive act. Thus this energy makes itself felt now in commands and now in prohibitions, according as the affectionate impulse or the hostile one snatches control of the pathway leading to discharge. If it happens that a compulsive command cannot be obeyed, the tension becomes intolerable and is perceived by the patient in the form of extreme anxiety. But the pathway leading to a substitutive act, even where the displacement has been on to something very small, is so hotly contested, that such an act can as a rule be carried out only in the shape of a protective measure intimately associated with the very impulse which it is designed to ward off.

[1909d, 2190]

I may now venture, upon the basis of the preceding discussion, to determine the psychological characteristic, so long sought after, which lends to the products of an obsessional neurosis their 'obsessive' or compulsive quality. A thought-process is obsessive or compulsive when, in consequence of an inhibition (due to a conflict of opposing impulses) at the motor end of the psychical system, it is undertaken with an expenditure of energy which (as regards both quality and quantity) is normally reserved for actions alone; or, in other words, an obsessive or compulsive thought is one whose function it is to represent an act regressively. No one, I think, will question my assumption that processes of thought are ordinarily conducted (on grounds of economy) with smaller displacements of energy, probably at a higher level, than are acts intended to bring about discharge or to modify the external world.

[1909d, 2192]

The obsessive thought which has forced its way into consciousness with such excessive violence has next to be secured against the efforts made by conscious thought to resolve it. As we already know, this protection is afforded by the distortion which the obsessive thought has undergone before becoming conscious. But this is not the only means employed. In addition, each separate obsessional idea is almost invariably removed from the situation in which it originated and in which, in spite of its distortion, it would be most easily comprehensible. With this end in view, in the first place an interval of time is inserted between the pathogenic situation and the obsession that arises from it, so as to lead astray any conscious investigation of its causal connections, and in the second place the content of the obsession is taken out of its particular setting by being generalized. Our patient's 'obsession for understanding' is an example of this (p. 2150). But perhaps a better one is afforded by another patient. This was a woman who prohibited herself from wearing any sort of personal adornment, though the exciting cause of the prohibition related only to one particular piece of jewellery: she had envied her mother the possession of it and had had hopes that one day she would inherit it. Finally, if we care to distinguish verbal distortion from distortion of content, there is yet another means by which the obsession is protected against conscious attempts at solution. And that is the choice of an indefinite or ambiguous wording. After being misunderstood, the wording may find its way into the patient's 'deliria', and whatever further processes of development or substitution his obsession undergoes will then be based upon the misunderstanding and not upon the proper sense of the text. Observation will show, however, that the deliria constantly tend to form new connections with that part of the matter and wording of the obsession which is not present in consciousness.

[1909d, 2192]
This interpretation by the psychological novelist cannot be put to the proof, but it can claim so much inner probability, and is so much in harmony with all that we otherwise know of Leonardo's emotional activity, that I cannot refrain from accepting it as correct. He had succeeded in subjecting his feelings to the yoke of research and in inhibiting their free utterance; but even for him there were occasions when what had been suppressed obtained expression forcibly. The death of the mother he had once loved so dearly was one of these. What we have before us in the account of the costs of the funeral is the expression - distorted out of all recognition - of his mourning for his mother. We wonder how such distortion could come about, and indeed we cannot understand it if we treat it as a normal mental process. But similar processes are well known to us in the abnormal conditions of neurosis and especially of what is known as 'obsessional neurosis'. There we can see how the expression of intense feelings, which have however become unconscious through repression, is displaced on to trivial and even foolish actions. The expression of these repressed feelings has been lowered by the forces opposed to them to such a degree that one would have had to form a most insignificant estimate of their intensity; but the imperative compulsiveness with which this trivial expressive act is performed betrays the real force of the impulses - a force which is rooted in the unconscious and which consciousness would like to deny. Only a comparison such as this with what happens in obsessional neurosis can explain Leonardo's account of the expenses of his mother's funeral. In his unconscious he was still tied to her by erotically coloured feelings, as he had been in childhood. The opposition that came from the subsequent repression of this childhood love did not allow him to set up a different and worthier memorial to her in his diary. But what emerged as a compromise from this neurotic conflict had to be carried out; and thus it was that the account was entered in the diary, and has come to the knowledge of posterity as something unintelligible.

[1910c, 2279]
Leonardo emerges from the obscurity of his boyhood as an artist, a painter and a sculptor, owing to a specific talent which may have been reinforced by the precocious awakening in the first years of childhood of his scopophilic instinct. We should be most glad to give an account of the way in which artistic activity derives from the primal instincts of the mind if it were not just here that our capacities fail us. We must be content to emphasize the fact - which it is hardly any longer possible to doubt - that what an artist creates provides at the same time an outlet for his sexual desire; and in Leonardo's case we can point to the information which comes from Vasari, that heads of laughing women and beautiful boys - in other words, representations of his sexual objects - were notable among his first artistic endeavours. In the bloom of his youth Leonardo appears at first to have worked without inhibition. Just as he modelled himself on his father in the outward conduct of his life, so too he passed through a period of masculine creative power and artistic productiveness in Milan, where a kindly fate enabled him to find a father substitute in the duke Lodovico Moro. But soon we and confirmation of our experience that the almost total repression of a real sexual life does not provide the most favourable conditions for the exercise of sublimated sexual trends. The pattern imposed by sexual life made itself felt. His activity and his ability to form quick decisions began to fail; his tendency towards deliberation and delay was already noticeable as a disturbing element in the 'Last Supper', and by influencing his technique it had a decisive effect on the fate of that great painting. Slowly there occurred in him a process which can only be compared to the regressions in neurotics. The development that turned him into an artist at puberty was overtaken by the process which led him to be an investigator, and which had its determinants in early infancy. The second sublimation of his erotic instinct gave place to the original sublimation for which the way had been prepared on the occasion of the first repression. He became an investigator, at first still in the service of his art, but later independently of it and away from it. With the loss of his patron, the substitute for his father, and with the increasingly sombre colours which his life took on, this regressive shift assumed larger and larger proportions. He became 'impacientissimo al pennello',¹ as we are told by a correspondent of the Countess Isabella d'Este, who was extremely eager to possess a painting from his hand. His infantile past had gained control over him. But the research which now took the place of artistic creation seems to have contained some of the features which distinguish the activity of unconscious instincts - insatiability, unyielding rigidity and the lack of an ability to adapt to real circumstances.

[1910c, 2301]
In our clinical history of a case we have insisted that the imposition of the prohibition in very early childhood is the determining point; a similar importance attaches in the subsequent developments to the mechanism of repression at the same early age. As a result of the repression which has been enforced and which involves a loss of memory - an amnesia - the motives for the prohibition (which is conscious) remain unknown; and all attempts at disposing of it by intellectual processes must fail, since they cannot find any base of attack. The prohibition owes its strength and its obsessive character precisely to its unconscious opponent, the concealed and undiminished desire - that is to say, to an internal necessity inaccessible to conscious inspection. The ease with which the prohibition can be transferred and extended reflects a process which falls in with the unconscious desire and is greatly facilitated by the psychological conditions that prevail in the unconscious. The instinctual desire is constantly shifting in order to escape from the impasse and endeavours to find substitutes - substitute objects and substitute acts - in place of the prohibited ones. In consequence of this, the prohibition itself shifts about as well, and extends to any new aims which the forbidden impulse may adopt. Any fresh advance made by the repressed libido is answered by a fresh sharpening of the prohibition. The mutual inhibition of the two conflicting forces produces a need for discharge, for reducing the prevailing tension; and to this may be attributed the reason for the performance of obsessive acts. In the case of a neurosis these are clearly compromise actions: from one point of view they are evidences of remorse, efforts at expiation, and so on, while on the other hand they are at the same time substitutive acts to compensate the instinct for what has been prohibited. It is a law of neurotic illness that these obsessive acts fall more and more under the sway of the instinct and approach nearer and nearer to the activity which was originally prohibited.

When a wife has lost her husband or a daughter her mother, it not infrequently happens that the survivor is overwhelmed by tormenting doubts (to which we give the name of 'obsessive self-reproaches') as to whether she may not herself have been responsible for the death of this cherished being through some act of carelessness or neglect. No amount of recollection of the care she lavished on the sufferer, no amount of objective disproof of the accusation, serves to bring the torment to an end. It may be regarded as a pathological form of mourning, and with the passage of time it gradually dies away. The psycho-analytic investigation of such cases has revealed the secret motives of the disorder. We find that in a certain sense these obsessive self-reproaches are justified, and that this is why they are proof against contradictions and protests. It is not that the mourner was really responsible for the death or was really guilty of neglect, as the self-reproaches declare to be the case. None the less there was something in her - a wish that was unconscious to herself - which would not have been dissatisfied by the occurrence of death and which might actually have brought it about if it had had the power. And after death has occurred, it is against this unconscious wish that the reproaches are a reaction. In almost every case where there is an intense emotional attachment to a particular person we find that behind the tender love there is a concealed hostility in the unconscious. This is the classical example, the prototype, of the ambivalence of human emotions. This ambivalence is present to a greater or less amount in the innate disposition of everyone; normally, there is not so much of it as to produce the obsessive self-reproaches we are considering. Where, however, it is copiously present in the disposition, it will manifest itself precisely in the subject's relation to those of whom he is most fond, in the place, in fact, where one would least expect to find it. It must be supposed that the presence of a particularly large amount of this original emotional ambivalence is characteristic of the disposition of obsessional neurotics - whom I have so often brought up for comparison in this discussion upon taboo.
One of the characteristics of this ambivalent relation which I have repeatedly stressed as fundamental - the fact that the positive current of desire is an unconscious one - opens the way to further considerations and to further possible explanations. Psychical processes in the unconscious are not in every respect identical with those with which our conscious mind is familiar; they enjoy some remarkable liberties that are forbidden to the latter. An unconscious impulse need not have arisen at the point where it makes its appearance; it may arise from some quite other region and have applied originally to quite other persons and connections; it may have reached the place at which it attracts our attention though the mechanism of 'displacement'. Owing, moreover, to the indestructibility and insusceptibility to correction which are attributes of unconscious processes, it may have survived from very early times to which it was appropriate into later times and circumstances in which its manifestations are bound to seem strange. These are no more than hints, but if they were attentively developed their importance for our understanding of the growth of civilization would become apparent.

[1912-1913, 2714]

In just the same may, an inhibition upon movement (an abasia or an agoraphobia) will gradually become more complete and more detailed, when once that system has succeeded in installing itself as a representative of an unconscious wish and of the defence against the wish. Whatever other unconscious phantasies and operative reminiscences may be present in the patient force their way to expression as symptoms along this same path, once it has been opened, and group themselves into an appropriate new arrangement within the framework of the inhibition upon movement. Thus it would be a vain and indeed a foolish task to attempt to understand the complexities and details of the symptoms of (for example) an agoraphobia on the basis of its underlying premises; for the whole consistency and strictness of the combination are merely apparent. Just as with the façades of dreams, if we look more attentively we find the most blatant inconsistency and arbitrariness in the structure of symptoms. The real reason for the details of a systematic phobia of this kind lies in concealed determinants, which need have nothing to do with an inhibition upon movement; and that, too, is why these phobias take such various and contradictory shapes in different people.

[1912-1913, 2738]

In another neurotic disorder, obsessional neurosis, the patients become the victims of distressing and apparently senseless ceremonials which take the form of the rhythmical repetition of the most trivial acts (such as washing or dressing) or of carrying out meaningless injunctions or of obeying mysterious prohibitions. It was nothing less than a triumph of psychoanalytic research when it succeeded in showing that all these obsessive acts, even the most insignificant and trivial of them, have a meaning, and that they are reflections, translated into indifferent terms, of conflicts in the patients' lives, of the struggle between temptations and moral restraints - reflections of the proscribed wish itself and of the punishment and atonement which that wish incurs. In another form of the same disorder the victim suffers from tormenting ideas (obsessions) which force themselves upon him and are accompanied by affects whose character and intensity are often only quite inadequately accounted for by the terms of the obsessive ideas themselves. Analytic investigation has shown in their case that the affects are entirely justified, since they correspond to self-reproaches which are based on something that is at least psychically real. But the ideas to which these affects are attached are not the original ones, but have found their way into their present position by a process of displacement - by being substituted for something that has been repressed. If these displacements can be reversed, the way is open to the discovery of the repressed ideas, and the relation between affect and idea is found to be perfectly appropriate.

[1913], 2810]
A totally different picture of repression is shown, once more, in the third disorder which we shall consider for the purposes of our illustration - in obsessional neurosis. Here we are at first in doubt what it is that we have to regard as the instinctual representative that is subjected to repression - whether it is a libidinal or a hostile trend. This uncertainty arises because obsessional neurosis has as its basis a regression owing to which a sadistic trend has been substituted for an affectionate one. It is this hostile impulsion against someone who is loved which is subjected to repression. The effect at an early stage of the work of repression is quite different from what it is at a later one. At first the repression is completely successful; the ideational content is rejected and the affect made to disappear. As a substitutive formation there arises an alteration in the ego in the shape of an increased conscientiousness, and this can hardly be called a symptom. Here, substitute and symptom do not coincide. From this we learn something, too, about the mechanism of repression. In this instance, as in all others, repression has brought about a withdrawal of libido; but here it has made use of reaction-formation for this purpose, by intensifying an opposite. Thus in this case the formation of a substitute has the same mechanism as repression and at bottom coincides with it, while chronologically, as well as conceptually, it is distinct from the formation of a symptom. It is very probable that the whole process is made possible by the ambivalent relationship into which the sadistic impulsion that has to be repressed has been introduced. But the repression, which was at first successful, does not hold firm; in the further course of things its failure becomes increasingly marked. The ambivalence which has enabled repression through reaction-formation to take place is also the point at which the repressed succeeds in returning. The vanished affect comes back in its transformed shape as social anxiety, moral anxiety and unlimited self-reproaches; the rejected idea is replaced by a substitute by displacement, often a displacement on to something very small or indifferent. A tendency to a complete re-establishment of the repressed idea is as a rule unmistakably present. The failure in the repression of the quantitative, affective factor brings into play the same mechanism of flight, by means of avoidance and prohibitions, as we have seen at work in the formation of hysterical phobias. The rejection of the idea from the conscious is, however, obstinately maintained, because it entails abstention from action, a motor fettering of the impulsion. Thus in obsessional neurosis the work of repression is prolonged in a sterile and interminable struggle.

[1915d, 2987]
On the occasion of a repetition (if there should be one) of this process, a first step is taken in the direction of mastering the unwelcome development of anxiety. The cathexis that has taken flight attaches itself to a substitutive idea which, on the one hand, is connected by association with the rejected idea, and, on the other, has escaped repression by reason of its remoteness from that idea. This substitutive idea - a 'substitute by displacement' - permits the still uninhibitable development of anxiety to be rationalized. It now plays the part of an anticathexis for the system Cs. (Pcs.), by securing it against an emergence in the Cs. of the repressed idea. On the other hand it is, or acts as if it were, the point of departure for the release of the anxiety-affect, which has now really become quite uninhibitable. Clinical observation shows, for instance, that a child suffering from an animal phobia experiences anxiety under two kinds of conditions: in the first place, when his repressed love-impulse becomes intensified, and, in the second, when he perceives the animal he is afraid of. The substitutive idea acts in the one instance as a point at which there is a passage across from the system Ucs. to the system Cs., and, in the other instance, as a self-sufficing source for the release of anxiety. The extending dominance of the system Cs. usually manifests itself in the fact that the first of these two modes of excitation of the substitutive idea gives place more and more to the second. The child may perhaps end by behaving as though he had no predilection whatever towards his father but had become quite free from him, and as though his fear of the animal was a real fear - except that this fear of the animal, fed as such a fear is from an unconscious instinctual source, proves obdurate and exaggerated in the face of all influences brought to bear from the system Cs., and thereby betrays its derivation from the system Ucs. - In the second phase of anxiety hysteria, therefore, the anticathexis from the system Cs. has led to substitute-formation.

Co-operation between a preconscious and an unconscious impulse, even when the latter is intensely repressed, may come about if there is a situation in which the unconscious impulse can act in the same sense as one of the dominant trends. The repression is removed in this instance, and the repressed activity is admitted as a reinforcement of the one intended by the ego. The unconscious becomes ego-syntonic in respect of this single conjunction without any change taking place in its repression apart from this. In this co-operation the influence of the Ucs. is unmistakable: the reinforced tendencies reveal themselves as being nevertheless different from the normal; they make specially perfect functioning possible, and they manifest a resistance in the face of opposition which is similar to that offered, for instance, by obsessional symptoms.

[1915e, 3005]

[1915e, 3017]
Certainly this is a crazy illness. The most extravagant psychiatric imagination would not, I think, have succeeded in constructing anything like it; and if one did not see it before one every day one would never bring oneself to believe in it. Do not suppose, however, that you will help the patient in the least by calling on him to take a new line, to cease to occupy himself with such foolish thoughts and to do something sensible instead of his childish pranks. He would like to do so himself, for he is completely clear in his head, shares your opinion of his obsessional symptoms and even puts it forward to you spontaneously. Only he cannot help himself. What is carried into action in an obsessional neurosis is sustained by an energy to which we probably know nothing comparable in normal mental life. There is only one thing he can do: he can make displacements, and exchanges, he can replace one foolish idea by another somewhat milder, he can proceed from one precaution or prohibition to another, instead of one ceremonial he can perform another. He can displace the obsession but not remove it. The ability to displace any symptom into something far removed from its original conformation is a main characteristic of his illness. Moreover it is a striking fact that in his condition the contradictions (polarities) with which mental life is interlaced emerge especially sharply differentiated. Alongside of obsessions with a positive and negative content, doubt makes itself felt in the intellectual field and little by little it begins to gnaw even at what is usually most certain. The whole position ends up in an ever-increasing degree of indecision, loss of energy and restriction of freedom. At the same time, the obsessional neurotic starts off with a very energetic disposition, he is often extraordinarily self-willed and as a rule he has intellectual gifts above the average. He has usually reached a satisfactorily high level of ethical development; he exhibits over-conscientiousness, and is more than ordinarily correct in his behaviour. You can imagine that no small amount of work is needed before one can make one's way any distance into this contradictory hotch-potch of character-traits and symptoms. And to begin with we aim at nothing whatever else than understanding a few of the symptoms and being able to interpret them.

[1916-1917, 3340]

Let us turn now to the second of the discoveries which follow from our analyses; in its case we need not fear having to make a subsequent qualification of our views. I have described to you how our first patient carried out a senseless obsessional action and how she reported an intimate memory from her past life as having some connection with it: and how afterwards I examined the connection between the two and discovered the intention of the obsessional action from its relation to the memory. But there is one factor which I have entirely neglected, though it deserves our fullest attention. However often the patient repeated her obsessional action, she knew nothing of its being derived from the experience she had had. The connection between the two was hidden from her; she could only quite truthfully reply that she did not know what it was that was making her carry out her action. Then suddenly one day, under the influence of the treatment, she succeeded in discovering the connection and reported it to me. But she still knew nothing of the intention with which she was performing the obsessional action - the intention of correcting a distressing portion of the past and of putting her beloved husband in a better light. It took a fairly long time and called for much labour before she understood and admitted to me that such a motive alone could have been the driving force of her obsessional action.

[1916-1917, 3354]
And we meet with what is in essence the same thing in our second patient. She had made a rule that the pillow must not touch the back of the bedstead, and she had to obey this rule though she did not know where it came from, what it meant or to what motives it owed its power. Whether she herself regarded the rule as a matter of indifference, or whether she struggled against it or raged against it or decided to transgress it - none of this made any difference to her carrying it out. It had to be obeyed, and she asked herself vainly why. We must recognize, however, that these symptoms of obsessional neurosis, these ideas and impulses which emerge one knows not whence, which prove so resistant to every influence from an otherwise normal mind, which give the patient himself the impression of being all-powerful guests from an alien world, immortal beings intruding into the turmoil of mortal life - these symptoms offer the plainest indication of there being a special region of the mind, shut off from the rest. They lead, by a path that cannot be missed, to a conviction of the existence of the unconscious in the mind; and that is precisely why clinical psychiatry, which is acquainted only with a psychology of consciousness, can deal with these symptoms in no other way than by declaring them to be signs of a special sort of degeneracy. Obsessional ideas and obsessional impulses are not, of course, themselves unconscious, any more than the performance of obsessional actions escapes conscious perception. They would not have become symptoms if they had not forced their way into consciousness. But their psychical predeterminants which we infer by means of analysis, the connections into which we insert them by interpretation, are unconscious, at least until we have made them conscious to the patient by the work of analysis.

We already know that neurotic symptoms are the outcome of a conflict which arises over a new method of satisfying the libido. The two forces which have fallen out meet once again in the symptom and are reconciled, as it were, by the compromise of the symptom that has been constructed. It is for that reason, too, that the symptom is so resistant: it is supported from both sides. We also know that one of the two partners to the conflict is the unsatisfied libido which has been repulsed by reality and must now seek for other paths to its satisfaction. If reality remains relentless even though the libido is ready to take another object in place of the one that has been refused to it, then it will finally be compelled to take the path of regression and strive to find satisfaction either in one of the organizations which it has already outgrown or from one of the objects which it has earlier abandoned. The libido is lured into the path of regression by the fixation which it has left behind it at these points in its development.

You will recall that at our first meeting of the present academic year I described a case to you of a woman suffering from delusions of jealousy. Now that we are so near its end you would no doubt like to hear how delusions are explained by psycho-analysis. But I have less to tell you about that than you expect. The fact that a delusion cannot be shaken by logical arguments or real experiences is explained in the same way as in the case of an obsession - by its relation to the unconscious, which is represented and held down by the delusion or by the obsession. The difference between the two is based on the difference between the topography and dynamics of the two illnesses.
Nothing has entered into you from without; a part of the activity of your own mind has been withdrawn from your knowledge and from the command of your will. That, too, is why you are so weak in your defence; you are using one part of your force to fight the other part and you cannot concentrate the whole of your force as you would against an external enemy. And it is not even the worst or least important part of your mental forces that has thus become antagonistic to you and independent of you. The blame, I am bound to say, lies with yourself. You over-estimated your strength when you thought you could treat your sexual instincts as you liked and could utterly ignore their intentions. The result is that they have rebelled and have taken their own obscure paths to escape this suppression; they have established their rights in a manner you cannot approve. How they have achieved this, and the paths which they have taken, have not come to your knowledge. All you have learned is the outcome of their work - the symptom which you experience as suffering. Thus you do not recognize it as a derivative of your own rejected instincts and do not know that it is a substitutive satisfaction of them. [1917a, 3613]
(3) Why does the emotional state that is associated with the obsessional idea persist indefinitely instead of vanishing like other states of our ego? [1895c, 322]
The proof of this is the fact that we can always find in the previous history of the patient, at the beginning of the obsession, the original idea that has been replaced. The replaced ideas all have common attributes; they correspond to really distressing experiences in the subject's sexual life which he is striving to forget. He succeeds merely in replacing the incompatible idea by another ill-adapted for being associated with the emotional state, which for its part remains unchanged. It is this *mésalliance* between the emotional state and the associated idea that accounts for the absurdity so characteristic of obsessions.

[1895c, 318]

The first form includes the typical obsessional ideas, in which the content engages the patient's attention and, as an affect, he merely feels an indefinite unpleasure, whereas the only affect which would be suitable to the obsessional idea would be one of self-reproach. The content of the obsessional idea is distorted in two ways in relation to the obsessional act of childhood. First, something contemporary is put in the place of something past; and secondly, something sexual is replaced by something analogous to it that is not sexual. These two alterations are the effect of the inclination to repress, still in force, which we will ascribe to the 'ego'. The influence of the re-activated pathogenic memory is shown by the fact that the content of the obsessional idea is still in part identical with what has been repressed or follows from it by a logical train of thought. If, with the help of the psycho-analytic method, we reconstruct the origin of an individual obsessional idea, we find that from a single current impression two different trains of thought have been set going. The one which has passed by way of the repressed memory proves to be as correctly logical in its structure as the other, although it is incapable of being conscious and insusceptible to correction. If the products of the two psychical operations do not tally, what takes place is not some sort of logical adjustment of the contradiction between them; instead, alongside of the *normal* intellectual outcome, there comes into consciousness, as a compromise between the resistance and the *pathological* intellectual product, an obsessional idea which appears absurd. If the two trains of thought lead to the same conclusion, they reinforce each other, so that an intellectual product that has been arrived at normally now behaves, psychologically, like an obsessional idea. Wherever a neurotic obsession emerges in the psychological sphere, it comes from repression. Obsessional ideas have, as it were, a compulsive psychical currency, not on account of their intrinsic value, but on account of the source from which they derive or which has added a contribution to their value.

[1896b, 390]
It is easy to see where the resemblances lie between neurotic ceremonials and the sacred acts of religious ritual: in the qualms of conscience brought on by their neglect, in their complete isolation from all other actions (shown in the prohibition against interruption) and in the conscientiousness with which they are carried out in every detail. But the differences are equally obvious, and a few of them are so glaring that they make the comparison a sacrilege: the greater individual variability of ceremonial actions in contrast to the stereotyped character of rituals (prayer, turning to the East, etc.), their private nature as opposed to the public and communal character of religious observances, above all, however, the fact that, while the minutiae of religious ceremonial are full of significance and have a symbolic meaning, those of neurotics seem foolish and senseless. In this respect an obsessional neurosis presents a travesty, half comic and half tragic, of a private religion. But it is precisely this sharpest difference between neurotic and religious ceremonial which disappears when, with the help of the psycho-analytic technique of investigation, one penetrates to the true meaning of obsessive actions.¹ In the course of such an investigation the appearance which obsessive actions afford of being foolish and senseless is completely effaced, and the reason for their having that appearance is explained. It is found that the obsessive actions are perfectly significant in every detail, that they serve important interests of the personality and that they give expression to experiences that are still operative and to thoughts that are cathexed with affect. They do this in two ways, either by direct or by symbolic representation; and they are consequently to be interpreted either historically or symbolically.

The technique of distortion by ellipsis seems to be typical of obsessional neuroses; I have come across it in the obsessional thoughts of other patients as well. One example, a particularly transparent one, is of especial interest on account of a certain structural similarity with the rat idea. It was a case of doubting, and occurred in a lady who suffers principally from obsessional acts. This lady was going for a walk with her husband in Nuremberg, and made him take her into a shop, where she purchased various objects for her child and amongst them a comb. Her husband, finding that the shopping was too long a business for his taste, said that he had noticed some coins in an antique shop on the way which he was anxious to secure, adding that after he had made his purchase he would come and fetch her in the shop in which they at present were. But he stayed away, as she thought, far too long. When he came back she accordingly asked him where he had been. 'Why,' he replied, 'at the antique shop I told you about.' At the same instant she was seized by a tormenting doubt whether she had not as a matter of fact always possessed the comb which she had just bought for her child. She was naturally quite unable to discover the simple mental link that was involved. There is nothing for it but to regard the doubt as having become displaced, and to reconstruct the complete chain of unconscious thoughts as follows: 'If it is true that you were only at the antique shop, if I am really to believe that, then I may just as well believe that this comb that I bought a moment ago has been in my possession for years.' Here, therefore, the lady was drawing a derisive and ironical parallel, just as when our patient thought: 'Oh yes, as sure as those two' (his father and the lady) 'will have children, I shall pay back the money to A.' In the lady's case the doubt was dependent upon her unconscious jealousy, which led her to suppose that her husband had spent the interval of his absence in paying a visit of gallantry.

[1909d, 2177]
(3) Finally, I have to explain to you what I mean by the 'general effect' of our work, and how I come to set hopes on it. What we have here is a very remarkable therapeutic constellation, the like of which is perhaps not to be found anywhere else and which will appear strange to you too at first, until you recognize in it something you have long been familiar with. You know, of course, that the psychoneuroses are substitutive satisfactions of some instinct the presence of which one is obliged to deny to oneself and others. Their capacity to exist depends on this distortion and lack of recognition. When the riddle they present is solved and the solution is accepted by the patients these diseases cease to be able to exist. There is hardly anything like this in medicine, though in fairy tales you hear of evil spirits whose power is broken as soon as you can tell them their name - the name which they have kept secret.

One of the characteristics of this ambivalent relation which I have repeatedly stressed as fundamental - the fact that the positive current of desire is an unconscious one - opens the way to further considerations and to further possible explanations. Psychical processes in the unconscious are not in every respect identical with those with which our conscious mind is familiar; they enjoy some remarkable liberties that are forbidden to the latter. An unconscious impulse need not have arisen at the point where it makes its appearance; it may arise from some quite other region and have applied originally to quite other persons and connections; it may have reached the place at which it attracts our attention though the mechanism of 'displacement'. Owing, moreover, to the indestructibility and insusceptibility to correction which are attributes of unconscious processes, it may have survived from very early times to which it was appropriate into later times and circumstances in which its manifestations are bound to seem strange. These are no more than hints, but if they were attentively developed their importance for our understanding of the growth of civilization would become apparent.

In just the same way, an inhibition upon movement (an abasia or an agoraphobia) will gradually become more complete and more detailed, when once that system has succeeded in installing itself as a representative of an unconscious wish and of the defence against the wish. Whatever other unconscious phantasies and operative reminiscences may be present in the patient force their way to expression as symptoms along this same path, once it has been opened, and group themselves into an appropriate new arrangement within the framework of the inhibition upon movement. Thus it would be a vain and indeed a foolish task to attempt to understand the complexities and details of the symptoms of (for example) an agoraphobia on the basis of its underlying premises; for the whole consistency and strictness of the combination are merely apparent. Just as with the façades of dreams, if we look more attentively we find the most blatant inconsistency and arbitrariness in the structure of symptoms. The real reason for the details of a systematic phobia of this kind lies in concealed determinants, which need have nothing to do with an inhibition upon movement; and that, too, is why these phobias take such various and contradictory shapes in different people.
There are cases in which one can observe how the obsession is transferred from the idea or from the affect on to the protective measure; others in which the obsession oscillates periodically between the symptom of the return of the repressed and the symptom of the secondary defence; and yet other cases in which no obsessional idea is constructed at all, but, instead, the repressed memory is at once represented by what is apparently a primary measure of defence. Here we reach at one bound the stage which elsewhere only completes the course run by the obsessional neurosis after the defensive struggle has taken place. Severe cases of this disorder end in the ceremonial actions becoming fixated, or in a general state of doubting mania, or in a life of eccentricity conditioned by phobias.
[1896b, 393]
It is easy to see where the resemblances lie between neurotic ceremonials and the sacred acts of religious ritual: in the qualms of conscience brought on by their neglect, in their complete isolation from all other actions (shown in the prohibition against interruption) and in the conscientiousness with which they are carried out in every detail. But the differences are equally obvious, and a few of them are so glaring that they make the comparison a sacrilege: the greater individual variability of ceremonial actions in contrast to the stereotyped character of rituals (prayer, turning to the East, etc.), their private nature as opposed to the public and communal character of religious observances, above all, however, the fact that, while the minutiae of religious ceremonial are full of significance and have a symbolic meaning, those of neurotics seem foolish and senseless. In this respect an obsessional neurosis presents a travesty, half comic and half tragic, of a private religion. But it is precisely this sharpest difference between neurotic and religious ceremonial which disappears when, with the help of the psycho-analytic technique of investigation, one penetrates to the true meaning of obsessive actions.¹ In the course of such an investigation the appearance which obsessive actions afford of being foolish and senseless is completely effaced, and the reason for their having that appearance is explained. It is found that the obsessive actions are perfectly significant in every detail, that they serve important interests of the personality and that they give expression to experiences that are still operative and to thoughts that are cathetized with affect. They do this in two ways, either by direct or by symbolic representation; and they are consequently to be interpreted either historically or symbolically.

These few examples, selected from the great number I have met with, are merely intended to illustrate my assertion that in obsessive actions everything has its meaning and can be interpreted. The same is true of ceremonials in the strict sense, only that the evidence for this would require a more circumstantial presentation. I am quite aware of how far our explanations of obsessive actions are apparently taking us from the sphere of religious thought.

Obsessional ideas, as is well known, have an appearance of being either without motive or without meaning, just a dreams have. The first problem is how to give them a sense and a status in the subject's mental life, so as to make them comprehensible and even obvious. The problem of translating them may seem insoluble; but we must never let ourselves be misled by that illusion. The wildest and most eccentric obsessional ideas can be cleared up if they are investigated deeply enough. The solution is effected by bringing the obsessional ideas into temporal relationship with the patient's experiences, that is to say, by enquiring when a particular obsessional idea made its first appearance and in what external circumstances it is apt to recur. When, as so often happens, an obsessional idea has not succeeded in establishing itself permanently, the task of clearing it up is correspondingly simplified. We can easily convince ourselves that, when once the interconnections between an obsessional idea and the patient's experiences have been discovered, there will be no difficulty in obtaining access to whatever else may be puzzling or worth knowing in the pathological structure we are dealing with - its meaning, the mechanism of its origin, and its derivation from the preponderant motive forces of the patient's mind.

¹ [1907b, 1903]
It was only then that it became possible to understand the inexplicable process by which his obsessional idea had been formed. With the assistance of our knowledge of infantile sexual theories and of symbolism (as learnt from the interpretation of dreams) the whole thing could be translated and given a meaning. When, at the afternoon halt (during which he had lost his pince-nez), the captain had told him about the rat punishment, the patient had only been struck at first by the combined cruelty and lasciviousness of the situation depicted. But immediately afterwards a connection had been set up with the scene from his childhood in which he himself had bitten some one. The captain - a man who could defend such punishments - had become a substitute for his father, and had thus drawn down upon himself a part of the reviving animosity which had burst out, on the original occasion, against his cruel father. The idea which came into his consciousness for a moment, to the effect that something of the sort might happen to some one he was fond of, is probably to be translated into a wish such as 'You ought to have the same thing done to you!' aimed at the teller of the story, but through him at his father. A day and a half later,¹ when the captain had handed him the packet upon which the charges were due and had requested him to pay back the 3.80 kronen to Lieutenant A., he had already been aware that his 'cruel superior' was making a mistake, and that the only person he owed anything to was the young lady at the post office. It might easily, therefore, have occurred to him to think of some derisive reply, such as, 'Will I, though?' or 'Pay your grandmother!' or 'Yes! You bet I'll pay him back the money!' - answers which would have been subject to no compulsive force. But instead, out of the stirrings of his father-complex and out of his memory of the scene from his childhood, there formed in his mind some such answer as: 'Yes! I'll pay back the money to A. when my father and the lady have children!' or 'As sure as my father and the lady can have children, I'll pay him back the money!' In short, a derisive affirmation attached to an absurd condition which could never be fulfilled.²

³

This misapprehension on the part of consciousness can be seen at work not only in reference to the obsessional ideas themselves, but also in reference to the products of the secondary defensive struggle, such, for instance, as the protective formulas. I can produce two good examples of this. Our patient used to employ as a defensive formula a rapidly pronounced 'aber' ['but'] accompanied by a gesture of repudiation. He told me on one occasion that this formula had become altered recently; he now no longer said 'aber' but 'abér'. When he was asked to give the reason for this new departure, he declared that the mute 'e' of the second syllable gave him no sense of security against the intrusion, which he so much dreaded, of some foreign and contradictory element, and that he had therefore decided to accent the 'e'. This explanation (an excellent sample of the obsessional neurotic style) was, however, clearly inadequate; the most that it could claim to be was a rationalization. The truth was that 'abér' was an approximation towards the similar-sounding 'abwehr' ['defence'], a term which he had learnt in the course of our theoretical discussions of psycho-analysis. He had thus put the treatment to an illegitimate and 'delirious' use in order to strengthen a defensive formula. Another time he told me about his principal magic word, which was an apotropaic against every evil; he had put it together out of the initial letters of the most powerfully beneficent of his prayers and had clapped on an 'amen' at the end of it. I cannot reproduce the word itself, for reasons which will become apparent immediately. For, when he told it me, I could not help noticing that the word was in fact an anagram of the name of his lady. Her name contained an 's', and this he had put last, that is, immediately before the 'amen' at the end. We may say, therefore, that by this process he had brought his 'Samen' ['semen'] into contact with the woman he loved; in imagination, that is to say, he had masturbated with her. He himself, however, had never noticed this very obvious connection; his defensive forces had allowed themselves to be fooled by the repressed ones. This is also a good example of the rule that in time the thing which is meant to be warded off invariably finds its way into the very means which is being used for warding it off.¹⁰ [1909d, 2169]
I have already asserted that obsessional thoughts have undergone a distortion similar to that undergone by dream-thoughts before they become the manifest content of a dream. The technique of this distortion may therefore be of interest to us, and there should be nothing to prevent our exhibiting its various modes by means of a series of obsessions which have been translated and made clear. But here again the conditions governing the publication of this case make it impossible for me to give more than a few specimens. Not all of the patient's obsessions were so complicated in their structure and so difficult to solve as the great rat idea. In some of the others a very simple technique was employed - namely, that of distortion by omission or ellipsis. This technique is pre-eminently applicable to jokes, but in our present case, too, it did useful work as a means of protecting things from being understood. [1909d, 2176]

In another neurotic disorder, obsessional neurosis, the patients become the victims of distressing and apparently senseless ceremonials which take the form of the rhythmical repetition of the most trivial acts (such as washing or dressing) or of carrying out meaningless injunctions or of obeying mysterious prohibitions. It was nothing less than a triumph of psychoanalytic research when it succeeded in showing that all these obsessive acts, even the most insignificant and trivial of them, have a meaning, and that they are reflections, translated into indifferent terms, of conflicts in the patients' lives, of the struggle between temptations and moral restraints - reflections of the proscribed wish itself and of the punishment and atonement which that wish incurs. In another form of the same disorder the victim suffers from tormenting ideas (obsessions) which force themselves upon him and are accompanied by affects whose character and intensity are often only quite inadequately accounted for by the terms of the obsessive ideas themselves. Analytic investigation has shown in their case that the affects are entirely justified, since they correspond to self-reproaches which are based on something that is at least psychically real. But the ideas to which these affects are attached are not the original ones, but have found their way into their present position by a process of displacement - by being substituted for something that has been repressed. If these displacements can be reversed, the way is open to the discovery of the repressed ideas, and the relation between affect and idea is found to be perfectly appropriate. [1913j, 2810]

When a doctor carries out the psycho-analytic treatment of a neurotic, his interest is by no means directed in the first instance to the patient's character. He would much rather know what the symptoms mean, what instinctual impulses are concealed behind them and are satisfied by them, and what course was followed by the mysterious path that has led from the instinctual wishes to the symptoms. But the technique which he is obliged to follow soon compels him to direct his immediate curiosity towards other objectives. He observes that his investigation is threatened by resistances set up against him by the patient, and these resistances he may justly count as part of the latter's character. This now acquires the first claim on his interest. [1916d, 3100]
It already seems proved that the obsessional action had a sense; it appears to have been a representation, a repetition, of the significant scene. But we are not obliged to come to a halt here. If we examine the relation between the two more closely, we shall probably obtain information about something that goes further - about the intention of the obsessional action. Its kernel was obviously the summoning of the housemaid, before whose eyes the patient displayed the stain, in contrast to her husband's remark that he would feel ashamed in front of the maid. Thus he, whose part she was playing, did not feel ashamed in front of the maid; accordingly the stain was in the right place. We see, therefore, that she was not simply repeating the scene, she was continuing and at the same time correcting it; she was putting it right. But by this she was also correcting the other thing, which had been so distressing that night and had made the expedient with the red ink necessary - his impotence. So the obsessional action was saying: 'No, it's not true. He had no need to feel ashamed in front of the housemaid; he was not impotent.' It represented this wish, in the manner of a dream, as fulfilled in a present-day action; it served the purpose of making her husband superior to his past mishap.

[1916-1917, 3343]

Let us turn now to the second of the discoveries which follow from our analyses; in its case we need not fear having to make a subsequent qualification of our views. I have described to you how our first patient carried out a senseless obsessional action and how she reported an intimate memory from her past life as having some connection with it: and how afterwards I examined the connection between the two and discovered the intention of the obsessional action from its relation to the memory. But there is one factor which I have entirely neglected, though it deserves our fullest attention. However often the patient repeated her obsessional action, she knew nothing of its being derived from the experience she had had. The connection between the two was hidden from her; she could only quite truthfully reply that she did not know what it was that was making her carry out her action. Then suddenly one day, under the influence of the treatment, she succeeded in discovering the connection and reported it to me. But she still knew nothing of the intention with which she was performing the obsessional action - the intention of correcting a distressing portion of the past and of putting her beloved husband in a better light. It took a fairly long time and called for much labour before she understood and admitted to me that such a motive alone could have been the driving force of her obsessional action.

[1916-1917, 3354]

At this point the second of the two observations which I mentioned to you earlier comes to our help. It is quite generally the case that analysis allows us to arrive at the intention of neurotic symptoms. This again will be nothing new to you. I have already demonstrated it to you in two cases of neurosis. But, after all, what do two cases amount to? You are right to insist on its being demonstrated to you in two hundred cases - in countless cases. The only trouble is that I cannot do that. Once again, your own experience must serve instead, or your belief, which on this point can appeal to the unanimous reports of all psycho-analysts.

[1916-1917, 3371]
Think of our first patient's obsessional action. The woman was without her husband, whom she loved intensely but with whom she could not share her life on account of his deficiencies and weaknesses. She had to remain faithful to him; she could not put anyone else in his place. Her obsessional symptom gave her what she longed for, set her husband on a pedestal, denied and corrected his weaknesses and above all his impotence. This symptom was fundamentally a wish-fulfilment, just like a dream - and moreover, what is not always true of a dream, an erotic wish-fulfilment. In the case of our second patient you could at least gather that her ceremonial sought to obstruct intercourse between her parents or prevent it from producing a new baby. You will also probably have guessed that it was at bottom endeavouring to put her herself in her mother's place. Once again, therefore, a setting-aside of interferences with sexual satisfaction and a fulfilment of the patient's own sexual wishes. I shall soon come to the complication I have hinted at.

[1916-1917, 3372]

In obsessional neurosis, on the contrary, it is the regression of the libido to the preliminary stage of the sadistic-anal organization that is the most striking fact and the one which is decisive for what is manifested in symptoms. The love-impulse is obliged, when this has happened, to disguise itself as a sadistic impulse. The obsessional idea 'I should like to kill you', when it has been freed from certain additions which are not a matter of chance but are indispensable, means at bottom nothing other than 'I should like to enjoy you in love'. If you consider further that there has been a simultaneous regression in regard to the object, so that these impulses apply only to those who are nearest and dearest to the patient, you can form some idea of the horror which these obsessions arouse in him and at the same time of the alien appearance which they present to his conscious perception. But repression, too, plays a great part in the mechanism of these neuroses, though in a cursory introduction like ours this is not easily demonstrated. A regression of the libido without repression would never produce a neurosis but would lead to a perversion. From this you can see that repression is the process which is most peculiar to neuroses and is most characteristic of them. Perhaps I may have an opportunity later of telling you what we know of the mechanism of the perversions, and you will see that in their case too things are not so simple as we should be glad to make them out.

[1916-1917, 3407]
I must give a few examples to illustrate my point. Those who are familiar with the findings of psycho-analytic investigation into the psychoneuroses will not be surprised to learn that what is being represented in obsessive actions or in ceremonials is derived from the most intimate, and for the most part from the sexual, experiences of the patient.
[1907b, 1904]

And one thing more. Were you not struck by the way in which this unobtrusive obsessional action has led us into the intimacies of the patient's life? A woman cannot have anything much more intimate to tell than the story of her wedding-night. Is it a matter of chance and of no further significance that we have arrived precisely at the intimacies of sexual life? No doubt it might be the result of the choice I have made on this occasion. Do not let us be too hasty in forming our judgement, and let us turn to my second example, which is of quite a different kind - a sample of a very common species, a sleep-ceremonial.
[1916-1917, 3344]
Such is my excuse for having curtailed so drastically the history of this case and its treatment. And I can offer still more cogent reasons for having confined myself to the statement only of some disconnected results of the psycho-analytic investigation of obsessional neuroses. I must confess that I have not yet succeeded in completely penetrating the complicated texture of a severe case of obsessional neurosis, and that, if I were to reproduce the analysis, it would be impossible for me to make the structure, such as by the help of analysis we know or suspect it to be, visible to others through the mass of therapeutic work superimposed upon it. What add so greatly to the difficulty of doing this are the resistances of the patients and the forms in which they are expressed. But even apart from this it must be admitted that an obsessional neurosis is in itself not an easy thing to understand - much less so than a case of hysteria. Actually, indeed, we should have expected to find the contrary. The language of an obsessional neurosis - the means by which it expresses its secret thoughts - is, as it were, only a dialect of the language of hysteria; but it is a dialect in which we ought to be able to find our way about more easily, since it is more nearly related to the forms of expression adopted by our conscious thought than is the language of hysteria. Above all, it does not involve the leap from a mental process to a somatic innervation - hysterical conversion - which can never be fully comprehensible to us.

[1909d, 2128]

I shall no doubt be overstepping common linguistic usage in postulating an interest in psycho-analysis on the part of philologists, that is of experts in speech. For in what follows 'speech' must be understood not merely to mean the expression of thought in words but to include the speech of gesture and every other method, such, for instance, as writing, by which mental activity can be expressed. That being so, it may be pointed out that the interpretations made by psycho-analysis are first and foremost translations from an alien method of expression into the one which is familiar to us. When we interpret a dream we are simply translating a particular thought-content (the latent dream-thoughts) from the 'language of dreams' into our waking speech. In the course of doing so we learn the peculiarities of this dream language and it is borne in upon us that it forms part of a highly archaic system of expression. Thus, to take an instance, there is no special indication for the negative in the language of dreams. Contraries may stand for each other in the dream's content and may be represented by the same element. Or we may put it like this: concepts are still ambivalent in dream-language, and unite within themselves contrary meanings - as is the case, according to the hypotheses of philologists, in the oldest roots of historical languages.¹ Another striking feature of our dream-language is its extremely frequent use of symbols, which make us able to some extent to translate the content of dreams without reference to the associations of the individual dreamer. Our researches have not yet sufficiently elucidated the essential nature of these symbols. They are in part substitutes and analogies based upon obvious similarities; but in some of these symbols the tertium comparationis which is presumably present escapes our conscious knowledge. It is precisely this latter class of symbols which must probably originate from the earliest phases of linguistic development and conceptual construction. In dreams it is above all the sexual organs and sexual activities which are represented symbolically instead of directly. A philologist, Hans Sperber, of Uppsala, has only recently (1912) attempted to prove that words which originally represented sexual activities have, on the basis of analogies of this kind, undergone an extraordinarily far-reaching change in their meaning.

[1913j, 2813]
The language of dreams may be looked upon as the method by which unconscious mental activity expresses itself. But the unconscious speaks more than one dialect. According to the differing psychological conditions governing and distinguishing the various forms of neurosis, we find regular modifications in the way in which unconscious mental impulses are expressed. While the gesture-language of hysteria agrees on the whole with the picture-language of dreams and visions, etc., the thought-language of obsessional neurosis and of the paraphrenias (dementia praecox and paranoia) exhibits special idiomatic peculiarities which, in a number of instances, we have been able to understand and interrelate. For instance, what a hysteric expresses by vomiting an obsessional will express by painstaking protective measures against infection, while a paraphrenic will be led to complaints or suspicions that he is being poisoned. These are all of them different representations of the patient's wish to become pregnant which have been repressed into the unconscious, or of his defensive reaction against that wish. [1913], 2814]
I return now to my earlier assertion that, in judging the neuroses, their full importance is not as a rule taken into account. I do not mean by this the undervaluation of these states shown in their frivolous dismissal by relatives and in the boasting assurances by doctors that a few weeks of cold water treatment or a few months of rest and convalescence will cure the condition. These are merely the opinions of quite ignorant doctors and laymen and are mostly no more than words intended to give the sufferer a short-lived consolation. It is, on the contrary, a well-known fact that a chronic neurosis, even if it does not totally put an end to the subject's capacity for existence, represents a severe handicap in his life, of the same order, perhaps, as tuberculosis or a cardiac defect. The situation would even be tolerable if neurotic illness were to exclude from civilized activities only a number of individuals who were in any case of the weaker sort, and allowed the rest to play their part in it at the cost of troubles that were merely subjective. But, far from this being so, I must insist upon the view that neuroses, whatever their extent and wherever they occur, always succeed in frustrating the purposes of civilization, and in that way actually perform the work of the suppressed mental forces that are hostile to civilization. Thus, when society pays for obedience to its far-reaching regulations by an increase in nervous illness, it cannot claim to have purchased a gain at the price of sacrifices; it cannot claim a gain at all. Let us, for instance, consider the very common case of a woman who does not love her husband, because, owing to the conditions under which she entered marriage, she has no reason to love him, but who very much wants to love him, because that alone corresponds to the ideal of marriage to which she has been brought up. She will in that case suppress every impulse which would express the truth and contradict her endeavours to fulfill her ideal, and she will make special efforts to play the part of a loving, affectionate and attentive wife. The outcome of this self-suppression will be a neurotic illness; and this neurosis will in a short time have taken revenge on the unloved husband and have caused him just as much lack of satisfaction and worry as would have resulted from an acknowledgement of the true state of affairs. This example is completely typical of what a neurosis achieves. A similar failure to obtain compensation is to be seen after the suppression of impulses inimical to civilization which are not directly sexual. If a man, for example, has become over-kind as a result of a violent suppression of a constitutional inclination to harshness and cruelty, he often loses so much energy in doing this that he fails to carry out all that his compensatory impulses require, and he may, after all, do less good on the whole than he would have done without the suppression. [1908d, 1962]
This misapprehension on the part of consciousness can be seen at work not only in reference to the obsessional ideas themselves, but also in reference to the products of the secondary defensive struggle, such, for instance, as the protective formulas. I can produce two good examples of this. Our patient used to employ as a defensive formula a rapidly pronounced ‘aber’ [‘but’] accompanied by a gesture of repudiation. He told me on one occasion that this formula had become altered recently; he now no longer said ‘áber’ but ‘abé’r’. When he was asked to give the reason for this new departure, he declared that the mute ‘e’ of the second syllable gave him no sense of security against the intrusion, which he so much dreaded, of some foreign and contradictory element, and that he had therefore decided to accent the ‘e’. This explanation (an excellent sample of the obsessional neurotic style) was, however, clearly inadequate; the most that it could claim to be was a rationalization. The truth was that ‘abé’r’ was an approximation towards the similar-sounding ‘abwehr’ [‘defence’], a term which he had learnt in the course of our theoretical discussions of psycho-analysis. He had thus put the treatment to an illegitimate and ‘delirious’ use in order to strengthen a defensive formula. Another time he told me about his principal magic word, which was an apotropaic against every evil; he had put it together out of the initial letters of the most powerfully beneficent of his prayers and had clapped on an ‘amen’ at the end of it. I cannot reproduce the word itself, for reasons which will become apparent immediately. For, when he told it me, I could not help noticing that the word was in fact an anagram of the name of his lady. Her name contained an ‘s’, and this he had put last, that is, immediately before the ‘amen’ at the end. We may say, therefore, that by this process he had brought his ‘Samen’ [‘semen’] into contact with the woman he loved; in imagination, that is to say, he had masturbated with her. He himself, however, had never noticed this very obvious connection; his defensive forces had allowed themselves to be fooled by the repressed ones. This is also a good example of the rule that in time the thing which is meant to be warded off invariably finds its way into the very means which is being used for warding it off.

[1909d, 2175]
It is this same doubt that leads the patient to uncertainty about his protective measures, and
to his continual repetition of them in order to banish that uncertainty; and it is this doubt, too,
that eventually brings it about that the patient's protective acts themselves become as
impossible to carry out as his original inhibited decision in connection with his love. At the
beginning of my investigations I was led to assume another and more general origin for the
uncertainty of obsessional neurotics and one which seemed to be nearer the normal. If, for
instance, while I am writing a letter some one interrupts me with questions, I afterwards feel a
quite justifiable uncertainty as to what I may not have written under the influence of the
disturbance, and, to make sure, I am obliged to read the letter over after I have finished it. In the
same way I might suppose that the uncertainty of obsessional neurotics, when they are praying,
for instance, is due to unconscious phantasies constantly mingling with their prayers and
disturbing them. This hypothesis is correct, but it may be easily reconciled with what I have just
said. It is true that the patient's uncertainty whether he has carried through a protective measure
is due to the disturbing effect of unconscious phantasies; but the content of these phantasies is
precisely the contrary impulse - which it was the very aim of the prayer to ward off. This became
clearly evident in our patient on one occasion, for the disturbing element did not remain
unconscious but made its appearance openly. The words he wanted to use in his prayer were,
'May God protect her', but a hostile 'not' suddenly darted out of his unconscious and inserted
itself into the sentence; and he understood that this was an attempt at a curse (p. 2152).
If the
'not' had remained mute, he would have found himself in a state of uncertainty and would have
kept on prolonging his prayers indefinitely. But since it became articulate he eventually gave up
praying. Before doing so, however, he, like other obsessional patients, tried every kind of
method for preventing the opposite feeling from insinuating itself. He shortened his prayers, for
instance, or said them more rapidly. And similarly other patients will endeavour to 'isolate' all
such protective acts from other things. But none of these technical procedures are of any avail
in the long run. If the impulse of love achieves any success by displacing itself on to some trivial
act, the impulse of hostility will very soon follow it on to its new ground and once more proceed
to undo all that it has done.
[1909d, 2189]

In our clinical history of a case we have insisted that the imposition of the prohibition in very
early childhood is the determining point; a similar importance attaches in the subsequent
developments to the mechanism of repression at the same early age. As a result of the
repression which has been enforced and which involves a loss of memory - an amnesia - the
motives for the prohibition (which is conscious) remain unknown; and all attempts at disposing
of it by intellectual processes must fail, since they cannot find any base of attack. The
prohibition owes its strength and its obsessive character precisely to its unconscious opponent,
the concealed and undiminished desire - that is to say, to an internal necessity inaccessible to
conscious inspection. The ease with which the prohibition can be transferred and extended
reflects a process which falls in with the unconscious desire and is greatly facilitated by the
psychological conditions that prevail in the unconscious. The instinctual desire is constantly
shifting in order to escape from the impasse and endeavours to find substitutes - substitute
objects and substitute acts - in place of the prohibited ones. In consequence of this, the
prohibition itself shifts about as well, and extends to any new aims which the forbidden impulse
may adopt. Any fresh advance made by the repressed libido is answered by a fresh sharpening
of the prohibition. The mutual inhibition of the two conflicting forces produces a need for
discharge, for reducing the prevailing tension; and to this may be attributed the reason for the
performance of obsessive acts. In the case of a neurosis these are clearly compromise actions:
from one point of view they are evidences of remorse, efforts at expiation, and so on, while on
the other hand they are at the same time substitutive acts to compensate the instinct for what
has been prohibited. It is a law of neurotic illness that these obsessive acts fall more and more
under the sway of the instinct and approach nearer and nearer to the activity which was
originally prohibited.
[1912-1913, 2678]
But the strongest support for our effort to equate taboo prohibitions with neurotic symptoms is to be found in the taboo ceremonials themselves, the effect of which upon the position of royalty has already been discussed. These ceremonials unmistakably reveal their double meaning and their derivation from ambivalent impulses, as soon as we are ready to allow that the results which they bring about were intended from the first. The taboo does not only pick out the king and exalt him above all common mortals, it also makes his existence a torment and an intolerable burden and reduces him to a bondage far worse than that of his subjects. Here, then, we have an exact counterpart of the obsessional act in the neurosis, in which the suppressed impulse and the impulse that suppresses it find simultaneous and common satisfaction. The obsessional act is *ostensibly* a protection against the prohibited act; but *actually*, in our view, it is a repetition of it. The 'ostensibly' applies to the *conscious* part of the mind, and the 'actually' to the *unconscious* part. In exactly the same way, the ceremonial taboo of kings is *ostensibly* the highest honour and protection for them, while *actually* it is a punishment for their exaltation, a revenge taken on them by their subjects. The experiences of Sancho Panza (as described by Cervantes) when he was Governor of his island convinced him that this view of court ceremonial was the only one that met the case. If we could hear the views of modern kings and rulers on the subject, we might find that there were many others who agreed with him. [1912-1913, 2696]

The primary obsessive acts of these neurotics are of an entirely magical character. If they are not charms, they are at all events counter-charms, designed to ward off the expectations of disaster with which the neurosis usually starts. Whenever I have succeeded in penetrating the mystery, I have found that the expected disaster was death. Schopenhauer has said that the problem of death stands at the outset of every philosophy; and we have already seen that the origin of the belief in souls and in demons, which is the essence of animism, goes back to the impression which is made upon men by death. It is difficult to judge whether the obsessive or protective acts performed by obsessional neurotics follow the law of similarity (or, as the case may be, of contrast); for as a rule, owing to the prevailing conditions of the neurosis, they have been distorted by being displaced on to something very small, some action in itself of the greatest triviality.¹ The protective formulas of obsessional neuroses, too, have their counterpart in the formulas of magic. It is possible, however, to describe the course of development of obsessive acts: we can show how they begin by being as remote as possible from anything sexual - magical defences against evil wishes - and how they end by being substitutes for the forbidden sexual act and the closest possible imitations of it. [1912-1913, 2730]
This may be illustrated by an example from a neurosis. In my essay on taboo I mentioned a woman patient of mine whose obsessional prohibitions showed the most perfect agreement with a Maori taboo (p. 2676). This woman's neurosis was aimed at her husband and culminated in her defence against an unconscious wish that he should die. Her manifest, systematic phobia, however, related to the mention of death in general, while her husband was entirely excluded from it and was never an object of her conscious solicitude. One day she heard her husband giving instructions that his razors, which had lost their edge, were to be taken to a particular shop to be re-set. Driven by a strange uneasiness, she herself set off for the shop. After reconnoitring the ground, she came back and insisted that her husband should get rid of the razors for good and all, since she had discovered that next door to the shop he had named there was an undertaker's establishment: owing to the plan he had made, she said, the razors had become inextricably involved with thoughts of death. This, then, was the systematic reason for her prohibition. We may be quite sure that, even without her discovery of the next-door shop, the patient would have come home with a prohibition against the razors. It would have been enough if she had met a hearse on her way to the shop, or someone dressed in mourning or carrying a funeral wreath. The net of possible determinants for the prohibition was spread wide enough to catch the quarry in any event; it merely depended on her decision whether to draw it together or not. It could be shown that on other occasions she would not put the determinants into operation, and she would explain this by saying it had been 'a better day'. The real cause of her prohibition upon the razors was, of course, as it was easy to discover, her repugnance to attaching any pleasurable feeling to the idea that her husband might cut his throat with the newly ground razors.

[1912-1913, 2738]
A totally different picture of repression is shown, once more, in the third disorder which we shall consider for the purposes of our illustration - in obsessional neurosis. Here we are at first in doubt what it is that we have to regard as the instinctual representative that is subjected to repression - whether it is a libidinal or a hostile trend. This uncertainty arises because obsessional neurosis has as its basis a regression owing to which a sadistic trend has been substituted for an affectionate one. It is this hostile impulsion against someone who is loved which is subjected to repression. The effect at an early stage of the work of repression is quite different from what it is at a later one. At first the repression is completely successful; the ideational content is rejected and the affect made to disappear. As a substitutive formation there arises an alteration in the ego in the shape of an increased conscientiousness, and this can hardly be called a symptom. Here, substitute and symptom do not coincide. From this we learn something, too, about the mechanism of repression. In this instance, as in all others, repression has brought about a withdrawal of libido; but here it has made use of reaction-formation for this purpose, by intensifying an opposite. Thus in this case the formation of a substitute has the same mechanism as repression and at bottom coincides with it, while chronologically, as well as conceptually, it is distinct from the formation of a symptom. It is very probable that the whole process is made possible by the ambivalent relationship into which the sadistic impulsion that has to be repressed has been introduced. But the repression, which was at first successful, does not hold firm; in the further course of things its failure becomes increasingly marked. The ambivalence which has enabled repression through reaction-formation to take place is also the point at which the repressed succeeds in returning. The vanished affect comes back in its transformed shape as social anxiety, moral anxiety and unlimited self-reproaches; the rejected idea is replaced by a substitute by displacement; often a displacement on to something very small or indifferent. A tendency to a complete re-establishment of the repressed idea is as a rule unmistakably present. The failure in the repression of the quantitative, affective factor brings into play the same mechanism of flight, by means of avoidance and prohibitions, as we have seen at work in the formation of hysterical phobias. The rejection of the idea from the conscious is, however, obstinately maintained, because it entails abstention from action, a motor fettering of the impulsion. Thus in obsessional neurosis the work of repression is prolonged in a sterile and interminable struggle.

[1915d, 2987]
Melancholia, therefore, borrows some of its features from mourning, and the others from the process of regression from narcissistic object-choice to narcissism. It is on the one hand, like mourning, a reaction to the real loss of a loved object; but over and above this, it is marked by a determinant which is absent in normal mourning or which, if it is present, transforms the latter into pathological mourning. The loss of a love-object is an excellent opportunity for the ambivalence in love-relationships to make itself effective and come into the open. Where there is a disposition to obsessional neurosis the conflict due to ambivalence gives a pathological cast to mourning and forces it to express itself in the form of self-reproaches to the effect that the mourner himself is to blame for the loss of the loved object, i.e. that he has willed it. These obsessional states of depression following upon the death of a loved person show us what the conflict due to ambivalence can achieve by itself when there is no regressive drawing-in of libido as well. In melancholia, the occasions which give rise to the illness extend for the most part beyond the clear case of a loss by death, and include all those situations of being slighted, neglected or disappointed, which can import opposed feelings of love and hate into the relationship or reinforce an already existing ambivalence. This conflict due to ambivalence, which sometimes arises more from real experiences, sometimes more from constitutional factors, must not be overlooked among the preconditions of melancholia. If the love for the object - a love which cannot be given up though the object itself is given up - takes refuge in narcissistic identification, then the hate comes into operation on this substitutive object, abusing it, debasing it, making it suffer and deriving sadistic satisfaction from its suffering. The self-tormenting in melancholia, which is without doubt enjoyable, signifies, just like the corresponding phenomenon in obsessional neurosis, a satisfaction of trends of sadism and hate which relate to an object, and which have been turned round upon the subject's own self in the ways we have been discussing. In both disorders the patients usually still succeed, by the circuitous path of self-punishment, in taking revenge on the original object and in tormenting their loved one through their illness, having resorted to it in order to avoid the need to express their hostility to him openly. After all, the person who has occasioned the patient's emotional disorder, and on whom his illness is centred, is usually to be found in his immediate environment. The melancholic's erotic cathexis in regard to his object has thus undergone a double vicissitude: part of it has regressed to identification, but the other part, under the influence of the conflict due to ambivalence, has been carried back to the stage of sadism which is nearer to that conflict.

[1917e, 3048]

Of the many symptomatic pictures in which obsessional neurosis appears, the most important turn out to be those provoked by the pressure of excessively strong sadistic sexual impulses (perverse, therefore, in their aim). The symptoms, indeed, in accordance with the structure of an obsessional neurosis, serve predominantly as a defence against these wishes or give expression to the struggle between satisfaction and defence. But satisfaction does not come off too badly either; it succeeds in roundabout ways in putting itself into effect in the patients' behaviour and is preferably directed against themselves and makes them into self-tormentors. Other forms of the neurosis, the brooding kinds, correspond to an excessive sexualization of actions which ordinarily have their place on the path to normal sexual satisfaction - an excessive sexualization of wanting to look or to touch or to explore. Here we have the explanation of the great importance of the fear of touching and of the obsession for washing. An unsuspectedly large proportion of obsessional actions may be traced back to masturbation, of which they are disguised repetitions and modifications; it is a familiar fact that masturbation, though a single and uniform action, accompanies the most various forms of sexual phantasying.

[1916-1917, 3380]
The influence that provoked this transformation was the acquaintance which he obtained through his mother's agency with the doctrines of religion and with the Bible story. This educational measure had the desired effect. The sadistic-masochistic sexual organization came slowly to an end, the wolf phobia quickly vanished, and, instead of sexuality being repudiated with anxiety, a higher method of suppressing it made its appearance. Piety became the dominant force in the child's life. These victories, however, were not won without struggles, of which his blasphemous thoughts were an indication, and of which the establishment of an obsessive exaggeration of religious ceremonial was the result.

[1918b, 3590]

'Nothing has entered into you from without; a part of the activity of your own mind has been withdrawn from your knowledge and from the command of your will. That, too, is why you are so weak in your defence; you are using one part of your force to fight the other part and you cannot concentrate the whole of your force as you would against an external enemy. And it is not even the worst or least important part of your mental forces that has thus become antagonistic to you and independent of you. The blame, I am bound to say, lies with yourself. You over-estimated your strength when you thought you could treat your sexual instincts as you liked and could utterly ignore their intentions. The result is that they have rebelled and have taken their own obscure paths to escape this suppression; they have established their rights in a manner you cannot approve. How they have achieved this, and the paths which they have taken, have not come to your knowledge. All you have learned is the outcome of their work - the symptom which you experience as suffering. Thus you do not recognize it as a derivative of your own rejected instincts and do not know that it is a substitutive satisfaction of them.

[1917a, 3613]

The reproaches of conscience in certain forms of obsessional neurosis are as distressing and tormenting, but here the situation is less perspicuous. It is noteworthy that the obsessional neurotic, in contrast to the melancholic, never in fact takes the step of self-destruction; it is as though he were immune against the danger of suicide, and he is far better protected from it than the hysteric. We can see that what guarantees the safety of the ego is the fact that the object has been retained. In obsessional neurosis it has become possible, through a regression to the pregenital organization, for the love-impulses to transform themselves into impulses of aggression against the object. Here again the instinct of destruction has been set free and it seeks to destroy the object, or at least it appears to have that intention. These purposes have not been adopted by the ego and it struggles against them with reaction-formations and precautionary measures; they remain in the id. The super-ego, however, behaves as if the ego were responsible for them and shows at the same time by the seriousness with which it chastises these destructive intentions that they are no mere semblance evoked by regression but an actual substitution of hate for love. Helpless in both directions, the ego defends itself vainly, alike against the instigations of the murderous id and against the reproaches of the punishing conscience. It succeeds in holding in check at least the most brutal actions of both sides; the first outcome is interminable self-torment, and eventually there follows a systematic torturing of the object, in so far as it is within reach.

[1923b, 3987]
Let us turn to the obsessional neuroses in the hope of learning more about the formation of symptoms. The symptoms belonging to this neurosis fall, in general, into two groups, each having an opposite trend. They are either prohibitions, precautions and expiations - that is, negative in character - or they are, on the contrary, substitutive satisfactions which often appear in symbolic disguise. The negative, defensive group of symptoms is the older of the two; but as illness is prolonged, the satisfactions, which scoff at all defensive measures, gain the upper hand. The symptom-formation scores a triumph if it succeeds in combining the prohibition with satisfaction so that what was originally a defensive command or prohibition acquires the significance of a satisfaction as well; and in order to achieve this end it will often make use of the most ingenious associative paths. Such an achievement demonstrates the tendency of the ego to synthesize, which we have already observed. In extreme cases the patient manages to make most of his symptoms acquire, in addition to their original meaning, a directly contrary one. This is a tribute to the power of ambivalence, which, for some unknown reason, plays such a large part in obsessional neuroses. In the crudest instance the symptom is diphasic: an action which carries out a certain injunction is immediately succeeded by another action which stops or undoes the first one even if it does not go quite so far as to carry out its opposite. [1926d, 4271]

Two impressions at once emerge from this brief survey of obsessional symptoms. The first is that a ceaseless struggle is being waged against the repressed, in which the repressing forces steadily lose ground; the second is that the ego and the super-ego have a specially large share in the formation of the symptoms. [1926d, 4272]

In enforcing regression, the ego scores its first success in its defensive struggle against the demands of the libido. (In this connection it is of advantage to distinguish the more general notion of 'defence' from 'repression'. Repression is only one of the mechanisms which defence makes use of.) It is perhaps in obsessional cases more than in normal or hysterical ones that we can most clearly recognize that the motive force of defence is the castration complex and that what is being fended off are the trends of the Oedipus complex. We are at present dealing with the beginning of the latency period, a period which is characterized by the dissolution of the Oedipus complex, the creation or consolidation of the super-ego and the erection of ethical and aesthetic barriers in the ego. In obsessional neuroses these processes are carried further than is normal. In addition to the destruction of the Oedipus complex a regressive degradation of the libido takes place, the super-ego becomes exceptionally severe and unkind, and the ego, in obedience to the super-ego, produces strong reaction-formations in the shape of conscientiousness, pity and cleanliness. Implacable, though not always on that account successful, severity is shown in condemning the temptation to continue early infantile masturbation, which now attaches itself to regressive (sadistic-anal) ideas but which nevertheless represents the unsubjugated part of the phallic organization. There is an inherent contradiction about this state of affairs, in which, precisely in the interests of masculinity (that is to say, from fear of castration), every activity belonging to masculinity is stopped. But here, too, obsessional neurosis is only overdoing the normal method of getting rid of the Oedipus complex. We once more find here an illustration of the truth that every exaggeration contains the seed of its own undoing. For, under the guise of obsessional acts, the masturbation that has been suppressed approaches ever more closely to satisfaction. [1926d, 4273]
I have already described the general tendency of symptom-formation in obsessional neurosis. It is to give ever greater room to substitutive satisfaction at the expense of frustration. Symptoms which once stood for a restriction of the ego come later on to represent satisfactions as well, thanks to the ego's inclination to synthesis, and it is quite clear that this second meaning gradually becomes the more important of the two. The result of this process, which approximates more and more to a complete failure of the original purpose of defence, is an extremely restricted ego which is reduced to seeking satisfaction in the symptoms. The displacement of the distribution of forces in favour of satisfaction may have the dreaded final outcome of paralysing the will of the ego, which in every decision it has to make is almost as strongly impelled from the one side as from the other. The over-acute conflict between id and super-ego which has dominated the illness from the very beginning may assume such extensive proportions that the ego, unable to carry out its office of mediator, can undertake nothing which is not drawn into the sphere of that conflict. [1926d, 4277]
A dream, as we have discovered, takes the place of a number of thoughts which are derived from our daily life and which form a completely logical sequence. We cannot doubt, then, that these thoughts originate from our normal mental life. All the attributes which we value highly in our trains of thought, and which characterize them as complex achievements of a high order, are to be found once more in dream-thoughts. There is no need to assume, however, that this activity of thought is performed during sleep - a possibility which would gravely confuse what has hitherto been our settled picture of the psychical state of sleep. On the contrary, these thoughts may very well have originated from the previous day, they may have proceeded unobserved by our consciousness from their start, and may already have been completed at the onset of sleep. The most that we can conclude from this is that it proves that the most complicated achievements of thought are possible without the assistance of consciousness - a fact which we could not fail to learn in any case from every psycho-analysis of a patient suffering from hysteria or from obsessional ideas. These dream-thoughts are certainly not in themselves inadmissible to consciousness; there may have been a number of reasons for their not having become conscious to us during the day. Becoming conscious is connected with the application of a particular psychical function, that of attention - a function which, as it seems, is only available in a specific quantity, and this may have been diverted from the train of thought in question on to some other purpose. There is another way, too, in which trains of thought of this kind may be withheld from consciousness. The course of our conscious reflections shows us that we follow a particular path in our application of attention. If, as we follow this path, we come upon an idea which will not bear criticism, we break off: we drop the cathectic attention. Now it seems that the train of thought which has thus been initiated and dropped can continue to spin itself out without attention being turned to it again, unless at some point or other it reaches a specially high degree of intensity which forces attention to it. Thus, if a train of thought is initially rejected (consciously, perhaps) by a judgement that it is wrong or that it is useless for the immediate intellectual purposes in view, the result may be that this train of thought will proceed, unobserved by consciousness, until the onset of sleep.

We find, accordingly: an erotic instinct and a revolt against it; a wish which has not yet become compulsive and, struggling against it, a fear which is already compulsive; a distressing affect and an impulsion towards the performance of defensive acts. The inventory of the neurosis has reached its full muster. Indeed, something more is present, namely, a kind of delusion or delirium with the strange content that his parents knew his thoughts because he spoke them out loud without his hearing himself do it. We shall not go far astray if we suppose that in making this attempt at an explanation the child had some inkling of those remarkable mental processes which we describe as unconscious and which we cannot dispense with if we are to throw any scientific light upon this obscure subject. 'I speak my thoughts out loud, without hearing them' sounds like a projection into the external world of our own hypothesis that he had thoughts without knowing anything about them; it sounds like an endopsychic perception of what has been repressed.
'I have decided to tell you something which I consider most important and which has tormented me from the very first.' He then told me at great length the story of the last illness of his father, who had died of emphysema nine years previously. One evening, thinking that the condition was one which would come to a crisis, he had asked the doctor when the danger could be regarded as over. 'The evening of the day after to-morrow', had been the reply. It had never entered his head that his father might not survive that limit. At half-past eleven at night he had lain down for an hour's rest. He had woken up at one o'clock, and had been told by a medical friend that his father had died. He had reproached himself with not having been present at his death; and the reproach had been intensified when the nurse told him that his father had spoken his name once during the last days, and had said to her as she came up to the bed: 'Is that Paul?' He had thought he noticed that his mother and sisters had been inclined to reproach themselves in a similar way; but they had never spoken about it. At first, however, the reproach had not tormented him. For a long time he had not realized the fact of his father's death. It had constantly happened that, when he heard a good joke, he would say to himself: 'I must tell Father that.' His imagination, too, had been occupied with his father, so that often, when there was a knock at the door, he would think: 'Here comes Father', and when he walked into a room he would expect to find his father in it. And although he had never forgotten that his father was dead, the prospect of seeing a ghostly apparition of this kind had had no terrors for him; on the contrary, he had greatly desired it. It had not been until eighteen months later that the recollection of his neglect had recurred to him and begun to torment him terribly, so that he had come to treat himself as a criminal. The occasion of this happening had been the death of an aunt by marriage and of a visit of condolence that he had paid at her house. From that time forward he had extended the structure of his obsessional thoughts so as to include the next world. The immediate consequence of this development had been that he became seriously incapacitated from working.¹ He told me that the only thing that had kept him going at that time had been the consolation given him by his friend, who had always brushed his self-reproaches aside on the ground that they were grossly exaggerated. Hearing this, I took the opportunity of giving him a first glance at the underlying principles of psycho-analytic therapy. When there is a mésalliance, I began, between an affect and its ideational content (in this instance, between the intensity of the self-reproach and the occasion for it), a layman will say that the affect is too great for the occasion - that it is exaggerated and that consequently the inference following from the self-reproach (the inference that the patient is a criminal) is false. On the contrary, the physician says: 'No. The affect is justified. The sense of guilt is not in itself open to further criticism. But it belongs to some other content, which is unknown (unconscious), and which requires to be looked for. The known ideational content has only got into its actual position owing to a false connection. We are not used to feeling strong affects without their having any ideational content, and therefore, if the content is missing, we seize as a substitute upon some other content which is in some way or other suitable, much as our police, when they cannot catch the right murderer, arrest a wrong one instead. Moreover, this fact of there being a false connection is the only way of accounting for the powerlessness of logical processes to combat the tormenting idea.' I concluded by admitting that this new way of looking at the matter gave immediate rise to some hard problems; for how could he admit that his self-reproach of being a criminal towards his father was justified, when he must know that as a matter of fact he had never committed any crime against him?

[1909d, 2142]
In this instance the connection between the compulsive idea and the patient's life is contained in the opening words of his story. His lady was absent, while he was working very hard for an examination so as to bring the possibility of an alliance with her nearer. While he was working he was overcome by a longing for his absent lady, and he thought of the cause of her absence. And now there came over him something which, if he had been a normal man, would probably have been some kind of feeling of annoyance with her grandmother: 'Why must the old woman get ill just at the very moment when I'm longing for her so frightfully?' We must suppose that something similar but far more intense passed through our patient's mind - an unconscious fit of rage which could combine with his longing and find expression in the exclamation: 'Oh, I should like to go and kill that old woman for robbing me of my love!' Thereupon followed the command: 'Kill yourself, as a punishment for these savage and murderous passions!' The whole process then passed into the obsessional patient's consciousness accompanied by the most violent affect and in a reverse order - the punitive command coming first, and the mention of the guilty outburst afterwards. I cannot think that this attempt at an explanation will seem forced or that it involves many hypothetical elements.

Another impulse, which might be described as indirectly suicidal and which was of longer duration, was not so easily explicable. For its relation to the patient's experiences succeeded in concealing itself behind one of those purely external associations which are so obnoxious to our consciousness. One day while he was away on his summer holidays the idea suddenly occurred to him that he was too fat [German 'dick'] and that he must make himself slimmer. So he began getting up from table before the pudding came round and tearing along the road without a hat in the blazing heat of an August sun. Then he would dash up a mountain at the double, till, dripping with perspiration, he was forced to come to a stop. On one occasion his suicidal intentions actually emerged without any disguise from behind this mania for slimming: as he was standing on the edge of a steep precipice he suddenly received a command to jump over, which would have been certain death. Our patient could think of no explanation of this senseless obsessional behaviour until it suddenly occurred to him that at that time his lady had also been stopping at the same resort; but she had been in the company of an English cousin, who was very attentive to her and of whom the patient had been very jealous. This cousin's name was Richard, and, according to the usual practice in England, he was known as Dick. Our patient, then, had wanted to kill this Dick; he had been far more jealous of him and enraged with him than he could admit to himself, and that was why he had imposed on himself this course of slimming by way of a punishment. This obsessional impulse may seem very different from the directly suicidal command which was discussed above, but they have nevertheless one important feature in common. For they both arose as reactions to a tremendous feeling of rage, which was inaccessible to the patient's consciousness and was directed against some one who had cropped up as an interference with the course of his love.¹

Only vague intelligence of these events reached the patient's consciousness. But his revolt against the captain's order and the sudden transformation of that revolt into its opposite were both represented there. First had come the idea that he was not to pay back the money, or it (that is, the rat punishment) would happen; and then had come the transformation of this idea into a vow to the opposite effect, as a punishment for his revolt.

¹[1909d, 2148]
I shall not in the present paper attempt any discussion of the psychological significance of obsessional thinking. Such a discussion would be of extraordinary value in its results, and would do more to clarify our ideas upon the nature of the conscious and the unconscious than any study of hysteria or the phenomena of hypnosis. It would be a most desirable thing if the philosophers and psychologists who develop brilliant theoretical views on the unconscious upon a basis of hearsay knowledge or from their own conventional definitions would first submit to the convincing impressions which may be gained from a first-hand study of the phenomena of obsessional thinking. We might almost go to the length of requiring it of them, if the task were not so far more laborious than the methods of work to which they are accustomed. I will only add here that in obsessional neuroses the unconscious mental processes occasionally break through into consciousness in their pure and undistorted form, that such incursions may take place at every possible stage of the unconscious process of thought, and that at the moment of the incursion the obsessional ideas can, for the most part, be recognized as formations of very long standing. This accounts for the striking circumstance that, when the analyst tries, with the patient's help, to discover the date of the first occurrence of an obsessional idea, the patient is obliged to place it further and further back as the analysis proceeds, and is constantly finding fresh 'first' occasions for the appearance of the obsession.

I refer to the omnipotence which he ascribed to his thoughts and feelings, and to his wishes, whether good or evil. It is, I must admit, decidedly tempting to declare that this idea was a delusion and that it oversteps the limits of obsessional neurosis. I have, however, come across the same conviction in another obsessional patient; and he was long ago restored to health and is leading a normal life. Indeed, all obsessional neurotics behave as though they shared this conviction. It will be our business to throw some light upon these patients' over-estimation of their powers. Assuming, without more ado, that this belief is a frank acknowledgement of a relic of the old megalomania of infancy, we will proceed to ask our patient for the grounds of his conviction. In reply, he adduces two experiences. When he returned for a second visit to the hydropathic establishment at which his disorder had been relieved for the first and only time, he asked to be given his old room, for its position had facilitated his relations with one of the nurses. He was told that the room was already taken and that it was occupied by an old professor. This piece of news considerably diminished his prospects of successful treatment, and he reacted to it with the unamiable thought: 'I wish he may be struck dead for it!' A fortnight later he was woken up from his sleep by the disturbing idea of a corpse; and in the morning he heard that the professor had really had a stroke, and that he had been carried up into his room at about the time he himself had woken up. The second experience related to an unmarried woman, no longer young, though with a great desire to be loved, who had paid him a great deal of attention and had once asked him point blank whether he could not love her. He had given her an evasive answer. A few days afterwards he heard that she had thrown herself out of a window. He then began to reproach himself, and said to himself that it would have been in his power to save her life by giving her his love. In this way he became convinced of the omnipotence of his love and of his hatred. Without denying the omnipotence of love we may point out that both these instances were concerned with death, and we may adopt the obvious explanation that, like other obsessional neurotics, our patient was compelled to overestimate the effects of his hostile feelings upon the external world, because a large part of their internal, mental effects escaped his conscious knowledge. His love - or rather his hatred - was in truth overpowering; it was precisely they that created the obsessional thoughts, of which he could not understand the origin and against which he strove in vain to defend himself.¹

¹[1909d, 2183]
It is this same doubt that leads the patient to uncertainty about his protective measures, and to his continual repetition of them in order to banish that uncertainty; and it is this doubt, too, that eventually brings it about that the patient's protective acts themselves become as impossible to carry out as his original inhibited decision in connection with his love. At the beginning of my investigations I was led to assume another and more general origin for the uncertainty of obsessional neurotics and one which seemed to be nearer the normal. If, for instance, while I am writing a letter some one interrupts me with questions, I afterwards feel a quite justifiable uncertainty as to what I may not have written under the influence of the disturbance, and, to make sure, I am obliged to read the letter over after I have finished it. In the same way I might suppose that the uncertainty of obsessional neurotics, when they are praying, for instance, is due to unconscious phantasies constantly mingling with their prayers and disturbing them. This hypothesis is correct, but it may be easily reconciled with what I have just said. It is true that the patient's uncertainty whether he has carried through a protective measure is due to the disturbing effect of unconscious phantasies; but the content of these phantasies is precisely the contrary impulse - which it was the very aim of the prayer to ward off. This became clearly evident in our patient on one occasion, for the disturbing element did not remain unconscious but made its appearance openly. The words he wanted to use in his prayer were, 'May God protect her', but a hostile 'not' suddenly darted out of his unconscious and inserted itself into the sentence; and he understood that this was an attempt at a curse (p. 2152). If the 'not' had remained mute, he would have found himself in a state of uncertainty and would have kept on prolonging his prayers indefinitely. But since it became articulate he eventually gave up praying. Before doing so, however, he, like other obsessional patients, tried every kind of method for preventing the opposite feeling from insinuating itself. He shortened his prayers, for instance, or said them more rapidly. And similarly other patients will endeavour to 'isolate' all such protective acts from other things. But none of these technical procedures are of any avail in the long run. If the impulse of love achieves any success by displacing itself on to some trivial act, the impulse of hostility will very soon follow it on to its new ground and once more proceed to undo all that it has done.

In the first place, then, it must be said that there is no sense in asking savages to tell us the real reason for their prohibitions - the origin of taboo. It follows from our postulates that they cannot answer, since their real reason must be 'unconscious'. We can, however, reconstruct the history of taboo as follows on the model of obsessional prohibitions. Taboos, we must suppose, are prohibitions of primaeval antiquity which were at some time externally imposed upon a generation of primitive men; they must, that is to say, no doubt have been impressed on them violently by the previous generation. These prohibitions must have concerned activities towards which there was a strong inclination. They must then have persisted from generation to generation, perhaps merely as a result of tradition transmitted through parental and social authority. Possibly, however, in later generations they may have become 'organized' as an inherited psychical endowment. Who can decide whether such things as 'innate ideas' exist, or whether in the present instance they have operated, either alone or in conjunction with education, to bring about the permanent fixing of taboos? But one thing would certainly follow from the persistence of the taboo, namely that the original desire to do the prohibited thing must also still persist among the tribes concerned. They must therefore have an ambivalent attitude towards their taboos. In their unconscious there is nothing they would like more than to violate them, but they are afraid to do so; they are afraid precisely because they would like to, and the fear is stronger than the desire. The desire is unconscious, however, in every individual member of the tribe just as it is in neurotics.
Suppose, on the other hand, that we were to take into account the finding arrived at by psycho-analysis from the dreams of normal people, to the effect that we ourselves are subject, more strongly and more often than we suspect, to a temptation to kill someone and that that temptation produces psychical effects even though it remains out of sight of our consciousness. Suppose, again, that we were to recognize the compulsive observances of certain neurotics as being guarantees against an intensified impulse to murder or as being self-punishments on account of it. In that case we should have to attach still greater importance to our thesis that where there is a prohibition there must be an underlying desire. We should have to suppose that the desire to murder is actually present in the unconscious and that neither taboos nor moral prohibitions are psychologically superfluous but that on the contrary they are explained and justified by the existence of an ambivalent attitude towards the impulse to murder.

It is in obsessional neuroses that the survival of the omnipotence of thoughts is most clearly visible and that the consequences of this primitive mode of thinking come closest to consciousness. But we must not be misled into supposing that it is a distinguishing feature of this particular neurosis, for analytic investigation reveals the same thing in the other neuroses as well. In all of them what determines the formation of symptoms is the reality not of experience but of thought. Neurotics live in a world apart, where, as I have said elsewhere, only 'neurotic currency' is legal tender; that is to say, they are only affected by what is thought with intensity and pictured with emotion, whereas agreement with external reality is a matter of no importance. What hysterics repeat in their attacks and fix by means of their symptoms are experiences which have occurred in that form only in their imagination though it is true that in the last resort those imagined experiences go back to actual events or are based upon them. To attribute the neurotic sense of guilt to real misdeeds would show an equal misunderstanding. An obsessional neurotic may be weighed down by a sense of guilt that would be appropriate in a mass-murderer, while in fact, from his childhood onwards, he has behaved to his fellow-men as the most considerate and scrupulous member of society. Nevertheless, his sense of guilt has a justification: it is founded on the intense and frequent death wishes against his fellows which are unconsciously at work in him. It has a justification if what we take into account are unconscious thoughts and not intentional deeds. Thus the omnipotence of thoughts, the overvaluation of mental processes as compared with reality, is seen to have unrestricted play in the emotional life of neurotic patients and in everything that derives from it. If one of them undergoes psycho-analytic treatment, which makes what is unconscious in him conscious, he will be unable to believe that thoughts are free and will constantly be afraid of expressing evil wishes, as though their expression would lead inevitably to their fulfilment. This behaviour, as well as the superstitions which he practises in ordinary life, reveals his resemblance to the savages who believe they can alter the external world by mere thinking.
In just the same way, an inhibition upon movement (an abasia or an agoraphobia) will gradually become more complete and more detailed, when once that system has succeeded in installing itself as a representative of an unconscious wish and of the defence against the wish. Whatever other unconscious phantasies and operative reminiscences may be present in the patient force their way to expression as symptoms along this same path, once it has been opened, and group themselves into an appropriate new arrangement within the framework of the inhibition upon movement. Thus it would be a vain and indeed a foolish task to attempt to understand the complexities and details of the symptoms of (for example) an agoraphobia on the basis of its underlying premises; for the whole consistency and strictness of the combination are merely apparent. Just as with the façades of dreams, if we look more attentively we find the most blatant inconsistency and arbitrariness in the structure of symptoms. The real reason for the details of a systematic phobia of this kind lies in concealed determinants, which need have nothing to do with an inhibition upon movement; and that, too, is why these phobias take such various and contradictory shapes in different people.

[1912-1913, 2738]

It may be that the symbolic meaning of the hat is derived from that of the head, in so far as a hat can be regarded as a prolonged, though detachable head. In this connection I am reminded of a symptom by means of which obsessional neurotics succeed in causing themselves continual torments. When they are in the street they are constantly on the look-out to see whether some acquaintance will greet them first by taking off his hat, or whether he seems to be waiting for their salutation; and they give up a number of their acquaintances after discovering that they no longer greet them or do not return their own salutation properly. There is no end to their difficulties in this connection; they find them everywhere as their mood and fancy dictate. It makes no difference to their behaviour when we tell them, what they all know already, that a salutation by taking off the hat has the meaning of an abasement before the person saluted - that a Spanish grandee, for example, enjoyed the privilege of remaining covered in the king's presence - and that their own sensitiveness on the subject of greeting therefore means that they are unwilling to show themselves less important than the other person thinks he is. The resistance of their sensitiveness to explanations such as this suggests that a motive less familiar to consciousness is at work; and the source of this excess of feeling might easily be found in its relation to the castration complex.

[1916c, 3122]

Let us turn now to the second of the discoveries which follow from our analyses; in its case we need not fear having to make a subsequent qualification of our views. I have described to you how our first patient carried out a senseless obsessional action and how she reported an intimate memory from her past life as having some connection with it: and how afterwards I examined the connection between the two and discovered the intention of the obsessional action from its relation to the memory. But there is one factor which I have entirely neglected, though it deserves our fullest attention. However often the patient repeated her obsessional action, she knew nothing of its being derived from the experience she had had. The connection between the two was hidden from her; she could only quite truthfully reply that she did not know what it was that was making her carry out her action. Then suddenly one day, under the influence of the treatment, she succeeded in discovering the connection and reported it to me. But she still knew nothing of the intention with which she was performing the obsessional action - the intention of correcting a distressing portion of the past and of putting her beloved husband in a better light. It took a fairly long time and called for much labour before she understood and admitted to me that such a motive alone could have been the driving force of her obsessional action.

[1916-1917, 3354]
The link with the scene after her unhappy wedding-night and the patient's affectionate motive constituted, taken together, what we have called the 'sense' of the obsessional action. But while she was carrying out the obsessional action this sense had been unknown to her in both directions - both its 'whence' and its 'whither'. Mental processes had therefore been at work in her and the obsessional action was the effect of them; she had been aware of this effect in a normal mental fashion, but none of the mental predeterminants of this effect came to the knowledge of her consciousness. She behaved in precisely the same way as a hypnotized subject whom Bernheim had ordered to open an umbrella in the hospital ward five minutes after he woke up. The man carried out this instruction when he was awake, but he could produce no motive for his action. It is a state of affairs of this sort that we have before our eyes when we speak of the existence of unconscious mental processes. We can challenge anyone in the world to give a more correct scientific account of this state of affairs, and if he does we will gladly renounce our hypothesis of unconscious mental processes. Till that happens, however, we will hold fast to the hypothesis; and if someone objects that here the unconscious is nothing real in a scientific sense, is a makeshift, une façon de parler, we can only shrug our shoulders resignedly and dismiss what he says as unintelligible. Something not real, which produces effects of such tangible reality as an obsessional action!
[1916-1917, 3354]

And we meet with what is in essence the same thing in our second patient. She had made a rule that the pillow must not touch the back of the bedstead, and she had to obey this rule though she did not know where it came from, what it meant or to what motives it owed its power. Whether she herself regarded the rule as a matter of indifference, or whether she struggled against it or raged against it or decided to transgress it - none of this made any difference to her carrying it out. It had to be obeyed, and she asked herself vainly why. We must recognize, however, that these symptoms of obsessional neurosis, these ideas and impulses which emerge one knows not whence, which prove so resistant to every influence from an otherwise normal mind, which give the patient himself the impression of being all-powerful guests from an alien world, immortal beings intruding into the turmoil of mortal life - these symptoms offer the plainest indication of there being a special region of the mind, shut off from the rest. They lead, by a path that cannot be missed, to a conviction of the existence of the unconscious in the mind; and that is precisely why clinical psychiatry, which is acquainted only with a psychology of consciousness, can deal with these symptoms in no other way than by declaring them to be signs of a special sort of degeneracy. Obsessional ideas and obsessional impulses are not, of course, themselves unconscious, any more than the performance of obsessional actions escapes conscious perception. They would not have become symptoms if they had not forced their way into consciousness. But their psychical predeterminants which we infer by means of analysis, the connections into which we insert them by interpretation, are unconscious, at least until we have made them conscious to the patient by the work of analysis. [1916-1917, 3355]
Nothing has entered into you from without; a part of the activity of your own mind has been withdrawn from your knowledge and from the command of your will. That, too, is why you are so weak in your defence; you are using one part of your force to fight the other part and you cannot concentrate the whole of your force as you would against an external enemy. And it is not even the worst or least important part of your mental forces that has thus become antagonistic to you and independent of you. The blame, I am bound to say, lies with yourself. You over-estimated your strength when you thought you could treat your sexual instincts as you liked and could utterly ignore their intentions. The result is that they have rebelled and have taken their own obscure paths to escape this suppression; they have established their rights in a manner you cannot approve. How they have achieved this, and the paths which they have taken, have not come to your knowledge. All you have learned is the outcome of their work - the symptom which you experience as suffering. Thus you do not recognize it as a derivative of your own rejected instincts and do not know that it is a substitutive satisfaction of them.

[1917a, 3613]

In certain forms of obsessional neurosis the sense of guilt is over-noisy but cannot justify itself to the ego. Consequently the patient's ego rebels against the imputation of guilt and seeks the physician's support in repudiating it. It would be folly to acquiesce in this, for to do so would have no effect. Analysis eventually shows that the super-ego is being influenced by processes that have remained unknown to the ego. It is possible to discover the repressed impulses which are really at the bottom of the sense of guilt. Thus in this case the super-ego knew more than the ego about the unconscious id.

[1923b, 3985]
I am certainly not the first person to have been struck by the resemblance between what are
called obsessive actions in sufferers from nervous affections and the observances by means of
which believers give expression to their piety. The term 'ceremonial', which has been applied to
some of these obsessive actions, is evidence of this. The resemblance, however, seems to me to
be more than a superficial one, so that an insight into the origin of neurotic ceremonials may
embolden us to draw inferences by analogy about the psychological processes of religious life.
[1907b, 1901]

It is easy to see where the resemblances lie between neurotic ceremonials and the sacred acts
of religious ritual: in the qualms of conscience brought on by their neglect, in their complete
isolation from all other actions (shown in the prohibition against interruption) and in the
conscientiousness with which they are carried out in every detail. But the differences are equally
obvious, and a few of them are so glaring that they make the comparison a sacrilege: the greater
individual variability of ceremonial actions in contrast to the stereotyped character of rituals
(prayer, turning to the East, etc.), their private nature as opposed to the public and communal
character of religious observances, above all, however, the fact that, while the minutiae of
religious ceremonial are full of significance and have a symbolic meaning, those of neurotics
seem foolish and senseless. In this respect an obsessional neurosis presents a travesty, half
comic and half tragic, of a private religion. But it is precisely this sharpest difference between
neurotic and religious ceremonial which disappears when, with the help of the psycho-analytic
technique of investigation, one penetrates to the true meaning of obsessive actions.¹ In the
course of such an investigation the appearance which obsessive actions afford of being foolish
and senseless is completely effaced, and the reason for their having that appearance is
explained. It is found that the obsessive actions are perfectly significant in every detail, that they
serve important interests of the personality and that they give expression to experiences that are
still operative and to thoughts that are cathected with affect. They do this in two ways, either by
direct or by symbolic representation; and they are consequently to be interpreted either
historically or symbolically.
[1907b, 1903]

Some features of this state of affairs may be seen in the sphere of religious life as well. The
formation of a religion, too, seems to be based on the suppression, the renunciation, of certain
instinctual impulses. These impulses, however, are not, as in the neuroses, exclusively
components of the sexual instinct; they are self-seeking, socially harmful instincts, though, even
so, they are usually not without a sexual component. A sense of guilt following upon continual
temptation and an expectant anxiety in the form of fear of divine punishment have, after all, been
familiar to us in the field of religion longer than in that of neurosis. Perhaps because of the
admixture of sexual components, perhaps because of some general characteristics of the
instincts, the suppression of instinct proves to be an inadequate and interminable process in
religious life also. Indeed, complete backslidings into sin are more common among pious people
than among neurotics and these give rise to a new form of religious activity, namely acts of
penance, which have their counterpart in obsessional neurosis.
[1907b, 1908]

In view of these similarities and analogies one might venture to regard obsessional neurosis as
a pathological counterpart of the formation of a religion, and to describe that neurosis as an
individual religiosity and religion as a universal obsessional neurosis. The most essential
similarity would reside in the underlying renunciation of the activation of instincts that are
constitutionally present; and the chief difference would lie in the nature of those instincts, which in
the neurosis are exclusively sexual in their origin, while in religion they spring from egoistic
sources.
[1907b, 1909]
It seems plausible to explain the complicated and contradictory attitude of primitive peoples to their rulers in some such way as the following. For superstitious and other reasons, a variety of different impulses find expression in relation to kings; and each of these impulses is developed to an extreme point without regard to the others. This gives rise to contradictions - by which, incidentally, a savage intellect is as little disturbed as is a highly civilized one when it comes to such matters as religion or 'loyalty'.

[1912-1913, 2694]

The neuroses exhibit on the one hand striking and far-reaching points of agreement with those great social institutions, art, religion and philosophy. But on the other hand they seem like distortions of them. It might be maintained that a case of hysteria is a caricature of a work of art, that an obsessional neurosis is a caricature of a religion and that a paranoic delusion is a caricature of a philosophical system. The divergence resolves itself ultimately into the fact that the neuroses are asocial structures; they endeavour to achieve by private means what is effected in society by collective effort. If we analyse the instincts at work in the neuroses, we find that the determining influence in them is exercised by instinctual forces of sexual origin; the corresponding cultural formations, on the other hand, are based upon social instincts, originating from the combination of egoistic and erotic elements. Sexual needs are not capable of uniting men in the same way as are the demands of self-preservation. Sexual satisfaction is essentially the private affair of each individual.

[1912-1913, 2717]

A little reflection was bound to show that it would be impossible to restrict to the provinces of dreams and nervous disorders a view such as this of the life of the human mind. If that view has hit upon a truth, it must apply equally to normal mental events, and even the highest achievements of the human spirit must bear a demonstrable relation to the factors found in pathology - to repression, to the efforts at mastering the unconscious and to the possibilities of satisfying the primitive instincts. There was thus an irresistible temptation and, indeed, a scientific duty, to apply the research methods of psycho-analysis, in regions far remote from its native soil, to the various mental sciences. And indeed psycho-analytic work upon patients itself pointed persistently in the direction of this new task, for it was obvious that the forms assumed by the different neuroses echoed the most highly admired productions of our culture. Thus hysterics are undoubtedly imaginative artists, even if they express their phantasies mimetically in the main and without considering their intelligibility to other people; the ceremonials and prohibitions of obsessional neurotics drive us to suppose that they have created a private religion of their own; and the delusions of paranoics have an unpalatable external similarity and internal kinship to the systems of our philosophers. It is impossible to escape the conclusion that these patients are, in an asocial fashion, making the very attempts at solving their conflicts and appeasing their pressing needs which, when those attempts are carried out in a fashion that is acceptable to the majority, are known as poetry, religion and philosophy.

[1919g, 3704]

If he is left to himself, a neurotic is obliged to replace by his own symptom formations the great group formations from which he is excluded. He creates his own world of imagination for himself, his own religion, his own system of delusions, and thus recapitulates the institutions of humanity in a distorted way which is clear evidence of the dominating part played by the directly sexual impulses.¹

[1921c, 3833]
To take an instance from another field. It is impossible to escape the impression of the perfect correspondence which can be discovered between the obsessive actions of certain obsessional patients and the religious observances of believers all over the world. Some cases of obsessional neurosis actually behave like a caricature of a private religion, so that it is tempting to liken the official religions to an obsessional neurosis that has been mitigated by becoming universalized. This comparison, which is no doubt highly objectionable to all believers, has nevertheless proved most fruitful psychologically. For psycho-analysis soon discovered in the case of obsessional neurosis what the forces are that struggle with one another in it till their conflicts find a remarkable expression in the ceremonial of obsessive actions. Nothing similar was suspected in the case of religious ceremonial until, by tracing back religious feeling to the relation with the father as its deepest root, it became possible to point to an analogous dynamic situation in that case too. This instance, moreover, may warn the reader that even in its application to non-medical fields psycho-analysis cannot avoid wounding cherished prejudices, touching upon deeply-rooted sensibilities and thus provoking enmities which have an essentially emotional basis.

[1924f, 4116]

I myself set a higher value on my contributions to the psychology of religion, which began with the establishment of a remarkable similarity between obsessive actions and religious practices or ritual (1907b). Without as yet understanding the deeper connections, I described the obsessional neurosis as a distorted private religion and religion as a kind of universal obsessional neurosis. Later on, in 1912, Jung's forcible indication of the far-reaching analogies between the mental products of neurotics and of primitive peoples led me to turn my attention to that subject. In four essays, which were collected into a book with the title of *Totem and Taboo*, I showed that the horror of incest was even more marked among primitive than among civilized races and had given rise to very special measures of defence against it. I examined the relations between taboo-prohibitions (the earliest form in which moral restrictions make their appearance) and emotional ambivalence; and I discovered under the primitive scheme of the universe known as 'animism' the principle of the over-estimation of the importance of psychical reality - the belief in 'the omnipotence of thoughts' - which lies at the root of magic as well. I developed the comparison with the obsessional neurosis at every point, and showed how many of the postulates of primitive mental life are still in force in that remarkable illness. Above all, however, I was attracted by totemism, the first system of organization in primitive tribes, a system in which the beginnings of social order are united with a rudimentary religion and the implacable domination of a small number of taboo-prohibitions. The being that is revered is ultimately always an animal, from which the clan also claims to be descended. Many indications pointed to the conclusion that every race, even the most highly developed, had once passed through the stage of totemism.

[1925d, 4239]
We now observe that the store of religious ideas includes not only wish-fulfilments but important historical recollections. This concurrent influence of past and present must give religion a truly incomparable wealth of power. But perhaps with the help of an analogy yet another discovery may begin to dawn on us. Though it is not a good plan to transplant ideas far from the soil in which they grew up, yet here is a conformity which we cannot avoid pointing out. We know that a human child cannot successfully complete its development to the civilized stage without passing through a phase of neurosis sometimes of greater and sometimes of less distinctness. This is because so many instinctual demands which will later be unserviceable cannot be suppressed by the rational operation of the child's intellect but have to be tamed by acts of repression, behind which, as a rule, lies the motive of anxiety. Most of these infantile neuroses are overcome spontaneously in the course of growing up, and this is especially true of the obsessional neuroses of childhood. The remainder can be cleared up later still by psycho-analytic treatment. In just the same way, one might assume, humanity as a whole, in its development through the ages, fell into states analogous to the neuroses, and for the same reasons - namely because in the times of its ignorance and intellectual weakness the instinctual renunciations indispensable for man's communal existence had only been achieved by it by means of purely affective forces. The precipitates of these processes resembling repression which took place in prehistoric times still remained attached to civilization for long periods. Religion would thus be the universal obsessional neurosis of humanity; like the obsessional neurosis of children, it arose out of the Oedipus complex, out of the relation to the father. If this view is right, it is to be supposed that a turning-away from religion is bound to occur with the fatal inevitability of a process of growth, and that we find ourselves at this very juncture in the middle of that phase of development. Our behaviour should therefore be modelled on that of a sensible teacher who does not oppose an impending new development but seeks to ease its path and mitigate the violence of its irruption. Our analogy does not, to be sure, exhaust the essential nature of religion. If, on the one hand, religion brings with it obsessional restrictions, exactly as an individual obsessional neurosis does, on the other hand it comprises a system of wishful illusions together with a disavowal of reality, such as we find in an isolated form nowhere else but in amentia, in a state of blissful hallucinatory confusion. But these are only analogies, by the help of which we endeavour to understand a social phenomenon; the pathology of the individual does not supply us with a fully valid counterpart.

It has been repeatedly pointed out (by myself and in particular by Theodor Reik) in how great detail the analogy between religion and obsessional neurosis can be followed out, and how many of the peculiarities and vicissitudes in the formation of religion can be understood in that light. And it tallies well with this that devout believers are safeguarded in a high degree against the risk of certain neurotic illnesses; their acceptance of the universal neurosis spares them the task of constructing a personal one.

'You have said yourself that religion is more than an obsessional neurosis. But you have not dealt with this other side of it. You are content to work out the analogy with a neurosis. Men, you say, must be freed from a neurosis. What else may be lost in the process is of no concern to you.'
The proof of this is the fact that we can always find in the previous history of the patient, at the beginning of the obsession, the original idea that has been replaced. The replaced ideas all have common attributes; they correspond to really distressing experiences in the subject's sexual life which he is striving to forget. He succeeds merely in replacing the incompatible idea by another ill-adapted for being associated with the emotional state, which for its part remains unchanged. It is this mésalliance between the emotional state and the associated idea that accounts for the absurdity so characteristic of obsessions.

The cause of this invulnerability of the obsessional idea and its derivatives is, however, nothing more than its connection with the repressed memory from early childhood. For if we can succeed in making that connection conscious - and psychotherapeutic methods already appear able to do so - the obsession, too, is resolved.

In the case of a psychical complex which has come under the influence of the censorship imposed by resistance, the affects are the constituent which is least influenced and which alone can give us a pointer as to how we should fill in the missing thoughts. This is seen even more clearly in the psychoneuroses than in dreams. Their affects are always appropriate, at least in their quality though we must allow for their intensity being increased owing to displacements of neurotic attention. If a hysteric is surprised at having to be so frightened of something trivial or if a man suffering from obsessions is surprised at such distressing self-reproaches arising out of a mere nothing, they have both gone astray, because they regard the ideational content - the triviality or the mere nothing - as what is essential; and they put up an unsuccessful fight because they take this ideational content as the starting-point of their thought-activity. Psychoanalysis can put them upon the right path by recognizing the affect as being, on the contrary, justified and by seeking out the idea which belongs to it but has been repressed and replaced by a substitute. A necessary premise to all this is that the release of affect and the ideational content do not constitute the indissoluble organic unity as which we are in the habit of treating them, but that these two separate entities may be merely soldered together and can thus be detached from each other by analysis. Dream-interpretation shows that this is in fact the case.

Now what is one to do in the face of a supervalent thought like this, after one has heard what its conscious grounds are and listened to the ineffectual protests made against it? Reflection will suggest that this excessively intense train of thought must owe its reinforcement to the unconscious. It cannot be resolved by any effort of thought, either because it itself reaches with its root down into unconscious, repressed material, or because another unconscious thought lies concealed behind it. In the latter case, the concealed thought is usually the direct contrary of the supervalent one. Contrary thoughts are always closely connected with each other and are often paired off in such a way that the one thought is excessively intensely conscious while its counterpart is repressed and unconscious. This relation between the two thoughts is an effect of the process of repression. For repression is often achieved by means of an excessive reinforcement of the thought contrary to the one which is to be repressed. This process I call reactive reinforcement, and the thought which asserts itself with excessive intensity in consciousness and (in the same way as a prejudice) cannot be removed I call a reactive thought. The two thoughts then act towards each other much like the two needles of an astatic galvanometer. The reactive thought keeps the objectionable one under repression by means of a certain surplus of intensity; but for that reason it itself is 'damped' and proof against conscious efforts of thought. So that the way to deprive the excessively intense thought of its reinforcement is by bringing its repressed contrary into consciousness.

[1895c, 318]

[1896b, 394]

[1900a, 905]

[1905e, 1391]
It is easy to see where the resemblances lie between neurotic ceremonials and the sacred acts of religious ritual: in the qualms of conscience brought on by their neglect, in their complete isolation from all other actions (shown in the prohibition against interruption) and in the conscientiousness with which they are carried out in every detail. But the differences are equally obvious, and a few of them are so glaring that they make the comparison a sacrilege: the greater individual variability of ceremonial actions in contrast to the stereotyped character of rituals (prayer, turning to the East, etc.), their private nature as opposed to the public and communal character of religious observances, above all, however, the fact that, while the minutiae of religious ceremonial are full of significance and have a symbolic meaning, those of neurotics seem foolish and senseless. In this respect an obsessional neurosis presents a travesty, half comic and half tragic, of a private religion. But it is precisely this sharpest difference between neurotic and religious ceremonial which disappears when, with the help of the psycho-analytic technique of investigation, one penetrates to the true meaning of obsessive actions.¹ In the course of such an investigation the appearance which obsessive actions afford of being foolish and senseless is completely effaced, and the reason for their having that appearance is explained. It is found that the obsessive actions are perfectly significant in every detail, that they serve important interests of the personality and that they give expression to experiences that are still operative and to thoughts that are cathected with affect. They do this in two ways, either by direct or by symbolic representation; and they are consequently to be interpreted either historically or symbolically.

[1907b, 1903]

It is one of the conditions of the illness that the person who is obeying a compulsion carries it out without understanding its meaning - or at any rate its chief meaning. It is only thanks to the efforts of psycho-analytic treatment that he becomes conscious of the meaning of his obsessive action and, with it, of the motives that are impelling him to it. We express this important fact by saying that the obsessive action serves to express unconscious motives and ideas. In this, we seem to find a further departure from religious practices; but we must remember that as a rule the ordinary pious individual, too, performs a ceremonial without concerning himself with its significance, although priests and scientific investigators may be familiar with the - mostly symbolic - meaning of the ritual. In all believers, however, the motives which impel them to religious practices are unknown to them or are represented in consciousness by others which are advanced in their place.

[1907b, 1906]

It not at all infrequently happens that it is only after doing a certain amount of psycho-analytic work with a patient that an analyst can succeed in learning the actual content of a phobia, the precise form of words of an obsessional impulse, and so on. Repression has not only descended upon the unconscious complexes, but it is continually attacking their derivatives as well, and even prevents the patient from becoming aware of the products of the disease itself. The analyst thus finds himself in the position, curious for a doctor, of coming to the help of a disease, and of procuring it its due of attention. But only those who entirely misunderstand the nature of psycho-analysis will lay stress upon this phase of the work and suppose that on its account harm is likely to be done by analysis. The fact is that you must catch your thief before you can hang him, and that it requires some expenditure of labour to get securely hold of the pathological structures - at the destruction of which the treatment is aimed.

[1909b, 2106]
'I have decided to tell you something which I consider most important and which has tormented me from the very first.' He then told me at great length the story of the last illness of his father, who had died of emphysema nine years previously. One evening, thinking that the condition was one which would come to a crisis, he had asked the doctor when the danger could be regarded as over. 'The evening of the day after to-morrow', had been the reply. It had never entered his head that his father might not survive that limit. At half-past eleven at night he had lain down for an hour's rest. He had woken up at one o'clock, and had been told by a medical friend that his father had died. He had reproached himself with not having been present at his death; and the reproach had been intensified when the nurse told him that his father had spoken his name once during the last days, and had said to her as she came up to the bed: 'Is that Paul?' He had thought he noticed that his mother and sisters had been inclined to reproach themselves in a similar way; but they had never spoken about it. At first, however, the reproach had not tormented him. For a long time he had not realized the fact of his father's death. It had constantly happened that, when he heard a good joke, he would say to himself: 'I must tell Father that.' His imagination, too, had been occupied with his father, so that often, when there was a knock at the door, he would think: 'Here comes Father', and when he walked into a room he would expect to find his father in it. And although he had never forgotten that his father was dead, the prospect of seeing a ghostly apparition of this kind had had no terrors for him; on the contrary, he had greatly desired it. It had not been until eighteen months later that the recollection of his neglect had recurred to him and begun to torment him terribly, so that he had come to treat himself as a criminal. The occasion of this happening had been the death of an aunt by marriage and of a visit of condolence that he had paid at her house. From that time forward he had extended the structure of his obsessional thoughts so as to include the next world. The immediate consequence of this development had been that he became seriously incapacitated from working.¹ He told me that the only thing that had kept him going at that time had been the consolation given him by his friend, who had always brushed his self-reproaches aside on the ground that they were grossly exaggerated. Hearing this, I took the opportunity of giving him a first glance at the underlying principles of psycho-analytic therapy. When there is a mésalliance, I began, between an affect and its ideational content (in this instance, between the intensity of the self-reproach and the occasion for it ), a layman will say that the affect is too great for the occasion - that it is exaggerated and that consequently the inference following from the self-reproach (the inference that the patient is a criminal) is false. On the contrary, the physician says: 'No. The affect is justified. The sense of guilt is not in itself open to further criticism. But it belongs to some other content, which is unknown (unconscious), and which requires to be looked for. The known ideational content has only got into its actual position owing to a false connection. We are not used to feeling strong affects without their having any ideational content, and therefore, if the content is missing, we seize as a substitute upon some other content which is in some way or other suitable, much as our police, when they cannot catch the right murderer, arrest a wrong one instead. Moreover, this fact of there being a false connection is the only way of accounting for the powerlessness of logical processes to combat the tormenting idea.' I concluded by admitting that this new way of looking at the matter gave immediate rise to some hard problems; for how could he admit that his self-reproach of being a criminal towards his father was justified, when he must know that as a matter of fact he had never committed any crime against him?

¹[1909d, 2142]
At the next session the patient showed great interest in what I had said, but ventured, so he
told me, to bring for ward a few doubts. - How, he asked, could the information that the self-
reproach, the sense of guilt, was justified have a therapeutic effect? - I explained that it was not
the information that had this effect, but the discovery of the unknown content to which the self-
reproach was really attached. - Yes, he said, that was the precise point to which his question
had been directed. - I then made some short observations upon the psychological differences
between the conscious and the unconscious, and upon the fact that everything conscious was
subject to a process of wearing-away, while what was unconscious was relatively
unchangeable; and I illustrated my remarks by pointing to the antiques standing about in my
room. They were, in fact, I said, only objects found in a tomb, and their burial had been their
preservation: the destruction of Pompeii was only beginning now that it had been dug up. - Was
there any guarantee, he next enquired, of what one’s attitude would be towards what was
discovered? One man, he thought, would no doubt behave in such a way as to get the better of
his self-reproach, but another would not. - No, I said, it followed from the nature of the
circumstances that in every case the affect would be overcome - for the most part during the
progress of the work itself. Every effort was made to preserve Pompeii, whereas people were
anxious to be rid of tormenting ideas like his. - He had said to himself, he went on, that a self-
reproach could only arise from a breach of a person’s own inner moral principles and not from
that of any external ones. - I agreed, and said that the man who merely breaks an external law
often regards himself as a hero. - Such an occurrence, he continued, was thus only possible
where a disintegration of the personality was already present. Was there a possibility of his
effecting a reintegration of his personality? If this could be done, he thought he would be able to
make a success of his life, perhaps more of one than most people. - I replied that I was in
complete agreement with this notion of a splitting of his personality. He had only to assimilate
this new contrast, between a moral self and an evil one, with the contrast I had already
mentioned, between the conscious and the unconscious. The moral self was the conscious, the
evil self was the unconscious.* - He then said that, though he considered himself a moral
person, he could quite definitely remember having done things in his childhood which came
from his other self. - I remarked that here he had incidentally hit upon one of the chief
characteristics of the unconscious, namely, its relation to the infantile. The unconscious, I
explained, was the infantile; it was that part of the self which had become separated off from it
in infancy, which had not shared the later stages of its development, and which had in
consequence become repressed. It was the derivatives of this repressed unconscious that were
responsible for the involuntary thoughts which constituted his illness. He might now, I added,
discover yet another characteristic of the unconscious; it was a discovery which I should be glad
to let him make for himself. - He found nothing more to say in this immediate connection, but
instead he expressed a doubt whether it was possible to undo modifications of such long
standing. What, in particular, could be done against his idea about the next world, for it could
not be refuted by logic? - I told him I did not dispute the gravity of his case nor the significance
of his pathological constrictions; but at the same time his youth was very much in his favour as
well as the intactness of his personality. In this connection I said a word or two upon the good
opinion I had formed of him, and this gave him visible pleasure.

[1909d, 2143]
Obsessional ideas, as is well known, have an appearance of being either without motive or without meaning, just as dreams have. The first problem is how to give them a sense and a status in the subject's mental life, so as to make them comprehensible and even obvious. The problem of translating them may seem insoluble; but we must never let ourselves be misled by that illusion. The wildest and most eccentric obsessional ideas can be cleared up if they are investigated deeply enough. The solution is effected by bringing the obsessional ideas into temporal relationship with the patient's experiences, that is to say, by enquiring when a particular obsessional idea made its first appearance and in what external circumstances it is apt to recur. When, as so often happens, an obsessional idea has not succeeded in establishing itself permanently, the task of clearing it up is correspondingly simplified. We can easily convince ourselves that, when once the interconnections between an obsessional idea and the patient's experiences have been discovered, there will be no difficulty in obtaining access to whatever else may be puzzling or worth knowing in the pathological structure we are dealing with - its meaning, the mechanism of its origin, and its derivation from the preponderant motive forces of the patient's mind.

The distinction between a primary and a secondary defensive struggle is no doubt well founded, but we find its value unexpectedly diminished when we discover that the patients themselves do not know the wording of their own obsessional ideas. This may sound paradoxical, but it is perfectly good sense. During the progress of a psycho-analysis it is not only the patient who plucks up courage, but his disease as well; it grows bold enough to speak more plainly than before. To drop the metaphor, what happens is that the patient, who his hitherto turned his eyes away in terror from his own pathological productions, begins to attend to them and obtains a clearer and more detailed view of them.¹

There are, besides this, two special ways in which a more precise knowledge of obsessional structures can be gained. In the first place, experience shows that an obsessional command (or whatever it may be), which in waking life is known only in a truncated and distorted form, like a mutilated telegraph message, may have its actual text brought to light in a dream. Such texts appear in dreams in the shape of speeches, and are thus an exception to the rule that speeches in dreams are derived from speeches in real life.² Secondly, in the course of the analytic examination of a case history, one becomes convinced that if a number of obsessions succeed one another they are often - even though their wording is not identical - ultimately one and the same. The obsession may have been successfully shaken off on its first appearance, but it comes back a second time in a distorted form and without being recognized, and may then perhaps be able to hold its own in the defensive struggle more effectively, precisely because of its distortion. But the original form is the correct one, and often displays its meaning quite openly. When we have at great pains elucidated an unintelligible obsessional idea, it often happens that the patient informs us that just such a notion, wish, or temptation as the one we have constructed did in fact make its appearance on one occasion before the obsessional idea had arisen, but that it did not persist. It would unfortunately involve us in too lengthy a digression if we were to give instances of this from the history of our present patient.
We are also now coming to the opinion that analytic technique must be modified in certain ways according to the nature of the disease and the dominant instinctual trends in the patient. We started out from the treatment of conversion hysteria; in anxiety hysteria (phobias) we must to some extent alter our procedure. For these patient cannot bring out the material necessary for resolving their phobia so long as they feel protected by obeying the condition which it lays down. One cannot, of course, succeed in getting them to give up their protective measures and work under the influence of anxiety from the beginning of the treatment. One must therefore help them by interpreting their unconscious to them until they can make up their minds to do without the protection of their phobia and expose themselves to a now greatly mitigated anxiety. Only after they have done so does the material become accessible, which, when it has been mastered, leads to a solution of the phobia. Other modifications of technique, which seem to me not yet ripe for discussion, will be required in the treatment of obsessional neurosis. In this connection very important questions arise, which have not hitherto been elucidated: how far the instincts which the patient is combating are to be allowed some satisfaction during the treatment, and what difference it makes whether these impulses are active (sadistic) or passive (masochistic) in their nature.

In another neurotic disorder, obsessional neurosis, the patients become the victims of distressing and apparently senseless ceremonials which take the form of the rhythmical repetition of the most trivial acts (such as washing or dressing) or of carrying out meaningless injunctions or of obeying mysterious prohibitions. It was nothing less than a triumph of psychoanalytic research when it succeeded in showing that all these obsessive acts, even the most insignificant and trivial of them, have a meaning, and that they are reflections, translated into indifferent terms, of conflicts in the patients' lives, of the struggle between temptations and moral restraints - reflections of the proscribed wish itself and of the punishment and atonement which that wish incurs. In another form of the same disorder the victim suffers from tormenting ideas (obsessions) which force themselves upon him and are accompanied by affects whose character and intensity are often only quite inadequately accounted for by the terms of the obsessive ideas themselves. Analytic investigation has shown in their case that the affects are entirely justified, since they correspond to self-reproaches which are based on something that is at least psychically real. But the ideas to which these affects are attached are not the original ones, but have found their way into their present position by a process of displacement - by being substituted for something that has been repressed. If these displacements can be reversed, the way is open to the discovery of the repressed ideas, and the relation between affect and idea is found to be perfectly appropriate.

In severe cases of obsessive acts a passive waiting attitude seems even less indicated. Indeed in general these cases incline to an 'asymptotic' process of recovery, an interminable protraction of the treatment. Their analysis is always in danger of bringing to light a great deal and changing nothing. I think there is little doubt that here the correct technique can only be to wait until the treatment itself has become a compulsion, and then with this counter-compulsion forcibly to suppress the compulsion of the disease. You will understand, however, that these two instances I have given you are only samples of the new developments towards which our therapy is tending.

[1910d, 2310]

[1913j, 2810]

[1919a, 3634]
In the girl's account of her conscious motives the father did not figure at all; there was not even any mention of fear of his anger. In the motives laid bare by the analysis, on the other hand, he played the principal part. Her relation to her father had the same decisive importance for the course and outcome of the analytic treatment, or rather, analytic exploration. Behind her pretended consideration for her parents, for whose sake she had been willing to make the attempt to be transformed, lay concealed her attitude of defiance and revenge against her father which held her fast to her homosexuality. Secure under this cover, the resistance set a considerable region free to analytic investigation. The analysis went forward almost without any signs of resistance, the patient participating actively with her intellect, though absolutely tranquil emotionally. Once when I expounded to her a specially important part of the theory, one touching her nearly, she replied in an inimitable tone, 'How very interesting', as though she were a grande dame being taken over a museum and glancing through her lorgnon at objects to which she was completely indifferent. The impression one had of her analysis was not unlike that of a hypnotic treatment, where the resistance has in the same way withdrawn to a certain boundary line, beyond which it proves to be unconquerable. The resistance very often pursues similar tactics - Russian tactics, as they might be called - in cases of obsessional neurosis. For a time, consequently, these cases yield the clearest results and permit a deep insight into the causation of the symptoms. But presently one begins to wonder how it is that such marked progress in analytic understanding can be unaccompanied by even the slightest change in the patient's compulsions and inhibitions, until at last one perceives that everything that has been accomplished is subject to a mental reservation of doubt, and that behind this protective barrier the neurosis can feel secure. 'It would be all very fine', thinks the patient, often quite consciously, 'if I were obliged to believe what the man says, but there is no question of that, and so long as this is so I need change nothing.' Then, when one comes to close quarters with the motives for this doubt, the fight with the resistances breaks out in earnest. [1920a, 3852]

In certain forms of obsessional neurosis the sense of guilt is over-noisy but cannot justify itself to the ego. Consequently the patient's ego rebels against the imputation of guilt and seeks the physician's support in repudiating it. It would be folly to acquiesce in this, for to do so would have no effect. Analysis eventually shows that the super-ego is being influenced by processes that have remained unknown to the ego. It is possible to discover the repressed impulses which are really at the bottom of the sense of guilt. Thus in this case the super-ego knew more than the ego about the unconscious id. [1923b, 3985]

We have all found by experience that it is especially difficult for an obsessional neurotic to carry out the fundamental rule of psycho-analysis. His ego is more watchful and makes sharper isolations, probably because of the high degree of tension due to conflict that exists between his super-ego and his id. While he is engaged in thinking, his ego has to keep off too much - the intrusion of unconscious phantasies and the manifestation of ambivalent trends. It must not relax, but is constantly prepared for a struggle. It fortifies this compulsion to concentrate and to isolate by the help of the magical acts of isolation which, in the form of symptoms, grow to be so noticeable and to have so much practical importance for the patient, but which are, of course, useless in themselves and are in the nature of ceremonials. [1926d, 4280]
Psycho-analysis finds a constantly increasing amount of support as a therapeutic procedure, owing to the fact that it can do more for its patients than any other method of treatment. The principle field of its application is in the milder neuroses - hysteria, phobias and obsessional states; and in malformations of character and sexual inhibitions or abnormalities it can also bring about marked improvements or even recoveries. Its influence upon dementia praecox and paranoia is doubtful; on the other hand, in favourable circumstances it can cope with depressive states, even if they are of a severe type.

[1926f, 4402]

We now observe that the store of religious ideas includes not only wish-fulfilments but important historical recollections. This concurrent influence of past and present must give religion a truly incomparable wealth of power. But perhaps with the help of an analogy yet another discovery may begin to dawn on us. Though it is not a good plan to transplant ideas far from the soil in which they grew up, yet here is a conformity which we cannot avoid pointing out. We know that a human child cannot successfully complete its development to the civilized stage without passing through a phase of neurosis sometimes of greater and sometimes of less distinctness. This is because so many instinctual demands which will later be unserviceable cannot be suppressed by the rational operation of the child's intellect but have to be tamed by acts of repression, behind which, as a rule, lies the motive of anxiety. Most of these infantile neuroses are overcome spontaneously in the course of growing up, and this is especially true of the obsessional neuroses of childhood. The remainder can be cleared up later still by psycho-analytic treatment. In just the same way, one might assume, humanity as a whole, in its development through the ages, fell into states analogous to the neuroses, and for the same reasons - namely because in the times of its ignorance and intellectual weakness the instinctual renunciations indispensable for man's communal existence had only been achieved by it by means of purely affective forces. The precipitates of these processes resembling repression which took place in prehistoric times still remained attached to civilization for long periods. Religion would thus be the universal obsessional neurosis of humanity; like the obsessional neurosis of children, it arose out of the Oedipus complex, out of the relation to the father. If this view is right, it is to be supposed that a turning-away from religion is bound to occur with the fatal inevitability of a process of growth, and that we find ourselves at this very juncture in the middle of that phase of development. Our behaviour should therefore be modelled on that of a sensible teacher who does not oppose an impending new development but seeks to ease its path and mitigate the violence of its irruption. Our analogy does not, to be sure, exhaust the essential nature of religion. If, on the one hand, religion brings with it obsessional restrictions, exactly as an individual obsessional neurosis does, on the other hand it comprises a system of wishful illusions together with a disavowal of reality, such as we find in an isolated form nowhere else but in amnesia, in a state of blissful hallucinatory confusion. But these are only analogies, by the help of which we endeavour to understand a social phenomenon; the pathology of the individual does not supply us with a fully valid counterpart.

[1927c, 4452]
As regards its intimate nature, anxiety neurosis presents the most interesting agreements with, and differences from, the other major neuroses, in particular neurasthenia and hysteria. It shares with neurasthenia one main characteristic - namely that the source of excitation, the precipitating cause of the disturbance, lies in the somatic field instead of the psychical one, as is the case in hysteria and obsessional neurosis. In other respects we rather find a kind of antithesis between the symptoms of anxiety neurosis and of neurasthenia, which might be brought out by such labels as 'accumulation of excitation' and 'impoverishment of excitation'. This antithesis does not prevent the two neuroses from being intermixed with each other; but it nevertheless shows itself in the fact that the most extreme forms of each are in both cases also the purest.

[1895b, 349]

In bringing this paper to a close I may express a hope that, though my communication is incomplete in every sense, it may at least stimulate other workers to throw more light upon the obsessional neurosis by a deeper investigation of the subject. What is characteristic of this neurosis - what differentiates it from hysteria - is not, in my opinion, to be found in instinctual life but in the psychological field. I cannot take leave of my patient without putting on paper my impression that he had, as it were, disintegrated into three personalities: into one unconscious personality, that is to say, and into two preconscious ones between which his consciousness could oscillate. His unconscious comprised those of his impulses which had been suppressed at an early age and which might be described as passionate and evil impulses. In his normal state he was kind, cheerful, and sensible - an enlightened and superior kind of person - while in his third psychological organization he paid homage to superstition and asceticism. Thus he was able to have two different creeds and two different outlooks upon life. This second preconscious personality comprised chiefly the reaction-formations against his repressed wishes, and it was easy to foresee that it would have swallowed up the normal personality if the illness had lasted much longer. I have at present an opportunity of studying a lady suffering severely from obsessional acts. She has become similarly disintegrated into an easy-going and lively personality and into an exceedingly gloomy and ascetic one. She puts forward the first of them as her official ego, while in fact she is dominated by the second. Both of these psychical organizations have access to her consciousness, but behind her ascetic personality may be discerned the unconscious part of her being - quite unknown to her and composed of ancient and long-repressed wishful impulses.¹

[1909d, 2194]

We have hitherto been dealing with the father-complex, which was the dominant element in Schreber's case and with the wishful phantasy round which the illness centred. But in all of this there is nothing characteristic of the form of disease known as paranoia, nothing that might not be found (and that has not in fact been found) in other kinds of neuroses. The distinctive character of paranoia (or of dementia paranoides) must be sought for elsewhere - namely, in the particular form assumed by the symptoms; and we shall expect to find that this is determined, not by the nature of the complexes themselves, but by the mechanism by which the symptoms are formed or by which repression is brought about. We should be inclined to say that what was characteristically paranoic about the illness was the fact that the patient, as a means of warding off a homosexual wishful phantasy, reacted precisely with delusions of persecution of this kind.

[1911c, 2429]
We see that, if we follow up this line of thought, we come up against the problem not only of hypochondria, but of the other 'actual' neuroses - neurasthenia and anxiety neurosis. Let us therefore stop at this point. It is not within the scope of a purely psychological inquiry to penetrate so far behind the frontiers of physiological research. I will merely mention that from this point of view we may suspect that the relation of hypochondria to paraphrenia is similar to that of the other 'actual' neuroses to hysteria and obsessional neurosis: we may suspect, that is, that it is dependent on ego-libido just as the others are on object-libido, and that hypochondriacal anxiety is the counterpart, as coming from ego-libido, to neurotic anxiety. Further, since we are already familiar with the idea that the mechanism of falling ill and of the formation of symptoms in the transference neuroses - the path from introversion to regression - is to be linked to a damming-up of object-libido,¹ we may come to closer quarters with the idea of a damming-up of ego-libido as well and may bring this idea into relation with the phenomena of hypochondria and paraphrenia.

¹[1914c, 2940]

I shall try here to penetrate a little further into the mechanism of paraphrenia and shall bring together those views which already seem to me to deserve consideration. The difference between paraphrenic affections and the transference neuroses appears to me to lie in the circumstance that, in the former, the libido that is liberated by frustration does not remain attached to objects in phantasy, but withdraws on to the ego. Megalomania would accordingly correspond to the psychical mastering of this latter amount of libido, and would thus be the counterpart of the introversion on to phantasies that is found in the transference neuroses; a failure of this psychical function gives rise to the hypochondria of paraphrenia and this is homologous to the anxiety of the transference neuroses. We know that this anxiety can be resolved by further psychical working over, i.e. by conversion, reaction-formation or the construction of protections (phobias). The corresponding process in paraphrenics is an attempt at restoration, to which the striking manifestations of the disease are due. Since paraphrenia frequently, if not usually, brings about only a partial detachment of the libido from objects, we can distinguish three groups of phenomena in the clinical picture: (1) those representing what remains of a normal state or of neurosis (residual phenomena); (2) those representing the morbid process (detachment of libido from its objects and, further, megalomania, hypochondria, affective disturbance and every kind of regression); (3) those representing restoration, in which the libido is once more attached to objects, after the manner of a hysteria (in dementia praecox or paraphrenia proper), or of an obsessional neurosis (in paranoia). This fresh libidinal cathexis differs from the primary one in that it starts from another level and under other conditions. The difference between the transference neuroses brought about in the case of this fresh kind of libidinal cathexis and the corresponding formations where the ego is normal should be able to afford us the deepest insight into the structure of our mental apparatus.

¹[1914c, 2941]

Finally, let us once more glance at the significant light which the topography of the process of repression throws for us on the mechanism of mental disturbances. In dreams the withdrawal of cathexis (libido or interest) affects all systems equally; in the transference neuroses, the Pcs. cathexis is withdrawn; in schizophrenia, the cathexis of the Ucs.; in amentia, that of the Cs. ¹[1917d, 3038]
This, then, is what I wanted to tell you about the formation of symptoms in the neuroses. But I must not fail to lay emphasis expressly once again on the fact that everything I have said here applies only to the formation of symptoms in hysteria. Even in obsessional neurosis there is much - apart from fundamentals, which remain unaltered - that will be found different. The anticathexes opposing the demands of the instincts (which we have already spoken of in the case of hysteria as well) become prominent in obsessional neurosis and dominate the clinical picture in the form of what are known as 'reaction formations'. We discover similar and even more far-reaching divergences in the other neuroses, where our researches into the mechanisms of symptom-formation are not yet concluded at any point.

One objection to it is that loss of an object (or loss of love on the part of the object) and the threat of castration are just as much dangers coming from outside as, let us say, a ferocious animal would be; they are not instinctual dangers. Nevertheless, the two cases are not the same. A wolf would probably attack us irrespectively of our behaviour towards it; but the loved person would not cease to love us nor should we be threatened with castration if we did not entertain certain feelings and intentions within us. Thus such instinctual impulses are determinants of external dangers and so become dangerous in themselves; and we can now proceed against the external danger by taking measures against the internal ones. In phobias of animals the danger seems to be still felt entirely as an external one, just as it has undergone an external displacement in the symptom. In obsessional neuroses the danger is much more internalized. That portion of anxiety in regard to the super-ego which constitutes social anxiety still represents an internal substitute for an external danger, while the other portion - moral anxiety - is already completely endopsychic.

There is another kind of anticathexis, however, which seems more suited to the peculiar character of hysteria. A repressed instinctual impulse can be activated (newly cathected) from two directions: from within, through reinforcement from its internal sources of excitation, and from without, through the perception of an object that it desires. The hysterical anticathexis is mainly directed outwards, against dangerous perceptions. It takes the form of a special kind of vigilance which, by means of restrictions of the ego, causes situations to be avoided that would entail such perceptions, or, if they do occur, manages to withdraw the subject's attention from them. Some French analysts, in particular Laforgue, have recently given this action of hysteria the special name of 'scotomization'. This technique of anticathexis is still more noticeable in the phobias, whose interest is concentrated on removing the subject ever further from the possibility of the occurrence of the feared perception. The fact that anticathexis has an opposite direction in hysteria and the phobias from what it has in obsessional neurosis - though the distinction is not an absolute one - seems to be significant. It suggests that there is an intimate connection between repression and external anticathexis on the one hand and between regression and internal anticathexis (i.e. alteration in the ego through reaction-formation) on the other. The task of defence against a dangerous perception is, incidentally, common to all neuroses. Various commands and prohibitions in obsessional neurosis have the same end in view.
Even a purely terminological innovation ought to justify its adoption; it ought to reflect some new point of view or some extension of knowledge. The revival of the concept of defence and the restriction of that of repression takes into account a fact which has long since been known but which has received added importance owing to some new discoveries. Our first observations of repression and of the formation of symptoms were made in connection with hysteria. We found that the perceptual content of exciting experiences and the ideational content of pathogenic structures of thought were forgotten and debarred from being reproduced in memory, and we therefore concluded that the keeping away from consciousness was a main characteristic of hysterical repression. Later on, when we came to study the obsessional neuroses, we found that in that illness pathogenic occurrences are not forgotten. They remain conscious but they are 'isolated' in some way that we cannot as yet grasp, so that much the same result is obtained as in hysterical amnesia. Nevertheless the difference is great enough to justify the belief that the process by which instinctual demands are set aside in obsessional neurosis cannot be the same as in hysteria. Further investigations have shown that in obsessional neurosis a regression of the instinctual impulses to an earlier libidinal stage is brought about through the opposition of the ego, and that this regression, although it does not make repression unnecessary, clearly works in the same sense as repression. We have seen, too, that in obsessional neurosis anticathexis, which is also presumably present in hysteria, plays a specially large part in protecting the ego by effecting a reactive alteration in it. Our attention has, moreover, been drawn to a process of 'isolation' (whose technique cannot as yet be elucidated) which finds direct symptomatic manifestation, and to a procedure, that may be called magical, of 'undoing' what has been done - a procedure about whose defensive purpose there can be no doubt, but which has no longer any resemblance to the process of 'repression'. These observations provide good enough grounds for re-introducing the old concept of defence, which can cover all these processes that have the same purpose - namely, the protection of the ego against instinctual demands - and for subsuming repression under it as a special case. The importance of this nomenclature is heightened if we consider the possibility that further investigations may show that there is an intimate connection between special forms of defence and particular illnesses, as, for instance, between repression and hysteria. In addition we may look forward to the possible discovery of yet another important correlation. It may well be that before its sharp cleavage into an ego and an id, and before the formation of a super-ego, the mental apparatus makes use of different methods of defence from those which it employs after it has reached these stages of organization.

[1926d, 4316]
If we consider a number of analyses of obsessional neurotics we shall find it impossible to escape the impression that a relation between love and hatred such as we have found in our present patient is among the most frequent, the most marked, and probably, therefore, the most important characteristics of obsessional neurosis. But however tempting it may be to bring the problem of the 'choice of neurosis' into connection with instinctual life, there are reasons enough for avoiding such a course. For we must remember that in every neurosis we come upon the same suppressed instincts behind the symptoms. After all, hatred, kept suppressed in the unconscious by love, plays a great part in the pathogenesis of hysteria and paranoia. We know too little of the nature of love to be able to arrive at any definite conclusion here; and, in particular, the relation between the negative factor in love and the sadistic components of the libido remains completely obscure. What follows is therefore to be regarded as no more than a provisional explanation. We may suppose, then, that in the cases of unconscious hatred with which we are concerned the sadistic components of love have, from constitutional causes, been exceptionally strongly developed, and have consequently undergone a premature and all too thorough suppression, and that the neurotic phenomena we have observed arise on the one hand from conscious feelings of affection which have become exaggerated as a reaction, and on the other hand from sadism persisting in the unconscious in the form of hatred.

[1909d, 2187]
The first task confronting psycho-analysis was to explain the neuroses; it used the two facts of resistance and transference as starting-points, and, taking into consideration the third fact of amnesia, accounted for them with its theories of repression, of the sexual motive forces in neurosis and of the unconscious. Psycho-analysis has never claimed to provide a complete theory of human mentality in general, but only expected that what it offered should be applied to supplement and correct the knowledge acquired by other means. Adler's theory, however, goes far beyond this point; it seeks at once to explain the behaviour and character of human beings as well as their neurotic and psychotic illnesses. It is actually more suited to any other field than that of neurosis, although for reasons connected with the history of its development it still places this in the foreground. For many years I had opportunities of studying Dr. Adler and have never refused to recognize his unusual ability, combined with a particularly speculative disposition. As an instance of the 'persecution' to which he asserts he has been subjected by me, I can point to the fact that after the Association was founded I made over to him the leadership of the Vienna group. It was not until urgent demands were put forward by all the members of the society that I let myself be persuaded to take the chair again at its scientific meetings. When I perceived how little gift Adler had precisely for judging unconscious material, my view changed to an expectation that he would succeed in discovering the connections of psycho-analysis with psychology and with the biological foundations of instinctual processes - an expectation which was in some sense justified by the valuable work he had done on 'organ-inferiority'. And he did in fact effect something of the kind; but his work conveys an impression 'as if' - to speak in his own 'jargon' - it was intended to prove that psycho-analysis was wrong in everything and that it had only attributed so much importance to sexual motive forces because of its credulity in accepting the assertions of neurotics. I may even speak publicly of the personal motive for his work, since he himself announced it in the presence of a small circle of members of the Vienna group: - ' Do you think it gives me such great pleasure to stand in your shadow my whole life long?' To be sure, I see nothing reprehensible in a younger man freely admitting his ambition, which one would in any case guess was among the incentives for his work. But even though a man is dominated by a motive of this kind he should know how to avoid being what the English, with their fine social tact, call 'unfair' - which in German can only be expressed by a much cruder word. How little Adler has succeeded in this is shown by the profusion of petty outbursts of malice which disfigure his writings and by the indications they contain of an uncontrolled craving for priority. At the Vienna Psycho-Analytical Society we once actually heard him claim priority for the conception of the 'unity of the neuroses' and for the 'dynamic view' of them. This came as a great surprise to me, for I had always believed that these two principles were stated by me before I ever made Adler's acquaintance.

One of the ways in which the ego is related to its neuroses is, however, so obvious that it was possible to take it into account from the first. It seems never to be absent; but it is most clearly recognizable in a disorder which we are even to-day far from understanding - traumatic neurosis. For you must know that the same factors always come into operation in the causation and mechanism of every possible form of neurosis; but the chief importance in the construction of the symptoms falls now upon one and now upon another of these factors. The position is like that among the members of a theatrical company. Each of them is regularly cast for his own stock role - hero, confidant, villain, and so on; but each of them will choose a different piece for his benefit performance. In the same way phantasies which turn into symptoms are nowhere more obvious than in hysteria; the anticathexes or reaction-formations of the ego dominate the picture in obsessional neurosis; what in the case of dreams we have termed 'secondary revision' stands in the forefront in paranoia in the shape of delusions, and so on.
There is another kind of anticathexis, however, which seems more suited to the peculiar character of hysteria. A repressed instinctual impulse can be activated (newly cathected) from two directions: from within, through reinforcement from its internal sources of excitation, and from without, through the perception of an object that it desires. The hysterical anticathexis is mainly directed outwards, against dangerous perceptions. It takes the form of a special kind of vigilance which, by means of restrictions of the ego, causes situations to be avoided that would entail such perceptions, or, if they do occur, manages to withdraw the subject's attention from them. Some French analysts, in particular Laforgue, have recently given this action of hysteria the special name of 'scotomization'. This technique of anticathexis is still more noticeable in the phobias, whose interest is concentrated on removing the subject ever further from the possibility of the occurrence of the feared perception. The fact that anticathexis has an opposite direction in hysteria and the phobias from what it has in obsessional neurosis - though the distinction is not an absolute one - seems to be significant. It suggests that there is an intimate connection between repression and external anticathexis on the one hand and between regression and internal anticathexis (i.e. alteration in the ego through reaction-formation) on the other. The task of defence against a dangerous perception is, incidentally, common to all neuroses. Various commands and prohibitions in obsessional neurosis have the same end in view. [1926d, 4311]
The significance of the erotogenic zones as apparatuses subordinate to the genitals and as substitutes for them is, among all the psychoneuroses, most clearly to be seen in hysteria; but this does not imply that that significance is any the less in the other forms of illness. It is only that in them it is less recognizable, because in their case (obsessional neurosis and paranoia) the formation of the symptoms takes place in regions of the mental apparatus which are more remote from the particular centres concerned with somatic control. In obsessional neurosis what is more striking is the significance of those impulses which create new sexual aims and seem independent of erotogenic zones. Nevertheless, in scopophilia and exhibitionism the eye corresponds to an erotogenic zone; while in the case of those components of the sexual instinct which involve pain and cruelty the same role is assumed by the skin - the skin, which in particular parts of the body has become differentiated into sense organs or modified into mucous membrane, and is thus the erotogenic zone par excellence.¹

[1905d, 1493]

In bringing this paper to a close I may express a hope that, though my communication is incomplete in every sense, it may at least stimulate other workers to throw more light upon the obsessional neurosis by a deeper investigation of the subject. What is characteristic of this neurosis - what differentiates it from hysteria - is not, in my opinion, to be found in instinctual life but in the psychological field. I cannot take leave of my patient without putting on paper my impression that he had, as it were, disintegrated into three personalities: into one unconscious personality, that is to say, and into two preconscious ones between which his consciousness could oscillate. His unconscious comprised those of his impulses which had been suppressed at an early age and which might be described as passionate and evil impulses. In his normal state he was kind, cheerful, and sensible - an enlightened and superior kind of person - while in his third psychological organization he paid homage to superstition and asceticism. Thus he was able to have two different creeds and two different outlooks upon life. This second preconscious personality comprised chiefly the reaction-formations against his repressed wishes, and it was easy to foresee that it would have swallowed up the normal personality if the illness had lasted much longer. I have at present an opportunity of studying a lady suffering severely from obsessional acts. She has become similarly disintegrated into an easy-going and lively personality and into an exceedingly gloomy and ascetic one. She puts forward the first of them as her official ego, while in fact she is dominated by the second. Both of these psychical organizations have access to her consciousness, but behind her ascetic personality may be discerned the unconscious part of her being - quite unknown to her and composed of ancient and long-repressed wishful impulses.¹

[1909d, 2194]
We must now try to obtain some insight into the *mechanism* of the process of repression. In particular we want to know whether there is a single mechanism only, or more than one, and whether perhaps each of the psychoneuroses is distinguished by a mechanism of repression peculiar to it. At the outset of this enquiry, however, we are met by complications. The mechanism of a repression becomes accessible to us only by our deducing that mechanism from the *outcome* of the repression. Confining our observations to the effect of repression on the ideational portion of the representative, we discover that as a rule it creates a *substitutive formation*. What is the mechanism by which such a substitute is formed? Or should we distinguish several mechanisms here as well? Further, we know that repression leaves *symptoms* behind it. May we then suppose that the forming of substitutes and the forming of symptoms coincide, and, if this is so on the whole, is the mechanism of forming symptoms the same as that of repression? The general probability would seem to be that the two are widely different, and that it is not the repression itself which produces substitutive formations and symptoms, but that these latter are indications of a *return of the repressed* and owe their existence to quite other processes. It would also seem advisable to examine the mechanisms by which substitutes and symptoms are formed before considering the mechanisms of repression.

Even a purely terminological innovation ought to justify its adoption; it ought to reflect some new point of view or some extension of knowledge. The revival of the concept of defence and the restriction of that of repression takes into account a fact which has long since been known but which has received added importance owing to some new discoveries. Our first observations of repression and of the formation of symptoms were made in connection with hysteria. We found that the perceptual content of exciting experiences and the ideational content of pathogenic structures of thought were forgotten and debarred from being reproduced in memory, and we therefore concluded that the keeping away from consciousness was a main characteristic of hysterical repression. Later on, when we came to study the obsessional neuroses, we found that in that illness pathogenic occurrences are not forgotten. They remain conscious but they are 'isolated' in some way that we cannot as yet grasp, so that much the same result is obtained as in hysterical amnesia. Nevertheless the difference is great enough to justify the belief that the process by which instinctual demands are set aside in obsessional neurosis cannot be the same as in hysteria. Further investigations have shown that in obsessional neurosis a repression of the instinctual impulses to an earlier libidinal stage is brought about through the opposition of the ego, and that this regression, although it does not make repression unnecessary, clearly works in the same sense as repression. We have seen, too, that in obsessional neurosis anticathexis, which is also presumably present in hysteria, plays a specially large part in protecting the ego by effecting a reactive alteration in it. Our attention has, moreover, been drawn to a process of 'isolation' (whose technique cannot as yet be elucidated) which finds direct symptomatic manifestation, and to a procedure, that may be called magical, of 'undoing' what has been done - a procedure about whose defensive purpose there can be no doubt, but which has no longer any resemblance to the process of 'repression'. These observations provide good enough grounds for re-introducing the old concept of *defence*, which can cover all these processes that have the same purpose - namely, the protection of the ego against instinctual demands - and for subsuming repression under it as a special case. The importance of this nomenclature is heightened if we consider the possibility that further investigations may show that there is an intimate connection between special forms of defence and particular illnesses, as, for instance, between repression and hysteria. In addition we may look forward to the possible discovery of yet another important correlation. It may well be that before its sharp cleavage into an ego and an id, and before the formation of a super-ego, the mental apparatus makes use of different methods of defence from those which it employs after it has reached these stages of organization.
In this manner I found that neurasthenia presented a monotonous clinical picture in which, as my analyses showed, a 'psychical mechanism' played no part. There was a sharp distinction between neurasthenia and 'obsessional neurosis', the neurosis of obsessional ideas proper. In this latter one I was able to recognize a complicated psychical mechanism, an aetiology similar to that of hysteria and an extensive possibility of reducing it by psychotherapy. On the other hand, it seemed to me absolutely necessary to detach from neurasthenia a complex of neurotic symptoms which depend on a quite different and indeed at bottom a contrary aetiology. The component symptoms of this complex are united by a characteristic which has already been recognized by Hecker (1893). For they are either symptoms or equivalents and rudiments of manifestations of anxiety; and for this reason I have given to this complex which is to be detached from neurasthenia the name of 'anxiety neurosis'. I have maintained that it arises from, an accumulation of physical tension, which is itself once more of sexual origin. This neurosis, too, has no psychical mechanism, but it invariably influences mental life, so that 'anxious expectation', phobias, hyperaesthesia to pains, etc., are among its regular manifestations. This anxiety neurosis, in my sense of the term, no doubt coincides in part with the neurosis which, under the name of 'hypochondria', finds a place in not a few descriptions alongside hysteria and neurasthenia. But I cannot regard the delimitation of hypochondria in any of the works in question as being the correct one, and the applicability of its name seems to me to be prejudiced by the fixed connection of that term with the symptom of 'fear of illness'.

I shall begin by challenging two assertions which are often found repeated in regard to the syndromes 'obsessions' and 'phobias'. It must be said, first, that they cannot be included under neurasthenia proper, since the patients afflicted with these symptoms are no more often neurasthenics than not; and secondly, that we are not justified in regarding them as the effect of mental degeneracy, because they are found in persons no more degenerate than the majority of neurotics in general, because they sometimes improve, and sometimes, indeed, we even succeed in curing them.¹

As regards its intimate nature, anxiety neurosis presents the most interesting agreements with, and differences from, the other major neuroses, in particular neurasthenia and hysteria. It shares with neurasthenia one main characteristic - namely that the source of excitation, the precipitating cause of the disturbance, lies in the somatic field instead of the psychical one, as is the case in hysteria and obsessional neurosis. In other respects we rather find a kind of antithesis between the symptoms of anxiety neurosis and of neurasthenia, which might be brought out by such labels as 'accumulation of excitation' and 'impoverishment of excitation'. This antithesis does not prevent the two neuroses from being intermixed with each other; but it nevertheless shows itself in the fact that the most extreme forms of each are in both cases also the purest.

¹ [1895d, 229]

[1895c, 317]
Psycho-analysis is unjustly reproached, Gentlemen, for leading to purely psychological theories of pathological problems. The emphasis which it lays on the pathogenic role of sexuality, which, after all, is certainly not an exclusively psychical factor should alone protect it from this reproach. Psycho-analysts never forget that the mental is based on the organic, although their work can only carry them as far as this basis and no beyond it. Thus psycho-analysis is ready to admit, and indeed to postulate, that not all disturbances of vision need be psychogenic, like those that are evoked by the repression of erotic scopophilia. If an organ which serves the two sorts of instinct increases its erotogenic role, it is in general to be expected that this will not occur without the excitability and innervation of the organ undergoing changes which will manifest themselves as disturbances of its function in the service of the ego. Indeed, if we find that an organ normally serving the purpose of sense-perception begins to behave like an actual genital when its erotogenic role is increased, we shall not regard it as improbable that toxic changes are also occurring in it. For lack of a better name we must retain the old unsuitable term of 'neurotic' disturbances for both classes of functional disturbances - those of physiological as well as those of toxic origin - which follow from an increase in the erotogenic factor. Generally speaking, the neurotic disturbances of vision stand in the same relation to the psychogenic ones as the 'actual neuroses' do to the psychoneuroses: psychogenic visual disturbances can no doubt hardly ever appear without neurotic ones, but the latter can appear without the former. These neurotic symptoms are unfortunately little appreciated and understood even today; for they are not directly accessible to psycho-analysis, and other methods of research have left the standpoint of sexuality out of account.

All this seems very clear, and yet it must be admitted the there is one factor which often makes it difficult to form a judgement. Some nervous states which we call the 'actual neuroses', such as typical neurasthenia and pure anxiety neurosis, obviously depend on the somatic factor in sexual life, while we have no certain picture as yet of the part played in them by the psychical factor and by repression. In such cases it is natural that the physician should first consider some 'actual' therapy, some alteration in the patient's somatic sexual activity, and he does so with perfect justification if his diagnosis is correct. The lady who consulted the young doctor complained chiefly of anxiety-states, and so he probably assumed that she was suffering from an anxiety neurosis, and felt justified in recommending a somatic therapy to her. Again a convenient misapprehension! A person suffering from anxiety is not for that reason necessarily suffering from anxiety neurosis: such a diagnosis of it cannot be based on the name; one has to know what signs constitute an anxiety neurosis, and be able to distinguish it from other pathological states which are also manifested by anxiety. My impression was that the lady in question was suffering from anxiety hysteria, and the whole value of such nosographical distinctions, one which quite justifies them, lies in the fact that they indicate a different aetiology and a different treatment. No one who took into consideration the possibility of anxiety hysteria in this case would have fallen into the error of neglecting the mental factors, as this physician did with his three alternatives.
But I still owe you further enlightenment, Gentlemen, on my reasons for not starting my account of the theory of the neuroses with the common neurotic state. You may perhaps suppose that it was because in that case I should have had greater difficulty in proving the sexual causation of the neuroses. But you would be wrong there. In the case of the transference neuroses one must work one's way through the interpretation of symptoms before one can arrive at that discovery. In the common forms of what are known as the 'actual neuroses' the aetiological significance of sexual life is a crude fact that springs to the observer's eyes. I came upon it more than twenty years ago when one day I asked myself the question of why in the examination of neurotics their sexual activities were so regularly excluded from consideration. At that time I sacrificed my popularity with my patients for the sake of these enquiries; but after only a brief effort I was able to declare that 'if the vita sexualis is normal, there can be no neurosis' - and by this I meant no 'actual neurosis'. No doubt this statement passes too lightly over people's individual differences; it suffers, too, from the indefiniteness inseparable from the judgement of what is 'normal'. But as a rough guide it retains its value to this day. I had by then reached the point of establishing specific relations between particular forms of neurosis and particular sexual noxae; and I have no doubt that I could repeat the same observations to-day if similar pathological material were still at my disposal. I found often enough that a man who indulged in a certain kind of incomplete sexual satisfaction (for instance, manual masturbation) had fallen ill of a particular form of 'actual neurosis', and that this neurosis promptly gave place to another if he replaced this sexual régime by another equally far from being irreproachable. I was then in a position to infer the change in a patient's sexual mode of life from an alteration in his condition. I also learnt then to stand obstinately by my suspicions till I had overcome the patients' disingenuousness and compelled them to confirm my views. It is true that thereafter they preferred to go to other doctors who did not make such keen enquiries about their sexual life.

[1916-1917, 3438]

Now, however, I must draw your attention to the decisive difference between the symptoms of the 'actual' neuroses and those of the psychoneuroses, the first group of which, the transference neuroses, have occupied us so much hitherto. In both cases the symptoms originate from the libido, and are thus abnormal employments of it, substitutive satisfactions. But the symptoms of the 'actual' neuroses - intracranial pressure, sensations of pain, a state of irritation in an organ, weakening or inhibition of a function - have no 'sense', no psychical meaning. They are not only manifested predominantly in the body (as are hysterical symptoms, for instance, as well), but they are also themselves entirely somatic processes, in the generating of which all the complicated mental mechanisms we have come to know are absent. Thus they really are what psychoneurotic symptoms were so long believed to be. But if so, how can they correspond to employments of the libido, which we have recognized as a force operating in the mind? Well, Gentlemen, that is a very simple matter. Let me remind you of one of the very first objections that were brought up against psycho-analysis. It was said then that it was occupied in finding a purely psychological theory of neurotic phenomena and this was quite hopeless, since psychological theories could never explain an illness. People had chosen to forget that the sexual function is not a purely psychical thing any more than it is a purely somatic one. It influences bodily and mental life alike. If in the symptoms of the psychoneuroses we have become acquainted with manifestations of disturbances in the psychical operation of the sexual function, we shall not be surprised to find in the 'actual' neuroses the direct somatic consequences of sexual disturbances.

[1916-1917, 3439]
Nevertheless you will rightly expect that we should devote some interest to the 'actual' neuroses as well. Their intimate clinical connection with the psychoneuroses would alone compel us to do so. I may inform you, then, that we distinguish three pure forms of 'actual' neuroses: neurasthenia, anxiety neurosis and hypochondria. Even this assertion is not uncontradicted. All the names are in use, it is true, but their content is indefinite and fluctuating. There are even doctors who oppose any dividing lines in the chaotic world of neurotic phenomena, any segregation of clinical entities or individual diseases, and who do not even recognize the distinction between the 'actual' neuroses and the psychoneuroses. I think they are going too far and have not chosen the path which leads to progress. The forms of neurosis which I have mentioned occur occasionally in their pure form; more often, however, they are intermixed with each other and with a psychoneurotic disorder. This need not lead us to abandon the distinction between them. Consider the difference between the study of minerals and of rocks in mineralogy. The minerals are described as individuals, no doubt on the basis of the fact that they often occur as crystals, sharply separated from their environment. Rocks consist of aggregations of minerals, which, we may be sure, have not come together by chance but as a result of what determined their origin. In the theory of the neuroses we still know too little of the course of their development to produce anything resembling petrology. But we are certainly doing the right thing if we start by isolating from the mass the individual clinical entities which we recognize and which are comparable to the minerals. [1916-1917, 3440]

The Aetiological Significance of Sexual Life. - The second novelty which emerged after the hypnotic technique had been replaced by free associations was of a clinical nature. It was discovered in the course of the prolonged search for the traumatic experiences from which hysterical symptoms appeared to be derived. The more carefully the search was pursued the more extensive seemed to be the network of aetiologically significant impressions involved, but the further back, too, did they reach into the patient's puberty or childhood. At the same time they assumed a uniform character and eventually it became inevitable to bow before the evidence and recognize that at the root of the formation of every symptom there were to be found traumatic experiences from early sexual life. Thus a sexual trauma stepped into the place of an ordinary trauma and the latter was seen to owe its aetiological significance to an associative or symbolic connection with the former, which had preceded it. An investigation of cases of common nervousness (falling into the two classes of neurasthenia and anxiety neurosis) which was simultaneously undertaken led to the conclusion that these disorders could be traced to contemporary abuses in the patients' sexual life and could be removed if these were brought to an end. It was thus easy to infer that neuroses in general are an expression of disturbances in sexual life, the so-called actual-neuroses being the consequences (by chemical agency) of contemporary injuries and the psycho-neuroses the consequences (by psychical modification) of bygone injuries to a biological function which had hitherto been gravely neglected by science. None of the theses of psycho-analysis has met with such tenacious scepticism or such embittered resistance as this assertion of the preponderating aetiological significance of sexual life in the neuroses. It should, however, be expressly remarked that, in its development up to the present day, psycho-analysis has found no reason to retreat from this opinion. [1923a, 3920]
I was thus led into regarding the neuroses as being without exception disturbances of the sexual function, the so-called 'actual neuroses' being the direct toxic expression of such disturbances and the psychoneuroses their mental expression. My medical conscience felt pleased at my having arrived at this conclusion. I hoped that I had filled up a gap in medical science, which, in dealing with a function of such great biological importance, had failed to take into account any injuries beyond those caused by infection or by gross anatomical lesions. The medical aspect of the matter was, moreover, supported by the fact that sexuality was not something purely mental. It had a somatic side as well, and it was possible to assign special chemical processes to it and to attribute sexual excitation to the presence of some particular, though at present unknown, substances. There must also have been some good reason why the true spontaneous neuroses resembled no group of diseases more closely than the phenomena of intoxication and abstinence, which are produced by the administration or privation of certain toxic substances, or than exophthalmic goitre, which is known to depend upon the product of the thyroid gland.
[1925d, 4203]
The symptomatology of hysteria and anxiety neurosis show many points in common which have not yet been sufficiently considered. The appearance of symptoms either in a chronic form or in attacks, the paraesthesias, grouped like aurae, the hyperaesthesias and pressure-points which are found in certain surrogates of an anxiety attack (in dyspnœa and heart-attacks), the intensification, through conversion, of pains which perhaps have an organic justification - these and other features which the two illnesses have in common even allow of a suspicion that not a little of what is attributed to hysteria might with more justice be put to the account of anxiety neurosis. If one goes into the mechanism of the two neuroses, so far as it has been possible to discover it hitherto, aspects come to light which suggest that anxiety neurosis is actually the somatic counterpart to hysteria. In the latter just as in the former there is an accumulation of excitation (which is perhaps the basis for the similarity between their symptoms we have mentioned). In the latter just as in the former we find a *psychical insufficiency, as a consequence of which abnormal somatic processes arise*. In the latter just as in the former, too, instead of a psychical working-over of the excitation, a deflection of it occurs into the somatic field; the difference is merely that in anxiety neurosis the excitation, in whose displacement the neurosis expresses itself, is purely somatic (somatic sexual excitation), whereas in hysteria it is psychical (provoked by conflict). Thus it is not to be wondered at that hysteria and anxiety neurosis regularly combine with each other, as is seen in ‘virginal anxiety’ or in ‘sexual hysteria’, and that hysteria simply borrows a number of its symptoms from anxiety neurosis, and so on. These intimate relations which anxiety neurosis has with hysteria provide a fresh argument, moreover, for insisting on the detachment of anxiety neurosis from neurasthenia; for if this detachment is not granted, we shall also be unable any longer to maintain the distinction which has been acquired with so much labour and which is so indispensable for the theory of the neuroses, between neurasthenia and hysteria.

5 I must not omit to remark at this point that I shall not consider any theory of paranoia trustworthy unless it also covers the *hypochondriacal* symptoms by which that disorder is almost invariably accompanied. It seems to me that hypochondria stands in the same relation to paranoia as anxiety neurosis does to hysteria.
As regards its intimate nature, anxiety neurosis presents the most interesting agreements with, and differences from, the other major neuroses, in particular neurasthenia and hysteria. It shares with neurasthenia one main characteristic - namely that the source of excitation, the precipitating cause of the disturbance, lies in the somatic field instead of the psychical one, as is the case in hysteria and obsessional neurosis. In other respects we rather find a kind of antithesis between the symptoms of anxiety neurosis and of neurasthenia, which might be brought out by such labels as 'accumulation of excitation' and 'impoverishment of excitation'. This antithesis does not prevent the two neuroses from being intermixed with each other; but it nevertheless shows itself in the fact that the most extreme forms of each are in both cases also the purest.

We know how important doubt is to the physician who is analysing an obsessional neurosis. It is the patient's strongest weapon, the favourite expedient of his resistance. This same doubt enabled our patient to lie entrenched behind a respectful indifference and to allow the efforts of the treatment to slip past him for years together. Nothing changed, and there was no way of convincing him. At last I recognized the importance of the intestinal trouble for my purposes; it represented the small trait of hysteria which is regularly to be found at the root of an obsessional neurosis. I promised the patient a complete recovery of his intestinal activity, and by means of this promise made his incredulity manifest. I then had the satisfaction of seeing his doubt dwindle away, as in the course of the work his bowel began, like a hysterically affected organ, to 'join in the conversation', and in a few week's time recovered its normal functions after their long impairment.

Obsessional neurosis is unquestionably the most interesting and repaying subject of analytic research. But as a problem it has not yet been mastered. It must be confessed that, if we endeavour to penetrate more deeply into its nature, we still have to rely upon doubtful assumptions and unconfirmed suppositions. Obsessional neurosis originates, no doubt, in the same situation as hysteria, namely, the necessity of fending off the libidinal demands of the Oedipus complex. Indeed, every obsessional neurosis seems to have a substratum of hysterical symptoms that have been formed at a very early stage. But it is subsequently shaped along quite different lines owing to a constitutional factor. The genital organization of the libido turns out to be feeble and insufficiently resistant, so that when the ego begins its defensive efforts the first thing it succeeds in doing is to throw back the genital organization (of the phallic phase), in whole or in part, to the earlier sadistic-anal level. This fact of regression is decisive for all that follows.
In other cases the multiplicity of aetiological factors is by no means fortuitous: one of the factors has brought the other into operation. For example, a woman with whom her husband practises coitus reservatus without regard to her satisfaction may find herself compelled to masturbate in order to put an end to the distressing excitation that follows such an act; as a result, she will produce, not an anxiety neurosis pure and simple, but an anxiety neurosis accompanied by symptoms of neurasthenia. Another woman suffering from the same noxa may have to fight against lascivious images against which she tries to defend herself; and in this way she will, through the coitus interruptus, acquire obsessions as well as an anxiety neurosis. Finally, as a result of coitus interruptus, a third woman may lose her affection for her husband and feel an attraction for another man, which she carefully keeps secret; in consequence, she will exhibit a mixture of anxiety neurosis and hysteria.

Such is my excuse for having curtailed so drastically the history of this case and its treatment. And I can offer still more cogent reasons for having confined myself to the statement only of some disconnected results of the psycho-analytic investigation of obsessional neuroses. I must confess that I have not yet succeeded in completely penetrating the complicated texture of a severe case of obsessional neurosis, and that, if I were to reproduce the analysis, it would be impossible for me to make the structure, such as by the help of analysis we know or suspect it to be, visible to others through the mass of therapeutic work superimposed upon it. What add so greatly to the difficulty of doing this are the resistances of the patients and the forms in which they are expressed. But even apart from this it must be admitted that an obsessional neurosis is in itself not an easy thing to understand - much less so than a case of hysteria. Actually, indeed, we should have expected to find the contrary. The language of an obsessional neurosis - the means by which it expresses its secret thoughts - is, as it were, only a dialect of the language of hysteria; but it is a dialect in which we ought to be able to find our way about more easily, since it is more nearly related to the forms of expression adopted by our conscious thought than is the language of hysteria. Above all, it does not involve the leap from a mental process to a somatic innervation - hysterical conversion - which can never be fully comprehensible to us.

Perhaps it is only because we are less familiar with obsessional neuroses that we do not find these expectations confirmed by the facts. Persons suffering from a severe degree of obsessional neurosis present themselves far less frequently for analytic treatment than hysterical patients. They disseminate their condition in daily life, too, as long as they possibly can, and often call in a physician only when their complaint has reached such an advanced stage as, had they been suffering, for instance, from tuberculosis of the lungs, would have led to their being refused admission to a sanatorium. I make this comparison, moreover, because, as with the chronic infectious disease which I have just mentioned, we can point to a number of brilliant therapeutic successes in severe no less than in light cases of obsessional neurosis, where these have been taken in hand at an early stage.
Compulsive acts like this, in two successive stages, of which the second neutralizes the first, are a typical occurrence in obsessional neuroses. The patient's consciousness naturally misunderstands them and puts forward a set of secondary motives to account for them - rationalizes them, in short. (Cf. Jones, 1908.) But their true significance lies in their being a representation of a conflict between two opposing impulses of approximately equal strength: and hitherto I have invariably found that this opposition has been one between love and hate. Compulsive acts of this sort are theoretically of special interest, for they show us a new type of method of constructing symptoms. What regularly occurs in hysteria is that a compromise is arrived at which enables both the opposing tendencies to find expression simultaneously - which kills two birds with one stone;¹ whereas here each of the two opposing tendencies finds satisfaction singly, first one and then the other, though naturally an attempt is made to establish some sort of logical connection (often in defiance of all logic) between the antagonists.²

In hysteria it is the rule that the precipitating causes of the illness are overtaken by amnesia no less than the infantile experiences by whose help the precipitating causes are able to transform their affective energy into symptoms. And where the amnesia cannot be complete, it nevertheless subjects the recent traumatic precipitating cause to a process of erosion and robs it at least of its most important components. In this amnesia we see the evidence of the repression which has taken place. The case is different in obsessional neuroses. The infantile preconditions of the neurosis may be overtaken by amnesia, though this is often an incomplete one; but the immediate occasions of the illness are, on the contrary, retained in the memory. Repression makes use of another, and in reality a simpler, mechanism. The trauma, instead of being forgotten, is deprived of its affective catheisis; so that what remains in consciousness is nothing but its ideational content, which is perfectly colourless and is judged to be unimportant. The distinction between what occurs in hysteria and in an obsessional neurosis lies in the psychological processes which we can reconstruct behind the phenomena; the result is almost always the same, for the colourless mnemic content is rarely reproduced and plays no part in the patient's mental activity. In order to differentiate between the two kinds of repression we have on the surface nothing to rely upon but the patient's assurance that he has a feeling in the one case of having always known the thing and in the other of having long ago forgotten it.¹
In bringing this paper to a close I may express a hope that, though my communication is incomplete in every sense, it may at least stimulate other workers to throw more light upon the obsessional neurosis by a deeper investigation of the subject. What is characteristic of this neurosis - what differentiates it from hysteria - is not, in my opinion, to be found in instinctual life but in the psychological field. I cannot take leave of my patient without putting on paper my impression that he had, as it were, disintegrated into three personalities: into one unconscious personality, that is to say, and into two preconscious ones between which his consciousness could oscillate. His unconscious comprised those of his impulses which had been suppressed at an early age and which might be described as passionate and evil impulses. In his normal state he was kind, cheerful, and sensible - an enlightened and superior kind of person - while in his third psychological organization he paid homage to superstition and asceticism. Thus he was able to have two different creeds and two different outlooks upon life. This second preconscious personality comprised chiefly the reaction-formations against his repressed wishes, and it was easy to foresee that it would have swallowed up the normal personality if the illness had lasted much longer. I have at present an opportunity of studying a lady suffering severely from obsessional acts. She has become similarly disintegrated into an easy-going and lively personality and into an exceedingly gloomy and ascetic one. She puts forward the first of them as her official ego, while in fact she is dominated by the second. Both of these psychical organizations have access to her consciousness, but behind her ascetic personality may be discerned the unconscious part of her being - quite unknown to her and composed of ancient and long-repressed wishful impulses.¹

This, then, is what I wanted to tell you about the formation of symptoms in the neuroses. But I must not fail to lay emphasis expressly once again on the fact that everything I have said here applies only to the formation of symptoms in hysteria. Even in obsessional neurosis there is much - apart from fundamentals, which remain unaltered - that will be found different. The anticathexes opposing the demands of the instincts (which we have already spoken of in the case of hysteria as well) become prominent in obsessional neurosis and dominate the clinical picture in the form of what are known as 'reaction formations'. We discover similar and even more far-reaching divergences in the other neuroses, where our researches into the mechanisms of symptom-formation are not yet concluded at any point.

[1909d, 2194]

[1916-1917, 3430]
The Theory of Repression. - These theoretical considerations, taken together with the immediate impressions derived from analytic work, lead to a view of the neuroses which may be described in the roughest outline as follows. The neuroses are the expression of conflicts between the ego and such of the sexual impulses as seem to the ego incompatible with its integrity or with its ethical standards. Since these impulses are not ego-syntonic, the ego has repressed them: that is to say, it has withdrawn its interest from them and has shut them off from becoming conscious as well as from obtaining satisfaction by motor discharge. If in the course of analytic work one attempts to make these repressed impulses conscious, one becomes aware of the repressive forces in the form of resistance. But the achievement of repression fails particularly readily in the case of the sexual instincts. Their dammed-up libido finds other ways out from the unconscious: for it regresses to earlier phases of development and earlier attitudes towards objects, and, at weak points in the libidinal development where there are infantile fixations, it breaks through into consciousness and obtains discharge. What results is a symptom and consequently in its essence a substitutive sexual satisfaction. Nevertheless the symptom cannot entirely escape from the repressive forces of the ego and must therefore submit to modifications and displacements exactly as happens with dreams - by means of which its characteristic of being a sexual satisfaction becomes unrecognizable. Consequently symptoms are in the nature of compromises between the repressed sexual instincts and the repressing ego-instincts; they represent a wish-fulfilment for both partners to the conflict simultaneously, but one which is incomplete for each of them. This is quite strictly true of the symptoms of hysteria, while in the symptoms of obsessional neurosis there is often a stronger emphasis upon the side of the repressing function owing to the erection of reaction-formations, which are assurances against sexual satisfaction.

[1923a, 3923]

It is essentially in hysteria and in states of a hysterical type that this is found. Here the mechanism by which the sense of guilt remains unconscious is easy to discover. The hysterical ego fends off a distressing perception with which the criticisms of its super-ego threaten it, in the same way in which it is in the habit of fending off an unendurable object-cathexis - by an act of repression. It is the ego, therefore, that is responsible for the sense of guilt remaining unconscious. We know that as a rule the ego carries out repressions in the service and at the behest of its super-ego; but this is a case in which it has turned the same weapon against its harsh taskmaster. In obsessional neurosis, as we know, the phenomena of reaction-formation predominate; but here the ego succeeds only in keeping at a distance the material to which the sense of guilt refers.

[1923b, 3985]

Obsessional neurosis is unquestionably the most interesting and repaying subject of analytic research. But as a problem it has not yet been mastered. It must be confessed that, if we endeavour to penetrate more deeply into its nature, we still have to rely upon doubtful assumptions and unconfirmed suppositions. Obsessional neurosis originates, no doubt, in the same situation as hysteria, namely, the necessity of fending off the libidinal demands of the Oedipus complex. Indeed, every obsessional neurosis seems to have a substratum of hysterical symptoms that have been formed at a very early stage. But it is subsequently shaped along quite different lines owing to a constitutional factor. The genital organization of the libido turns out to be feeble and insufficiently resistant, so that when the ego begins its defensive efforts the first thing it succeeds in doing is to throw back the genital organization (of the phallic phase), in whole or in part, to the earlier sadistic-anal level. This fact of regression is decisive for all that follows.

[1926d, 4272]
Another possibility has to be considered. Perhaps regression is the result not of a constitutional factor but of a time-factor. It may be that regression is rendered possible not because the genital organization of the libido is too feeble but because the opposition of the ego begins too early, while the sadistic phase is at its height. I am not prepared to express a definite opinion on this point, but I may say that analytic observation does not speak in favour of such an assumption. It shows rather that, by the time an obsessional neurosis is entered upon, the phallic stage has already been reached. Moreover, the onset of this neurosis belongs to a later time of life than that of hysteria - to the second period of childhood, after the latency period has set in. In a woman patient whose case I was able to study and who was overtaken by this disorder at a very late date, it became clear that the determining cause of her regression and of the emergence of her obsessional neurosis was a real occurrence through which her genital life, which had up till then been intact, lost all its value.¹

In the course of these struggles we come across two activities of the ego which form symptoms and which deserve special attention because they are obviously surrogates of repression and therefore well calculated to illustrate its purpose and technique. The fact that such auxiliary and substitutive techniques emerge may argue that true repression has met with difficulties in its functioning. If one considers how much more the ego is the scene of action of symptom-formation in obsessional neurosis than it is in hysteria and with what tenacity the ego clings to its relations to reality and to consciousness, employing all its intellectual faculties to that end - and indeed how the very process of thinking becomes hypercathected and erotized - then one may perhaps come to a better understanding of these variations of repression.

The second of these techniques which we are setting out to describe for the first time, that of isolation, is peculiar to obsessional neurosis. It, too, takes place in the motor sphere. When something unpleasant has happened to the subject or when he himself has done something which has a significance for his neurosis, he interpolates an interval during which nothing further must happen - during which he must perceive nothing and do nothing. This behaviour, which seems strange at first sight, is soon seen to have a relation to repression. We know that in hysteria it is possible to cause a traumatic experience to be overtaken by amnesia. In obsessional neurosis this can often not be achieved: the experience is not forgotten, but, instead, it is deprived of its affect, and its associative connections are suppressed or interrupted so that it remains as though isolated and is not reproduced in the ordinary processes of thought. The effect of this isolation is the same as the effect of repression with amnesia. This technique, then, is reproduced in the isolations of obsessional neurosis; and it is at the same time given motor reinforcement for magical purposes. The elements that are held apart in this way are precisely those which belong together associatively. The motor isolation is meant to ensure an interruption of the connection in thought. The normal phenomenon of concentration provides a pretext for this kind of neurotic procedure: what seems to us important in the way of an impression or a piece of work must not be interfered with by the simultaneous claims of any other mental processes or activities. But even a normal person uses concentration to keep away not only what is irrelevant or unimportant, but, above all, what is unsuitable because it is contradictory. He is most disturbed by those elements which once belonged together but which have been torn apart in the course of his development - as, for instance, by manifestations of the ambivalence of his father-complex in his relation to God, or by impulses attached to his excretory organs in his emotions of love. Thus, in the normal course of things, the ego has a great deal of isolating work to do in its function of directing the current of thought. And, as we know, we are obliged, in carrying out our analytic technique, to train it to relinquish that function for the time being, eminently justified as it usually is.

[1926d, 4272]

[1926d, 4278]
When, in an earlier part of this discussion, we found that the danger of castration was of importance in more than one neurotic illness, we put ourselves on guard against overestimating that factor, since it could not be a decisive one for the female sex, who are undoubtedly more subject to neuroses than men. We now see that there is no danger of our regarding castration anxiety as the sole motive force of the defensive processes which lead to neurosis. I have shown elsewhere how little girls, in the course of their development, are led into making a tender object-cathexis by their castration complex. It is precisely in women that the danger situation of loss of object seems to have remained the most effective. All we need to do is to make a slight modification in our description of their determinant of anxiety, in the sense that it is no longer a matter of feeling the want of, or actually losing the object itself, but of losing the object's love. Since there is no doubt that hysteria has a strong affinity with femininity, just as obsessional neurosis has with masculinity, it appears probable that, as a determinant of anxiety, loss of love plays much the same part in hysteria as the threat of castration does in phobias and fear of the super-ego in obsessional neurosis.

An important element in the theory of repression is the view that repression is not an event that occurs once but that it requires a permanent expenditure. If this expenditure were to cease, the repressed impulse, which is being fed all the time from its sources, would on the next occasion flow along the channels from which it had been forced away, and the repression would either fail in its purpose or would have to be repeated an indefinite number of times. Thus it is because instincts are continuous in their nature that the ego has to make its defensive action secure by a permanent expenditure. This action undertaken to protect repression is observable in analytic treatment as resistance. Resistance presupposes the existence of what I have called anticathexis. An anticathexis of this kind is clearly seen in obsessional neurosis. It appears there in the form of an alteration of the ego, as a reaction-formation in the ego, and is effected by the reinforcement of the attitude which is the opposite of the instinctual trend that has to be repressed - as, for instance, in pity, conscientiousness and cleanliness. These reaction-formations of obsessional neurosis are essentially exaggerations of the normal traits of character which develop during the latency period. The presence of an anticathexis in hysteria is much more difficult to detect, though theoretically it is equally indispensable. In hysteria, too, a certain amount of alteration of the ego through reaction-formation is unmistakable and in some circumstances becomes so marked that it forces itself on our attention as the principal symptom. The conflict due to ambivalence, for instance, is resolved in hysteria by this means. The subject's hatred of a person whom he loves is kept down by an exaggerated amount of tenderness for him and apprehensiveness about him. But the difference between reaction-formations in obsessional neurosis and in hysteria is that in the latter they do not have the universality of a character-trait but are confined to particular relationships. A hysterical woman, for instance, may be specially affectionate with her own children whom at bottom she hates; but she will not on that account be more loving in general than other women or even more affectionate to other children. The reaction-formation of hysteria clings tenaciously to a particular object and never spreads over into a general disposition of the ego, whereas what is characteristic of obsessional neurosis is precisely a spreading-over of this kind - a loosening of relations to the object and a facilitation of displacement in the choice of object.

[1926d, 4298]

[1926d, 4310]
There is another kind of anticathexis, however, which seems more suited to the peculiar character of hysteria. A repressed instinctual impulse can be activated (newly cathected) from two directions: from within, through reinforcement from its internal sources of excitation, and from without, through the perception of an object that it desires. The hysterical anticathexis is mainly directed outwards, against dangerous perceptions. It takes the form of a special kind of vigilance which, by means of restrictions of the ego, causes situations to be avoided that would entail such perceptions, or, if they do occur, manages to withdraw the subject's attention from them. Some French analysts, in particular Laforgue, have recently given this action of hysteria the special name of 'scotomization'. This technique of anticathexis is still more noticeable in the phobias, whose interest is concentrated on removing the subject ever further from the possibility of the occurrence of the feared perception. The fact that anticathexis has an opposite direction in hysteria and the phobias from what it has in obsessional neurosis - though the distinction is not an absolute one - seems to be significant. It suggests that there is an intimate connection between repression and external anticathexis on the one hand and between regression and internal anticathexis (i.e. alteration in the ego through reaction-formation) on the other. The task of defence against a dangerous perception is, incidentally, common to all neuroses. Various commands and prohibitions in obsessional neurosis have the same end in view.

Even a purely terminological innovation ought to justify its adoption; it ought to reflect some new point of view or some extension of knowledge. The revival of the concept of defence and the restriction of that of repression takes into account a fact which has long since been known but which has received added importance owing to some new discoveries. Our first observations of repression and of the formation of symptoms were made in connection with hysteria. We found that the perceptual content of exciting experiences and the ideational content of pathogenic structures of thought were forgotten and debarred from being reproduced in memory, and we therefore concluded that the keeping away from consciousness was a main characteristic of hysterical repression. Later on, when we came to study the obsessional neuroses, we found that in that illness pathogenic occurrences are not forgotten. They remain conscious but they are 'isolated' in some way that we cannot as yet grasp, so that much the same result is obtained as in hysterical amnesia. Nevertheless the difference is great enough to justify the belief that the process by which instinctual demands are set aside in obsessional neurosis cannot be the same as in hysteria. Further investigations have shown that in obsessional neurosis a regression of the instinctual impulses to an earlier libidinal stage is brought about through the opposition of the ego, and that this regression, although it does not make repression unnecessary, clearly works in the same sense as repression. We have seen, too, that in obsessional neurosis anticathexis, which is also presumably present in hysteria, plays a specially large part in protecting the ego by effecting a reactive alteration in it. Our attention has, moreover, been drawn to a process of 'isolation' (whose technique cannot as yet be elucidated) which finds direct symptomatic manifestation, and to a procedure, that may be called magical, of 'undoing' what has been done - a procedure about whose defensive purpose there can be no doubt, but which has no longer any resemblance to the process of 'repression'. These observations provide good enough grounds for re-introducing the old concept of defence, which can cover all these processes that have the same purpose - namely, the protection of the ego against instinctual demands - and for subsuming repression under it as a special case. The importance of this nomenclature is heightened if we consider the possibility that further investigations may show that there is an intimate connection between special forms of defence and particular illnesses, as, for instance, between repression and hysteria. In addition we may look forward to the possible discovery of yet another important correlation. It may well be that before its sharp cleavage into an ego and an id, and before the formation of a super-ego, the mental apparatus makes use of different methods of defence from those which it employs after it has reached these stages of organization.
Obsessions and phobias are separate neuroses, with a special mechanism and aetiology which I have succeeded in demonstrating in a certain number of cases, and which, I hope, will prove similar in a good number of fresh cases.

As regards classification of the subject, I propose in the first place to exclude a group of intense obsessions which are nothing but memories, unaltered images of important events. As an example, I may cite Pascal's obsession: he always thought he saw an abyss on his left hand 'after he had nearly been thrown into the Seine in his coach'. Such obsessions and phobias, which might be called traumatic, are allied to the symptoms of hysteria.

Two constituents are found in every obsession: (1) an idea that forces itself upon the patient (2) an associated emotional state. Now in the group of phobias this emotional state is always one of 'anxiety', while in true obsessions other emotional states, such as doubt, remorse, or anger, may occur just as well as anxiety. I will first attempt to explain the really remarkable psychological mechanism of true obsessions, a mechanism quite different from that of the phobias.

In addition to these two groups of true obsessions there is the class of 'phobias', which must now be considered. I have already mentioned the great difference between obsessions and phobias: that in the latter the emotion is always one of anxiety, fear. I might add that obsessions are varied and more specialized, phobias are more monotonous and typical. But this distinction is not of capital importance.

The mechanism of phobias is entirely different from that of obsessions. Substitution is no longer the predominant feature in the former; psychological analysis reveals no incompatible, replaced idea in them. Nothing is ever found but the emotional state of anxiety which, by a kind of selective process, brings up all the ideas adapted to become the subject of a phobia. In the case of agoraphobia, etc., we often find the recollection of an anxiety attack; and what the patient actually fears is the occurrence of such an attack under the special conditions in which he believes he cannot escape it.

The anxiety belonging to this emotional state, which underlies all phobias, is not derived from any memory; we may well wonder what the source of this powerful condition of the nervous system can be.

The relation of these phobias to the phobias of obsessional neurosis, whose mechanism I made clear in an earlier paper¹ in this periodical, is of the following kind. What they have in common is that in both an idea becomes obsessional as a result of being attached to an available affect. The mechanism of transposition of affect thus holds good for both kinds of phobia. But in the phobias of anxiety neurosis (1) this affect always has the same colour, which is that of anxiety; and (2) the affect does not originate in a repressed idea, but turns out to be not further reducible by psychological analysis, nor amenable to psychotherapy. The mechanism of substitution, therefore, does not hold good for the phobias of anxiety neurosis.
The transformation did not occur spontaneously, through internal development, but through an outside influence. Its visible effect was that the patient's relation to his father, which stood in the foreground, and which had so far found expression in the wolf phobia, was now manifested in obsessional piety. I cannot refrain from pointing out that the course of events in this part of the patient's history affords an unmistakable confirmation of an assertion which I made in *Totem and Taboo* upon the relation of the totem animal to the deity.¹ I there decided in favour of the view that the idea of God was not a development from the totem, but replaced it after arising independently from a root common to both ideas. The totem, I maintained, was the first father-surrogate, and the god was a later one, in which the father had regained his human shape. And we find the same thing with our patient. In his wolf phobia he had gone through the stage of the totemic father-surrogate; but that stage was now broken off, and, as a result of new relations between him and his father, was replaced by a phase of religious piety.

¹ [1918b, 3590]

That there is a relationship between inhibition and anxiety is pretty evident. Some inhibitions obviously represent a relinquishment of a function because its exercise would produce anxiety. Many women are openly afraid of the sexual function. We class this anxiety under hysteria, just as we do the defensive symptom of disgust which, arising originally as a deferred reaction to the experiencing of a passive sexual act, appears later whenever the idea of such an act is presented. Furthermore, many obsessional acts turn out to be measures of precaution and security against sexual experiences and are thus of a phobic character.

¹ [1926d, 4249]
In the classificatory system of the neuroses no definite position has hitherto been assigned to ‘phobias’. It seems certain that they should only be regarded as syndromes which may form part of various neuroses and that we need not rank them as an independent pathological process. For phobias of the kind to which little Hans's belongs, and which are in fact the most common, the name of ‘anxiety-hysteria’ seems to me not inappropriate; I suggested the term to Dr. W. Stekel when he was undertaking a description of neurotic anxiety states," and I hope it will come into general use. It finds its justification in the similarity between the psychological structure of these phobias and that of hysteria - a similarity which is complete except upon a single point. That point, however, is a decisive one and well adapted for purposes of differentiation. For in anxiety-hysteria the libido which has been liberated from the pathogenic material by repression is not converted (that is, diverted from the mental sphere into a somatic innervation), but is set free In the clinical cases that we meet with, this 'anxiety-hysteria' may be combined with 'conversion-hysteria' in any proportion. There exist cases of pure conversion-hysteria without any trace of anxiety, just as there are cases of simple anxiety-hysteria, which exhibit feelings of anxiety and phobias, but have no admixture of conversion. The case of little Hans is one of the latter sort.
[1909b, 2099]
Nevertheless, in spite of the apparent triviality of these phenomena, the psycho-analytic explanation of parapraxes involves some slight modifications in our view of the world. We find that even normal people are far more frequently moved by contradictory motives than we should have expected. The number of occurrences that can be described as ‘accidental’ is considerably diminished. It is almost a consolation to be able to exclude the loss of objects from among the chance events of life; our blunders often turn out to be a cover for our secret intentions. But what is more important - many serious accidents that we should otherwise have ascribed entirely to chance reveal under analysis the participation of the subject’s own volition, though without its being clearly admitted by him. The distinction between a chance accident and deliberate self-destruction, which in practice is so often hard to draw, becomes even more dubious when looked at from an analytic point of view.

[1913, 2805]

You will ask whether it may not be possible, however, to do justice to the part played by the ego in neurotic states and in the formation of symptoms without at the same time grossly neglecting the factors revealed by psycho-analysis. My reply is that that must certainly be possible and will sooner or later be done; but the road followed by the work of psycho-analysis does not admit of actually beginning with this. It is of course possible to foresee when psycho-analysis will be confronted by this task. There are neuroses in which the ego plays a far more intensive part than in those we have studied hitherto; we call them the ‘narcissistic’ neuroses. The investigation of these disorders will enable us to form an impartial and trustworthy judgement of the share taken by the ego in the onset of neuroses.

[1916-1917, 3434]

We began at an early date to extend psycho-analytic observations to these other illnesses. Already in 1908 Karl Abraham, after an exchange of thoughts with me, pronounced the main characteristic of dementia praecox (which was reckoned among the psychoses) to be that in it the libidinal cathexis of objects was lacking. But the question then arose of what happened to the libido of dementia praecox patients which was turned away from objects. Abraham did not hesitate to give the answer: it is turned back on to the ego and this reflexive turning-back is the source of the megalomania in dementia praecox. Megalomania is in every way comparable to the familiar sexual overvaluation of the object in erotic life. In this way for the first time we learnt to understand a trait in a psychotic illness by relating it to normal erotic life.

[1916-1917, 3461]
Here is my reply. Your first objection sounds well enough. Consideration of the states of sleep, of illness and of being in love in themselves would probably never have led us to distinguish an ego-libido from an object-libido or libido from interest. But there you are neglecting the investigations from which we started and in the light of which we now look at the mental situations under discussion. The differentiation between libido and interest - that is to say, between the sexual and the self-preservative instincts - was forced upon us by our discovery of the conflict out of which the transference neuroses arise. Since then we cannot give it up. The hypothesis that object-libido can be transformed into ego-libido, that we must therefore take an ego-libido into account, seems to us the only one which is able to resolve the enigma of what are termed the narcissistic neuroses - dementia praecox, for instance - and to account for the resemblances and dissimilarities between them and hysteria or obsessions. We are now applying to illness, sleep and being in love what we have elsewhere found inescapably established. We should proceed further with applications of this kind and see where they will take us to. The only thesis which is not an immediate precipitate of our analytic experience is to the effect that libido remains libido, whether it is directed to objects or to one's own ego, and never turns into egoistic interest, and the converse is also true. This thesis, however, is equivalent to the separation between the sexual and ego-instincts which we have already considered critically and to which we shall continue to hold for heuristic reasons until its possible collapse.

[1916-1917, 3465]

Your second observation, too, raises a justifiable question, but it is aimed in the wrong direction. It is true that a withdrawal of the object-libido into the ego is not directly pathogenic; it takes place, indeed, as we know, every time before we go to sleep, only to be reversed when we wake up. The amoeba withdraws its protrusions only to send them out again at the first opportunity. But it is quite a different thing when a particular, very energetic process forces a withdrawal of libido from objects. Here the libido that has become narcissistic cannot find its way back to objects, and this interference with the libido's mobility certainly becomes pathogenic. It seems that an accumulation of narcissistic libido beyond a certain amount is not tolerated. We may even imagine that it was for that very reason that object-cathexes originally came about, that the ego was obliged to send out its libido so as not to fall ill as a result of its being dammed up. If it lay within our plan to go more deeply into dementia praecox, I would show you that the process which detaches the libido from objects and cuts off its return to them is closely related to the process of repression and is to be looked at as its counterpart. But you would, first and foremost, find yourselves on familiar ground when you learnt that the determinants of this process are almost identical - so far as we know at present - with those of repression. The conflict seems to be the same and to be carried on between the same forces. If the outcome is so different from, for instance, that in hysteria, the reason can only depend on a difference in innate disposition. The weak spot in the libidinal development of these patients lies in a different phase; the determining fixation, which, as you will recollect, permits the irruption that leads to the formation of symptoms, lies elsewhere, probably in the stage of primitive narcissism to which dementia praecox returns in its final outcome. It is very remarkable that in the case of all the narcissistic neuroses we have to assume fixation points for the libido going back to far earlier phases of development than in hysteria or obsessional neurosis. As you heard, however, the concepts which we arrived at during our study of the transference neuroses are adequate in helping us to find our way about in the narcissistic neuroses which are so much more severe in practice. The conformities go very far; at bottom the field of phenomena is the same. And you can imagine how small a prospect anyone has of explaining these disorders (which belong within the sphere of psychiatry) who is not forearmed for his task with an analytic knowledge of the transference neuroses.

[1916-1917, 3466]
The clinical picture of dementia praecox (which, incidentally, is very changeable) is not determined exclusively by the symptoms arising from the forcing away of the libido on objects and its accumulation in the ego as narcissistic libido. A large part, rather, is played by other phenomena, which are derived from efforts of the libido to attain objects once more and which thus correspond to an attempt at restitution or recovery. These latter symptoms are indeed the more striking and noisy; they exhibit an undeniable resemblance to those of hysteria or, less frequently, of obsessional neurosis, but nevertheless differ from them in every respect. It seems as though in dementia praecox the libido, in its efforts once more to reach objects (that is, the presentations of objects), does in fact snatch hold something of them, but, as it were, only their shadows - I mean the word-presentations belonging to them. I cannot say more about this now, but I believe that this behaviour of the libido as it strives to find its way back has enabled us to obtain an insight into what really constitutes the difference between a conscious and an unconscious idea.

I have now led you into the region in which the next advances in the work of analysis are to be expected. Since we have ventured to operate with the concept of ego-libido the narcissistic neuroses have become accessible to us; the task before us is to arrive at a dynamic elucidation of these disorders and at the same time to complete our knowledge of mental life by coming to understand the ego. The ego-psychology after which we are seeking must not be based on the data of our self-perceptions but (as in the case of the libido) on the analysis of disturbances and disruptions of the ego. It is likely that we shall have a low opinion of our present knowledge of the vicissitudes of the libido, which we have gained from a study of the transference neuroses, when we have achieved this greater task. But hitherto we have not made much progress with it. The narcissistic neuroses can scarcely be attacked with the technique that has served us with the transference neuroses. You will soon learn why. What always happens with them is that, after proceeding for a short distance, we come up against a wall which brings us to a stop. Even with the transference neuroses, as you know, we met with barriers of resistance, but we were able to demolish them bit by bit. In the narcissistic neuroses the resistance is unconquerable; at the most, we are able to cast an inquisitive glance over the top of the wall and spy out what is going on on the other side of it. Our technical methods must accordingly be replaced by others; and we do not know yet whether we shall succeed in finding substitute. Nevertheless, we have no lack of material with these patients either. They make a large number of remarks, even if they do not answer our questions, and for the time being it is our business to interpret these remarks with the help of the understanding we have gained from the symptoms of the transference neuroses. The agreement is great enough to guarantee us some initial advantage. It remains to be seen how far this technique will take us.

There are difficulties in addition which hold up our advance. The narcissistic disorders and the psychoses related to them can only be deciphered by observers who have been trained through the analytic study of the transference neuroses. But our psychiatrists are not students of psycho-analysis and we psycho-analysts see too few psychiatric cases. A race of psychiatrists must first grow up who have passed through the school of psycho-analysis as a preparatory science. A start in that direction is now being made in America, where very many leading psychiatrists lecture to students on the theories of psycho-analysis and where the proprietors of institutions and the directors of insane asylums endeavour to observe their patients in conformity with those theories. Nevertheless we too, over here, have succeeded sometimes in casting a glance over the narcissistic wall and in what follows I shall tell you a little of what we think we have detected.
I told you too that we hoped that the analysis of the narcissistic disorders would give us an insight into the way in which our ego is put together and built up out of different agencies. We have already made a start with this at one point. From the analysis of delusions of observation we have drawn the conclusion that there actually exists in the ego an agency which unceasingly observes, criticizes and compares, and in that way sets itself over against the other part of the ego. We believe, therefore, that the patient is betraying a truth to us which is not yet sufficiently appreciated when he complains that he is spied upon and observed at every step he takes and that every one of his thoughts is reported and criticized. His only mistake is in regarding this uncomfortable power as something alien to him and placing it outside himself. He senses an agency holding sway in his ego which measures his actual ego and each of its activities by an ideal ego that he has created for himself in the course of his development. We believe, too, that this creation was made with the intention of re-establishing the self-satisfaction which was attached to primary infantile narcissism but which since then has suffered so many disturbances and mortifications. We know the self-observing agency as the ego-censor, the conscience; it is this that exercises the dream-censorship during the night, from which the repressions of inadmissible wishful impulses proceed. When in delusions of observation it becomes split up, it reveals to us its origin from the influences of parents, educators and social environment - from an identification with some of these model figures.

Apart from this, the war neuroses are only traumatic neuroses, which, as we know, occur in peace-time too after frightening experiences or severe accidents, without any reference to a conflict in the ego.

It only became possible to extend the libido theory to the narcissistic neuroses after the concept of a ‘narcissistic libido’ had been put forward and applied - a concept, that is, of an amount of sexual energy attached to the ego itself and finding satisfaction in the ego just as satisfaction is usually found only in objects. This entirely legitimate development of the concept of sexuality promises to accomplish as much for the severer neuroses and for the psychoses as can be expected of a theory which is feeling its way forwards on an empirical basis. The traumatic neuroses of peace will also fit into the scheme as soon as a successful outcome has been reached of our investigations into the relations which undoubtedly exist between fright, anxiety and narcissistic libido.

Narcissism. - The most important theoretical advance has certainly been the application of the libido theory to the repressing ego. The ego itself came to be regarded as a reservoir of what was described as narcissistic libido, from which the libidinal cathexes of objects flowed out and into which they could be once more withdrawn. By the help of this conception it became possible to embark upon the analysis of the ego and to make a clinical distinction of the psychoneuroses into transference neuroses and narcissistic disorders. In the former (hysteria and obsessional neurosis) the subject has at his disposal a quantity of libido striving to be transferred on to extraneous objects, and use is made of this in carrying out analytic treatment; on the other hand, the narcissistic disorders (dementia praecox, paranoia, melancholia) are characterized by a withdrawal of the libido from objects and they are therefore scarcely accessible to analytic therapy. But their therapeutic inaccessibility has not prevented analysis from making the most fruitful beginnings in the deeper study of these illnesses, which are counted among the psychoses.
Narcissism. - A decisive advance was made when the analysis of dementia praecox and other psychotic disorders was ventured upon and thus the examination was begun of the ego itself, which had so far been known only as the agency of repression and opposition. It was found that the pathogenic process in dementia praecox is the withdrawal of the libido from objects and its introduction into the ego, while the clamorous symptoms of the disease arise from the vain struggles of the libido to find a pathway back to objects. It thus turned out to be possible for object-libido to change into cathexis of the ego and vice versa. Further reflection showed that this process must be presumed to occur on the largest scale and that the ego is to be regarded as a great reservoir of libido from which libido is sent out to objects and which is always ready to absorb libido flowing back from objects. Thus the instincts of self-preservation were also of a libidinal nature: they were sexual instincts which, instead of external objects, had taken the subject's own ego as an object. Clinical experience had made us familiar with people who behaved in a striking fashion as though they were in love with themselves and this perversion had been given the name of narcissism. The libido of the self-preservation instincts was now described as narcissistic libido and it was recognized that a high degree of this self-love constituted the primary and normal state of things. The earlier formula laid down for the transference neuroses consequently required to be modified, though not corrected. It was better, instead of speaking of a conflict between sexual instincts and ego instincts, to speak of a conflict between object-libido and ego-libido, or, since the nature of these instincts was the same, between the object-cathexes and the ego.

[1923a, 3933]

In the work I have mentioned I described the numerous dependent relationships of the ego, its intermediate position between the external world and the id and its efforts to humour all its masters at once. In connection with a train of thought raised in other quarters, which was concerned with the origin and prevention of the psychoses, a simple formula has now occurred to me which deals with what is perhaps the most important genetic difference between a neurosis and a psychosis: neurosis is the result of a conflict between the ego and its id, whereas psychosis is the analogous outcome of a similar disturbance in the relations between the ego and the external world.

[1924b, 4065]
The aetiology common to the onset of a psychoneurosis and of a psychosis always remains
the same. It consists in a frustration, a non-fulfilment of one of those childhood wishes which are
for ever undefeated and which are so deeply rooted in our phylogenetically determined
organization. This frustration is in the last resort always an external one; but in the individual
case it may proceed from the internal agency (in the super-ego) which has taken over the
representation of the demands of reality. The pathogenic effect depends on whether, in a
conflictual tension of this kind, the ego remains true to its dependence on the external world and
attempts to silence the id, or whether it lets itself be overcome by the id and thus torn away from
reality. A complication is introduced into this apparently simple situation, however, by the
existence of the super-ego, which, though a link that is not yet clear to us, unites in itself
influences coming from the id as well as from the external world, and is to some extent an ideal
model of what the whole endeavour of the ego is aiming at - a reconciliation between its various
dependent relationships. The attitude of the super-ego should be taken into account - which has
not hitherto been done - in every form of psychical illness. We may provisionally assume that
there must also be illnesses which are based on a conflict between the ego and the super-ego.
Analysis gives us a right to suppose that melancholia is a typical example of this group; and we
would set aside the name of 'narcissistic psychoneuroses' for disorders of that kind. Nor will it
clash with our impressions if we find reasons for separating states like melancholia from the
other psychoses. We now see that we have been able to make our simple genetic formula more
complete, without dropping it. Transference neuroses correspond to a conflict between the ego
and the id; narcissistic neuroses, to a conflict between the ego and the super-ego; and
psychoses, to one between the ego and the external world. It is true that we cannot tell at once
whether we have really gained any new knowledge by this, or have only enriched our store of
formulas; but I think that this possible application of the proposed differentiation of the mental
apparatus into an ego, a super-ego and an id cannot fail to give us courage to keep that
hypothesis steadily in view.

The psycho-analytic view would also have to include in narcissistic disorders all the ailments
described in psychiatry as 'functional psychoses'. It could not be doubted that neuroses and
psychoses are not separated by a hard and fast line, any more than health and neurosis; and it
was plausible to explain the mysterious psychotic phenomena by the discoveries achieved on
the neuroses, which had hitherto been equally incomprehensible. The present writer had
himself, during the period of his isolation, made a case of paranoid illness partly intelligible by
an analytic investigation and had pointed out in this unquestionable psychosis the same
contents (complexes) and a similar interplay of forces as in the simple neuroses. Bleuler
followed out the indications of what he called 'Freudian mechanisms' in a whole number of
psychoses, and Jung won high opinions as an analyst at a single blow when, in 1907, he
explained the most eccentric symptoms in the end-stages of dementia praecox from the
individual life-histories of the patients. The comprehensive study of schizophrenia by Bleuler
(1911) probably demonstrated once and for all the justification of a psycho-analytic angle of
approach for the understanding of these psychoses.
The neuroses were the first subject of analysis, and for a long time they were the only one. No analyst could doubt that medical practice was wrong in separating those disorders from the psychoses and in attaching them to the organic nervous diseases. The theory of the neuroses belongs to psychiatry and is indispensable as an introduction to it. It would seem, however, that the analytic study of the psychoses is impracticable owing to its lack of therapeutic results. Mental patients are as a rule without the capacity for forming a positive transference, so that the principal instrument of analytic technique is inapplicable to them. There are nevertheless a number of methods of approach to be found. Transference is often not so completely absent but that it can be used to a certain extent; and analysis has achieved undoubted successes with cyclical depressions, light paranoid modifications, and partial schizophrenias. It has at least been a benefit to science that in many cases the diagnosis can oscillate for quite a long time between assuming the presence of a psychoneurosis or of a dementia praecox; for therapeutic attempts initiated in such cases have resulted in valuable discoveries before they have had to be broken off. But the chief consideration in this connection is that so many things that in the neuroses have to be laboriously fetched up from the depths are found in the psychoses on the surface, visible to every eye. For that reason the best subjects for the demonstration of many of the assertions of analysis are provided by the psychiatric clinic. It was thus bound to happen before long that analysis would find its way to the objects of psychiatric observation. I was able very early (1896) to establish in a case of paranoid dementia the presence of the same aetiological factors and the same emotional complexes as in the neuroses. Jung explained some most puzzling stereotypies in dements by bringing them into relation with the patients' life-histories; Bleuler demonstrated the existence in various psychoses of mechanisms like those which analysis had discovered in neurotics. Since then analysts have never relaxed their efforts to come to an understanding of the psychoses. Especially since it has been possible to work with the concept of narcissism, they have managed, now in this place and now in that, to get a glimpse beyond the wall. Most of all, no doubt, was achieved by Abraham in his elucidation of the melancholias. It is true that in this sphere all our knowledge is not yet converted into therapeutic power; but the mere theoretical gain is not to be despised, and we may be content to wait for its practical application. In the long run even the psychiatrists cannot resist the convincing force of their own clinical material. At the present time German psychiatry is undergoing a kind of 'peaceful penetration' by analytic views. While they continually declare that they will never be psycho-analysts, that they do not belong to the 'orthodox' school or agree with its exaggerations, and in particular that they do not believe in the predominance of the sexual factor, nevertheless the majority of the younger workers take over one piece or another of analytic theory and apply it in their own fashion to the material. All the signs point to the proximity of further developments in the same direction.

We have arrived at a general acquaintance with the psychical apparatus, with the parts, organs and agencies of which it is composed, with the forces which operate in it and with the functions allotted to its parts. The neuroses and psychoses are the states in which disturbances in the functioning of the apparatus come to expression. We have chosen the neuroses as the subjects of our study because they alone seem accessible to the psychological methods of our intervention. While we are trying to influence them, we collect observations which give us a picture of their origin and of the manner in which they arise.
After this preliminary stage a transformation sets in whose mechanism is known to us but whose motive forces we do not yet understand. The child's love for his mother cannot continue to develop consciously any further; it succumbs to repression. The boy represses his love for his mother: he puts himself in her place, identifies himself with her, and takes his own person as a model in whose likeness he chooses the new objects of his love. In this way he has become a homosexual. What he has in fact done is to slip back to auto-erotism: for the boys whom he now loves as he grows up are after all only substitutive figures and revivals of himself in childhood - boys whom he loves in the way in which his mother loved him when he was a child. He finds the objects of his love along the path of narcissism, as we say; for Narcissus, according to the Greek legend, was a youth who preferred his own reflection to everything else and who was changed into the lovely flower of that name.

I shall now endeavour (and I think the attempt is neither unnecessary nor unjustifiable) to show that the knowledge of psychological processes, which, thanks to psycho-analysis, we now possess, already enables us to understand the part played by a homosexual wish in the development of paranoia. Recent investigations¹ have directed our attention to a stage in the development of the libido which it passes through on the way from auto-eroticism to object-love.² This stage has been given the name of narcissism. What happens is this. There comes a time in the development of the individual at which he unifies his sexual instincts (which have hitherto been engaged in auto-erotic activities) in order to obtain a love-object; and he begins by taking himself, his own body, as his love-object, and only subsequently proceeds from this to the choice of some person other than himself as his object. This half-way phase between auto-erotism and object-love may perhaps be indispensable normally; but it appears that many people linger unusually long in this condition, and that many of its features are carried over by them into the later stages of their development. What is of chief importance in the subject's self thus chosen as a love object may already be the genitals. The line of development then leads on to the choice of an external object with similar genitals - that is, to homosexual object-choice - and thence to heterosexuality. People who are manifest homosexuals in later life have, it may be presumed, never emancipated themselves from the binding condition that the object of their choice must possess genitals like their own; and in this connection the infantile sexual theories which attribute the same kind of genitals to both sexes exert much influence.

[1910c, 2274]

[1911c, 2430]
In my *Three Essays on the Theory of Sexuality* I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics *endeavour to protect themselves against any such sexualization of their social instinctual cathexes*, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) *schizophrenia*; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients’ dispositional fixations.

[1911c, 2431]

I may tell you at once that these first explanations of Abraham's have been accepted in psycho-analysis and have become the basis of our attitude to the psychoses. We thus slowly became familiar with the notion that the libido, which we find attached to objects and which is the expression of an effort to obtain satisfaction in connection with those objects, can also leave the objects and set the subject's own ego in their place; and this notion was gradually built up more and more consistently. The name for this way of allocating the libido - 'narcissism' - was borrowed by us from a perversion described by Paul Näcke in which an adult treats his own body with all the caresses that are usually devoted to an outside sexual object.

[1916-1917, 3461]

This is the place for two remarks. First, how do we differentiate between the concepts of narcissism and egoism? Well, narcissism, I believe, is the libidinal complement to egoism. When we speak of egoism, we have in view only the individual's *advantage*; when we talk of narcissism we are also taking his libidinal satisfaction into account. As practical motives the two can be traced separately for quite a distance. It is possible to be absolutely egoistic and yet maintain powerful object-cathexes, in so far as libidinal satisfaction in relation to the object forms part of the ego's needs. In that case, egoism will see to it that striving for the object involves no damage to the ego. It is possible to be egoistic and at the same time to be excessively narcissistic - that is to say, to have very little need for an object, whether, once more, for the purpose of direct sexual satisfaction, or in connection with the higher aspirations, derived from sexual need, which we are occasionally in the habit of contrasting with 'sensuality' under the name of 'love'. In all these connections egoism is what is self-evident and constant, while narcissism is the variable element. The opposite to egoism, *altruism*, does not, as a concept, coincide with libidinal object-cathexis, but is distinguished from it by the absence of longings for sexual satisfaction. When someone is completely in love, however, altruism converges with libidinal object-cathexis. As a rule the sexual object attracts a portion of the ego's narcissism to itself, and this becomes noticeable as what is known as the 'sexual overvaluation' of the object. If in addition there is an altruistic transposition of egoism on to the sexual object, the object becomes supremely powerful; it has, as it were, absorbed the ego.

[1916-1917, 3462]
But I shall resist the temptation of going further here or of discussing other situations which can be understood or pictured if we adopt the hypothesis that the object-libido may withdraw into the ego - for I am obliged to meet two objections which, as I know, are now attracting your attention. In the first place you want to call me to account because in talking of sleep, illness and similar situations I invariably try to separate libido from interest, sexual from ego-instincts, where observations can be fully satisfied by the hypothesis of a single and uniform energy which, being freely mobile, cathects now the object and now the ego, in obedience to one or the other instinct. And in the second place you want to know how I can venture to treat the detaching of the libido from the object as the source of a pathological state, when a transposition of this kind of object-libido into ego-libido (or, more generally, into ego-energy) is among the normal processes of mental dynamics which are repeated daily and every night.

Here is my reply. Your first objection sounds well enough. Consideration of the states of sleep, of illness and of being in love in themselves would probably never have led us to distinguish an ego-libido from an object-libido or libido from interest. But there you are neglecting the investigations from which we started and in the light of which we now look at the mental situations under discussion. The differentiation between libido and interest - that is to say, between the sexual and the self-preservative instincts - was forced upon us by our discovery of the conflict out of which the transference neuroses arise. Since then we cannot give it up. The hypothesis that object-libido can be transformed into ego-libido, that we must therefore take an ego-libido into account, seems to us the only one which is able to resolve the enigma of what are termed the narcissistic neuroses - dementia praecox, for instance - and to account for the resemblances and dissimilarities between them and hysteria or obsessions. We are now applying to illness, sleep and being in love what we have elsewhere found inescapably established. We should proceed further with applications of this kind and see where they will take us to. The only thesis which is not an immediate precipitate of our analytic experience is to the effect that libido remains libido, whether it is directed to objects or to one's own ego, and never turns into egoistic interest, and the converse is also true. This thesis, however, is equivalent to the separation between the sexual and ego-instincts which we have already considered critically and to which we shall continue to hold for heuristic reasons until its possible collapse.

[1916-1917, 3465]
Your second observation, too, raises a justifiable question, but it is aimed in the wrong direction. It is true that a withdrawal of the object-libido into the ego is not directly pathogenic; it takes place, indeed, as we know, every time before we go to sleep, only to be reversed when we wake up. The amoeba withdraws its protrusions only to send them out again at the first opportunity. But it is quite a different thing when a particular, very energetic process forces a withdrawal of libido from objects. Here the libido that has become narcissistic cannot find its way back to objects, and this interference with the libido's mobility certainly becomes pathogenic. It seems that an accumulation of narcissistic libido beyond a certain amount is not tolerated. We may even imagine that it was for that very reason that object-cathexes originally came about, that the ego was obliged to send out its libido so as not to fall ill as a result of its being dammed up. If it lay within our plan to go more deeply into dementia praecox, I would show you that the process which detaches the libido from objects and cuts off its return to them is closely related to the process of repression and is to be looked at as its counterpart. But you would, first and foremost, find yourselves on familiar ground when you learnt that the determinants of this process are almost identical - so far as we know at present - with those of repression. The conflict seems to be the same and to be carried on between the same forces. If the outcome is so different from, for instance, that in hysteria, the reason can only depend on a difference in innate disposition. The weak spot in the libidinal development of these patients lies in a different phase; the determining fixation, which, as you will recollect, permits the irruption that leads to the formation of symptoms, lies elsewhere, probably in the stage of primitive narcissism to which dementia praecox returns in its final outcome. It is very remarkable that in the case of all the narcissistic neuroses we have to assume fixation points for the libido going back to far earlier phases of development than in hysteria or obsessional neurosis. As you heard, however, the concepts which we arrived at during our study of the transference neuroses are adequate in helping us to find our way about in the narcissistic neuroses which are so much more severe in practice. The conformities go very far; at bottom the field of phenomena is the same. And you can imagine how small a prospect anyone has of explaining these disorders (which belong within the sphere of psychiatry) who is not forearmed for his task with an analytic knowledge of the transference neuroses.

I have now led you into the region in which the next advances in the work of analysis are to be expected. Since we have ventured to operate with the concept of ego-libido the narcissistic neuroses have become accessible to us; the task before us is to arrive at a dynamic elucidation of these disorders and at the same time to complete our knowledge of mental life by coming to understand the ego. The ego-psychology after which we are seeking must not be based on the data of our self-perceptions but (as in the case of the libido) on the analysis of disturbances and disruptions of the ego. It is likely that we shall have a low opinion of our present knowledge of the vicissitudes of the libido, which we have gained from a study of the transference neuroses, when we have achieved this greater task. But hitherto we have not made much progress with it. The narcissistic neuroses can scarcely be attacked with the technique that has served us with the transference neuroses. You will soon learn why. What always happens with them is that, after proceeding for a short distance, we come up against a wall which brings us to a stop. Even with the transference neuroses, as you know, we met with barriers of resistance, but we were able to demolish them bit by bit. In the narcissistic neuroses the resistance is unconquerable; at the most, we are able to cast an inquisitive glance over the top of the wall and spy out what is going on on the other side of it. Our technical methods must accordingly be replaced by others; and we do not know yet whether we shall succeed in finding substitute. Nevertheless, we have no lack of material with these patients either. They make a large number of remarks, even if they do not answer our questions, and for the time being it is our business to interpret these remarks with the help of the understanding we have gained from the symptoms of the transference neuroses. The agreement is great enough to guarantee us some initial advantage. It remains to be seen how far this technique will take us.
These are a few of the findings which have hitherto been reached from the application of psycho-analysis to the narcissistic disorders. No doubt there are not yet enough of them and they still lack the precision which can only be attained from established familiarity with a new field. We owe all of them to a use of the concept of ego-libido or narcissistic libido, by whose help we can extend to the narcissistic neuroses the views which have proved their value with the transference neuroses. Now, however, you will ask whether it is possible that we shall succeed in subsuming all the disturbances of the narcissistic illnesses and of the psychoses under the libido theory, whether we look upon the libidinal factor in mental life as universally guilty of the causation of illness, and need never attribute the responsibility for it to changes in the functioning of the self-preservative instinct. Well, Ladies and Gentlemen, this question seems to me to call for no urgent reply, and, above all, not to be ripe for judgement. We can confidently leave it over in expectation of the progress of our scientific work. I should not be surprised if it turned out that the power to produce pathogenic effects was in fact a prerogative of the libidinal instincts, so that the libido theory could celebrate its triumph all along the line from the simplest 'actual' neurosis to the most severe alienation of the personality. We after all know that it is a characteristic feature of the libido that it struggles against submitting to the reality of the universe - to Ananke. But I regard it as extremely probable that the ego-instincts are carried along secondarily by the pathogenic instigation of the libido and forced into functional disturbances. Nor can I think that it would be a disaster to the trend of our researches, if what lies before us is the discovery that in severe psychoses the ego-instincts themselves have gone astray as a primary fact. The future will give the answer - to you, at any rate.

Moreover, a juster appreciation of the process of repression in our present case would lead us to deny that narcissistic masculinity was the sole motive force. The homosexual attitude which came into being during the dream was of such overwhelming intensity that the little boy’s ego found itself unable to cope with it and so defended itself against it by the process of repression. The narcissistic masculinity which attached to his genitals, being opposed to the homosexual attitude, was drawn in, in order to assist the ego in carrying out the task. Merely to avoid misunderstandings, I will add that all narcissistic impulses operate from the ego and have their permanent seat in the ego, and that repressions are directed against libidinal object cathexes.

The condition in which the ego retains the libido is called by us 'narcissism', in reference to the Greek legend of the youth Narcissus who was in love with his own reflection.

It only became possible to extend the libido theory to the narcissistic neuroses after the concept of a ‘narcissistic libido’ had been put forward and applied - a concept, that is, of an amount of sexual energy attached to the ego itself and finding satisfaction in the ego just as satisfaction is usually found only in objects. This entirely legitimate development of the concept of sexuality promises to accomplish as much for the severer neuroses and for the psychoses as can be expected of a theory which is feeling its way forwards on an empirical basis. The traumatic neuroses of peace will also fit into the scheme as soon as a successful outcome has been reached of our investigations into the relations which undoubtedly exist between fright, anxiety and narcissistic libido.
Let us make a bold attempt at another step forward. It is generally considered that the union of a number of cells into a vital association - the multicellular character of organisms - has become a means of prolonging their life. One cell helps to preserve the life of another, and the community of cells can survive even if individual cells have to die. We have already heard that conjugation, too, the temporary coalescence of two unicellular organisms, has a life-preserving and rejuvenating effect on both of them. Accordingly, we might attempt to apply the libido theory which has been arrived at in psycho-analysis to the mutual relationship of cells. We might suppose that the life instincts or sexual instincts which are active in each cell take the other cells as their object, that they partly neutralize the death instincts (that is, the processes set up by them) in those cells and thus preserve their life; while the other cells do the same for them, and still others sacrifice themselves in the performance of this libidinal function. The germ-cells themselves would behave in a completely 'narcissistic' fashion - to use the phrase that we are accustomed to use in the theory of the neuroses to describe a whole individual who retains his libido in his ego and pays none of it out in object-cathexes. The germ-cells require their libido, the activity of their life instincts, for themselves, as a reserve against their later momentous constructive activity. (The cells of the malignant neoplasms which destroy the organism should also perhaps be described as narcissistic in this same sense: pathology is prepared to regard their germs as innate and to ascribe embryonic attributes to them.) In this way the libido of our sexual instincts would coincide with the Eros of the poets and philosophers which holds all living things together.

The next step was taken when psycho-analysis felt its way closer towards the psychological ego, which it had first come to know only as a repressive, censoring agency, capable of erecting protective structures and reactive formations. Critical and far-seeing minds had, it is true, long since objected to the concept of libido being restricted to the energy of the sexual instincts directed towards an object. But they failed to explain how they had arrived at their better knowledge or to derive from it anything of which analysis could make use. Advancing more cautiously, psycho-analysis observed the regularity with which libido is withdrawn from the object and directed on to the ego (the process of introversion); and, by studying the libidinal development of children in its earliest phases, came to the conclusion that the ego is the true and original reservoir of libido, and that it is only from that reservoir that libido is extended on to objects. The ego now found its position among sexual objects and was at once given the foremost place among them. Libido which was in this way lodged in the ego was described as 'narcissistic'.¹ This narcissistic libido was of course also a manifestation of the force of the sexual instinct in the analytical sense of those words, and it had necessarily to be identified with the 'self-preservative instincts' whose existence had been recognized from the first. Thus the original opposition between the ego-instincts and the sexual instincts proved to be inadequate. A portion of the ego-instincts was seen to be libidinal; sexual instincts - probably alongside others - operated in the ego. Nevertheless we are justified in saying that the old formula which lays it down that psychoneuroses are based on a conflict between ego-instincts and sexual instincts contains nothing that we need reject to-day. It is merely that the distinction between the two kinds of instinct, which was originally regarded as in some sort of way qualitative, must now be characterized differently - namely as being topographical. And in particular it is still true that the transference neuroses, the essential subject of psycho-analytic study, are the result of a conflict between the ego and the libidinal cathexis of objects.

¹[1920g, 3751]
Not, however, without the addition of a few words of critical reflection. It may be asked whether and how far I am myself convinced of the truth of the hypotheses that have been set out in these pages. My answer would be that I am not convinced myself and that I do not seek to persuade other people to believe in them. Or, more precisely, that I do not know how far I believe in them. There is no reason, as it seems to me, why the emotional factor of conviction should enter into this question at all. It is surely possible to throw oneself into a line of thought and to follow it wherever it leads out of simple scientific curiosity, or, if the reader prefers, as an advocate diaboli, who is not on that account himself sold to the devil. I do not dispute the fact that the third step in the theory of the instincts, which I have taken here, cannot lay claim to the same degree of certainty as the two earlier ones - the extension of the concept of sexuality and the hypothesis of narcissism. These two innovations were a direct translation of observation into theory and were no more open to sources of error than is inevitable in all such cases. It is true that my assertion of the regressive character of instincts also rests upon observed material - namely on the facts of the compulsion to repeat. It may be, however, that I have overestimated their significance. And in any case it is impossible to pursue an idea of this kind except by repeatedly combining factual material with what is purely speculative and thus diverging widely from empirical observation. The more frequently this is done in the course of constructing a theory, the more untrustworthy, as we know, must be the final result. But the degree of uncertainty is not assignable. One may have made a lucky hit or one may have gone shamefully astray. I do not think a large part is played by what is called 'intuition' in work of this kind. From what I have seen of intuition, it seems to me to be the product of a kind of intellectual impartiality. Unfortunately, however, people are seldom impartial where ultimate things, the great problems of science and life, are concerned. Each of us is governed in such cases by deep-rooted internal prejudices, into whose hands our speculation unwittingly plays. Since we have such good grounds for being distrustful, our attitude towards the results of our own deliberations cannot well be other than one of cool benevolence. I hasten to add, however, that self-criticism such as this is far from binding one to any special tolerance towards dissentient opinions. It is perfectly legitimate to reject remorselessly theories which are contradicted by the very first steps in the analysis of observed facts, while yet being aware at the same time that the validity of one's own theory is only a provisional one.

¹ I will add a few words to clarify our terminology, which has undergone some development in the course of the present work. We came to know what the 'sexual instincts' were from their relation to the sexes and to the reproductive function. We retained this name after we had been obliged by the findings of psychoanalysis to connect them less closely with reproduction. With the hypothesis of narcissistic libido and the extension of the concept of libido to the individual cells, the sexual instinct was transformed for us into Eros, which seeks to force together and hold together the portions of living substance. What are commonly called the sexual instincts are looked upon by us as the part of Eros which is directed towards objects. Our speculations have suggested that Eros operates from the beginning of life and appears as a 'life instinct' in opposition to the 'death instinct' which was brought into being by the coming to life of inorganic substance. These speculations seek to solve the riddle of life by supposing that these two instincts were struggling with each other from the very first. It is not so easy, perhaps, to follow the transformations through which the concept of the 'ego-instincts' has passed. To begin with we applied that name to all the instinctual trends (of which we had no closer knowledge) which could be distinguished from the sexual instincts directed towards an object; and we opposed the ego-instincts to the sexual instincts of which the libido is the manifestation. Subsequently we came to closer grips with the analysis of the ego and recognized that a portion of the 'ego-instincts' is also of a libidinal character and has taken the subject's own ego as its object. These narcissistic self-preservative instincts had thenceforward to be counted among the libidinal sexual instincts. The opposition between the ego-instincts and the sexual instincts was transformed into one between the ego-instincts and the object-instincts, both of a libidinal nature. But in its place a fresh opposition appeared between the libidinal (ego- and object-) instincts and others, which must be presumed to be present in the ego and which may perhaps actually be observed in the destructive instincts. Our speculations have transformed this opposition into one between the life instincts (Eros) and the death instincts.

[1920g, 3759]
The relations of an individual to his parents and to his brothers and sisters, to the object of his love, and to his physician - in fact all the relations which have hitherto been the chief subject of psycho-analytic research - may claim to be considered as social phenomena; and in this respect they may be contrasted with certain other processes, described by us as 'narcissistic', in which the satisfaction of the instincts is partially or totally withdrawn from the influence of other people. The contrast between social and narcissistic - Bleuler would perhaps call them 'autistic' - mental acts therefore falls wholly within the domain of individual psychology, and is not well calculated to differentiate it from a social or group psychology.

Libido is an expression taken from the theory of the emotions. We call by that name the energy, regarded as a quantitative magnitude (though not at present actually measurable), of those instincts which have to do with all that may be comprised under the word 'love'. The nucleus of what we mean by love naturally consists (and this is what is commonly called love, and what the poets sing of) in sexual love with sexual union as its aim. But we do not separate from this - what in any case has a share in the name 'love' - on the one hand, self-love, and on the other, love for parents and children, friendship and love for humanity in general, and also devotion to concrete objects and to abstract ideas. Our justification lies in the fact that psycho-analytic research has taught us that all these tendencies are an expression of the same instinctual impulses; in relations between the sexes these impulses force their way towards sexual union, but in other circumstances they are diverted from this aim or are prevented from reaching it, though always preserving enough of their original nature to keep their identity recognizable (as in such features as the longing for proximity, and self-sacrifice).

Narcissism. - The most important theoretical advance has certainly been the application of the libido theory to the repressing ego. The ego itself came to be regarded as a reservoir of what was described as narcissistic libido, from which the libidinal cathectes of objects flowed out and into which they could be once more withdrawn. By the help of this conception it became possible to embark upon the analysis of the ego and to make a clinical distinction of the psychoneuroses into transference neuroses and narcissistic disorders. In the former (hysteria and obsessional neurosis) the subject has at his disposal a quantity of libido striving to be transferred on to extraneous objects, and use is made of this in carrying out analytic treatment; on the other hand, the narcissistic disorders (dementia praecox, paranoia, melancholia) are characterized by a withdrawal of the libido from objects and they are therefore scarcely accessible to analytic therapy. But their therapeutic inaccessibility has not prevented analysis from making the most fruitful beginnings in the deeper study of these illnesses, which are counted among the psychoses.
Narcissism. - A decisive advance was made when the analysis of dementia praecox and other psychotic disorders was ventured upon and thus the examination was begun of the ego itself, which had so far been known only as the agency of repression and opposition. It was found that the pathogenic process in dementia praecox is the withdrawal of the libido from objects and its introduction into the ego, while the clamorous symptoms of the disease arise from the vain struggles of the libido to find a pathway back to objects. It thus turned out to be possible for object-libido to change into cathexis of the ego and vice versa. Further reflection showed that this process must be presumed to occur on the largest scale and that the ego is to be regarded as a great reservoir of libido from which libido is sent out to objects and which is always ready to absorb libido flowing back from objects. Thus the instincts of self-preservation were also of a libidinal nature: they were sexual instincts which, instead of external objects, had taken the subject's own ego as an object. Clinical experience had made us familiar with people who behaved in a striking fashion as though they were in love with themselves and this perversion had been given the name of narcissism. The libido of the self-preservation instincts was now described as narcissistic libido and it was recognized that a high degree of this self-love constituted the primary and normal state of things. The earlier formula laid down for the transference neuroses consequently required to be modified, though not corrected. It was better, instead of speaking of a conflict between sexual instincts and ego instincts, to speak of a conflict between object-libido and ego-libido, or, since the nature of these instincts was the same, between the object-cathexes and the ego.

This would seem to imply an important amplification of the theory of narcissism. At the very beginning, all the libido is accumulated in the id, while the ego is still in process of formation or is still feeble. The id sends part of this libido out into erotic object-cathexes, whereupon the ego, now grown stronger, tries to get hold of this object-libido and to force itself on the id as a love-object. The narcissism of the ego is thus a secondary one, which has been withdrawn from objects.

Among the hypothetical concepts which enable the doctor to deal with the analytic material, the first to be mentioned is that of 'libido'. Libido means in psycho-analysis in the first instance the force (thought of as quantitatively variable and measurable) of the sexual instincts directed towards an object - 'sexual' in the extended sense required by analytic theory. Further study showed that it was necessary to set alongside this 'object-libido' a 'narcissistic' or 'ego-libido', directed to the subject's own ego; and the interaction of these two forces has enabled us to account for a great number of normal and abnormal processes in mental life. A rough distinction was soon made between what are known as the 'transference neuroses' and the narcissistic disorders. The former (hysteria and obsessional neurosis) are the objects proper of psycho-analytic treatment, while the others, the narcissistic neuroses, though they can, it is true, be examined by the help of analysis, offer fundamental difficulties to therapeutic influence. It is true that the libido theory of psycho-analysis is by no means complete and that its relation to a general theory of the instincts is not yet clear, for psycho-analysis is a young science, quite unfinished and in a stage of rapid development. Here, however, it should be emphatically pointed out how erroneous the charge of pan-sexualism is which is so often levelled at psycho-analysis. It seeks to show that psycho-analytic theory knows of no mental motive forces other than purely sexual ones and in doing so exploits popular prejudices by using the word 'sexual' not in its analytic but in its vulgar sense.
The World War, which broke up so many other organizations, could do nothing against our 'International'. The first meeting after the war took place in 1920, at The Hague, on neutral ground. It was moving to see how hospitably the Dutch welcomed the starving and impoverished subjects of the Central European states; and I believe this was the first occasion in a ruined world on which Englishmen and Germans sat at the same table for the friendly discussion of scientific interests. Both in Germany and in the countries of Western Europe the war had actually stimulated interest in psycho-analysis. The observation of war neuroses had at last opened the eyes of the medical profession to the importance of psychogenesis in neurotic disturbances, and some of our psychological conceptions, such as the 'gain from illness' and the 'flight into illness', quickly became popular. The last Congress before the German collapse, which was held at Budapest in 1918, was attended by official representatives of the allied governments of the Central European powers, and they agreed to the establishment of psycho-analytic Centres for the treatment of war neuroses. But this point was never reached. Similarly too the comprehensive plans made by one of our leading members, Dr. Anton von Freund, for establishing in Budapest a centre for analytic study and treatment came to grief as a result of the political upheavals that followed soon afterwards and of the premature death of their irreplaceable author. At a later date some of his ideas were put into execution by Max Eitingon, who in 1920 founded a psycho-analytical clinic in Berlin. During the brief period of Bolshevik rule in Hungary, Ferenczi was still able to carry on a successful course of instruction as the official representative of psycho-analysis at the University of Budapest. After the war our opponents were pleased to announce that events had produced a conclusive argument against the validity of the theses of analysis. The war neuroses, they said, had proved that sexual factors were unnecessary to the aetiology of neurotic disorders. But their triumph was frivolous and premature. For on the one hand no one had been able to carry out a thorough analysis of a case of war neurosis, so that in fact nothing whatever was known for certain as to their motivation and no conclusions could be drawn from this uncertainty; while on the other hand psycho-analysis had long before arrived at the concept of narcissism and of narcissistic neuroses, in which the subject's libido is attached to his own ego instead of to an object. Though on other occasions, therefore, the charge was brought against psycho-analysis of having made an unjustifiable extension of the concept of sexuality, yet, when it became convenient for controversial ends, this crime was forgotten and we were once more held down to the narrowest meaning of the word.

If the preliminary cathartic period is left on one side, the history of psycho-analysis falls from my point of view into two phases. In the first of these I stood alone and had to do all the work myself: this was from 1895-6 until 1906 or 1907. In the second phase, lasting from then until the present time, the contributions of my pupils and collaborators have been growing more and more in importance, so that to-day, when a grave illness warns me of the approaching end, I can think with a quiet mind of the cessation of my own labours. For that very reason, however, it is impossible for me in this Autobiographical Study to deal as fully with the progress of psycho-analysis during the second phase as I did with its gradual rise during the first phase, which was concerned with my own activity alone. I feel that I should only be justified in mentioning here those new discoveries in which I still played a prominent part, in particular, therefore, those made in the sphere of narcissism, of the theory of the instincts, and of the application of psycho-analysis to the psychoses.

[1925d, 4229]

[1925d, 4230]
In the Oedipus complex the libido was seen to be attached to the image of the parental figures. But earlier there was a period in which there were no such objects. There followed from this fact the concept (of fundamental importance for the libido theory) of a state in which the subject's libido filled his own ego and had that for its object. This state could be called narcissism or self-love. A moment's reflection showed that this state never completely ceases. All through the subject's life his ego remains the great reservoir of his libido, from which object-cathexes are sent out and into which the libido can stream back again from the objects. Thus narcissistic libido is constantly being transformed into object-libido, and vice versa. An excellent instance of the length to which this transformation can go is afforded by the state of being in love, whether in a sexual or sublimated manner, which goes so far as involving a sacrifice of the self. Whereas hitherto in considering the process of repression attention had only been paid to what was repressed, these ideas made it possible to form a correct estimate of the repressing forces too. It had been said that repression was set in action by the instincts of self-preservation operating in the ego (the 'ego-instincts') and that it was brought to bear upon the libidinal instincts. But since the instincts of self-preservation were now recognized as also being of a libidinal nature, as being narcissistic libido, the process of repression was seen to be a process occurring within the libido itself; narcissistic libido was opposed to object-libido, the interest of self-preservation was defending itself against the demands of object-love, and therefore against the demands of sexuality in the narrower sense as well. [1925d, 4231]
The neuroses were the first subject of analysis, and for a long time they were the only one. No analyst could doubt that medical practice was wrong in separating those disorders from the psychoses and in attaching them to the organic nervous diseases. The theory of the neuroses belongs to psychiatry and is indispensable as an introduction to it. It would seem, however, that the analytic study of the psychoses is impracticable owing to its lack of therapeutic results. Mental patients are as a rule without the capacity for forming a positive transference, so that the principal instrument of analytic technique is inapplicable to them. There are nevertheless a number of methods of approach to be found. Transference is often not so completely absent but that it can be used to a certain extent; and analysis has achieved undoubted successes with cyclical depressions, light paranoic modifications, and partial schizophrenias. It has at least been a benefit to science that in many cases the diagnosis can oscillate for quite a long time between assuming the presence of a psychoneurosis or of a dementia praecox; for therapeutic attempts initiated in such cases have resulted in valuable discoveries before they have had to be broken off. But the chief consideration in this connection is that so many things that in the neuroses have to be laboriously fetched up from the depths are found in the psychoses on the surface, visible to every eye. For that reason the best subjects for the demonstration of many of the assertions of analysis are provided by the psychiatric clinic. It was thus bound to happen before long that analysis would find its way to the objects of psychiatric observation. I was able very early (1896) to establish in a case of paranoid dementia the presence of the same aetiological factors and the same emotional complexes as in the neuroses. Jung explained some most puzzling stereotypies in dments by bringing them into relation with the patients' life-histories; Bleuler demonstrated the existence in various psychoses of mechanisms like those which analysis had discovered in neurotics. Since then analysts have never relaxed their efforts to come to an understanding of the psychoses. Especially since it has been possible to work with the concept of narcissism, they have managed, now in this place and now in that, to get a glimpse beyond the wall. Most of all, no doubt, was achieved by Abraham in his elucidation of the melancholias. It is true that in this sphere all our knowledge is not yet converted into therapeutic power; but the mere theoretical gain is not to be despised, and we may be content to wait for its practical application. In the long run even the psychiatrists cannot resist the convincing force of their own clinical material. At the present time German psychiatry is undergoing a kind of 'peaceful penetration' by analytic views. While they continually declare that they will never be psycho-analysts, that they do not belong to the 'orthodox' school or agree with its exaggerations, and in particular that they do not believe in the predominance of the sexual factor, nevertheless the majority of the younger workers take over one piece or another of analytic theory and apply it in their own fashion to the material. All the signs point to the proximity of further developments in the same direction.

[1925d, 4235]
If anxiety is a reaction of the ego to danger, we shall be tempted to regard the traumatic neuroses, which so often follow upon a narrow escape from death, as a direct result of a fear of death (or fear for life) and to dismiss from our minds the question of castration and the dependent relationships of the ego. Most of those who observed the traumatic neuroses that occurred during the last war took this line, and triumphantly announced that proof was now forthcoming that a threat to the instinct of self-preservation could by itself produce a neurosis without any admixture of sexual factors and without requiring any of the complicated hypotheses of psycho-analysis. It is in fact greatly to be regretted that not a single analysis of a traumatic neurosis of any value is extant. And it is to be regretted, not because such an analysis would contradict the aetiological importance of sexuality - for any such contradiction has long since been disposed of by the introduction of the concept of narcissism, which brings the libidinal cathexis of the ego into line with the catheaxes of objects and emphasizes the libidinal character of the instinct of self-preservation - but because, in the absence of any analyses of this kind, we have lost a most precious opportunity of drawing decisive conclusions about the relations between anxiety and the formation of symptoms. In view of all that we know about the structure of the comparatively simple neuroses of everyday life, it would seem highly improbable that a neurosis could come into being merely because of the objective presence of danger, without any participation of the deeper levels of the mental apparatus. But the unconscious seems to contain nothing that could give any content to our concept of the annihilation of life. Castration can be pictured on the basis of the daily experience of the faeces being separated from the body or on the basis of losing the mother's breast at weaning. But nothing resembling death can ever have been experienced; or if it has, as in fainting, it has left no observable traces behind. I am therefore inclined to adhere to the view that the fear of death should be regarded as analogous to the fear of castration and that the situation to which the ego is reacting is one of being abandoned by the protecting super-ego - the powers of destiny - so that it has no longer any safeguard against all the dangers that surround it. In addition, it must be remembered that in the experiences which lead to a traumatic neurosis the protective shield against external stimuli is broken through and excessive amounts of excitation impinge upon the mental apparatus; so that we have here a second possibility - that anxiety is not only being signalled as an affect but is also being freshly created out of the economic conditions of the situation.
[1926d, 4286]
Every analyst will admit that even to-day this view has not the sound of a long-discarded error. Nevertheless, alterations in it became essential, as our enquiries advanced from the repressed to the repressing forces, from the object-instincts to the ego. The decisive step forward was the introduction of the concept of narcissism - that is to say, the discovery that the ego itself is cathected with libido, that the ego, indeed, is the libido's original home, and remains to some extent its headquarters. This narcissistic libido turns towards objects, and thus becomes object-libido; and it can change back into narcissistic libido once more. The concept of narcissism made it possible to obtain an analytic understanding of the traumatic neuroses and of many of the affections bordering on the psychoses, as well as of the latter themselves. It was not necessary to give up our interpretation of the transference neuroses as attempts made by the ego to defend itself against sexuality; but the concept of libido was endangered. Since the ego-instincts, too, were libidinal, it seemed for a time inevitable that we should make libido coincide with instinctual energy in general, as C. G. Jung had already advocated earlier. Nevertheless, there still remained in me a kind of conviction, for which I was not as yet able to find reasons, that the instincts could not all be of the same kind. My next step was taken in *Beyond the Pleasure Principle* (1920g), when the compulsion to repeat and the conservative character of instinctual life first attracted my attention. Starting from speculations on the beginning of life and from biological parallels, I drew the conclusion that, besides the instinct to preserve living substance and to join it into ever larger units,¹ there must exist another, contrary instinct seeking to dissolve those units and to bring them back to their primaeval, inorganic state. That is to say, as well as Eros there was an instinct of death. The phenomena of life could be explained from the concurrent or mutually opposing action of these two instincts. It was not easy, however, to demonstrate the activities of this supposed death instinct. The manifestations of Eros were conspicuous and noisy enough. It might be assumed that the death instinct operated silently within the organism towards its dissolution, but that, of course, was no proof. A more fruitful idea was that a portion of the instinct is diverted towards the external world and comes to light as an instinct of aggressiveness and destructiveness. In this way the instinct itself could be pressed into the service of Eros, in that the organism was destroying some other thing, whether animate or inanimate, instead of destroying its own self. Conversely, any restriction of this aggressiveness directed outwards would be bound to increase the self-destruction, which is in any case proceeding. At the same time one can suspect from this example that the two kinds of instinct seldom - perhaps never - appear in isolation from each other, but are alloyed with each other in varying and very different proportions and so become unrecognizable to our judgement. In sadism, long since known to us as a component instinct of sexuality, we should have before us a particularly strong alloy of this kind between trends of love and the destructive instinct; while its counterpart, masochism, would be a union between destructiveness directed inwards and sexuality - a union which makes what is otherwise an imperceptible trend into a conspicuous and tangible one. [1930a, 4509]
It is now time, however, for me to go back both in history and in my subject-matter and once more to take up the most general problems of instinctual life. To begin with, the opposition between the ego-instincts and the sexual instincts lay at the base of our libido theory. When later on we began to study the ego itself more closely and arrived at the conception of narcissism, this distinction itself lost its foundation. In rare cases one can observe that the ego has taken itself as an object and is behaving as though it were in love with itself. Hence the term 'narcissism', borrowed from the Greek myth. But that is only an extreme exaggeration of a normal state of affairs. We came to understand that the ego is always the main reservoir of libido, from which libidinal cathexes of objects go out and into which they return again, while the major part of this libido remains permanently in the ego. Thus ego-libido is being constantly changed into object-libido and object-libido into ego-libido. But in that case they could not be different in their nature and it could have no sense to distinguish the energy of the one from the energy of the other; we could either drop the term 'libido' or use it as synonymous with psychical energy in general.

[1933a, 4706]
It should be the task of a libido theory of neurotic and psychotic disorders to express all the observed phenomena and inferred processes in terms of the economics of the libido. It is easy to guess that the vicissitudes of the ego-libido will have the major part to play in this connection, especially when it is a question of explaining the deeper psychotic disturbances. We are then faced by the difficulty that our method of research, psycho-analysis, for the moment affords us assured information only on the transformations that take place in the object-libido,¹ but is unable to make any immediate distinction between the ego-libido and the other forms of energy operating in the ego.³

¹ [Footnote added 1915:] Psycho-analysis informs us that there are two methods of finding an object. The first, described in the text, is the ‘anaclitic’ or ‘attachment’ one, based on attachment to early infantile prototypes. The second is the narcissistic one, which seeks for the subject's own ego and finds it again in other people. This latter method is of particularly great importance in cases where the outcome is a pathological one, but it is not relevant to the present context.

² [1905d, 1532]

³ [1905d, 1535]

It is true that during the analysis Hans had to be told many things that he could not say himself, that he had to be presented with thoughts which he had so far shown no signs of possessing, and that his attention had to be turned in the direction from which his father was expecting something to come. This detracts from the evidential value of the analysis; but the procedure is the same in every case. For a psycho-analysis is not an impartial scientific investigation, but a therapeutic measure. Its essence is not to prove anything, but merely to alter something. In a psycho-analysis the physician always gives his patient (sometimes to a greater and some times to a less extent) the conscious anticipatory ideas by the help of which he is put in a position to recognize and to grasp the unconscious material. For there are some patients who need more of such assistance and some who need less; but there are none who get through without some of it. Slight disorders may perhaps be brought to an end by the subject's unaided efforts, but never a neurosis - a thing which has set itself up against the ego as an element alien to it. To get the better of such an element another person must be brought in, and in so far as that other person can be of assistance the neurosis will be curable. If it is in the very nature of any neurosis to turn away from the 'other person' - and this seems to be one of the characteristics of the states grouped together under the name of dementia praecox - then for that very reason such a state will be incurable by any efforts of ours. It is true that a child, on account of the small development of his intellectual systems, requires especially energetic assistance. But, after all, the information which the physician gives his patient is itself derived in its turn from analytical experience; and indeed it is sufficiently convincing if, at the cost of this intervention by the physician, we are enabled to discover the structure of the pathogenic material and simultaneously to dissipate it.

[1909b, 2089]
In my *Three Essays on the Theory of Sexuality* I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics *endeavour to protect themselves against any such sexualization of their social instinctual cathexes*, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) *schizophrenia*; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.

I have proposed that two groups of such primal instincts should be distinguished: the *ego*, or *self-preservative*, instincts and the *sexual* instincts. But this supposition has not the status of a necessary postulate, as has, for instance, our assumption about the biological purpose of the mental apparatus (p. 2960); it is merely a working hypothesis, to be retained only so long as it proves useful, and it will make little difference to the results of our work of description and classification if it is replaced by another. The occasion for this hypothesis arose in the course of the evolution of psycho-analysis, which was first employed upon the psychoneuroses, or, more precisely, upon the group described as 'transference neuroses' (hysteria and obsessional neurosis); these showed that at the root of all such affections there is to be found a conflict between the claims of sexuality and those of the ego. It is always possible that an exhaustive study of the other neurotic affections (especially of the narcissistic psychoneuroses, the schizophrenias) may oblige us to alter this formula and to make a different classification of the primal instincts. But for the present we do not know of any such formula, nor have we met with any argument unfavourable to drawing this contrast between sexual and ego-instincts.

What we have put together in the preceding discussions is probably as much as we can say about the *Ucs*. so long as we only draw upon our knowledge of dream-life and the transference neuroses. It is certainly not much, and at some points it gives an impression of obscurity and confusion; and above all it offers us no possibility of co-ordinating or subsuming the *Ucs*. into any context with which we are already familiar. It is only the analysis of one of the affections which we call narcissistic psychoneuroses that promises to furnish us with conceptions through which the enigmatic *Ucs*. will be brought more within our reach and, as it were, made tangible.
In the case of schizophrenia, on the other hand, we have been driven to the assumption that after the process of repression the libido that has been withdrawn does not seek a new object, but retreats into the ego; that is to say, that here the object-cathexes are given up and a primitive objectless condition of narcissism is re-established. The incapacity of these patients for transference (so far as the pathological process extends), their consequent inaccessibility to therapeutic efforts, their characteristic repudiation of the external world, the appearance of signs of a hypercathexis of their own ego, the final outcome in complete apathy - all these clinical features seem to agree excellently with the assumption that their object-cathexes have been given up. As regards the relation of the two psychical systems to each other, all observers have been struck by the fact that in schizophrenia a great deal is expressed as being conscious which in the transference neuroses can only be shown to be present in the Ucs. by psychoanalysis. But to begin with we were not able to establish any intelligible connection between the ego-object relation and the relationships of consciousness.

[1915e, 3019]

You will ask whether it may not be possible, however, to do justice to the part played by the ego in neurotic states and in the formation of symptoms without at the same time grossly neglecting the factors revealed by psycho-analysis. My reply is that that must certainly be possible and will sooner or later be done; but the road followed by the work of psycho-analysis does not admit of actually beginning with this. It is of course possible to foresee when psycho-analysis will be confronted by this task. There are neuroses in which the ego plays a far more intensive part than in those we have studied hitherto; we call them the 'narcissistic' neuroses. The investigation of these disorders will enable us to form an impartial and trustworthy judgement of the share taken by the ego in the onset of neuroses.

[1916-1917, 3434]

We began at an early date to extend psycho-analytic observations to these other illnesses. Already in 1908 Karl Abraham, after an exchange of thoughts with me, pronounced the main characteristic of dementia praecox (which was reckoned among the psychoses) to be that in it the libidinal cathexis of objects was lacking. But the question then arose of what happened to the libido of dementia praecox patients which was turned away from objects. Abraham did not hesitate to give the answer: it is turned back on to the ego and this reflexive turning-back is the source of the megalomania in dementia praecox. Megalomania is in every way comparable to the familiar sexual overvaluation of the object in erotic life. In this way for the first time we learnt to understand a trait in a psychotic illness by relating it to normal erotic life.

[1916-1917, 3461]

I may tell you at once that these first explanations of Abraham's have been accepted in psycho-analysis and have become the basis of our attitude to the psychoses. We thus slowly became familiar with the notion that the libido, which we find attached to objects and which is the expression of an effort to obtain satisfaction in connection with those objects, can also leave the objects and set the subject's own ego in their place; and this notion was gradually built up more and more consistently. The name for this way of allocating the libido - 'narcissism' - was borrowed by us from a perversion described by Paul Näcke in which an adult treats his own body with all the caresses that are usually devoted to an outside sexual object.

[1916-1917, 3461]
But I shall resist the temptation of going further here or of discussing other situations which can be understood or pictured if we adopt the hypothesis that the object-libido may withdraw into the ego - for I am obliged to meet two objections which, as I know, are now attracting your attention. In the first place you want to call me to account because in talking of sleep, illness and similar situations I invariably try to separate libido from interest, sexual from ego-instincts, where observations can be fully satisfied by the hypothesis of a single and uniform energy which, being freely mobile, cathects now the object and now the ego, in obedience to one or the other instinct. And in the second place you want to know how I can venture to treat the detaching of the libido from the object as the source of a pathological state, when a transposition of this kind of object-libido into ego-libido (or, more generally, into ego-energy) is among the normal processes of mental dynamics which are repeated daily and every night.

Here is my reply. Your first objection sounds well enough. Consideration of the states of sleep, of illness and of being in love in themselves would probably never have led us to distinguish an ego-libido from an object-libido or libido from interest. But there you are neglecting the investigations from which we started and in the light of which we now look at the mental situations under discussion. The differentiation between libido and interest - that is to say, between the sexual and the self-preservative instincts - was forced upon us by our discovery of the conflict out of which the transference neuroses arise. Since then we cannot give it up. The hypothesis that object-libido can be transformed into ego-libido, that we must therefore take an ego-libido into account, seems to us the only one which is able to resolve the enigma of what are termed the narcissistic neuroses - dementia praecox, for instance - and to account for the resemblances and dissimilarities between them and hysteria or obsessions. We are now applying to illness, sleep and being in love what we have elsewhere found inescapably established. We should proceed further with applications of this kind and see where they will take us to. The only thesis which is not an immediate precipitate of our analytic experience is to the effect that libido remains libido, whether it is directed to objects or to one's own ego, and never turns into egoistic interest, and the converse is also true. This thesis, however, is equivalent to the separation between the sexual and ego-instincts which we have already considered critically and to which we shall continue to hold for heuristic reasons until its possible collapse.

[1916-1917, 3465]
Your second observation, too, raises a justifiable question, but it is aimed in the wrong direction. It is true that a withdrawal of the object-libido into the ego is not directly pathogenic; it takes place, indeed, as we know, every time before we go to sleep, only to be reversed when we wake up. The amoeba withdraws its protrusions only to send them out again at the first opportunity. But it is quite a different thing when a particular, very energetic process forces a withdrawal of libido from objects. Here the libido that has become narcissistic cannot find its way back to objects, and this interference with the libido's mobility certainly becomes pathogenic. It seems that an accumulation of narcissistic libido beyond a certain amount is not tolerated. We may even imagine that it was for that very reason that object-cathexes originally came about, that the ego was obliged to send out its libido so as not to fall ill as a result of its being dammed up. If it lay within our plan to go more deeply into dementia praecox, I would show you that the process which detaches the libido from objects and cuts off its return to them is closely related to the process of repression and is to be looked at as its counterpart. But you would, first and foremost, find yourselves on familiar ground when you learnt that the determinants of this process are almost identical - so far as we know at present - with those of repression. The conflict seems to be the same and to be carried on between the same forces. If the outcome is so different from, for instance, that in hysteria, the reason can only depend on a difference in innate disposition. The weak spot in the libidinal development of these patients lies in a different phase; the determining fixation, which, as you will recollect, permits the irruption that leads to the formation of symptoms, lies elsewhere, probably in the stage of primitive narcissism to which dementia praecox returns in its final outcome. It is very remarkable that in the case of all the narcissistic neuroses we have to assume fixation points for the libido going back to far earlier phases of development than in hysteria or obsessional neurosis. As you heard, however, the concepts which we arrived at during our study of the transference neuroses are adequate in helping us to find our way about in the narcissistic neuroses which are so much more severe in practice. The conformities go very far; at bottom the field of phenomena is the same. And you can imagine how small a prospect anyone has of explaining these disorders (which belong within the sphere of psychiatry) who is not forearmed for his task with an analytic knowledge of the transference neuroses.

[1916-1917, 3466]

The clinical picture of dementia praecox (which, incidentally, is very changeable) is not determined exclusively by the symptoms arising from the forcing away of the libido on objects and its accumulation in the ego as narcissistic libido. A large part, rather, is played by other phenomena, which are derived from efforts of the libido to attain objects once more and which thus correspond to an attempt at restitution or recovery. These latter symptoms are indeed the more striking and noisy; they exhibit an undeniable resemblance to those of hysteria or, less frequently, of obsessional neurosis, but nevertheless differ from them in every respect. It seems as though in dementia praecox the libido, in its efforts once more to reach objects (that is, the presentations of objects), does in fact snatch hold something of them, but, as it were, only their shadows - I mean the word-presentations belonging to them. I cannot say more about this now, but I believe that this behaviour of the libido as it strives to find its way back has enabled us to obtain an insight into what really constitutes the difference between a conscious and an unconscious idea.

[1916-1917, 3466]
These are a few of the findings which have hitherto been reached from the application of psycho-analysis to the narcissistic disorders. No doubt there are not yet enough of them and they still lack the precision which can only be attained from established familiarity with a new field. We owe all of them to a use of the concept of ego-libido or narcissistic libido, by whose help we can extend to the narcissistic neuroses the views which have proved their value with the transference neuroses. Now, however, you will ask whether it is possible that we shall succeed in subsuming all the disturbances of the narcissistic illnesses and of the psychoses under the libido theory, whether we look upon the libidinal factor in mental life as universally guilty of the causation of illness, and need never attribute the responsibility for it to changes in the functioning of the self-preservative instinct. Well, Ladies and Gentlemen, this question seems to me to call for no urgent reply, and, above all, not to be ripe for judgement. We can confidently leave it over in expectation of the progress of our scientific work. I should not be surprised if it turned out that the power to produce pathogenic effects was in fact a prerogative of the libidinal instincts, so that the libido theory could celebrate its triumph all along the line from the simplest 'actual' neurosis to the most severe alienation of the personality. We after all know that it is a characteristic feature of the libido that it struggles against submitting to the reality of the universe - to Ananke. But I regard it as extremely probable that the ego-instincts are carried along secondarily by the pathogenic instigation of the libido and forced into functional disturbances. Nor can I think that it would be a disaster to the trend of our researches, if what lies before us is the discovery that in severe psychoses the ego-instincts themselves have gone astray as a primary fact. The future will give the answer - to you, at any rate.

[1916-1917, 3473]

On the basis of our clinical impressions we maintained that these patients' object-cathexes must have been given up and that their object-libido must have been transformed into ego-libido. Through this characteristic we distinguished them from the first group of neurotics (sufferers from hysteria, anxiety-hysteria and obsessional neurosis). This suspicion is now confirmed by their behaviour in our attempts at therapy. They manifest no transference and for that reason are inaccessible to our efforts and cannot be cured by us.

[1916-1917, 3489]

The acceptance of suggestions on individual points is no doubt discouraged by the fact that during the treatment we are struggling unceasingly against resistances which are able to transform themselves into negative (hostile) transferences. Nor must we fail to point out that a large number of the individual findings of analysis, which might otherwise be suspected to being products of suggestion, are confirmed from another and irreproachable source. Our guarantors in this case are the sufferers from dementia praecox and paranoia, who are of course far above any suspicion of being influenced by suggestion. The translations of symbols and the phantasies, which these patients produce for us and which in them have forced their way through into consciousness, coincide faithfully with the results of our investigations into the unconscious of transference neurotics and thus confirm the objective correctness of our interpretations, on which doubt is so often thrown. You will not, I think, be going astray if you trust analysis on these points.

[1916-1917, 3493]
It only became possible to extend the libido theory to the narcissistic neuroses after the concept of a 'narcissistic libido' had been put forward and applied - a concept, that is, of an amount of sexual energy attached to the ego itself and finding satisfaction in the ego just as satisfaction is usually found only in objects. This entirely legitimate development of the concept of sexuality promises to accomplish as much for the severer neuroses and for the psychoses as can be expected of a theory which is feeling its way forwards on an empirical basis. The traumatic neuroses of peace will also fit into the scheme as soon as a successful outcome has been reached of our investigations into the relations which undoubtedly exist between fright, anxiety and narcissistic libido.

[1919d, 3667]

Narcissism. - The most important theoretical advance has certainly been the application of the libido theory to the repressing ego. The ego itself came to be regarded as a reservoir of what was described as narcissistic libido, from which the libidinal cathexes of objects flowed out and into which they could be once more withdrawn. By the help of this conception it became possible to embark upon the analysis of the ego and to make a clinical distinction of the psychoneuroses into transference neuroses and narcissistic disorders. In the former (hysteria and obsessional neurosis) the subject has at his disposal a quantity of libido striving to be transferred on to extraneous objects, and use is made of this in carrying out analytic treatment; on the other hand, the narcissistic disorders (dementia praecox, paranoia, melancholia) are characterized by a withdrawal of the libido from objects and they are therefore scarcely accessible to analytic therapy. But their therapeutic inaccessibility has not prevented analysis from making the most fruitful beginnings in the deeper study of these illnesses, which are counted among the psychoses.

[1923a, 3925]

Narcissism. - A decisive advance was made when the analysis of dementia praecox and other psychotic disorders was ventured upon and thus the examination was begun of the ego itself, which had so far been known only as the agency of repression and opposition. It was found that the pathogenic process in dementia praecox is the withdrawal of the libido from objects and its introduction into the ego, while the clamorous symptoms of the disease arise from the vain struggles of the libido to find a pathway back to objects. It thus turned out to be possible for object-libido to change into cathexis of the ego and vice versa. Further reflection showed that this process must be presumed to occur on the largest scale and that the ego is to be regarded as a great reservoir of libido from which libido is sent out to objects and which is always ready to absorb libido flowing back from objects. Thus the instincts of self-preservation were also of a libidinal nature: they were sexual instincts which, instead of external objects, had taken the subject's own ego as an object. Clinical experience had made us familiar with people who behaved in a striking fashion as though they were in love with themselves and this perversion had been given the name of narcissism. The libido of the self-preservative instincts was now described as narcissistic libido and it was recognized that a high degree of this self-love constituted the primary and normal state of things. The earlier formula laid down for the transference neuroses consequently required to be modified, though not corrected. It was better, instead of speaking of a conflict between sexual instincts and ego instincts, to speak of a conflict between object-libido and ego-libido, or, since the nature of these instincts was the same, between the object-cathexes and the ego.

[1923a, 3933]
The World War, which broke up so many other organizations, could do nothing against our 'International'. The first meeting after the war took place in 1920, at The Hague, on neutral ground. It was moving to see how hospitably the Dutch welcomed the starving and impoverished subjects of the Central European states; and I believe this was the first occasion in a ruined world on which Englishmen and Germans sat at the same table for the friendly discussion of scientific interests. Both in Germany and in the countries of Western Europe the war had actually stimulated interest in psycho-analysis. The observation of war neuroses had at last opened the eyes of the medical profession to the importance of psychogenesis in neurotic disturbances, and some of our psychological conceptions, such as the 'gain from illness' and the 'flight into illness', quickly became popular. The last Congress before the German collapse, which was held at Budapest in 1918, was attended by official representatives of the allied governments of the Central European powers, and they agreed to the establishment of psycho-analytic Centres for the treatment of war neuroses. But this point was never reached. Similarly too the comprehensive plans made by one of our leading members, Dr. Anton von Freund, for establishing in Budapest a centre for analytic study and treatment came to grief as a result of the political upheavals that followed soon afterwards and of the premature death of their irreplaceable author. At a later date some of his ideas were put into execution by Max Eitingon, who in 1920 founded a psycho-analytical clinic in Berlin. During the brief period of Bolshevik rule in Hungary, Ferenczi was still able to carry on a successful course of instruction as the official representative of psycho-analysis at the University of Budapest. After the war our opponents were pleased to announce that events had produced a conclusive argument against the validity of the theses of analysis. The war neuroses, they said, had proved that sexual factors were unnecessary to the aetiology of neurotic disorders. But their triumph was frivolous and premature. For on the one hand no one had been able to carry out a thorough analysis of a case of war neurosis, so that in fact nothing whatever was known for certain as to their motivation and no conclusions could be drawn from this uncertainty; while on the other hand psycho-analysis had long before arrived at the concept of narcissism and of narcissistic neuroses, in which the subject's libido is attached to his own ego instead of to an object. Though on other occasions, therefore, the charge was brought against psycho-analysis of having made an unjustifiable extension of the concept of sexuality, yet, when it became convenient for controversial ends, this crime was forgotten and we were once more held down to the narrowest meaning of the word.

[1925d, 4229]
Every analyst will admit that even to-day this view has not the sound of a long-discarded error. Nevertheless, alterations in it became essential, as our enquiries advanced from the repressed to the repressing forces, from the object-instincts to the ego. The decisive step forward was the introduction of the concept of narcissism - that is to say, the discovery that the ego itself is cathected with libido, that the ego, indeed, is the libido's original home, and remains to some extent its headquarters. This narcissistic libido turns towards objects, and thus becomes object-libido; and it can change back into narcissistic libido once more. The concept of narcissism made it possible to obtain an analytic understanding of the traumatic neuroses and of many of the affections bordering on the psychoses, as well as of the latter themselves. It was not necessary to give up our interpretation of the transference neuroses as attempts made by the ego to defend itself against sexuality; but the concept of libido was endangered. Since the ego-instincts, too, were libidinal, it seemed for a time inevitable that we should make libido coincide with instinctual energy in general, as C. G. Jung had already advocated earlier. Nevertheless, there still remained in me a kind of conviction, for which I was not as yet able to find reasons, that the instincts could not all be of the same kind. My next step was taken in *Beyond the Pleasure Principle* (1920), when the compulsion to repeat and the conservative character of instinctual life first attracted my attention. Starting from speculations on the beginning of life and from biological parallels, I drew the conclusion that, besides the instinct to preserve living substance and to join it into ever larger units,¹ there must exist another, contrary instinct seeking to dissolve those units and to bring them back to their primaeval, inorganic state. That is to say, as well as Eros there was an instinct of death. The phenomena of life could be explained from the concurrent or mutually opposing action of these two instincts. It was not easy, however, to demonstrate the activities of this supposed death instinct. The manifestations of Eros were conspicuous and noisy enough. It might be assumed that the death instinct operated silently within the organism towards its dissolution, but that, of course, was no proof. A more fruitful idea was that a portion of the instinct is diverted towards the external world and comes to light as an instinct of aggressiveness and destructiveness. In this way the instinct itself could be pressed into the service of Eros, in that the organism was destroying some other thing, whether animate or inanimate, instead of destroying its own self. Conversely, any restriction of this aggressiveness directed outwards would be bound to increase the self-destruction, which is in any case proceeding. At the same time one can suspect from this example that the two kinds of instinct seldom - perhaps never - appear in isolation from each other, but are alloyed with each other in varying and very different proportions and so become unrecognizable to our judgement. In sadism, long since known to us as a component instinct of sexuality, we should have before us a particularly strong alloy of this kind between trends of love and the destructive instinct; while its counterpart, masochism, would be a union between destructiveness directed inwards and sexuality - a union which makes what is otherwise an imperceptible trend into a conspicuous and tangible one.

[1930a, 4509]
Of the two kinds of regression of the libido, that to an earlier phase of the sexual organization is by far the more striking. Since this is absent in hysteria, and since our whole view of the neuroses is still far too much under the influence of the study of hysteria, which was chronologically the first, the significance of libidinal regression also became clear to us far later than that of repression. We must be prepared to find that our views will be subjected to still further extensions and revaluations when we are able to take into consideration not only hysteria and obsessional neurosis but also the other, narcissistic neuroses.

[1916-1917, 3406]

Your second observation, too, raises a justifiable question, but it is aimed in the wrong direction. It is true that a withdrawal of the object-libido into the ego is not directly pathogenic; it takes place, indeed, as we know, every time before we go to sleep, only to be reversed when we wake up. The amoeba withdraws its protrusions only to send them out again at the first opportunity. But it is quite a different thing when a particular, very energetic process forces a withdrawal of libido from objects. Here the libido that has become narcissistic cannot find its way back to objects, and this interference with the libido's mobility certainly becomes pathogenic. It seems that an accumulation of narcissistic libido beyond a certain amount is not tolerated. We may even imagine that it was for that very reason that object-cathexes originally came about, that the ego was obliged to send out its libido so as not to fall ill as a result of its being dammed up. If it lay within our plan to go more deeply into dementia praecox, I would show you that the process which detaches the libido from objects and cuts off its return to them is closely related to the process of repression and is to be looked at as its counterpart. But you would, first and foremost, find yourselves on familiar ground when you learnt that the determinants of this process are almost identical - so far as we know at present - with those of repression. The conflict seems to be the same and to be carried on between the same forces. If the outcome is so different from, for instance, that in hysteria, the reason can only depend on a difference in innate disposition. The weak spot in the libidinal development of these patients lies in a different phase; the determining fixation, which, as you will recollect, permits the irruption that leads to the formation of symptoms, lies elsewhere, probably in the stage of primitive narcissism to which dementia praecox returns in its final outcome. It is very remarkable that in the case of all the narcissistic neuroses we have to assume fixation points for the libido going back to far earlier phases of development than in hysteria or obsessional neurosis. As you heard, however, the concepts which we arrived at during our study of the transference neuroses are adequate in helping us to find our way about in the narcissistic neuroses which are so much more severe in practice. The conformities go very far; at bottom the field of phenomena is the same. And you can imagine how small a prospect anyone has of explaining these disorders (which belong within the sphere of psychiatry) who is not forearmed for his task with an analytic knowledge of the transference neuroses.

[1916-1917, 3466]
I have now led you into the region in which the next advances in the work of analysis are to be expected. Since we have ventured to operate with the concept of ego-libido the narcissistic neuroses have become accessible to us; the task before us is to arrive at a dynamic elucidation of these disorders and at the same time to complete our knowledge of mental life by coming to understand the ego. The ego-psychology after which we are seeking must not be based on the data of our self-perceptions but (as in the case of the libido) on the analysis of disturbances and disruptions of the ego. It is likely that we shall have a low opinion of our present knowledge of the vicissitudes of the libido, which we have gained from a study of the transference neuroses, when we have achieved this greater task. But hitherto we have not made much progress with it. The narcissistic neuroses can scarcely be attacked with the technique that has served us with the transference neuroses. You will soon learn why. What always happens with them is that, after proceeding for a short distance, we come up against a wall which brings us to a stop. Even with the transference neuroses, as you know, we met with barriers of resistance, but we were able to demolish them bit by bit. In the narcissistic neuroses the resistance is unconquerable; at the most, we are able to cast an inquisitive glance over the top of the wall and spy out what is going on on the other side of it. Our technical methods must accordingly be replaced by others; and we do not know yet whether we shall succeed in finding substitute. Nevertheless, we have no lack of material with these patients either. They make a large number of remarks, even if they do not answer our questions, and for the time being it is our business to interpret these remarks with the help of the understanding we have gained from the symptoms of the transference neuroses. The agreement is great enough to guarantee us some initial advantage. It remains to be seen how far this technique will take us.

[1916-1917, 3467]

On the basis of our clinical impressions we maintained that these patients’ object-cathexes must have been given up and that their object-libido must have been transformed into ego-libido. Through this characteristic we distinguished them from the first group of neurotics (sufferers from hysteria, anxiety-hysteria and obsessional neurosis). This suspicion is now confirmed by their behaviour in our attempts at therapy. They manifest no transference and for that reason are inaccessible to our efforts and cannot be cured by us.

[1916-1917, 3489]

Apart from this, the war neuroses are only traumatic neuroses, which, as we know, occur in peace-time too after frightening experiences or severe accidents, without any reference to a conflict in the ego.

[1919d, 3667]

Narcissism. - The most important theoretical advance has certainly been the application of the libido theory to the repressing ego. The ego itself came to be regarded as a reservoir of what was described as narcissistic libido, from which the libidinal cathexes of objects flowed out and into which they could be once more withdrawn. By the help of this conception it became possible to embark upon the analysis of the ego and to make a clinical distinction of the psychoneuroses into transference neuroses and narcissistic disorders. In the former (hysteria and obsessional neurosis) the subject has at his disposal a quantity of libido striving to be transferred on to extraneous objects, and use is made of this in carrying out analytic treatment; on the other hand, the narcissistic disorders (dementia praecox, paranoia, melancholia) are characterized by a withdrawal of the libido from objects and they are therefore scarcely accessible to analytic therapy. But their therapeutic inaccessibility has not prevented analysis from making the most fruitful beginnings in the deeper study of these illnesses, which are counted among the psychoses.

[1923a, 3925]
The psycho-analytic view would also have to include in narcissistic disorders all the ailments described in psychiatry as 'functional psychoses'. It could not be doubted that neuroses and psychoses are not separated by a hard and fast line, any more than health and neurosis; and it was plausible to explain the mysterious psychotic phenomena by the discoveries achieved on the neuroses, which had hitherto been equally incomprehensible. The present writer had himself, during the period of his isolation, made a case of paranoid illness partly intelligible by an analytic investigation and had pointed out in this unquestionable psychosis the same contents (complexes) and a similar interplay of forces as in the simple neuroses. Bleuler followed out the indications of what he called 'Freudian mechanisms' in a whole number of psychoses, and Jung won high opinions as an analyst at a single blow when, in 1907, he explained the most eccentric symptoms in the end-stages of dementia praecox from the individual life-histories of the patients. The comprehensive study of schizophrenia by Bleuler (1911) probably demonstrated once and for all the justification of a psycho-analytic angle of approach for the understanding of these psychoses.

The World War, which broke up so many other organizations, could do nothing against our 'International'. The first meeting after the war took place in 1920, at The Hague, on neutral ground. It was moving to see how hospitably the Dutch welcomed the starving and impoverished subjects of the Central European states; and I believe this was the first occasion in a ruined world on which Englishmen and Germans sat at the same table for the friendly discussion of scientific interests. Both in Germany and in the countries of Western Europe the war had actually stimulated interest in psycho-analysis. The observation of war neuroses had at last opened the eyes of the medical profession to the importance of psychogenesis in neurotic disturbances, and some of our psychological conceptions, such as the 'gain from illness' and the 'flight into illness', quickly became popular. The last Congress before the German collapse, which was held at Budapest in 1918, was attended by official representatives of the allied governments of the Central European powers, and they agreed to the establishment of psycho-analytic Centres for the treatment of war neuroses. But this point was never reached. Similarly too the comprehensive plans made by one of our leading members, Dr. Anton von Freund, for establishing in Budapest a centre for analytic study and treatment came to grief as a result of the political upheavals that followed soon afterwards and of the premature death of their irreplaceable author. At a later date some of his ideas were put into execution by Max Eitingon, who in 1920 founded a psycho-analytical clinic in Berlin. During the brief period of Bolshevik rule in Hungary, Ferenczi was still able to carry on a successful course of instruction as the official representative of psycho-analysis at the University of Budapest. After the war our opponents were pleased to announce that events had produced a conclusive argument against the validity of the theses of analysis. The war neuroses, they said, had proved that sexual factors were unnecessary to the aetiology of neurotic disorders. But their triumph was frivolous and premature. For on the one hand no one had been able to carry out a thorough analysis of a case of war neurosis, so that in fact nothing whatever was known for certain as to their motivation and no conclusions could be drawn from this uncertainty; while on the other hand psycho-analysis had long before arrived at the concept of narcissism and of narcissistic neuroses, in which the subject's libido is attached to his own ego instead of to an object. Though on other occasions, therefore, the charge was brought against psycho-analysis of having made an unjustifiable extension of the concept of sexuality, yet, when it became convenient for controversial ends, this crime was forgotten and we were once more held down to the narrowest meaning of the word.

[1924f, 4114]

[1925d, 4229]
We can follow the object-libido through still further vicissitudes. When it is withdrawn from objects, it is held in suspense in peculiar conditions of tension and is finally drawn back into the ego, so that it becomes ego-libido once again. In contrast to object-libido, we also describe ego-libido as 'narcissistic' libido. From the vantage-point of psycho-analysis we can look across a frontier, which we may not pass, at the activities of narcissistic libido, and may form some idea of the relation between it and object-libido.¹ Narcissistic or ego-libido seems to be the great reservoir from which the object-cathexes are sent out and into which they are withdrawn once more; the narcissistic libidinal cathexis of the ego is the original state of things, realized in earliest childhood, and is merely covered by the later extrusions of libido, but in essentials persists behind them.

¹ [Footnote added 1924:] Since neuroses other than the transference neuroses have become to a greater extent accessible to psycho-analysis, this limitation has lost its earlier validity.

Certain special difficulties seem to me to lie in the way of a direct study of narcissism. Our chief means of access to it will probably remain the analysis of the paraphrenias. Just as the transference neuroses have enabled us to trace the libidinal instinctual impulses, so dementia praecox and paranoia will give us an insight into the psychology of the ego. Once more, in order to arrive at an understanding of what seems so simple in normal phenomena, we shall have to turn to the field of pathology with its distortions and exaggerations. At the same time, other means of approach remain open to us, by which we may obtain a better knowledge of narcissism. These I shall now discuss in the following order: the study of organic disease, of hypochondria and of the erotic life of the sexes.

I have now led you into the region in which the next advances in the work of analysis are to be expected. Since we have ventured to operate with the concept of ego-libido the narcissistic neuroses have become accessible to us; the task before us is to arrive at a dynamic elucidation of these disorders and at the same time to complete our knowledge of mental life by coming to understand the ego. The ego-psychology after which we are seeking must not be based on the data of our self-perceptions but (as in the case of the libido) on the analysis of disturbances and disruptions of the ego. It is likely that we shall have a low opinion of our present knowledge of the vicissitudes of the libido, which we have gained from a study of the transference neuroses, when we have achieved this greater task. But hitherto we have not made much progress with it. The narcissistic neuroses can scarcely be attacked with the technique that has served us with the transference neuroses. You will soon learn why. What always happens with them is that, after proceeding for a short distance, we come up against a wall which brings us to a stop. Even with the transference neuroses, as you know, we met with barriers of resistance, but we were able to demolish them bit by bit. In the narcissistic neuroses the resistance is unconquerable; at the most, we are able to cast an inquisitive glance over the top of the wall and spy out what is going on on the other side of it. Our technical methods must accordingly be replaced by others; and we do not know yet whether we shall succeed in finding substitute. Nevertheless, we have no lack of material with these patients either. They make a large number of remarks, even if they do not answer our questions, and for the time being it is our business to interpret these remarks with the help of the understanding we have gained from the symptoms of the transference neuroses. The agreement is great enough to guarantee us some initial advantage. It remains to be seen how far this technique will take us.

¹ [Footnote added 1924:] Since neuroses other than the transference neuroses have become to a greater extent accessible to psycho-analysis, this limitation has lost its earlier validity.

[1905d, 1532]

[1905d, 1532]

[1914c, 2938]

[1916-1917, 3467]
There are difficulties in addition which hold up our advance. The narcissistic disorders and the psychoses related to them can only be deciphered by observers who have been trained through the analytic study of the transference neuroses. But our psychiatrists are not students of psycho-analysis and we psycho-analysts see too few psychiatric cases. A race of psychiatrists must first grow up who have passed through the school of psycho-analysis as a preparatory science. A start in that direction is now being made in America, where very many leading psychiatrists lecture to students on the theories of psycho-analysis and where the proprietors of institutions and the directors of insane asylums endeavour to observe their patients in conformity with those theories. Nevertheless we too, over here, have succeeded sometimes in casting a glance over the narcissistic wall and in what follows I shall tell you a little of what we think we have detected.
[1916-1917, 3467]

Apart from this, the war neuroses are only traumatic neuroses, which, as we know, occur in peace-time too after frightening experiences or severe accidents, without any reference to a conflict in the ego.
[1919d, 3667]

*Narcissism.* - The most important theoretical advance has certainly been the application of the libido theory to the repressing ego. The ego itself came to be regarded as a reservoir of what was described as narcissistic libido, from which the libidinal catheces of objects flowed out and into which they could be once more withdrawn. By the help of this conception it became possible to embark upon the analysis of the ego and to make a clinical distinction of the psychoneuroses into *transference neuroses* and *narcissistic disorders*. In the former (hysteria and obsessional neurosis) the subject has at his disposal a quantity of libido striving to be transferred on to extraneous objects, and use is made of this in carrying out analytic treatment; on the other hand, the narcissistic disorders (dementia praecox, paranoia, melancholia) are characterized by a withdrawal of the libido from objects and they are therefore scarcely accessible to analytic therapy. But their therapeutic inaccessibility has not prevented analysis from making the most fruitful beginnings in the deeper study of these illnesses, which are counted among the psychoses.
[1923a, 3925]
The neuroses were the first subject of analysis, and for a long time they were the only one. No analyst could doubt that medical practice was wrong in separating those disorders from the psychoses and in attaching them to the organic nervous diseases. The theory of the neuroses belongs to psychiatry and is indispensable as an introduction to it. It would seem, however, that the analytic study of the psychoses is impracticable owing to its lack of therapeutic results. Mental patients are as a rule without the capacity for forming a positive transference, so that the principal instrument of analytic technique is inapplicable to them. There are nevertheless a number of methods of approach to be found. Transference is often not so completely absent but that it can be used to a certain extent; and analysis has achieved undoubted successes with cyclical depressions, light paranoic modifications, and partial schizophrenias. It has at least been a benefit to science that in many cases the diagnosis can oscillate for quite a long time between assuming the presence of a psychoneurosis or of a dementia praecox; for therapeutic attempts initiated in such cases have resulted in valuable discoveries before they have had to be broken off. But the chief consideration in this connection is that so many things that in the neuroses have to be laboriously fetched up from the depths are found in the psychoses on the surface, visible to every eye. For that reason the best subjects for the demonstration of many of the assertions of analysis are provided by the psychiatric clinic. It was thus bound to happen before long that analysis would find its way to the objects of psychiatric observation. I was able very early (1896) to establish in a case of paranoid dementia the presence of the same aetiological factors and the same emotional complexes as in the neuroses. Jung explained some most puzzling stereotypies in dementia by bringing them into relation with the patients' life-histories; Bleuler demonstrated the existence in various psychoses of mechanisms like those which analysis had discovered in neurotics. Since then analysts have never relaxed their efforts to come to an understanding of the psychoses. Especially since it has been possible to work with the concept of narcissism, they have managed, now in this place and now in that, to get a glimpse beyond the wall. Most of all, no doubt, was achieved by Abraham in his elucidation of the melancholias. It is true that in this sphere all our knowledge is not yet converted into therapeutic power; but the mere theoretical gain is not to be despised, and we may be content to wait for its practical application. In the long run even the psychiatrists cannot resist the convincing force of their own clinical material. At the present time German psychiatry is undergoing a kind of 'peaceful penetration' by analytic views. While they continually declare that they will never be psycho-analysts, that they do not belong to the 'orthodox' school or agree with its exaggerations, and in particular that they do not believe in the predominance of the sexual factor, nevertheless the majority of the younger workers take over one piece or another of analytic theory and apply it in their own fashion to the material. All the signs point to the proximity of further developments in the same direction.

[1925d, 4235]
Spitta (1882, 199), in much the same way as Maury (1854), enumerates as follows the different points of agreement which constitute the basis for this comparison: '(1) Self-consciousness is suspended or at least retarded, which results in a lack of insight into the nature of the condition, with consequent inability to feel surprise and loss of moral consciousness. (2) Perception by the sense organs is modified: being diminished in dreams but as a rule greatly increased in insanity. (3) Interconnection of ideas occurs exclusively according to the laws of association and reproduction; ideas thus fall into sequences automatically and there is a consequent lack of proportion in the relation between ideas (exaggerations and illusions). All this leads to (4) an alteration or in some cases a reversal of personality and occasionally of character traits (perverse conduct).

Radestock (1879, 219) adds a few more features - analogies between the material in the two cases: 'The majority of hallucinations and illusions occur in the region of the senses of sight and hearing and of coenaesthesia. As in the case of dreams, the senses of smell and taste provide the fewest elements. - Both in patients suffering from fever and in dreamers memories arise from the remote past; both sleeping and sick men recollect things which waking and healthy men seem to have forgotten.' The analogy between dreams and psychoses is only fully appreciated when it is seen to extend to the details of expressive movement and to particular characteristics of facial expression.

'The chief feature of dreams and of insanity lies in their eccentric trains of thought and their weakness of judgement.' In both states we find an over-valuation of the subject's own mental achievements which seems senseless to a sober view; the rapid sequence of ideas in dreams is paralleled by the flight of ideas in psychoses. In both there is a complete lack of sense of time. In dreams the personality may be split - when, for instance, the dreamer's own knowledge is divided between two persons and when, in the dream, the extraneous ego corrects the actual one. This is precisely on a par with the splitting of the personality that is familiar to us in hallucinatory paranoia; the dreamer too hears his own thoughts pronounced by extraneous voices. Even chronic delusional ideas have their analogy in stereotyped recurrent pathological dreams (le rêve obsédant). - It not infrequently happens that after recovering from a delirium patients will say that the whole period of their illness seems to them like a not unpleasant dream: indeed they will sometimes tell us that even during the illness they have occasionally had a feeling that they are only caught up in a dream - as is often the case in dreams occurring in sleep.
The unconscious wishful impulses clearly try to make themselves effective in daytime as well, and the fact of transference, as well as the psychoses, show us that they endeavour to force their way by way of the preconscious system into consciousness and to obtain control of the power of movement. Thus the censorship between the *Ucs* and the *Pcs*, the assumption of whose existence is positively forced upon us by dreams, deserves to be recognized and respected as the watchman of our mental health. Must we not regard it, however, as an act of carelessness on the part of that watchman that it relaxes its activities during the night, allows the suppressed impulses in the *Ucs* to find expression, and makes it possible for hallucinatory regression to occur once more? I think not. For even though this critical watchman goes to rest - and we have proof that its slumbers are not deep - it also shuts the door upon the power of movement. No matter what impulses from the normally inhibited *Ucs* may prance upon the stage, we need feel no concern; they remain harmless, since they are unable to set in motion the motor apparatus by which alone they might modify the external world. The state of sleep guarantees the security of the citadel that must be guarded. The position is less harmless when what brings about the displacement of forces is not the nightly relaxation in the critical censorship’s output of force, but a pathological reduction in that force or a pathological intensification of the unconscious excitations while the preconscious is still cathected and the gateway to the power of movement stands open. When this is so, the watchman is overpowered, the unconscious excitations overwhelm the *Pcs*, and thence obtain control over our speech and actions; or they forcibly bring about hallucinatory regression and direct the course of the apparatus (which was not designed for their use) by virtue of the attraction exercised by perceptions on the distribution of our psychical energy. To this state of things we give the name of psychosis.

[1900a, 997]

² I may here add a few supplementary interpretations to those that have already been given: The 'Madonna' was obviously Dora herself; in the first place because of the 'adorer' who had sent her the pictures, in the second place because of the motherliness she had shown towards his children, and lastly because she had had a child though she was still a girl (this being a direct allusion to the phantasy of childbirth). Moreover, the notion of the 'Madonna' is a favourite counter-idea in the mind of girls who feel themselves oppressed by imputations of sexual guilt, - which was the case with Dora. A first suspicion of this connection came to me while I was working as a physician at the Psychiatric Clinic of the University. I there came across a case of confusional insanity with hallucinations, in which the attack, which ran a rapid course, turned out to be a reaction to a reproach made against the patient by her fiancé. - If the analysis had been continued, Dora's maternal longing for a child would probably have been revealed as an obscure though powerful motive in her behaviour. The numerous questions which she had been raising latterly seem to have been belated derivatives of questions inspired by the sexual curiosity which she had tried to gratify with the encyclopaedia. The subjects which she read up in it were presumably pregnancy, childbirth, virginity, and so on. - In reproducing the dream Dora had forgotten one of the questions which need to be inserted into the course of the second situation in the dream. This question could only be; 'Does Herr -- live here?' or 'Where does Herr -- live?' There must have been some reason for her having forgotten this apparently innocent question, especially as she need not have brought it into the dream at all. This reason, it seems to me, lay in her surname itself, which also denoted an object and in fact more than one kind of object, and which could therefore be regarded as an 'ambiguous' word. Unluckily I cannot give the name and show how well designed it was to indicate something 'ambiguous' and 'improper'. This interpretation was supported by the discovery of a similar play upon words in another part of the dream, where the material was derived from Dora's recollections of her aunt's death ('they have already gone to the cemetery') and where there was similarly a play upon her aunt's *name*. These improper words seemed to point to a second and oral source of information, since the encyclopaedia would not cover them. I should not have been surprised to hear that this source had been Frau K. herself, Dora's calumniator. In that case she would have been the one person whom Dora gener­ously spared, while she pursued the others with an almost malignant vindictiveness. Behind the almost limitless series of displacements which were thus brought to light, it was possible to divine the operation of a simple factor - Dora's deep-rooted homosexual love for Frau K.

[1905e, 1439]
Medical research has at last shown that people of this kind are not to be looked upon as suffering from a disease of the stomach or of the eyes or whatever it may be, but that it must be a question in their case of an illness of the nervous system as a whole. Examination of the brain and nerves of these patients has so far, however, revealed no perceptible changes; and, indeed, some of the features of their symptomatology prohibit any expectation that even more accurate methods of investigation could ever discover changes of a sort that would throw light upon the illness. This condition has been described as 'nervousness' (neurasthenia or hysteria) and has been characterized as a merely 'functional' disorder of the nervous system.¹

Incidentally, an exhaustive examination of the brain (after the patient's death) has been equally without results in the case of many more permanent nervous disorders, as well as in illnesses with exclusively mental symptoms, such as what are known as obsessions and delusional insanity.

[1890a, 1587]

On the basis of suitable specimens of innocent jokes, in which there was no fear of our judgement being disturbed by their content or purpose, we were driven to conclude that the techniques of jokes are themselves sources of pleasure; and we shall now try to discover whether it may perhaps be possible to trace that pleasure back to economy in psychical expenditure. In one group of these jokes (play upon words) the technique consisted in focusing our psychical attitude upon the sound of the word instead of upon its meaning - in making the (acoustic) word presentation itself take the place of its significance as given by its relations to thing-presentations. It may really be suspected that in doing so we are bringing about a great relief in psychical work and that when we make serious use of words we are obliged to hold ourselves back with a certain effort from this comfortable procedure. We can observe how pathological states of thought-activity, in which the possibility of concentrating psychical expenditure on a particular point is probably restricted, do in fact give this sort of sound-presentation of the word greater prominence than its meaning, and that sufferers in such states proceed in their speech on the lines (as the formula runs) of the 'external' instead of the 'internal' associations of the word-presentation. We notice, too, that children, who, as we know, are in the habit of still treating words as things, tend to expect words that are the same or similar to have the same meaning behind them - which is a source of many mistakes that are laughed at by grown-up people. If, therefore, we derive unmistakable enjoyment in jokes from being transported by the use of the same or a similar word from one circle of ideas to another, remote one (in the 'Home-Roulard', for instance, from the kitchen to politics), this enjoyment is no doubt correctly to be attributed to economy in psychical expenditure. The pleasure in a joke arising from a 'short-circuit' like this seems to be the greater the more alien the two circles of ideas that are brought together by the same word - the further apart they are, and thus the greater the economy which the joke's technical method provides in the train of thought. We may notice, too, that here jokes are making use of a method of linking things up which is rejected and studiously avoided by serious thought.¹

[1905c, 1712]

¹ The highly remarkable and still insufficiently appreciated behaviour of the relation between contraries in the unconscious is no doubt likely to help our understanding of 'negativism' in neurotic and insane patients. (Cf. the two last works on the subject: Bleuler, 1904 and Gross, 1904. [Added 1912:] See also my review of 'The Antithetical Meaning of Primal Words' (1910e).)

[1905c, 1758]
In the course of the psychotherapeutic treatment of a delusion or of an analogous disorder, ambiguous speeches of this kind are often produced by the patient, as new symptoms of the briefest duration; and it can happen that the doctor finds himself too in the position of making use of them. In that way it not infrequently happens that with the meaning that is intended for the patient's conscious he stirs up an understanding of the meaning that applies to his unconscious. I know from experience that the part thus played by ambiguity is apt to raise the greatest objection in the uninitiated and to give rise to the greatest misunderstandings. But in any case our author was right in giving a place in his creation to a picture of this characteristic feature of what takes place in the formation of dreams and delusions.

[1907a, 1879]

Thus in little Hans's sexual constitution the genital zone was from the outset the one among his erogenous zones which afforded him the most intense pleasure. The only other similar pleasure of which he gave evidence was excretory pleasure, the pleasure attached to the orifices through which micturition and evacuation of the bowels are effected. In his final phantasy of bliss, with which his illness was overcome, he imagined he had children, whom he took to the W.C., whom he made to widdle, whose behinds he wiped - for whom, in short, he did 'everything one can do with children'; it therefore seems impossible to avoid the assumption that during the period when he himself had been looked after as an infant these same performances had been the source of pleasurable sensations for him. He had obtained this pleasure from his erogenous zones with the help of the person who had looked after him - his mother, in fact; and thus the pleasure already pointed the way to object-choice. But it is just possible that at a still earlier date he had been in the habit of giving himself this pleasure auto-erotically - that he had been one of those children who like retaining their excreta till they can derive a voluptuous sensation from their evacuation. I say no more than that it is possible, because the matter was not cleared up in the analysis; the 'making a row with the legs' (kicking about), of which he was so much frightened later on, points in that direction. But in any case these sources of pleasure had no particularly striking importance with Hans, as they so often have with other children. He early became clean in his habits, and neither bed-wetting nor diurnal incontinence played any part during his first years; no trace was observed in him of any inclination to play with his excrement, a propensity which is so revolting in adults, and which commonly makes its reappearance at the termination of processes of psychical involution.

[1909b, 2092]

Already a few years back we ventured, with the help of these hypotheses, to approach the problem of choice of neurosis. Our method of work, which aims at discovering normal conditions by studying their disturbances, led us to adopt a very singular and unexpected line of attack. The order in which the main forms of psychoneurosis are usually enumerated - Hysteria, Obsessional Neurosis, Paranoia, Dementia Praecox - corresponds (even though not quite exactly) to the order of the ages at which the onset of these disorders occurs. Hysterical forms of illness can be observed even in earliest childhood; obsessional neurosis usually shows its first symptoms in the second period of childhood (between the ages of six and eight); while the two other psychoneuroses, which I have brought together under the heading of 'paraphrenia', do not appear until after puberty and during adult life. It is these disorders - the last to emerge - which were the first to show themselves accessible to our enquiry into the dispositions that result in the choice of neurosis. The characteristics peculiar to both of them - megalomania, turning away from the world of objects, increased difficulty in transference - have obliged us to conclude that their dispositional fixation is to be looked for in a stage of libidinal development before object-choice has been established - that is in the phase of auto-eroticism and of narcissism. Thus these forms of illness, which make their appearance so late, go back to very early inhibitions and fixations.

[1913i, 2624]
It is of especial interest to us to have established the fact that repression can succeed in inhibiting an instinctual impulse from being turned into a manifestation of affect. This shows us that the system Cs. normally controls affectivity as well as access to motility; and it enhances the importance of repression, since it shows that repression results not only in withholding things from consciousness, but also in preventing the development of affect and the setting-off of muscular activity. Conversely, too, we may say that as long as the system Cs. controls affectivity and motility, the mental condition of the person in question is spoken of as normal. Nevertheless, there is an unmistakable difference in the relation of the controlling system to the two contiguous processes of discharge.¹ Whereas the control by the Cs. over voluntary motility is firmly rooted, regularly withstands the onslaught of neurosis and only breaks down in psychosis, control by the Cs. over the development of affects is less secure. Even within the limits of normal life we can recognize that a constant struggle for primacy over affectivity goes on between the two systems Cs. and Ucs., that certain spheres of influence are marked off from one another and that intermixtures between the operative forces occur.

[1915e, 3002]

The content of the system Pcs. (or Cs.) is derived partly from instinctual life (through the medium of the Ucs.), and partly from perception. It is doubtful how far the processes of this system can exert a direct influence on the Ucs.; examination of pathological cases often reveals an almost incredible independence and lack of susceptibility to influence on the part of the Ucs. A complete divergence of their trends, a total severance of the two systems, is what above all characterizes a condition of illness. Nevertheless, psycho-analytic treatment is based upon an influencing of the Ucs. from the direction of the Cs., and at any rate shows that this, though a laborious task, is not impossible. The derivatives of the Ucs. which act as intermediaries between the two systems open the way, as we have already said, towards accomplishing this. But we may safely assume that a spontaneously effected alteration in the Ucs. from the direction of the Cs. is a difficult and slow process.

[1915e, 3016]

In the case of schizophrenia, on the other hand, we have been driven to the assumption that after the process of repression the libido that has been withdrawn does not seek a new object, but retreats into the ego; that is to say, that here the object-cathexes are given up and a primitive objectless condition of narcissism is re-established. The incapacity of these patients for transference (so far as the pathological process extends), their consequent inaccessibility to therapeutic efforts, their characteristic repudiation of the external world, the appearance of signs of a hypercathexis of their own ego, the final outcome in complete apathy - all these clinical features seem to agree excellently with the assumption that their object-cathexes have been given up. As regards the relation of the two psychical systems to each other, all observers have been struck by the fact that in schizophrenia a great deal is expressed as being conscious which in the transference neuroses can only be shown to be present in the Ucs. by psycho-analysis. But to begin with we were not able to establish any intelligible connection between the ego-object relation and the relationships of consciousness.

[1915e, 3019]
What are called mental diseases inevitably produce an impression in the layman that intellectual and mental life have been destroyed. In reality, the destruction only applies to later acquisitions and developments. The essence of mental disease lies in a return to earlier states of affective life and of functioning. An excellent example of the plasticity of mental life is afforded by the state of sleep, which is our goal every night. Since we have learnt to interpret even absurd and confused dreams, we know that whenever we go to sleep we throw off our hard-won morality like a garment, and put it on again next morning. This stripping of ourselves is not, of course, dangerous, because we are paralysed, condemned to inactivity, by the state of sleep. It is only dreams that can tell us about the regression of our emotional life to one of the earliest stages of development. For instance, it is noteworthy that all our dreams are governed by purely egoistic motives. One of my English friends put forward this thesis at a scientific meeting in America, whereupon a lady who was present remarked that that might be the case in Austria, but she could assert as regards herself and her friends that they were altruistic even in their dreams. My friend, although himself of English race, was obliged to contradict the lady emphatically on the ground of his personal experience in dream-analysis, and to declare that in their dreams high-minded American ladies were quite as egoistic as the Austrians.

I have nothing to suggest which could have a decisive influence on the solution of this problem. The idea of men's receiving an intimation of their connection with the world around them through an immediate feeling which is from the outset directed to that purpose sounds so strange and fits in so badly with the fabric of our psychology that one is justified in attempting to discover a psycho-analytic - that is, a genetic - explanation of such a feeling. The following line of thought suggests itself. Normally, there is nothing of which we are more certain than the feeling of our self, of our own ego. This ego appears to us as something autonomous and unitary, marked off distinctly from everything else. That such an appearance is deceptive, and that on the contrary the ego is continued inwards, without any sharp delimitation, into an unconscious mental entity which we designate as the id and for which it serves as a kind of façade - this was a discovery first made by psycho-analytic research, which should still have much more to tell us about the relation of the ego to the id. But towards the outside, at any rate, the ego seems to maintain clear and sharp lines of demarcation. There is only one state - admittedly an unusual state, but not one that can be stigmatized as pathological - in which it does not do this. At the height of being in love the boundary between ego and object threatens to melt away. Against all the evidence of his senses, a man who is in love declares that 'I' and 'you' are one, and is prepared to behave as if it were a fact. What can be temporarily done away with by a physiological function must also, of course, be liable to be disturbed by pathological processes. Pathology has made us acquainted with a great number of states in which the boundary lines between the ego and the external world become uncertain or in which they are actually drawn incorrectly. There are cases in which parts of a person's own body, even portions of his own mental life - his perceptions, thoughts and feelings - , appear alien to him and as not belonging to his ego; there are other cases in which he ascribes to the external world things that clearly originate in his own ego and that ought to be acknowledged by it. Thus even the feeling of our own ego is subject to disturbances and the boundaries of the ego are not constant.

A dream, then, is a psychosis, with all the absurdities, delusions and illusions of a psychosis. A psychosis of short duration, no doubt, harmless, even entrusted with a useful function, introduced with the subject's consent and terminated by an act of his will. None the less it is a psychosis, and we learn from it that even so deep-going an alteration of mental life as this can be undone and can give place to the normal function. Is it too bold, then, to hope that it must also be possible to submit the dreaded spontaneous illnesses of mental life to our influence and bring about their cure?
This page intentionally left blank
We see that, if we follow up this line of thought, we come up against the problem not only of hypochondria, but of the other 'actual' neuroses - neurasthenia and anxiety neurosis. Let us therefore stop at this point. It is not within the scope of a purely psychological inquiry to penetrate so far behind the frontiers of physiological research. I will merely mention that from this point of view we may suspect that the relation of hypochondria to paraphrenia is similar to that of the other 'actual' neuroses to hysteria and obsessional neurosis: we may suspect, that is, that it is dependent on ego-libido just as the others are on object-libido, and that hypochondriacal anxiety is the counterpart, as coming from ego-libido, to neurotic anxiety.

Further, since we are already familiar with the idea that the mechanism of falling ill and of the formation of symptoms in the transference neuroses - the path from introversion to regression - is to be linked to a damming-up of object-libido,¹ we may come to closer quarters with the idea of a damming-up of ego-libido as well and may bring this idea into relation with the phenomena of hypochondria and paraphrenia.

You will ask whether it may not be possible, however, to do justice to the part played by the ego in neurotic states and in the formation of symptoms without at the same time grossly neglecting the factors revealed by psycho-analysis. My reply is that that must certainly be possible and will sooner or later be done; but the road followed by the work of psycho-analysis does not admit of actually beginning with this. There are neuroses in which the ego plays a far more intensive part than in those we have studied hitherto; we call them the 'narcissistic' neuroses. The investigation of these disorders will enable us to form an impartial and trustworthy judgement of the share taken by the ego in the onset of neuroses.

One of the ways in which the ego is related to its neuroses is, however, so obvious that it was possible to take it into account from the first. It seems never to be absent; but it is most clearly recognizable in a disorder which we are even to-day far from understanding - traumatic neurosis. For you must know that the same factors always come into operation in the causation and mechanism of every possible form of neurosis; but the chief importance in the construction of the symptoms falls now upon one and now upon another of these factors. The position is like that among the members of a theatrical company. Each of them is regularly cast for his own stock role - hero, confidant, villain, and so on; but each of them will choose a different piece for his benefit performance. In the same way phantasies which turn into symptoms are nowhere more obvious than in hysteria; the anticathexes or reaction-formations of the ego dominate the picture in obsessional neurosis; what in the case of dreams we have termed 'secondary revision' stands in the forefront in paranoia in the shape of delusions, and so on.

We began at an early date to extend psycho-analytic observations to these other illnesses. Already in 1908 Karl Abraham, after an exchange of thoughts with me, pronounced the main characteristic of dementia praecox (which was reckoned among the psychoses) to be that in it the libidinal cathexis of objects was lacking. But the question then arose of what happened to the libido of dementia praecox patients which was turned away from objects. Abraham did not hesitate to give the answer: it is turned back on to the ego and this reflexive turning-back is the source of the megalomania in dementia praecox. Megalomania is in every way comparable to the familiar sexual overvaluation of the object in erotic life. In this way for the first time we learnt to understand a trait in a psychotic illness by relating it to normal erotic life.
These are a few of the findings which have hitherto been reached from the application of psycho-analysis to the narcissistic disorders. No doubt there are not yet enough of them and they still lack the precision which can only be attained from established familiarity with a new field. We owe all of them to a use of the concept of ego-libido or narcissistic libido, by whose help we can extend to the narcissistic neuroses the views which have proved their value with the transference neuroses. Now, however, you will ask whether it is possible that we shall succeed in subsuming all the disturbances of the narcissistic illnesses and of the psychoses under the libido theory, whether we look upon the libidinal factor in mental life as universally guilty of the causation of illness, and need never attribute the responsibility for it to changes in the functioning of the self-preservative instinct. Well, Ladies and Gentlemen, this question seems to me to call for no urgent reply, and, above all, not to be ripe for judgement. We can confidently leave it over in expectation of the progress of our scientific work. I should not be surprised if it turned out that the power to produce pathogenic effects was in fact a prerogative of the libidinal instincts, so that the libido theory could celebrate its triumph all along the line from the simplest 'actual' neurosis to the most severe alienation of the personality. We after all know that it is a characteristic feature of the libido that it struggles against submitting to the reality of the universe - to Ananke. But I regard it as extremely probable that the ego-instincts are carried along secondarily by the pathogenic instigation of the libido and forced into functional disturbances. Nor can I think that it would be a disaster to the trend of our researches, if what lies before us is the discovery that in severe psychoses the ego-instincts themselves have gone astray as a primary fact. The future will give the answer - to you, at any rate.

[1916-1917, 3473]

In the work I have mentioned I described the numerous dependent relationships of the ego, its intermediate position between the external world and the id and its efforts to humour all its masters at once. In connection with a train of thought raised in other quarters, which was concerned with the origin and prevention of the psychoses, a simple formula has now occurred to me which deals with what is perhaps the most important genetic difference between a neurosis and a psychosis: neurosis is the result of a conflict between the ego and its id, whereas psychosis is the analogous outcome of a similar disturbance in the relations between the ego and the external world.

[1924b, 4065]

On the other side, it is equally easy, from the knowledge we have so far gained of the mechanism of the psychoses, to adduce examples which point to a disturbance in the relationship between the ego and the external world. In Meynert's amentia - an acute hallucinatory confusion which is perhaps the most extreme and striking form of psychosis - either the external world is not perceived at all, or the perception of it has no effect whatever. Normally, the external world governs the ego in two ways: firstly, by current, present perceptions which are always renewable, and secondly, by the store of memories of earlier perceptions which, in the shape of an 'internal world', form a possession of the ego and a constituent part of it. In amentia, not only is the acceptance of new perceptions refused, but the external world, too, which, as a copy of the external world, has up till now represented it, loses its significance (its cathexis) - The ego creates, autocratically, a new external and internal world; and there can be no doubt of two facts - that this new world is constructed in accordance with the id's wishful impulses, and that the motive of this dissociation from the external world is some very serious frustration by reality of a wish - a frustration which seems intolerable. The close affinity of this psychosis to normal dreams is unmistakable. A precondition of dreaming, moreover, is a state of sleep, and one of the features of sleep is a complete turning away from perception and the external world.

[1924b, 4066]
The aetiology common to the onset of a psychoneurosis and of a psychosis always remains the same. It consists in a frustration, a non-fulfilment of one of those childhood wishes which are for ever undefeated and which are so deeply rooted in our phylogenetically determined organization. This frustration is in the last resort always an external one; but in the individual case it may proceed from the internal agency (in the super-ego) which has taken over the representation of the demands of reality. The pathogenic effect depends on whether, in a conflictual tension of this kind, the ego remains true to its dependence on the external world and attempts to silence the id, or whether it lets itself be overcome by the id and thus torn away from reality. A complication is introduced into this apparently simple situation, however, by the existence of the super-ego, which, though a link that is not yet clear to us, unites in itself influences coming from the id as well as from the external world, and is to some extent an ideal model of what the whole endeavour of the ego is aiming at - a reconciliation between its various dependent relationships. The attitude of the super-ego should be taken into account - which has not hitherto been done - in every form of psychical illness. We may provisionally assume that there must also be illnesses which are based on a conflict between the ego and the super-ego. Analysis gives us a right to suppose that melancholia is a typical example of this group; and we would set aside the name of 'narcissistic psychoneuroses' for disorders of that kind. Nor will it clash with our impressions if we find reasons for separating states like melancholia from the other psychoses. We now see that we have been able to make our simple genetic formula more complete, without dropping it. Transference neuroses correspond to a conflict between the ego and the id; narcissistic neuroses, to a conflict between the ego and the super-ego; and psychoses, to one between the ego and the external world. It is true that we cannot tell at once whether we have really gained any new knowledge by this, or have only enriched our store of formulas; but I think that this possible application of the proposed differentiation of the mental apparatus into an ego, a super-ego and an id cannot fail to give us courage to keep that hypothesis steadily in view.

In conclusion, there remains to be considered the question of what the mechanism, analogous to repression, can be by means of which the ego detaches itself from the external world. This cannot, I think, be answered without fresh investigations; but such a mechanism, it would seem, must, like repression, comprise a withdrawal of the cathexis sent out by the ego.

We might expect that when a psychosis comes into being, something analogous to the process in a neurosis occurs, though, of course, between different agencies of the mind; thus we might expect that in a psychosis, too, two steps could be discerned, of which the first would drag the ego away, this time from reality, while the second would try to make good the damage done and re-establish the subject's relations to reality at the expense of the id. And, in fact, some analogy of the sort can be observed in a psychosis. Here, too, there are two steps, the second of which has the character of a reparation. But beyond that the analogy gives way to a far more extensive similarity between the two processes. The second step of the psychosis is indeed intended to make good the loss of reality, not, however, at the expense of a restriction of the id - as happens in neurosis at the expense of the relation to reality - but in another, more autocratic manner, by the creation of a new reality which no longer raises the same objections as the old one that has been given up. The second step, therefore, both in neurosis and psychosis, is supported by the same trends. In both cases it serves the desire for power of the id, which will not allow itself to be dictated to by reality. Both neurosis and psychosis are thus the expression of a rebellion on the part of the id against the external world, of its unwillingness - or, if one prefers, its incapacity - to adapt itself to the exigencies of reality, to 'Αυάγχη [Necessity]. Neurosis and psychosis differ from each other far more in their first, introductory, reaction than in the attempt at reparation which follows it.
You have long been aware that this censorship is not an institution peculiar to dream-life. You know that the conflict between the two psychical agencies, which we - inaccurately - describe as the 'unconscious repressed' and the 'conscious', dominates our whole mental life and that the resistance against the interpretation of dreams, the sign of the dream-censorship, is nothing other than the resistance due to repression by which the two agencies are separated. You know too that the conflict between these two agencies may under certain conditions produce other psychical structures which, like dreams, are the outcome of compromises; and you will not expect me to repeat to you here everything that was contained in my introduction to the theory of the neuroses in order to demonstrate to you what we know of the determinants of the formation of such compromises. You have realized that the dream is a pathological product, the first member of the class which includes hysterical symptoms, obsessions and delusions, but that it is distinguished from the others by its transitoriness and by its occurrence under conditions which are part of normal life. For let us bear firmly in mind that, as was already pointed out by Aristotle, dream life is the way in which our mind works during the state of sleep. The state of sleep involves a turning-away from the real external world, and there we have the necessary condition for the development of a psychosis. The most careful study of the severe psychoses will not reveal to us a single feature that is more characteristic of those pathological conditions. In psychoses, however, the turning-away from reality is brought about in two kinds of way: either by the unconscious repressed becoming excessively strong so that it overpowers the conscious, which is attached to reality, or because reality has become so intolerably distressing that the threatened ego throws itself into the arms of the unconscious instinctual forces in a desperate revolt. The harmless dream-psychosis is the result of a withdrawal from the external world which is consciously willed and only temporary, and it disappears when relations to the external world are resumed. During the isolation of the sleeping individual an alteration in the distribution of his psychical energy also sets in; a part of the expenditure on repression, which is normally required in order to hold the unconscious down, can be saved, for if the unconscious makes use of its relative liberation for active purposes, it finds its path to motility closed and the only path open to it is the harmless one leading to hallucinatory satisfaction. Now, therefore, a dream can be formed; but the fact of the dream-censorship shows that even during sleep enough of the resistance due to repression is retained.

[1933a, 4629]

(b) All these phenomena, the symptoms as well as the restrictions on the ego and the stable character-changes, have a compulsive quality: that is to say that they have great psychical intensity and at the same time exhibit a far-reaching independence of the organization of the other mental processes, which are adjusted to the demands of the real external world and obey the laws of logical thinking. They are insufficiently or not at all influenced by external reality, pay no attention to it or to its psychical representatives, so that they may easily come into active opposition to both of them. They are, one might say, a State within a State, an inaccessible party, with which co-operation is impossible, but which may succeed in overcoming what is known as the normal party and forcing it into its service. If this happens, it implies a domination by an internal psychical reality over the reality of the external world and the path to a psychosis lies open. Even if things do not go so far, the practical importance of this situation can scarcely be overestimated. The inhibition upon the life of those who are dominated by a neurosis and their incapacity for living constitute a most important factor in a human society and we may recognize in their condition a direct expression of their fixation to an early portion of their past.

[1939a, 4901]
We already know a number of things preliminary to such an undertaking. According to our hypothesis it is the ego's task to meet the demands raised by its three dependent relations to reality, to the id and to the super-ego - and nevertheless at the same time to preserve its own organization and maintain its own autonomy. The necessary precondition of the pathological states under discussion can only be a relative or absolute weakening of the ego which makes the fulfilment of its tasks impossible. The severest demand on the ego is probably the keeping down of the instinctual claims of the id, to accomplish which it is obliged to maintain large expenditures of energy on anticathexes. But the demands made by the super-ego too may become so powerful and so relentless that the ego may be paralysed, as it were, in the face of its other tasks. We may suspect that, in the economic conflicts which arise at this point, the id and the super-ego often make common cause against the hard-pressed ego which tries to cling to reality in order to retain its normal state. If the other two become too strong, they succeed in loosening and altering the ego's organization, so that its proper relation to reality is disturbed or even brought to an end. We have seen it happen in dreaming: when the ego is detached from the reality of the external world, it slips down, under the influence of the internal world, into psychosis.

[1940a [1938], 4982]

These recollections might have been described as hallucinations if a belief in their actual presence had been added to their clearness. The importance of this analogy seemed greater when I noticed that true hallucinations occasionally occurred in the case of other patients who were certainly not psychotic. My line of thought proceeded as follows. Perhaps it may be a general characteristic of hallucinations to which sufficient attention has not hitherto been paid that in them something that has been experienced in infancy and then forgotten returns - something that the child has seen or heard at a time when he could still hardly speak and that now forces its way into consciousness, probably distorted and displaced owing to the operation of forces that are opposed to this return. And, in view of the close relation between hallucinations and particular forms of psychosis, our line of thought may be carried still further. It may be that the delusions into which these hallucinations are so constantly incorporated may themselves be less independent of the upward drive of the unconscious and the return of the repressed than we usually assume. In the mechanism of a delusion we stress as a rule only two factors: the turning away from the real world and its motive forces on the one hand, and the influence exercised by wish-fulfilment on the content of the delusion on the other. But may it not be that the dynamic process is rather that the turning away from reality is exploited by the upward drive of the repressed in order to force its content into consciousness, while the resistances stirred up by this process and the trend to wish-fulfilment share the responsibility for the distortion and displacement of what is recollected? This is after all the familiar mechanism of dreams, which intuition has equated with madness from time immemorial.

[1937d, 5058]
The fact to which I now wish to call attention is that the content of a hallucinatory psychosis of this sort consists precisely in the accentuation of the idea which was threatened by the precipitating cause of the onset of the illness. One is therefore justified in saying that the ego has fended off the incompatible idea through a flight into psychosis. The process by which this has been achieved once more eludes the subject's self perception, as it eludes psychologico-clinical analysis. It must be regarded as the expression of a pathological disposition of a fairly high degree and it may be described more or less as follows. The ego breaks away from the incompatible idea; but the latter is inseparably connected with a piece of reality, so that, in so far as the ego achieves this result, it, too, has detached itself wholly or in part from reality. In my opinion this latter event is the condition under which the subject's ideas receive the vividness of hallucinations; and thus when the defence has been successfully carried out he finds himself in a state of hallucinatory confusion.

[1894a, 314]

(1) Our first reflection will tell us that it cannot be the case that this detachment of the libido occurs exclusively in paranoia; nor can it be that, where it occurs elsewhere, it has such disastrous consequences. It is quite possible that a detachment of the libido is the essential and regular mechanism of every repression. We can have no positive knowledge on that point until the other disorders that are based upon repression have been similarly examined. But it is certain that in normal mental life (and not only in periods of mourning) we are constantly detaching our libido in this way from people or from other objects without falling ill. When Faust freed himself from the world by uttering his curses, the result was not a paranoia or any other neurosis but simply a certain general frame of mind. The detachment of the libido, therefore, cannot in itself be the pathogenic factor in paranoia; there must be some special characteristic which distinguishes a paranoic detachment of the libido from other kinds. It is not difficult to suggest what that characteristic may be. What use is made of the libido after it has been set free by the process of detachment? A normal person will at once begin looking about for a substitute for the lost attachment; and until that substitute has been found the liberated libido will be kept in suspension within his mind, and will there give rise to tensions and colour his mood. In hysteria the liberated libido becomes transformed into somatic innervations or into anxiety. But in paranoia the clinical evidence goes to show that the libido, after it has been withdrawn from the object, is put to a special use. It will be remembered that the majority of cases of paranoia exhibit traces of megalomania, and that megalomania can by itself constitute a paranoia. From this it may be concluded that in paranoia the liberated libido becomes attached to the ego, and is used for the aggrandizement of the ego. A return is thus made to the stage of narcissism (known to us from the development of the libido), in which a person's only sexual object is his own ego. On the basis of this clinical evidence we can suppose that paranoids have brought along with them a fixation at the stage of narcissism, and we can assert that the length of the step back from sublimated homosexuality to narcissism is a measure of the amount of regression characteristic of paranoia.

[1911c, 2438]
We have long observed that every neurosis has as its result, and probably therefore as its purpose, a forcing of the patient out of real life, an alienating of him from reality. Nor could a fact such as this escape the observation of Pierre Janet; he spoke: of a loss of ‘la fonction du réel’ [‘the function of reality’] as being a special characteristic of neurotics, but without discovering the connection of this disturbance with the fundamental determinants of neurosis.¹ By introducing the process of repression into the genesis of the neuroses we have been able to gain some insight into this connection. Neurotics turn away from reality because they find it unbearable - either the whole or parts of it. The most extreme type of this turning away from reality is shown by certain cases of hallucinatory psychosis which seek to deny the particular event that occasioned the outbreak of their insanity (Griesinger). But in fact every neurotic does the same with some fragment of reality.² And we are now confronted with the task of investigating the development of the relation of neurotics and of mankind in general to reality, and in this way of bringing the psychological significance of the real external world into the structure of our theories.

[1911b, 2552]

Already a few years back we ventured, with the help of these hypotheses, to approach the problem of choice of neurosis. Our method of work, which aims at discovering normal conditions by studying their disturbances, led us to adopt a very singular and unexpected line of attack. The order in which the main forms of psychoneurosis are usually enumerated - Hysteria, Obsessional Neurosis, Paranoia, Dementia Praecox - corresponds (even though not quite exactly) to the order of the ages at which the onset of these disorders occurs. Hysterical forms of illness can be observed even in earliest childhood; obsessional neurosis usually shows its first symptoms in the second period of childhood (between the ages of six and eight); while the two other psychoneuroses, which I have brought together under the heading of ‘paraphrenia’, do not appear until after puberty and during adult life. It is these disorders - the last to emerge - which were the first to show themselves accessible to our enquiry into the dispositions that result in the choice of neurosis. The characteristics peculiar to both of them - megalomania, turning away from the world of objects, increased difficulty in transference - have obliged us to conclude that their dispositional fixation is to be looked for in a stage of libidinal development before object-choice has been established - that is in the phase of auto-erotism and of narcissism. Thus these forms of illness, which make their appearance so late, go back to very early inhibitions and fixations.

[1913i, 2624]
A pressing motive for occupying ourselves with the conception of a primary and normal narcissism arose when the attempt was made to subsume what we know of dementia praecox (Kraepelin) or schizophrenia (Bleuler) under the hypothesis of the libido theory. Patients of this kind, whom I have proposed to term paraphrenics, display two fundamental characteristics: megalomania and diversion of their interest from the external world - from people and things. In consequence of the latter change, they become inaccessible to the influence of psychoanalysis and cannot be cured by our efforts. But the paraphrenic's turning away from the external world needs to be more precisely characterized. A patient suffering from hysteria or obsessional neurosis has also, as far as his illness extends, given up his relation to reality. But analysis shows that he has by no means broken off his erotic relations to people and things. He still retains them in phantasy; i.e. he has, on the one hand, substituted for real objects imaginary ones from his memory, or has mixed the latter with the former; and on the other hand, he has renounced the initiation of motor activities for the attainment of his aims in connection with those objects. Only to this condition of the libido may we legitimately apply the term 'introversion' of the libido which is used by Jung indiscriminately. It is otherwise with the paraphrenic. He seems really to have withdrawn his libido from people and things in the external world, without replacing them by others in phantasy. When he does so replace them, the process seems to be a secondary one and to be part of an attempt at recovery, designed to lead the libido back to objects.¹

[1914c, 2932]
It would, of course, be a different matter if it were proved that the libido theory has already come to grief in the attempt to explain the latter disease. This has been asserted by C. G. Jung (1912) and it is on that account that I have been obliged to enter upon this last discussion, which I would gladly have been spared. I should have preferred to follow to its end the course embarked upon in the analysis of the Schreber case without any discussion of its premisses. But Jung's assertion is, to say the least of it, premature. The grounds he gives for it are scanty. In the first place, he appeals to an admission of my own that I myself have been obliged, owing to the difficulties of the Schreber analysis, to extend the concept of libido (that is, to give up its sexual content) and to identify libido with psychical interest in general. Ferenczi (1913b), in an exhaustive criticism of Jung's work, has already said all that is necessary in correction of this erroneous interpretation. I can only corroborate his criticism and repeat that I have never made any such retractation of the libido theory. Another argument of Jung's, namely, that we cannot suppose that the withdrawal of the libido is in itself enough to bring about the loss of the normal function of reality, is no argument but a dictum. It 'begs the question',¹ and saves discussion; for whether and how this is possible was precisely the point that should have been under investigation. In his next major work, Jung (1913) just misses the solution I had long since indicated: 'At the same time', he writes, 'there is this to be further taken into consideration (a point to which, incidentally, Freud refers in his work on the Schreber case) - that the introversion of the *libido sexualis* leads to a cathexis of the "ego", and that it may possibly be this that produces the result of a loss of reality. It is indeed a tempting possibility to explain the psychology of the loss of reality in this fashion.' But Jung does not enter much further into a discussion of this possibility. A few lines later he dismisses it with the remark that this determinant 'would result in the psychology of an ascetic anchorite, not in a dementia praecox'. How little this inapt analogy can help us to decide the question may be learnt from the consideration that an anchorite of this kind, who 'tries to eradicate every trace of sexual interest' (but only in the popular sense of the word 'sexual'), does not even necessarily display any pathogenic allocation of the libido. He may have diverted his sexual interest from human beings entirely, and yet may have sublimated it into a heightened interest in the divine, in nature, or in the animal kingdom, without his libido having undergone an introversion on to his phantasies or a return to his ego. This analogy would seem to rule out in advance the possibility of differentiating between interest emanating from erotic sources and from others. Let us remember, further, that the researches of the Swiss school, however valuable, have elucidated only two features in the picture of dementia praecox - the presence in it of complexes known to us both in healthy and neurotic subjects, and the similarity of the phantasies that occur in it to popular myths - but that they have not been able to throw any further light on the mechanism of the disease. We may repudiate Jung's assertion, then, that the libido theory has come to grief in the attempt to explain dementia praecox, and that it is therefore disposed of for the other neuroses as well.

[1914c, 2937]
I shall try here to penetrate a little further into the mechanism of paraphrenia and shall bring together those views which already seem to me to deserve consideration. The difference between paraphrenic affections and the transference neuroses appears to me to lie in the circumstance that, in the former, the libido that is liberated by frustration does not remain attached to objects in phantasy, but withdraws on to the ego. Megalomania would accordingly correspond to the psychical mastering of this latter amount of libido, and would thus be the counterpart of the introversion on to phantasies that is found in the transference neuroses; a failure of this psychical function gives rise to the hypochondria of paraphrenia and this is homologous to the anxiety of the transference neuroses. We know that this anxiety can be resolved by further psychical working over, i.e. by conversion, reaction-formation or the construction of protections (phobias). The corresponding process in paraphrenics is an attempt at restoration, to which the striking manifestations of the disease are due. Since paraphrenia frequently, if not usually, brings about only a partial detachment of the libido from objects, we can distinguish three groups of phenomena in the clinical picture: (1) those representing what remains of a normal state or of neurosis (residual phenomena); (2) those representing the morbid process (detachment of libido from its objects and, further, megalomania, hypochondria, affective disturbance and every kind of regression); (3) those representing restoration, in which the libido is once more attached to objects, after the manner of a hysteria (in dementia praecox or paraphrenia proper), or of an obsessional neurosis (in paranoia). This fresh libidinal cathexis differs from the primary one in that it starts from another level and under other conditions. The difference between the transference neuroses brought about in the case of this fresh kind of libidinal cathexis and the corresponding formations where the ego is normal should be able to afford us the deepest insight into the structure of our mental apparatus.

On the other hand, we can already learn from pathology the way in which reality-testing may be done away with or put out of action. We shall see this more clearly in the wishful psychosis of amentia than in that of dreams. Amentia is the reaction to a loss which reality affirms, but which the ego has to deny, since it finds it insupportable. Thereupon the ego breaks off its relation to reality; it withdraws the cathexis from the system of perceptions, Cs. - or rather, perhaps, it withdraws a cathexis, the special nature of which may be the subject of further enquiry. With this turning away from reality, reality-testing is got rid of, the (unrepressed, completely conscious) wishful phantasies are able to press forward into the system, and they are there regarded as a better reality. Such a withdrawal may be put on a par with the processes of repression. Amentia presents the interesting spectacle of a breach between the ego and one of its organs - one which had perhaps been its most faithful servant and had been bound up with it the most intimately.²

[1914c, 2941]

[1917d, 3037]
In what, now, does the work which mourning performs consist? I do not think there is anything far-fetched in presenting it in the following way. Reality-testing has shown that the loved object no longer exists, and it proceeds to demand that all libido shall be withdrawn from its attachments to that object. This demand arouses understandable opposition - it is a matter of general observation that people never willingly abandon a libidinal position, not even, indeed, when a substitute is already beckoning to them. This opposition can be so intense that a turning away from reality takes place and a clinging to the object through the medium of a hallucinatory wishful psychosis.¹ Normally, respect for reality gains the day. Nevertheless its orders cannot be obeyed at once. They are carried out bit by bit, at great expense of time and cathetic energy, and in the meantime the existence of the lost object is psychically prolonged. Each single one of the memories and expectations in which the libido is bound to the object is brought up and hypercathected, and detachment of the libido is accomplished in respect of it. Why this compromise by which the command of reality is carried out piecemeal should be so extraordinarily painful is not at all easy to explain in terms of economics. It is remarkable that this painful unpleasure is taken as a matter of course by us. The fact is, however, that when the work of mourning is completed the ego becomes free and uninhibited again.
[1917e, 3042]

On the other side, it is equally easy, from the knowledge we have so far gained of the mechanism of the psychoses, to adduce examples which point to a disturbance in the relationship between the ego and the external world. In Meynert's amentia - an acute hallucinatory confusion which is perhaps the most extreme and striking form of psychosis - either the external world is not perceived at all, or the perception of it has no effect whatever. Normally, the external world governs the ego in two ways: firstly, by current, present perceptions which are always renewable, and secondly, by the store of memories of earlier perceptions which, in the shape of an 'internal world', form a possession of the ego and a constituent part of it. In amentia, not only is the acceptance of new perceptions refused, but the internal world, too, which, as a copy of the external world, has up till now represented it, loses its significance (its cathexis) - The ego creates, autocratically, a new external and internal world; and there can be no doubt of two facts - that this new world is constructed in accordance with the id's wishful impulses, and that the motive of this dissociation from the external world is some very serious frustration by reality of a wish - a frustration which seems intolerable. The close affinity of this psychosis to normal dreams is unmistakable. A precondition of dreaming, moreover, is a state of sleep, and one of the features of sleep is a complete turning away from perception and the external world.
[1924b, 4066]
The aetiology common to the onset of a psychoneurosis and of a psychosis always remains the same. It consists in a frustration, a non-fulfilment of one of those childhood wishes which are for ever undefeated and which are so deeply rooted in our phylogenetically determined organization. This frustration is in the last resort always an external one; but in the individual case it may proceed from the internal agency (in the super-ego) which has taken over the representation of the demands of reality. The pathogenic effect depends on whether, in a conflictual tension of this kind, the ego remains true to its dependence on the external world and attempts to silence the id, or whether it lets itself be overcome by the id and thus torn away from reality. A complication is introduced into this apparently simple situation, however, by the existence of the super-ego, which, though a link that is not yet clear to us, unites in itself influences coming from the id as well as from the external world, and is to some extent an ideal model of what the whole endeavour of the ego is aiming at - a reconciliation between its various dependent relationships. The attitude of the super-ego should be taken into account - which has not hitherto been done - in every form of psychical illness. We may provisionally assume that there must also be illnesses which are based on a conflict between the ego and the super-ego. Analysis gives us a right to suppose that melancholia is a typical example of this group; and we would set aside the name of ‘narcissistic psychoneuroses’ for disorders of that kind. Nor will it clash with our impressions if we find reasons for separating states like melancholia from the other psychoses. We now see that we have been able to make our simple genetic formula more complete, without dropping it. Transference neuroses correspond to a conflict between the ego and the id; narcissistic neuroses, to a conflict between the ego and the super-ego; and psychoses, to one between the ego and the external world. It is true that we cannot tell at once whether we have really gained any new knowledge by this, or have only enriched our store of formulas; but I think that this possible application of the proposed differentiation of the mental apparatus into an ego, a super-ego and an id cannot fail to give us courage to keep that hypothesis steadily in view.

[1924b, 4067]

In conclusion, there remains to be considered the question of what the mechanism, analogous to repression, can be by means of which the ego detaches itself from the external world. This cannot, I think, be answered without fresh investigations; but such a mechanism, it would seem, must, like repression, comprise a withdrawal of the cathexis sent out by the ego.

[1924b, 4068]

We might expect that when a psychosis comes into being, something analogous to the process in a neurosis occurs, though, of course, between different agencies of the mind; thus we might expect that in a psychosis, too, two steps could be discerned, of which the first would drag the ego away, this time from reality, while the second would try to make good the damage done and re-establish the subject's relations to reality at the expense of the id. And, in fact, some analogy of the sort can be observed in a psychosis. Here, too, there are two steps, the second of which has the character of a reparation. But beyond that the analogy gives way to a far more extensive similarity between the two processes. The second step of the psychosis is indeed intended to make good the loss of reality, not, however, at the expense of a restriction of the id - as happens in neurosis at the expense of the relation to reality - but in another, more autocratic manner, by the creation of a new reality which no longer raises the same objections as the old one that has been given up. The second step, therefore, both in neurosis and psychosis, is supported by the same trends. In both cases it serves the desire for power of the id, which will not allow itself to be dictated to by reality. Both neurosis and psychosis are thus the expression of a rebellion on the part of the id against the external world, of its unwillingness - or, if one prefers, its incapacity - to adapt itself to the exigencies of reality, to 'Αυάγχη [Necessity]. Neurosis and psychosis differ from each other far more in their first, introductory, reaction than in the attempt at reparation which follows it.

[1924e, 4095]
Accordingly, the initial difference is expressed thus in the final outcome: in neurosis a piece of reality is avoided by a sort of flight, whereas in psychosis it is remodelled. Or we might say: in psychosis, the initial flight is succeeded by an active phase of remodelling; in neurosis, the initial obedience is succeeded by a deferred attempt at flight. Or again, expressed in yet another way: neurosis does not disavow the reality, it only ignores it; psychosis disavows it and tries to replace it. We call behaviour 'normal' or 'healthy', if it combines certain features of both reactions - if it disavows the reality as little as does a neurosis, but if it then exerts itself, as does a psychosis, to effect an alteration of that reality. Of course, this expedient, normal, behaviour leads to work being carried out on the external world; it does not stop, as in psychosis, at effecting internal changes. It is no longer autoplastic but alloplastic.

In a psychosis, the transforming of reality is carried out upon the psychical precipitates of former relations to it - that is, upon the memory-traces, ideas and judgements which have been previously derived from reality and by which reality was represented in the mind. But this relation was never a closed one; it was continually being enriched and altered by fresh perceptions. Thus the psychosis is also faced with the task of procuring for itself perceptions of a kind which shall correspond to the new reality; and this is most radically effected by means of hallucination. The fact that, in so many forms and cases of psychosis, the paramnesias, the delusions and the hallucinations that occur are of a most distressing character and are bound up with a generation of anxiety - this fact is without doubt a sign that the whole process of remodelling is carried through against forces which oppose it violently. We may construct the process on the model of a neurosis, with which we are more familiar. There we see that a reaction of anxiety sets in whenever the repressed instinct makes a thrust forward, and that the outcome of the conflict is only a compromise and does not provide complete satisfaction. Probably in a psychosis the rejected piece of reality constantly forces itself upon the mind, just as the repressed instinct does in a neurosis, and that is why in both cases the consequences too are the same. The elucidation of the various mechanisms which are designed, in the psychoses, to turn the subject away from reality and to reconstruct reality - this is a task for specialized psychiatric study which has not yet been taken in hand.

A neurosis usually contents itself with avoiding the piece of reality in question and protecting itself against coming into contact with it. The sharp distinction between neurosis and psychosis, however, is weakened by the circumstance that in neurosis, too, there is no lack of attempts to replace a disagreeable reality by one which is more in keeping with the subject's wishes. This is made possible by the existence of a world of phantasy, of a domain which became separated from the real external world at the time of the introduction of the reality principle. This domain has since been kept free from the demands of the exigencies of life, like a kind of 'reservation'; it is not inaccessible to the ego, but is only loosely attached to it. It is from this world of phantasy that the neurosis draws the material for its new wishful constructions, and it usually finds that material along the path of regression to a more satisfying real past.

It can hardly be doubted that the world of phantasy plays the same part in psychosis and that there, too, it is the storehouse from which the materials or the pattern for building the new reality are derived. But whereas the new, imaginary external world of a psychosis attempts to put itself in the place of external reality, that of a neurosis, on the contrary, is apt, like the play of children, to attach itself to a piece of reality - a different piece from the one against which it has to defend itself - and to lend that piece a special importance and a secret meaning which we (not always quite appropriately) call a symbolic one. Thus we see that both in neurosis and psychosis there comes into consideration the question not only of a loss of reality but also of a substitute for reality.
Here what has been named the masculinity complex of women branches off. It may put great difficulties in the way of their regular development towards femininity, if it cannot be got over soon enough. The hope of some day obtaining a penis in spite of everything and so of becoming like a man may persist to an incredibly late age and may become a motive for strange and otherwise unaccountable actions. Or again, a process may set in which I should like to call a 'disavowal', a process which in the mental life of children seems neither uncommon nor very dangerous but which in an adult would mean the beginning of a psychosis. Thus a girl may refuse to accept the fact of being castrated, may harden herself in the conviction that she does possess a penis, and may subsequently be compelled to behave as though she were a man. [1925], 4151

'What a remarkable business! I shall follow your advice and not make criticisms, since you only want to show me what psycho-analysis believes about the origin of neurosis so that you can go on to say how it sets about combating it. I should have various questions to ask and later on I shall raise some of them. But at the moment I myself feel tempted for once to carry your train of thought further and to venture upon a theory of my own. You have expounded the relation between external world, ego and id, and you have laid it down as the determinant of a neurosis that the ego in its dependence on the external world struggles against the id. Is not the opposite case conceivable of the ego in a conflict of this kind allowing itself to be dragged away by the id and disavowing its regard for the external world? What happens in a case like that? From my lay notions of the nature of insanity I should say that such a decision on the part of the ego might be the determinant of insanity. After all, a turning-away of that kind from reality seems to be the essence of insanity.' [1926e], 4347

Another procedure operates more energetically and more thoroughly. It regards reality as the sole enemy and as the source of all suffering, with which it is impossible to live, so that one must break off all relations with it if one is to be in any way happy. The hermit turns his back on the world and will have no truck with it. But one can do more than that; one can try to re-create the world, to build up in its stead another world in which its most unbearable features are eliminated and replaced by others that are in conformity with one's own wishes. But whoever, in desperate defiance, sets out upon this path to happiness will as a rule attain nothing. Reality is too strong for him. He becomes a madman, who for the most part finds no one to help him in carrying through his delusion. It is asserted, however, that each one of us behaves in some one respect like a paranoic, corrects some aspect of the world which is unbearable to him by the construction of a wish and introduces this delusion into reality. A special importance attaches to the case in which this attempt to procure a certainty of happiness and a protection against suffering through a delusional remoulding of reality is made by a considerable number of people in common. The religions of mankind must be classed among the mass delusions of this kind. No one, needless to say, who shares a delusion ever recognizes it as such. [1930a], 4480
In spite of the incompleteness, I will venture on a few remarks as a conclusion to our enquiry. The programme of becoming happy, which the pleasure principle imposes on us, cannot be fulfilled; yet we must not - indeed, we cannot - give up our efforts to bring it nearer to fulfilment by some means or other. Very different paths may be taken in that direction, and we may give priority either to the positive aspect of the aim, that of gaining pleasure, or to its negative one, that of avoiding unpleasure. By none of these paths can we attain all that we desire. Happiness, in the reduced sense in which we recognize it as possible, is a problem of the economics of the individual's libido. There is no golden rule which applies to everyone: every man must find out for himself in what particular fashion he can be saved. All kinds of different factors will operate to direct his choice. It is a question of how much real satisfaction he can expect to get from the external world, how far he is led to make himself independent of it, and, finally, how much strength he feels he has for altering the world to suit his wishes. In this, his psychical constitution will play a decisive part, irrespectively of the external circumstances. The man who is predominantly erotic will give first preference to his emotional relationships to other people; the narcissistic man, who inclines to be self-sufficient, will seek his main satisfactions in his internal mental processes; the man of action will never give up the external world on which he can try out his strength. As regards the second of these types, the nature of his talents and the amount of instinctual sublimation open to him will decide where he shall locate his interests. Any choice that is pushed to an extreme will be penalized by exposing the individual to the dangers which arise if a technique of living that has been chosen as an exclusive one should prove inadequate. Just as a cautious business-man avoids tying up all his capital in one concern, so, perhaps, worldly wisdom will advise us not to look for the whole of our satisfaction from a single aspiration. Its success is never certain, for that depends on the convergence of many factors, perhaps on none more than on the capacity of the psychical constitution to adapt its function to the environment and then to exploit that environment for a yield of pleasure. A person who is born with a specially unfavourable instinctual constitution, and who has not properly undergone the transformation and rearrangement of his libidinal components which is indispensable for later achievements, will find it hard to obtain happiness from his external situation, especially if he is faced with tasks of some difficulty. As a last technique of living, which will at least bring him substitutive satisfactions, he is offered that of a flight into neurotic illness - a flight which he usually accomplishes when he is still young. The man who sees his pursuit of happiness come to nothing in later years can still find consolation in the yield of pleasure of chronic intoxication; or he can embark on the desperate attempt at rebellion seen in a psychosis.¹

These last two features - the rejection of the claims of reality and the putting through of the pleasure principle - bring humour near to the regressive or reactionary processes which engage our attention so extensively in psychopathology. Its fending off of the possibility of suffering places it among the great series of methods which the human mind has constructed in order to evade the compulsion to suffer - a series which begins with neurosis and culminates in madness and which includes intoxication, self-absorption and ecstasy. Thanks to this connection, humour possesses a dignity which is wholly lacking, for instance, in jokes, for jokes either serve simply to obtain a yield of pleasure or place the yield of pleasure that has been obtained in the service of aggression. In what, then, does the humorous attitude consist, an attitude by means of which a person refuses to suffer, emphasizes the invincibility of his ego by the real world, victoriously maintains the pleasure principle - and all this, in contrast to other methods having the same purposes, without overstepping the bounds of mental health? The two achievements seem incompatible.

[1930a, 4482]

[1927d, 4543]
You have long been aware that this censorship is not an institution peculiar to dream-life. You know that the conflict between the two psychical agencies, which we - inaccurately - describe as the 'unconscious repressed' and the 'conscious', dominates our whole mental life and that the resistance against the interpretation of dreams, the sign of the dream-censorship, is nothing other than the resistance due to repression by which the two agencies are separated. You know too that the conflict between these two agencies may under certain conditions produce other psychical structures which, like dreams, are the outcome of compromises; and you will not expect me to repeat to you here everything that was contained in my introduction to the theory of the neuroses in order to demonstrate to you what we know of the determinants of the formation of such compromises. You have realized that the dream is a pathological product, the first member of the class which includes hysterical symptoms, obsessions and delusions, but that it is distinguished from the others by its transitoriness and by its occurrence under conditions which are part of normal life. For let us bear firmly in mind that, as was already pointed out by Aristotle, dream life is the way in which our mind works during the state of sleep. The state of sleep involves a turning-away from the real external world, and there we have the necessary condition for the development of a psychosis. The most careful study of the severe psychoses will not reveal to us a single feature that is more characteristic of those pathological conditions. In psychoses, however, the turning-away from reality is brought about in two kinds of way: either by the unconscious repressed becoming excessively strong so that it overpowers the conscious, which is attached to reality, or because reality has become so intolerably distressing that the threatened ego throws itself into the arms of the unconscious instinctual forces in a desperate revolt. The harmless dream psychosis is the result of a withdrawal from the external world which is consciously willed and only temporary, and it disappears when relations to the external world are resumed. During the isolation of the sleeping individual an alteration in the distribution of his psychical energy also sets in; a part of the expenditure on repression, which is normally required in order to hold the unconscious down, can be saved, for if the unconscious makes use of its relative liberation for active purposes, it finds its path to motility closed and the only path open to it is the harmless one leading to hallucinatory satisfaction. Now, therefore, a dream can be formed; but the fact of the dream-censorship shows that even during sleep enough of the resistance due to repression is retained.

[1933a, 4629]

The situation in which we find ourselves at the beginning of our enquiry may be expected itself to point the way for us. We wish to make the ego the matter of our enquiry, our very own ego. But is that possible? After all, the ego is in its very essence a subject; how can it be made into an object? Well, there is no doubt that it can be. The ego can take itself as an object, can treat itself like other objects, can observe itself, criticize itself, and do Heaven knows what with itself. In this, one part of the ego is setting itself over against the rest. So the ego can be split; it splits itself during a number of its functions - temporarily at least. Its parts can come together again afterwards. That is not exactly a novelty, though it may perhaps be putting an unusual emphasis on what is generally known. On the other hand, we are familiar with the notion that pathology, by making things larger and coarser, can draw our attention to normal conditions which would otherwise have escaped us. Where it points to a breach or a rent, there may normally be an articulation present. If we throw a crystal to the floor, it breaks; but not into haphazard pieces. It comes apart along its lines of cleavage into fragments whose boundaries, though they were invisible, were predetermined by the crystal's structure. Mental patients are split and broken structures of this same kind. Even we cannot withhold from them something of the reverential awe which peoples of the past felt for the insane. They have turned away from external reality, but for that very reason they know more about internal, psychical reality and can reveal a number of things to us that would otherwise be inaccessible to us.

[1933a, 4667]
We already know a number of things preliminary to such an undertaking. According to our hypothesis it is the ego's task to meet the demands raised by its three dependent relations to reality, to the id and to the super-ego - and nevertheless at the same time to preserve its own organization and maintain its own autonomy. The necessary precondition of the pathological states under discussion can only be a relative or absolute weakening of the ego which makes the fulfilment of its tasks impossible. The severest demand on the ego is probably the keeping down of the instinctual claims of the id, to accomplish which it is obliged to maintain large expenditures of energy on anticathexes. But the demands made by the super-ego too may become so powerful and so relentless that the ego may be paralysed, as it were, in the face of its other tasks. We may suspect that, in the economic conflicts which arise at this point, the id and the super-ego often make common cause against the hard-pressed ego which tries to cling to reality in order to retain its normal state. If the other two become too strong, they succeed in loosening and altering the ego's organization, so that its proper relation to reality is disturbed or even brought to an end. We have seen it happen in dreaming: when the ego is detached from the reality of the external world, it slips down, under the influence of the internal world, into psychosis.

[1940a [1938], 4982]

No sooner have we taken this step than a first disappointment awaits us, a first warning against over-confidence. If the patient's ego is to be a useful ally in our common work, it must, however hard it may be pressed by the hostile powers, have retained a certain amount of coherence and some fragment of understanding for the demands of reality. But this is not to be expected of the ego of a psychotic; it cannot observe a pact of this kind, indeed it can scarcely enter into one. It will very soon have tossed us away and the help we offer it and sent us to join the portions of the external world which no longer mean anything to it. Thus we discover that we must renounce the idea of trying our plan of cure upon psychotics - renounce it perhaps for ever or perhaps only for the time being, till we have found some other plan better adapted for them.

[1940a [1938], 4983]
We have repeatedly had to insist on the fact that the ego owes its origin as well as the most important of its acquired characteristics to its relation to the real external world. We are thus prepared to assume that the ego's pathological states, in which it most approximates once again to the id, are founded on a cessation or slackening of that relation to the external world. This tallies very well with what we learn from clinical experience - namely, that the precipitating cause of the outbreak of a psychosis is either that reality has become intolerably painful or that the instincts have become extraordinarily intensifyed - both of which, in view of the rival claims made on the ego by the id and the external world, must lead to the same result. The problem of psychoses would be simple and perspicuous if the ego's detachment from reality could be carried through completely. But that seems to happen only rarely or perhaps never. Even in a state so far removed from the reality of the external world as one of hallucinatory confusion, one learns from patients after their recovery that at the time in some corner of their mind (as they put it) there was a normal person hidden, who, like a detached spectator, watched the hubbub of illness go past him. I do not know if we may assume that this is so in general, but I can report the same of other psychoses with a less tempestuous course. I call to mind a case of chronic paranoia in which after each attack of jealousy a dream conveyed to the analyst a correct picture of the precipitating cause, free from any delusion. An interesting contrast was thus brought to light: while we are accustomed to discover from the dreams of neurotics jealousies which are alien to their waking lives, in this psychotic case the delusion which dominated the patient in the day-time was corrected by his dream. We may probably take it as being generally true that what occurs in all these cases is a psychical \textit{split}. Two psychical attitudes have been formed instead of a single one - one, the normal one, which takes account of reality, and another which under the influence of the instincts detaches the ego from reality. The two exist alongside of each other. The issue depends on their relative strength. If the second is or becomes the stronger, the necessary precondition for a psychosis is present. If the relation is reversed, then there is an apparent cure of the delusional disorder. Actually it has only retreated into the unconscious - just as numerous observations lead us to believe that the delusion existed ready-made for a long time before its manifest irruption.

These recollections might have been described as hallucinations if a belief in their actual presence had been added to their clearness. The importance of this analogy seemed greater when I noticed that true hallucinations occasionally occurred in the case of other patients who were certainly not psychotic. My line of thought proceeded as follows. Perhaps it may be a general characteristic of hallucinations to which sufficient attention has not hitherto been paid that in them something that has been experienced in infancy and then forgotten returns - something that the child has seen or heard at a time when he could still hardly speak and that now forces its way into consciousness, probably distorted and displaced owing to the operation of forces that are opposed to this return. And, in view of the close relation between hallucinations and particular forms of psychosis, our line of thought may be carried still further. It may be that the delusions into which these hallucinations are so constantly incorporated may themselves be less independent of the upward drive of the unconscious and the return of the repressed than we usually assume. In the mechanism of a delusion we stress as a rule only two factors: the turning away from the real world and its motive forces on the one hand, and the influence exercised by wish-fulfilment on the content of the delusion on the other. But may it not be that the dynamic process is rather that the turning away from reality is exploited by the upward drive of the repressed in order to force its content into consciousness, while the resistances stirred up by this process and the trend to wish-fulfilment share the responsibility for the distortion and displacement of what is recollected? This is after all the familiar mechanism of dreams, which intuition has equated with madness from time immemorial.
I am aware that it is of small service to handle so important a subject in the cursory fashion that I have here employed. But none the less I have not been able to resist the seduction of an analogy. The delusions of patients appear to me to be the equivalents of the constructions which we build up in the course of an analytic treatment - attempts at explanation and cure, though it is true that these, under the conditions of a psychosis, can do no more than replace the fragment of reality that is being disavowed in the present by another fragment that had already been disavowed in the remote past. It will be the task of each individual investigation to reveal the intimate connections between the material of the present disavowal and that of the original repression. Just as our construction is only effective because it recovers a fragment of lost experience, so the delusion owes its convincing power to the element of historical truth which it inserts in the place of the rejected reality. In this way a proposition which I originally asserted only of hysteria would apply also to delusions - namely, that those who are subject to them are suffering from their own reminiscences. I never intended by this short formula to dispute the complexity of the causation of the illness or to exclude the operation of many other factors. [1937d, 5059]

The usual result of the fright of castration, the result that passes as the normal one, is that, either immediately or after some considerable struggle, the boy gives way to the threat and obeys the prohibition either wholly or at least in part (that is, by no longer touching his genitals with his hand). In other words, he gives up, in whole or in part, the satisfaction of the instinct. We are prepared to hear, however, that our present patient found another way out. He created a substitute for the penis which he missed in females - that is to say, a fetish. In so doing, it is true that he had disavowed reality, but he had saved his own penis. So long as he was not obliged to acknowledge that females have lost their penis, there was no need for him to believe the threat that had been made against him: he need have no fears for his own penis, so he could proceed with his masturbation undisturbed. This behaviour on the part of our patient strikes us forcibly as being a turning away from reality - a procedure which we should prefer to reserve for psychoses. And it is in fact not very different. Yet we will suspend our judgement, for upon closer inspection we shall discover a not unimportant distinction. The boy did not simply contradict his perceptions and hallucinate a penis where there was none to be seen; he effected no more than a displacement of value - he transferred the importance of the penis to another part of the body, a procedure in which he was assisted by the mechanism of regression (in a manner which need not here be explained). This displacement, it is true, related only to the female body; as regards his own penis nothing was changed. [1940e [1938], 5064]
One such change was the replacement of Flechsig by the superior figure of God. This seems at first as though it were a sign of aggravation of the conflict, an intensification of the unbearable persecution, but it soon becomes evident that it was preparing the way for the second change and, with it, the solution of the conflict. It was impossible for Schreber to become reconciled to playing the part of a female wanton towards his doctor; but the task of providing God Himself with the voluptuous sensations that He required called up no such resistance on the part of his ego. Emasculation was now no longer a disgrace; it became 'consonant with the Order of Things', it took its place in a great cosmic chain of events, and was instrumental in the re-creation of humanity after its extinction. 'A new race of men, born from the spirit of Schreber' would, so he thought, revere as their ancestor this man who believed himself the victim of persecution. By this means an outlet was provided which would satisfy both of the contending forces. His ego found compensation in his megalomania, while his feminine wishful phantasy made its way through and became acceptable. The struggle and the illness could cease. The patient's sense of reality, however, which had in the meantime become stronger, compelled him to postpone the solution from the present to the remote future, and to content himself with what might be described as an asymptotic wish-fulfilment.¹ Some time or other, he anticipated, his transformation into a woman would come about; until then the personality of Dr. Schreber would remain indestructible.

[1911c, 2420]

In textbooks of psychiatry we frequently come across statements to the effect that megalomania can develop out of delusions of persecution. The process is supposed to be as follows. The patient is primarily the victim of a delusion that he is being persecuted by powers of the greatest might. He then feels a need to account to himself for this, and in that way hits on the idea that he himself is a very exalted personage and worthy of such persecution. The development of megalomania is thus attributed by the textbooks to a process which (borrowing a useful word from Ernest Jones) we may describe as 'rationalization'. But to ascribe such important affective consequences to a rationalization is, as it seems to us, an entirely unpsychological proceeding; and we would consequently draw a sharp distinction between our opinion and the one which we have quoted from the textbooks. We are making no claim, for the moment, to knowing the origin of the megalomania.

[1911c, 2420]
Turning once more to the case of Schreber, we are bound to admit that any attempt at throwing light upon the transformation in his delusion brings us up against extraordinary difficulties. In what manner and by what means was the ascent from Flechsig to God brought about? From what source did he derive the megalomania which so fortunately enabled him to become reconciled to his persecution, or, in analytical phraseology, to accept the wishful phantasy which had had to be repressed? The *Denkwürdigkeiten* give us a first clue; for they show us that in the patient's mind 'Flechsig' and 'God' belonged to the same class. In one of his phantasies he overheard a conversation between Flechsig and his wife, in which the former asserted that he was 'God Flechsig', so that his wife thought he had gone mad (82). But there is another feature in the development of Schreber's delusions which claims our attention. If we take a survey of the delusions as a whole we see that the persecutor is divided into Flechsig and God; in just the same way Flechsig himself subsequently splits up into two personalities, the 'upper' and the 'middle' Flechsig, and God into the 'lower' and the 'upper' God. In the later stages of the illness the decomposition of Flechsig goes further still (193). A process of decomposition of this kind is very characteristic of paranoia. Paranoia decomposes just as hysteria condenses. Or rather, paranoia resolves once more into their elements the products of the condensations and identifications which are effected in the unconscious. The frequent repetition of the decomposing process in Schreber's case would, according to Jung, be an expression of the importance which the person in question possessed for him.¹ All of this dividing up of Flechsig and God into a number of persons thus had the same meaning as the splitting of the persecutor into Flechsig and God. They were all duplications of one and the same important relationship.² But, in order to interpret all these details, we must further draw attention to our view of this decomposition of the persecutor into Flechsig and God as a paranoid reaction to a previously established identification of the two figures or their belonging to the same class. If the persecutor Flechsig was originally a person whom Schreber loved, then God must also simply be the reappearance of some one else whom he loved, and probably some one of greater importance.

[1911c, 2421]
(1) Our first reflection will tell us that it cannot be the case that this detachment of the libido occurs exclusively in paranoia; nor can it be that, where it occurs elsewhere, it has such disastrous consequences. It is quite possible that a detachment of the libido is the essential and regular mechanism of every repression. We can have no positive knowledge on that point until the other disorders that are based upon repression have been similarly examined. But it is certain that in normal mental life (and not only in periods of mourning) we are constantly detaching our libido in this way from people or from other objects without falling ill. When Faust freed himself from the world by uttering his curses, the result was not a paranoia or any other neurosis but simply a certain general frame of mind. The detachment of the libido, therefore, cannot in itself be the pathogenic factor in paranoia; there must be some special characteristic which distinguishes a paranoid detachment of the libido from other kinds. It is not difficult to suggest what that characteristic may be. What use is made of the libido after it has been set free by the process of detachment? A normal person will at once begin looking about for a substitute for the lost attachment; and until that substitute has been found the liberated libido will be kept in suspension within his mind, and will there give rise to tensions and colour his mood. In hysteria the liberated libido becomes transformed into somatic innervations or into anxiety. But in paranoia the clinical evidence goes to show that the libido, after it has been withdrawn from the object, is put to a special use. It will be remembered that the majority of cases of paranoia exhibit traces of megalomania, and that megalomania can by itself constitute a paranoia. From this it may be concluded that in paranoia the liberated libido becomes attached to the ego, and is used for the aggrandizement of the ego. A return is thus made to the stage of narcissism (known to us from the development of the libido), in which a person's only sexual object is his own ego. On the basis of this clinical evidence we can suppose that paranoids have brought along with them a fixation at the stage of narcissism, and we can assert that the length of the step back from sublimated homosexuality to narcissism is a measure of the amount of regression characteristic of paranoia. [1911c, 2438]
An equally plausible objection can be based upon Schreber's case history, as well as upon many others. For it can be urged that the delusions of persecution (which were directed against Flechsig) unquestionably made their appearance at an earlier date than the phantasy of the end of the world; so that what is supposed to have been a return of the repressed actually preceded the repression itself - and this is patent nonsense. In order to meet this objection we must leave the high ground of generalization and descend to the detailed consideration of actual circumstances, which are undoubtedly very much more complicated. We must admit the possibility that a detachment of the libido such as we are discussing might just as easily be a partial one, a drawing back from some single complex, as a general one. A partial detachment should be by far the commoner of the two, and should precede a general one, since to begin with it is only for a partial detachment that the influences of life provide a motive. The process may then stop at the stage of a partial detachment or it may spread to a general one, which will loudly proclaim its presence in the symptoms of megalomania. Thus the detachment of the libido from the figure of Flechsig may nevertheless have been what was primary in the case of Schreber; it was immediately followed by the appearance of the delusion, which brought back the libido on to Flechsig again (though with a negative sign to mark the fact that repression had taken place) and thus annulled the work of repression. And now the battle of repression broke out anew, but this time with more powerful weapons. In proportion as the object of contention became the most important thing in the external world, trying on the one hand to draw the whole of the libido on to itself, and on the other hand mobilizing all the resistances against itself, so the struggle raging around this single object became more and more comparable to a general engagement; till at length a victory for the forces of repression found expression in a conviction that the world had come to an end and that the self alone survived. If we review the ingenious constructions which were raised by Schreber's delusion in the domain of religion - the hierarchy of God, the proved souls, the fore-courts of Heaven, the lower and the upper God - we can gauge in retrospect the wealth of sublimations which were brought down in ruin by the catastrophe of the general detachment of his libido.

Already a few years back we ventured, with the help of these hypotheses, to approach the problem of choice of neurosis. Our method of work, which aims at discovering normal conditions by studying their disturbances, led us to adopt a very singular and unexpected line of attack. The order in which the main forms of psychoneurosis are usually enumerated - Hysteria, Obsessional Neurosis, Paranoia, Dementia Praecox - corresponds (even though not quite exactly) to the order of the ages at which the onset of these disorders occurs. Hysterical forms of illness can be observed even in earliest childhood; obsessional neurosis usually shows its first symptoms in the second period of childhood (between the ages of six and eight); while the two other psychoneuroses, which I have brought together under the heading of 'paraphrenia', do not appear until after puberty and during adult life. It is these disorders - the last to emerge - which were the first to show themselves accessible to our enquiry into the dispositions that result in the choice of neurosis. The characteristics peculiar to both of them - megalomania, turning away from the world of objects, increased difficulty in transference - have obliged us to conclude that their dispositional fixation is to be looked for in a stage of libidinal development before object-choice has been established - that is in the phase of auto-erotism and of narcissism. Thus these forms of illness, which make their appearance so late, go back to very early inhibitions and fixations.
A pressing motive for occupying ourselves with the conception of a primary and normal narcissism arose when the attempt was made to subsume what we know of dementia praecox (Kraepelin) or schizophrenia (Bleuler) under the hypothesis of the libido theory. Patients of this kind, whom I have proposed to term paraphrenics, display two fundamental characteristics: megalomania and diversion of their interest from the external world - from people and things. In consequence of the latter change, they become inaccessible to the influence of psycho-analysis and cannot be cured by our efforts. But the paraphrenic's turning away from the external world needs to be more precisely characterized. A patient suffering from hysteria or obsessional neurosis has also, as far as his illness extends, given up his relation to reality. But analysis shows that he has by no means broken off his erotic relations to people and things. He still retains them in phantasy; i.e. he has, on the one hand, substituted for real objects imaginary ones from his memory, or has mixed the latter with the former; and on the other hand, he has renounced the initiation of motor activities for the attainment of his aims in connection with those objects. Only to this condition of the libido may we legitimately apply the term 'introversion' of the libido which is used by Jung indiscriminately. It is otherwise with the paraphrenic. He seems really to have withdrawn his libido from people and things in the external world, without replacing them by others in phantasy. When he does so replace them, the process seems to be a secondary one and to be part of an attempt at recovery, designed to lead the libido back to objects.¹

[1914c, 2932]

The question arises: What happens to the libido which has been withdrawn from external objects in schizophrenia? The megalomania characteristic of these states points the way. This megalomania has no doubt come into being at the expense of object-libido. The libido that has been withdrawn from the external world has been directed to the ego and thus gives rise to an attitude which may be called narcissism. But the megalomania itself is no new creation; on the contrary, it is, as we know, a magnification and plainer manifestation of a condition which had already existed previously. This leads us to look upon the narcissism which arises through the drawing in of object-cathexes as a secondary one, superimposed upon a primary narcissism that is obscured by a number of different influences.

[1914c, 2932]

We have recognized our mental apparatus as being first and foremost a device designed for mastering excitations which would otherwise be felt as distressing or would have pathogenic effects. Working them over in the mind helps remarkably towards an internal draining away of excitations which are incapable of direct discharge outwards, or for which such a discharge is for the moment undesirable. In the first instance, however, it is a matter of indifference whether this internal process of working-over is carried out upon real or imaginary objects. The difference does not appear till later - if the turning of the libido on to unreal objects (introversion) has led to its being dammed up. In paraphrenics, megalomania allows of a similar internal working-over of libido which has returned to the ego; perhaps it is only when the megalomania fails that the damming-up of libido in the ego becomes pathogenic and starts the process of recovery which gives us the impression of being a disease.

[1914c, 2940]
I shall try here to penetrate a little further into the mechanism of paraphrenia and shall bring together those views which already seem to me to deserve consideration. The difference between paraphrenic affections and the transference neuroses appears to me to lie in the circumstance that, in the former, the libido that is liberated by frustration does not remain attached to objects in phantasy, but withdraws on to the ego. Megalomania would accordingly correspond to the psychical mastering of this latter amount of libido, and would thus be the counterpart of the introversion on to phantasies that is found in the transference neuroses; a failure of this psychical function gives rise to the hypochondria of paraphrenia and this is homologous to the anxiety of the transference neuroses. We know that this anxiety can be resolved by further psychical working over, i.e. by conversion, reaction-formation or the construction of protections (phobias). The corresponding process in paraphrenics is an attempt at restoration, to which the striking manifestations of the disease are due. Since paraphrenia frequently, if not usually, brings about only a partial detachment of the libido from objects, we can distinguish three groups of phenomena in the clinical picture: (1) those representing what remains of a normal state or of neurosis (residual phenomena); (2) those representing the morbid process (detachment of libido from its objects and, further, megalomania, hypochondria, affective disturbance and every kind of regression); (3) those representing restoration, in which the libido is once more attached to objects, after the manner of a hysteria (in dementia praecox or paraphrenia proper), or of an obsessional neurosis (in paranoia). This fresh libidinal cathexis differs from the primary one in that it starts from another level and under other conditions. The difference between the transference neuroses brought about in the case of this fresh kind of libidinal cathexis and the corresponding formations where the ego is normal should be able to afford us the deepest insight into the structure of our mental apparatus.

[1914c, 2941]

Applying our distinction between sexual and ego-instincts, we must recognize that self-regard has a specially intimate dependence on narcissistic libido. Here we are supported by two fundamental facts: that in paraphrenics self-regard is increased, while in the transference neuroses it is diminished; and that in love-relations not being loved lowers the self-regarding feelings, while being loved raises them. As we have indicated, the aim and the satisfaction in a narcissistic object-choice is to be loved.

[1914c, 2951]

In the case of schizophrenia, on the other hand, we have been driven to the assumption that after the process of repression the libido that has been withdrawn does not seek a new object, but retreats into the ego; that is to say, that here the object-cathexes are given up and a primitive objectless condition of narcissism is re-established. The incapacity of these patients for transference (so far as the pathological process extends), their consequent inaccessibility to therapeutic efforts, their characteristic repudiation of the external world, the appearance of signs of a hypercathexis of their own ego, the final outcome in complete apathy - all these clinical features seem to agree excellently with the assumption that their object-cathexes have been given up. As regards the relation of the two psychical systems to each other, all observers have been struck by the fact that in schizophrenia a great deal is expressed as being conscious which in the transference neuroses can only be shown to be present in the Ucs. by psycho-analysis. But to begin with we were not able to establish any intelligible connection between the ego-object relation and the relationships of consciousness.

[1915e, 3019]
If now we put this finding alongside the hypothesis that in schizophrenia object-cathexes are given up, we shall be obliged to modify the hypothesis by adding that the cathexis of the word-presentations of objects is retained. What we have permissibly called the conscious presentation of the object can now be split up into the presentation of the word and the presentation of the thing; the latter consists in the cathexis, if not of the direct memory-images of the thing, at least of remoter memory-traces derived from these. We now seem to know all at once what the difference is between a conscious and an unconscious presentation. The two are not, as we supposed, different registrations of the same content in different psychical localities, nor yet different functional states of cathexis in the same locality; but the conscious presentation comprises the presentation of the thing plus the presentation of the word belonging to it, while the unconscious presentation is the presentation of the thing alone. The system Ucs. contains the thing-cathexes of the objects, the first and true object-cathexes; the system Pcs. comes about by this thing-presentation being hypercathected through being linked with the word-presentations corresponding to it. It is these hypercathexes, we may suppose, that bring about a higher psychical organization and make it possible for the primary process to be succeeded by the secondary process which is dominant in the Pcs. Now, too, we are in a position to state precisely what it is that repression denies to the rejected presentation in the transference neuroses: what it denies to the presentation is translation into words which shall remain attached to the object. A presentation which is not put into words, or a psychical act which is not hypercathected, remains thereafter in the Ucs. in a state of repression.

[1915e, 3022]

We began at an early date to extend psycho-analytic observations to these other illnesses. Already in 1908 Karl Abraham, after an exchange of thoughts with me, pronounced the main characteristic of dementia praecox (which was reckoned among the psychoses) to be that in it the libidinal cathexis of objects was lacking. But the question then arose of what happened to the libido of dementia praecox patients which was turned away from objects. Abraham did not hesitate to give the answer: it is turned back on to the ego and this reflexive turning-back is the source of the megalomania in dementia praecox. Megalomania is in every way comparable to the familiar sexual overvaluation of the object in erotic life. In this way for the first time we learnt to understand a trait in a psychotic illness by relating it to normal erotic life.

[1916-1917, 3461]
The form of disease known as paranoia, chronic systematic insanity, occupies an unsettled position in the attempts at classification made by present-day psychiatry. There is, however, no doubt of its close affinity to dementia praecox. I once ventured to suggest that paranoia and dementia praecox should be brought together under the common designation of 'paraphrenia'. The forms of paranoia are described according to their content as megalomania, persecution mania, erotomania, delusions of jealousy, and so on. We shall not expect anything much in the way of an attempt at an explanation from psychiatry. Here is an example of one, though, it is true, one that is out of date and does not carry much weight - an attempt to derive one symptom from another by means of an intellectual rationalization: it is suggested that the patient, who, owing to a primary disposition, believes that he is being persecuted, infers from his persecution that he must be someone of quite particular importance and so develops megalomania. According to our analytic view the megalomania is the direct result of a magnification of the ego due to the drawing in of the libidinal object-cathexes - a secondary narcissism which is a return of the original early infantile one. We have, however, made a few observations of persecution mania which have induced us to follow a particular track. The first thing that struck us was that in the large majority of cases the persecutor was of the same sex as the persecuted patient. This was still open to an innocent explanation; but in a few cases that were thoroughly studied it was clear that the person of the same sex whom the patient loved most had, since his illness, been turned into his persecutor. This made a further development possible: namely, the replacement of the beloved person, along the line of familiar resemblances, by someone else - for instance, a father by a schoolmaster or by some superior. Experiences of this kind in ever increasing numbers led us to conclude that paranoia persecutoria is the form of the disease in which a person is defending himself against a homosexual impulse which has become too powerful. The change over from affection to hatred, which, it is well known, may become a serious threat to the life of the loved and hated object, corresponds in such cases to the transformation of libidinal impulses into anxiety which is a regular outcome of the process of repression. Listen, for instance, to what is, once again, the most recent instance of my observations in this connection.

[1916-1917, 3468]

On the basis of our clinical impressions we maintained that these patients' object-cathexes must have been given up and that their object-libido must have been transformed into ego-libido. Through this characteristic we distinguished them from the first group of neurotics (sufferers from hysteria, anxiety-hysteria and obsessional neurosis). This suspicion is now confirmed by their behaviour in our attempts at therapy. They manifest no transference and for that reason are inaccessible to our efforts and cannot be cured by us.

[1916-1917, 3489]

_Narcissism_. - The most important theoretical advance has certainly been the application of the libido theory to the repressing ego. The ego itself came to be regarded as a reservoir of what was described as narcissistic libido, from which the libidinal cathexes of objects flowed out and into which they could be once more withdrawn. By the help of this conception it became possible to embark upon the analysis of the ego and to make a clinical distinction of the psychoneuroses into _transference neuroses_ and _narcissistic_ disorders. In the former (hysteria and obsessional neurosis) the subject has at his disposal a quantity of libido striving to be transferred on to extraneous objects, and use is made of this in carrying out analytic treatment; on the other hand, the narcissistic disorders (dementia praecox, paranoia, melancholia) are characterized by a withdrawal of the libido from objects and they are therefore scarcely accessible to analytic therapy. But their therapeutic inaccessibility has not prevented analysis from making the most fruitful beginnings in the deeper study of these illnesses, which are counted among the psychoses.

[1923a, 3925]
In conclusion, there remains to be considered the question of what the mechanism, analogous to repression, can be by means of which the ego detaches itself from the external world. This cannot, I think, be answered without fresh investigations; but such a mechanism, it would seem, must, like repression, comprise a withdrawal of the cathexis sent out by the ego.
[1924b, 4068]
'The chief feature of dreams and of insanity lies in their eccentric trains of thought and their weakness of judgement.' In both states we find an over-valuation of the subject's own mental achievements which seems senseless to a sober view; the rapid sequence of ideas in dreams is paralleled by the flight of ideas in psychoses. In both there is a complete lack of sense of time. In dreams the personality may be split - when, for instance, the dreamer's own knowledge is divided between two persons and when, in the dream, the extraneous ego corrects the actual one. This is precisely on a par with the splitting of the personality that is familiar to us in hallucinatory paranoia; the dreamer too hears his own thoughts pronounced by extraneous voices. Even chronic delusional ideas have their analogy in stereotyped recurrent pathological dreams (le rêve obsédant). - It not infrequently happens that after recovering from a delirium patients will say that the whole period of their illness seems to them like a not unpleasant dream: indeed they will sometimes tell us that even during the illness they have occasionally had a feeling that they are only caught up in a dream - as is often the case in dreams occurring in sleep. [1900a, 596]

The condition of sleep, too, resembles illness in implying a narcissistic withdrawal of the positions of the libido on to the subject's own self, or, more precisely, on to the single wish to sleep. The egoism of dreams fits very well into this context. In both states we have, if nothing else, examples of changes in the distribution of libido that are consequent upon an alteration of the ego. [1914c, 2939]

What is performed in amentia by this 'repression' is performed in dreams by voluntary renunciation. The state of sleep does not wish to know anything of the external world; it takes no interest in reality, or only so far as abandoning the state of sleep - waking up - is concerned. Hence it withdraws cathexis from the system Cs. as well as from the other systems, the Pcs. and the Ucs., in so far as the catheaxes in them obey the wish to sleep. With the system Cs. thus uncathedected, the possibility of reality-testing is abandoned; and the excitations which, independently of the state of sleep, have entered on the path of regression will find that path clear as far as the system Cs. where they will count as undisputed reality.¹ [1917d, 3038]

Finally, let us once more glance at the significant light which the topography of the process of repression throws for us on the mechanism of mental disturbances. In dreams the withdrawal of cathexis (libido or interest) affects all systems equally; in the transference neuroses, the Pcs. cathexis is withdrawn; in schizophrenia, the cathexis of the Ucs.; in amentia, that of the Cs. [1917d, 3038]
Your second observation, too, raises a justifiable question, but it is aimed in the wrong direction. It is true that a withdrawal of the object-libido into the ego is not directly pathogenic; it takes place, indeed, as we know, every time before we go to sleep, only to be reversed when we wake up. The amoeba withdraws its protrusions only to send them out again at the first opportunity. But it is quite a different thing when a particular, very energetic process forces a withdrawal of libido from objects. Here the libido that has become narcissistic cannot find its way back to objects, and this interference with the libido's mobility certainly becomes pathogenic. It seems that an accumulation of narcissistic libido beyond a certain amount is not tolerated. We may even imagine that it was for that very reason that object-cathexes originally came about, that the ego was obliged to send out its libido so as not to fall ill as a result of its being dammed up. If it lay within our plan to go more deeply into dementia praecox, I would show you that the process which detaches the libido from objects and cuts off its return to them is closely related to the process of repression and is to be looked at as its counterpart. But you would, first and foremost, find yourselves on familiar ground when you learnt that the determinants of this process are almost identical - so far as we know at present - with those of repression. The conflict seems to be the same and to be carried on between the same forces. If the outcome is so different from, for instance, that in hysteria, the reason can only depend on a difference in innate disposition. The weak spot in the libidinal development of these patients lies in a different phase; the determining fixation, which, as you will recollect, permits the irruption that leads to the formation of symptoms, lies elsewhere, probably in the stage of primitive narcissism to which dementia praecox returns in its final outcome. It is very remarkable that in the case of all the narcissistic neuroses we have to assume fixation points for the libido going back to far earlier phases of development than in hysteria or obsessional neurosis. As you heard, however, the concepts which we arrived at during our study of the transference neuroses are adequate in helping us to find our way about in the narcissistic neuroses which are so much more severe in practice. The conformities go very far; at bottom the field of phenomena is the same. And you can imagine how small a prospect anyone has of explaining these disorders (which belong within the sphere of psychiatry) who is not forearmed for his task with an analytic knowledge of the transference neuroses.

On the other side, it is equally easy, from the knowledge we have so far gained of the mechanism of the psychoses, to adduce examples which point to a disturbance in the relationship between the ego and the external world. In Meynert's amentia - an acute hallucinatory confusion which is perhaps the most extreme and striking form of psychosis - either the external world is not perceived at all, or the perception of it has no effect whatever. Normally, the external world governs the ego in two ways: firstly, by current, present perceptions which are always renewable, and secondly, by the store of memories of earlier perceptions which, in the shape of an 'internal world', form a possession of the ego and a constituent part of it. In amentia, not only is the acceptance of new perceptions refused, but the internal world, too, which, as a copy of the external world, has up till now represented it, loses its significance (its cathexis) - The ego creates, autocratically, a new external and internal world; and there can be no doubt of two facts - that this new world is constructed in accordance with the id's wishful impulses, and that the motive of this dissociation from the external world is some very serious frustration by reality of a wish - a frustration which seems intolerable. The close affinity of this psychosis to normal dreams is unmistakable. A precondition of dreaming, moreover, is a state of sleep, and one of the features of sleep is a complete turning away from perception and the external world.
We already know a number of things preliminary to such an undertaking. According to our hypothesis it is the ego's task to meet the demands raised by its three dependent relations to reality, to the id and to the super-ego - and nevertheless at the same time to preserve its own organization and maintain its own autonomy. The necessary precondition of the pathological states under discussion can only be a relative or absolute weakening of the ego which makes the fulfilment of its tasks impossible. The severest demand on the ego is probably the keeping down of the instinctual claims of the id, to accomplish which it is obliged to maintain large expenditures of energy on anticathexes. But the demands made by the super-ego too may become so powerful and so relentless that the ego may be paralysed, as it were, in the face of its other tasks. We may suspect that, in the economic conflicts which arise at this point, the id and the super-ego often make common cause against the hard-pressed ego which tries to cling to reality in order to retain its normal state. If the other two become too strong, they succeed in loosening and altering the ego's organization, so that its proper relation to reality is disturbed or even brought to an end. We have seen it happen in dreaming: when the ego is detached from the reality of the external world, it slips down, under the influence of the internal world, into psychosis.

These recollections might have been described as hallucinations if a belief in their actual presence had been added to their clearness. The importance of this analogy seemed greater when I noticed that true hallucinations occasionally occurred in the case of other patients who were certainly not psychotic. My line of thought proceeded as follows. Perhaps it may be a general characteristic of hallucinations to which sufficient attention has not hitherto been paid that in them something that has been experienced in infancy and then forgotten returns - something that the child has seen or heard at a time when he could still hardly speak and that now forces its way into consciousness, probably distorted and displaced owing to the operation of forces that are opposed to this return. And, in view of the close relation between hallucinations and particular forms of psychosis, our line of thought may be carried still further. It may be that the delusions into which these hallucinations are so constantly incorporated may themselves be less independent of the upward drive of the unconscious and the return of the repressed than we usually assume. In the mechanism of a delusion we stress as a rule only two factors: the turning away from the real world and its motive forces on the one hand, and the influence exercised by wish-fulfilment on the content of the delusion on the other. But may it not be that the dynamic process is rather that the turning away from reality is exploited by the upward drive of the repressed in order to force its content into consciousness, while the resistances stirred up by this process and the trend to wish-fulfilment share the responsibility for the distortion and displacement of what is recollected? This is after all the familiar mechanism of dreams, which intuition has equated with madness from time immemorial.
On the other hand, we can already learn from pathology the way in which reality-testing may be done away with or put out of action. We shall see this more clearly in the wishful psychosis of amentia than in that of dreams. Amentia is the reaction to a loss which reality affirms, but which the ego has to deny, since it finds it insupportable. Thereupon the ego breaks off its relation to reality; it withdraws the cathexis from the system of perceptions, Cs. - or rather, perhaps, it withdraws a cathexis, the special nature of which may be the subject of further enquiry. With this turning away from reality, reality-testing is got rid of, the (unrepressed, completely conscious) wishful phantasies are able to press forward into the system, and they are there regarded as a better reality. Such a withdrawal may be put on a par with the processes of repression. Amentia presents the interesting spectacle of a breach between the ego and one of its organs - one which had perhaps been its most faithful servant and had been bound up with it the most intimately.²

[1917d, 3037]

As regards the hallucinatory psychosis of dementia praecox, we shall infer from our discussion that that psychosis cannot be among the initial symptoms of the affection. It becomes possible only when the patient's ego is so far disintegrated that reality-testing no longer stands in the way of hallucination.

[1917d, 3038]

Conscious processes on the periphery of the ego and everything else in the ego unconscious - such would be the simplest state of affairs that we might picture. And such may in fact be the state that prevails in animals. But in men there is an added complication through which internal processes in the ego may also acquire the quality of consciousness. This is the work of the function of speech, which brings material in the ego into a firm connection with mnemic residues of visual, but more particularly of auditory, perceptions. Thenceforward the perceptual periphery of the cortical layer can be excited to a much greater extent from inside as well, internal events such as passages of ideas and thought-processes can become conscious, and a special device is called for in order to distinguish between the two possibilities - a device known as reality-testing. The equation 'perception = reality (external world)' no longer holds. Errors, which can now easily arise and do so regularly in dreams, are called hallucinations.

[1940a [1938], 4972]
As regards the hallucinatory psychosis of dementia praecox, we shall infer from our discussion that that psychosis cannot be among the initial symptoms of the affection. It becomes possible only when the patient's ego is so far disintegrated that reality-testing no longer stands in the way of hallucination.

The situation in which we find ourselves at the beginning of our enquiry may be expected itself to point the way for us. We wish to make the ego the matter of our enquiry, our very own ego. But is that possible? After all, the ego is in its very essence a subject; how can it be made into an object? Well, there is no doubt that it can be. The ego can take itself as an object, can treat itself like other objects, can observe itself, criticize itself, and do Heaven knows what with itself. In this, one part of the ego is setting itself over against the rest. So the ego can be split; it splits itself during a number of its functions - temporarily at least. Its parts can come together again afterwards. That is not exactly a novelty, though it may perhaps be putting an unusual emphasis on what is generally known. On the other hand, we are familiar with the notion that pathology, by making things larger and coarser, can draw our attention to normal conditions which would otherwise have escaped us. Where it points to a breach or a rent, there may normally be an articulation present. If we throw a crystal to the floor, it breaks; but not into haphazard pieces. It comes apart along its lines of cleavage into fragments whose boundaries, though they were invisible, were predetermined by the crystal's structure. Mental patients are split and broken structures of this same kind. Even we cannot withhold from them something of the reverential awe which peoples of the past felt for the insane. They have turned away from external reality, but for that very reason they know more about internal, psychical reality and can reveal a number of things to us that would otherwise be inaccessible to us.

[1917d, 3038]

[1933a, 4667]
In the case of schizophrenia, on the other hand, we have been driven to the assumption that after the process of repression the libido that has been withdrawn does not seek a new object, but retreats into the ego; that is to say, that here the object-cathexes are given up and a primitive objectless condition of narcissism is re-established. The incapacity of these patients for transference (so far as the pathological process extends), their consequent inaccessibility to therapeutic efforts, their characteristic repudiation of the external world, the appearance of signs of a hypercathexis of their own ego, the final outcome in complete apathy - all these clinical features seem to agree excellently with the assumption that their object-cathexes have been given up. As regards the relation of the two psychical systems to each other, all observers have been struck by the fact that in schizophrenia a great deal is expressed as being conscious which in the transference neuroses can only be shown to be present in the Ucs. by psychoanalysis. But to begin with we were not able to establish any intelligible connection between the ego-object relation and the relationships of consciousness.

[1915e, 3019]

We have repeatedly had to insist on the fact that the ego owes its origin as well as the most important of its acquired characteristics to its relation to the real external world. We are thus prepared to assume that the ego's pathological states, in which it most approximates once again to the id, are founded on a cessation or slackening of that relation to the external world. This tallies very well with what we learn from clinical experience - namely, that the precipitating cause of the outbreak of a psychosis is either that reality has become intolerably painful or that the instincts have become extraordinarily intensified - both of which, in view of the rival claims made on the ego by the id and the external world, must lead to the same result. The problem of psychoses would be simple and perspicuous if the ego's detachment from reality could be carried through completely. But that seems to happen only rarely or perhaps never. Even in a state so far removed from the reality of the external world as one of hallucinatory confusion, one learns from patients after their recovery that at the time in some corner of their mind (as they put it) there was a normal person hidden, who, like a detached spectator, watched the hubbub of illness go past him. I do not know if we may assume that this is so in general, but I can report the same of other psychoses with a less tempestuous course. I call to mind a case of chronic paranoia in which after each attack of jealousy a dream conveyed to the analyst a correct picture of the precipitating cause, free from any delusion. An interesting contrast was thus brought to light: while we are accustomed to discover from the dreams of neurotics jealousies which are alien to their waking lives, in this psychotic case the delusion which dominated the patient in the day-time was corrected by his dream. We may probably take it as being generally true that what occurs in all these cases is a psychical split. Two psychical attitudes have been formed instead of a single one - one, the normal one, which takes account of reality, and another which under the influence of the instincts detaches the ego from reality. The two exist alongside of each other. The issue depends on their relative strength. If the second is or becomes the stronger, the necessary precondition for a psychosis is present. If the relation is reversed, then there is an apparent cure of the delusional disorder. Actually it has only retreated into the unconscious - just as numerous observations lead us to believe that the delusion existed ready-made for a long time before its manifest irruption.

[1940a [1938], 5007]
Thus we have attributed three qualities to psychical processes: they are either conscious, preconscious or unconscious. The division between the three classes of material which possess these qualities is neither absolute nor permanent. What is preconscious becomes conscious, as we have seen, without any assistance from us; what is unconscious can, through our efforts, be made conscious, and in the process we may have a feeling that we are often overcoming very strong resistances. When we attempt to do this with someone else, we should not forget that the conscious filling-in of the gaps in his perceptions - the construction we are presenting him with - does not mean as yet that we have made the unconscious material in question conscious to him. All that is true so far is that the material is present in him in two records, once in the conscious reconstruction he has been given, and besides this in its original unconscious state. Our continued efforts usually succeed eventually in making this unconscious material conscious to him himself, as a result of which the two records are brought to coincide. The amount of effort we have to use, by which we estimate the resistance against the material becoming conscious, varies in magnitude in individual cases. For instance, what comes about in an analytic treatment as a result of our efforts can also occur spontaneously: material which is ordinarily unconscious can transform itself into preconscious material and then becomes conscious - a thing that happens to a large extent in psychotic states. From this we infer that the maintenance of certain internal resistances is a sine qua non of normality. A relaxation of resistances such as this, with a consequent pushing forward of unconscious material, takes place regularly in the state of sleep, and thus brings about a necessary precondition for the construction of dreams. Conversely, preconscious material can become temporarily inaccessible and cut off by resistances, as happens when something is temporarily forgotten or escapes the memory; or a preconscious thought can even be temporarily put back into the unconscious state, as seems to be a precondition in the case of jokes. We shall see that a similar transformation back of preconscious material or processes into the unconscious state plays a great part in the causation of neurotic disorders.

[1940a [1938], 4970]
The unconscious wishful impulses clearly try to make themselves effective in daytime as well, and the fact of transference, as well as the psychoses, show us that they endeavour to force their way by way of the preconscious system into consciousness and to obtain control of the power of movement. Thus the censorship between the Ucs. and the Pcs., the assumption of whose existence is positively forced upon us by dreams, deserves to be recognized and respected as the watchman of our mental health. Must we not regard it, however, as an act of carelessness on the part of that watchman that it relaxes its activities during the night, allows the suppressed impulses in the Ucs. to find expression, and makes it possible for hallucinatory regression to occur once more? I think not. For even though this critical watchman goes to rest - and we have proof that its slumbers are not deep - it also shuts the door upon the power of movement. No matter what impulses from the normally inhibited Ucs. may prance upon the stage, we need feel no concern; they remain harmless, since they are unable to set in motion the motor apparatus by which alone they might modify the external world. The state of sleep guarantees the security of the citadel that must be guarded. The position is less harmless when what brings about the displacement of forces is not the nightly relaxation in the critical censorship's output of force, but a pathological reduction in that force or a pathological intensification of the unconscious excitations while the preconscious is still cathected and the gateway to the power of movement stands open. When this is so, the watchman is overpowered, the unconscious excitations overwhelm the Pcs., and thence obtain control over our speech and actions; or they forcibly bring about hallucinatory regression and direct the course of the apparatus (which was not designed for their use) by virtue of the attraction exercised by perceptions on the distribution of our psychical energy. To this state of things we give the name of psychosis.

The aetiology common to the onset of a psychoneurosis and of a psychosis always remains the same. It consists in a frustration, a non-fulfilment of one of those childhood wishes which are for ever undefeated and which are so deeply rooted in our phylogenetically determined organization. This frustration is in the last resort always an external one; but in the individual case it may proceed from the internal agency (in the super-ego) which has taken over the representation of the demands of reality. The pathogenic effect depends on whether, in a conflictual tension of this kind, the ego remains true to its dependence on the external world and attempts to silence the id, or whether it lets itself be overcome by the id and thus torn away from reality. A complication is introduced into this apparently simple situation, however, by the existence of the super-ego, which, though a link that is not yet clear to us, unites in itself influences coming from the id as well as from the external world, and is to some extent an ideal model of what the whole endeavour of the ego is aiming at - a reconciliation between its various dependent relationships. The attitude of the super-ego should be taken into account - which has not hitherto been done - in every form of psychical illness. We may provisionally assume that there must also be illnesses which are based on a conflict between the ego and the super-ego. Analysis gives us a right to suppose that melancholia is a typical example of this group; and we would set aside the name of 'narcissistic psychoneuroses' for disorders of that kind. Nor will it clash with our impressions if we find reasons for separating states like melancholia from the other psychoses. We now see that we have been able to make our simple genetic formula more complete, without dropping it. Transference neuroses correspond to a conflict between the ego and the id; narcissistic neuroses, to a conflict between the ego and the super-ego; and psychoses, to one between the ego and the external world. It is true that we cannot tell at once whether we have really gained any new knowledge by this, or have only enriched our store of formulas; but I think that this possible application of the proposed differentiation of the mental apparatus into an ego, a super-ego and an id cannot fail to give us courage to keep that hypothesis steadily in view.

[1900a, 997]
[1924b, 4067]
You have long been aware that this censorship is not an institution peculiar to dream-life. You know that the conflict between the two psychical agencies, which we - inaccurately - describe as the 'unconscious repressed' and the 'conscious', dominates our whole mental life and that the resistance against the interpretation of dreams, the sign of the dream-censorship, is nothing other than the resistance due to repression by which the two agencies are separated. You know too that the conflict between these two agencies may under certain conditions produce other psychical structures which, like dreams, are the outcome of compromises; and you will not expect me to repeat to you here everything that was contained in my introduction to the theory of the neuroses in order to demonstrate to you what we know of the determinants of the formation of such compromises. You have realized that the dream is a pathological product, the first member of the class which includes hysterical symptoms, obsessions and delusions, but that it is distinguished from the others by its transitoriness and by its occurrence under conditions which are part of normal life. For let us bear firmly in mind that, as was already pointed out by Aristotle, dream life is the way in which our mind works during the state of sleep. The state of sleep involves a turning-away from the real external world, and there we have the necessary condition for the development of a psychosis. The most careful study of the severe psychoses will not reveal to us a single feature that is more characteristic of those pathological conditions. In psychoses, however, the turning-away from reality is brought about in two kinds of way: either by the unconscious repressed becoming excessively strong so that it overpowers the conscious, which is attached to reality, or because reality has become so intolerably distressing that the threatened ego throws itself into the arms of the unconscious instinctual forces in a desperate revolt. The harmless dream-psychosis is the result of a withdrawal from the external world which is consciously willed and only temporary, and it disappears when relations to the external world are resumed. During the isolation of the sleeping individual an alteration in the distribution of his psychical energy also sets in; a part of the expenditure on repression, which is normally required in order to hold the unconscious down, can be saved, for if the unconscious makes use of its relative liberation for active purposes, it finds its path to motility closed and the only path open to it is the harmless one leading to hallucinatory satisfaction. Now, therefore, a dream can be formed; but the fact of the dream-censorship shows that even during sleep enough of the resistance due to repression is retained.

[1933a, 4629]
In both the instances considered so far, defence against the incompatible idea was effected by separating it from its affect; the idea itself remained in consciousness, even though weakened and isolated. There is, however, a much more energetic and successful kind of defence. Here, the ego rejects the incompatible idea together with its affect and behaves as if the idea had never occurred to the ego at all. But from the moment at which this has been successfully done the subject is in a psychosis, which can only be classified as ‘hallucinatory confusion’. A single example may serve to illustrate this statement:

[1894a, 313]

The fact to which I now wish to call attention is that the content of a hallucinatory psychosis of this sort consists precisely in the accentuation of the idea which was threatened by the precipitating cause of the onset of the illness. One is therefore justified in saying that the ego has fended off the incompatible idea through a flight into psychosis. The process by which this has been achieved once more eludes the subject's self perception, as it eludes psychologico-clinical analysis. It must be regarded as the expression of a pathological disposition of a fairly high degree and it may be described more or less as follows. The ego breaks away from the incompatible idea; but the latter is inseparably connected with a piece of reality, so that, in so far as the ego achieves this result, it, too, has detached itself wholly or in part from reality. In my opinion this latter event is the condition under which the subject's ideas receive the vividness of hallucinations; and thus when the defence has been successfully carried out he finds himself in a state of hallucinatory confusion.

[1894a, 314]

I have only very few analyses of psychoses of this sort at my disposal. But I think we have to do here with a type of psychical illness which is very frequently employed. For no insane asylum is without what must be regarded as analogous examples - the mother who has fallen ill from the loss of her baby, and now rocks a piece of wood ceaselessly in her arms, or the jilted bride who, arrayed in her wedding-dress, has for years been waiting for her bridegroom.

[1894a, 314]

'A man tormented by physical and mental suffering obtains from dreams what reality denies him: health and happiness. So too in mental disease there are bright pictures of happiness, grandeur, eminence and wealth. The supposed possession of property and the imaginary fulfilment of wishes - the withholding or destruction of which actually affords a psychological basis for insanity - often constitute the chief content of a delirium. A woman who has lost a loved child experiences the joys of motherhood in her delirium; a man who has lost his money believes himself immensely rich; a girl who has been deceived feels that she is tenderly loved.'

[1900a, 596]
But the dream was not content with 'suggesting away' my boil by obstinately insisting upon an idea that was inconsistent with it and so behaving like the hallucinatory delusion of the mother who had lost her child or the merchant whose losses had robbed him of his fortune.¹ The details of the sensation which was being repudiated and of the picture which was employed in order to repress that sensation also served the dream as a means of connecting other material that was currently active in my mind with the situation in the dream and of giving that material representation. I was riding on a grey horse, whose colour corresponded precisely to the pepper-and-salt colour of the suit my colleague P. was wearing when I had last met him in the country. The cause of my boils had been ascribed to my eating highly-spiced food - an aetiology that was at least preferable to the sugar which might also occur to one in connection with boils. My friend P. liked to ride the high horse over me ever since he had taken over one of my women patients on whom I had pulled off some remarkable feats. (In the dream I began by riding tangentially - like the feat of a trick rider.) But in fact, like the horse in the anecdote of the Sunday horseman, this patient had taken me wherever she felt inclined. Thus the horse acquired the symbolic meaning of a woman patient. (It was highly intelligent in the dream.) 'I felt quite at home up there' referred to the position I had occupied in this patient's house before I was replaced by P. Not long before, one of my few patrons among the leading physicians in this city had remarked to me in connection with this same house: 'You struck me as being firmly in the saddle there.' It was a remarkable feat, too, to be able to carry on my psychotherapeutic work for eight or ten hours a day while I was having so much pain. But I knew that I could not go on long with my peculiarly difficult work unless I was in completely sound physical health; and my dream was full of gloomy allusions to the situation in which I should then find myself. (The note which neurasthenics bring with them to show the doctor; no work, no food.) In the course of further interpretation I saw that the dream-work had succeeded in finding a path from the wishful situation of riding to some scenes of quarrelling from my very early childhood which must have occurred between me and a nephew of mine, a year my senior, who was at present living in England. Furthermore, the dream had derived some of its elements from my travels in Italy: the street in the dream was composed of impressions of Verona and Siena. A still deeper interpretation led to sexual dream-thoughts, and I recalled the meaning which references to Italy seem to have had in the dreams of a woman patient who had never visited that lovely country: 'gen Italien [to Italy]' - 'Genitalien [genitals]'; and this was connected, too, with the house in which I had preceded my friend P. as physician, as well as with the situation of my boil.

[1900a, 710]
There can be no doubt that that apparatus has only reached its present perfection after a long period of development. Let us attempt to carry it back to an earlier stage of its functioning capacity. Hypotheses, whose justification must be looked for in other directions, tell us that at first the apparatus’s efforts were directed towards keeping itself so far as possible free from stimuli; consequently its first structure followed the plan of a reflex apparatus, so that any sensory excitation impinging on it could be promptly discharged along a motor path. But the exigencies of life interfere with this simple function, and it is to them, too, that the apparatus owes the impetus to further development. The exigencies of life confront it first in the form of the major somatic needs. The excitations produced by internal needs seek discharge in movement, which may be described as an ‘internal change’ or an ‘expression of emotion.’ A hungry baby screams or kicks helplessly. But the situation remains unaltered, for the excitation arising from an internal need is not due to a force producing a momentary impact but to one which is in continuous operation. A change can only come about if in some way or other (in the case of the baby, through outside help) an ‘experience of satisfaction’ can be achieved which puts an end to the internal stimulus. An essential component of this experience of satisfaction is a particular perception (that of nourishment, in our example) the mnemonic image of which remains associated thenceforward with the memory trace of the excitation produced by the need. As a result of the link that has thus been established, next time this need arises a psychical impulse will at once emerge which will seek to re-cathect the mnemonic image of the perception and to re-evoke the perception itself, that is to say, to re-establish the situation of the original satisfaction. An impulse of this kind is what we call a wish; the reappearance of the perception is the fulfilment of the wish; and the shortest path to the fulfilment of the wish is a path leading direct from the excitation produced by the need to a complete cathexis of the perception. Nothing prevents us from assuming that there was a primitive state of the psychical apparatus in which this path was actually traversed, that is, in which wishing ended in hallucinating. Thus the aim of this first psychical activity was to produce a ‘perceptual identity’ - a repetition of the perception which was linked with the satisfaction of the need.

[1900a, 995]
The bitter experience of life must have changed this primitive thought-activity into a more expedient secondary one. The establishment of a perceptual identity along the short path of regression within the apparatus does not have the same result elsewhere in the mind as does the cathexis of the same perception from without. Satisfaction does not follow; the need persists. An internal cathexis could only have the same value as an external one if it were maintained unceasingly, as in fact occurs in hallucinatory psychoses and hunger phantasies, which exhaust their whole psychic activity in clinging to the object of their wish. In order to arrive at a more efficient expenditure of psychical force, it is necessary to bring the regression to a halt before it becomes complete, so that it does not proceed beyond the mnemic image, and is able to seek out other paths which lead eventually to the desired perceptual identity being established from the direction of the external world.¹ This inhibition of the regression and the subsequent diversion of the excitation become the business of a second system, which is in control of voluntary movement - which for the first time, that is, makes use of movement for purposes remembered in advance. But all the complicated thought-activity which is spun out from the mnemic image to the moment at which the perceptual identity is established by the external world - all this activity of thought merely constitutes a roundabout path to wish-fulfilment which has been made necessary by experience.² Thought is after all nothing but a substitute for a hallucinatory wish; and it is self-evident that dreams must be wish-fulfilments, since nothing but a wish can set our mental apparatus at work. Dreams, which fulfil their wishes along the short path of regression, have merely preserved for us in that respect a sample of the psychical apparatus's primary method of working, a method which was abandoned as being inefficient. What once dominated waking life, while the mind was still young and incompetent, seems now to have been banished into the night - just as the primitive weapons, the bows and arrows, that have been abandoned by adult men, turn up once more in the nursery. Dreaming is a piece of infantile mental life that has been superseded. These methods of working on the part of the psychical apparatus, which are normally suppressed in waking hours, become current once more in psychosis and then reveal their incapacity for satisfying our needs in relation to the external world.³

[1900a, 996]
In the most favourable cases the generation of unpleasure ceases along with the withdrawal of cathexis from the transference thoughts in the Pcs.; and this outcome signifies that the intervention of the unpleasure principle has served a useful purpose. But it is another matter when the repressed unconscious wish receives an organic reinforcement, which it passes on to its transference thoughts; in that way it may place them in a position to make an attempt at forcing their way through with their excitation, even if they have lost their cathexis from the Pcs. There then follows a defensive struggle - for the Pcs. in turn reinforces its opposition to the repressed thoughts (i.e. produces an 'anticathexis') - and thereafter the transference thoughts, which are the vehicles of the unconscious wish, force their way through in some form of compromise which is reached by the production of a symptom. But from the moment at which the repressed thoughts are strongly cathected by the unconscious wishful impulse and, on the other hand, abandoned by the preconscious cathexis, they become subject to the primary psychical process and their one aim is motor discharge or, if the path is open, hallucinatory revival of the desired perceptual identity. We have already found empirically that the irrational processes we have described are only carried out with thoughts that are under repression. We can now see our way a little further into the whole position. The irrational processes which occur in the psychical apparatus are the primary ones. They appear wherever ideas are abandoned by the preconscious cathexis, are left to themselves and can become charged with the uninhibited energy from the unconscious which is striving to find an outlet. Some other observations lend support to the view that these processes which are described as irrational are not in fact falsifications of normal processes - intellectual errors - but are modes of activity of the psychical apparatus that have been freed from an inhibition. Thus we find that the transition from preconscious excitation to movement is governed by the same processes, and that the linking of preconscious ideas to words may easily exhibit the same displacements and confusions, which are then attributed to inattention. Evidence, finally, of the increase in activity which becomes necessary when these primary modes of functioning are inhibited is to be found in the fact that we produce a comic effect, that is, a surplus of energy which has to be discharged in laughter, if we allow these modes of thinking to force their way through into consciousness. [1900a, 1032]

Medical research has at last shown that people of this kind are not to be looked upon as suffering from a disease of the stomach or of the eyes or whatever it may be, but that it must be a question in their case of an illness of the nervous system as a whole. Examination of the brain and nerves of these patients has so far, however, revealed no perceptible changes; and, indeed, some of the features of their symptomatology prohibit any expectation that even more accurate methods of investigation could ever discover changes of a sort that would throw light upon the illness. This condition has been described as 'nervousness' (neurasthenia or hysteria) and has been characterized as a merely 'functional' disorder of the nervous system.¹ Incidentally, an exhaustive examination of the brain (after the patient's death) has been equally without results in the case of many more permanent nervous disorders, as well as in illnesses with exclusively mental symptoms, such as what are known as obsessions and delusional insanity. [1890a, 1587]
We are beginning to understand now, and to feel some hope. If the young lady in whose form Gradiva had come to life again accepted Hanold's delusion so fully, she was probably doing so in order to set him free from it. There was no other way of doing so; to contradict it would have put an end to any such possibility. Even the serious treatment of a real case of illness of the kind could proceed in no other way than to begin by taking up the same ground as the delusional structure and then investigating it as completely as possible. If Zoe was the right person for the job, we shall soon learn, no doubt, how to cure a delusion like our hero's. We should also be glad to know how such delusions arise. It would be a strange coincidence - but, nevertheless, not without an example or parallel - if the treatment of the delusion were to coincide with its investigation and if the explanation of its origin were to be revealed precisely while it was being dissected. We may suspect, of course, that, if so, our case of illness might end up as a 'commonplace' love-story. But the healing power of love against a delusion is not to be despised - and was not our hero's infatuation for his Gradiva sculpture a complete instance of being in love, though of being in love with something past and lifeless?

[1907a, 1825]

If the cloacal theory of birth is preserved in consciousness during later years of childhood, as occasionally happens, it is accompanied too by a solution - no longer, it is true, a primary one - of the problem of the origin of babies. Here it is like being in a fairy story; one eats some particular thing and gets a child from it. This infantile theory of birth is revived in cases of insanity. A manic woman, for instance, will lead the visiting doctor to a little heap of faeces which she has deposited in a corner of her cell, and say to him with a laugh: 'That's the baby I had to-day.'

[1908c, 1974]

Our hypotheses as to the dispositional fixations in paranoia and paraphrenia make it easy to see that a case may begin with paranoic symptoms and may yet develop into a dementia praecox, and that paranoid and schizophrenic phenomena may be combined in any proportion. And we can understand how a clinical picture such as Schreber's can come about, and merit the name of a paranoid dementia, from the fact that in its production of a wishful phantasy and of hallucinations it shows paraphrenic traits, while in its exciting cause, in its use of the mechanism of projection, and in its outcome it exhibits a paranoid character. For it is possible for several fixations to be left behind in the course of development, and each of these in succession may allow an irruption of the libido that has been pushed off - beginning, perhaps, with the later acquired fixations, and going on, as the illness develops, to the original ones that lie nearer the starting-point. We should be glad to know to what conditions the relatively favourable issue of the present case is due; for we cannot willingly attribute the whole responsibility for the outcome to anything so casual as the 'improvement due to change in domicile',¹ which set in after the patient's removal from Flechsig's clinic. But our insufficient acquaintance with the intimate circumstances of the history of the case makes it impossible to give an answer to this interesting question. It may be suspected, however, that what enabled Schreber to reconcile himself to his homosexual phantasy, and so made it possible for his illness to terminate in something approximating to a recovery, may have been the fact that his father-complex was in the main positively toned and that in real life the later years of his relationship with an excellent father had probably been unclouded.

[1911c, 2443]
Similar considerations apply to the deliria and hallucinations, as well as to the delusional systems, exhibited by various psychotic patients. Where hitherto nothing but the most freakish capriciousness has seemed to prevail, psycho-analytic research has introduced law, order and connection, or has at least allowed us to suspect their presence where its work is still incomplete. The most heterogeneous forms of mental disorder are revealed as the results of processes which are at bottom identical and which can be understood and described by means of psychological concepts. What had already been discovered in the formation of dreams is operative everywhere - psychical conflict, the repression of certain instinctual impulses which have been pushed back into the unconscious by other mental forces, reaction formations set up by the repressing forces, and substitutes constructed by the instincts which have been repressed but have not been robbed of all their energy. The accompanying processes of condensation and displacement, so familiar to us in dreams, are also to be found everywhere. The multiplicity of clinical pictures observed by psychiatrists depends upon two other things: the multiplicity of the psychical mechanisms at the disposal of the repressive process and the multiplicity of developmental dispositions which give the repressed impulses an opportunity for breaking through into substitutive structures.

[1913j, 2811]

The formation of the wishful phantasy and its regression to hallucination are the most essential parts of the dream-work, but they do not belong exclusively to dreams. They are also found in two morbid states: in acute hallucinatory confusion (Meynert's 'amentia'), and in the hallucinatory phase of schizophrenia. The hallucinatory delirium of amentia is a clearly recognizable wishful phantasy, often completely well ordered like a perfect day-dream. One might speak quite generally of a 'hallucinatory wishful psychosis', and attribute it equally to dreams and amentia. There are even dreams which consist of nothing but undistorted wishful phantasies with a very rich content. The hallucinatory phase of schizophrenia has been less thoroughly studied; it seems as a rule to be of a composite nature, but in its essence it might well correspond to a fresh attempt at restitution, designed to restore a libidinal cathexis to the ideas of objects.¹ I cannot extend the comparison to the other hallucinatory states in various pathological disorders, because in their case I have no experience of my own upon which to draw, and cannot utilize that of other observers.

[1917d, 3034]
Let us be clear that the hallucinatory wishful psychosis - in dreams or elsewhere - achieves two by no means identical results. It not only brings hidden or repressed wishes into consciousness; it also represents them, with the subject's entire belief, as fulfilled. The concurrence of these two results calls for explanation. It is quite impossible to maintain that unconscious wishes must necessarily be taken for realities when once they have become conscious; for, as we know, our judgement is very well able to distinguish realities from ideas and wishes, however intense they may be. On the other hand, it seems justifiable to assume that belief in reality is bound up with perception through the senses. When once a thought has followed the path to regression as far back as to the unconscious memory-traces of objects and thence to perception, we accept the perception of it as real. So hallucination brings belief in reality with it. We now have to ask ourselves what determines the coming into being of a hallucination. The first answer would be regression, and this would replace the problem of the origin of hallucination by that of the mechanism of regression. As regards dreams, this latter problem need not remain long unanswered. Regression of Pcs. dream-thoughts to mnemic images of things is clearly the result of the attraction which the Ucs. instinctual representatives - e.g. repressed memories of experiences - exercise upon the thoughts which have been put into words. But we soon perceive that we are on a false scent. If the secret of hallucination is nothing else than that of regression, every regression of sufficient intensity would produce hallucination with belief in its reality. But we are quite familiar with situations in which a process of regressive reflection brings to consciousness very clear visual mnemic images, though we do not on that account for a single moment take them for real perceptions. Again, we could very well imagine the dream-work penetrating to mnemic images of this kind, making conscious to us that was previously unconscious, and holding up to us a wishful phantasy which rouses our longing, but which we should not regard as a real fulfilment of the wish. Hallucination must therefore be something more than the regressive revival of mnemic images that are in themselves Ucs.

Let us, furthermore, bear in mind the great practical importance of distinguishing perceptions from ideas, however intensely recalled. Our whole relation to the external world, to reality, depends on our ability to do so. We have put forward the fiction that we did not always possess this ability and that at the beginning of our mental life we did in fact hallucinate the satisfying object when we felt the need for it. But in such a situation satisfaction did not occur, and this failure must very soon have moved us to create some contrivance with the help of which it was possible to distinguish such wishful perceptions from a real fulfilment and to avoid them for the future. In other words, we gave up hallucinatory satisfaction of our wishes at a very early period and set up a kind of 'reality-testing'. The question now arises in what this reality-testing consisted, and how the hallucinatory wishful psychosis of dreams and amnesia and similar conditions succeeds in abolishing it and in re-establishing the old mode of satisfaction.

On the other hand, we can already learn from pathology the way in which reality-testing may be done away with or put out of action. We shall see this more clearly in the wishful psychosis of amnesia than in that of dreams. Amentia is the reaction to a loss which reality affirms, but which the ego has to deny, since it finds it insupportable. Thereupon the ego breaks off its relation to reality; it withdraws the cathectic from the system of perceptions, Cs. - or rather, perhaps, it withdraws a cathectic, the special nature of which may be the subject of further enquiry. With this turning away from reality, reality-testing is got rid of, the (unrepressed, completely conscious) wishful phantasies are able to press forward into the system, and they are there regarded as a better reality. Such a withdrawal may be put on a par with the processes of repression. Amentia presents the interesting spectacle of a breach between the ego and one of its organs - one which had perhaps been its most faithful servant and had been bound up with it the most intimately.
I may venture to suggest in this connection that the toxic hallucinoses, too, e.g. alcoholic delirium, are to be understood in an analogous fashion. Here the unbearable loss imposed by reality would be precisely the loss of alcohol. When the latter is supplied, the hallucinations cease.

Finally, let us once more glance at the significant light which the topography of the process of repression throws for us on the mechanism of mental disturbances. In dreams the withdrawal of cathectic (libido or interest) affects all systems equally; in the transference neuroses, the Pcs. cathexis is withdrawn; in schizophrenia, the cathectic of the Ucs.; in amentia, that of the Cs.

In what, now, does the work which mourning performs consist? I do not think there is anything far-fetched in presenting it in the following way. Reality-testing has shown that the loved object no longer exists, and it proceeds to demand that all libido shall be withdrawn from its attachments to that object. This demand arouses understandable opposition - it is a matter of general observation that people never willingly abandon a libidinal position, not even, indeed, when a substitute is already beckoning to them. This opposition can be so intense that a turning away from reality takes place and a clinging to the object through the medium of a hallucinatory wishful psychosis. Normally, respect for reality gains the day. Nevertheless its orders cannot be obeyed at once. They are carried out bit by bit, at great expense of time and cathectic energy, and in the meantime the existence of the lost object is psychically prolonged. Each single one of the memories and expectations in which the libido is bound to the object is brought up and hypercathected, and detachment of the libido is accomplished in respect of it. Why this compromise by which the command of reality is carried out piecemeal should be so extraordinarily painful is not at all easy to explain in terms of economics. It is remarkable that this painful unpleasure is taken as a matter of course by us. The fact is, however, that when the work of mourning is completed the ego becomes free and uninhibited again.

On the other side, it is equally easy, from the knowledge we have so far gained of the mechanism of the psychoses, to adduce examples which point to a disturbance in the relationship between the ego and the external world. In Meynert's amentia - an acute hallucinatory confusion which is perhaps the most extreme and striking form of psychosis - either the external world is not perceived at all, or the perception of it has no effect whatever. Normally, the external world governs the ego in two ways: firstly, by current, present perceptions which are always renewable, and secondly, by the store of memories of earlier perceptions which, in the shape of an 'internal world', form a possession of the ego and a constituent part of it. In amentia, not only is the acceptance of new perceptions refused, but the internal world, too, which, as a copy of the external world, has up till now represented it, loses its significance (its cathectic) - The ego creates, autocratically, a new external and internal world; and there can be no doubt of two facts - that this new world is constructed in accordance with the id's wishful impulses, and that the motive of this dissociation from the external world is some very serious frustration by reality of a wish - a frustration which seems intolerable. The close affinity of this psychosis to normal dreams is unmistakable. A precondition of dreaming, moreover, is a state of sleep, and one of the features of sleep is a complete turning away from perception and the external world.
This does not in the least mean that these wishes are to be pushed contemptuously on one side or their value for human life under-estimated. We are ready to trace out the fulfilsments of them which they have created for themselves in the products of art and in the systems of religion and philosophy; but we cannot nevertheless overlook the fact that it would be illegitimate and highly inexpedient to allow these demands to be transferred to the sphere of knowledge. For this would be to lay open the paths which lead to psychosis, whether to individual or group psychosis, and would withdraw valuable amounts of energy from endeavours which are directed towards reality in order, so far as possible, to find satisfaction in it for wishes and needs.

[1933a, 4758]

These recollections might have been described as hallucinations if a belief in their actual presence had been added to their clearness. The importance of this analogy seemed greater when I noticed that true hallucinations occasionally occurred in the case of other patients who were certainly not psychotic. My line of thought proceeded as follows. Perhaps it may be a general characteristic of hallucinations to which sufficient attention has not hitherto been paid that in them something that has been experienced in infancy and then forgotten returns - something that the child has seen or heard at a time when he could still hardly speak and that now forces its way into consciousness, probably distorted and displaced owing to the operation of forces that are opposed to this return. And, in view of the close relation between hallucinations and particular forms of psychosis, our line of thought may be carried still further. It may be that the delusions into which these hallucinations are so constantly incorporated may themselves be less independent of the upward drive of the unconscious and the return of the repressed than we usually assume. In the mechanism of a delusion we stress as a rule only two factors: the turning away from the real world and its motive forces on the one hand, and the influence exercised by wish-fulfilment on the content of the delusion on the other. But may it not be that the dynamic process is rather that the turning away from reality is exploited by the upward drive of the repressed in order to force its content into consciousness, while the resistances stirred up by this process and the trend to wish-fulfilment share the responsibility for the distortion and displacement of what is recollected? This is after all the familiar mechanism of dreams, which intuition has equated with madness from time immemorial.

[1937d, 5058]
I have only very few analyses of psychoses of this sort at my disposal. But I think we have to do here with a type of psychical illness which is very frequently employed. For no insane asylum is without what must be regarded as analogous examples - the mother who has fallen ill from the loss of her baby, and now rocks a piece of wood unceasingly in her arms, or the jilted bride who, arrayed in her wedding-dress, has for years been waiting for her bridegroom.

[1894a, 314]

On the other side, it is equally easy, from the knowledge we have so far gained of the mechanism of the psychoses, to adduce examples which point to a disturbance in the relationship between the ego and the external world. In Meynert's amentia - an acute hallucinatory confusion which is perhaps the most extreme and striking form of psychosis - either the external world is not perceived at all, or the perception of it has no effect whatever. Normally, the external world governs the ego in two ways: firstly, by current, present perceptions which are always renewable, and secondly, by the store of memories of earlier perceptions which, in the shape of an "internal world", form a possession of the ego and a constituent part of it. In amentia, not only is the acceptance of new perceptions refused, but the internal world, too, which, as a copy of the external world, has up till now represented it, loses its significance (its cathexis) - The ego creates, autocratically, a new external and internal world; and there can be no doubt of two facts - that this new world is constructed in accordance with the id's wishful impulses, and that the motive of this dissociation from the external world is some very serious frustration by reality of a wish - a frustration which seems intolerable. The close affinity of this psychosis to normal dreams is unmistakable. A precondition of dreaming, moreover, is a state of sleep, and one of the features of sleep is a complete turning away from perception and the external world.

[1924b, 4066]
And the paranoic builds it again, not more splendid, it is true, but at least so that he can once more live in it. He builds it up by the world of his delusions. The delusional formation, which we take to be the pathological product, is in reality an attempt at recovery, a process of reconstruction. Such a reconstruction after the catastrophe is successful to a greater or lesser extent, but never wholly so; in Schreber's words, there has been a 'profound internal change' in the world. But the human subject has recaptured a relation, and often a very intense one, to the people and things in the world, even though the relation is a hostile one now, where formerly it was hopefully affectionate. We may say, then, that the process of repression proper consists in a detachment of the libido from people - and things - that were previously loved. It happens silently; we receive no intelligence of it, but can only infer it from subsequent events. What forces itself so noisily upon our attention is the process of recovery, which undoes the work of repression and brings back the libido again on to the people it had abandoned. In paranoia this process is carried out by the method of projection. It was incorrect to say that the perception which was suppressed internally is projected outwards; the truth is rather, as we now see, that what was abolished internally returns from without. The thorough examination of the process of projection which we have postponed to another occasion will clear up our remaining doubts on this subject.

On the other hand, we can already learn from pathology the way in which reality-testing may be done away with or put out of action. We shall see this more clearly in the wishful psychosis of amentia than in that of dreams. Amentia is the reaction to a loss which reality affirms, but which the ego has to deny, since it finds it insupportable. Thereupon the ego breaks off its relation to reality; it withdraws the cathexis from the system of perceptions, Cs. - or rather, perhaps, it withdraws a cathexis, the special nature of which may be the subject of further enquiry. With this turning away from reality, reality-testing is got rid of, the (unrepressed, completely conscious) wishful phantasies are able to press forward into the system, and they are there regarded as a better reality. Such a withdrawal may be put on a par with the processes of repression. Amentia presents the interesting spectacle of a breach between the ego and one of its organs - one which had perhaps been its most faithful servant and had been bound up with it the most intimately.²

On the other side, it is equally easy, from the knowledge we have so far gained of the mechanism of the psychoses, to adduce examples which point to a disturbance in the relationship between the ego and the external world. In Meynert's amentia - an acute hallucinatory confusion which is perhaps the most extreme and striking form of psychosis - either the external world is not perceived at all, or the perception of it has no effect whatever. Normally, the external world governs the ego in two ways: firstly, by current, present perceptions which are always renewable, and secondly, by the store of memories of earlier perceptions which, in the shape of an 'internal world', form a possession of the ego and a constituent part of it. In amentia, not only is the acceptance of new perceptions refused, but the internal world, too, which, as a copy of the external world, has up till now represented it, loses its significance (its cathexis) - The ego creates, autocratically, a new external and internal world; and there can be no doubt of two facts - that this new world is constructed in accordance with the id's wishful impulses, and that the motive of this dissociation from the external world is some very serious frustration by reality of a wish - a frustration which seems intolerable. The close affinity of this psychosis to normal dreams is unmistakable. A precondition of dreaming, moreover, is a state of sleep, and one of the features of sleep is a complete turning away from perception and the external world.
We might expect that when a psychosis comes into being, something analogous to the process in a neurosis occurs, though, of course, between different agencies of the mind; thus we might expect that in a psychosis, too, two steps could be discerned, of which the first would drag the ego away, this time from reality, while the second would try to make good the damage done and re-establish the subject's relations to reality at the expense of the id. And, in fact, some analogy of the sort can be observed in a psychosis. Here, too, there are two steps, the second of which has the character of a reparation. But beyond that the analogy gives way to a far more extensive similarity between the two processes. The second step of the psychosis is indeed intended to make good the loss of reality, not, however, at the expense of a restriction of the id - as happens in neurosis at the expense of the relation to reality - but in another, more autocratic manner, by the creation of a new reality which no longer raises the same objections as the old one that has been given up. The second step, therefore, both in neurosis and psychosis, is supported by the same trends. In both cases it serves the desire for power of the id, which will not allow itself to be dictated to by reality. Both neurosis and psychosis are thus the expression of a rebellion on the part of the id against the external world, of its unwillingness - or, if one prefers, its incapacity - to adapt itself to the exigencies of reality, to 'Αυάγχη [Necessity]. Neurosis and psychosis differ from each other far more in their first, introductory, reaction than in the attempt at reparation which follows it. [1924e, 4095]

Accordingly, the initial difference is expressed thus in the final outcome: in neurosis a piece of reality is avoided by a sort of flight, whereas in psychosis it is remodelled. Or we might say: in psychosis, the initial flight is succeeded by an active phase of remodelling; in neurosis, the initial obedience is succeeded by a deferred attempt at flight. Or again, expressed in yet another way: neurosis does not disavow the reality, it only ignores it; psychosis disavows it and tries to replace it. We call behaviour 'normal' or 'healthy', if it combines certain features of both reactions - if it disavows the reality as little as does a neurosis, but if it then exerts itself, as does a psychosis, to effect an alteration of that reality. Of course, this expedient, normal, behaviour leads to work being carried out on the external world; it does not stop, as in psychosis, at effecting internal changes. It is no longer autoplasic but alloplastic. [1924e, 4096]

In a psychosis, the transforming of reality is carried out upon the psychical precipitates of former relations to it - that is, upon the memory-traces, ideas and judgements which have been previously derived from reality and by which reality was represented in the mind. But this relation was never a closed one; it was continually being enriched and altered by fresh perceptions. Thus the psychosis is also faced with the task of procuring for itself perceptions of a kind which shall correspond to the new reality; and this is most radically effected by means of hallucination. The fact that, in so many forms and cases of psychosis, the paramnesias, the delusions and the hallucinations that occur are of a most distressing character and are bound up with a generation of anxiety - this fact is without doubt a sign that the whole process of remodelling is carried through against forces which oppose it violently. We may construct the process on the model of a neurosis, with which we are more familiar. There we see that a reaction of anxiety sets in whenever the repressed instinct makes a thrust forward, and that the outcome of the conflict is only a compromise and does not provide complete satisfaction. Probably in a psychosis the rejected piece of reality constantly forces itself upon the mind, just as the repressed instinct does in a neurosis, and that is why in both cases the consequences too are the same. The elucidation of the various mechanisms which are designed, in the psychoses, to turn the subject away from reality and to reconstruct reality - this is a task for specialized psychiatric study which has not yet been taken in hand. [1924e, 4096]
There is, therefore, a further analogy between a neurosis and a psychosis, in that in both of them the task which is undertaken in the second step is partly unsuccessful. For the repressed instinct is unable to procure a full substitute (in neurosis); and the representation of reality cannot be remoulded into satisfying forms (not, at least, in every species of mental illness). But the emphasis is different in the two cases. In a psychosis it falls entirely on the first step, which is pathological in itself and cannot but lead to illness. In a neurosis, on the other hand, it falls on the second step, on the failure of the repression, whereas the first step may succeed, and does succeed in innumerable instances without overstepping the bounds of health - even though it does so at a certain price and not without leaving behind traces of the psychical expenditure it has called for. These distinctions, and perhaps many others as well, are a result of the topographical difference in the initial situation of the pathogenic conflict - namely whether in it the ego yielded to its allegiance to the real world or to its dependence on the id.
[1924e, 4097]

A neurosis usually contents itself with avoiding the piece of reality in question and protecting itself against coming into contact with it. The sharp distinction between neurosis and psychosis, however, is weakened by the circumstance that in neurosis, too, there is no lack of attempts to replace a disagreeable reality by one which is more in keeping with the subject's wishes. This is made possible by the existence of a world of phantasy, of a domain which became separated from the real external world at the time of the introduction of the reality principle. This domain has since been kept free from the demands of the exigencies of life, like a kind of 'reservation'; it is not inaccessible to the ego, but is only loosely attached to it. It is from this world of phantasy that the neurosis draws the material for its new wishful constructions, and it usually finds that material along the path of regression to a more satisfying real past.
[1924e, 4097]

It can hardly be doubted that the world of phantasy plays the same part in psychosis and that there, too, it is the storehouse from which the materials or the pattern for building the new reality are derived. But whereas the new, imaginary external world of a psychosis attempts to put itself in the place of external reality, that of a neurosis, on the contrary, is apt, like the play of children, to attach itself to a piece of reality - a different piece from the one against which it has to defend itself - and to lend that piece a special importance and a secret meaning which we (not always quite appropriately) call a symbolic one. Thus we see that both in neurosis and psychosis there comes into consideration the question not only of a loss of reality but also of a substitute for reality.
[1924e, 4098]
The interest taken by the hero of the story in this relief is the basic psychological fact in the narrative. It was not immediately explicable. 'Dr. Norbert Hanold, Lecturer in Archaeology, did not in fact find in the relief anything calling for special notice from the point of view of his branch of science.' (3.)¹ 'He could not explain to himself what there was in it that had provoked his attention. He only knew that he had been attracted by something and that the effect had continued unchanged ever since.' But his imagination was occupied with the sculpture without ceasing. He found something 'of to-day' about it, as though the artist had had a glimpse in the street and captured it 'from the life'. He gave the girl thus pictured as she stepped along the name of 'Gradiva' - 'the girl who steps along'. He made up a story that she was no doubt the daughter of an aristocratic family, perhaps 'of a patrician aedile, who carried out his office in the service of Ceres', and that she was on her way to the goddess's temple. Then he found it hard to fit her quiet, calm nature into the busy life of a capital city. He convinced himself, rather, that she must be transported to Pompeii, and that somewhere there she was stepping across the curious stepping-stones which have been dug up and which made it possible to cross dry-foot from one side of the street to the other in rainy weather, though allowing carriage-wheels to pass between them as well. Her features struck him as having a Greek look and he had no doubt that she was of Hellenic origin. Little by little he brought the whole of his archaeological learning into the service of these and other phantasies relating to the original who had been the model for the relief.

[1907a, 1816]
The first manifestations of the process that had been set going in Hanold by the relief were phantasies, which played around the figure represented in it. The figure seemed to him to have something 'of to-day' about her, in the best sense of the words, and it was as though the artist had captured her 'from the life' stepping along the street. He gave the girl in the ancient relief the name of 'Gradiva', which he constructed on the model of an epithet of the war-god striding into battle - 'Mars Gradivus'. He endowed her personality with more and more characteristics. She may have been the daughter of a respected personage, of a patrician, perhaps, who was connected with the temple service of a deity. He thought he could trace a Greek origin in her features; and finally he felt compelled to remove her from the busy life of a capital and to transport her to the more peaceful Pompeii, and there he made her step across the lava stepping-stones which made it possible to cross from one side of the street to the other. These products of his phantasy seem arbitrary enough, but at the same time innocently unsuspicious. And, indeed, even when for the first time they gave rise to an incitement to action - when the archaeologist, obsessed by the problem of whether this posture of the feet corresponded to reality, began to make observations from life in order to examine the feet of contemporary women and girls - even this action was screened by conscious scientific motives, as though all his interest in the sculpture of Gradiva had sprung from the soil of his professional concern with archaeology. The women and girls in the street, whom he chose as the subjects of his investigation, must, of course, have taken another, crudely erotic view of his behaviour, and we cannot but think them right. We ourselves can be in no doubt that Hanold was as much in ignorance of the motives of his researches as he was of the origin of his phantasies about Gradiva. These, as we learned later, were echoes of his memories of his youthful love, derivatives of those memories, transformations and distortions of them, after they had failed to make their way into his consciousness in an unmodified form. The ostensibly aesthetic judgement that the sculpture had something 'of to-day' about it took the place of his knowledge that a gait of that kind belonged to a girl whom he knew and who stepped across the street at the present time. Behind the impression of the sculpture being 'from the life' and the phantasy of its subject being Greek lay his memory of the name Zoe, which means 'life' in Greek. 'Gradiva', as we learn from our hero himself at the end of the story, after he has been cured of his delusion, is a good translation of the surname 'Bertgang' which means something like 'someone who steps along brilliantly or splendidly'. The details about Gradiva's father originated from Hanold's knowledge that Zoe Bertgang was the daughter of a respected teacher at the University, which can well be translated into classical terms as 'temple-service'. Finally, his phantasy transported her to Pompeii, not 'because her quiet, calm nature seemed to demand it', but because no other or better analogy could be found in his science for his remarkable state, in which he became aware of his memories of his childhood friendship through obscure channels of information. Once he had made his own childhood coincide with the classical past (which it was so easy for him to do), there was a perfect similarity between the burial of Pompeii - the disappearance of the past combined with its preservation - and repression, of which he possessed a knowledge through what might be described as 'endopsychic' perception. In this he was employing the same symbolism that the author makes the girl use consciously towards the conclusion of the story: 'I told myself I should be able to dig out something interesting here even by myself. Of course I hadn't counted on making the find that I have . . .' (124.) And at the very end she replied to Hanold's plan for their honeymoon with a reference to 'her childhood friend who had also in a sense been dug out of the ruins again'. (150.)

[1907a, 1849]
Let us recall all that we have heard about the nature and origin of the phantasies which are the precursors of delusions. They are substitutes for and derivatives of repressed memories which a resistance will not allow to enter consciousness unaltered, but which can purchase the possibility of becoming conscious by taking account, by means of changes and distortions, of the resistance's censorship. When this compromise has been accomplished, the memories have turned into the phantasies, which can easily be misunderstood by the conscious personality - that is, understood so as to fit in with the dominant psychical current. Now let us suppose that dream-images are what might be described as the creations of people's physiological delusions - the products of the compromise in the struggle between what is repressed and what is dominant which is probably present in every human being, including those who in the day-time are perfectly sound in mind. We shall then understand that dream-images have to be regarded as something distorted, behind which something else must be looked for, something not distorted, but in some sense objectionable, like Hanold's repressed memories behind his phantasies. We can give expression to the contrast which we have thus recognized, by distinguishing what the dreamer remembers when he wakes up as the manifest content of the dream from what constituted the basis of the dream before the distortion imposed by the censorship - namely, the latent dream-thoughts. Thus, interpreting a dream consists in translating the manifest content of the dream into the latent dream-thoughts, in undoing the distortion which the dream-thoughts have had to submit to from the censorship of the resistance. If we apply these notions to the dream we are concerned with, we shall find that its latent dream-thoughts can only have been: 'the girl you are looking for with the graceful gait is really living in this town with you.' But in that form the thought could not become conscious. It was obstructed by the fact that a phantasy had laid it down, as the result of an earlier compromise, that Gradiva was a Pompeian; consequently, if the real fact that she was living in the same place and at the same time was to be affirmed, there was no choice but to adopt the distortion: 'You are living at Pompeii at the time of Gradiva.' This then was the idea which was realized by the manifest content of the dream, and was represented as a present event actually being experienced.

[1907a, 1855]

There is a great deal more that could be said about phantasies; but I will only allude as briefly as possible to certain points. If phantasies become over-luxuriant and over-powerful, the conditions are laid for an onset of neurosis or psychosis. Phantasies, moreover, are the immediate mental precursors of the distressing symptoms complained of by our patients. Here a broad by-path branches off into pathology.

[1908e, 1925]
It would, of course, be a different matter if it were proved that the libido theory has already come to grief in the attempt to explain the latter disease. This has been asserted by C. G. Jung (1912) and it is on that account that I have been obliged to enter upon this last discussion, which I would gladly have been spared. I should have preferred to follow to its end the course embarked upon in the analysis of the Schreber case without any discussion of its premisses. But Jung's assertion is, to say the least of it, premature. The grounds he gives for it are scanty.

In the first place, he appeals to an admission of my own that I myself have been obliged, owing to the difficulties of the Schreber analysis, to extend the concept of libido (that is, to give up its sexual content) and to identify libido with psychical interest in general. Ferenczi (1913b), in an exhaustive criticism of Jung's work, has already said all that is necessary in correction of this erroneous interpretation. I can only corroborate his criticism and repeat that I have never made any such retractation of the libido theory. Another argument of Jung's, namely, that we cannot suppose that the withdrawal of the libido is in itself enough to bring about the loss of the normal function of reality, is no argument but a dictum. It 'begs the question',¹ and saves discussion; for whether and how this is possible was precisely the point that should have been under investigation. In his next major work, Jung (1913) just misses the solution I had long since indicated: 'At the same time', he writes, 'there is this to be further taken into consideration (a point to which, incidentally, Freud refers in his work on the Schreber case) - that the introversion of the libido sexualis leads to a cathexis of the "ego", and that it may possibly be this that produces the result of a loss of reality. It is indeed a tempting possibility to explain the psychology of the loss of reality in this fashion.' But Jung does not enter much further into a discussion of this possibility. A few lines later he dismisses it with the remark that this determinant 'would result in the psychology of an ascetic anchorite, not in a dementia praecox'.

How little this inapt analogy can help us to decide the question may be learnt from the consideration that an anchorite of this kind, who 'tries to eradicate every trace of sexual interest' (but only in the popular sense of the word 'sexual'), does not even necessarily display any pathogenic allocation of the libido. He may have diverted his sexual interest from human beings entirely, and yet may have sublimated it into a heightened interest in the divine, in nature, or in the animal kingdom, without his libido having undergone an introversion on to his phantasies or a return to his ego. This analogy would seem to rule out in advance the possibility of differentiating between interest emanating from erotic sources and from others. Let us remember, further, that the researches of the Swiss school, however valuable, have elucidated only two features in the picture of dementia praecox - the presence in it of complexes known to us both in healthy and neurotic subjects, and the similarity of the phantasies that occur in it to popular myths - but that they have not been able to throw any further light on the mechanism of the disease. We may repudiate Jung's assertion, then, that the libido theory has come to grief in the attempt to explain dementia praecox, and that it is therefore disposed of for the other neuroses as well.

[1914c, 2937]

The formation of the wishful phantasy and its regression to hallucination are the most essential parts of the dream-work, but they do not belong exclusively to dreams. They are also found in two morbid states: in acute hallucinatory confusion (Meynert's 'amentia'), and in the hallucinatory phase of schizophrenia. The hallucinatory delirium of amentia is a clearly recognizable wishful phantasy, often completely well ordered like a perfect day-dream. One might speak quite generally of a 'hallucinatory wishful psychosis', and attribute it equally to dreams and amentia. There are even dreams which consist of nothing but undistorted wishful phantasies with a very rich content. The hallucinatory phase of schizophrenia has been less thoroughly studied; it seems as a rule to be of a composite nature, but in its essence it might well correspond to a fresh attempt at restitution, designed to restore a libidinal cathexis to the ideas of objects.¹ I cannot extend the comparison to the other hallucinatory states in various pathological disorders, because in their case I have no experience of my own upon which to draw, and cannot utilize that of other observers.

[1917d, 3034]
On the other hand, we can already learn from pathology the way in which reality-testing may be done away with or put out of action. We shall see this more clearly in the wishful psychosis of amentia than in that of dreams. Amentia is the reaction to a loss which reality affirms, but which the ego has to deny, since it finds it insupportable. Thereupon the ego breaks off its relation to reality; it withdraws the cathexis from the system of perceptions, Cs. - or rather, perhaps, it withdraws a cathexis, the special nature of which may be the subject of further enquiry. With this turning away from reality, reality-testing is got rid of, the (unrepressed, completely conscious) wishful phantasies are able to press forward into the system, and they are there regarded as a better reality. Such a withdrawal may be put on a par with the processes of repression. Amentia presents the interesting spectacle of a breach between the ego and one of its organs - one which had perhaps been its most faithful servant and had been bound up with it the most intimately.

The acceptance of suggestions on individual points is no doubt discouraged by the fact that during the treatment we are struggling unceasingly against resistances which are able to transform themselves into negative (hostile) transferences. Nor must we fail to point out that a large number of the individual findings of analysis, which might otherwise be suspected to being products of suggestion, are confirmed from another and irreproachable source. Our guarantors in this case are the sufferers from dementia praecox and paranoia, who are of course far above any suspicion of being influenced by suggestion. The translations of symbols and the phantasies, which these patients produce for us and which in them have forced their way through into consciousness, coincide faithfully with the results of our investigations into the unconscious of transference neurotics and thus confirm the objective correctness of our interpretations, on which doubt is so often thrown. You will not, I think, be going astray if you trust analysis on these points.

A neurosis usually contents itself with avoiding the piece of reality in question and protecting itself against coming into contact with it. The sharp distinction between neurosis and psychosis, however, is weakened by the circumstance that in neurosis, too, there is no lack of attempts to replace a disagreeable reality by one which is more in keeping with the subject's wishes. This is made possible by the existence of a world of phantasy, of a domain which became separated from the real external world at the time of the introduction of the reality principle. This domain has since been kept free from the demands of the exigencies of life, like a kind of 'reservation'; it is not inaccessible to the ego, but is only loosely attached to it. It is from this world of phantasy that the neurosis draws the material for its new wishful constructions, and it usually finds that material along the path of regression to a more satisfying real past.

It can hardly be doubted that the world of phantasy plays the same part in psychosis and that there, too, it is the storehouse from which the materials or the pattern for building the new reality are derived. But whereas the new, imaginary external world of a psychosis attempts to put itself in the place of external reality, that of a neurosis, on the contrary, is apt, like the play of children, to attach itself to a piece of reality - a different piece from the one against which it has to defend itself - and to lend that piece a special importance and a secret meaning which we (not always quite appropriately) call a symbolic one. Thus we see that both in neurosis and psychosis there comes into consideration the question not only of a loss of reality but also of a substitute for reality.
The unconscious wishful impulses clearly try to make themselves effective in daytime as well, and the fact of transference, as well as the psychoses, show us that they endeavour to force their way by way of the preconscious system into consciousness and to obtain control of the power of movement. Thus the censorship between the *Ucs* and the *Pcs*, the assumption of whose existence is positively forced upon us by dreams, deserves to be recognized and respected as the watchman of our mental health. Must we not regard it, however, as an act of carelessness on the part of that watchman that it relaxes its activities during the night, allows the suppressed impulses in the *Ucs* to find expression, and makes it possible for hallucinatory regression to occur once more? I think not. For even though this critical watchman goes to rest - and we have proof that its slumbers are not deep - it also shuts the door upon the power of movement. No matter what impulses from the normally inhibited *Ucs* may prance upon the stage, we need feel no concern; they remain harmless, since they are unable to set in motion the motor apparatus by which alone they might modify the external world. The state of sleep guarantees the security of the citadel that must be guarded. The position is less harmless when what brings about the displacement of forces is not the nightly relaxation in the critical censorship's output of force, but a pathological reduction in that force or a pathological intensification of the unconscious excitations while the preconscious is still cathected and the gateway to the power of movement stands open. When this is so, the watchman is overpowered, the unconscious excitations overwhelm the *Pcs*, and thence obtain control over our speech and actions; or they forcibly bring about hallucinatory regression and direct the course of the apparatus (which was not designed for their use) by virtue of the attraction exercised by perceptions on the distribution of our psychical energy. To this state of things we give the name of psychosis.

We already know a number of things preliminary to such an undertaking. According to our hypothesis it is the ego's task to meet the demands raised by its three dependent relations to reality, to the id and to the super-ego - and nevertheless at the same time to preserve its own organization and maintain its own autonomy. The necessary precondition of the pathological states under discussion can only be a relative or absolute weakening of the ego which makes the fulfilment of its tasks impossible. The severest demand on the ego is probably the keeping down of the instinctual claims of the id, to accomplish which it is obliged to maintain large expenditures of energy on anticathexes. But the demands made by the super-ego too may become so powerful and so relentless that the ego may be paralysed, as it were, in the face of its other tasks. We may suspect that, in the economic conflicts which arise at this point, the id and the super-ego often make common cause against the hard-pressed ego which tries to cling to reality in order to retain its normal state. If the other two become too strong, they succeed in loosening and altering the ego's organization, so that its proper relation to reality is disturbed or even brought to an end. We have seen it happen in dreaming: when the ego is detached from the reality of the external world, it slips down, under the influence of the internal world, into psychosis.
Our plan of cure is based on these discoveries. The ego is weakened by the internal conflict and we must go to its help. The position is like that in a civil war which has to be decided by the assistance of an ally from outside. The analytic physician and the patient's weakened ego, basing themselves on the real external world, have to band themselves together into a party against the enemies, the instinctual demands of the id and the conscientious demands of the super-ego. We form a pact with each other. The sick ego promises us the most complete candour - promises, that is, to put at our disposal all the material which its self-perception yields; we assure the patient of the strictest discretion and place at his service our experience in interpreting material that has been influenced by the unconscious. Our knowledge is to make up for his ignorance and to give his ego back its mastery over lost provinces of his mental life. This pact constitutes the analytic situation.

There is, however, another class of psychical patients who clearly resemble the psychotics very closely - the vast number of people suffering severely from neuroses. The determinants of their illness as well as its pathogenic mechanisms must be the same or at least very similar. But their ego has proved more resistant and has become less disorganized. Many of them, in spite of their maladies and the inadequacies resulting from them, have been able to maintain themselves in real life. These neurotics may show themselves ready to accept our help. We will confine our interest to them and see how far and by what methods we are able to 'cure' them.

[1940a [1938], 4983]
I told you too that we hoped that the analysis of the narcissistic disorders would give us an insight into the way in which our ego is put together and built up out of different agencies. We have already made a start with this at one point. From the analysis of delusions of observation we have drawn the conclusion that there actually exists in the ego an agency which unceasingly observes, criticizes and compares, and in that way sets itself over against the other part of the ego. We believe, therefore, that the patient is betraying a truth to us which is not yet sufficiently appreciated when he complains that he is spied upon and observed at every step he takes and that every one of his thoughts is reported and criticized. His only mistake is in regarding this uncomfortable power as something alien to him and placing it outside himself. He senses an agency holding sway in his ego which measures his actual ego and each of its activities by an ideal ego that he has created for himself in the course of his development. We believe, too, that this creation was made with the intention of re-establishing the self-satisfaction which was attached to primary infantile narcissism but which since then has suffered so many disturbances and mortifications. We know the self-observing agency as the ego-censor, the conscience; it is this that exercises the dream-censorship during the night, from which the repressions of inadmissible wishful impulses proceed. When in delusions of observation it becomes split up, it reveals to us its origin from the influences of parents, educators and social environment - from an identification with some of these model figures.
[1916-1917, 3472]

Little light is thrown upon the genesis of masochism by our discussion of the beating-phantasy. To begin with, there seems to be a confirmation of the view that masochism is not the manifestation of a primary instinct, but originates from sadism which has been turned round upon the self - that is to say, by means of regression from an object to the ego.¹ Instincts with a passive aim must be taken for granted as existing, especially among women. But passivity is not the whole of masochism. The characteristic of unpleasure belongs to it as well, - a bewildering accompaniment to the satisfaction of an instinct. The transformation of sadism into masochism appears to be due to the influence of the sense of guilt which takes part in the act of repression. Thus repression is operative here in three ways: it renders the consequences of the genital organization unconscious, it compels that organization itself to regress to the earlier sadistic-anal stage, and it transforms the sadism of this stage into masochism, which is passive and again in a certain sense narcissistic. The second of these three effects is made possible by the weakness of the genital organization, which must be presupposed in these cases. The third becomes necessary because the sense of guilt takes as much objection to sadism as to incestuous object-choice genitally conceived. Again, the analyses do not tell us the origin of the sense of guilt itself. It seems to be brought along by the new phase upon which the child is entering, and, if it afterwards persists, it seems to correspond to a scar-like formation which is similar to the sense of inferiority. According to our present orientation in the structure of the ego, which is as yet uncertain, we should assign it to the agency in the mind which sets itself up as a critical conscience over against the rest of the ego, which produces Silberer's functional phenomenon in dreams, and which cuts itself loose from the ego in delusions of being watched.
[1919e, 3654]
We are aware that what we have been able to contribute towards the explanation of the libidinal structure of groups leads back to the distinction between the ego and the ego ideal and to the double kind of tie which this makes possible - identification, and putting the object in the place of the ego ideal. The assumption of this kind of differentiating grade in the ego as a first step in an analysis of the ego must gradually establish its justification in the most various regions of psychology. In my paper on narcissism I have put together all the pathological material that could at the moment be used in support of this differentiation. But it may be expected that when we penetrate deeper into the psychology of the psychoses its significance will be discovered to be far greater. Let us reflect that the ego now enters into the relation of an object to the ego ideal which has been developed out of it, and that all the interplay between an external object and the ego as a whole, with which our study of the neuroses has made us acquainted, may possibly be repeated upon this new scene of action within the ego.

The aetiology common to the onset of a psychoneurosis and of a psychosis always remains the same. It consists in a frustration, a non-fulfilment of one of those childhood wishes which are for ever undefeated and which are so deeply rooted in our phylogenetically determined organization. This frustration is in the last resort always an external one; but in the individual case it may proceed from the internal agency (in the super-ego) which has taken over the representation of the demands of reality. The pathogenic effect depends on whether, in a conflictual tension of this kind, the ego remains true to its dependence on the external world and attempts to silence the id, or whether it lets itself be overcome by the id and thus torn away from reality. A complication is introduced into this apparently simple situation, however, by the existence of the super-ego, which, though a link that is not yet clear to us, unites in itself influences coming from the id as well as from the external world, and is to some extent an ideal model of what the whole endeavour of the ego is aiming at - a reconciliation between its various dependent relationships. The attitude of the super-ego should be taken into account - which has not hitherto been done - in every form of psychical illness. We may provisionally assume that there must also be illnesses which are based on a conflict between the ego and the super-ego. Analysis gives us a right to suppose that melancholia is a typical example of this group; and we would set aside the name of 'narcissistic psychoneuroses' for disorders of that kind. Nor will it clash with our impressions if we find reasons for separating states like melancholia from the other psychoses. We now see that we have been able to make our simple genetic formula more complete, without dropping it. Transference neuroses correspond to a conflict between the ego and the id; narcissistic neuroses, to a conflict between the ego and the super-ego; and psychoses, to one between the ego and the external world. It is true that we cannot tell at once whether we have really gained any new knowledge by this, or have only enriched our store of formulas; but I think that this possible application of the proposed differentiation of the mental apparatus into an ego, a super-ego and an id cannot fail to give us courage to keep that hypothesis steadily in view.

We describe one group of these patients as suffering from delusions of being observed. They complain to us that perpetually, and down to their most intimate actions, they are being molested by the observation of unknown powers - presumably persons - and that in hallucinations they hear these persons reporting the outcome of their observation: 'now he's going to say this, now he's dressing to go out' and so on. Observation of this sort is not yet the same thing as persecution, but it is not far from it; it presupposes that people distrust them, and expect to catch them carrying out forbidden actions for which they would be punished. How would it be if these insane people were right, if in each of us there is present in his ego an agency like this which observes and threatens to punish, and which in them has merely become sharply divided from their ego and mistakenly displaced into external reality?

[1921c, 3821]
[1924b, 4067]
[1933a, 4668]
And here is another warning, to conclude these remarks, which have certainly been exacting and not, perhaps, very illuminating. In thinking of this division of the personality into an ego, a super-ego and an id, you will not, of course, have pictured sharp frontiers like the artificial ones drawn in political geography. We cannot do justice to the characteristics of the mind by linear outlines like those in a drawing or in primitive painting, but rather by areas of colour melting into one another as they are presented by modern artists. After making the separation we must allow what we have separated to merge together once more. You must not judge too harshly a first attempt at giving a pictorial representations of something so intangible as psychical processes. It is highly probable that the development of these divisions is subject to great variations in different individuals; it is possible that in the course of actual functioning they may change and go through a temporary phase of involution. Particularly in the case of what is phylogenetically the last and most delicate of these divisions - the differentiation between the ego and the super-ego - something of the sort seems to be true. There is no question but that the same thing results from psychical illness. It is easy to imagine, too, that certain mystical practices may succeed in upsetting the normal relations between the different regions of the mind, so that, for instance, perception may be able to grasp happenings in the depths of the ego and in the id which were otherwise inaccessible to it. It may safely be doubted, however, whether this road will lead us to the ultimate truths from which salvation is to be expected. Nevertheless it may be admitted that the therapeutic efforts of psycho-analysis have chosen a similar line of approach. Its intention is, indeed, to strengthen the ego, to make it more independent of the super-ego, to widen its field of perception and enlarge its organization, so that it can appropriate fresh portions of the id. Where id was, there ego shall be. It is a work of culture - not unlike the draining of the Zuider Zee.

[1933a, 4687]
For it is demonstrably untrue that we are being carried along a purposeless stream of ideas when, in the process of interpreting a dream, we abandon reflection and allow involuntary ideas to emerge. It can be shown that all that we can ever get rid of are purposive ideas that are known to us; as soon as we have done this, unknown - or, as we inaccurately say, 'unconscious' - purposive ideas take charge and thereafter determine the course of the involuntary ideas. No influence that we can bring to bear upon our mental processes can ever enable us to think without purposive ideas; nor am I aware of any states of psychical confusion which can do so.¹ Psychiatrists have been far too ready in this respect to abandon their belief in the connectedness of psychical processes. I know for a fact that trains of thought without purposive ideas no more occur in hysteria and paranoia than they do in the formation or resolution of dreams. It may be that they do not occur in any of the endogenous psychical disorders. Even the deliria of confusional states may have a meaning, if we are to accept Leuret's brilliant suggestion that they are only unintelligible to us owing to the gaps in them. I myself have formed the same opinion when I have had the opportunity of observing them. Deliria are the work of a censorship which no longer takes the trouble to conceal its operation; instead of collaborating in producing a new version that shall be unobjectionable, it ruthlessly deletes whatever it disapproves of, so that what remains becomes quite disconnected. This censorship acts exactly like the censorship of newspapers at the Russian frontier, which allows foreign journals to fall into the hands of the readers whom it is its business to protect only after a quantity of passages have been blacked out.

¹[1900a, 962]

The two instances that I have quoted are neither of them entirely devoid of connection with the state of sleep and for that reason are perhaps not well chosen for what I want them to prove. I will therefore refer the reader to my analysis of a woman suffering from hallucinatory paranoia (Freud, 1896b) as well as to the findings in my still unpublished studies on the psychology of the psychoneuroses, for evidence that in such instances of the regressive transformation of thoughts we must not overlook the influence of memories, mostly from childhood, which have been suppressed or have remained unconscious. The thoughts which are connected with a memory of this kind and which are forbidden expression by the censorship are, as it were, attracted by the memory into regression as being the form of representation in which the memory itself is couched. I may also recall that one of the facts arrived at in the Studies on Hysteria was that when it was possible to bring infantile scenes (whether they were memories or phantasies) into consciousness, they were seen like hallucinations and lost that characteristic only in the process of being reported. It is moreover a familiar observation that, even in those whose memory is not normally of a visual type, the earliest recollections of childhood retain far into life the quality of sensory vividness.

¹[1900a, 978]
The unconscious wishful impulses clearly try to make themselves effective in daytime as well, and the fact of transference, as well as the psychoses, show us that they endeavour to force their way by way of the preconscious system into consciousness and to obtain control of the power of movement. Thus the censorship between the Ucs. and the Pcs., the assumption of whose existence is positively forced upon us by dreams, deserves to be recognized and respected as the watchman of our mental health. Must we not regard it, however, as an act of carelessness on the part of that watchman that it relaxes its activities during the night, allows the suppressed impulses in the Ucs. to find expression, and makes it possible for hallucinatory regression to occur once more? I think not. For even though this critical watchman goes to rest - and we have proof that its slumbers are not deep - it also shuts the door upon the power of movement. No matter what impulses from the normally inhibited Ucs. may prance upon the stage, we need feel no concern; they remain harmless, since they are unable to set in motion the motor apparatus by which alone they might modify the external world. The state of sleep guarantees the security of the citadel that must be guarded. The position is less harmless when what brings about the displacement of forces is not the nightly relaxation in the critical censorship's output of force, but a pathological reduction in that force or a pathological intensification of the unconscious excitations while the preconscious is still cathected and the gateway to the power of movement stands open. When this is so, the watchman is overpowered, the unconscious excitations overwhelm the Pcs., and thence obtain control over our speech and actions; or they forcibly bring about hallucinatory regression and direct the course of the apparatus (which was not designed for their use) by virtue of the attraction exercised by perceptions on the distribution of our psychical energy. To this state of things we give the name of psychosis.

[1900a, 997]

¹ In doing so we should not forget to take into account the distortion due to the censorship which is still at work even in psychoses.

[1905c, 1755]
The two instances that I have quoted are neither of them entirely devoid of connection with the state of sleep and for that reason are perhaps not well chosen for what I want them to prove. I will therefore refer the reader to my analysis of a woman suffering from hallucinatory paranoia (Freud, 1896b) as well as to the findings in my still unpublished studies on the psychology of the psychoneuroses, for evidence that in such instances of the regressive transformation of thoughts we must not overlook the influence of memories, mostly from childhood, which have been suppressed or have remained unconscious. It is moreover a familiar observation that, even in those whose memory is not normally of a visual type, the earliest recollections of childhood retain far into life the quality of sensory vividness. [1900a, 978]

Finally, let us once more glance at the significant light which the topography of the process of repression throws for us on the mechanism of mental disturbances. In dreams the withdrawal of cathexis (libido or interest) affects all systems equally; in the transference neuroses, the Pcs. cathexis is withdrawn; in schizophrenia, the cathexis of the Ucs.; in amnesia, that of the Cs. [1917d, 3038]
In explaining regression in dreams, however, we must bear in mind the regressions which also occur in pathological waking states; and here the explanation just given leaves us in the lurch. For in those cases regression occurs in spite of a sensory current flowing without interruption in a forward direction. My explanation of hallucinations in hysteria and paranoia and of visions in mentally normal subjects is that they are in fact regressions - that is, thoughts transformed into images - but that the only thoughts that undergo this transformation are those which are intimately linked with memories that have been suppressed or have remained unconscious.

[1900a, 977]

The two instances that I have quoted are neither of them entirely devoid of connection with the state of sleep and for that reason are perhaps not well chosen for what I want them to prove. I will therefore refer the reader to my analysis of a woman suffering from hallucinatory paranoia (Freud, 1896b) as well as to the findings in my still unpublished studies on the psychology of the psychoneuroses, for evidence that in such instances of the regressive transformation of thoughts we must not overlook the influence of memories, mostly from childhood, which have been suppressed or have remained unconscious. When this is so, the watchman is overpowered, the unconscious excitations overwhelm the Pcs., and thence obtain control over our speech and actions; or they forcibly bring about hallucinatory regression and direct the course of the apparatus (which was not designed for their use) by virtue of the attraction exercised by perceptions on the distribution of our psychical energy. To this state of things we give the name of psychosis.

[1900a, 997]
The application of a few of the rules of dream-interpretation to Hanold's first dream has thus resulted in making it intelligible to us in its main features and in inserting it into the nexus of the story. Surely, then, the author must have observed these rules in creating it? We might ask another question, too: why did the author introduce a dream at all to bring about the further development of the delusion? In my opinion it was an ingenious notion and once again true to reality. We have already heard that in real illnesses a delusion very often arises in connection with a dream, and, after what we have learnt about the nature of dreams, there is no need to see a fresh riddle in this fact. Dreams and delusions arise from the same source - from what is repressed. Dreams are, as one might say, the physiological delusions of normal people. Before what is repressed has become strong enough to break through into waking life as a delusion, it may easily have achieved a first success, under the more favourable conditions of the state of sleep, in the form of a dream with persisting effects. For during sleep, along with a general lowering of mental activity, there is a relaxation in the strength of the resistance with which the dominant psychical forces oppose what is repressed. It is this relaxation that makes the formation of dreams possible, and that is why dreams give us our best access to a knowledge of the unconscious part of the mind - except that, as a rule, with the re-establishment of the psychical cathexes of waking life, the dream once more takes to flight and the ground that had been won by the unconscious is evacuated once again. [1907a, 1858]
Dream-distortion was the profoundest and most difficult problem of dream life. And light was thrown on it by the following consideration, which placed dreams in a class along with other psychopathological formations and revealed them, as it were, as the normal psychoses of human beings. For our mind, that precious instrument by whose means we maintain ourselves in life, is no peacefully self-contained unity. It is rather to be compared with a modern State in which a mob, eager for enjoyment and destruction, has to be held down forcibly by a prudent superior class. The whole flux of our mental life and everything that finds expression in our thoughts are derivations and representatives of the multifarious instincts that are innate in our physical constitution. But these instincts are not all equally susceptible to direction and education, or equally ready to fall in with the demands of the external world and of human society. A number of them have retained their primitive, ungovernable nature; if we let them have their way, they would infallibly bring us to ruin. Consequently, learning by experience, we have developed organizations in our mind which, in the form of inhibitions, set themselves up against the direct manifestations of the instincts. Every impulse in the nature of a wish that arises from the sources of instinctual energy must submit itself to examination by the highest agencies of our mind, and, if it is not approved, is rejected and restrained from exercising any influence upon our movements - that is, from coming into execution. Often enough, indeed, such wishes are even forbidden to enter consciousness, which is habitually unaware even of the existence of these dangerous instinctual sources. We describe such impulses as being repressed from the point of view of consciousness, and as surviving only in the unconscious. If what is repressed contrives somehow to force its way into consciousness or into movement or into both, we are no longer normal: at that point the whole range of neurotic and psychotic symptoms arise. The maintenance of the necessary inhibitions and repressions imposes upon our mind a great expenditure of energy, from which it is glad to be relieved. A good opportunity for this seems to be offered at night by the state of sleep, since sleep involves a cessation of our motor functions. The situation seems safe, and the severity of our internal police-force may therefore be relaxed. It is not entirely withdrawn, since one cannot be certain: it may be that the unconscious never sleeps at all. And now the reduction of pressure upon the repressed unconscious produces its effect. Wishes arise from it which during sleep might find the entrance to consciousness open. If we were to know them we should be appalled, alike by their subject-matter, their unrestraint and indeed the mere possibility of their existence. This, however, occurs only seldom, and when it does we awake as speedily as possible, in a state of fear. But as a rule our consciousness does not experience the dream as it really was. It is true that the inhibitory forces (the dream censorship, as we may call them) are not completely awake, but neither are they wholly asleep. They have had an influence on the dream while it was struggling to find an expression in words and pictures, they have got rid of what was most objectionable, they have altered other parts of it till they are unrecognizable, they have severed real connections while introducing false ones, until the honest but brutal wishful phantasy which lay behind the dream has turned into the manifest dream as we remember it - more or less confused and almost always strange and incomprehensible. Thus the dream (or the distortion which characterizes it) is the expression of a compromise, the evidence of a conflict between the mutually incompatible impulses and strivings of our mental life. And do not let us forget that the same process, the same interplay of forces, which explains the dreams of a normal sleeper, gives us the key to understanding all the phenomena of neurosis and psychosis.

[1932c, 4809]
These recollections might have been described as hallucinations if a belief in their actual presence had been added to their cleanness. The importance of this analogy seemed greater when I noticed that true hallucinations occasionally occurred in the case of other patients who were certainly not psychotic. My line of thought proceeded as follows. Perhaps it may be a general characteristic of hallucinations to which sufficient attention has not hitherto been paid that in them something that has been experienced in infancy and then forgotten returns—something that the child has seen or heard at a time when he could still hardly speak and that now forces its way into consciousness, probably distorted and displaced owing to the operation of forces that are opposed to this return. And, in view of the close relation between hallucinations and particular forms of psychosis, our line of thought may be carried still further. It may be that the delusions into which these hallucinations are so constantly incorporated may themselves be less independent of the upward drive of the unconscious and the return of the repressed than we usually assume. In the mechanism of a delusion we stress as a rule only two factors: the turning away from the real world and its motive forces on the one hand, and the influence exercised by wish-fulfilment on the content of the delusion on the other. But may it not be that the dynamic process is rather that the turning away from reality is exploited by the upward drive of the repressed in order to force its content into consciousness, while the resistances stirred up by this process and the trend to wish-fulfilment share the responsibility for the distortion and displacement of what is recollected? This is after all the familiar mechanism of dreams, which intuition has equated with madness from time immemorial.

[1937d, 5058]
In explaining regression in dreams, however, we must bear in mind the regressions which also occur in pathological waking states; and here the explanation just given leaves us in the lurch. For in those cases regression occurs in spite of a sensory current flowing without interruption in a forward direction. My explanation of hallucinations in hysteria and paranoia and of visions in mentally normal subjects is that they are in fact regressions - that is, thoughts transformed into images - but that the only thoughts that undergo this transformation are those which are intimately linked with memories that have been suppressed or have remained unconscious.

[1900a, 977]

The two instances that I have quoted are neither of them entirely devoid of connection with the state of sleep and for that reason are perhaps not well chosen for what I want them to prove. I will therefore refer the reader to my analysis of a woman suffering from hallucinatory paranoia (Freud, 1896b) as well as to the findings in my still unpublished studies on the psychology of the psychoneuroses, for evidence that in such instances of the regressive transformation of thoughts we must not overlook the influence of memories, mostly from childhood, which have been suppressed or have remained unconscious. The thoughts which are connected with a memory of this kind and which are forbidden expression by the censorship are, as it were, attracted by the memory into regression as being the form of representation in which the memory itself is couched. I may also recall that one of the facts arrived at in the Studies on Hysteria was that when it was possible to bring infantile scenes (whether they were memories or phantasies) into consciousness, they were seen like hallucinations and lost that characteristic only in the process of being reported. It is moreover a familiar observation that, even in those whose memory is not normally of a visual type, the earliest recollections of childhood retain far into life the quality of sensory vividness.

[1900a, 978]

The unconscious wishful impulses clearly try to make themselves effective in daytime as well, and the fact of transference, as well as the psychoses, show us that they endeavour to force their way by way of the preconscious system into consciousness and to obtain control of the power of movement. Thus the censorship between the $\text{Ucs.}$ and the $\text{Pcs.}$, the assumption of whose existence is positively forced upon us by dreams, deserves to be recognized and respected as the watchman of our mental health. Must we not regard it, however, as an act of carelessness on the part of that watchman that it relaxes its activities during the night, allows the suppressed impulses in the $\text{Ucs.}$ to find expression, and makes it possible for hallucinatory regression to occur once more? I think not. For even though this critical watchman goes to rest - and we have proof that its slumbers are not deep - it also shuts the door upon the power of movement. No matter what impulses from the normally inhibited $\text{Ucs.}$ may prance upon the stage, we need feel no concern; they remain harmless, since they are unable to set in motion the motor apparatus by which alone they might modify the external world. The state of sleep guarantees the security of the citadel that must be guarded. The position is less harmless when what brings about the displacement of forces is not the nightly relaxation in the critical censorship's output of force, but a pathological reduction in that force or a pathological intensification of the unconscious excitations while the preconscious is still cathetted and the gateway to the power of movement stands open. When this is so, the watchman is overpowered, the unconscious excitations overwhelm the $\text{Pcs.}$, and thence obtain control over our speech and actions; or they forcibly bring about hallucinatory regression and direct the course of the apparatus (which was not designed for their use) by virtue of the attraction exercised by perceptions on the distribution of our psychical energy. To this state of things we give the name of psychosis.

[1900a, 997]
In my *Three Essays on the Theory of Sexuality* I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paraanoics *endeavour to protect themselves against any such sexualization of their social instinctual cathexes*, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) *schizophrenia*; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients’ dispositional fixations.

What are called mental diseases inevitably produce an impression in the layman that intellectual and mental life have been destroyed. In reality, the destruction only applies to later acquisitions and developments. The essence of mental disease lies in a return to earlier states of affective life and of functioning. An excellent example of the plasticity of mental life is afforded by the state of sleep, which is our goal every night. Since we have learnt to interpret even absurd and confused dreams, we know that whenever we go to sleep we throw off our hard-won morality like a garment, and put it on again next morning. This stripping of ourselves is not, of course, dangerous, because we are paralysed, condemned to inactivity, by the state of sleep. It is only dreams that can tell us about the regression of our emotional life to one of the earliest stages of development. For instance, it is noteworthy that all our dreams are governed by purely egoistic motives. One of my English friends put forward this thesis at a scientific meeting in America, whereupon a lady who was present remarked that that might be the case in Austria, but she could assert as regards herself and her friends that they were altruistic even in their dreams. My friend, although himself of English race, was obliged to contradict the lady emphatically on the ground of his personal experience in dream-analysis, and to declare that in their dreams high-minded American ladies were quite as egoistic as the Austrians.

A neurosis usually contents itself with avoiding the piece of reality in question and protecting itself against coming into contact with it. The sharp distinction between neurosis and psychosis, however, is weakened by the circumstance that in neurosis, too, there is no lack of attempts to replace a disagreeable reality by one which is more in keeping with the subject's wishes. This is made possible by the existence of a *world of phantasy*, of a domain which became separated from the real external world at the time of the introduction of the reality principle. This domain has since been kept free from the demands of the exigencies of life, like a kind of 'reservation'; it is not inaccessible to the ego, but is only loosely attached to it. It is from this world of phantasy that the neurosis draws the material for its new wishful constructions, and it usually finds that material along the path of regression to a more satisfying real past.
The two instances that I have quoted are neither of them entirely devoid of connection with the state of sleep and for that reason are perhaps not well chosen for what I want them to prove. I will therefore refer the reader to my analysis of a woman suffering from hallucinatory paranoia (Freud, 1896b) as well as to the findings in my still unpublished studies on the psychology of the psychoneuroses, for evidence that in such instances of the regressive transformation of thoughts we must not overlook the influence of memories, mostly from childhood, which have been suppressed or have remained unconscious. The thoughts which are connected with a memory of this kind and which are forbidden expression by the censorship are, as it were, attracted by the memory into regression as being the form of representation in which the memory itself is couched. I may also recall that one of the facts arrived at in the Studies on Hysteria was that when it was possible to bring infantile scenes (whether they were memories or phantasies) into consciousness, they were seen like hallucinations and lost that characteristic only in the process of being reported. It is moreover a familiar observation that, even in those whose memory is not normally of a visual type, the earliest recollections of childhood retain far into life the quality of sensory vividness.

So there had been a childhood friendship between them - perhaps a childhood love - which justified the 'du'. This solution, it may be, falls just as flat as the one we first suspected. We are brought to a much deeper level, however, when we realize that this childhood relationship unexpectedly explains a number of details in what had happened in their contemporary contact. Consider, for instance, the slapping of Zoe-Gradiva's hand. Norbert Hanold found a most convincing reason for it in the necessity for reaching an experimental answer to the problem of the apparition's physical reality. But was it not at the same time remarkably like a revival of the impulse for the 'bumping and thumping' whose dominance in their childhood was shown by Zoe's words? And think, again, of how Gradiva asked the archaeologist whether it did not seem to him that they had shared a meal like this two thousand years before. This unintelligible question suddenly seems to have a sense, if we once more replace the historical past by the personal one - childhood -, of which the girl still had lively memories but which the young man appeared to have forgotten. And now the discovery dawns upon us that the young archaeologist's phantasies about his Gradiva may have been an echo of his forgotten childhood memories. If so, they were not capricious products of his imagination, but determined, without his knowing it, by the store of childhood impressions which he had forgotten, but which were still at work in him. It should be possible for us to show the origin of the phantasies in detail, even though we can only guess at them. He imagined, for instance, that Gradiva must be of Greek origin and that she was the daughter of a respected personage - a priest of Ceres, perhaps. This seems to fit in pretty well with his knowing that she bore the Greek name of Zoe and that she belonged to the family of a Professor of Zoology. But if Hanold's phantasies were transformed memories, we may expect to find an indication of the source of those phantasies in the information given us by Zoe Bertgang. Let us listen to what she has to say. She has told us of their intimate friendship in their childhood, and we shall now hear of the further course taken by this childhood relationship.
This view of delusions is not, I think, entirely new, but it nevertheless emphasizes a point of view which is not usually brought into the foreground. The essence of it is that there is not only method in madness, as the poet has already perceived, but also a fragment of historical truth; and it is plausible to suppose that the compulsive belief attaching to delusions derives its strength precisely from infantile sources of this kind. All that I can produce to-day in support of this theory are reminiscences, not fresh impressions. It would probably be worth while to make an attempt to study cases of the disorder in question on the basis of the hypotheses that have been here put forward and also to carry out their treatment on those same lines. The vain effort would be abandoned of convincing the patient of the error of his delusion and of its contradiction of reality; and, on the contrary, the recognition of its kernel of truth would afford common ground upon which the therapeutic work could develop. That work would consist in liberating the fragment of historical truth from its distortions and its attachments to the actual present day and in leading it back to the point in the past to which it belongs. The transposing of material from a forgotten past on to the present or on to an expectation of the future is indeed a habitual occurrence in neurotics no less than in psychotics. Often enough, when a neurotic is led by an anxiety-state to expect the occurrence of some terrible event, he is in fact merely under the influence of a repressed memory (which is seeking to enter consciousness but cannot become conscious) that something which was at that time terrifying did really happen. I believe that we should gain a great deal of valuable knowledge from work of this kind upon psychotics even if it led to no therapeutic success.

I am aware that it is of small service to handle so important a subject in the cursory fashion that I have here employed. But none the less I have not been able to resist the seduction of an analogy. The delusions of patients appear to me to be the equivalents of the constructions which we build up in the course of an analytic treatment - attempts at explanation and cure, though it is true that these, under the conditions of a psychosis, can do no more than replace the fragment of reality that is being disavowed in the present by another fragment that had already been disavowed in the remote past. It will be the task of each individual investigation to reveal the intimate connections between the material of the present disavowal and that of the original repression. Just as our construction is only effective because it recovers a fragment of lost experience, so the delusion owes its convincing power to the element of historical truth which it inserts in the place of the rejected reality. In this way a proposition which I originally asserted only of hysteria would apply also to delusions - namely, that those who are subject to them are suffering from their own reminiscences. I never intended by this short formula to dispute the complexity of the causation of the illness or to exclude the operation of many other factors.

[1937d, 5058]
In another neurotic disorder, dementia praecox (paraphrenia or schizophrenia), a condition which is in fact incurable, the patient is left, in the most severe cases, in a state of apparently complete apathy. Often his sole remaining actions are certain movements and gestures which are repeated monotonously and have been given the name of 'stereotypies'. An analytic investigation of residues of this kind, made by Jung, has shown that they are the remains of perfectly significant mimetic actions, which at one time gave expression to the subject's ruling wishes. The craziest speeches and the queerest poses and attitudes adopted by these patients become intelligible and can be given a place in the chain of their mental processes if they are approached on the basis of psycho-analytic hypotheses.

The language of dreams may be looked upon as the method by which unconscious mental activity expresses itself. But the unconscious speaks more than one dialect. According to the differing psychological conditions governing and distinguishing the various forms of neurosis, we find regular modifications in the way in which unconscious mental impulses are expressed. While the gesture-language of hysteria agrees on the whole with the picture-language of dreams and visions, etc., the thought-language of obsessional neurosis and of the paraphrenias (dementia praecox and paranoia) exhibits special idiomatic peculiarities which, in a number of instances, we have been able to understand and interrelate. For instance, what a hysterical expresses by vomiting or an obsessional will express by painstaking protective measures against infection, while a paraphrenic will be led to complaints or suspicions that he is being poisoned. These are all of them different representations of the patient's wish to become pregnant which have been repressed into the unconscious, or of his defensive reaction against that wish.

When a doctor carries out the psycho-analytic treatment of a neurotic, his interest is by no means directed in the first instance to the patient's character. He would much rather know what the symptoms mean, what instinctual impulses are concealed behind them and are satisfied by them, and what course was followed by the mysterious path that has led from the instinctual wishes to the symptoms. But the technique which he is obliged to follow soon compels him to direct his immediate curiosity towards other objectives. He observes that his investigation is threatened by resistances set up against him by the patient, and these resistances he may justly count as part of the latter's character. This now acquires the first claim on his interest.

One of the ways in which the ego is related to its neuroses is, however, so obvious that it was possible to take it into account from the first. It seems never to be absent; but it is most clearly recognizable in a disorder which we are even to-day far from understanding - traumatic neurosis. For you must know that the same factors always come into operation in the causation and mechanism of every possible form of neurosis; but the chief importance in the construction of the symptoms falls now upon one and now upon another of these factors. The position is like that among the members of a theatrical company. Each of them is regularly cast for his own stock role - hero, confidant, villain, and so on; but each of them will choose a different piece for his benefit performance. In the same way phantasies which turn into symptoms are nowhere more obvious than in hysteria; the anticathexes or reaction-formations of the ego dominate the picture in obsessional neurosis; what in the case of dreams we have termed 'secondary revision' stands in the forefront in paranoia in the shape of delusions, and so on.
In considering the question of abstinence, the distinction is not nearly strictly enough made between two forms of it - namely abstention from any sexual activity whatever and abstention from sexual intercourse with the opposite sex. Many people who boast of succeeding in being abstinent have only been able to do so with the help of masturbation and similar satisfactions which are linked with the auto-erotic sexual activities of early childhood. But precisely because of this connection such substitutive means of sexual satisfaction are by no means harmless; they predispose to the numerous varieties of neuroses and psychoses which are conditional on an involution of sexual life to its infantile forms. Masturbation, moreover, is far from meeting the ideal demands of civilized sexual morality, and consequently drives young people into the same conflicts with the ideals of education which they hoped to escape by abstinence. Furthermore, it vitiates the character through indulgence, and this in more than one way. In the first place, it teaches people to achieve important aims without taking trouble and by easy paths instead of through an energetic exertion of force - that is, it follows the principle that sexuality lays down the pattern of behaviour; secondly, in the phantasies that accompany satisfaction the sexual object is raised to a degree of excellence which is not easily found again in reality. A witty writer (Karl Kraus in the Vienna paper Die Fackel) once expressed this truth in reverse by cynically remarking: 'Copulation is no more than an unsatisfying substitute for masturbation.'

[1908d, 1960]

In my Three Essays on the Theory of Sexuality I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics endeavour to protect themselves against any such sexualization of their social instinctual cathexes, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-eroticism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) schizophrenia; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.

[1911c, 2431]
(1) Our first reflection will tell us that it cannot be the case that this detachment of the libido occurs exclusively in paranoia; nor can it be that, where it occurs elsewhere, it has such disastrous consequences. It is quite possible that a detachment of the libido is the essential and regular mechanism of every repression. We can have no positive knowledge on that point until the other disorders that are based upon repression have been similarly examined. But it is certain that in normal mental life (and not only in periods of mourning) we are constantly detaching our libido in this way from people or from other objects without falling ill. When Faust freed himself from the world by uttering his curses, the result was not a paranoia or any other neurosis but simply a certain general frame of mind. The detachment of the libido, therefore, cannot in itself be the pathogenic factor in paranoia; there must be some special characteristic which distinguishes a paranoid detachment of the libido from other kinds. It is not difficult to suggest what that characteristic may be. What use is made of the libido after it has been set free by the process of detachment? A normal person will at once begin looking about for a substitute for the lost attachment; and until that substitute has been found the liberated libido will be kept in suspension within his mind, and will there give rise to tensions and colour his mood. In hysteria the liberated libido becomes transformed into somatic innervations or into anxiety. But in paranoia the clinical evidence goes to show that the libido, after it has been withdrawn from the object, is put to a special use. It will be remembered that the majority of cases of paranoia exhibit traces of megalomania, and that megalomania can by itself constitute a paranoia. From this it may be concluded that in paranoia the liberated libido becomes attached to the ego, and is used for the aggrandizement of the ego. A return is thus made to the stage of narcissism (known to us from the development of the libido), in which a person's only sexual object is his own ego. On the basis of this clinical evidence we can suppose that paranoics have brought along with them a fixation at the stage of narcissism, and we can assert that the length of the step back from sublimated homosexuality to narcissism is a measure of the amount of regression characteristic of paranoia.

Further study has shown that it is expedient and indeed indispensable to insert a third stage between these two, or, putting it in another way, to divide the first stage, that of auto-erotism, into two. At this intermediate stage, the importance of which is being made more and more evident by research, the hitherto isolated sexual instincts have already come together into a single whole and have also found an object. But this object is not an external one, extraneous to the subject, but it is his own ego, which has been constituted at about this same time. Bearing in mind pathological fixations of this new stage, which become observable later, we have given it the name of 'narcissism'. The subject behaves as though he were in love with himself; his egoistic instincts and his libidinal wishes are not yet separable under our analysis.

[1911c, 2438]

[1912-1913, 2731]
Your second observation, too, raises a justifiable question, but it is aimed in the wrong direction. It is true that a withdrawal of the object-libido into the ego is not directly pathogenic; it takes place, indeed, as we know, every time before we go to sleep, only to be reversed when we wake up. The amoeba withdraws its protrusions only to send them out again at the first opportunity. But it is quite a different thing when a particular, very energetic process forces a withdrawal of libido from objects. Here the libido that has become narcissistic cannot find its way back to objects, and this interference with the libido's mobility certainly becomes pathogenic. It seems that an accumulation of narcissistic libido beyond a certain amount is not tolerated. We may even imagine that it was for that very reason that object-cathexes originally came about, that the ego was obliged to send out its libido so as not to fall ill as a result of its being dammed up. If it lay within our plan to go more deeply into dementia praecox, I would show you that the process which detaches the libido from objects and cuts off its return to them is closely related to the process of repression and is to be looked at as its counterpart. But you would, first and foremost, find yourselves on familiar ground when you learnt that the determinants of this process are almost identical - so far as we know at present - with those of repression. The conflict seems to be the same and to be carried on between the same forces. If the outcome is so different from, for instance, that in hysteria, the reason can only depend on a difference in innate disposition. The weak spot in the libidinal development of these patients lies in a different phase; the determining fixation, which, as you will recollect, permits the irruption that leads to the formation of symptoms, lies elsewhere, probably in the stage of primitive narcissism to which dementia praecox returns in its final outcome. It is very remarkable that in the case of all the narcissistic neuroses we have to assume fixation points for the libido going back to far earlier phases of development than in hysteria or obsessional neurosis. As you heard, however, the concepts which we arrived at during our study of the transference neuroses are adequate in helping us to find our way about in the narcissistic neuroses which are so much more severe in practice. The conformities go very far; at bottom the field of phenomena is the same. And you can imagine how small a prospect anyone has of explaining these disorders (which belong within the sphere of psychiatry) who is not forearmed for his task with an analytic knowledge of the transference neuroses.

[1916-1917, 3466]

Homosexual object-choice originally lies closer to narcissism than does the heterosexual kind. When it is a question, therefore, of repelling an undesirably strong homosexual impulse, the path back to narcissism is made particularly easy. Hitherto I have had very little opportunity of talking to you about the foundations of erotic life so far as we have discovered them, and it is too late now to catch up on the omission. This much, however, I can emphasize to you. Object-choice, the step forward in the development of the libido which is made after the narcissistic stage, can take place according to two different types: either according to the narcissistic type, where the subject's own ego is replaced by another one that is as similar as possible, or according to the attachment type, where people who have become precious through satisfying the other vital needs are chosen as objects by the libido as well. A strong libidinal fixation to the narcissistic type of object-choice is to be included in the predisposition to manifest homosexuality.

[1916-1917, 3470]

It seems easy to infer that when people of the erotic type fall ill they will develop hysteria, just as those of the obsessional type will develop obsessional neurosis; but these inferences, too, share the uncertainty which I have just stressed. People of the narcissistic type who are exposed to a frustration from the external world, though otherwise independent, are peculiarly disposed to psychosis; and they also present essential preconditions for criminality.

[1931a, 4587]
A more revealing light is thrown upon the psychological position of these incompatible thoughts by another remark of Hildebrandt's (1875, 55), to the effect that dreams give us an occasional glimpse into depths and recesses of our nature to which we usually have no access in our waking state. Kant expresses the same idea in a passage in his *Anthropologie* in which he declares that dreams seem to exist in order to show us our hidden natures and to reveal to us, not what we are, but what we might have been if we had been brought up differently. Radestock (1879, 84), too, says that dreams often do no more than reveal to us what we would not admit to ourselves and that it is therefore unfair of us to stigmatize them as liars and deceivers. Erdmann writes: 'Dreams have never shown me what I ought to think of a man; but I have occasionally learnt from a dream, greatly to my own astonishment, what I do think of a man and how I feel towards him.' Similarly I. H. Fichte (1864, I, 539) remarks: 'The nature of our dreams gives a far more truthful reflection of our whole disposition than we are able to learn of it from self-observation in waking life.

[1900a, 577]

² I may here add a few supplementary interpretations to those that have already been given: The 'Madonna' was obviously Dora herself; in the first place because of the 'adorer' who had sent her the pictures, in the second place because she had won Herr K.'s love chiefly by the motherliness she had shown towards his children, and lastly because she had had a child though she was still a girl (this being a direct allusion to the phantasy of childbirth). Moreover, the notion of the 'Madonna' is a favourite counter-idea in the mind of girls who feel themselves oppressed by imputations of sexual guilt, - which was the case with Dora. A first suspicion of this connection came to me while I was working as a physician at the Psychiatric Clinic of the University. I there came across a case of confusional insanity with hallucinations, in which the attack, which ran a rapid course, turned out to be a reaction to a reproach made against the patient by her fiancé. - If the analysis had been continued, Dora's maternal longing for a child would probably have been revealed as an obscure though powerful motive in her behaviour. The numerous questions which she had been raising latterly seem to have been belated derivatives of questions inspired by the sexual curiosity which she had tried to gratify with the encyclopaedia. The subjects which she read up in it were presumably pregnancy, childbirth, virginity, and so on. - In reproducing the dream Dora had forgotten one of the questions which need to be inserted into the course of the second situation in the dream. This question could only be; 'Does Herr -- live here?' or 'Where does Herr -- live?' There must have been some reason for her having forgotten this apparently innocent question, especially as she need not have brought it into the dream at all. This reason, it seems to me, lay in her surname itself, which also denoted an object and in fact more than one kind of object, and which could therefore be regarded as an 'ambiguous' word. Unluckily I cannot give the name and show how well designed it was to indicate something 'ambiguous' and 'improper'. This interpretation was supported by the discovery of a similar play upon words in another part of the dream, where the material was derived from Dora's recollections of her aunt's death ('they have already gone to the cemetery') and where there was similarly a play upon her aunt's name. These improper words seemed to point to a second and oral source of information, since the encyclopaedia would not cover them. I should not have been surprised to hear that this source had been Frau K. herself, Dora's calumniator. In that case she would have been the one person whom Dora generously spared, while she pursued the others with an almost malignant vindictiveness. Behind the almost limitless series of displacements which were thus brought to light, it was possible to divine the operation of a single simple factor - Dora's deep-rooted homosexual love for Frau K.

[1905e, 1439]
The question of why this outburst of homosexual libido overtook the patient precisely at this period (that is, between the dates of his appointment and of his move to Dresden) cannot be answered in the absence of more precise knowledge of the story of his life. Generally speaking, every human being oscillates all through his life between heterosexual and homosexual feelings, and any frustration or disappointment in one direction is apt to drive him over into the other. We know nothing of these factors in Schreber's case, but we must not omit to draw attention to a somatic factor which may very well have been relevant. At the time of this illness Dr. Schreber was fifty-one years old, and he had therefore reached an age which is of critical importance in sexual life. It is a period at which in women the sexual function, after a phase of intensified activity, enters upon a process of far-reaching involution; nor do men appear to be exempt from its influence, for men as well as women are subject to a 'climacteric' and to the susceptibilities to disease which go along with it.¹

[1911c, 2418]

In my Three Essays on the Theory of Sexuality I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics endeavour to protect themselves against any such sexualization of their social instinctual cathexes, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) schizophrenia; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.

[1911c, 2431]
(d) Just as the third type has brought the dispositional determinant before us almost in isolation, so the fourth type, which now follows, draws our attention to another factor, which comes into consideration in every single case and might easily for that very reason be overlooked in a theoretical discussion. We see people fall ill who have hitherto been healthy, who have met with no fresh experience and whose relation to the external world has undergone no change, so that the onset of their illness inevitably gives an impression of spontaneity. A closer consideration of such cases, however, shows us that none the less a change has taken place in them whose importance we must rate very highly as a cause of illness. As a result of their having reached a particular period of life, and in conformity with regular biological processes, the quantity of libido in their mental economy has experienced an increase which is in itself enough to upset the equilibrium of their health and to set up the necessary conditions for a neurosis. It is well known that more or less sudden increases of libido of this kind are habitually associated with puberty and the menopause - with the attainment of a certain age in women; in some people they may in addition be manifested in periodicities that are still unknown. Here the damming-up of libido is the primary factor; it becomes pathogenic as a consequence of a relative frustration on the part of the external world, which would still have granted satisfaction to a smaller claim by the libido. The unsatisfied and dammed-up libido can once again open up paths to regression and kindle the same conflicts which we have demonstrated in the case of absolute external frustration. We are reminded in this way that the quantitative factor should not be left out of account in any consideration of the precipitating causes of illness. All the other factors - frustration, fixation, developmental inhibition - remain ineffective unless they affect a certain amount of libido and bring about a damming-up of libido of a certain height. It is true that we are unable to measure this amount of libido which seems to us indispensable for a pathogenic effect; we can only postulate it after the resulting illness has started. There is only one direction in which we can determine it more precisely. We may assume that it is not a question of an absolute quantity, but of the relation between the quota of libido in operation and the quantity of libido which the individual ego is able to deal with - that is, to hold under tension, to sublimate or to employ directly. For this reason a relative increase in the quantity of libido may have the same effects as an absolute one. An enfeeblement of the ego owing to organic illness or owing to some special demand upon its energy will be able to cause the emergence of neuroses which would otherwise have remained latent in spite of any disposition that might be present.

[1912c, 2563]

Stekel shares with many non-psycho-analytic writers an inclination to reject the morphological differentiations which we have made within the jumble of the neuroses and to lump them all together under one heading - under psychasthenia, perhaps. We have often contradicted him on this, and have held fast to our expectation that the morphologico-clinical differences will prove valuable as indications that have not yet been understood of essentially distinct processes. When he - justly - points out to us that he has regularly found the same complexes present in what are termed neurasthenics as in other neurotics, his argument fails to meet the point at issue. We have long known that the same complexes and conflicts are to be looked for, too, in all normal and healthy people. In fact, we have grown accustomed to attributing to every civilized human being a certain amount of repression of perverse impulses, a certain amount of anal erotism, of homosexuality and so on, as well as a piece of father-complex and mother-complex and of other complexes besides - just as in the chemical analysis of an organic substance we have every hope of finding certain elements: carbon, oxygen, hydrogen, nitrogen and a trace of sulphur. What distinguishes organic substances from one another is the relative amounts of these elements and the way in which the links between them are constituted. In the same way, in the case of normal and neurotic people what is in question is not whether these complexes and conflicts exist but whether they have become pathogenic and, if so, by means of what mechanisms they have become so.

[1912f, 2570]
You have long been aware that this censorship is not an institution peculiar to dream-life. You know that the conflict between the two psychical agencies, which we - inaccurately - describe as the 'unconscious repressed' and the 'conscious', dominates our whole mental life and that the resistance against the interpretation of dreams, the sign of the dream-censorship, is nothing other than the resistance due to repression by which the two agencies are separated. You know too that the conflict between these two agencies may under certain conditions produce other psychical structures which, like dreams, are the outcome of compromises; and you will not expect me to repeat to you here everything that was contained in my introduction to the theory of the neuroses in order to demonstrate to you what we know of the determinants of the formation of such compromises. You have realized that the dream is a pathological product, the first member of the class which includes hysterical symptoms, obsessions and delusions, but that it is distinguished from the others by its transitoriness and by its occurrence under conditions which are part of normal life. For let us bear firmly in mind that, as was already pointed out by Aristotle, dream life is the way in which our mind works during the state of sleep. The state of sleep involves a turning-away from the real external world, and there we have the necessary condition for the development of a psychosis. The most careful study of the severe psychoses will not reveal to us a single feature that is more characteristic of those pathological conditions. In psychoses, however, the turning-away from reality is brought about in two kinds of way: either by the unconscious repressed becoming excessively strong so that it overwhelms the conscious, which is attached to reality, or because reality has become so intolerably distressing that the threatened ego throws itself into the arms of the unconscious instinctual forces in a desperate revolt. The harmless dream-psychosis is the result of a withdrawal from the external world which is consciously willed and only temporary, and it disappears when relations to the external world are resumed. During the isolation of the sleeping individual an alteration in the distribution of his psychical energy also sets in; a part of the expenditure on repression, which is normally required in order to hold the unconscious down, can be saved, for if the unconscious makes use of its relative liberation for active purposes, it finds its path to motility closed and the only path open to it is the harmless one leading to hallucinatory satisfaction. Now, therefore, a dream can be formed; but the fact of the dream-censorship shows that even during sleep enough of the resistance due to repression is retained.
[1933a, 4629]
We have repeatedly had to insist on the fact that the ego owes its origin as well as the most important of its acquired characteristics to its relation to the real external world. We are thus prepared to assume that the ego's pathological states, in which it most approximates once again to the id, are founded on a cessation or slackening of that relation to the external world. This tallies very well with what we learn from clinical experience - namely, that the precipitating cause of the outbreak of a psychosis is either that reality has become intolerably painful or that the instincts have become extraordinarily intensified - both of which, in view of the rival claims made on the ego by the id and the external world, must lead to the same result. The problem of psychoses would be simple and perspicuous if the ego's detachment from reality could be carried through completely. But that seems to happen only rarely or perhaps never. Even in a state so far removed from the reality of the external world as one of hallucinatory confusion, one learns from patients after their recovery that at the time in some corner of their mind (as they put it) there was a normal person hidden, who, like a detached spectator, watched the hubbub of illness go past him. I do not know if we may assume that this is so in general, but I can report the same of other psychoses with a less tempestuous course. I call to mind a case of chronic paranoia in which after each attack of jealousy a dream conveyed to the analyst a correct picture of the precipitating cause, free from any delusion. An interesting contrast was thus brought to light: while we are accustomed to discover from the dreams of neurotics jealousies which are alien to their waking lives, in this psychotic case the delusion which dominated the patient in the day-time was corrected by his dream. We may probably take it as being generally true that what occurs in all these cases is a psychical split. Two psychical attitudes have been formed instead of a single one - one, the normal one, which takes account of reality, and another which under the influence of the instincts detaches the ego from reality. The two exist alongside of each other. The issue depends on their relative strength. If the second is or becomes the stronger, the necessary precondition for a psychosis is present. If the relation is reversed, then there is an apparent cure of the delusional disorder. Actually it has only retreated into the unconscious - just as numerous observations lead us to believe that the delusion existed ready-made for a long time before its manifest irruption.

[1940a [1938], 5007]
The unconscious wishful impulses clearly try to make themselves effective in daytime as well, and the fact of transference, as well as the psychoses, show us that they endeavor to force their way by way of the preconscious system into consciousness and to obtain control of the power of movement. Thus the censorship between the Ucs. and the Pcs., the assumption of whose existence is positively forced upon us by dreams, deserves to be recognized and respected as the watchman of our mental health. Must we not regard it, however, as an act of carelessness on the part of that watchman that it relaxes its activities during the night, allows the suppressed impulses in the Ucs. to find expression, and makes it possible for hallucinatory regression to occur once more? I think not. For even though this critical watchman goes to rest - and we have proof that its slumbers are not deep - it also shuts the door upon the power of movement. No matter what impulses from the normally inhibited Ucs. may prance upon the stage, we need feel no concern; they remain harmless, since they are unable to set in motion the motor apparatus by which alone they might modify the external world. The state of sleep guarantees the security of the citadel that must be guarded. The position is less harmless when what brings about the displacement of forces is not the nightly relaxation in the critical censorship's output of force, but a pathological reduction in that force or a pathological intensification of the unconscious excitations while the preconscious is still cathected and the gateway to the power of movement stands open. When this is so, the watchman is overpowered, the unconscious excitations overwhelm the Pcs., and thence obtain control over our speech and actions; or they forcibly bring about hallucinatory regression and direct the course of the apparatus (which was not designed for their use) by virtue of the attraction exercised by perceptions on the distribution of our psychical energy. To this state of things we give the name of psychosis.

[1900a, 997]

Let me at this point state the principal finding to which we have been led by the psychoanalytic investigation of neurotics. The neuroses have no psychical content that is peculiar to them and that might not equally be found in healthy people. Or, as Jung has expressed it, neurotics fall ill of the same complexes against which we healthy people struggle as well. Whether that struggle ends in health, in neurosis, or in a countervailing superiority of achievement, depends on quantitative considerations, on the relative strength of the conflicting forces.

[1910a, 2235]
In my *Three Essays on the Theory of Sexuality* I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics *endeavour to protect themselves against any such sexualization of their social instinctual catheces*, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) *schizophrenia*; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.

[1911c, 2431]
Just as the third type has brought the dispositional determinant before us almost in isolation, so the fourth type, which now follows, draws our attention to another factor, which comes into consideration in every single case and might easily for that very reason be overlooked in a theoretical discussion. We see people fall ill who have hitherto been healthy, who have met with no fresh experience and whose relation to the external world has undergone no change, so that the onset of their illness inevitably gives an impression of spontaneity. A closer consideration of such cases, however, shows us that none the less a change has taken place in them whose importance we must rate very highly as a cause of illness. As a result of their having reached a particular period of life, and in conformity with regular biological processes, the quantity of libido in their mental economy has experienced an increase which is in itself enough to upset the equilibrium of their health and to set up the necessary conditions for a neurosis. It is well known that more or less sudden increases of libido of this kind are habitually associated with puberty and the menopause - with the attainment of a certain age in women; in some people they may in addition be manifested in periodicities that are still unknown. Here the damming-up of libido is the primary factor; it becomes pathogenic as a consequence of a relative frustration on the part of the external world, which would still have granted satisfaction to a smaller claim by the libido. The unsatisfied and dammed-up libido can once again open up paths to regression and kindle the same conflicts which we have demonstrated in the case of absolute external frustration. We are reminded in this way that the quantitative factor should not be left out of account in any consideration of the precipitating causes of illness. All the other factors - frustration, fixation, developmental inhibition - remain ineffective unless they affect a certain amount of libido and bring about a damming-up of libido of a certain height. It is true that we are unable to measure this amount of libido which seems to us indispensable for a pathogenic effect; we can only postulate it after the resulting illness has started. There is only one direction in which we can determine it more precisely. We may assume that it is not a question of an absolute quantity, but of the relation between the quota of libido in operation and the quantity of libido which the individual ego is able to deal with - that is, to hold under tension, to sublimate or to employ directly. For this reason a relative increase in the quantity of libido may have the same effects as an absolute one. An enfeeblement of the ego owing to organic illness or owing to some special demand upon its energy will be able to cause the emergence of neuroses which would otherwise have remained latent in spite of any disposition that might be present.

Stekel shares with many non-psycho-analytic writers an inclination to reject the morphological differentiations which we have made within the jumble of the neuroses and to lump them all together under one heading - under psychasthenia, perhaps. We have often contradicted him on this, and have held fast to our expectation that the morphologico-clinical differences will prove valuable as indications that have not yet been understood of essentially distinct processes. When he - justly - points out to us that he has regularly found the same complexes present in what are termed neurasthenics as in other neurotics, his argument falls to meet the point at issue. We have long known that the same complexes and conflicts are to be looked for, too, in all normal and healthy people. In fact, we have grown accustomed to attributing to every civilized human being a certain amount of repression of perverse impulses, a certain amount of anal erotism, of homosexuality and so on, as well as a piece of father-complex and mother-complex and of other complexes besides - just as in the chemical analysis of an organic substance we have every hope of finding certain elements: carbon, oxygen, hydrogen, nitrogen and a trace of sulphur. What distinguishes organic substances from one another is the relative amounts of these elements and the way in which the links between them are constituted. In the same way, in the case of normal and neurotic people what is in question is not whether these complexes and conflicts exist but whether they have become pathogenic and, if so, by means of what mechanisms they have become so.
Your second observation, too, raises a justifiable question, but it is aimed in the wrong direction. It is true that a withdrawal of the object-libido into the ego is not directly pathogenic; it takes place, indeed, as we know, every time before we go to sleep, only to be reversed when we wake up. The amoeba withdraws its protrusions only to send them out again at the first opportunity. But it is quite a different thing when a particular, very energetic process forces a withdrawal of libido from objects. Here the libido that has become narcissistic cannot find its way back to objects, and this interference with the libido's mobility certainly becomes pathogenic. It seems that an accumulation of narcissistic libido beyond a certain amount is not tolerated. We may even imagine that it was for that very reason that object-cathexes originally came about, that the ego was obliged to send out its libido so as not to fall ill as a result of its being dammed up. If it lay within our plan to go more deeply into dementia praecox, I would show you that the process which detaches the libido from objects and cuts off its return to them is closely related to the process of repression and is to be looked at as its counterpart. But you would, first and foremost, find yourselves on familiar ground when you learnt that the determinants of this process are almost identical - so far as we know at present - with those of repression. The conflict seems to be the same and to be carried on between the same forces. If the outcome is so different from, for instance, that in hysteria, the reason can only depend on a difference in innate disposition. The weak spot in the libidinal development of these patients lies in a different phase; the determining fixation, which, as you will recollect, permits the irruption that leads to the formation of symptoms, lies elsewhere, probably in the stage of primitive narcissism to which dementia praecox returns in its final outcome. It is very remarkable that in the case of all the narcissistic neuroses we have to assume fixation points for the libido going back to far earlier phases of development than in hysteria or obsessional neurosis. As you heard, however, the concepts which we arrived at during our study of the transference neuroses are adequate in helping us to find our way about in the narcissistic neuroses which are so much more severe in practice. The conformities go very far; at bottom the field of phenomena is the same. And you can imagine how small a prospect anyone has of explaining these disorders (which belong within the sphere of psychiatry) who is not forearmed for his task with an analytic knowledge of the transference neuroses.

[1916-1917, 3466]
For a time psycho-analysis seemed fated to merge into psychology without being able to show why the psychology of the sick differed from that of the normal. In the course of its advance, however, it came up against the problem of dreams, which are abnormal products of the mind created by normal men under regularly recurrent physiological conditions. When psycho-analysis had solved the problem of dreams, it had discovered in unconscious psychical processes the common ground in which the highest and the lowest of mental impulses have their roots and from which spring the most normal as well as the most morbid and erratic of mental productions. The new picture of the workings of the mind began to grow ever clearer and more complete. It was a picture of obscure instinctual forces organic in origin, striving towards inborn aims, and, above them, of an agency comprising more highly organized mental structures - acquisitions of human evolution made under the impact of human history -, an agency which has taken over portions of the instinctual impulses, has developed them further or has even directed them towards higher aims, but which in any case binds them firmly and manipulates their energy to suit its own purposes. This higher organization, however, which is known to us as the ego, has rejected another portion of these same elementary instinctual impulses as being unserviceable because they cannot be fitted into the organic unity of the individual or because they rebel against the individual's cultural aims. The ego is not in a position to exterminate these unsubdued mental powers, but it turns its back on them, lets them remain at the lowest psychological level, defends itself from their demands by the energetic erection of protective and antithetical barriers or seeks to come to terms with them by means of substitutive satisfactions. These instincts which have fallen victim to repression - untamed and indestructible, yet inhibited from any kind of activity - together with their primitive mental representatives, constitute the mental underworld, the nucleus of the true unconscious, and are at every moment ready to assert their demands and, by hook or by crook, to force their way forward to satisfaction. To this is due the instability of the proud superstructure of the mind, the emergence at night of the proscribed and repressed material in the form of dreams, and the tendency to fall ill with neuroses and psychoses as soon as the balance of power between the ego and the repressed shifts to the disadvantage of the ego.

[1919g, 3703]

It seems to me that we have here an important discovery - namely, that the qualitative factor, the presence of certain neurotic formations, has less practical significance than the quantitative factor, the degree of attention or, more correctly, the amount of cathexis that these structures are able to attract to themselves. Our consideration of the first case, the jealous paranoia, led to a similar estimate of the importance of the quantitative factor, by showing that there also the abnormality essentially consisted in the hypercathexis of the interpretations of someone else's unconscious. We have long known of an analogous fact in the analysis of hysteria. The pathogenic phantasies, derivatives of repressed instinctual impulses, are for a long time tolerated alongside the normal life of the mind, and have no pathogenic effect until by a revolution in the libidinal economy they receive a hypercathexis; not till then does the conflict which leads to the formation of symptoms break out. Thus as our knowledge grows we are increasingly impelled to bring the economic point of view into the foreground. I should also like to throw out the question whether this quantitative factor that I am now dwelling on does not suffice to cover the phenomena which Bleuler and others have lately proposed to name 'switching'. One need only assume that an increase in resistance in the course taken by the psychical current in one direction results in a hypercathexis of another path and thus causes the flow to be switched into that path.

[1922b, 3905]
Only let us hold fast to this: the nodal point and pivot of the whole situation is the relative strength of the ego organization. We shall then find it easy to complete our aetiological survey. As what may be called the normal causes of neurotic illness we already know the feebleness of the childhood ego, the task of dealing with the early sexual impulses and the effects of the more or less chance experiences of childhood. Is it not possible, however, that yet other factors play a part, derived from the time before the beginning of the child's life? For instance, an innate strength and unruliness of the instinctual life in the id, which from the outset sets the ego tasks too hard for it? Or a special developmental feebleness of the ego due to unknown reasons? Such factors must of course acquire an aetiological importance, in some cases a transcendent one. We have invariably to reckon with the instinctual strength of the id; if it has developed to excess, the prospects of our therapy are poor. We still know too little of the causes of a developmental inhibition of the ego. These then would be the cases of neurosis with an essentially constitutional basis. Without some such constitutional, congenital favouring factors a neurosis can, no doubt, scarcely come about.

In order to remain faithful to our customary phraseology, we shall have to speak, not of transposing the psychical accent, but of displacing large amounts of cathexis. The question then is whether we are entitled to picture extensive displacements like this from one agency of the mental apparatus to another. It looks like a new hypothesis constructed ad hoc. Yet we may remind ourselves that we have repeatedly (even though not sufficiently often) taken a factor of this kind into account in our attempts at a metapsychological picture of mental events. Thus, for instance, we supposed that the difference between an ordinary erotic object-cathexis and the state of being in love is that in the latter incomparably more cathexis passes over to the object and that the ego empties itself as it were in favour of the object. In studying some cases of paranoia I was able to establish the fact that ideas of persecution are formed early and exist for a long time without any perceptible effect, until, as the result of some particular precipitating event, they receive sufficient amounts of cathexis to cause them to become dominant. The cure, too, of such paranoic attacks would lie not so much in a resolution and correction of the delusional ideas as in a withdrawal from them of the cathexis which has been lent to them. The alternations between melancholia and mania, between a cruel suppression of the ego by the super-ego and a liberation of the ego after that pressure, suggests a shift of cathexis of this kind; such a shift, moreover, would have to be brought in to explain a whole number of phenomena belonging to normal mental life. If this has been done hitherto only to a very limited extent, that is on account of our usual caution - something which deserves only praise. The region in which we feel secure is that of the pathology of mental life; it is here that we make our observations and acquire our convictions. For the present we venture to form a judgement on the normal mind only in so far as we can discern what is normal in the isolations and distortions of the pathological material. When once we have overcome this hesitancy we shall recognize what a large contribution is made to the understanding of mental processes by the static conditions as well as by the dynamic changes in the quantity of energetic cathexis.

During the study of the sexual functions we have been able to gain a first, preliminary conviction, or rather a suspicion, of two discoveries which will later be found to be important over the whole of our field. Firstly, the normal and abnormal manifestations observed by us (that is, the phenomenology of the subject) need to be described from the point of view of their dynamics and economics (in our case, from the point of view of the quantitative distribution of the libido). And secondly, the aetiology of the disorders which we study is to be looked for in the individual's developmental history - that is to say, in his early life.
We already know a number of things preliminary to such an undertaking. According to our hypothesis it is the ego's task to meet the demands raised by its three dependent relations to reality, to the id and to the super-ego - and nevertheless at the same time to preserve its own organization and maintain its own autonomy. The necessary precondition of the pathological states under discussion can only be a relative or absolute weakening of the ego which makes the fulfilment of its tasks impossible. The severest demand on the ego is probably the keeping down of the instinctual claims of the id, to accomplish which it is obliged to maintain large expenditures of energy on anticathexes. But the demands made by the super-ego too may become so powerful and so relentless that the ego may be paralysed, as it were, in the face of its other tasks. We may suspect that, in the economic conflicts which arise at this point, the id and the super-ego often make common cause against the hard-pressed ego which tries to cling to reality in order to retain its normal state. If the other two become too strong, they succeed in loosening and altering the ego's organization, so that its proper relation to reality is disturbed or even brought to an end. We have seen it happen in dreaming: when the ego is detached from the reality of the external world, it slips down, under the influence of the internal world, into psychosis.

We have repeatedly had to insist on the fact that the ego owes its origin as well as the most important of its acquired characteristics to its relation to the real external world. We are thus prepared to assume that the ego's pathological states, in which it most approximates once again to the id, are founded on a cessation or slackening of that relation to the external world. This tallies very well with what we learn from clinical experience - namely, that the precipitating cause of the outbreak of a psychosis is either that reality has become intolerably painful or that the instincts have become extraordinarily intensified - both of which, in view of the rival claims made on the ego by the id and the external world, must lead to the same result. The problem of psychoses would be simple and perspicuous if the ego's detachment from reality could be carried through completely. But that seems to happen only rarely or perhaps never. Even in a state so far removed from the reality of the external world as one of hallucinatory confusion, one learns from patients after their recovery that at the time in some corner of their mind (as they put it) there was a normal person hidden, who, like a detached spectator, watched the hubbub of illness go past him. I do not know if we may assume that this is so in general, but I can report the same of other psychoses with a less tempestuous course. I call to mind a case of chronic paranoia in which after each attack of jealousy a dream conveyed to the analyst a correct picture of the precipitating cause, free from any delusion. An interesting contrast was thus brought to light: while we are accustomed to discover from the dreams of neurotics jealousies which are alien to their waking lives, in this psychotic case the delusion which dominated the patient in the day-time was corrected by his dream. We may probably take it as being generally true that what occurs in all these cases is a psychical split. Two psychical attitudes have been formed instead of a single one - one, the normal one, which takes account of reality, and another which under the influence of the instincts detaches the ego from reality. The two exist alongside of each other. The issue depends on their relative strength. If the second is or becomes the stronger, the necessary precondition for a psychosis is present. If the relation is reversed, then there is an apparent cure of the delusional disorder. Actually it has only retreated into the unconscious - just as numerous observations lead us to believe that the delusion existed ready-made for a long time before its manifest irruption.
(3) A third consideration which arises from the views that have been developed in these pages is as follows. Are we to suppose that a general detachment of the libido from the external world would be an effective enough agent to account for the ‘end of the world’? Or would not the ego-cathexes which still remained in existence have been sufficient to maintain rapport with the external world? To meet this difficulty we should either have to assume that what we call libidinal cathexis (that is, interest emanating from erotic sources) coincides with interest in general, or we should have to consider the possibility that a very widespread disturbance in the distribution of libido may bring about a corresponding disturbance in the ego-cathexes. But these are problems which we are still quite helpless and incompetent to solve. It would be otherwise if we could start out from some well-grounded theory of instincts; but in fact we have nothing of the kind at our disposal. We regard instinct as being the concept on the frontier-line between the somatic and the mental, and see in it the psychical representative of organic forces. Further, we accept the popular distinction between ego-instincts and a sexual instinct; for such a distinction seems to agree with the biological conception that the individual has a double orientation, aiming on the one hand at self-preservation and on the other at the preservation of the species. But beyond this are only hypotheses, which we have taken up - and are quite ready to drop again - in order to help us to find our bearings in the chaos of the obscurer processes of the mind. What we expect from psycho-analytic investigations of pathological mental processes is precisely that they shall drive us to some conclusions on questions connected with the theory of instincts. These investigations, however, are in their infancy and are only being carried out by isolated workers, so that the hopes we place in them must still remain unfulfilled. We can no more dismiss the possibility that disturbances of the libido may react upon the ego-cathexes than we can overlook the converse possibility - namely, that a secondary or induced disturbance of the libidinal processes may result from abnormal changes in the ego. Indeed, it is probable that processes of this kind constitute the distinctive characteristic of psychoses. How much of all this may apply to paranoia it is impossible at present to say. There is one consideration, however, on which I should like to lay stress. It cannot be asserted that a paranoic, even at the height of the repression, withdraws his interest from the external world completely - as must be considered to occur in certain other kinds of hallucinatory psychosis (such a Meynert’s amentia). The paranoic perceives the external world and takes into account any alterations that may happen in it, and the effect it makes upon him stimulates him to invent explanatory theories (such as Schreber’s ‘cursorily improvised men’). It therefore appears to me far more probable that the paranoic’s altered relation to the world is to be explained entirely or in the main by the loss of his libidinal interest.

[1911c, 2440]

Concerning the third factor, the alteration of the ego, we have as yet said nothing. When we turn our attention to it, the first impression we receive is that there is much to ask and much to answer here, and that what we have to say about it will prove to be very inadequate. This first impression is confirmed when we go further into the problem. As is well known, the analytic situation consists in our allying ourselves with the ego of the person under treatment, in order to subdue portions of his id which are uncontrolled - that is to say to include them in the synthesis of his ego. The fact that a co-operation of this kind habitually fails in the case of psychotics affords us a first solid footing for our judgement. The ego, if we are to be able to make such a pact with it, must be a normal one. But a normal ego of this sort is, like normality in general, an ideal fiction. The abnormal ego, which is unserviceable for our purposes, is unfortunately no fiction. Every normal person, in fact, is only normal on the average. His ego approximates to that of the psychotic in some part or other and to a greater or lesser extent; and the degree of its remoteness from one end of the series and of its proximity to the other will furnish us with a provisional measure of what we have so indefinitely termed an ‘alteration of the ego’.

[1937c, 5030]
If we ask what is the source of the great variety of kinds and degrees of alteration of the ego, we cannot escape the first obvious alternative, that such alterations are either congenital or acquired. Of these, the second sort will be the easier to treat. If they are acquired, it will certainly have been in the course of development, starting from the first years of life. For the ego has to try from the very outset to fulfil its task of mediating between its id and the external world in the service of the pleasure principle, and to protect the id from the dangers of the external world. If, in the course of these efforts, the ego learns to adopt a defensive attitude towards its own id as well and to treat the latter's instinctual demands as external dangers, this happens, at any rate in part, because it understands that a satisfaction of instinct would lead to conflicts with the external world. Thereafter, under the influence of education, the ego grows accustomed to removing the scene of the fight from outside to within and to mastering the internal danger before it has become an external one; and probably it is most often right in doing so. During this fight on two fronts - later there will be a third front as well - the ego makes use of various procedures for fulfilling its task, which, to put it in general terms, is to avoid danger, anxiety and unpleasure. We call these procedures 'mechanisms of defence'. Our knowledge of them is not yet sufficiently complete. Anna Freud's book (1936) has given us a first insight into their multiplicity and many-sided significance. [1937c, 5031]
I find myself for a moment in the interesting position of not knowing whether what I have to say should be regarded as something long familiar and obvious or as something entirely new and puzzling. But I am inclined to think the latter.

[1940e [1938], 5062]

I have at last been struck by the fact that the ego of a person whom we know as a patient in analysis must, dozens of years earlier, when it was young, have behaved in a remarkable manner in certain particular situations of pressure. We can assign in general and somewhat vague terms the conditions under which this comes about, by saying that it occurs under the influence of a psychical trauma. I prefer to select a single sharply defined special case, though it certainly does not cover all the possible modes of causation.

[1940e [1938], 5062]

Let us suppose, then, that a child's ego is under the sway of a powerful instinctual demand which it is accustomed to satisfy and that it is suddenly frightened by an experience which teaches it that the continuance of this satisfaction will result in an almost intolerable real danger. It must now decide either to recognize the real danger, give way to it and renounce the instinctual satisfaction, or to disavow reality and make itself believe that there is no reason for fear, so that it may be able to retain the satisfaction. Thus there is a conflict between the demand by the instinct and the prohibition by reality. But in fact the child takes neither course, or rather he takes both simultaneously, which comes to the same thing. He replies to the conflict with two contrary reactions, both of which are valid and effective. On the one hand, with the help of certain mechanisms he rejects reality and refuses to accept any prohibition; on the other hand, in the same breath he recognizes the danger of reality, takes over the fear of that danger as a pathological symptom and tries subsequently to divest himself of the fear. It must be confessed that this is a very ingenious solution of the difficulty. Both of the parties to the dispute obtain their share: the instinct is allowed to retain its satisfaction and proper respect is shown to reality. But everything has to be paid for in one way or another, and this success is achieved at the price of a rift in the ego which never heals but which increases as time goes on. The two contrary reactions to the conflict persist as the centre-point of a splitting of the ego. The whole process seems so strange to us because we take for granted the synthetic nature of the processes of the ego. But we are clearly at fault in this. The synthetic function of the ego, though it is of such extraordinary importance, is subject to particular conditions and is liable to a whole number of disturbances.

[1940e [1938], 5062]
In bringing this paper to a close I may express a hope that, though my communication is incomplete in every sense, it may at least stimulate other workers to throw more light upon the obsessional neurosis by a deeper investigation of the subject. What is characteristic of this neurosis - what differentiates it from hysteria - is not, in my opinion, to be found in instinctual life but in the psychological field. I cannot take leave of my patient without putting on paper my impression that he had, as it were, disintegrated into three personalities: into one unconscious personality, that is to say, and into two preconscious ones between which his consciousness could oscillate. His unconscious comprised those of his impulses which had been suppressed at an early age and which might be described as passionate and evil impulses. In his normal state he was kind, cheerful, and sensible - an enlightened and superior kind of person - while in his third psychological organization he paid homage to superstition and asceticism. Thus he was able to have two different creeds and two different outlooks upon life. This second preconscious personality comprised chiefly the reaction-formations against his repressed wishes, and it was easy to foresee that it would have swallowed up the normal personality if the illness had lasted much longer. I have at present an opportunity of studying a lady suffering severely from obsessional acts. She has become similarly disintegrated into an easy-going and lively personality and into an exceedingly gloomy and ascetic one. She puts forward the first of them as her official ego, while in fact she is dominated by the second. Both of these psychical organizations have access to her consciousness, but behind her ascetic personality may be discerned the unconscious part of her being - quite unknown to her and composed of ancient and long-repressed wishful impulses.¹

Before continuing my exposition I will refer to two objections which are likely to be raised at this point. The first of these may be stated thus: instead of subscribing to the hypothesis of unconscious ideas of which we know nothing, we had better assume that consciousness can be split up, so that certain ideas or other psychical acts may constitute a consciousness apart; which has become detached and estranged from the bulk of conscious psychical activity. Well-known pathological cases like that of Dr. Azam seem to go far to show that the splitting up of consciousness is no fanciful imagination.

I venture to urge against this theory that it is a gratuitous assumption, based on the abuse of the word 'conscious'. We have no right to extend the meaning of this word so far as to make it include a consciousness of which its owner himself is not aware. If philosophers find difficulty in accepting the existence of unconscious ideas, the existence of an unconscious consciousness seems to me even more objectionable. The cases described as splitting of consciousness, like Dr. Azam's, might better be denoted as shifting of consciousness, - that function - or whatever it be - oscillating between two different psychical complexes which become conscious and unconscious in alternation.

¹ [1909d, 2194]

[1912g, 2580]
This process of inference, when applied to oneself in spite of internal opposition, does not, however, lead to the disclosure of an unconscious; it leads logically to the assumption of another, second consciousness which is united in one’s self with the consciousness one knows. But at this point, certain criticisms may fairly be made. In the first place, a consciousness of which its own possessor knows nothing is something very different from a consciousness belonging to another person, and it is questionable whether such a consciousness, lacking, as it does, its most important characteristic, deserves any discussion at all. Those who have resisted the assumption of an unconscious psychological are not likely to be ready to exchange it for an unconscious consciousness. The second place, analysis shows that the different latent mental processes inferred by us enjoy a high degree of mutual independence, as though they had no connection with one another, and knew nothing of one another. We must be prepared, if so, to assume the existence in us not only of a second consciousness, but of a third, fourth, perhaps of an unlimited number of states of consciousness, all unknown to us and to one another. In the third place - and this is the most weighty argument of all - we have to take into account the fact that analytic investigation reveals some of these latent processes as having characteristics and peculiarities which seem alien to us, or even incredible, and which run directly counter to the attributes of consciousness with which we are familiar. Thus we have grounds for modifying our inference about ourselves and saying that what is proved is not the existence of a second consciousness in us, but the existence of psychological acts which lack consciousness. We shall also be right in rejecting the term ‘subconsciousness’ as incorrect and misleading. The well-known cases of ‘double conscience’¹ (splitting of consciousness) prove nothing against our view. We may most aptly describe them as cases of a splitting of the mental activities into two groups, and say that the same consciousness turns to one or the other of these groups alternately.

[1915e, 2994]

The situation in which we find ourselves at the beginning of our enquiry may be expected itself to point the way for us. We wish to make the ego the matter of our enquiry, our very own ego. But is that possible? After all, the ego is in its very essence a subject; how can it be made into an object? Well, there is no doubt that it can be. The ego can take itself as an object, can treat itself like other objects, can observe itself, criticize itself, and do Heaven knows what with itself. In this, one part of the ego is setting itself over against the rest. So the ego can be split; it splits itself during a number of its functions - temporarily at least. Its parts can come together again afterwards. That is not exactly a novelty, though it may perhaps be putting an unusual emphasis on what is generally known. On the other hand, we are familiar with the notion that pathology, by making things larger and coarser, can draw our attention to normal conditions which would otherwise have escaped us. Where it points to a breach or a rent, there may normally be an articulation present. If we throw a crystal to the floor, it breaks; but not into haphazard pieces. It comes apart along its lines of cleavage into fragments whose boundaries, though they were invisible, were predetermined by the crystal’s structure. Mental patients are split and broken structures of this same kind. Even we cannot withhold from them something of the reverential awe which peoples of the past felt for the insane. They have turned away from external reality, but for that very reason they know more about internal, psychical reality and can reveal a number of things to us that would otherwise be inaccessible to us.

[1933a, 4667]
We have repeatedly had to insist on the fact that the ego owes its origin as well as the most important of its acquired characteristics to its relation to the real external world. We are thus prepared to assume that the ego's pathological states, in which it most approximates once again to the id, are founded on a cessation or slackening of that relation to the external world. This tallies very well with what we learn from clinical experience - namely, that the precipitating cause of the outbreak of a psychosis is either that reality has become intolerably painful or that the instincts have become extraordinarily intensified - both of which, in view of the rival claims made on the ego by the id and the external world, must lead to the same result. The problem of psychoses would be simple and perspicuous if the ego's detachment from reality could be carried through completely. But that seems to happen only rarely or perhaps never. Even in a state so far removed from the reality of the external world as one of hallucinatory confusion, one learns from patients after their recovery that at the time in some corner of their mind (as they put it) there was a normal person hidden, who, like a detached spectator, watched the hubbub of illness go past him. I do not know if we may assume that this is so in general, but I can report the same of other psychoses with a less tempestuous course. I call to mind a case of chronic paranoia in which after each attack of jealousy a dream conveyed to the analyst a correct picture of the precipitating cause, free from any delusion. An interesting contrast was thus brought to light: while we are accustomed to discover from the dreams of neurotics jealousies which are alien to their waking lives, in this psychotic case the delusion which dominated the patient in the day-time was corrected by his dream. We may probably take it as being generally true that what occurs in all these cases is a psychical split. Two psychical attitudes have been formed instead of a single one - one, the normal one, which takes account of reality, and another which under the influence of the instincts detaches the ego from reality. The two exist alongside of each other. The issue depends on their relative strength. If the second is or becomes the stronger, the necessary precondition for a psychosis is present. If the relation is reversed, then there is an apparent cure of the delusional disorder. Actually it has only retreated into the unconscious - just as numerous observations lead us to believe that the delusion existed ready-made for a long time before its manifest irruption.

[1940a [1938], 5007]
The view which postulates that in all psychoses there is a splitting of the ego could not call for so much notice if it did not turn out to apply to other states more like the neuroses and, finally, to the neuroses themselves. I first became convinced of this in cases fetishism. This abnormality, which may be counted as one of the perversions, is, as is well known, based on the patient (who is almost always male) not recognizing the fact that females have no penis - a fact which is extremely undesirable to him since it is a proof of the possibility of his being castrated himself. He therefore disavows his own sense-perception which showed him that the female genitals lack a penis and holds fast to the contrary conviction. The disavowed perception does not, however, remain entirely without influence for, in spite of everything, he has not the courage to assert that he actually saw a penis. He takes hold of something else instead - a part of the body or some other object - and assigns it the role of the penis which he cannot do without. It is usually something that he in fact saw at the moment at which he saw the female genitals, or it is something that can suitably serve as a symbolic substitute for the penis. Now it would be incorrect to describe this process when a fetish is constructed as a splitting of the ego; it is a compromise formed with the help of displacement, such as we have been familiar with in dreams. But our observations show us still more. The creation of the fetish was due to an intention to destroy the evidence for the possibility of castration, so that fear of castration could be avoided. If females, like other living creatures, possess a penis, there is no need to tremble for the continued possession of one's own penis. Now we come across fetishists who have developed the same fear of castration as non-fetishists and react in the same way to it. Their behaviour is therefore simultaneously expressing two contrary premisses. On the one hand they are disavowing the fact of their perception - the fact that they saw no penis in the female genitals; and on the other hand they are recognizing the fact that females have no penis and are drawing the correct conclusions from it. The two attitudes persist side by side throughout their lives without influencing each other. Here is what may rightly be called a splitting of the ego. This circumstance also enables us to understand how it is that fetishism is so often only partially developed. It does not govern the choice of object exclusively but leaves room for a greater or lesser amount of normal sexual behaviour; sometimes, indeed, it retires into playing a modest part or is limited to a mere hint. In fetishists, therefore, the detachment of the ego from the reality of the external world has never succeeded completely.
[1940a [1938], 5008]
It must not be thought that fetishism presents an exceptional case as regards a splitting of the ego; it is merely a particularly favourable subject for studying the question. Let us return to our thesis that the childish ego, under the domination of the real world, gets rid of undesirable instinctual demands by what are called repressions. We will now supplement this by further asserting that, during the same period of life, the ego often enough finds itself in the position of fending off some demand from the external world which it feels distressing and that this is effected by means of a disavowal of the perceptions which bring to knowledge this demand from reality. Disavowals of this kind occur very often and not only with fetishists; and whenever we are in a position to study them they turn out to be half-measures, incomplete attempts at detachment from reality. The disavowal is always supplemented by an acknowledgement; two contrary and independent attitudes always arise and result in the situation of there being a splitting of the ego. Once more the issue depends on which of the two can seize hold of the greater intensity.

The facts of this splitting of the ego, which we have just described, are neither so new nor so strange as they may at first appear. It is indeed a universal characteristic of neuroses that there are present in the subject's mental life, as regards some particular behaviour, two different attitudes, contrary to each other and independent of each other. In the case of neuroses, however, one of these attitudes belongs to the ego and the contrary one, which is repressed, belongs to the id. The difference between this case and the other is essentially a topographical or structural one, and it is not always easy to decide in an individual instance with which of the two possibilities one is dealing. They have, however, the following important characteristic in common. Whatever the ego does in its efforts of defence, whether it seeks to disavow a portion of the real external world or whether it seeks to reject an instinctual demand from the internal world, its success is never complete and unqualified. The outcome always lies in two contrary attitudes, of which the defeated, weaker one, no less than the other, leads to psychical complications. In conclusion, it is only necessary to point out how little of all these processes becomes known to us through our conscious perception.

Let us suppose, then, that a child's ego is under the sway of a powerful instinctual demand which it is accustomed to satisfy and that it is suddenly frightened by an experience which teaches it that the continuance of this satisfaction will result in an almost intolerable real danger. It must now decide either to recognize the real danger, give way to it and renounce the instinctual satisfaction, or to disavow reality and make itself believe that there is no reason for fear, so that it may be able to retain the satisfaction. Thus there is a conflict between the demand by the instinct and the prohibition by reality. But in fact the child takes neither course, or rather he takes both simultaneously, which comes to the same thing. He replies to the conflict with two contrary reactions, both of which are valid and effective. On the one hand, with the help of certain mechanisms he rejects reality and refuses to accept any prohibition; on the other hand, in the same breath he recognizes the danger of reality, takes over the fear of that danger as a pathological symptom and tries subsequently to divest himself of the fear. It must be confessed that this is a very ingenious solution of the difficulty. Both of the parties to the dispute obtain their share: the instinct is allowed to retain its satisfaction and proper respect is shown to reality. But everything has to be paid for in one way or another, and this success is achieved at the price of a rift in the ego which never heals but which increases as time goes on. The two contrary reactions to the conflict persist as the centre-point of a splitting of the ego. The whole process seems so strange to us because we take for granted the synthetic nature of the processes of the ego. But we are clearly at fault in this. The synthetic function of the ego, though it is of such extraordinary importance, is subject to particular conditions and is liable to a whole number of disturbances.
The usual result of the fright of castration, the result that passes as the normal one, is that, either immediately or after some considerable struggle, the boy gives way to the threat and obeys the prohibition either wholly or at least in part (that is, by no longer touching his genitals with his hand). In other words, he gives up, in whole or in part, the satisfaction of the instinct. We are prepared to hear, however, that our present patient found another way out. He created a substitute for the penis which he missed in females - that is to say, a fetish. In so doing, it is true that he had disavowed reality, but he had saved his own penis. So long as he was not obliged to acknowledge that females have lost their penis, there was no need for him to believe the threat that had been made against him: he need have no fears for his own penis, so he could proceed with his masturbation undisturbed. This behaviour on the part of our patient strikes us forcibly as being a turning away from reality - a procedure which we should prefer to reserve for psychoses. And it is in fact not very different. Yet we will suspend our judgement, for upon closer inspection we shall discover a not unimportant distinction. The boy did not simply contradict his perceptions and hallucinate a penis where there was none to be seen; he effected no more than a displacement of value - he transferred the importance of the penis to another part of the body, a procedure in which he was assisted by the mechanism of regression (in a manner which need not here be explained). This displacement, it is true, related only to the female body; as regards his own penis nothing was changed.

This way of dealing with reality, which almost deserves to be described as artful, was decisive as regards the boy's practical behaviour. He continued with his masturbation as though it implied no danger to his penis; but at the same time, in complete contradiction to his apparent boldness or indifference, he developed a symptom which showed that he nevertheless did recognize the danger. He had been threatened with being castrated by his father, and immediately afterwards, simultaneously with the creation of his fetish, he developed an intense fear of his father punishing him, which it required the whole force of his masculinity to master and overcompensate. This fear of his father, too, was silent on the subject of castration: by the help of regression to an oral phase, it assumed the form of a fear of being eaten by his father. At this point it is impossible to forget a primitive fragment of Greek mythology which tells how Kronos, the old Father God, swallowed his children and sought to swallow his youngest son Zeus like the rest, and how Zeus was saved by the craft of his mother and later on castrated his father. But we must return to our case history and add that the boy produced yet another symptom, though it was a slight one, which he has retained to this day. This was an anxious susceptibility against either of his little toes being touched, as though, in all the to and fro between disavowal and acknowledgement, it was nevertheless castration that found the clearer expression. . . .
(8) In Lichtenberg’s Witzige und Satirische Einfälle a remark occurs which is no doubt derived from a piece of observation and which comprises virtually the whole theory of misreading: 'He had read Homer so much that he always read "Agamemnon" instead of "angenommen" [supposed].'

[1901b, 1198]

We have repeatedly had to insist on the fact that the ego owes its origin as well as the most important of its acquired characteristics to its relation to the real external world. We are thus prepared to assume that the ego's pathological states, in which it most approximates once again to the id, are founded on a cessation or slackening of that relation to the external world. This tallies very well with what we learn from clinical experience - namely, that the precipitating cause of the outbreak of a psychosis is either that reality has become intolerably painful or that the instincts have become extraordinarily intensified - both of which, in view of the rival claims made on the ego by the id and the external world, must lead to the same result. Actually it has only retreated into the unconscious - just as numerous observations lead us to believe that the delusion existed ready-made for a long time before its manifest irruption.

[1940a [1938], 5007]
In bringing this paper to a close I may express a hope that, though my communication is incomplete in every sense, it may at least stimulate other workers to throw more light upon the obsessional neurosis by a deeper investigation of the subject. What is characteristic of this neurosis - what differentiates it from hysteria - is not, in my opinion, to be found in instinctual life but in the psychological field. I cannot take leave of my patient without putting on paper my impression that he had, as it were, disintegrated into three personalities: into one unconscious personality, that is to say, and into two preconscious ones between which his consciousness could oscillate. His unconscious comprised those of his impulses which had been suppressed at an early age and which might be described as passionate and evil impulses. In his normal state he was kind, cheerful, and sensible - an enlightened and superior kind of person - while in his third psychological organization he paid homage to superstition and asceticism. Thus he was able to have two different creeds and two different outlooks upon life. This second preconscious personality comprised chiefly the reaction-formations against his repressed wishes, and it was easy to foresee that it would have swallowed up the normal personality if the illness had lasted much longer. I have at present an opportunity of studying a lady suffering severely from obsessional acts. She has become similarly disintegrated into an easy-going and lively personality and into an exceedingly gloomy and ascetic one. She puts forward the first of them as her official ego, while in fact she is dominated by the second. Both of these psychical organizations have access to her consciousness, but behind her ascetic personality may be discerned the unconscious part of her being - quite unknown to her and composed of ancient and long-repressed wishful impulses.¹

¹ I believe that when poets complain that two souls dwell in the human breast, and when popular psychologists talk of the splitting of people’s egos, what they are thinking of is this division (in the sphere of ego-psychology) between the critical agency and the rest of the ego, and not the antithesis discovered by psycho-analysis between the ego and what is unconscious and repressed. It is true that the distinction between these two antitheses is to some extent effaced by the circumstance that foremost among the things that are rejected by the criticism of the ego are derivatives of the repressed. [1909d, 2194]

¹ In young children, for instance, ambivalent emotional attitudes towards those who are nearest to them exist side by side for a long time, without either of them interfering with the expression of the other and opposite one. If eventually a conflict breaks out between the two, it is often settled by the child making a change of object and displacing one of the ambivalent emotions on to a substitute. The history of the development of a neurosis in an adult will also show that a suppressed emotion may frequently persist for a long time in unconscious or even in conscious phantasies, the content of which naturally runs directly counter to some predominant tendency, and yet that this opposition does not result in any proceedings on the part of the ego against what it has repudiated. The phantasy is tolerated for quite a long time, until suddenly one day, usually as a result of an increase in the affective cathexis of the phantasy, a conflict breaks out between it and the ego with all the usual consequences. In the process of a child’s development into a mature adult there is a more and more extensive integration of his personality, a co-ordination of the separate instinctual impulses and purposive trends which have grown up in him independently of one another. The analogous process in the domain of sexual life has long been known to us as the co-ordination of all the sexual instincts into a definitive genital organization. (Three Essays on the Theory of Sexuality, 1905d.) Moreover, that the unification of the ego is liable to the same interferences as that of the libido is shown by numerous familiar instances, such as that of men of science who have preserved their faith in the Bible, and other similar cases. - The various possible ways in which the ego can later disintegrate form a special chapter in psychopathology. [1921c, 3774]
The facts of this splitting of the ego, which we have just described, are neither so new nor so strange as they may at first appear. It is indeed a universal characteristic of neuroses that there are present in the subject's mental life, as regards some particular behaviour, two different attitudes, contrary to each other and independent of each other. In the case of neuroses, however, one of these attitudes belongs to the ego and the contrary one, which is repressed, belongs to the id. The difference between this case and the other is essentially a topographical or structural one, and it is not always easy to decide in an individual instance with which of the two possibilities one is dealing. They have, however, the following important characteristic in common. Whatever the ego does in its efforts of defence, whether it seeks to disavow a portion of the real external world or whether it seeks to reject an instinctual demand from the internal world, its success is never complete and unqualified. The outcome always lies in two contrary attitudes, of which the defeated, weaker one, no less than the other, leads to psychical complications. In conclusion, it is only necessary to point out how little of all these processes becomes known to us through our conscious perception.

[1940a [1938], 5009]
What happened, therefore, was that the boy refused to take cognizance of the fact of his having perceived that a woman does not possess a penis. No, that could not be true: for if a woman had been castrated, then his own possession of a penis was in danger; and against that there rose in rebellion the portion of his narcissism which Nature has, as a precaution, attached to that particular organ. In later life a grown man may perhaps experience a similar panic when the cry goes up that Throne and Altar are in danger, and similar illogical consequences will ensue. If I am not mistaken, Laforgue would say in this case that the boy 'scotomizes' his perception of the woman's lack of a penis.¹ A new technical term is justified when it describes a new fact or emphasizes it. This is not so here. The oldest word in our psycho-analytic terminology, 'repression', already relates to this pathological process. If we wanted to differentiate more sharply between the vicissitude of the idea as distinct from that of the affect, and reserve the word 'Verdrängung' ['repression'] for the affect, then the correct German word for the vicissitude of the idea would be 'Verleugnung' ['disavowal']. 'Scotomization' seems to me particularly unsuitable, for it suggests that the perception is entirely wiped out, so that the result is the same as when a visual impression falls on the blind spot in the retina. In the situation we are considering, on the contrary, we see that the perception has persisted, and that a very energetic action has been undertaken to maintain the disavowal. It is not true that, after the child has made his observation of the woman, he has preserved unaltered his belief that women have a phallus. He has retained that belief, but he has also given it up. In the conflict between the weight of the unwelcome perception and the force of his counter-wish, a compromise has been reached, as is only possible under the dominance of the unconscious laws of thought - the primary processes. Yes, in his mind the woman has got a penis, in spite of everything; but this penis is no longer the same as it was before. Something else has taken its place, has been appointed its substitute, as it were, and now inherits the interest which was formerly directed to its predecessor. But this interest suffers an extraordinary increase as well, because the horror of castration has set up a memorial to itself in the creation of this substitute. Furthermore, an aversion, which is never absent in any fetishist, to the real female genitals remains a stigma indelebile of the repression that has taken place. We can now see what the fetish achieves and what it is that maintains it. It remains a token of triumph over the threat of castration and a protection against it. It also saves the fetishist from becoming a homosexual, by endowing women with the characteristic which makes them tolerable as sexual objects. In later life, the fetishist feels that he enjoys yet another advantage from his substitute for a genital. The meaning of the fetish is not known to other people, so the fetish is not withheld from him: it is easily accessible and he can readily obtain the sexual satisfaction attached to it. What other men have to woo and make exertions for can be had by the fetishist with no trouble at all.

But further research led to another solution of the contradiction. It turned out that the two young men had no more 'scotomized' their father's death than a fetishist does the castration of women. It was only one current in their mental life that had not recognized their father's death; there was another current which took full account of that fact. The attitude which fitted in with the wish and the attitude which fitted in with reality existed side by side. In one of my two cases this split had formed the basis of a moderately severe obsessional neurosis. The patient oscillated in every situation in life between two assumptions: the one, that his father was still alive and was hindering his activities; the other, opposite one, that he was entitled to regard himself as his father's successor. I may thus keep to the expectation that in a psychosis the one current - that which fitted in with reality - would have in fact been absent.

¹ [1927e, 4536]

But further research led to another solution of the contradiction. It turned out that the two young men had no more 'scotomized' their father's death than a fetishist does the castration of women. It was only one current in their mental life that had not recognized their father's death; there was another current which took full account of that fact. The attitude which fitted in with the wish and the attitude which fitted in with reality existed side by side. In one of my two cases this split had formed the basis of a moderately severe obsessional neurosis. I may thus keep to the expectation that in a psychosis the one current - that which fitted in with reality - would have in fact been absent.

[1927e, 4538]
Returning to my description of fetishism, I may say that there are many and weighty additional proofs of the divided attitude of fetishists to the question of the castration of women. In very subtle instances both the disavowal and the affirmation of the castration have found their way into the construction of the fetish itself. This was so in the case of a man whose fetish was an athletic support-belt which could also be worn as bathing drawers. This piece of clothing covered up the genitals entirely and concealed the distinction between them. Analysis showed that it signified that women were castrated and that they were not castrated; and it also allowed of the hypothesis that men were castrated, for all these possibilities could equally well be concealed under the belt - the earliest rudiment of which in his childhood had been the fig-leaf on a statue. A fetish of this sort, doubly derived from contrary ideas, is of course especially durable. In other instances the divided attitude shows itself in what the fetishist does with his fetish, whether in reality or in his imagination. To point out that he reveres his fetish is not the whole story; in many cases he treats it in a way which is obviously equivalent to a representation of castration. This happens particularly if he has developed a strong identification with his father and plays the part of the latter; for it is to him that as a child he ascribed the woman's castration. Affection and hostility in the treatment of the fetish - which run parallel with the disavowal and the acknowledgement of castration - are mixed in unequal proportions in different cases, so that the one or the other is more clearly recognizable. We seem here to approach an understanding, even if a distant one, of the behaviour of the 'coupeur de nattes'. In him the need to carry out the castration which he disavows has come to the front. His action contains in itself the two mutually incompatible assertions: 'the woman has still got a penis' and 'my father has castrated the woman'. Another variant, which is also a parallel to fetishism in social psychology, might be seen in the Chinese custom of mutilating the female foot and then revering it like a fetish after it has been mutilated. It seems as though the Chinese male wants to thank the woman for having submitted to being castrated.

[1927e, 4538]
The view which postulates that in all psychoses there is a splitting of the ego could not call for so much notice if it did not turn out to apply to other states more like the neuroses and, finally, to the neuroses themselves. I first became convinced of this in cases fetishism. This abnormality, which may be counted as one of the perversions, is, as is well known, based on the patient (who is almost always male) not recognizing the fact that females have no penis - a fact which is extremely undesirable to him since it is a proof of the possibility of his being castrated himself. He therefore disavows his own sense-perception which showed him that the female genitals lack a penis and holds fast to the contrary conviction. The disavowed perception does not, however, remain entirely without influence for, in spite of everything, he has not the courage to assert that he actually saw a penis. He takes hold of something else instead - a part of the body or some other object - and assigns it the role of the penis which he cannot do without. It is usually something that he in fact saw at the moment at which he saw the female genitals, or it is something that can suitably serve as a symbolic substitute for the penis. Now it would be incorrect to describe this process when a fetish is constructed as a splitting of the ego; it is a compromise formed with the help of displacement, such as we have been familiar with in dreams. But our observations show us still more. The creation of the fetish was due to an intention to destroy the evidence for the possibility of castration, so that fear of castration could be avoided. If females, like other living creatures, possess a penis, there is no need to tremble for the continued possession of one's own penis. Now we come across fetishists who have developed the same fear of castration as non-fetishists and react in the same way to it. Their behaviour is therefore simultaneously expressing two contrary premisses. On the one hand they are disavowing the fact of their perception - the fact that they saw no penis in the female genitals; and on the other hand they are recognizing the fact that females have no penis and are drawing the correct conclusions from it. The two attitudes persist side by side throughout their lives without influencing each other. Here is what may rightly be called a splitting of the ego. This circumstance also enables us to understand how it is that fetishism is so often only partially developed. It does not govern the choice of object exclusively but leaves room for a greater or lesser amount of normal sexual behaviour; sometimes, indeed, it retires into playing a modest part or is limited to a mere hint. In festishists, therefore, the detachment of the ego from the reality of the external world has never succeeded completely.

[1940a [1938], 5008]

It must not be thought that fetishism presents an exceptional case as regards a splitting of the ego; it is merely a particularly favourable subject for studying the question. Let us return to our thesis that the childish ego, under the domination of the real world, gets rid of undesirable instinctual demands by what are called repressions. We will now supplement this by further asserting that, during the same period of life, the ego often enough finds itself in the position of fending off some demand from the external world which it feels distressing and that this is effected by means of a disavowal of the perceptions which bring to knowledge this demand from reality. Disavowals of this kind occur very often and not only with fetishists; and whenever we are in a position to study them they turn out to be half-measures, incomplete attempts at detachment from reality. The disavowal is always supplemented by an acknowledgement; two contrary and independent attitudes always arise and result in the situation of there being a splitting of the ego. Once more the issue depends on which of the two can seize hold of the greater intensity.

[1940a [1938], 5009]
It will assist if I introduce an individual case history into this schematic disquisition. A little boy, while he was between three and four years of age, had become acquainted with the female genitals through being seduced by an older girl. After these relations had been broken off, he carried on the sexual stimulation set going in this way by zealously practising manual masturbation; but he was soon caught at it by his energetic nurse and was threatened with castration, the carrying out of which was, as usual, ascribed to his father. There were thus present in this case conditions calculated to produce a tremendous effect of fright. A threat of castration by itself need not produce a great impression. A child will refuse to believe in it, for he cannot easily imagine the possibility of losing such a highly prized part of his body. His sight of the female genitals might have convinced our child of that possibility. But he drew no such conclusion from it, since his disinclination to doing so was too great and there was no motive present which could compel him to. On the contrary, whatever uneasiness he may have felt was calmed by the reflection that what was missing would yet make its appearance: she would grow one (a penis) later. Anyone who has observed enough small boys will be able to recollect having come across some such remark at the sight of a baby sister's genitals. But it is different if both factors are present together. In that case the threat revives the memory of the perception which had hitherto been regarded as harmless and finds in that memory a dreaded confirmation. The little boy now thinks he understands why the girl's genitals showed no sign of a penis and no longer ventures to doubt that his own genitals may meet with the same fate. Thenceforward he cannot help believing in the reality of the danger of castration.

The usual result of the fright of castration, the result that passes as the normal one, is that, either immediately or after some considerable struggle, the boy gives way to the threat and obeys the prohibition either wholly or at least in part (that is, by no longer touching his genitals with his hand). In other words, he gives up, in whole or in part, the satisfaction of the instinct. We are prepared to hear, however, that our present patient found another way out. He created a substitute for the penis which he missed in females - that is to say, a fetish. In so doing, it is true that he had disavowed reality, but he had saved his own penis. So long as he was not obliged to acknowledge that females have lost their penis, there was no need for him to believe the threat that had been made against him: he need have no fears for his own penis, so he could proceed with his masturbation undisturbed. This behaviour on the part of our patient strikes us forcibly as being a turning away from reality - a procedure which we should prefer to reserve for psychoses. And it is in fact not very different. Yet we will suspend our judgement, for upon closer inspection we shall discover a not unimportant distinction. The boy did not simply contradict his perceptions and hallucinate a penis where there was none to be seen; he effected no more than a displacement of value - he transferred the importance of the penis to another part of the body, a procedure in which he was assisted by the mechanism of regression (in a manner which need not here be explained). This displacement, it is true, related only to the female body; as regards his own penis nothing was changed.
This way of dealing with reality, which almost deserves to be described as artful, was decisive as regards the boy's practical behaviour. He continued with his masturbation as though it implied no danger to his penis; but at the same time, in complete contradiction to his apparent boldness or indifference, he developed a symptom which showed that he nevertheless did recognize the danger. He had been threatened with being castrated by his father, and immediately afterwards, simultaneously with the creation of his fetish, he developed an intense fear of his father punishing him, which it required the whole force of his masculinity to master and overcompensate. This fear of his father, too, was silent on the subject of castration: by the help of regression to an oral phase, it assumed the form of a fear of being eaten by his father. At this point it is impossible to forget a primitive fragment of Greek mythology which tells how Kronos, the old Father God, swallowed his children and sought to swallow his youngest son Zeus like the rest, and how Zeus was saved by the craft of his mother and later on castrated his father. But we must return to our case history and add that the boy produced yet another symptom, though it was a slight one, which he has retained to this day. This was an anxious susceptibility against either of his little toes being touched, as though, in all the to and fro between disavowal and acknowledgement, it was nevertheless castration that found the clearer expression. . . .

[1940e [1938], 5064]
In young children, for instance, ambivalent emotional attitudes towards those who are nearest to them exist side by side for a long time, without either of them interfering with the expression of the other and opposite one. If eventually a conflict breaks out between the two, it is often settled by the child making a change of object and displacing one of the ambivalent emotions on to a substitute. The history of the development of a neurosis in an adult will also show that a suppressed emotion may frequently persist for a long time in unconscious or even in conscious phantasies, the content of which naturally runs directly counter to some predominant tendency, and yet that this opposition does not result in any proceedings on the part of the ego against what it has repudiated. The phantasy is tolerated for quite a long time, until suddenly one day, usually as a result of an increase in the affective cathexis of the phantasy, a conflict breaks out between it and the ego with all the usual consequences. In the process of a child's development into a mature adult there is a more and more extensive integration of his personality, a co-ordination of the separate instinctual impulses and purposive trends which have grown up in him independently of one another. The analogous process in the domain of sexual life has long been known to us as the co-ordination of all the sexual instincts into a definitive genital organization. (Three Essays on the Theory of Sexuality, 1905d.) Moreover, that the unification of the ego is liable to the same interferences as that of the libido is shown by numerous familiar instances, such as that of men of science who have preserved their faith in the Bible, and other similar cases. - The various possible ways in which the ego can later disintegrate form a special chapter in psychopathology. [1921c, 3774]
The fact to which I now wish to call attention is that the content of a hallucinatory psychosis of this sort consists precisely in the accentuation of the idea which was threatened by the precipitating cause of the onset of the illness. One is therefore justified in saying that the ego has fended off the incompatible idea through a flight into psychosis. The process by which this has been achieved once more eludes the subject's self perception, as it eludes psychologico-clinical analysis. It must be regarded as the expression of a pathological disposition of a fairly high degree and it may be described more or less as follows. The ego breaks away from the incompatible idea; but the latter is inseparably connected with a piece of reality, so that, in so far as the ego achieves this result, it, too, has detached itself wholly or in part from reality. In my opinion this latter event is the condition under which the subject's ideas receive the vividness of hallucinations; and thus when the defence has been successfully carried out he finds himself in a state of hallucinatory confusion.

[1894a, 314]
We are beginning to understand now, and to feel some hope. If the young lady in whose form Gradiva had come to life again accepted Hanold's delusion so fully, she was probably doing so in order to set him free from it. There was no other way of doing so; to contradict it would have put an end to any such possibility. Even the serious treatment of a real case of illness of the kind could proceed in no other way than to begin by taking up the same ground as the delusional structure and then investigating it as completely as possible. If Zoe was the right person for the job, we shall soon learn, no doubt, how to cure a delusion like our hero's. We should also be glad to know how such delusions arise. It would be a strange coincidence - but, nevertheless, not without an example or parallel - if the treatment of the delusion were to coincide with its investigation and if the explanation of its origin were to be revealed precisely while it was being dissected. We may suspect, of course, that, if so, our case of illness might end up as a 'commonplace' love-story. But the healing power of love against a delusion is not to be despised - and was not our hero's infatuation for his Gradiva sculpture a complete instance of being in love, though of being in love with something past and lifeless?

I told you too that we hoped that the analysis of the narcissistic disorders would give us an insight into the way in which our ego is put together and built up out of different agencies. We have already made a start with this at one point. From the analysis of delusions of observation we have drawn the conclusion that there actually exists in the ego an agency which unceasingly observes, criticizes and compares, and in that way sets itself over against the other part of the ego. We believe, therefore, that the patient is betraying a truth to us which is not yet sufficiently appreciated when he complains that he is spied upon and observed at every step he takes and that every one of his thoughts is reported and criticized. His only mistake is in regarding this uncomfortable power as something alien to him and placing it outside himself. He senses an agency holding sway in his ego which measures his actual ego and each of its activities by an ideal ego that he has created for himself in the course of his development. We believe, too, that this creation was made with the intention of re-establishing the self-satisfaction which was attached to primary infantile narcissism but which since then has suffered so many disturbances and mortifications. We know the self-observing agency as the ego-censor, the conscience; it is this that exercises the dream-censorship during the night, from which the repressions of inadmissible wishful impulses proceed. When in delusions of observation it becomes split up, it reveals to us its origin from the influences of parents, educators and social environment - from an identification with some of these model figures.

It cannot be proved, but also cannot be disproved, that instead of this, what happened was the following. Her mother told her one day that her son had sent a telepathic message; whereupon the conviction at once arose in her mind that she had had the same experience at the same time. Such illusions of memory arise in the mind with a compelling force which they draw from real sources; but they turn psychical reality into material reality. The strength of the illusion lies in its being an excellent way of expressing the sister's proneness to identify herself with her mother. 'You are anxious about the boy, but I am really his mother, and his cry was meant for me; I had this telepathic message.' The sister would naturally firmly reject our attempt at explanation and would hold to her belief in the authenticity of her experience. But she could not do otherwise. She would be bound to believe in the reality of the pathological effect so long as the reality of its unconscious premises were unknown to her. Every such delusion derives its strength and its unassailable character from having a source in unconscious psychical reality. I note in passing that it is not incumbent on us here to explain the mother's experience or to investigate its authenticity.
In a psychosis, the transforming of reality is carried out upon the psychical precipitates of former relations to it - that is, upon the memory-traces, ideas and judgements which have been previously derived from reality and by which reality was represented in the mind. But this relation was never a closed one; it was continually being enriched and altered by fresh perceptions. Thus the psychosis is also faced with the task of procuring for itself perceptions of a kind which shall correspond to the new reality; and this is most radically effected by means of hallucination. The fact that, in so many forms and cases of psychosis, the paramnesias, the delusions and the hallucinations that occur are of a most distressing character and are bound up with a generation of anxiety - this fact is without doubt a sign that the whole process of remodelling is carried through against forces which oppose it violently. We may construct the process on the model of a neurosis, with which we are more familiar. There we see that a reaction of anxiety sets in whenever the repressed instinct makes a thrust forward, and that the outcome of the conflict is only a compromise and does not provide complete satisfaction. Probably in a psychosis the rejected piece of reality constantly forces itself upon the mind, just as the repressed instinct does in a neurosis, and that is why in both cases the consequences too are the same. The elucidation of the various mechanisms which are designed, in the psychoses, to turn the subject away from reality and to reconstruct reality - this is a task for specialized psychiatric study which has not yet been taken in hand.

Another procedure operates more energetically and more thoroughly. It regards reality as the sole enemy and as the source of all suffering, with which it is impossible to live, so that one must break off all relations with it if one is to be in any way happy. The hermit turns his back on the world and will have no truck with it. But one can do more than that; one can try to re-create the world, to build up in its stead another world in which its most unbearable features are eliminated and replaced by others that are in conformity with one's own wishes. But whoever, in desperate defiance, sets out upon this path to happiness will as a rule attain nothing. Reality is too strong for him. He becomes a madman, who for the most part finds no one to help him in carrying through his delusion. It is asserted, however, that each one of us behaves in some one respect like a paranoic, corrects some aspect of the world which is unbearable to him by the construction of a wish and introduces this delusion into reality. A special importance attaches to the case in which this attempt to procure a certainty of happiness and a protection against suffering through a delusional remoulding of reality is made by a considerable number of people in common. The religions of mankind must be classed among the mass delusions of this kind. No one, needless to say, who shares a delusion ever recognizes it as such.

It is worth specially stressing the fact that each portion which returns from oblivion asserts itself with peculiar force, exercises an incomparably powerful influence on people in the mass, and raises an irresistible claim to truth against which logical objections remain powerless: a kind of 'credo quia absurdum'. This remarkable feature can only be understood on the pattern of the delusions of psychotics. We have long understood that a portion of forgotten truth lies hidden in delusional ideas, that when this returns it has to put up with distortions and misunderstandings, and that the compulsive conviction which attaches to the delusion arises from this core of truth and spreads out on to the errors that wrap it round. We must grant an ingredient such as this of what may be called historical truth to the dogmas of religion as well, which, it is true, bear the character of psychotic symptoms but which, as group phenomena, escape the curse of isolation.
We have learnt from the psycho-analyses of individuals that their earliest impressions, received at a time when the child was scarcely yet capable of speaking, produce at some time or another effects of a compulsive character without themselves being consciously remembered. We believe we have a right to make the same assumption about the earliest experiences of the whole of humanity. One of these effects would be the emergence of the idea of a single great god - an idea which must be recognized as a completely justified memory, though, it is true, one that has been distorted. An idea such as this has a compulsive character: it must be believed. To the extent to which it is distorted, it may be described as a delusion; in so far as it brings a return of the past, it must be called the truth. Psychiatric delusions, too, contain a small fragment of truth and the patient’s conviction extends over from this truth on to its delusional wrappings.

[1939a, 4947]

This view of delusions is not, I think, entirely new, but it nevertheless emphasizes a point of view which is not usually brought into the foreground. The essence of it is that there is not only method in madness, as the poet has already perceived, but also a fragment of historical truth; and it is plausible to suppose that the compulsive belief attaching to delusions derives its strength precisely from infantile sources of this kind. All that I can produce to-day in support of this theory are reminiscences, not fresh impressions. It would probably be worth while to make an attempt to study cases of the disorder in question on the basis of the hypotheses that have been here put forward and also to carry out their treatment on those same lines. The vain effort would be abandoned of convincing the patient of the error of his delusion and of its contradiction of reality; and, on the contrary, the recognition of its kernel of truth would afford common ground upon which the therapeutic work could develop. That work would consist in liberating the fragment of historical truth from its distortions and its attachments to the actual present day and in leading it back to the point in the past to which it belongs. The transposing of material from a forgotten past on to the present or on to an expectation of the future is indeed a habitual occurrence in neurotics no less than in psychotics. Often enough, when a neurotic is led by an anxiety-state to expect the occurrence of some terrible event, he is in fact merely under the influence of a repressed memory (which is seeking to enter consciousness but cannot become conscious) that something which was at that time terrifying did really happen. I believe that we should gain a great deal of valuable knowledge from work of this kind upon psychotics even if it led to no therapeutic success.

[1937d, 5058]

I am aware that it is of small service to handle so important a subject in the cursory fashion that I have here employed. But none the less I have not been able to resist the seduction of an analogy. The delusions of patients appear to me to be the equivalents of the constructions which we build up in the course of an analytic treatment - attempts at explanation and cure, though it is true that these, under the conditions of a psychosis, can do no more than replace the fragment of reality that is being disavowed in the present by another fragment that had already been disavowed in the remote past. It will be the task of each individual investigation to reveal the intimate connections between the material of the present disavowal and that of the original repression. Just as our construction is only effective because it recovers a fragment of lost experience, so the delusion owes its convincing power to the element of historical truth which it inserts in the place of the rejected reality. In this way a proposition which I originally asserted only of hysteria would apply also to delusions - namely, that those who are subject to them are suffering from their own reminiscences. I never intended by this short formula to dispute the complexity of the causation of the illness or to exclude the operation of many other factors.

[1937d, 5059]
If we consider mankind as a whole and substitute it for the single human individual, we
discover that it too has developed delusions which are inaccessible to logical criticism and
which contradict reality. If, in spite of this, they are able to exert an extraordinary power over
men, investigation leads us to the same explanation as in the case of the single individual. They
owe their power to the element of *historical truth* which they have brought up from the
repression of the forgotten and primaeval past.
[1937d, 5059]
The fact to which I now wish to call attention is that the content of a hallucinatory psychosis of this sort consists precisely in the accentuation of the idea which was threatened by the precipitating cause of the onset of the illness. One is therefore justified in saying that the ego has fended off the incompatible idea through a flight into psychosis. The process by which this has been achieved once more eludes the subject's self perception, as it eludes psychologico-clinical analysis. It must be regarded as the expression of a pathological disposition of a fairly high degree and it may be described more or less as follows. The ego breaks away from the incompatible idea; but the latter is inseparably connected with a piece of reality, so that, in so far as the ego achieves this result, it, too, has detached itself wholly or in part from reality. In my opinion this latter event is the condition under which the subject's ideas receive the vividness of hallucinations; and thus when the defence has been successfully carried out he finds himself in a state of hallucinatory confusion.

[1894a, 314]

In explaining regression in dreams, however, we must bear in mind the regressions which also occur in pathological waking states; and here the explanation just given leaves us in the lurch. For in those cases regression occurs in spite of a sensory current flowing without interruption in a forward direction. My explanation of hallucinations in hysteria and paranoia and of visions in mentally normal subjects is that they are in fact regressions - that is, thoughts transformed into images - but that the only thoughts that undergo this transformation are those which are intimately linked with memories that have been suppressed of have remained unconscious.

[1900a, 977]

The two instances that I have quoted are neither of them entirely devoid of connection with the state of sleep and for that reason are perhaps not well chosen for what I want them to prove. I will therefore refer the reader to my analysis of a woman suffering from hallucinatory paranoia (Freud, 1896b) as well as to the findings in my still unpublished studies on the psychology of the psychoneuroses, for evidence that in such instances of the regressive transformation of thoughts we must not overlook the influence of memories, mostly from childhood, which have been suppressed or have remained unconscious. The thoughts which are connected with a memory of this kind and which are forbidden expression by the censorship are, as it were, attracted by the memory into regression as being the form of representation in which the memory itself is couched. I may also recall that one of the facts arrived at in the Studies on Hysteria was that when it was possible to bring infantile scenes (whether they were memories or phantasies) into consciousness, they were seen like hallucinations and lost that characteristic only in the process of being reported. It is moreover a familiar observation that, even in those whose memory is not normally of a visual type, the earliest recollections of childhood retain far into life the quality of sensory vividness.

[1900a, 978]
Let us bring together what we have found out about the peculiar propensity of dreams to recast their ideational content into sensory images. We have not explained this feature of the dream-work, we have not traced it back to any known psychological laws; but we have rather picked it out as something that suggests unknown implications and we have characterized it with the word 'regressive.' We have put forward the view that in all probability this regression, wherever it may occur, is an effect of a resistance opposing the progress of a thought into consciousness along the normal path, and of a simultaneous attraction exercised upon the thought by the presence of memories possessing great sensory force.¹ In the case of dreams, regression may perhaps be further facilitated by the cessation of the progressive current - which streams in during the daytime from the sense organs; in other forms of regression, the absence of this accessory factor must be made up for by a greater intensity of the other motives for regression. Nor must we forget to observe that in these pathological cases of regression as well as in dreams the process of transference of energy must differ from what it is in regressions occurring in normal mental life, since in the former cases that process makes possible a complete hallucinatory cathexis of the perceptual systems. What we have described, in our analysis of the dream-work, as 'regard for representability' might be brought into connection with the selective attraction exercised by the visually recollected scenes touched upon by the dream-thoughts.

¹ [Footnote added 1919:] I have tried to penetrate further into an understanding of the state of things prevailing during sleep and of the determining conditions of hallucination in a paper entitled 'A Metapsychological Supplement to the Theory of Dreams'.

[1900a, 987]

The bitter experience of life must have changed this primitive thought-activity into a more expedient secondary one. The establishment of a perceptual identity along the short path of regression within the apparatus does not have the same result elsewhere in the mind as does the cathexis of the same perception from without. Satisfaction does not follow; the need persists. An internal cathexis could only have the same value as an external one if it were maintained unceasingly, as in fact occurs in hallucinatory psychoses and hunger phantasies, which exhaust their whole psychic activity in clinging to the object of their wish. In order to arrive at a more efficient expenditure of psychical force, it is necessary to bring the regression to a halt before it becomes complete, so that it does not proceed beyond the mnemonic image, and is able to seek out other paths which lead eventually to the desired perceptual identity being established from the direction of the external world.¹ This inhibition of the regression and the subsequent diversion of the excitation become the business of a second system, which is in control of voluntary movement - which for the first time, that is, makes use of movement for purposes remembered in advance. But all the complicated thought-activity which is spun out from the mnemonic image to the moment at which the perceptual identity is established by the external world - all this activity of thought merely constitutes a roundabout path to wish-fulfilment which has been made necessary by experience.² Thought is after all nothing but a substitute for a hallucinatory wish; and it is self-evident that dreams must be wish-fulfilments, since nothing but a wish can set our mental apparatus at work. Dreams, which fulfil their wishes along the short path of regression, have merely preserved for us in that respect a sample of the psychical apparatus's primary method of working, a method which was abandoned as being inefficient. What once dominated waking life, while the mind was still young and incompetent, seems now to have been banished into the night - just as the primitive weapons, the bows and arrows, that have been abandoned by adult men, turn up once more in the nursery. Dreaming is a piece of infantile mental life that has been superseded. These methods of working on the part of the psychical apparatus, which are normally suppressed in waking hours, become current once more in psychosis and then reveal their incapacity for satisfying our needs in relation to the external world.³

[1900a, 996]
The unconscious wishful impulses clearly try to make themselves effective in daytime as well, and the fact of transference, as well as the psychoses, show us that they endeavour to force their way by way of the preconscious system into consciousness and to obtain control of the power of movement. Thus the censorship between the \textit{Ucs.} and the \textit{Pcs.}, the assumption of whose existence is positively forced upon us by dreams, deserves to be recognized and respected as the watchman of our mental health. Must we not regard it, however, as an act of carelessness on the part of that watchman that it relaxes its activities during the night, allows the suppressed impulses in the \textit{Ucs.} to find expression, and makes it possible for hallucinatory regression to occur once more? I think not. For even though this critical watchman goes to rest - and we have proof that its slumbers are not deep - it also shuts the door upon the power of movement. No matter what impulses from the normally inhibited \textit{Ucs.} may prance upon the stage, we need feel no concern; they remain harmless, since they are unable to set in motion the motor apparatus by which alone they might modify the external world. The state of sleep guarantees the security of the citadel that must be guarded. The position is less harmless when what brings about the displacement of forces is not the nightly relaxation in the critical censorship's output of force, but a pathological reduction in that force or a pathological intensification of the unconscious excitations while the preconscious is still cathected and the gateway to the power of movement stands open. When this is so, the watchman is overpowered, the unconscious excitations overwhelm the \textit{Pcs.}, and thence obtain control over our speech and actions; or they forcibly bring about hallucinatory regression and direct the course of the apparatus (which was not designed for their use) by virtue of the attraction exercised by perceptions on the distribution of our psychical energy. To this state of things we give the name of psychosis.

[1900a, 997]
In the most favourable cases the generation of unpleasure ceases along with the withdrawal of cathexis from the transference thoughts in the \textit{Pcs}; and this outcome signifies that the intervention of the unpleasure principle has served a useful purpose. But it is another matter when the repressed unconscious wish receives an organic reinforcement, which it passes on to its transference thoughts; in that way it may place them in a position to make an attempt at forcing their way through with their excitation, even if they have lost their cathexis from the \textit{Pcs}. There then follows a defensive struggle - for the \textit{Pcs} in turn reinforces its opposition to the repressed thoughts (i.e. produces an 'anticathexis') - and thereafter the transference thoughts, which are the vehicles of the unconscious wish, force their way through in some form of compromise which is reached by the production of a symptom. But from the moment at which the repressed thoughts are strongly cathected by the unconscious wishful impulse and, on the other hand, abandoned by the preconscious cathexis, they become subject to the primary psychical process and their one aim is motor discharge or, if the path is open, hallucinatory revival of the desired perceptual identity. We have already found empirically that the irrational processes we have described are only carried out with thoughts that are under repression. We can now see our way a little further into the whole position. The irrational processes which occur in the psychical apparatus are the \textit{primary} ones. They appear wherever ideas are abandoned by the preconscious cathexis, are left to themselves and can become charged with the uninhibited energy from the unconscious which is striving to find an outlet. Some other observations lend support to the view that these processes which are described as irrational are not in fact falsifications of normal processes - intellectual errors - but are modes of activity of the psychical apparatus that have been freed from an inhibition. Thus we find that the transition from preconscious excitation to movement is governed by the same processes, and that the linking of preconscious ideas to words may easily exhibit the same displacements and confusions, which are then attributed to inattention. Evidence, finally, of the increase in activity which becomes necessary when these primary modes of functioning are inhibited is to be found in the fact that we produce a \textit{comic} effect, that is, a surplus of energy which has to be discharged in \textit{laughter}, if we allow these modes of thinking to force their way through into \textit{consciousness}.

[1900a, 1032]

These statements are of decisive importance in determining the view we are to take of the delusion of emasculation and in thus giving us a general understanding of the case. It may be added that the 'voices' which the patient heard never treated his transformation into a woman as anything but a sexual disgrace, which gave them an excuse for jeering at him. 'Rays of God' not infrequently thought themselves entitled to mock at me by calling me "Miss Schreber", in allusion to the emasculation which, it was alleged, I was about to undergo." (127.) Or they would say: 'So this sets up to have been a Senatspräsident, this person who lets himself be f--d!' Or again: 'Don't you feel ashamed in front of your wife?'

[1911c, 2396]
Abraham has very convincingly shown¹ that the turning away of the libido from the external world is a particularly clearly-marked feature in dementia praecox. From this feature we infer that the repression is effected by means of detachment of the libido. Here once more we may regard the phase of violent hallucinations as a struggle between repression and an attempt at recovery by bringing the libido back again on to its objects. Jung, with extraordinary analytic acumen, has perceived that the deliria² and motor stereotypes occurring in this disorder are the residues of former object-cathexes, clung to with great persistence. This attempt at recovery, which observers mistake for the disease itself, does not, as in paranoia, make use of projection, but employs a hallucinatory (hysterical) mechanism. This is one of the two major respects in which dementia praecox differs from paranoia; and this difference can be explained genetically from another direction. The second difference is shown by the outcome of the disease in those cases where the process has not remained too restricted. The prognosis is on the whole more unfavourable than in paranoia. The victory lies with repression and not, as in the former, with reconstruction. The regression extends not merely to narcissism (manifesting itself in the shape of megalomania) but to a complete abandonment of object-love and a return to infantile auto-erotism. The dispositional fixation must therefore be situated further back than in paranoia, and must lie some where at the beginning of the course of development from auto-erotism to object-love. Moreover, it is not at all likely that homosexual impulsions, which are so frequently - perhaps invariably - to be found in paranoia, play an equally important part in the aetiology of that far more comprehensive disorder, dementia praecox.

¹ [1911c, 2442]

² It seems unnecessary to add anything in the way of an interpretation of this little occurrence, so far as it throws light upon the phenomenon of 'fausse reconnaissance'. As regards the subject-matter of the patient's vision, I may remark that, particularly in relation to the castration complex, similar hallucinatory falsifications are of not infrequent occurrence, and that they can just as easily serve the purpose of correcting unwelcome perceptions.

³ [1914a, 2840]

We must, however, put off discussing this difficulty till we can focus our interest upon the system Cs. itself. In the present connection we may be allowed to assume that hallucination consists in a cathexis of the system Cs. (Pcpt.), which, however, is not effected - as normally - from without, but from within, and that a necessary condition for the occurrence of hallucination is that regression shall be carried far enough to reach this system itself and in so doing be able to pass over reality-testing.¹

¹ [1917d, 3036]

¹ I may add by way of supplement that any attempt to explain hallucination would have to start out from negative rather than positive hallucination.

² [1917d, 3036]

It is to these phenomena, then, that I now propose to draw your attention. But you will protest with some annoyance: 'There are so many vast problems in the wide universe, as well as within the narrower confines of our minds, so many marvels in the field of mental disorders, which require and deserve to have light thrown upon them, that it does really seem gratuitous to waste labour and interest on such trivialities. If you could make us understand why a person with sound eyes and ears can see and hear in broad daylight things that are not there, why another person suddenly thinks he is being persecuted by the people of whom he has hitherto been most fond, or puts forward the cleverest arguments in support of delusional beliefs which any child could see were nonsensical, then we should have some opinion of psycho-analysis. But if it can do no more than ask us to consider why a speaker at a banquet uses one word instead of another or why a housewife has mislaid her keys, and similar futilities, then we shall know how to put our time and interest to better uses.'

³ [1916-1917, 3137]
On the other side, it is equally easy, from the knowledge we have so far gained of the mechanism of the psychoses, to adduce examples which point to a disturbance in the relationship between the ego and the external world. In Meynert's amentia - an acute hallucinatory confusion which is perhaps the most extreme and striking form of psychosis - either the external world is not perceived at all, or the perception of it has no effect whatever. Normally, the external world governs the ego in two ways: firstly, by current, present perceptions which are always renewable, and secondly, by the store of memories of earlier perceptions which, in the shape of an 'internal world', form a possession of the ego and a constituent part of it. In amentia, not only is the acceptance of new perceptions refused, but the internal world, too, which, as a copy of the external world, has up till now represented it, loses its significance (its cathexis) - The ego creates, autocratically, a new external and internal world; and there can be no doubt of two facts - that this new world is constructed in accordance with the id's wishful impulses, and that the motive of this dissociation from the external world is some very serious frustration by reality of a wish - a frustration which seems intolerable. The close affinity of this psychosis to normal dreams is unmistakable. A precondition of dreaming, moreover, is a state of sleep, and one of the features of sleep is a complete turning away from perception and the external world.

[1924b, 4066]

In a psychosis, the transforming of reality is carried out upon the psychical precipitates of former relations to it - that is, upon the memory-traces, ideas and judgements which have been previously derived from reality and by which reality was represented in the mind. But this relation was never a closed one; it was continually being enriched and altered by fresh perceptions. Thus the psychosis is also faced with the task of procuring for itself perceptions of a kind which shall correspond to the new reality; and this is most radically effected by means of hallucination. The fact that, in so many forms and cases of psychosis, the paramnesias, the delusions and the hallucinations that occur are of a most distressing character and are bound up with a generation of anxiety - this fact is without doubt a sign that the whole process of remodelling is carried through against forces which oppose it violently. We may construct the process on the model of a neurosis, with which we are more familiar. There we see that a reaction of anxiety sets in whenever the repressed instinct makes a thrust forward, and that the outcome of the conflict is only a compromise and does not provide complete satisfaction. Probably in a psychosis the rejected piece of reality constantly forces itself upon the mind, just as the repressed instinct does in a neurosis, and that is why in both cases the consequences too are the same. The elucidation of the various mechanisms which are designed, in the psychoses, to turn the subject away from reality and to reconstruct reality - this is a task for specialized psychiatric study which has not yet been taken in hand.

[1924e, 4096]

Conscious processes on the periphery of the ego and everything else in the ego unconscious - such would be the simplest state of affairs that we might picture. And such may in fact be the state that prevails in animals. But in men there is an added complication through which internal processes in the ego may also acquire the quality of consciousness. This is the work of the function of speech, which brings material in the ego into a firm connection with mnemonic residues of visual, but more particularly of auditory, perceptions. Thenceforward the perceptual periphery of the cortical layer can be excited to a much greater extent from inside as well, internal events such as passages of ideas and thought-processes can become conscious, and a special device is called for in order to distinguish between the two possibilities - a device known as reality-testing. The equation 'perception = reality (external world)' no longer holds. Errors, which can now easily arise and do so regularly in dreams, are called hallucinations.

[1940a [1938], 4972]
The usual result of the fright of castration, the result that passes as the normal one, is that, either immediately or after some considerable struggle, the boy gives way to the threat and obeys the prohibition either wholly or at least in part (that is, by no longer touching his genitals with his hand). In other words, he gives up, in whole or in part, the satisfaction of the instinct. We are prepared to hear, however, that our present patient found another way out. He created a substitute for the penis which he missed in females - that is to say, a fetish. In so doing, it is true that he had disavowed reality, but he had saved his own penis. So long as he was not obliged to acknowledge that females have lost their penis, there was no need for him to believe the threat that had been made against him: he need have no fears for his own penis, so he could proceed with his masturbation undisturbed. This behaviour on the part of our patient strikes us forcibly as being a turning away from reality - a procedure which we should prefer to reserve for psychoses. And it is in fact not very different. Yet we will suspend our judgement, for upon closer inspection we shall discover a not unimportant distinction. The boy did not simply contradict his perceptions and hallucinate a penis where there was none to be seen; he effected no more than a displacement of value - he transferred the importance of the penis to another part of the body, a procedure in which he was assisted by the mechanism of regression (in a manner which need not here be explained). This displacement, it is true, related only to the female body; as regards his own penis nothing was changed.
[1940e [1938], 5064]
The verbal malformations in dreams greatly resemble those which are familiar in paranoia but which are also present in hysteria and obsessions. The linguistic tricks performed by children, who sometimes actually treat words as though they were objects and moreover invent new languages and artificial syntactic forms, are the common source of these things in dreams and psychoneuroses alike.

[1900a, 776]

The analysis of the nonsensical verbal forms that occur in dreams is particularly well calculated to exhibit the dream work's achievements in the way of condensation. The reader should not conclude from the paucity of the instances which I have given that material of this kind is rare or observed at all exceptionally. On the contrary, it is very common. But as a result of the fact that dream-interpretation is dependent upon psycho-analytic treatment, only a very small number of instances are observed and recorded and the analyses of such instances are as a rule only intelligible to experts in the pathology of the neuroses. Thus a dream of this kind was reported by Dr. von Karpinska (1914) containing the nonsensical verbal form: 'Svingnum elvi.' It is also worth mentioning those cases in which a word appears in a dream which is not in itself meaningless but which has lost its proper meaning and combines a number of other meanings to which it is related in just the same way as a 'meaningless' word would be. This is what occurred, for instance, in the ten-year-old boy's dream of a 'category' which was recorded by Tausk (1913). 'Category' in that case meant 'female genitals', and to 'categorate' meant the same as 'to micturate.'

[1900a, 776]

On the basis of suitable specimens of innocent jokes, in which there was no fear of our judgement being disturbed by their content or purpose, we were driven to conclude that the techniques of jokes are themselves sources of pleasure; and we shall now try to discover whether it may perhaps be possible to trace that pleasure back to economy in psychical expenditure. In one group of these jokes (play upon words) the technique consisted in focusing our psychical attitude upon the sound of the word instead of upon its meaning - in making the (acoustic) word presentation itself take the place of its significance as given by its relations to thing-presentations. It may really be suspected that in doing so we are bringing about a great relief in psychical work and that when we make serious use of words we are obliged to hold ourselves back with a certain effort from this comfortable procedure. We can observe how pathological states of thought-activity, in which the possibility of concentrating psychical expenditure on a particular point is probably restricted, do in fact give this sort of sound-presentation of the word greater prominence than its meaning, and that sufferers in such states proceed in their speech on the lines (as the formula runs) of the 'external' instead of the 'internal' associations of the word-presentation. We notice, too, that children, who, as we know, are in the habit of still treating words as things, tend to expect words that are the same or similar to have the same meaning behind them - which is a source of many mistakes that are laughed at by grown-up people. If, therefore, we derive unmistakable enjoyment in jokes from being transported by the use of the same or a similar word from one circle of ideas to another, remote one (in the 'Home-Roulard', for instance, from the kitchen to politics), this enjoyment is no doubt correctly to be attributed to economy in psychical expenditure. The pleasure in a joke arising from a 'short-circuit' like this seems to be the greater the more alien the two circles of ideas that are brought together by the same word - the further apart they are, and thus the greater the economy which the joke's technical method provides in the train of thought. We may notice, too, that here jokes are making use of a method of linking things up which is rejected and studiously avoided by serious thought.

[1905c, 1712]
During the period in which a child is learning how to handle the vocabulary of his mother-tongue, it gives him obvious pleasure to 'experiment with it in play', to use Groos's words. And he puts words together without regard to the condition that they should make sense, in order to obtain from them the pleasurable effect of rhythm or rhyme. Little by little he is forbidden this enjoyment, till all that remains permitted to him are significant combinations of words. But when he is older attempts still emerge at disregarding the restrictions that have been learnt on the use of words. Words are disfigured by particular little additions being made to them, their forms are altered by certain manipulations (e.g. by reduplications or 'Zittersprache'), or a private language may even be constructed for use among playmates. These attempts are found again among certain categories of mental patients. [1905c, 1716]

In the course of the psychotherapeutic treatment of a delusion or of an analogous disorder, ambiguous speeches of this kind are often produced by the patient, as new symptoms of the briefest duration; and it can happen that the doctor finds himself too in the position of making use of them. In that way it not infrequently happens that with the meaning that is intended for the patient's conscious he stirs up an understanding of the meaning that applies to his unconscious. I know from experience that the part thus played by ambiguity is apt to raise the greatest objection in the uninitiated and to give rise to the greatest misunderstandings. But in any case our author was right in giving a place in his creation to a picture of this characteristic feature of what takes place in the formation of dreams and delusions. [1907a, 1879]
The study of judgement affords us, perhaps for the first time, an insight into the origin of an intellectual function from the interplay of the primary instinctual impulses. Judging is a continuation, along lines of expediency, of the original process by which the ego took things into itself or expelled them from itself, according to the pleasure principle. The polarity of judgement appears to correspond to the opposition of the two groups of instincts which we have supposed to exist. Affirmation - as a substitute for uniting - belongs to Eros; negation - the successor to expulsion - belongs to the instinct of destruction. The general wish to negate, the negativism which is displayed by some psychotics, is probably to be regarded as a sign of a defusion of instincts that has taken place through a withdrawal of the libidinal components. But the performance of the function of judgement is not made possible until the creation of the symbol of negation has endowed thinking with a first measure of freedom from the consequences of repression and, with it, from the compulsion of the pleasure principle.
[1925h, 4143]
Similar considerations apply to the deliria and hallucinations, as well as to the delusional systems, exhibited by various psychotic patients. Where hitherto nothing but the most freakish capriciousness has seemed to prevail, psycho-analytic research has introduced law, order and connection, or has at least allowed us to suspect their presence where its work is still incomplete. The most heterogeneous forms of mental disorder are revealed as the results of processes which are at bottom identical and which can be understood and described by means of psychological concepts. What had already been discovered in the formation of dreams is operative everywhere - psychical conflict, the repression of certain instinctual impulses which have been pushed back into the unconscious by other mental forces, reaction formations set up by the repressing forces, and substitutes constructed by the instincts which have been repressed but have not been robbed of all their energy. The accompanying processes of condensation and displacement, so familiar to us in dreams, are also to be found everywhere. The multiplicity of clinical pictures observed by psychiatrists depends upon two other things: the multiplicity of the psychical mechanisms at the disposal of the repressive process and the multiplicity of developmental dispositions which give the repressed impulses an opportunity for breaking through into substitutive structures.

[1913j, 2811]

We began at an early date to extend psycho-analytic observations to these other illnesses. Already in 1908 Karl Abraham, after an exchange of thoughts with me, pronounced the main characteristic of dementia praecox (which was reckoned among the psychoses) to be that in it the libidinal cathexis of objects was lacking. But the question then arose of what happened to the libido of dementia praecox patients which was turned away from objects. Abraham did not hesitate to give the answer: it is turned back on to the ego and this reflexive turning-back is the source of the megalomania in dementia praecox. Megalomania is in every way comparable to the familiar sexual overvaluation of the object in erotic life. In this way for the first time we learnt to understand a trait in a psychotic illness by relating it to normal erotic life.

[1916-1917, 3461]

I told you too that we hoped that the analysis of the narcissistic disorders would give us an insight into the way in which our ego is put together and built up out of different agencies. We have already made a start with this at one point. From the analysis of delusions of observation we have drawn the conclusion that there actually exists in the ego an agency which unceasingly observes, criticizes and compares, and in that way sets itself over against the other part of the ego. We believe, therefore, that the patient is betraying a truth to us which is not yet sufficiently appreciated when he complains that he is spied upon and observed at every step he takes and that every one of his thoughts is reported and criticized. His only mistake is in regarding this uncomfortable power as something alien to him and placing it outside himself. He senses an agency holding sway in his ego which measures his actual ego and each of its activities by an ideal ego that he has created for himself in the course of his development. We believe, too, that this creation was made with the intention of re-establishing the self-satisfaction which was attached to primary infantile narcissism but which since then has suffered so many disturbances and mortifications. We know the self-observing agency as the ego-censor, the conscience; it is this that exercises the dream-censorship during the night, from which the repressions of inadmissible wishful impulses proceed. When in delusions of observation it becomes split up, it reveals to us its origin from the influences of parents, educators and social environment - from an identification with some of these model figures.

[1916-1917, 3472]
Little light is thrown upon the genesis of masochism by our discussion of the beating-phanstasy. To begin with, there seems to be a confirmation of the view that masochism is not the manifestation of a primary instinct, but originates from sadism which has been turned round upon the self - that is to say, by means of regression from an object to the ego.¹ Instincts with a passive aim must be taken for granted as existing, especially among women. But passivity is not the whole of masochism. The characteristic of unpleasure belongs to it as well, - a bewildering accompaniment to the satisfaction of an instinct. The transformation of sadism into masochism appears to be due to the influence of the sense of guilt which takes part in the act of repression. Thus repression is operative here in three ways: it renders the consequences of the genital organization unconscious, it compels that organization itself to regress to the earlier sadistic-anal stage, and it transforms the sadism of this stage into masochism, which is passive and again in a certain sense narcissistic. The second of these three effects is made possible by the weakness of the genital organization, which must be presupposed in these cases. The third becomes necessary because the sense of guilt takes as much objection to sadism as to incestuous object-choice genitally conceived. Again, the analyses do not tell us the origin of the sense of guilt itself. It seems to be brought along by the new phase upon which the child is entering, and, if it afterwards persists, it seems to correspond to a scar-like formation which is similar to the sense of inferiority. According to our present orientation in the structure of the ego, which is as yet uncertain, we should assign it to the agency in the mind which sets itself up as a critical conscience over against the rest of the ego, which produces Silberer's functional phenomenon in dreams, and which cuts itself loose from the ego in delusions of being watched. [1919e, 3654]

The idea of the 'double' does not necessarily disappear with the passing of primary narcissism, for it can receive fresh meaning from the later stages of the ego's development. A special agency is slowly formed there, which is able to stand over against the rest of the ego, which has the function of observing and criticizing the self and of exercising a censorship within the mind, and which we become aware of as our 'conscience'. In the pathological case of delusions of being watched, this mental agency becomes isolated, dissociated from the ego, and discernible to the physician's eye. The fact that an agency of this kind exists, which is able to treat the rest of the ego like an object - the fact, that is, that man is capable of self-observation - renders it possible to invest the old idea of a 'double' with a new meaning and to ascribe a number of things to it - above all, those things which seem to self-criticism to belong to the old surmounted narcissism of earliest times.¹ [1919h, 3687]
But these melancholias also show us something else, which may be of importance for our later discussions. They show us the ego divided, fallen apart into two pieces, one of which rages against the second. This second piece is the one which has been altered by introjection and which contains the lost object. But the piece which behaves so cruelly is not unknown to us either. It comprises the conscience, a critical agency within the ego, which even in normal times takes up a critical attitude towards the ego, though never so relentlessly and so unjustifiably. On previous occasions we have been driven to the hypothesis that some such agency develops in our ego which may cut itself off from the rest of the ego and come into conflict with it. We have called it the ‘ego ideal’, and by way of functions we have ascribed to it self-observation, the moral conscience, the censorship of dreams, and the chief influence in repression. We have said that it is the heir to the original narcissism in which the childish ego enjoyed self-sufficiency; it gradually gathers up from the influences of the environment the demands which that environment makes upon the ego and which the ego cannot always rise to; so that a man, when he cannot be satisfied with his ego itself, may nevertheless be able to find satisfaction in the ego ideal which has been differentiated out of the ego. In delusions of observation, as we have further shown, the disintegration of this agency has become patent, and has thus revealed its origin in the influence of superior powers, and above all of parents. But we have not forgotten to add that the amount of distance between this ego ideal and the real ego is very variable from one individual to another, and that with many people this differentiation within the ego does not go further than with children.

We describe one group of these patients as suffering from delusions of being observed. They complain to us that perpetually, and down to their most intimate actions, they are being molested by the observation of unknown powers - presumably persons - and that in hallucinations they hear these persons reporting the outcome of their observation: ‘now he’s going to say this, now he’s dressing to go out’ and so on. Observation of this sort is not yet the same thing as persecution, but it is not far from it; it presupposes that people distrust them, and expect to catch them carrying out forbidden actions for which they would be punished. How would it be if these insane people were right, if in each of us there is present in his ego an agency like this which observes and threatens to punish, and which in them has merely become sharply divided from their ego and mistakenly displaced into external reality?

I cannot tell whether the same thing will happen to you as to me. Ever since, under the powerful impression of this clinical picture, I formed the idea that the separation of the observing agency from the rest of the ego might be a regular feature of the ego’s structure, that idea has never left me, and I was driven to investigate the further characteristics and connections of the agency which was thus separated off. The next step is quickly taken. The content of the delusions of being observed already suggests that the observing is only a preparation for judging and punishing, and we accordingly guess that another function of this agency must be what we call our conscience. There is scarcely anything else in us that we so regularly separate from our ego and so easily set over against it as precisely our conscience. I feel an inclination to do something that I think will give me pleasure, but I abandon it on the ground that my conscience does not allow it. Or I have let myself be persuaded by too great an expectation of pleasure into doing something to which the voice of conscience has objected and after the deed my conscience punishes me with distressing reproaches and causes me to feel remorse for the deed. I might simply say that the special agency which I am beginning to distinguish in the ego is conscience. But it is more prudent to keep the agency as something independent and to suppose that conscience is one of its functions and that self-observation, which is an essential preliminary to the judging activity of conscience, is another of them. And since when we recognize that something has a separate existence we give it a name of its own, from this time forward I will describe this agency in the ego as the ‘super-ego’.
And here is another warning, to conclude these remarks, which have certainly been exacting and not, perhaps, very illuminating. In thinking of this division of the personality into an ego, a super-ego and an id, you will not, of course, have pictured sharp frontiers like the artificial ones drawn in political geography. We cannot do justice to the characteristics of the mind by linear outlines like those in a drawing or in primitive painting, but rather by areas of colour melting into one another as they are presented by modern artists. After making the separation we must allow what we have separated to merge together once more. You must not judge too harshly a first attempt at giving a pictorial representations of something so intangible as psychical processes. It is highly probable that the development of these divisions is subject to great variations in different individuals; it is possible that in the course of actual functioning they may change and go through a temporary phase of involution. Particularly in the case of what is phylogenetically the last and most delicate of these divisions - the differentiation between the ego and the super-ego - something of the sort seems to be true. There is no question but that the same thing results from psychical illness. It is easy to imagine, too, that certain mystical practices may succeed in upsetting the normal relations between the different regions of the mind, so that, for instance, perception may be able to grasp happenings in the depths of the ego and in the id which were otherwise inaccessible to it. It may safely be doubted, however, whether this road will lead us to the ultimate truths from which salvation is to be expected. Nevertheless it may be admitted that the therapeutic efforts of psycho-analysis have chosen a similar line of approach. Its intention is, indeed, to strengthen the ego, to make it more independent of the super-ego, to widen its field of perception and enlarge its organization, so that it can appropriate fresh portions of the id. Where id was, there ego shall be. It is a work of culture - not unlike the draining of the Zuider Zee.
[1933a, 4687]
It is perhaps not superfluous to point out that the three methods of defence here described and, along with them, the three forms of illness to which those methods lead, may be combined in the same person. The simultaneous appearance of phobias and hysterical symptoms which is so often observed in practice is one of the factors which render it difficult to separate hysteria clearly from other neuroses and which make it necessary to set up the category of 'mixed neuroses'. It is true that hallucinatory confusion is not often compatible with a persistence of hysteria, nor, as a rule, of obsessions. On the other hand, it is not rare for a psychosis of defence episodically to break through the course of a hysterical or mixed neurosis.

[1894a, 314]
The fact to which I now wish to call attention is that the content of a hallucinatory psychosis of this sort consists precisely in the accentuation of the idea which was threatened by the precipitating cause of the onset of the illness. One is therefore justified in saying that the ego has fended off the incompatible idea through a flight into psychosis. The process by which this has been achieved once more eludes the subject's self perception, as it eludes psychologico-clinical analysis. It must be regarded as the expression of a pathological disposition of a fairly high degree and it may be described more or less as follows. The ego breaks away from the incompatible idea; but the latter is inseparably connected with a piece of reality, so that, in so far as the ego achieves this result, it, too, has detached itself wholly or in part from reality. In my opinion this latter event is the condition under which the subject's ideas receive the vividness of hallucinations; and thus when the defence has been successfully carried out he finds himself in a state of hallucinatory confusion.

This obscure region of the story is made intelligible to us by some explanations which we derive from the later remarks of Zoe Bertgang. It was in fact the original of Gradiva, Fräulein Zoe herself, whom Hanold saw out of his window walking past in the street (89.) and whom he nearly overtook. If this had happened, the information given him by the dream - that she was in fact living at the same time and in the same town as he was - would by a lucky chance have received an irresistible confirmation, which would have brought about the collapse of his internal struggle. But the canary, whose singing sent Hanold off on his distant journey, belonged to Zoe, and its cage stood in her window diagonally across the street from Hanold's house. (135.) Hanold, who, according to the girl's accusation, had the gift of 'negative hallucination', who possessed the art of not seeing and not recognizing people who were actually present, must from the first have had an unconscious knowledge of what we only learned later. The indications of Zoe's proximity (her appearance in the street and her bird's singing so near his window) intensified the effect of the dream, and in this position, so perilous for his resistance to his erotic feelings, he took to flight. His journey was a result of his resistance gathering new strength after the surge forward of his erotic desires in the dream; it was an attempt at flight from the physical presence of the girl he loved. In a practical sense it meant a victory for repression, just as his earlier activity, his 'pedestrian researches' upon women and girls, had meant a victory for erotism. But everywhere in these oscillations in the struggle the compromise character of the outcome was preserved: the journey to Pompeii, which was supposed to lead him away from the living Zoe, led him at least to her surrogate, to Gradiva. The journey which was undertaken in defiance of the latent dream-thoughts, was nevertheless following the path to Pompeii that was pointed out by the manifest content of the dream. Thus at every fresh struggle between erotism and resistance we find the delusion triumphant.
(1) A girl suffered from obsessional self-reproaches. If she read something in the papers about coiners, the thought would occur to her that she, too, had made counterfeit money; if a murder had been committed by an unknown person, she would ask herself anxiously whether it was not she who had done the deed. At the same time she was perfectly conscious of the absurdity of these obsessional reproaches. For a time, this sense of guilt gained such an ascendancy over her that her powers of criticism were stifled and she accused herself to her relatives and her doctor of having really committed all these crimes. (This was an example of a psychosis through simple intensification - an 'Überwältigungpsychose'.) Close questioning then revealed the source from which her sense of guilt arose. Stimulated by a chance voluptuous sensation, she had allowed herself to be led astray by a woman friend into masturbating, and had practise it for years, fully conscious of her wrong-doing and to the accompaniment of the most violent, but, as usual, ineffective self-reproaches. An excessive indulgence after going to a ball had produced the intensification that led to the psychosis. After a few months of treatment and the strictest surveillance, the girl recovered.

[1894a, 310]
In both the instances considered so far, defence against the incompatible idea was effected by separating it from its affect; the idea itself remained in consciousness, even though weakened and isolated. There is, however, a much more energetic and successful kind of defence. Here, the ego rejects the incompatible idea together with its affect and behaves as if the idea had never occurred to the ego at all. But from the moment at which this has been successfully done the subject is in a psychosis, which can only be classified as ‘hallucinatory confusion.’ A single example may serve to illustrate this statement:

[1894a, 313]

² I may here add a few supplementary interpretations to those that have already been given: The ‘Madonna’ was obviously Dora herself; in the first place because of the ‘adorer’ who had sent her the pictures, in the second place because she had won Herr K.’s love chiefly by the motherliness she had shown towards his children, and lastly because she had had a child though she was still a girl (this being a direct allusion to the phantasy of childbirth). Moreover, the notion of the ‘Madonna’ is a favourite counter-idea in the mind of girls who feel themselves oppressed by imputations of sexual guilt, - which was the case with Dora. A first suspicion of this connection came to me while I was working as a physician at the Psychiatric Clinic of the University. I there came across a case of confusional insanity with hallucinations, in which the attack, which ran a rapid course, turned out to be a reaction to a reproach made against the patient by her fiancé. - If the analysis had been continued, Dora’s maternal longing for a child would probably have been revealed as an obscure though powerful motive in her behaviour. The numerous questions which she had been raising latterly seem to have been belated derivatives of questions inspired by the sexual curiosity which she had tried to gratify with the encyclopaedia. The subjects which she read up in it were presumably pregnancy, childbirth, virginity, and so on. - In reproducing the dream Dora had forgotten one of the questions which need to be inserted into the course of the second situation in the dream. This question could only be; ‘Does Herr -- live here?’ or ‘Where does Herr -- live?’ There must have been some reason for her having forgotten this apparently innocent question, especially as she need not have brought it into the dream at all. This reason, it seems to me, lay in her surname itself, which also denoted an object and in fact more than one kind of object, and which could therefore be regarded as an ‘ambiguous’ word. Unluckily I cannot give the name and show how well designed it was to indicate something ‘ambiguous’ and ‘improper’. This interpretation was supported by the discovery of a similar play upon words in another part of the dream, where the material was derived from Dora’s recollections of her aunt’s death (‘they have already gone to the cemetery’) and where there was similarly a play upon her aunt’s name. These improper words seemed to point to a second and oral source of information, since the encyclopaedia would not cover them. I should not have been surprised to hear that this source had been Frau K. herself, Dora’s calumniator. In that case she would have been the one person whom Dora generously spared, while she pursued the others with an almost malignant vindictiveness. Behind the almost limitless series of displacements which were thus brought to light, it was possible to divine the operation of a single simple factor - Dora’s deep-rooted homosexual love for Frau K.

[1905e, 1439]

Similar considerations apply to the deliria and hallucinations, as well as to the delusional systems, exhibited by various psychotic patients. Where hitherto nothing but the most freakish capriciousness has seemed to prevail, psycho-analytic research has introduced law, order and connection, or has at least allowed us to suspect their presence where its work is still incomplete. The most heterogeneous forms of mental disorder are revealed as the results of processes which are at bottom identical and which can be understood and described by means of psychological concepts. What had already been discovered in the formation of dreams is operative everywhere - psychical conflict, the repression of certain instinctual impulses which have been pushed back into the unconscious by other mental forces, reaction formations set up by the repressing forces, and substitutes constructed by the instincts which have been repressed but have not been robbed of all their energy. The accompanying processes of condensation and displacement, so familiar to us in dreams, are also to be found everywhere. The multiplicity of clinical pictures observed by psychiatrists depends upon two other things: the multiplicity of the psychical mechanisms at the disposal of the repressive process and the multiplicity of developmental dispositions which give the repressed impulses an opportunity for breaking through into substitutive structures.

[1913j, 2811]
The formation of the wishful phantasy and its regression to hallucination are the most essential parts of the dream-work, but they do not belong exclusively to dreams. They are also found in two morbid states: in acute hallucinatory confusion (Meynert's 'amentia'), and in the hallucinatory phase of schizophrenia. The hallucinatory delirium of amentia is a clearly recognizable wishful phantasy, often completely well ordered like a perfect day-dream. One might speak quite generally of a 'hallucinatory wishful psychosis', and attribute it equally to dreams and amentia. There are even dreams which consist of nothing but undistorted wishful phantasies with a very rich content. The hallucinatory phase of schizophrenia has been less thoroughly studied; it seems as a rule to be of a composite nature, but in its essence it might well correspond to a fresh attempt at restitution, designed to restore a libidinal cathexis to the ideas of objects.¹ I cannot extend the comparison to the other hallucinatory states in various pathological disorders, because in their case I have no experience of my own upon which to draw, and cannot utilize that of other observers.

[1917d, 3034]

Finally, let us once more glance at the significant light which the topography of the process of repression throws for us on the mechanism of mental disturbances. In dreams the withdrawal of cathexis (libido or interest) affects all systems equally; in the transference neuroses, the Pcs. cathexis is withdrawn; in schizophrenia, the cathexis of the Ucs.; in amentia, that of the Cs.

[1917d, 3038]

On the other side, it is equally easy, from the knowledge we have so far gained of the mechanism of the psychoses, to adduce examples which point to a disturbance in the relationship between the ego and the external world. In Meynert's amentia - an acute hallucinatory confusion which is perhaps the most extreme and striking form of psychosis - either the external world is not perceived at all, or the perception of it has no effect whatever. Normally, the external world governs the ego in two ways: firstly, by current, present perceptions which are always renewable, and secondly, by the store of memories of earlier perceptions which, in the shape of an 'internal world', form a possession of the ego and a constituent part of it. In amentia, not only is the acceptance of new perceptions refused, but the internal world, too, which, as a copy of the external world, has up till now represented it, loses its significance (its cathexis) - The ego creates, autocratically, a new external and internal world; and there can be no doubt of two facts - that this new world is constructed in accordance with the id's wishful impulses, and that the motive of this dissociation from the external world is some very serious frustration by reality of a wish - a frustration which seems intolerable. The close affinity of this psychosis to normal dreams is unmistakable. A precondition of dreaming, moreover, is a state of sleep, and one of the features of sleep is a complete turning away from perception and the external world.

[1924b, 4066]
We now observe that the store of religious ideas includes not only wish-fulfillments but important historical recollections. This concurrent influence of past and present must give religion a truly incomparable wealth of power. But perhaps with the help of an analogy yet another discovery may begin to dawn on us. Though it is not a good plan to transplant ideas far from the soil in which they grew up, yet here is a conformity which we cannot avoid pointing out. We know that a human child cannot successfully complete its development to the civilized stage without passing through a phase of neurosis sometimes of greater and sometimes of less distinctness. This is because so many instinctual demands which will later be unserviceable cannot be suppressed by the rational operation of the child's intellect but have to be tamed by acts of repression, behind which, as a rule, lies the motive of anxiety. Most of these infantile neuroses are overcome spontaneously in the course of growing up, and this is especially true of the obsessional neuroses of childhood. The remainder can be cleared up later still by psycho-analytic treatment. In just the same way, one might assume, humanity as a whole, in its development through the ages, fell into states analogous to the neuroses, and for the same reasons - namely because in the times of its ignorance and intellectual weakness the instinctual renunciations indispensable for man's communal existence had only been achieved by it by means of purely affective forces. The precipitates of these processes resembling repression which took place in prehistoric times still remained attached to civilization for long periods. Religion would thus be the universal obsessional neurosis of humanity; like the obsessional neurosis of children, it arose out of the Oedipus complex, out of the relation to the father. If this view is right, it is to be supposed that a turning-away from religion is bound to occur with the fatal inevitability of a process of growth, and that we find ourselves at this very juncture in the middle of that phase of development. Our behaviour should therefore be modelled on that of a sensible teacher who does not oppose an impending new development but seeks to ease its path and mitigate the violence of its irruption. Our analogy does not, to be sure, exhaust the essential nature of religion. If, on the one hand, religion brings with it obsessional restrictions, exactly as an individual obsessional neurosis does, on the other hand it comprises a system of wishful illusions together with a disavowal of reality, such as we find in an isolated form nowhere else but in amentia, in a state of blissful hallucinatory confusion. But these are only analogies, by the help of which we endeavour to understand a social phenomenon; the pathology of the individual does not supply us with a fully valid counterpart.

[1927c, 4452]
We have repeatedly had to insist on the fact that the ego owes its origin as well as the most important of its acquired characteristics to its relation to the real external world. We are thus prepared to assume that the ego's pathological states, in which it most approximates once again to the id, are founded on a cessation or slackening of that relation to the external world. This tallies very well with what we learn from clinical experience - namely, that the precipitating cause of the outbreak of a psychosis is either that reality has become intolerably painful or that the instincts have become extraordinarily intensified - both of which, in view of the rival claims made on the ego by the id and the external world, must lead to the same result. The problem of psychoses would be simple and perspicuous if the ego's detachment from reality could be carried through completely. But that seems to happen only rarely or perhaps never. Even in a state so far removed from the reality of the external world as one of hallucinatory confusion, one learns from patients after their recovery that at the time in some corner of their mind (as they put it) there was a normal person hidden, who, like a detached spectator, watched the hubbub of illness go past him. I do not know if we may assume that this is so in general, but I can report the same of other psychoses with a less tempestuous course. I call to mind a case of chronic paranoia in which after each attack of jealousy a dream conveyed to the analyst a correct picture of the precipitating cause, free from any delusion. An interesting contrast was thus brought to light: while we are accustomed to discover from the dreams of neurotics jealousies which are alien to their waking lives, in this psychotic case the delusion which dominated the patient in the day-time was corrected by his dream. We may probably take it as being generally true that what occurs in all these cases is a psychical split. Two psychical attitudes have been formed instead of a single one - one, the normal one, which takes account of reality, and another which under the influence of the instincts detaches the ego from reality. The two exist alongside of each other. The issue depends on their relative strength. If the second is or becomes the stronger, the necessary precondition for a psychosis is present. If the relation is reversed, then there is an apparent cure of the delusional disorder. Actually it has only retreated into the unconscious - just as numerous observations lead us to believe that the delusion existed ready-made for a long time before its manifest irruption.

[1940a [1938], 5007]
These ‘absences’ had already been observed before she took to her bed; she used then to stop in the middle of a sentence, repeat her last words and after a short pause go on talking. These interruptions gradually increased till they reached the dimensions that have just been described; and during the climax of the illness, when the contractures had extended to the left side of her body, it was only for a short time during the day that she was to any degree normal. But the disturbances invaded even her moments of relatively clear consciousness. There were extremely rapid changes of mood leading to excessive but quite temporary high spirits, and at other times severe anxiety, stubborn opposition to every therapeutic effort and frightening hallucinations of black snakes, which was how she saw her hair, ribbons and similar things. At the same time she kept on telling herself not to be so silly: what she was seeing was really only her hair, etc. At moments when her mind was quite clear she would complain of the profound darkness in her head, of not being able to think, of becoming blind and deaf, of having two selves, a real one and an evil one which forced her to behave badly, and so on.

Nevertheless, though her two states were thus sharply separated, not only did the secondary state intrude into the first one, but - and this was at all events frequently true, and even when she was in a very bad condition - a clear-sighted and calm observer sat, as she put it, in a corner of her brain and looked on at all the mad business. This persistence of clear thinking while the psychosis was actually going on found expression in a very curious way. At a time when, after the hysterical phenomena had ceased, the patient was passing through a temporary depression, she brought up a number of childish fears and self-reproaches, and among them the idea that she had not been ill at all and that the whole business had been simulated. Similar observations, as we know, have frequently been made. When a disorder of this kind has cleared up and the two states of consciousness have once more become merged into one, the patients, looking back to the past, see themselves as the single undivided personality which was aware of all the nonsense; they think they could have prevented it if they had wanted to, and thus they feel as though they had done all the mischief deliberately. - It should be added that this normal thinking which persisted during the secondary state must have fluctuated enormously in its amount and must very often have been completely absent.
A third consideration which arises from the views that have been developed in these pages is as follows. Are we to suppose that a general detachment of the libido from the external world would be an effective enough agent to account for the ‘end of the world’? Or would not the ego-cathexes which still remained in existence have been sufficient to maintain rapport with the external world? To meet this difficulty we should either have to assume that what we call libidinal cathexis (that is, interest emanating from erotic sources) coincides with interest in general, or we should have to consider the possibility that a very widespread disturbance in the distribution of libido may bring about a corresponding disturbance in the ego-cathexes. But these are problems which we are still quite helpless and incompetent to solve. It would be otherwise if we could start out from some well-grounded theory of instincts; but in fact we have nothing of the kind at our disposal. We regard instinct as being the concept on the frontier-line between the somatic and the mental, and see in it the psychical representative of organic forces. Further, we accept the popular distinction between ego-instincts and a sexual instinct; for such a distinction seems to agree with the biological conception that the individual has a double orientation, aiming on the one hand at self-preservation and on the other at the preservation of the species. But beyond this are only hypotheses, which we have taken up - and are quite ready to drop again - in order to help us to find our bearings in the chaos of the obscurer processes of the mind. What we expect from psycho-analytic investigations of pathological mental processes is precisely that they shall drive us to some conclusions on questions connected with the theory of instincts. These investigations, however, are in their infancy and are only being carried out by isolated workers, so that the hopes we place in them must still remain unfulfilled. We can no more dismiss the possibility that disturbances of the libido may react upon the ego-cathexes than we can overlook the converse possibility - namely, that a secondary or induced disturbance of the libidinal processes may result from abnormal changes in the ego. Indeed, it is probable that processes of this kind constitute the distinctive characteristic of psychoses. How much of all this may apply to paranoia it is impossible at present to say. There is one consideration, however, on which I should like to lay stress. It cannot be asserted that a paranoic, even at the height of the repression, withdraws his interest from the external world completely - as must be considered to occur in certain other kinds of hallucinatory psychosis (such as Meynert’s amentia). The paranoic perceives the external world and takes into account any alterations that may happen in it, and the effect it makes upon him stimulates him to invent explanatory theories (such as Schreber’s ‘cursorily improvised men’). It therefore appears to me far more probable that the paranoic’s altered relation to the world is to be explained entirely or in the main by the loss of his libidinal interest.
[1911c, 2440]
We have repeatedly had to insist on the fact that the ego owes its origin as well as the most important of its acquired characteristics to its relation to the real external world. We are thus prepared to assume that the ego's pathological states, in which it most approximates once again to the id, are founded on a cessation or slackening of that relation to the external world. This tallies very well with what we learn from clinical experience - namely, that the precipitating cause of the outbreak of a psychosis is either that reality has become intolerably painful or that the instincts have become extraordinarily intensified - both of which, in view of the rival claims made on the ego by the id and the external world, must lead to the same result. The problem of psychoses would be simple and perspicuous if the ego's detachment from reality could be carried through completely. But that seems to happen only rarely or perhaps never. Even in a state so far removed from the reality of the external world as one of hallucinatory confusion, one learns from patients after their recovery that at the time in some corner of their mind (as they put it) there was a normal person hidden, who, like a detached spectator, watched the hubbub of illness go past him. I do not know if we may assume that this is so in general, but I can report the same of other psychoses with a less tempestuous course. I call to mind a case of chronic paranoia in which after each attack of jealousy a dream conveyed to the analyst a correct picture of the precipitating cause, free from any delusion. An interesting contrast was thus brought to light: while we are accustomed to discover from the dreams of neurotics jealousies which are alien to their waking lives, in this psychotic case the delusion which dominated the patient in the day-time was corrected by his dream. We may probably take it as being generally true that what occurs in all these cases is a psychical split. Two psychical attitudes have been formed instead of a single one - one, the normal one, which takes account of reality, and another which under the influence of the instincts detaches the ego from reality. The two exist alongside of each other. The issue depends on their relative strength. If the second is or becomes the stronger, the necessary precondition for a psychosis is present. If the relation is reversed, then there is an apparent cure of the delusional disorder. Actually it has only retreated into the unconscious - just as numerous observations lead us to believe that the delusion existed ready-made for a long time before its manifest irruption.

[1940a [1938], 5007]
And the paranoic builds it again, not more splendid, it is true, but at least so that he can once more live in it. He builds it up by the world of his delusions. The delusional formation, which we take to be the pathological product, is in reality an attempt at recovery, a process of reconstruction. Such a reconstruction after the catastrophe is successful to a greater or lesser extent, but never wholly so; in Schreber's words, there has been a 'profound internal change' in the world. But the human subject has recaptured a relation, and often a very intense one, to the people and things in the world, even though the relation is a hostile one now, where formerly it was hopefully affectionate. We may say, then, that the process of repression proper consists in a detachment of the libido from people - and things - that were previously loved. It happens silently; we receive no intelligence of it, but can only infer it from subsequent events. What forces itself so noisily upon our attention is the process of recovery, which undoes the work of repression and brings back the libido again on to the people it had abandoned. In paranoia this process is carried out by the method of projection. It was incorrect to say that the perception which was suppressed internally is projected outwards; the truth is rather, as we now see, that what was abolished internally returns from without. The thorough examination of the process of projection which we have postponed to another occasion will clear up our remaining doubts on this subject.

Abraham has very convincingly shown¹ that the turning away of the libido from the external world is a particularly clearly-marked feature in dementia praecox. From this feature we infer that the repression is effected by means of detachment of the libido. Here once more we may regard the phase of violent hallucinations as a struggle between repression and an attempt at recovery by bringing the libido back again on to its objects. Jung, with extraordinary analytic acumen, has perceived that the deliria² and motor stereotypes occurring in this disorder are the residues of former object-cathexes, clung to with great persistence. This attempt at recovery, which observers mistake for the disease itself, does not, as in paranoia, make use of projection, but employs a hallucinatory (hysterical) mechanism. This is one of the two major respects in which dementia praecox differs from paranoia; and this difference can be explained genetically from another direction. The second difference is shown by the outcome of the disease in those cases where the process has not remained too restricted. The prognosis is on the whole more unfavourable than in paranoia. The victory lies with repression and not, as in the former, with reconstruction. The regression extends not merely to narcissism (manifesting itself in the shape of megalomania) but to a complete abandonment of object-love and a return to infantile auto-eroticism. The dispositional fixation must therefore be situated further back than in paranoia, and must lie some where at the beginning of the course of development from auto-eroticism to object-love. Moreover, it is not at all likely that homosexual impulses, which are so frequently - perhaps invariably - to be found in paranoia, play an equally important part in the aetiology of that far more comprehensive disorder, dementia praecox.
Since I neither fear the criticism of others nor shrink from criticizing myself, I have no motive for avoiding the mention of a similarity which may possibly damage our libido theory in the estimation of many of my readers. Schreber's 'rays of God', which are made up of a condensation of the sun's rays, of nerve fibres, and of spermatozoa, are in reality nothing else than a concrete representation and projection outwards of libidinal cathexes; and they thus lend his delusions a striking conformity with our theory. His belief that the world must come to an end because his ego was attracting all the rays to itself, his anxious concern at a later period, during the process of reconstruction, lest God should sever His ray-connection with him, - these and many other details of Schreber's delusional structure sound almost like endopsychic perceptions of the processes whose existence I have assumed in these page as the basis of our explanation of paranoia. I can nevertheless call a friend and fellow-specialist to witness that I had developed my theory of paranoia before I became acquainted with the contents of Schreber's book. It remains for the future to decide whether there is more delusion in my theory than I should like to admit, or whether there is more truth in Schreber's delusion than other people are as yet prepared to believe.

[1911c, 2444]

The formation of the wishful phantasy and its regression to hallucination are the most essential parts of the dream-work, but they do not belong exclusively to dreams. They are also found in two morbid states: in acute hallucinatory confusion (Meynert's 'amentia'), and in the hallucinatory phase of schizophrenia. The hallucinatory delirium of amentia is a clearly recognizable wishful phantasy, often completely well ordered like a perfect day-dream. One might speak quite generally of a 'hallucinatory wishful psychosis', and attribute it equally to dreams and amentia. There are even dreams which consist of nothing but undistorted wishful phantasies with a very rich content. The hallucinatory phase of schizophrenia has been less thoroughly studied; it seems as a rule to be of a composite nature, but in its essence it might well correspond to a fresh attempt at restitution, designed to restore a libidinal cathexis to the ideas of objects.¹ I cannot extend the comparison to the other hallucinatory states in various pathological disorders, because in their case I have no experience of my own upon which to draw, and cannot utilize that of other observers.

[1917d, 3034]

The clinical picture of dementia praecox (which, incidentally, is very changeable) is not determined exclusively by the symptoms arising from the forcing away of the libido on objects and its accumulation in the ego as narcissistic libido. A large part, rather, is played by other phenomena, which are derived from efforts of the libido to attain objects once more and which thus correspond to an attempt at restitution or recovery. These latter symptoms are indeed the more striking and noisy; they exhibit an undeniable resemblance to those of hysteria or, less frequently, of obsessional neurosis, but nevertheless differ from them in every respect. It seems as though in dementia praecox the libido, in its efforts once more to reach objects (that is, the presentations of objects), does in fact snatch hold of something of them, but, as it were, only their shadows - I mean the word-presentations belonging to them. I cannot say more about this now, but I believe that this behaviour of the libido as it strives to find its way back has enabled us to obtain an insight into what really constitutes the difference between a conscious and an unconscious idea.

[1916-1917, 3466]
I can do so in a few words, and you will see how simply the riddle can be solved and how well everything fits together. Observation shows that sufferers from narcissistic neuroses have no capacity for transference or only insufficient residues of it. They reject the doctor, not with hostility but with indifference. For that reason they cannot be influenced by him either; what he says leaves them cold, makes no impression on them; consequently the mechanism of cure which we carry through with other people - the revival of the pathogenic conflict and the overcoming of the resistance due to repression - cannot be operated with them. They remain as they are. Often they have already undertaken attempts at recovery on their own account which have led to pathological results. We cannot alter this in any way.

[1916-1917, 3489]

Narcissism. - A decisive advance was made when the analysis of dementia praecox and other psychotic disorders was ventured upon and thus the examination was begun of the ego itself, which had so far been known only as the agency of repression and opposition. It was found that the pathogenic process in dementia praecox is the withdrawal of the libido from objects and its introduction into the ego, while the clamorous symptoms of the disease arise from the vain struggles of the libido to find a pathway back to objects. It thus turned out to be possible for object-libido to change into cathexis of the ego and vice versa. Further reflection showed that this process must be presumed to occur on the largest scale and that the ego is to be regarded as a great reservoir of libido from which libido is sent out to objects and which is always ready to absorb libido flowing back from objects. Thus the instincts of self-preservation were also of a libidinal nature: they were sexual instincts which, instead of external objects, had taken the subject's own ego as an object. Clinical experience had made us familiar with people who behaved in a striking fashion as though they were in love with themselves and this perversion had been given the name of narcissism. The libido of the self-preservative instincts was now described as narcissistic libido and it was recognized that a high degree of this self-love constituted the primary and normal state of things. The earlier formula laid down for the transference neuroses consequently required to be modified, though not corrected. It was better, instead of speaking of a conflict between sexual instincts and ego instincts, to speak of a conflict between object-libido and ego-libido, or, since the nature of these instincts was the same, between the object-cathexes and the ego.

[1923a, 3933]

We know that other forms of psychosis, the schizophrenias, are inclined to end in affective hebetude - that is, in a loss of all participation in the external world. In regard to the genesis of delusions, a fair number of analyses have taught us that the delusion is found applied like a patch over the place where originally a rent had appeared in the ego's relation to the external world. If this precondition of a conflict with the external world is not much more noticeable to us than it now is, that is because, in the clinical picture of the psychosis, the manifestations of the pathogenic process are often overlaid by manifestations of an attempt at a cure or a reconstruction.

[1924b, 4067]
We might expect that when a psychosis comes into being, something analogous to the process in a neurosis occurs, though, of course, between different agencies of the mind; thus we might expect that in a psychosis, too, two steps could be discerned, of which the first would drag the ego away, this time from reality, while the second would try to make good the damage done and re-establish the subject's relations to reality at the expense of the id. And, in fact, some analogy of the sort can be observed in a psychosis. Here, too, there are two steps, the second of which has the character of a reparation. But beyond that the analogy gives way to a far more extensive similarity between the two processes. The second step of the psychosis is indeed intended to make good the loss of reality, not, however, at the expense of a restriction of the id - as happens in neurosis at the expense of the relation to reality - but in another, more autocratic manner, by the creation of a new reality which no longer raises the same objections as the old one that has been given up. The second step, therefore, both in neurosis and psychosis, is supported by the same trends. In both cases it serves the desire for power of the id, which will not allow itself to be dictated to by reality. Both neurosis and psychosis are thus the expression of a rebellion on the part of the id against the external world, of its unwillingness - or, if one prefers, its incapacity - to adapt itself to the exigencies of reality, to 'Αυάγχη [Necessity]. Neurosis and psychosis differ from each other far more in their first, introductory, reaction than in the attempt at reparation which follows it.

[1924e, 4095]

I am aware that it is of small service to handle so important a subject in the cursory fashion that I have here employed. But none the less I have not been able to resist the seduction of an analogy. The delusions of patients appear to me to be the equivalents of the constructions which we build up in the course of an analytic treatment - attempts at explanation and cure, though it is true that these, under the conditions of a psychosis, can do no more than replace the fragment of reality that is being disavowed in the present by another fragment that had already been disavowed in the remote past. It will be the task of each individual investigation to reveal the intimate connections between the material of the present disavowal and that of the original repression. Just as our construction is only effective because it recovers a fragment of lost experience, so the delusion owes its convincing power to the element of historical truth which it inserts in the place of the rejected reality. In this way a proposition which I originally asserted only of hysteria would apply also to delusions - namely, that those who are subject to them are suffering from their own reminiscences. I never intended by this short formula to dispute the complexity of the causation of the illness or to exclude the operation of many other factors.

[1937d, 5059]
Although it is a digression from our aim, we cannot avoid giving our attention for a moment longer to the ego's object-identifications. If they obtain the upper hand and become too numerous, unduly powerful and incompatible with one another, a pathological outcome will not be far off. It may come to a disruption of the ego in consequence of the different identifications becoming cut off from one another by resistances; perhaps the secret of the cases of what is described as 'multiple personality' is that the different identifications seize hold of consciousness in turn. Even when things do not go so far as this, there remains the question of conflicts between the various identifications into which the ego comes apart, conflicts which cannot after all be described as entirely pathological.

[1923b, 3964]

These derealizations are remarkable phenomena which are still little understood. They are spoken of as 'sensations', but they are obviously complicated processes, attached to particular mental contents and bound up with decisions made about those contents. They arise very frequently in certain mental diseases, but they are not unknown among normal people, just as hallucinations occasionally occur in the healthy. Nevertheless they are certainly failures in functioning and, like dreams, which, in spite of their regular occurrence in healthy people, serve us as models of psychological disorder, they are abnormal structures. These phenomena are to be observed in two forms: the subject feels either that a piece of reality or that a piece of his own self is strange to him. In the latter case we speak of 'depersonalizations'; derealizations and depersonalizations are intimately connected. There is another set of phenomena which may be regarded as their positive counterparts - what are known as 'fausse reconnaissance', 'déjà vu', 'déjà raconté' etc., illusions in which we seek to accept something as belonging to our ego, just as in the derealizations we are anxious to keep something out of us. A naïvely mystical and unpsychological attempt at explaining the phenomena of 'déjà vu' endeavours to find evidence in it of a former existence of our mental self. Depersonalization leads us on to the extraordinary condition of 'double conscience', which is more correctly described as 'split personality'. But all of this is so obscure and has been so little mastered scientifically that I must refrain from talking about it any more to you.

[1936a, 4828]
The sympathies of the girl herself, who, as I have said, became my patient at the age of eighteen, had always been with the father's side of the family, and ever since she had fallen ill she had taken as her model the aunt who has just been mentioned. There could be no doubt, too, that it was from her father's family that she had derived not only her natural gifts and her intellectual precocity but also the predisposition to her illness. I never made her mother's acquaintance. From the accounts given me by the girl and her father I was led to imagine her as an uncultivated woman and above all as a foolish one, who had concentrated all her interests upon domestic affairs, especially since her husband's illness and the estrangement to which it led. She presented the picture, in fact, of what might be called the 'housewife's psychosis'. She had no understanding of her children’s more active interests, and was occupied all day long in cleaning the house with its furniture and utensils and in keeping them clean - to such an extent as to make it almost impossible to use or enjoy them. This condition, traces of which are to be found often enough in normal housewives, inevitably reminds one of forms of obsessional washing and other kinds of obsessional cleanliness. But such women (and this applied to the patient's mother) are entirely without insight into their illness, so that one essential characteristic of an 'obsessional neurosis' is lacking. The relations between the girl and her mother had been unfriendly for years. The daughter looked down on her mother and used to criticize her mercilessly, and she had withdrawn completely from her influence.¹

In the work I have mentioned I described the numerous dependent relationships of the ego, its intermediate position between the external world and the id and its efforts to humour all its masters at once. In connection with a train of thought raised in other quarters, which was concerned with the origin and prevention of the psychoses, a simple formula has now occurred to me which deals with what is perhaps the most important genetic difference between a neurosis and a psychosis: neurosis is the result of a conflict between the ego and its id, whereas psychosis is the analogous outcome of a similar disturbance in the relations between the ego and the external world.

There are certainly good grounds for being suspicious of such simple solutions of a problem. Moreover, the most that we may expect is that this formula will turn out to be correct in the roughest outline. But even that would be something. One recalls at once, too, a whole number of discoveries and findings which seem to support our thesis. All our analyses go to show that the transference neuroses originate from the ego's refusing to accept a powerful instinctual impulse in the id or to help it to find a motor outlet, or from the ego's forbidding that impulse the object at which it is aiming. In such a case the ego defends itself against the instinctual impulse by the mechanism of repression. The repressed material struggles against this fate. It creates for itself, along paths over which the ego has no power, a substitutive representation (which forces itself upon the ego by way of a compromise) - the symptom. The ego finds its unity threatened and impaired by this intruder, and it continues to struggle against the symptom, just as it fended off the original instinctual impulse. All this produces the picture of a neurosis. It is no contradiction to this that, in undertaking the repression, the ego is at bottom following the commands of its super-ego - commands which, in their turn, originate from influences in the external world that have found representation in the super-ego. The fact remains that the ego has taken sides with those powers, that in it their demands have more strength than the instinctual demands of the id, and that the ego is the power which sets the repression in motion against the portion of the id concerned and which fortifies the repression by means of the anticathexis of resistance. The ego has come into conflict with the id in the service of the super-ego and of reality; and this is the state of affairs in every transference neurosis.
On the other side, it is equally easy, from the knowledge we have so far gained of the mechanism of the psychoses, to adduce examples which point to a disturbance in the relationship between the ego and the external world. In Meynert's amentia - an acute hallucinatory confusion which is perhaps the most extreme and striking form of psychosis - either the external world is not perceived at all, or the perception of it has no effect whatever. Normally, the external world governs the ego in two ways: firstly, by current, present perceptions which are always renewable, and secondly, by the store of memories of earlier perceptions which, in the shape of an 'internal world', form a possession of the ego and a constituent part of it. In amentia, not only is the acceptance of new perceptions refused, but the internal world, too, which, as a copy of the external world, has up till now represented it, loses its significance (its cathexis) - The ego creates, autocratically, a new external and internal world; and there can be no doubt of two facts - that this new world is constructed in accordance with the id's wishful impulses, and that the motive of this dissociation from the external world is some very serious frustration by reality of a wish - a frustration which seems intolerable. The close affinity of this psychosis to normal dreams is unmistakable. A precondition of dreaming, moreover, is a state of sleep, and one of the features of sleep is a complete turning away from perception and the external world.

[1924b, 4066]

The aetiology common to the onset of a psychoneurosis and of a psychosis always remains the same. It consists in a frustration, a non-fulfilment of one of those childhood wishes which are forever undefeated and which are so deeply rooted in our phylogenetically determined organization. This frustration is in the last resort always an external one; but in the individual case it may proceed from the internal agency (in the super-ego) which has taken over the representation of the demands of reality. The pathogenic effect depends on whether, in a conflictual tension of this kind, the ego remains true to its dependence on the external world and attempts to silence the id, or whether it lets itself be overcome by the id and thus torn away from reality. A complication is introduced into this apparently simple situation, however, by the existence of the super-ego, which, though a link that is not yet clear to us, unites in itself influences coming from the id as well as from the external world, and is to some extent an ideal model of what the whole endeavour of the ego is aiming at - a reconciliation between its various dependent relationships. The attitude of the super-ego should be taken into account - which has not hitherto been done - in every form of psychical illness. We may provisionally assume that there must also be illnesses which are based on a conflict between the ego and the super-ego. Analysis gives us a right to suppose that melancholia is a typical example of this group; and we would set aside the name of 'narcissistic psychoneuroses' for disorders of that kind. Nor will it clash with our impressions if we find reasons for separating states like melancholia from the other psychoses. We now see that we have been able to make our simple genetic formula more complete, without dropping it. Transference neuroses correspond to a conflict between the ego and the id; narcissistic neuroses, to a conflict between the ego and the super-ego; and psychoses, to one between the ego and the external world. It is true that we cannot tell at once whether we have really gained any new knowledge by this, or have only enriched our store of formulas; but I think that this possible application of the proposed differentiation of the mental apparatus into an ego, a super-ego and an id cannot fail to give us courage to keep that hypothesis steadily in view.

[1924b, 4067]
The thesis that neuroses and psychoses originate in the ego's conflicts with its various ruling agencies - that is, therefore, that they reflect a failure in the functioning of the ego, which is at pains to reconcile all the various demands made on it - this thesis needs to be supplemented in one further point. One would like to know in what circumstances and by what means the ego can succeed in emerging from such conflicts, which are certainly always present, without falling ill. This is a new field of research, in which no doubt the most varied factors will come up for examination. Two of them, however, can be stressed at once. In the first place, the outcome of all such situations will undoubtedly depend on economic considerations - on the relative magnitudes of the trends which are struggling with one another. In the second place, it will be possible for the ego to avoid a rupture in any direction by deforming itself, by submitting to encroachments on its own unity and even perhaps by effecting a cleavage or division of itself. In this way the inconsistencies, eccentricities and follies of men would appear in a similar light to their sexual perversions, though the acceptance of which they spare themselves repressions.

[1924b, 4068]

I have recently¹ indicated as one of the features which differentiate a neurosis from a psychosis the fact that in a neurosis the ego, in its dependence on reality, suppresses a piece of the id (of instinctual life), whereas in a psychosis, this same ego, in the service of the id, withdraws from a piece of reality. Thus for a neurosis the decisive factor would be the predominance of the influence of reality, whereas for a psychosis it would be the predominance of the id. In a psychosis, a loss of reality would necessarily be present, whereas in a neurosis, it would seem, this loss would be avoided.

[1924e, 4094]

But this does not at all agree with the observation which all of us can make that every neurosis disturbs the patient's relation to reality in some way, that it serves him as a means of withdrawing from reality, and that, in its severe forms, it actually signifies a flight from real life. This contradiction seems a serious one; but it is easily resolved, and the explanation of it will in fact help us to understand neuroses.

[1924e, 4094]

For the contradiction exists only as long as we keep our eyes fixed on the situation at the beginning of the neurosis, in which the ego, in the service of reality, sets about the repression of an instinctual impulse. This, however, is not yet the neurosis itself. The neurosis consists rather in the processes which provide a compensation for the portion of the id that has been damaged - that is to say, in the reaction against the repression and in the failure of the repression. The loosening of the relation to reality is a consequence of this second step in the formation of a neurosis, and it ought not to surprise us if a detailed examination shows that the loss of reality affects precisely that piece of reality as a result of whose demands the instinctual repression ensued.

[1924e, 4094]
Incidentally, the same objection arises in a specially marked manner when we are dealing with a neurosis in which the exciting cause (the 'traumatic scene') is known, and in which one can see how the person concerned turns away from the experience and consigns it to amnesia. Let me go back by way of example to a case analysed a great many years ago,¹ in which the patient, a young woman, was in love with her brother-in-law. Standing beside her sister's deathbed, she was horrified at having the thought: 'Now he is free and can marry me.' This scene was instantly forgotten, and thus the process of regression, which led to her hysterical pains, was set in motion. It is instructive precisely in this case, moreover, to learn along what path the neurosis attempted to solve the conflict. It took away from the value of the change that had occurred in reality, by repressing the instinctual demand which had emerged - that is, her love for her brother-in-law. The psychotic reaction would have been a disavowal of the fact of her sister's death.

[1924e, 4095]

We might expect that when a psychosis comes into being, something analogous to the process in a neurosis occurs, though, of course, between different agencies of the mind; thus we might expect that in a psychosis, too, two steps could be discerned, of which the first would drag the ego away, this time from reality, while the second would try to make good the damage done and re-establish the subject's relations to reality at the expense of the id. And, in fact, some analogy of the sort can be observed in a psychosis. Here, too, there are two steps, the second of which has the character of a reparation. But beyond that the analogy gives way to a far more extensive similarity between the two processes. The second step of the psychosis is indeed intended to make good the loss of reality, not, however, at the expense of a restriction of the id - as happens in neurosis at the expense of the relation to reality - but in another, more autocratic manner, by the creation of a new reality which no longer raises the same objections as the old one that has been given up. The second step, therefore, both in neurosis and psychosis, is supported by the same trends. In both cases it serves the desire for power of the id, which will not allow itself to be dictated to by reality. Both neurosis and psychosis are thus the expression of a rebellion on the part of the id against the external world, of its unwillingness - or, if one prefers, its incapacity - to adapt itself to the exigencies of reality, to Αὐάγχη [Necessity]. Neurosis and psychosis differ from each other far more in their first, introductory, reaction than in the attempt at reparation which follows it.

[1924e, 4095]

Accordingly, the initial difference is expressed thus in the final outcome: in neurosis a piece of reality is avoided by a sort of flight, whereas in psychosis it is remodelled. Or we might say: in psychosis, the initial flight is succeeded by an active phase of remodelling; in neurosis, the initial obedience is succeeded by a deferred attempt at flight. Or again, expressed in yet another way: neurosis does not disavow the reality, it only ignores it; psychosis disavows it and tries to replace it. We call behaviour 'normal' or 'healthy', if it combines certain features of both reactions - if it disavows the reality as little as does a neurosis, but if it then exerts itself, as does a psychosis, to effect an alteration of that reality. Of course, this expedient, normal, behaviour leads to work being carried out on the external world: it does not stop, as in psychosis, at effecting internal changes. It is no longer autoplastic but alloplastic.

[1924e, 4096]
In a psychosis, the transforming of reality is carried out upon the psychical precipitates of former relations to it - that is, upon the memory-traces, ideas and judgements which have been previously derived from reality and by which reality was represented in the mind. But this relation was never a closed one; it was continually being enriched and altered by fresh perceptions. Thus the psychosis is also faced with the task of procuring for itself perceptions of a kind which shall correspond to the new reality; and this is most radically effected by means of hallucination. The fact that, in so many forms and cases of psychosis, the paramnesias, the delusions and the hallucinations that occur are of a most distressing character and are bound up with a generation of anxiety - this fact is without doubt a sign that the whole process of remodelling is carried through against forces which oppose it violently. We may construct the process on the model of a neurosis, with which we are more familiar. There we see that a reaction of anxiety sets in whenever the repressed instinct makes a thrust forward, and that the outcome of the conflict is only a compromise and does not provide complete satisfaction. Probably in a psychosis the rejected piece of reality constantly forces itself upon the mind, just as the repressed instinct does in a neurosis, and that is why in both cases the consequences too are the same. The elucidation of the various mechanisms which are designed, in the psychoses, to turn the subject away from reality and to reconstruct reality - this is a task for specialized psychiatric study which has not yet been taken in hand.

There is, therefore, a further analogy between a neurosis and a psychosis, in that in both of them the task which is undertaken in the second step is partly unsuccessful. For the repressed instinct is unable to procure a full substitute (in neurosis); and the representation of reality cannot be remoulded into satisfying forms (not, at least, in every species of mental illness). But the emphasis is different in the two cases. In a psychosis it falls entirely on the first step, which is pathological in itself and cannot but lead to illness. In a neurosis, on the other hand, it falls on the second step, on the failure of the repression, whereas the first step may succeed, and does succeed in innumerable instances without overstepping the bounds of health - even though it does so at a certain price and not without leaving behind traces of the psychical expenditure it has called for. These distinctions, and perhaps many others as well, are a result of the topographical difference in the initial situation of the pathogenic conflict - namely whether in it the ego yielded to its allegiance to the real world or to its dependence on the id.

A neurosis usually contents itself with avoiding the piece of reality in question and protecting itself against coming into contact with it. The sharp distinction between neurosis and psychosis, however, is weakened by the circumstance that in neurosis, too, there is no lack of attempts to replace a disagreeable reality by one which is more in keeping with the subject's wishes. This is made possible by the existence of a world of phantasy, of a domain which became separated from the real external world at the time of the introduction of the reality principle. This domain has since been kept free from the demands of the exigencies of life, like a kind of 'reservation'; it is not inaccessible to the ego, but is only loosely attached to it. It is from this world of phantasy that the neurosis draws the material for its new wishful constructions, and it usually finds that material along the path of regression to a more satisfying real past.
It can hardly be doubted that the world of phantasy plays the same part in psychosis and that there, too, it is the storehouse from which the materials or the pattern for building the new reality are derived. But whereas the new, imaginary external world of a psychosis attempts to put itself in the place of external reality, that of a neurosis, on the contrary, is apt, like the play of children, to attach itself to a piece of reality - a different piece from the one against which it has to defend itself - and to lend that piece a special importance and a secret meaning which we (not always quite appropriately) call a symbol one. Thus we see that both in neurosis and psychosis there comes into consideration the question not only of a loss of reality but also of a substitute for reality.

[1924e, 4098]

The psycho-analytic view would also have to include in narcissistic disorders all the ailments described in psychiatry as 'functional psychoses'. It could not be doubted that neuroses and psychoses are not separated by a hard and fast line, any more than health and neurosis; and it was plausible to explain the mysterious psychotic phenomena by the discoveries achieved on the neuroses, which had hitherto been equally incomprehensible. The present writer had himself, during the period of his isolation, made a case of paranoid illness partly intelligible by an analytic investigation and had pointed out in this unquestionable psychosis the same contents (complexes) and a similar interplay of forces as in the simple neuroses. Bleuler followed out the indications of what he called 'Freudian mechanisms' in a whole number of psychoses, and Jung won high opinions as an analyst at a single blow when, in 1907, he explained the most eccentric symptoms in the end-stages of dementia praecox from the individual life-histories of the patients. The comprehensive study of schizophrenia by Bleuler (1911) probably demonstrated once and for all the justification of a psycho-analytic angle of approach for the understanding of these psychoses.

[1924f, 4114]

In this way psychiatry became the first field to which psycho-analysis was applied and it has remained so ever since. The same research workers who have done most to deepen analytic knowledge of the neuroses, such as Karl Abraham in Berlin and Sándor Ferenczi in Budapest (to name only the most prominent), have also played a leading part in throwing analytic light on the psychoses. The conviction of the unity and intimate connection of all the disorders that present themselves as neurotic and psychotic phenomena is becoming more and more firmly established despite all the efforts of the psychiatrists. People are beginning to understand - best of all, perhaps, in America - that the psycho-analytic study of the neuroses is the only preparation for an understanding of the psychoses, and that psycho-analysis is destined to make possible a scientific psychiatry of the future which will not need to content itself with describing curious clinical pictures and unintelligible sequences of events and with tracing the influence of gross anatomical and toxic traumas upon a mental apparatus which is inaccessible to our knowledge.

[1924f, 4114]
The neuroses were the first subject of analysis, and for a long time they were the only one. No analyst could doubt that medical practice was wrong in separating those disorders from the psychoses and in attaching them to the organic nervous diseases. The theory of the neuroses belongs to psychiatry and is indispensable as an introduction to it. It would seem, however, that the analytic study of the psychoses is impracticable owing to its lack of therapeutic results. Mental patients are as a rule without the capacity for forming a positive transference, so that the principal instrument of analytic technique is inapplicable to them. There are nevertheless a number of methods of approach to be found. Transference is often not so completely absent but that it can be used to a certain extent; and analysis has achieved undoubted successes with cyclical depressions, light paranoic modifications, and partial schizophrenias. It has at least been a benefit to science that in many cases the diagnosis can oscillate for quite a long time between assuming the presence of a psychoneurosis or of a dementia praecox; for therapeutic attempts initiated in such cases have resulted in valuable discoveries before they have had to be broken off. But the chief consideration in this connection is that so many things that in the neuroses have to be laboriously fetched up from the depths are found in the psychoses on the surface, visible to every eye. For that reason the best subjects for the demonstration of many of the assertions of analysis are provided by the psychiatric clinic. It was thus bound to happen before long that analysis would find its way to the objects of psychiatric observation. I was able very early (1896) to establish in a case of paranoid dementia the presence of the same aetiological factors and the same emotional complexes as in the neuroses. Jung explained some most puzzling stereotipies in dements by bringing them into relation with the patients' life-histories; Bleuler demonstrated the existence in various psychoses of mechanisms like those which analysis had discovered in neurotics. Since then analysts have never relaxed their efforts to come to an understanding of the psychoses. Especially since it has been possible to work with the concept of narcissism, they have managed, now in this place and now in that, to get a glimpse beyond the wall. Most of all, no doubt, was achieved by Abraham in his elucidation of the melancholias. It is true that in this sphere all our knowledge is not yet converted into therapeutic power; but the mere theoretical gain is not to be despised, and we may be content to wait for its practical application. In the long run even the psychiatrists cannot resist the convincing force of their own clinical material. At the present time German psychiatry is undergoing a kind of 'peaceful penetration' by analytic views. While they continually declare that they will never be psycho-analysts, that they do not belong to the 'orthodox' school or agree with its exaggerations, and in particular that they do not believe in the predominance of the sexual factor, nevertheless the majority of the younger workers take over one piece or another of analytic theory and apply it in their own fashion to the material. All the signs point to the proximity of further developments in the same direction.

[1925d, 4235]

'What a remarkable business! I shall follow your advice and not make criticisms, since you only want to show me what psycho-analysis believes about the origin of neurosis so that you can go on to say how it sets about combating it. I should have various questions to ask and later on I shall raise some of them. But at the moment I myself feel tempted for once to carry your train of thought further and to venture upon a theory of my own. You have expounded the relation between external world, ego and id, and you have laid it down as the determinant of a neurosis that the ego in its dependence on the external world struggles against the id. Is not the opposite case conceivable of the ego in a conflict of this kind allowing itself to be dragged away by the id and disavowing its regard for the external world? What happens in a case like that? From my lay notions of the nature of insanity I should say that such a decision on the part of the ego might be the determinant of insanity. After all, a turning-away of that kind from reality seems to be the essence of insanity.'

[1926e, 4347]
Yes. I myself have thought of that possibility, and indeed I believe it meets the facts - though to prove the suspicion true would call for a discussion of some highly complicated considerations. Neuroses and psychoses are evidently intimately related, but they must nevertheless differ in some decisive respect. That might well be the side taken by the ego in a conflict of this kind. In both cases the id would retain its characteristic of blind inflexibility.
[1926e, 4347]

For me, the explanation of fetishism had another point of theoretical interest as well. Recently, along quite speculative lines, I arrived at the proposition that the essential difference between neurosis and psychosis was that in the former the ego, in the service of reality, suppresses a piece of the id, whereas in a psychosis it lets itself be induced by the id to detach itself from a piece of reality. I returned to this theme once again later on.¹ But soon after this I had reason to regret that I had ventured so far. In the analysis of two young men I learned that each - one when he was two years old and the other when he was ten - had failed to take cognizance of the death of his beloved father - had 'scotomized' it - and yet neither of them had developed a psychosis. Thus a piece of reality which was undoubtedly important had been disavowed by the ego, just as the unwelcome fact of women's castration is disavowed in fetishists. I also began to suspect that similar occurrences in childhood are by no means rare, and I believed that I had been guilty of an error in my characterization of neurosis and psychosis. It is true that there was one way out of the difficulty. My formula needed only to hold good where there was a higher degree of differentiation in the psychical apparatus; things might be permissible to a child which would entail severe injury to an adult.
[1927e, 4537]

But further research led to another solution of the contradiction. It turned out that the two young men had no more 'scotomized' their father's death than a fetishist does the castration of women. It was only one current in their mental life that had not recognized their father's death; there was another current which took full account of that fact. The attitude which fitted in with the wish and the attitude which fitted in with reality existed side by side. In one of my two cases this split had formed the basis of a moderately severe obsessional neurosis. The patient oscillated in every situation in life between two assumptions: the one, that his father was still alive and was hindering his activities; the other, opposite one, that he was entitled to regard himself as his father's successor. I may thus keep to the expectation that in a psychosis the one current - that which fitted in with reality - would have in fact been absent.
[1927e, 4538]
Compared with the other psychotherapeutic procedures psycho-analysis is beyond any doubt the most powerful. It is just and fair, too, that this should be so for it is also the most laborious and time-consuming; it would not be used on slight cases. In suitable cases it is possible by its means to get rid of disturbances and bring about changes for which in pre-analytic times one would not have ventured to hope. But it has its very appreciable limits. The therapeutic ambition of some of my adherents has made the greatest efforts to overcome these obstacles so that every sort of neurotic disorder might be curable by psycho-analysis. They have endeavoured to compress the work of analysis into a shorter duration, to intensify transference so that it may be able to overcome any resistance, to unite other forms of influence with it so as to compel a cure. These efforts are certainly praiseworthy, but, in my opinion, they are vain. They bring with them, too, a danger of being oneself forced away from analysis and drawn into a boundless course of experimentation. The expectation that every neurotic phenomenon can be cured may, I suspect, be derived from the layman’s belief that the neuroses are something quite unnecessary which have no right whatever to exist. Whereas in fact they are severe, constitutionally fixed illnesses, which rarely restrict themselves to only a few attacks but persist as a rule over long periods or throughout life. Our analytic experience that they can be extensively influenced, if the historical precipitating causes and accidental auxiliary factors of the illness can be dealt with, has led us to neglect the constitutional factor in our therapeutic practice, and in any case we can do nothing about it; but in theory we ought always to bear it in mind. The radical inaccessibility of the psychoses to analytic treatment should, in view of their close relationship to the neuroses, restrict our pretensions in regard to these latter. The therapeutic effectiveness of psycho-analysis remains cramped by a number of weighty and scarcely assailable factors. In the case of children, where one might count on the greatest successes, the difficulties are the external ones connected with their relation to their parents, though these difficulties are after all a necessary part of being a child. In the case of adults the difficulties arise in the first instance from two factors: the amount of psychical rigidity present and the form of the illness with all that covers in the way of deeper determinants. [1933a, 4752]

There is, however, another class of psychical patients who clearly resemble the psychotics very closely - the vast number of people suffering severely from neuroses. The determinants of their illness as well as its pathogenic mechanisms must be the same or at least very similar. But their ego has proved more resistant and has become less disorganized. Many of them, in spite of their maladies and the inadequacies resulting from them, have been able to maintain themselves in real life. These neurotics may show themselves ready to accept our help. We will confine our interest to them and see how far and by what methods we are able to ‘cure’ them. [1940a [1938], 4983]
Thus we have attributed three qualities to psychical processes: they are either conscious, preconscious or unconscious. The division between the three classes of material which possess these qualities is neither absolute nor permanent. What is preconscious becomes conscious, as we have seen, without any assistance from us; what is unconscious can, through our efforts, be made conscious, and in the process we may have a feeling that we are often overcoming very strong resistances. When we attempt to do this with someone else, we should not forget that the conscious filling-in of the gaps in his perceptions - the construction we are presenting him with - does not mean as yet that we have made the unconscious material in question conscious to him. All that is true so far is that the material is present in him in two records, once in the conscious reconstruction he has been given, and besides this in its original unconscious state. Our continued efforts usually succeed eventually in making this unconscious material conscious to him himself, as a result of which the two records are brought to coincide. The amount of effort we have to use, by which we estimate the resistance against the material becoming conscious, varies in magnitude in individual cases. For instance, what comes about in an analytic treatment as a result of our efforts can also occur spontaneously: material which is ordinarily unconscious can transform itself into preconscious material and then becomes conscious - a thing that happens to a large extent in psychotic states. From this we infer that the maintenance of certain internal resistances is a *sine qua non* of normality. A relaxation of resistances such as this, with a consequent pushing forward of unconscious material, takes place regularly in the state of sleep, and thus brings about a necessary precondition for the construction of dreams.

Conversely, preconscious material can become temporarily inaccessible and cut off by resistances, as happens when something is temporarily forgotten or escapes the memory; or a preconscious thought can even be temporarily put back into the unconscious state, as seems to be a precondition in the case of jokes. We shall see that a similar transformation back of preconscious material or processes into the unconscious state plays a great part in the causation of neurotic disorders.

With the mention of resistance we have reached the second and more important part of our task. We have already learnt that the ego protects itself against the invasion of undesired elements from the unconscious and repressed id by means of anticathexes, which must remain intact if it is to function normally. The more hard-pressed the ego feels, the more convulsively it clings (as though in a fright) to these anticathexes, in order to protect what remains of itself from further irruptions. But this defensive purpose does not by any means accord with the aims of our treatment. What we desire, on the contrary, is that the ego, emboldened by the certainty of our help, shall dare to take the offensive in order to reconquer what has been lost. And it is here that we become aware of the strength of these anticathexes in the form of resistances to our work. The ego draws back in alarm from such undertakings, which seem dangerous and threaten displeasure; it must be constantly encouraged and soothed if it is not to fail us. This resistance, which persists throughout the whole treatment and is renewed at every fresh piece of work, is known, not quite correctly, as the *resistance due to repression*. We shall find that it is not the only one that faces us. It is interesting to notice that in this situation the party-divisions are to some extent reversed: for the ego struggles against our instigation, while the unconscious, which is ordinarily our opponent, comes to our help, since it has a natural 'upward drive' and desires nothing better than to press forward across its settled frontiers into the ego and so to consciousness. The struggle which develops, if we gain our end and can induce the ego to overcome its resistances, is carried through under our direction and with our assistance. Its outcome is a matter of indifference: whether it results in the ego accepting, after a fresh examination, an instinctual demand which it has hitherto rejected, or whether it dismisses it once more, this time for good and all. In either case a permanent danger has been disposed of, the compass of the ego has been extended and a wasteful expenditure of energy has been made unnecessary.
Hitherto it has been a premiss of our work that we can distinguish the ego-instincts from the sexual ones by their manifestations. With the transference neuroses this could be done without difficulty. We termed the cathexes of energy which the ego directs towards the objects of its sexual desires 'libido'; all the others, which are sent out by the self-preservative instincts, we termed 'interest'. By tracing the course of the libidinal cathexes, their transformations and final vicissitudes, we were able to obtain a first insight into the machinery of the mental forces. For this purpose the transference neuroses offered us the most favourable material. But the ego, its composition out of various organizations and their construction and mode of functioning, remained hidden from us; and we were driven to suspect that only the analysis of other neurotic disorders would be able to bring us the necessary insight.

[1916-1917, 3460]

We began at an early date to extend psycho-analytic observations to these other illnesses. Already in 1908 Karl Abraham, after an exchange of thoughts with me, pronounced the main characteristic of dementia praecox (which was reckoned among the psychoses) to be that in it the libidinal cathexis of objects was lacking. But the question then arose of what happened to the libido of dementia praecox patients which was turned away from objects. Abraham did not hesitate to give the answer: it is turned back on to the ego and this reflexive turning-back is the source of the megalomania in dementia praecox. Megalomania is in every way comparable to the familiar sexual overvaluation of the object in erotic life. In this way for the first time we learnt to understand a trait in a psychotic illness by relating it to normal erotic life.

[1916-1917, 3461]

I told you too that we hoped that the analysis of the narcissistic disorders would give us an insight into the way in which our ego is put together and built up out of different agencies. We have already made a start with this at one point. From the analysis of delusions of observation we have drawn the conclusion that there actually exists in the ego an agency which unceasingly observes, criticizes and compares, and in that way sets itself over against the other part of the ego. We believe, therefore, that the patient is betraying a truth to us which is not yet sufficiently appreciated when he complains that he is spied upon and observed at every step he takes and that every one of his thoughts is reported and criticized. His only mistake is in regarding this uncomfortable power as something alien to him and placing it outside himself. He senses an agency holding sway in his ego which measures his actual ego and each of its activities by an ideal ego that he has created for himself in the course of his development. We believe, too, that this creation was made with the intention of re-establishing the self-satisfaction which was attached to primary infantile narcissism but which since then has suffered so many disturbances and mortifications. We know the self-observing agency as the ego-censor, the conscience; it is this that exercises the dream-censorship during the night, from which the repressions of inadmissible wishful impulses proceed. When in delusions of observation it becomes split up, it reveals to us its origin from the influences of parents, educators and social environment - from an identification with some of these model figures.

[1916-1917, 3472]
In the Oedipus complex the libido was seen to be attached to the image of the parental figures. But earlier there was a period in which there were no such objects. There followed from this fact the concept (of fundamental importance for the libido theory) of a state in which the subject's libido filled his own ego and had that for its object. This state could be called narcissism or self-love. A moment's reflection showed that this state never completely ceases. All through the subject's life his ego remains the great reservoir of his libido, from which object-cathexes are sent out and into which the libido can stream back again from the objects. Thus narcissistic libido is constantly being transformed into object-libido, and vice versa. An excellent instance of the length to which this transformation can go is afforded by the state of being in love, whether in a sexual or sublimated manner, which goes so far as involving a sacrifice of the self. Whereas hitherto in considering the process of repression attention had only been paid to what was repressed, these ideas made it possible to form a correct estimate of the repressing forces too. It had been said that repression was set in action by the instincts of self-preservation operating in the ego (the 'ego-instincts') and that it was brought to bear upon the libidinal instincts. But since the instincts of self-preservation were now recognized as also being of a libidinal nature, as being narcissistic libido, the process of repression was seen to be a process occurring within the libido itself; narcissistic libido was opposed to object-libido, the interest of self-preservation was defending itself against the demands of object-love, and therefore against the demands of sexuality in the narrower sense as well.

[1925d, 4231]
The neuroses were the first subject of analysis, and for a long time they were the only one. No analyst could doubt that medical practice was wrong in separating those disorders from the psychoses and in attaching them to the organic nervous diseases. The theory of the neuroses belongs to psychiatry and is indispensable as an introduction to it. It would seem, however, that the analytic study of the psychoses is impracticable owing to its lack of therapeutic results. Mental patients are as a rule without the capacity for forming a positive transference, so that the principal instrument of analytic technique is inapplicable to them. There are nevertheless a number of methods of approach to be found. Transference is often not so completely absent but that it can be used to a certain extent; and analysis has achieved undoubted successes with cyclical depressions, light paranoic modifications, and partial schizophrenias. It has at least been a benefit to science that in many cases the diagnosis can oscillate for quite a long time between assuming the presence of a psychoneurosis or of a dementia praecox; for therapeutic attempts initiated in such cases have resulted in valuable discoveries before they have had to be broken off. But the chief consideration in this connection is that so many things that in the neuroses have to be laboriously fetched up from the depths are found in the psychoses on the surface, visible to every eye. For that reason the best subjects for the demonstration of many of the assertions of analysis are provided by the psychiatric clinic. It was thus bound to happen before long that analysis would find its way to the objects of psychiatric observation. I was able very early (1896) to establish in a case of paranoid dementia the presence of the same aetiological factors and the same emotional complexes as in the neuroses. Jung explained some most puzzling stereotypies in dements by bringing them into relation with the patients' life-histories; Bleuler demonstrated the existence in various psychoses of mechanisms like those which analysis had discovered in neurotics. Since then analysts have never relaxed their efforts to come to an understanding of the psychoses. Especially since it has been possible to work with the concept of narcissism, they have managed, now in this place and now in that, to get a glimpse beyond the wall. Most of all, no doubt, was achieved by Abraham in his elucidation of the melancholias. It is true that in this sphere all our knowledge is not yet converted into therapeutic power; but the mere theoretical gain is not to be despised, and we may be content to wait for its practical application. In the long run even the psychiatrists cannot resist the convincing force of their own clinical material. At the present time German psychiatry is undergoing a kind of 'peaceful penetration' by analytic views. While they continually declare that they will never be psycho-analysts, that they do not belong to the 'orthodox' school or agree with its exaggerations, and in particular that they do not believe in the predominance of the sexual factor, nevertheless the majority of the younger workers take over one piece or another of analytic theory and apply it in their own fashion to the material. All the signs point to the proximity of further developments in the same direction.
[1925d, 4235]
To be quite safe, one should limit one's choice of patients to those who possess a normal mental condition, since in the psycho-analytic method this is used as a foothold from which to obtain control of the morbid manifestations. Psychoses, states of confusion and deeply-rooted (I might say toxic) depression are therefore not suitable for psycho-analysis; at least not for the method as it has been practised up to the present. I do not regard it as by any means impossible that by suitable changes in the method we may succeed in overcoming this contraindication - and so be able to initiate a psychotherapy of the psychoses.

We are beginning to understand now, and to feel some hope. If the young lady in whose form Gradiva had come to life again accepted Hanold's delusion so fully, she was probably doing so in order to set him free from it. There was no other way of doing so; to contradict it would have put an end to any such possibility. Even the serious treatment of a real case of illness of the kind could proceed in no other way than to begin by taking up the same ground as the delusional structure and then investigating it as completely as possible. If Zoe was the right person for the job, we shall soon learn, no doubt, how to cure a delusion like our hero's. We should also be glad to know how such delusions arise. It would be a strange coincidence - but, nevertheless, not without an example or parallel - if the treatment of the delusion were to coincide with its investigation and if the explanation of its origin were to be revealed precisely while it was being dissected. We may suspect, of course, that, if so, our case of illness might end up as a 'commonplace' love-story. But the healing power of love against a delusion is not to be despised - and was not our hero's infatuation for his Gradiva sculpture a complete instance of being in love, though of being in love with something past and lifeless?

Fräulein Zoe seems herself to have shared our view of the young archaeologist's delusion, for the satisfaction she expressed at the end of her 'frank, detailed and instructive speech of castigation' could scarcely have been based on anything but a recognition that from the very first his interest in Gradiva had related to herself. It was this which she had not expected of him, but which, in spite of all its delusional disguise, she saw for what it was. The psychical treatment she had carried out, however, had now accomplished its beneficent effect on him. He felt free, for his delusion had now been replaced by the thing of which it could only have been a distorted and inadequate copy. Nor did he any longer hesitate to remember her and to recognize her as the kind, cheerful, clever playmate who in essentials was not in any way changed. But he found something else very strange-
The tracing back of the delusion and its resolution were now complete. What the author now adds is no doubt designed to serve as a harmonious end to his story. We cannot but feel reassured about the future when we hear that the young man, who had earlier been obliged to play the pitiable part of a person in urgent need of treatment, advanced still further on the road to recovery and succeeded in arousing in her some of the feelings under which he himself had suffered before. Thus it was that he made her jealous by mentioning the sympathetic young lady who had previously interrupted their tête-à-tête in the House of Meleager, and by confessing that she had been the first woman for whom he had felt a very great liking.

Whereupon Zoe prepared to take a chilly leave of him, remarking that everything had now returned to reason - she herself not least; he could look up Gisa Hartleben (or whatever she was now called) again and give her some scientific assistance over the purpose of her visit to Pompeii; she herself, however, must go back to the Albergo del Sole where her father was expecting her for lunch; perhaps they would meet again some time at a party in Germany or in the moon. But once more he was able to make the troublesome fly an excuse for taking possession first of her cheek and then of her lips, and to set in motion the aggressiveness which is a man's inevitable duty in love making. Once only a shadow seemed to fall on their happiness, when Zoe declared that now she really must go back to her father or he will starve at the Sole. 'Your father? . . . what will happen? . . .' (147.) But the clever girl was able swiftly to quiet his concern. 'Probably nothing will happen. I'm not an indispensable part of his zoological collection. If I had been, perhaps I shouldn't have been so foolish as to give my heart to you.' In the exceptional event, however, of her father taking a different view from hers, there was a safe expedient. Hanold need only cross to Capri, catch a *Lacerta faraglionensis* there (he could practise the technique on her little finger), set the creature free over here, catch it again before the zoologist's eyes, and let him choose between a *faraglionensis* on the mainland and his daughter. The scheme, it is easy to see, was one in which the mockery was tinged with bitterness; it was a warning, as it were, to her fiancé not to keep too closely to the model on which she had chosen him. Here again Norbert Hanold reassures us, by showing by all sorts of apparently small signs the great transformation that had taken place in him. He proposed that he and his Zoe should come for their honeymoon to Italy and Pompeii, just as though he had never been indignant with the honeymooning Edwins and Angelinas. He had completely lost from his memory all his feelings against those happy pairs, who had so unnecessarily travelled more than a hundred miles from their German home. The author is certainly right in bringing forward a loss of memory like this as the most trustworthy sign of a change of attitude. Zoe's reply to the plan for the scene of their honeymoon suggested by 'her childhood friend who had also in a sense been dug out of the ruins again' (150.) was that she did not feel quite alive enough yet to make a geographical decision of that sort.

[1907a, 1840]
With the appearance of Zoe Bertgang as Gradiva, which marks the climax of tension in the story, our interest, too, soon takes a new direction. So far we have been assisting at the development of a delusion; now we are to witness its cure. And we may ask whether the author has given a purely fanciful account of the course of this cure or whether he has constructed it in accordance with possibilities actually present. Zoe's own words during her conversation with her newly-married friend give us a definite right to ascribe to her an intention to bring about the cure. (124.) But how did she set about it? When she had got over the indignation aroused in her by his suggestion that she should lie down to sleep again as she had 'then', she returned next day at the same mid-day hour to the same spot, and proceeded to entice out of Hanold all the secret knowledge her ignorance of which had prevented her from understanding his behaviour the day before. She learnt about his dream, about the sculpture of Gradiva, and about the peculiarity of gait which she herself shared with it. She accepted the role of the ghost awakened to life for a brief hour, a role for which, as she perceived, his delusion had cast her, and, by accepting the flowers of the dead which he had brought without conscious purpose, and by expressing a regret that he had not given her roses, she gently hinted in ambiguous words at the possibility of his taking up a new position. (90.)

In the course of the psychotherapeutic treatment of a delusion or of an analogous disorder, ambiguous speeches of this kind are often produced by the patient, as new symptoms of the briefest duration; and it can happen that the doctor finds himself too in the position of making use of them. In that way it not infrequently happens that with the meaning that is intended for the patient's conscious he stirs up an understanding of the meaning that applies to his unconscious. I know from experience that the part thus played by ambiguity is apt to raise the greatest objection in the uninitiated and to give rise to the greatest misunderstandings. But in any case our author was right in giving a place in his creation to a picture of this characteristic feature of what takes place in the formation of dreams and delusions.

The emergence of Zoe as a physician, as I have already remarked, arouses a new interest in us. We shall be anxious to learn whether a cure of the kind she performed upon Hanold is conceivable or even possible, and whether the author has taken as correct a view of the conditions for the disappearance of a delusion as he has of those for its genesis.

We shall unquestionably be met at this point by an opinion which denies that the case presented by the author possesses any such general interest and disputes the existence of any problem requiring solution. Hanold, it will be said, had no alternative but to abandon his delusion, after its subject, the supposed 'Gradiva' herself, had shown him that all his hypotheses were incorrect and after she had given him the most natural explanations of everything puzzling - for instance, of how it was that she had known his name. This would be the logical end of the matter; but since the girl had incidentally revealed her love to him, the author, no doubt to the satisfaction of his female readers, arranged that his story, a not uninteresting one otherwise, should have the usual happy ending in marriage. It would have been more consistent and equally possible, the argument will proceed, if the young scientist, after his error had been pointed out, had taken his leave of the lady with polite thanks and given as the reason for refusing her love the fact that he was able to feel an intense interest in antique women made of bronze or marble, and in their originals if they were accessible to contact, but that he did not know what to do with contemporary girls of flesh and blood. The author, in short, had quite arbitrarily tacked a love story on to his archaeological phantasy.
Thus the author has drawn the closest link between the clearing up of the delusion and the outbreak of a craving for love, and he has paved the way for the inevitable outcome in a courtship. He knows the essential nature of the delusion better than his critics: he knows that a component of loving desire had combined with a component of resistance to it in bringing about the delusion, and he makes the girl who undertakes the cure sensitive to the element in Hanold's delusion which is agreeable to her. It was only this knowledge which could decide her to devote herself to the treatment; it was only the certainty of being loved by him that could induce her to admit her love to him. The treatment consisted in giving him back from outside the repressed memories which he could not set free from inside; but it would have had no effect if in the course of it the therapist had not taken his feelings into account and if her ultimate translation of the delusion had not been: 'Look, all this only means that you love me. [1907a, 1881]

The procedure which the author makes his Zoe adopt for curing her childhood friend's delusion shows a far-reaching similarity - no, a complete agreement in its essence - with a therapeutic method which was introduced into medical practice in 1895 by Dr. Josef Breuer and myself, and to the perfecting of which I have since then devoted myself. This method of treatment, to which Breuer first gave the name of 'cathartic' but which I prefer to describe as 'analytic', consists, as applied to patients suffering from disorders analogous to Hanold's delusion, in bringing to their consciousness, to some extent forcibly, the unconscious whose repression led to their falling ill - exactly as Gradiva did with the repressed memories of her childhood relations. Gradiva, it is true, could carry out this task more easily than a doctor: in several respects she was in what may be described as an ideal position for it. The doctor, who has no pre-existing knowledge of his patient and possesses no conscious memory of what is unconsciously at work in him, must call a complicated technique to his help in order to make up for this disadvantage. He must learn how to infer with great certainty from the conscious associations and communications of the patient what is repressed in him, how to discover his unconscious as it betrays itself behind his conscious words and acts. He then brings about something like what Norbert Hanold grasped at the end of the story when he translated back the name 'Gradiva' into 'Bertgang'. The disorder vanishes while being traced back to its origin; analysis, too, brings simultaneous cure. [1907a, 1881]
It is quite possible that the author's disavowal does not stop at this. He may perhaps altogether deny any knowledge of the rules which we have shown that he has followed, and he may repudiate all the purposes we have recognized in his work. I do not regard this as improbable; but if it is so, there are only two possible explanations. It may be that we have produced a complete caricature of an interpretation by introducing into an innocent work of art purposes of which its creator had no notion, and by so doing have shown once more how easy it is to find what one is looking for and what is occupying one's own mind - a possibility of which the strangest examples are to be found in the history of literature. Let every reader now make up his mind whether he is able to accept this explanation. We ourselves, of course, hold to the other view, the remaining alternative. Our opinion is that the author need have known nothing of these rules and purposes, so that he could disavow them in good faith, but that nevertheless we have not discovered anything in his work that is not already in it. We probably draw from the same source and work upon the same object, each of us by another method. And the agreement of our results seems to guarantee that we have both worked correctly. Our procedure consists in the conscious observation of abnormal mental processes in other people so as to be able to elicit and announce their laws. The author no doubt proceeds differently. He directs his attention to the unconscious in his own mind, he listens to its possible developments and lends them artistic expression instead of suppressing them by conscious criticism. Thus he experiences from himself what we learn from others - the laws which the activities of this unconscious must obey. But he need not state these laws, nor even be clearly aware of them; as a result of the tolerance of his intelligence, they are incorporated within his creations. We discover these laws by analysing his writings just as we find them from cases of real illness; but the conclusion seems inescapable that either both of us, the writer and the doctor, have misunderstood the unconscious in the same way, or we have both understood it correctly. This conclusion is of great value to us, and it is on its account that it has been worth while to investigate by the methods of medical psycho-analysis the way in which the formation and the cure of the delusions as well as the dreams are represented in Jensen's Gradiva.

Abraham has very convincingly shown¹ that the turning away of the libido from the external world is a particularly clearly-marked feature in dementia praecox. From this feature we infer that the repression is effected by means of detachment of the libido. Here once more we may regard the phase of violent hallucinations as a struggle between repression and an attempt at recovery by bringing the libido back again on to its objects. Jung, with extraordinary analytic acumen, has perceived that the deliria² and motor stereotypes occurring in this disorder are the residues of former object-cathexes, clung to with great persistence. This attempt at recovery, which observers mistake for the disease itself, does not, as in paranoia, make use of projection, but employs a hallucinatory (hysterical) mechanism. This is one of the two major respects in which dementia praecox differs from paranoia; and this difference can be explained genetically from another direction. The second difference is shown by the outcome of the disease in those cases where the process has not remained too restricted. The prognosis is on the whole more unfavourable than in paranoia. The victory lies with repression and not, as in the former, with reconstruction. The regression extends not merely to narcissism (manifesting itself in the shape of megalomania) but to a complete abandonment of object-love and a return to infantile auto-erotism. The dispositional fixation must therefore be situated further back than in paranoia, and must lie some where at the beginning of the course of development from auto-erotism to object-love. Moreover, it is not at all likely that homosexual impulsions, which are so frequently - perhaps invariably - to be found in paranoia, play an equally important part in the aetiology of that far more comprehensive disorder, dementia praecox.

[1907a, 1883]

[1911c, 2442]
Your second observation, too, raises a justifiable question, but it is aimed in the wrong direction. It is true that a withdrawal of the object-libido into the ego is not directly pathogenic; it takes place, indeed, as we know, every time before we go to sleep, only to be reversed when we wake up. The amoeba withdraws its protrusions only to send them out again at the first opportunity. But it is quite a different thing when a particular, very energetic process forces a withdrawal of libido from objects. Here the libido that has become narcissistic cannot find its way back to objects, and this interference with the libido's mobility certainly becomes pathogenic. It seems that an accumulation of narcissistic libido beyond a certain amount is not tolerated. We may even imagine that it was for that very reason that object-cathexes originally came about, that the ego was obliged to send out its libido so as not to fall ill as a result of its being dammed up. If it lay within our plan to go more deeply into dementia praecox, I would show you that the process which detaches the libido from objects and cuts off its return to them is closely related to the process of repression and is to be looked at as its counterpart. But you would, first and foremost, find yourselves on familiar ground when you learnt that the determinants of this process are almost identical - so far as we know at present - with those of repression. The conflict seems to be the same and to be carried on between the same forces. If the outcome is so different from, for instance, that in hysteria, the reason can only depend on a difference in innate disposition. The weak spot in the libidinal development of these patients lies in a different phase; the determining fixation, which, as you will recollect, permits the eruption that leads to the formation of symptoms, lies elsewhere, probably in the stage of primitive narcissism to which dementia praecox returns in its final outcome. It is very remarkable that in the case of all the narcissistic neuroses we have to assume fixation points for the libido going back to far earlier phases of development than in hysteria or obsessional neurosis. As you heard, however, the concepts which we arrived at during our study of the transference neuroses are adequate in helping us to find our way about in the narcissistic neuroses which are so much more severe in practice. The conformities go very far; at bottom the field of phenomena is the same. And you can imagine how small a prospect anyone has of explaining these disorders (which belong within the sphere of psychiatry) who is not forearmed for his task with an analytic knowledge of the transference neuroses.

I have now led you into the region in which the next advances in the work of analysis are to be expected. Since we have ventured to operate with the concept of ego-libido the narcissistic neuroses have become accessible to us; the task before us is to arrive at a dynamic elucidation of these disorders and at the same time to complete our knowledge of mental life by coming to understand the ego. The ego-psychology after which we are seeking must not be based on the data of our self-perceptions but (as in the case of the libido) on the analysis of disturbances and disruptions of the ego. It is likely that we shall have a low opinion of our present knowledge of the vicissitudes of the libido, which we have gained from a study of the transference neuroses, when we have achieved this greater task. But hitherto we have not made much progress with it. The narcissistic neuroses can scarcely be attacked with the technique that has served us with the transference neuroses. You will soon learn why. What always happens with them is that, after proceeding for a short distance, we come up against a wall which brings us to a stop. Even with the transference neuroses, as you know, we met with barriers of resistance, but we were able to demolish them bit by bit. In the narcissistic neuroses the resistance is unconquerable; at the most, we are able to cast an inquisitive glance over the top of the wall and spy out what is going on on the other side of it. Our technical methods must accordingly be replaced by others; and we do not know yet whether we shall succeed in finding substitute. Nevertheless, we have no lack of material with these patients either. They make a large number of remarks, even if they do not answer our questions, and for the time being it is our business to interpret these remarks with the help of the understanding we have gained from the symptoms of the transference neuroses. The agreement is great enough to guarantee us some initial advantage. It remains to be seen how far this technique will take us.
There are, however, other forms of illness in which, in spite of the conditions being the same, our therapeutic procedure is never successful. In them, too, it had been a question of an original conflict between the ego and the libido which led to repression - though this may call for a different topographical description; in them, too, it is possible to trace the points in the patient's life at which the repressions occurred; we make use of the same procedure, are ready to make the same promises and give the same help by the offer of anticipatory ideas; and once again the lapse of time between the repressions and the present day favours a different outcome to the conflict. And yet we do not succeed in lifting a single resistance or getting rid of a single repression. These patients, paranoics, melancholics, sufferers from dementia praecox, remain on the whole unaffected and proof against psycho-analytic therapy. What can be the reason for this? Not any lack of intelligence. A certain amount of intellectual capacity is naturally required in our patients; but there is certainly no lack of it in, for instance, the extremely shrewd combinatory paranoics. Nor do any of the other motives seem to be absent. Thus the melancholics have a very high degree of consciousness, absent in paranoics, that they are ill and that that is why they suffer so much; but this does not make them more accessible. We are faced here by a fact which we do not understand and which therefore leads us to doubt whether we have really understood all the determinants of our possible success with the other neuroses.

There is every reason now for us to improve our earlier dynamic account of the therapeutic process and to bring it into harmony with our new realization. If the patient is to fight his way through the normal conflict with the resistances which we have uncovered for him in the analysis, he is in need of a powerful stimulus which will influence the decision in the sense which we desire, leading to recovery. Otherwise it might happen that he would choose in favour of repeating the earlier outcome and would allow what had been brought up into consciousness to slip back again into repression. At this point what turns the scale in his struggle is not his intellectual insight which is neither strong enough nor free enough for such an achievement - but simply and solely his relation to the doctor. In so far as his transference bears a 'plus' sign, it clothes the doctor with authority and is transformed into belief in his communications and explanations. In the absence of such a transference, or if it is a negative one, the patient would never even give a hearing to the doctor and his arguments. In this his belief is repeating the story of its own development; it is a derivative of love and, to start with, needed no arguments. Only later did he allow them enough room to submit them to examination, provided they were brought forward by someone he loved. Without such supports arguments carried no weight, and in most people's lives they never do. Thus in general a man is only accessible from the intellectual side too, in so far as he is capable of a libidinal cathexis of objects; and we have good reason to recognize and to dread in the amount of his narcissism a barrier against the possibility of being influenced by even the best analytic technique.

What you are throwing up at me in this is uncommonly interesting and must be answered. But I cannot do so to-day: we have not the time. Till our next meeting, then. I will answer you, you will see. But to-day I must finish what I have begun. I promised to make you understand by the help of the fact of transference why our therapeutic efforts have no success with the narcissistic neuroses.
I can do so in a few words, and you will see how simply the riddle can be solved and how well everything fits together. Observation shows that sufferers from narcissistic neuroses have no capacity for transference or only insufficient residues of it. They reject the doctor, not with hostility but with indifference. For that reason they cannot be influenced by him either; what he says leaves them cold, makes no impression on them; consequently the mechanism of cure which we carry through with other people - the revival of the pathogenic conflict and the overcoming of the resistance due to repression - cannot be operated with them. They remain as they are. Often they have already undertaken attempts at recovery on their own account which have led to pathological results. We cannot alter this in any way.

On the basis of our clinical impressions we maintained that these patients' object-cathexes must have been given up and that their object-libido must have been transformed into ego-libido. Through this characteristic we distinguished them from the first group of neurotics (sufferers from hysteria, anxiety-hysteria and obsessional neurosis). This suspicion is now confirmed by their behaviour in our attempts at therapy. They manifest no transference and for that reason are inaccessible to our efforts and cannot be cured by us.

Thus our therapeutic work falls into two phases. In the first, all the libido is forced from the symptoms into the transference and concentrated there; in the second, the struggle is waged around this new object and the libido is liberated from it. The change which is decisive for a favourable outcome is the elimination of repression in this renewed conflict so that the libido cannot withdraw once more from the ego by flight into the unconscious. This is made possible by the alteration of the ego which is accomplished under the influence of the doctor's suggestion. By means of the work of interpretation, which transforms what is unconscious into what is conscious, the ego is enlarged at the cost of this unconscious; by means of instruction, it is made conciliatory towards the libido and inclined to grant it some satisfaction, and its repugnance to the claims of the libido is diminished by the possibility of disposing of a portion of it by sublimation. The more closely events in the treatment coincide with this ideal description, the greater will be the success of the psycho-analytic therapy. It finds its limits in the lack of mobility of the libido, which may refuse to leave its objects, and the rigidity of narcissism, which will not allow transference on to objects to increase beyond certain bounds. Further light may perhaps be thrown on the dynamics of the process of cure if I say that we get hold of the whole of the libido which has been withdrawn from the dominance of the ego by attracting a portion of it on to ourselves by means of the transference.
Many attempts at treatment miscarried during the early period of analysis because they were undertaken in cases which were altogether unsuited to the procedure and which we should exclude to-day on the basis of our present view of the indications for treatment. But these indications, too, could only be arrived at by experiment. In those days we did not know a priori that paranoia and dementia praecox in strongly marked forms are inaccessible, and we had a right to make trial of the method on all kinds of disorders. But most of the failures of those early years were due not to the doctor's fault or an unsuitable choice of patients but to unfavourable external conditions. Here we have only dealt with internal resistances, those of the patient, which are inevitable and can be overcome. The external resistances which arise from the patient's circumstances, from his environment, are of small theoretical interest but of the greatest practical importance. Psycho-analytic treatment may be compared with a surgical operation and may similarly claim to be carried out under arrangements that will be the most favourable for its success. You know the precautionary measures adopted by a surgeon: a suitable room, good lighting, assistants, exclusion of the patient's relatives, and so on. Ask yourselves now how many of these operations would turn out successfully if they had to take place in the presence of all the members of the patient's family, who would stick their noses into the field of the operation and exclaim aloud at every incision. In psycho-analytic treatments the intervention of relatives is a positive danger and a danger one does not know how to meet. One is armed against the patient's internal resistances which one knows are inevitable, but how can one ward off these external resistances? No kind of explanations make any impression on the patient's relatives; they cannot be induced to keep at a distance from the whole business, and one cannot make common cause with them because of the risk of losing the confidence of the patient, who - quite rightly moreover - expects the person in whom he has put his trust to take his side. No one who has any experience of the rifts which so often divide a family will, if he is an analyst, be surprised to find that the patient's closest relatives sometimes betray less interest in his recovering than in his remaining as he is. When, as so often, the neurosis is related to conflicts between members of a family, the healthy party will not hesitate long in choosing between his own interest and the sick party's recovery. It is not to be wondered at, indeed, if a husband looks with disfavour on a treatment in which, as he may rightly suspect, the whole catalogue of his sins will be brought to light. Nor do we wonder at it; but we cannot in that case blame ourselves if our efforts remain unsuccessful and the treatment is broken off prematurely because the husband's resistance is added to that of his sick wife. We had in fact undertaken something which in the prevailing circumstances was unrealizable.

[1916-1917, 3498]

I have argued elsewhere¹ that 'war neuroses' (in so far as that term implies something more than a reference to the circumstances of the illness's onset) may very well be traumatic neuroses which have been facilitated by a conflict in the ego. The fact to which I have referred in the first paragraph of Chapter II, that a gross physical injury caused simultaneously by the trauma diminishes the chances that a neurosis will develop, becomes intelligible if one bears in mind two facts which have been stressed by psycho-analytic research: firstly, that mechanical agitation must be recognized as one of the sources of sexual excitation,² and secondly, that painful and feverish illnesses exercise a powerful effect, so long as they last, on the distribution of libido. Thus, on the one hand, the mechanical violence of the trauma would liberate a quantity of sexual excitation which, owing to the lack of preparation for anxiety, would have a traumatic effect; but, on the other hand, the simultaneous physical injury, by calling for a narcissistic hypercathexis of the injured organ,³ would bind the excess of excitation. It is also well known, though the libido theory has not yet made sufficient use of the fact, that such severe disorders in the distribution of libido as melancholia are temporarily brought to an end by intercurrent organic illness, and indeed that even a fully developed condition of dementia praecox is capable of a temporary remission in these same circumstances.

[1920g, 3736]
Narcissism. - The most important theoretical advance has certainly been the application of the libido theory to the repressing ego. The ego itself came to be regarded as a reservoir of what was described as narcissistic libido, from which the libidinal cathexes of objects flowed out and into which they could be once more withdrawn. By the help of this conception it became possible to embark upon the analysis of the ego and to make a clinical distinction of the psychoneuroses into transference neuroses and narcissistic disorders. In the former (hysteria and obsessional neurosis) the subject has at his disposal a quantity of libido striving to be transferred on to extraneous objects, and use is made of this in carrying out analytic treatment; on the other hand, the narcissistic disorders (dementia praecox, paranoia, melancholia) are characterized by a withdrawal of the libido from objects and they are therefore scarcely accessible to analytic therapy. But their therapeutic inaccessibility has not prevented analysis from making the most fruitful beginnings in the deeper study of these illnesses, which are counted among the psychoses.

[1923a, 3925]

There is no doubt that there is something in these people that sets itself against their recovery, and its approach is dreaded as though it were a danger. We are accustomed to say that the need for illness has got the upper hand in them over the desire for recovery. If we analyse this resistance in the usual way then, even after allowance has been made for an attitude of defiance towards the physician and for fixation to the various forms of gain from illness, the greater part of it is still left over; and this reveals itself as the most powerful of all obstacles to recovery, more powerful than the familiar ones of narcissistic inaccessibility, a negative attitude towards the physician and clinging to the gain from illness.

[1923b, 3983]

Among the hypothetical concepts which enable the doctor to deal with the analytic material, the first to be mentioned is that of 'libido'. Libido means in psycho-analysis in the first instance the force (thought of as quantitatively variable and measurable) of the sexual instincts directed towards an object - 'sexual' in the extended sense required by analytic theory. Further study showed that it was necessary to set alongside this 'object-libido' a 'narcissistic' or 'ego-libido', directed to the subject's own ego: and the interaction of these two forces has enabled us to account for a great number of normal and abnormal processes in mental life. A rough distinction was soon made between what are known as the 'transference neuroses' and the narcissistic disorders. The former (hysteria and obsessional neurosis) are the objects proper of psycho-analytic treatment, while the others, the narcissistic neuroses, though they can, it is true, be examined by the help of analysis, offer fundamental difficulties to therapeutic influence. It is true that the libido theory of psycho-analysis is by no means complete and that its relation to a general theory of the instincts is not yet clear, for psycho-analysis is a young science, quite unfinished and in a stage of rapid development. Here, however, it should be emphatically pointed out how erroneous the charge of pan-sexualism is which is so often levelled at psycho-analysis. It seeks to show that psycho-analytic theory knows of no mental motive forces other than purely sexual ones and in doing so exploits popular prejudices by using the word 'sexual' not in its analytic but in its vulgar sense.

[1924f, 4113]
In this way psychiatry became the first field to which psycho-analysis was applied and it has remained so ever since. The same research workers who have done most to deepen analytic knowledge of the neuroses, such as Karl Abraham in Berlin and Sándor Ferenczi in Budapest (to name only the most prominent), have also played a leading part in throwing analytic light on the psychoses. The conviction of the unity and intimate connection of all the disorders that present themselves as neurotic and psychotic phenomena is becoming more and more firmly established despite all the efforts of the psychiatrists. People are beginning to understand - best of all, perhaps, in America - that the psycho-analytic study of the neuroses is the only preparation for an understanding of the psychoses, and that psycho-analysis is destined to make possible a scientific psychiatry of the future which will not need to content itself with describing curious clinical pictures and unintelligible sequences of events and with tracing the influence of gross anatomical and toxic traumas upon a mental apparatus which is inaccessible to our knowledge.

[1924f, 4114]

I now come to the description of a factor which adds an essential feature to my picture of analysis and which can claim, alike technically and theoretically, to be regarded as of the first importance. In every analytic treatment there arises, without the physician's agency, an intense emotional relationship between the patient and the analyst which is not to be accounted for by the actual situation. It can be of a positive or of a negative character and can vary between the extremes of a passionate, completely sensual love and the unbridled expression of an embittered defiance and hatred. This transference - to give it its short name - soon replaces in the patient's mind the desire to be cured, and, so long as it is affectionate and moderate, becomes the agent of the physician's influence and neither more nor less than the mainspring of the joint work of analysis. Later on, when it has become passionate or has been converted into hostility, it becomes the principal tool of the resistance. It may then happen that it will paralyse the patient's powers of associating and endanger the success of the treatment. Yet it would be senseless to try to evade it; for an analysis without transference is an impossibility. It must not be supposed, however, that transference is created by analysis and does not occur apart from it. Transference is merely uncovered and isolated by analysis. It is a universal phenomenon of the human mind, it decides the success of all medical influence, and in fact dominates the whole of each person's relations to his human environment. We can easily recognize it as the same dynamic factor which the hypnotists have named 'suggestibility', which is the agent of hypnotic rapport and whose incalculable behaviour led to difficulties with the cathartic method as well. When there is no inclination to a transference of emotion such as this, or when it has become entirely negative, as happens in dementia praecox or paranoia, then there is also no possibility of influencing the patient by psychological means.

[1925d, 4217]
The neuroses were the first subject of analysis, and for a long time they were the only one. No analyst could doubt that medical practice was wrong in separating those disorders from the psychoses and in attaching them to the organic nervous diseases. The theory of the neuroses belongs to psychiatry and is indispensable as an introduction to it. It would seem, however, that the analytic study of the psychoses is impracticable owing to its lack of therapeutic results. Mental patients are as a rule without the capacity for forming a positive transference, so that the principal instrument of analytic technique is inapplicable to them. There are nevertheless a number of methods of approach to be found. Transference is often not so completely absent but that it can be used to a certain extent; and analysis has achieved undoubted successes with cyclical depressions, light paranoic modifications, and partial schizophrenias. It has at least been a benefit to science that in many cases the diagnosis can oscillate for quite a long time between assuming the presence of a psychoneurosis or of a dementia praecox; for therapeutic attempts initiated in such cases have resulted in valuable discoveries before they have had to be broken off. But the chief consideration in this connection is that so many things that in the neuroses have to be laboriously fetched up from the depths are found in the psychoses on the surface, visible to every eye. For that reason the best subjects for the demonstration of many of the assertions of analysis are provided by the psychiatric clinic. It was thus bound to happen before long that analysis would find its way to the objects of psychiatric observation. I was able very early (1896) to establish in a case of paranoid dementia the presence of the same aetiological factors and the same emotional complexes as in the neuroses. Jung explained some most puzzling stereotypies in dementias by bringing them into relation with the patients' life-histories; Bleuler demonstrated the existence in various psychoses of mechanisms like those which analysis had discovered in neurotics. Since then analysts have never relaxed their efforts to come to an understanding of the psychoses. Especially since it has been possible to work with the concept of narcissism, they have managed, now in this place and now in that, to get a glimpse beyond the wall. Most of all, no doubt, was achieved by Abraham in his elucidation of the melancholias. It is true that in this sphere all our knowledge is not yet converted into therapeutic power; but the mere theoretical gain is not to be despised, and we may be content to wait for its practical application. In the long run even the psychiatrists cannot resist the convincing force of their own clinical material. At the present time German psychiatry is undergoing a kind of 'peaceful penetration' by analytic views. While they continually declare that they will never be psycho-analysts, that they do not belong to the 'orthodox' school or agree with its exaggerations, and in particular that they do not believe in the predominance of the sexual factor, nevertheless the majority of the younger workers take over one piece or another of analytic theory and apply it in their own fashion to the material. All the signs point to the proximity of further developments in the same direction.

[1925d, 4235]
Compared with the other psychotherapeutic procedures psycho-analysis is beyond any doubt the most powerful. It is just and fair, too, that this should be so for it is also the most laborious and time-consuming; it would not be used on slight cases. In suitable cases it is possible by its means to get rid of disturbances and bring about changes for which in pre-analytic times one would not have ventured to hope. But it has its very appreciable limits. The therapeutic ambition of some of my adherents has made the greatest efforts to overcome these obstacles so that every sort of neurotic disorder might be curable by psycho-analysis. They have endeavoured to compress the work of analysis into a shorter duration, to intensify transference so that it may be able to overcome any resistance, to unite other forms of influence with it so as to compel a cure. These efforts are certainly praiseworthy, but, in my opinion, they are vain. They bring with them, too, a danger of being oneself forced away from analysis and drawn into a boundless course of experimentation. The expectation that every neurotic phenomenon can be cured may, I suspect, be derived from the layman's belief that the neuroses are something quite unnecessary which have no right whatever to exist. Whereas in fact they are severe, constitutionally fixed illnesses, which rarely restrict themselves to only a few attacks but persist as a rule over long periods or throughout life. Our analytic experience that they can be extensively influenced, if the historical precipitating causes and accidental auxiliary factors of the illness can be dealt with, has led us to neglect the constitutional factor in our therapeutic practice, and in any case we can do nothing about it; but in theory we ought always to bear it in mind. The radical inaccessibility of the psychoses to analytic treatment should, in view of their close relationship to the neuroses, restrict our pretensions in regard to these latter. The therapeutic effectiveness of psycho-analysis remains cramped by a number of weighty and scarcely assailable factors. In the case of children, where one might count on the greatest successes, the difficulties are the external ones connected with their relation to their parents, though these difficulties are after all a necessary part of being a child. In the case of adults the difficulties arise in the first instance from two factors: the amount of psychical rigidity present and the form of the illness with all that that covers in the way of deeper determinants. 

1933a, 4752

The first of these factors is often unjustly overlooked. However great may be the plasticity of mental life and the possibility of reviving old conditions, not everything can be brought to life again. Some changes seem to be definitive and correspond to scars formed when a process has run its course. On other occasions one has an impression of a general stiffening of mental life; the psychical processes, to which one could very well indicate other paths, seem incapable of abandoning the old ones. But perhaps this is the same thing as what I mentioned just now, only looked at differently. All too often one seems to see that it is only the treatment's lack of the necessary motive force that prevents one from bringing the change about. One particular dependent relation, one special instinctual component, is too powerful in comparison with the opposing forces that we are able to mobilize. This is quite generally true with the psychoses. We understand them well enough to know the point at which the levers should be applied, but they would not be able to move the weight. It is here, indeed, that hope for the future lies: the possibility that our knowledge of the operation of the hormones (you know what they are) may give us the means of successfully combating the quantitative factors of the illnesses: but we are far from that to-day. I realize that the uncertainty in all these matters is a constant instigation towards perfecting analysis and in particular the transference. Beginners in analysis especially are left in doubt in case of a failure whether they should blame the peculiarities of the case or their own clumsy handling of the therapeutic procedure. But, as I have said already, I do not think much can be achieved by efforts in this direction. 

1933a, 4753
The second limitation upon analytic successes is given by the form of the illness. You know already that the field of application of analytic therapy lies in the transference neuroses - phobias, hysteria, obsessional neurosis - and further, abnormalities of character which have been developed in place of these illnesses. Everything differing from these, narcissistic and psychotic conditions, is unsuitable to a greater or less extent. It would be entirely legitimate to guard against failures by carefully excluding such cases. This precaution would lead to a great improvement in the statistics of analysis. There is, however, a pitfall here. Our diagnoses are very often made only after the event. They resemble the Scottish King's test for identifying witches that I read about in Victor Hugo. This king declared that he was in possession of an infallible method of recognizing a witch. He had the women stewed in a cauldron of boiling water and then tasted the broth. Afterwards he was able to say: 'That was a witch', or 'No, that was not one.' It is the same with us, except that we are the sufferers. We cannot judge the patient who comes for treatment (or, in the same way, the candidate who comes for training) till we have studied him analytically for a few weeks or months. We are in fact buying a pig in a poke. The patient brings along indefinite general ailments which do not admit of a conclusive diagnosis. After this period of testing it may turn out that the case is an unsuitable one. If so we send him away if he is a candidate, or continue the trial a little longer if he is a patient on the chance that we may yet see things in a more favourable light. The patient has his revenge by adding to our list of failures, and the rejected candidate does so perhaps, if he is paranoid, by writing books on psycho-analysis himself. As you see, our precautions have been of no avail. [1933a, 4754]

A dream, then, is a psychosis, with all the absurdities, delusions and illusions of a psychosis. A psychosis of short duration, no doubt, harmless, even entrusted with a useful function, introduced with the subject's consent and terminated by an act of his will. None the less it is a psychosis, and we learn from it that even so deep-going an alteration of mental life as this can be undone and can give place to the normal function. Is it too bold, then, to hope that it must also be possible to submit the dreaded spontaneous illnesses of mental life to our influence and bring about their cure? [1940a [1938], 4982]

Our plan of cure is based on these discoveries. The ego is weakened by the internal conflict and we must go to its help. The position is like that in a civil war which has to be decided by the assistance of an ally from outside. The analytic physician and the patient's weakened ego, basing themselves on the real external world, have to band themselves together into a party against the enemies, the instinctual demands of the id and the conscientious demands of the super-ego. We form a pact with each other. The sick ego promises us the most complete candour - promises, that is, to put at our disposal all the material which its self-perception yields it; we assure the patient of the strictest discretion and place at his service our experience in interpreting material that has been influenced by the unconscious. Our knowledge is to make up for his ignorance and to give his ego back its mastery over lost provinces of his mental life. This pact constitutes the analytic situation. [1940a [1938], 4983]

No sooner have we taken this step than a first disappointment awaits us, a first warning against over-confidence. If the patient's ego is to be a useful ally in our common work, it must, however hard it may be pressed by the hostile powers, have retained a certain amount of coherence and some fragment of understanding for the demands of reality. But this is not to be expected of the ego of a psychotic; it cannot observe a pact of this kind, indeed it can scarcely enter into one. It will very soon have tossed us away and the help we offer it and sent us to join the potions of the external world which no longer mean anything to it. Thus we discover that we must renounce the idea of trying our plan of cure upon psychotics - renounce it perhaps for ever or perhaps only for the time being, till we have found some other plan better adapted for them. [1940a [1938], 4983]
We have arrived at a general acquaintance with the psychical apparatus, with the parts, organs and agencies of which it is composed, with the forces which operate in it and with the functions allotted to its parts. The neuroses and psychoses are the states in which disturbances in the functioning of the apparatus come to expression. We have chosen the neuroses as the subjects of our study because they alone seem accessible to the psychological methods of our intervention. While we are trying to influence them, we collect observations which give us a picture of their origin and of the manner in which they arise.

The study of a mental disorder occurring during sleep, which is transient and harmless and which, indeed, performs a useful function, has given us a key to the understanding of the mental diseases which are permanent and injurious to life. And we may now venture on the assertion that the psychology of consciousness was no better capable of understanding the normal functioning of the mind than of understanding dreams. The data of conscious self-perception, which alone were at its disposal, have proved in every respect inadequate to fathom the profusion and complexity of the processes of the mind, to reveal their interconnections and so to recognize the determinants of their disturbances.

Concerning the third factor, the alteration of the ego, we have as yet said nothing. When we turn our attention to it, the first impression we receive is that there is much to ask and much to answer here, and that what we have to say about it will prove to be very inadequate. This first impression is confirmed when we go further into the problem. As is well known, the analytic situation consists in our allying ourselves with the ego of the person under treatment, in order to subdue portions of his id which are uncontrolled - that is to say to include them in the synthesis of his ego. The fact that a co-operation of this kind habitually fails in the case of psychotics affords us a first solid footing for our judgement. The ego, if we are to be able to make such a pact with it, must be a normal one. But a normal ego of this sort is, like normality in general, an ideal fiction. The abnormal ego, which is unserviceable for our purposes, is unfortunately no fiction. Every normal person, in fact, is only normal on the average. His ego approximates to that of the psychotic in some part or other and to a greater or lesser extent; and the degree of its remoteness from one end of the series and of its proximity to the other will furnish us with a provisional measure of what we have so indefinitely termed an 'alteration of the ego'.
This view of delusions is not, I think, entirely new, but it nevertheless emphasizes a point of view which is not usually brought into the foreground. The essence of it is that there is not only method in madness, as the poet has already perceived, but also a fragment of historical truth; and it is plausible to suppose that the compulsive belief attaching to delusions derives its strength precisely from infantile sources of this kind. All that I can produce to-day in support of this theory are reminiscences, not fresh impressions. It would probably be worth while to make an attempt to study cases of the disorder in question on the basis of the hypotheses that have been here put forward and also to carry out their treatment on those same lines. The vain effort would be abandoned of convincing the patient of the error of his delusion and of its contradiction of reality; and, on the contrary, the recognition of its kernel of truth would afford common ground upon which the therapeutic work could develop. That work would consist in liberating the fragment of historical truth from its distortions and its attachments to the actual present day and in leading it back to the point in the past to which it belongs. The transposing of material from a forgotten past on to the present or on to an expectation of the future is indeed a habitual occurrence in neurotics no less than in psychotics. Often enough, when a neurotic is led by an anxiety-state to expect the occurrence of some terrible event, he is in fact merely under the influence of a repressed memory (which is seeking to enter consciousness but cannot become conscious) that something which was at that time terrifying did really happen. I believe that we should gain a great deal of valuable knowledge from work of this kind upon psychotics even if it led to no therapeutic success.

[1937d, 5058]
A supervalent thought of this kind is often the only symptom, beyond deep depression, of a pathological condition which is usually described as 'melancholia', but which can be cleared up by psycho-analysis like a hysteria.
[1905e, 1391]

Dreams having served us as the prototype in normal life of narcissistic mental disorders, we will now try to throw some light on the nature of melancholia by comparing it with the normal affect of mourning. This time, however, we must begin by making an admission, as a warning against any over-estimation of the value of our conclusions. Melancholia, whose definition fluctuates even in descriptive psychiatry, takes on various clinical forms the grouping together of which into a single unity does not seem to be established with certainty; and some of these forms suggest somatic rather than psychogenic affections. Our material, apart from such impressions as are open to every observer, is limited to a small number of cases whose psychogenic nature was indisputable. We shall, therefore, from the outset drop all claim to general validity for our conclusions, and we shall console ourselves by reflecting that, with the means of investigation at our disposal to-day, we could hardly discover anything that was not typical, if not of a whole class of disorders, at least of a small group of them.
[1917e, 3041]

The distinguishing mental features of melancholia are a profoundly painful dejection, cessation of interest in the outside world, loss of the capacity to love, inhibition of all activity, and a lowering of the self-regarding feelings to a degree that finds utterance in self-reproaches and self-revilings, and culminates in a delusional expectation of punishment. This picture becomes a little more intelligible when we consider that, with one exception, the same traits are met with in mourning. The disturbance of self-regard is absent in mourning; but otherwise the features are the same. Profound mourning, the reaction to the loss of someone who is loved, contains the same painful frame of mind, the same loss of interest in the outside world - in so far as it does not recall him - the same loss of capacity to adopt any new object of love (which would mean replacing him) and the same turning away from any activity that is not connected with thoughts of him. It is easy to see that this inhibition and circumscription of the ego is the expression of an exclusive devotion to mourning which leaves nothing over for other purposes or other interests. It is really only because we know so well how to explain it that this attitude does not seem to us pathological.
[1917e, 3042]

We should regard it as an appropriate comparison, too, to call the mood of mourning a 'painful' one. We shall probably see the justification for this when we are in a position to give a characterization of the economics of pain.
[1917e, 3042]
In mourning we found that the inhibition and loss of interest are fully accounted for by the work of mourning in which the ego is absorbed. In melancholia, the unknown loss will result in a similar internal work and will therefore be responsible for the melancholic inhibition. The difference is that the inhibition of the melancholic seems puzzling to us because we cannot see what it is that is absorbing him so entirely. The melancholic displays something else besides which is lacking in mourning - an extraordinary diminution in his self-regard, an impoverishment of his ego on a grand scale. In mourning it is the world which has become poor and empty; in melancholia it is the ego itself. The patient represents his ego to us as worthless, incapable of any achievement and morally despicable; he reproaches himself, vilifies himself and expects to be cast out and punished. He abases himself before everyone and commiserates with his own relatives for being connected with anyone so unworthy. He is not of the opinion that a change has taken place in him, but extends his self-criticism back over the past; he declares that he was never any better. This picture of a delusion of (mainly moral) inferiority is completed by sleeplessness and refusal to take nourishment, and - what is psychologically very remarkable - by an overcoming of the instinct which compels every living thing to cling to life.

[1917e, 3043]

It would be equally fruitless from a scientific and a therapeutic point of view to contradict a patient who brings these accusations against his ego. He must surely be right in some way and be describing something that is as it seems to him to be. Indeed, we must at once confirm some of his statements without reservation. He really is as lacking in interest and as incapable of love and achievement as he says. But that, as we know, is secondary; it is the effect of the internal work which is consuming his ego work which is unknown to us but which is comparable to the work of mourning. He also seems to us justified in certain other self-accusations; it is merely that he has a keener eye for the truth than other people who are not melancholic. When in his heightened self-criticism he describes himself as petty, egoistic, dishonest, lacking in independence, one whose sole aim has been to hide the weaknesses of his own nature, it may be, so far as we know, that he has come pretty near to understanding himself; we only wonder why a man has to be ill before he can be accessible to a truth of this kind. For there can be no doubt that if anyone holds and expresses to others an opinion of himself such as this (an opinion which Hamlet held both of himself and of everyone else ¹), he is ill, whether he is speaking the truth or whether he is being more or less unfair to himself. Nor is it difficult to see that there is no correspondence, so far as we can judge, between the degree of self-abasement and its real justification. A good, capable, conscientious woman will speak no better of herself after she develops melancholia than one who is in fact worthless; indeed, the former is perhaps more likely to fall ill of the disease than the latter, of whom we too should have nothing good to say. Finally, it must strike us that after all the melancholic does not behave in quite the same way as a person who is crushed by remorse and self-reproach in a normal fashion. Feelings of shame in front of other people, which would more than anything characterize this latter condition, are lacking in the melancholic, or at least they are not prominent in him. One might emphasize the presence in him of an almost opposite trait of insistent communicativeness which finds satisfaction in self-exposure.

[1917e, 3044]

The essential thing, therefore, is not whether the melancholic's distressing self-denigration is correct, in the sense that his self-criticism agrees with the opinion of other people. The point must rather be that he is giving a correct description of his psychological situation. He has lost his self-respect and he must have good reason for this. It is true that we are then faced with a contradiction that presents a problem which is hard to solve. The analogy with mourning led us to conclude that he had suffered a loss in regard to an object; what he tells us points to a loss in regard to his ego.

[1917e, 3045]
Before going into this contradiction, let us dwell for a moment on the view which the melancholic's disorder affords of the constitution of the human ego. We see how in him one part of the ego sets itself over against the other, judges it critically, and, as it were, takes it as its object. Our suspicion that the critical agency which is here split off from the ego might also show its independence in other circumstances will be confirmed by every further observation. We shall really find grounds for distinguishing this agency from the rest of the ego. What we are here becoming acquainted with is the agency commonly called 'conscience'; we shall count it, along with the censorship of consciousness and reality-testing, among the major institutions of the ego, and we shall come upon evidence to show that it can become diseased on its own account. In the clinical picture of melancholia, dissatisfaction with the ego on moral grounds is the most outstanding feature. The patient's self-evaluation concerns itself much less frequently with bodily infirmity, ugliness or weakness, or with social inferiority; of this category, it is only his fears and asseverations of becoming poor that occupy a prominent position.

The woman who loudly pities her husband for being tied to such an incapable wife as herself is really accusing her husband of being incapable, in whatever sense she may mean this. There is no need to be greatly surprised that a few genuine self-reproaches are scattered among those that have been transposed back. These are allowed to obtrude themselves, since they help to mask the others and make recognition of the true state of affairs impossible. Moreover, they derive from the pros and cons of the conflict of love that has led to the loss of love. The behaviour of the patients, too, now becomes much more intelligible. Their complaints are really 'plaints' in the old sense of the word. They are not ashamed and do not hide themselves, since everything derogatory that they say about themselves is at bottom said about someone else. Moreover, they are far from evincing towards those around them the attitude of humility and submissiveness that would alone befit such worthless people. On the contrary, they make the greatest nuisance of themselves, and always seem as though they felt slighted and had been treated with great injustice. All this is possible only because the reactions expressed in their behaviour still proceed from a mental constellation of revolt, which has then, by a certain process, passed over into the crushed state of melancholia.

One or two things may be directly inferred with regard to the preconditions and effects of a process such as this. On the one hand, a strong fixation to the loved object must have been present; on the other hand, in contradiction to this, the object-cathexis must have had little power of resistance. As Otto Rank has aptly remarked, this contradiction seems to imply that the object-choice has been effected on a narcissistic basis, so that the object-cathexis, when obstacles come in its way, can regress to narcissism. The narcissistic identification with the object then becomes a substitute for the erotic cathexis, the result of which is that in spite of the conflict with the loved person the love-relation need not be given up. This substitution of identification for object-love is an important mechanism in the narcissistic affections; Karl Landauer (1914) has lately been able to point to it in the process of recovery in a case of schizophrenia. It represents, of course, a regression from one type of object-choice to original narcissism. We have elsewhere shown that identification is a preliminary stage of object-choice, that it is the first way - and one that is expressed in an ambivalent fashion - in which the ego picks out an object. The ego wants to incorporate this object into itself, and, in accordance with the oral or cannibalistic phase of libidinal development in which it is, it wants to do so by devouring it. Abraham is undoubtedly right in attributing to this connection the refusal of nourishment met with in severe forms of melancholia.
As regards one particular striking feature of melancholia that we have mentioned, the prominence of the fear of becoming poor, it seems plausible to suppose that it is derived from anal erotism which has been torn out of its context and altered in a regressive sense. [1917e, 3049]

As with paranoia, so also with melancholia (of which, incidentally, many different clinical forms have been described) we have found a point at which it has become possible to obtain some insight into the internal structure of the disease. We have discovered that the self-reproaches, with which these melancholic patients torment themselves in the most merciless fashion, in fact apply to another person, the sexual object which they have lost or which has become valueless to them through its own fault. From this we can conclude that the melancholic has, it is true, withdrawn his libido from the object, but that, by a process which we must call 'narcissistic identification', the object has been set up in the ego itself, has been as it were, projected on to the ego. (Here I can only give you a pictorial description and not an ordered account on topographical and dynamic lines.) The subject's own ego is then treated like the object that has been abandoned, and it is subjected to all the acts of aggression and expressions of vengefulness which have been aimed at the object. A melancholic's propensity to suicide is also made more intelligible if we consider that the patient's embitterment strikes with a single blow at his own ego and at the loved and hated object. In melancholia, as well as in other narcissistic disorders, a particular trait in the patient's emotional life emerges with peculiar emphasis - what, since Bleuler, we have been accustomed to describe as 'ambivalence'. By this we mean the direction towards the same person of contrary - affectionate and hostile - feelings. Unluckily I have been unable in the course of these lectures to tell you more about this emotional ambivalence. [1916-1917, 3471]

There are, however, other forms of illness in which, in spite of the conditions being the same, our therapeutic procedure is never successful. In them, too, it had been a question of an original conflict between the ego and the libido which led to repression - though this may call for a different topographical description; in them, too, it is possible to trace the points in the patient's life at which the repressions occurred; we make use of the same procedure, are ready to make the same promises and give the same help by the offer of anticipatory ideas; and once again the lapse of time between the repressions and the present day favours a different outcome to the conflict. And yet we do not succeed in lifting a single resistance or getting rid of a single repression. These patients, paranoics, melancholics, sufferers from dementia praecox, remain on the whole unaffected and proof against psycho-analytic therapy. What can be the reason for this? Not any lack of intelligence. A certain amount of intellectual capacity is naturally required in our patients; but there is certainly no lack of it in, for instance, the extremely shrewd combinatory paranoics. Nor do any of the other motives seem to be absent. Thus the melancholics have a very high degree of consciousness, absent in paranoics, that they are ill and that that is why they suffer so much; but this does not make them more accessible. We are faced here by a fact which we do not understand and which therefore leads us to doubt whether we have really understood all the determinants of our possible success with the other neuroses. [1916-1917, 3480]
I have argued elsewhere¹ that ‘war neuroses’ (in so far as that term implies something more than a reference to the circumstances of the illness's onset) may very well be traumatic neuroses which have been facilitated by a conflict in the ego. The fact to which I have referred in the first paragraph of Chapter II, that a gross physical injury caused simultaneously by the trauma diminishes the chances that a neurosis will develop, becomes intelligible if one bears in mind two facts which have been stressed by psycho-analytic research: firstly, that mechanical agitation must be recognized as one of the sources of sexual excitation,² and secondly, that painful and feverish illnesses exercise a powerful effect, so long as they last, on the distribution of libido. Thus, on the one hand, the mechanical violence of the trauma would liberate a quantity of sexual excitation which, owing to the lack of preparation for anxiety, would have a traumatic effect; but, on the other hand, the simultaneous physical injury, by calling for a narcissistic hypercathexis of the injured organ,³ would bind the excess of excitation. It is also well known, though the libido theory has not yet made sufficient use of the fact, that such severe disorders in the distribution of libido as melancholia are temporarily brought to an end by intercurrent organic illness, and in fact that even a fully developed condition of dementia praecox is capable of a temporary remission in these same circumstances.

Another such instance of introjection of the object has been provided by the analysis of melancholia, an affection which counts among the most notable of its exciting causes the real or emotional loss of a loved object. A leading characteristic of these cases is a cruel self-depreciation of the ego combined with relentless self-criticism and bitter self-reproaches. Analyses have shown that this disparagement and these reproaches apply at bottom to the object and represent the ego’s revenge upon it. The shadow of the object has fallen upon the ego, as I have said elsewhere.¹ The introjection of the object is here unmistakably clear.

But these melancholias also show us something else, which may be of importance for our later discussions. They show us the ego divided, fallen apart into two pieces, one of which rages against the second. This second piece is the one which has been altered by introjection and which contains the lost object. But the piece which behaves so cruelly is not unknown to us either. It comprises the conscience, a critical agency within the ego, which even in normal times takes up a critical attitude towards the ego, though never so relentlessly and so unjustifiably. On previous occasions² we have been driven to the hypothesis that some such agency develops in our ego which may cut itself off from the rest of the ego and come into conflict with it. We have called it the ‘ego ideal’, and by way of functions we have ascribed to it self-observation, the moral conscience, the censorship of dreams, and the chief influence in repression. We have said that it is the heir to the original narcissism in which the childish ego enjoyed self-sufficiency; it gradually gathers up from the influences of the environment the demands which that environment makes upon the ego and which the ego cannot always rise to; so that a man, when he cannot be satisfied with his ego itself, may nevertheless be able to find satisfaction in the ego ideal which has been differentiated out of the ego. In delusions of observation, as we have further shown, the disintegration of this agency has become patent, and has thus revealed its origin in the influence of superior powers, and above all of parents.³ But we have not forgotten to add that the amount of distance between this ego ideal and the real ego is very variable from one individual to another, and that with many people this differentiation within the ego does not go further than with children.

A change into mania is not an indispensable feature of the symptomatology of melancholic depression. There are simple melancholias, some in single and some in recurrent attacks, which never show this development.
On the other hand there are melancholias in which the precipitating cause clearly plays an aetiological part. They are those which occur after the loss of a loved object, whether by death or as the result of circumstances which have necessitated the withdrawal of the libido from the object. A psychogenic melancholia of this sort can end in mania, and this cycle can be repeated several times, just as easily as in a case which appears to be spontaneous. Thus the state of things is somewhat obscure, especially as only a few forms and cases of melancholia have been submitted to psycho-analytic investigation.¹ So far we only understand those cases in which the object is given up because it has shown itself unworthy of love. It is then set up again inside the ego, by means of identification, and severely condemned by the ego ideal. The reproaches and attacks directed towards the object come to light in the shape of melancholic self-reproaches.²

Nevertheless I see no difficulty in assigning to the factor of the periodic rebellion of the ego against the ego ideal a share in both kinds of melancholia, the psychogenic as well as the spontaneous. In the spontaneous kind it may be supposed that the ego ideal is inclined to display a peculiar strictness, which then results automatically in its temporary suspension. In the psychogenic kind the ego would be incited to rebellion by ill-treatment on the part of its ideal - an ill-treatment which it encounters when there has been identification with a rejected object.

In melancholia the impression that the super-ego has obtained a hold upon consciousness is even stronger. But here the ego ventures no objection; it admits its guilt and submits to the punishment. We understand the difference. In obsessional neurosis what were in question were objectionable impulses which remained outside the ego, while in melancholic the object to which the super-ego’s wrath applies has been taken into the ego through identification.

It is certainly not clear why the sense of guilt reaches such an extraordinary strength in these two neurotic disorders; but the main problem presented in this state of affairs lies in another direction. We shall postpone discussion of it until we have dealt with the other cases in which the sense of guilt remains unconscious.
The aetiology common to the onset of a psychoneurosis and of a psychosis always remains the same. It consists in a frustration, a non-fulfilment of one of those childhood wishes which are for ever undefeated and which are so deeply rooted in our phylogenetically determined organization. This frustration is in the last resort always an external one; but in the individual case it may proceed from the internal agency (in the super-ego) which has taken over the representation of the demands of reality. The pathogenic effect depends on whether, in a conflictual tension of this kind, the ego remains true to its dependence on the external world and attempts to silence the id, or whether it lets itself be overcome by the id and thus torn away from reality. A complication is introduced into this apparently simple situation, however, by the existence of the super-ego, which, though a link that is not yet clear to us, unites in itself influences coming from the id as well as from the external world, and is to some extent an ideal model of what the whole endeavour of the ego is aiming at - a reconciliation between its various dependent relationships. The attitude of the super-ego should be taken into account - which has not hitherto been done - in every form of psychical illness. We may provisionally assume that there must also be illnesses which are based on a conflict between the ego and the super-ego. Analysis gives us a right to suppose that melancholia is a typical example of this group; and we would set aside the name of 'narcissistic psychoneuropses' for disorders of that kind. Nor will it clash with our impressions if we find reasons for separating states like melancholia from the other psychoses. We now see that we have been able to make our simple genetic formula more complete, without dropping it. Transference neuroses correspond to a conflict between the ego and the id; narcissistic neuroses, to a conflict between the ego and the super-ego; and psychoses, to one between the ego and the external world. It is true that we cannot tell at once whether we have really gained any new knowledge by this, or have only enriched our store of formulas; but I think that this possible application of the proposed differentiation of the mental apparatus into an ego, a super-ego and an id cannot fail to give us courage to keep that hypothesis steadily in view.

[1924b, 4067]

The more generalized inhibitions of the ego obey a different mechanism of a simple kind. When the ego is involved in a particularly difficult psychical task, as occurs in mourning, or when there is some tremendous suppression of affect or when a continual flood of sexual phantasies has to be kept down, it loses so much of the energy at its disposal that it has to cut down the expenditure of it at many points at once. It is in the position of a speculator whose money has become tied up in his various enterprises. I came across an instructive example of this kind of intense, though short-lived, general inhibition. The patient, an obsessional neurotic, used to be overcome by a paralysing fatigue which lasted for one or more days whenever something occurred which should obviously have thrown him into a rage. We have here a point from which it should be possible to reach an understanding of the condition of general inhibition which characterizes states of depression, including the gravest form of them, melancholia.

[1926d, 4251]
Hardly have we familiarized ourselves with the idea of a super-ego like this which enjoys a certain degree of autonomy, follows its own intentions and is independent of the ego for its supply of energy, than a clinical picture forces itself on our notice which throws a striking light on the severity of this agency and indeed its cruelty, and on its changing relations to the ego. I am thinking of the condition of melancholia, or, more precisely, of melancholic attacks, which you too will have heard plenty about, even if you are not psychiatrists. The most striking feature of this illness, of whose causation and mechanism we know much too little, is the way in which the super-ego - 'conscience', you may call it, quietly - treats the ego. While a melancholic can, like other people, show a greater or lesser degree of severity to himself in his healthy periods, during a melancholic attack his super-ego becomes over-severe, abuses the poor ego, humiliates it and ill-treats it, threatens it with the direst punishments, reproaches it for actions in the remotest past which had been taken lightly at the time - as though it had spent the whole interval in collecting accusations and had only been waiting for its present access of strength in order to bring them up and make a condemnatory judgement on their basis. The super-ego applies the strictest moral standard to the helpless ego which is at its mercy; in general it represents the claims of morality, and we realize all at once that our moral sense of guilt is the expression of the tension between the ego and the super-ego. It is a most remarkable experience to see morality, which is supposed to have been given us by God and thus deeply implanted in us, functioning as a periodic phenomenon. For after a certain number of months the whole moral fuss is over, the criticism of the super-ego is silent, the ego is rehabilitated and again enjoys all the rights of man till the next attack. In some forms of the disease, indeed, something of a contrary sort occurs in the intervals; the ego finds itself in a blissful state of intoxication, it celebrates a triumph, as though the super-ego had lost all its strength or had melted into the ego; and this liberated, manic ego permits itself a truly uninhibited satisfaction of all its appetites. Here are happenings rich in unsolved riddles!

[1933a, 4669]
It is difficult to make any statement of general validity about neurasthenia, so long as we use that name to cover all the things which Beard has included under it. In my opinion, it can be nothing but a gain to neuropathology if we make an attempt to separate from neurasthenia proper all those neurotic disturbances in which, on the one hand, the symptoms are more firmly linked to one another than to the typical symptoms of neurasthenia (such as intracranial pressure, spinal irritation, and dyspepsia with flatulence and constipation); and which, on the other hand, exhibit essential differences in their aetiology and mechanism from the typical neurasthenic neurosis. If we accept this plan, we shall soon obtain a fairly uniform picture of neurasthenia. We shall then be in a position to differentiate from genuine neurasthenia more sharply than has hitherto been possible various pseudo-neurasthenias (such as the clinical picture of the organically determined nasal reflex neurosis, the nervous disorders of the cachexias and arterio-sclerosis, the preliminary stages of general paralysis of the insane, and of some psychoses). Further, it will be possible - as Möbius has proposed - to eliminate some of the status nervosi of hereditarily degenerate individuals; and we shall also discover reasons why a number of neuroses which are to-day described as neurasthenia - in particular, neuroses of an intermittent or periodical nature - ought rather to be included under melancholia. But the most marked change of all will be introduced if we decide to detach from neurasthenia the syndrome which I propose to describe in the following pages and which satisfies especially fully the conditions set out above. The symptoms of this syndrome are clinically much more closely related to one another than to those of genuine neurasthenia (that is, they frequently appear together and they replace one another in the course of the illness); and both the aetiology and the mechanism of this neurosis are fundamentally different from the aetiology and mechanism of genuine neurasthenia as it will be left after this separation has been effected.

[1895b, 327]
As with paranoia, so also with melancholia (of which, incidentally, many different clinical forms have been described) we have found a point at which it has become possible to obtain some insight into the internal structure of the disease. We have discovered that the self-reproaches, with which these melancholic patients torment themselves in the most merciless fashion, in fact apply to another person, the sexual object which they have lost or which has become valueless to them through its own fault. From this we can conclude that the melancholic has, it is true, withdrawn his libido from the object, but that, by a process which we must call 'narcissistic identification', the object has been set up in the ego itself, has been as it were, projected on to the ego. (Here I can only give you a pictorial description and not an ordered account on topographical and dynamic lines.) The subject's own ego is then treated like the object that has been abandoned, and it is subjected to all the acts of aggression and expressions of vengefulness which have been aimed at the object. A melancholic's propensity to suicide is also made more intelligible if we consider that the patient's embitterment strikes with a single blow at his own ego and at the loved and hated object. In melancholia, as well as in other narcissistic disorders, a particular trait in the patient's emotional life emerges with peculiar emphasis - what, since Bleuler, we have been accustomed to describe as 'ambivalence'. By this we mean the direction towards the same person of contrary - affectionate and hostile - feelings. Unluckily I have been unable in the course of these lectures to tell you more about this emotional ambivalence.

Let us keep to what is clear: On the basis of our analysis of the ego it cannot be doubted that in cases of mania the ego and the ego ideal have fused together, so that the person, in a mood of triumph and self-satisfaction, disturbed by no self-criticism, can enjoy the abolition of his inhibitions, his feelings of consideration for others, and his self-reproaches. It is not so obvious, but nevertheless very probable, that the misery of the melancholic is the expression of a sharp conflict between the two agencies of his ego, a conflict in which the ideal, in an excess of sensitiveness, relentlessly exhibits its condemnation of the ego in delusions of inferiority and in self-depreciation. The only question is whether we are to look for the causes of these altered relations between the ego and the ego ideal in the periodic rebellions, which we have postulated above, against the new institution, or whether we are to make other circumstances responsible for them.

On the other hand there are melancholias in which the precipitating cause clearly plays an aetiological part. They are those which occur after the loss of a loved object, whether by death or as the result of circumstances which have necessitated the withdrawal of the libido from the object. A psychogenic melancholia of this sort can end in mania, and this cycle can be repeated several times, just as easily as in a case which appears to be spontaneous. Thus the state of things is somewhat obscure, especially as only a few forms and cases of melancholia have been submitted to psycho-analytic investigation. So far we only understand those cases in which the object is given up because it has shown itself unworthy of love. It is then set up again inside the ego, by means of identification, and severely condemned by the ego ideal. The reproaches and attacks directed towards the object come to light in the shape of melancholic self-reproaches.
At this point we must widen our range a little. We succeeded in explaining the painful disorder of melancholia by supposing that an object which was lost has been set up again inside the ego - that is, that an object-cathexis has been replaced by an identification.⁵ At that time, however, we did not appreciate the full significance of this process and did not know how common and how typical it is. Since then we have come to understand that this kind of substitution has a great share in determining the form taken by the ego and that it makes an essential contribution towards building up what is called its 'character'.
[1923b, 3962]

An interpretation of the normal, conscious sense of guilt (conscience) presents no difficulties; it is based on the tension between the ego and the ego ideal and is the expression of a condemnation of the ego by its critical agency. The feelings of inferiority so well known in neurotics are presumably not far removed from it. In two very familiar maladies the sense of guilt is over-strongly conscious; in them the ego ideal displays particular severity and often rages against the ego in a cruel fashion. The attitude of the ego ideal in these two conditions, obsessional neurosis and melancholia, presents, alongside of this similarity, differences that are no less significant.
[1923b, 3985]

Let us again consider obsessional neurosis for a moment. The state of affairs is different here. The defusion of love into aggressiveness has not been effected by the work of the ego, but is the result of a regression which has come about in the id. But this process has extended beyond the id to the super-ego, which now increases its severity towards the innocent ego. It would seem, however, that in this case, no less than in that of melancholia, the ego, having gained control over the libido by means of identification, is punished for doing so by the super-ego through the instrumentality of the aggressiveness which was mixed with the libido.
[1923b, 3989]

The fear of death in melancholia only admits of one explanation: that the ego gives itself up because it feels itself hated and persecuted by the super-ego, instead of loved. To the ego, therefore, living means the same as being loved - being loved by the super-ego, which here again appears as the representative of the id. The super-ego fulfils the same function of protecting and saving that was fulfilled in earlier days by the father and later by Providence or Destiny. But, when the ego finds itself in an excessive real danger which it believes itself unable to overcome by its own strength, it is bound to draw the same conclusion. It sees itself deserted by all protecting forces and lets itself die. Here, moreover, is once again the same situation as that which underlay the first great anxiety-state of birth and the infantile anxiety of longing - the anxiety due to separation from the protecting mother.
[1923b, 3992]
It is true that it is by no means easy to demonstrate the traces of this satanic view of the father in the mental life of the individual. When a boy draws grotesque faces and caricatures, we may no doubt be able to show that he is jeering at his father in them; and when a person of either sex is afraid of robbers and burglars at night, it is not hard to recognize these as split off portions of the father.¹ The animals, too, which appear in children's animal phobias are most often father-substitutes, as were the totem animals of primaeval times. But that the Devil is a duplicate of the father and can act as a substitute for him has not been shown so clearly elsewhere as in the demonological neurosis of this seventeenth-century painter. That is why, at the beginning of this paper, I foretold that a demonological case history of this kind would yield in the form of pure metal material which, in the neuroses of a later epoch (no longer superstitious but hypochondriacal instead) has to be laboriously extracted by analytic work from the ore of free associations and symptoms.² A deeper penetration into the analysis of our painter's illness will probably bring stronger conviction. It is no unusual thing for a man to acquire a melancholic depression and an inhibition in his work as a result of his father's death. When this happens, we conclude that the man had been attached to his father with an especially strong love, and we remember how often a severe melancholia appears as a neurotic form of mourning.

[1923d, 4011]
We shall discover in various connections how much our enquiries benefit if certain states and phenomena which may be regarded as normal prototypes of pathological affections are brought up for purposes of comparison. Among these we may include such affective states as grief and being in love, as well as the state of sleep and the phenomenon of dreaming.

[1917d, 3027]

Dreams having served us as the prototype in normal life of narcissistic mental disorders, we will now try to throw some light on the nature of melancholia by comparing it with the normal affect of mourning. This time, however, we must begin by making an admission, as a warning against any over-estimation of the value of our conclusions. Melancholia, whose definition fluctuates even in descriptive psychiatry, takes on various clinical forms the grouping together of which into a single unity does not seem to be established with certainty; and some of these forms suggest somatic rather than psychogenic affections. Our material, apart from such impressions as are open to every observer, is limited to a small number of cases whose psychogenic nature was indisputable. We shall, therefore, from the outset drop all claim to general validity for our conclusions, and we shall console ourselves by reflecting that, with the means of investigation at our disposal to-day, we could hardly discover anything that was not typical, if not of a whole class of disorders, at least of a small group of them.

[1917e, 3041]

I cannot promise that this attempt will prove entirely satisfactory. It hardly carries us much beyond the possibility of taking one's initial bearings. We have two things to go upon: the first is a psycho-analytic impression, and the second what we may perhaps call a matter of general economic experience. The impression which several psycho-analytic investigators have already put into words is that the content of mania is no different from that of melancholia, that both disorders are wrestling with the same 'complex', but that probably in melancholia the ego has succumbed to the complex whereas in mania it has mastered it or pushed it aside. Our second pointer is afforded by the observation that all states such as joy, exultation or triumph, which give us the normal model for mania, depend on the same economic conditions. What has happened here is that, as a result of some influence, a large expenditure of psychical energy, long maintained or habitually occurring, has at last become unnecessary, so that it is available for numerous applications and possibilities of discharge - when, for instance, some poor wretch, by winning a large sum of money, is suddenly relieved from chronic worry about his daily bread, or when a long and arduous struggle is finally crowned with success, or when a man finds himself in a position to throw off at a single blow some oppressive compulsion, some false position which he has long had to keep up, and so on. All such situations are characterized by high spirits, by the signs of discharge of joyful emotion and by increased readiness for all kinds of action - in just the same way as in mania, and in complete contrast to the depression and inhibition of melancholia. We may venture to assert that mania is nothing other than a triumph of this sort, only that here again what the ego has surmounted and what it is triumphing over remain hidden from it. Alcoholic intoxication, which belongs to the same class of states, may (in so far as it is an elated one) be explained in the same way; here there is probably a suspension, produced by toxins, of expenditures of energy in repression. The popular view likes to assume that a person in a manic state of this kind finds such delight in movement and action because he is so 'cheerful'. This false connection must of course be put right. The fact is that the economic condition in the subject's mind referred to above has been fulfilled, and this is the reason why he is in such high spirits on the one hand and so uninhibited in action on the other.

[1917e, 3050]
We began at an early date to extend psycho-analytic observations to these other illnesses. Already in 1908 Karl Abraham, after an exchange of thoughts with me, pronounced the main characteristic of dementia praecox (which was reckoned among the psychoses) to be that *in it the libidinal cathexis of objects was lacking*. But the question then arose of what happened to the libido of dementia praecox patients which was turned away from objects. Abraham did not hesitate to give the answer: it is turned back on to the ego and *this reflexive turning-back is the source of the megalomania* in dementia praecox. Megalomania is in every way comparable to the familiar sexual overvaluation of the object in erotic life. In this way for the first time we learnt to understand a trait in a psychotic illness by relating it to normal erotic life. [1916-1917, 3461]
He went on to adduce the fact of his illness having become so enormously intensified since his father's death; and I said I agreed with him in so far as I regarded his sorrow at his father's death as the chief source of the intensity of his illness. His sorrow had found, as it were, a pathological expression in his illness. Whereas, I told him, a normal period of mourning would last from one to two years, a pathological one like this would last indefinitely.

[1909d, 2146]

Gentlemen, - I have an impression that, in spite of all the valuable material that has been brought before us in this discussion, we have not reached a decision on the problem that interests us. We were anxious above all to know how it becomes possible for the extraordinarily powerful life instinct to be overcome: whether this can only come about with the help of a disappointed libido or whether the ego can renounce its self-preservation for its own egoistic motives. It may be that we have failed to answer this psychological question because we have no adequate means of approaching it. We can, I think, only take as our starting-point the condition of melancholia, which is so familiar to us clinically, and a comparison between it and the affect of mourning. The affective processes in melancholia, however, and the vicissitudes undergone by the libido in that condition, are totally unknown to us. Nor have we arrived at a psycho-analytic understanding of the chronic affect of mourning. Let us suspend our judgement till experience has solved this problem.

[1910g, 2381]

Dreams having served us as the prototype in normal life of narcissistic mental disorders, we will now try to throw some light on the nature of melancholia by comparing it with the normal affect of mourning. This time, however, we must begin by making an admission, as a warning against any over-estimation of the value of our conclusions. Melancholia, whose definition fluctuates even in descriptive psychiatry, takes on various clinical forms the grouping together of which into a single unity does not seem to be established with certainty; and some of these forms suggest somatic rather than psychogenic affections. Our material, apart from such impressions as are open to every observer, is limited to a small number of cases whose psychogenic nature was indisputable. We shall, therefore, from the outset drop all claim to general validity for our conclusions, and we shall console ourselves by reflecting that, with the means of investigation at our disposal to-day, we could hardly discover anything that was not typical, if not of a whole class of disorders, at least of a small group of them.

[1917e, 3041]

The correlation of melancholia and mourning seems justified by the general picture of the two conditions.¹ Moreover, the exciting causes due to environmental influences are, so far as we can discern them at all, the same for both conditions. Mourning is regularly the reaction to the loss of a loved person, or to the loss of some abstraction which has taken the place of one, such as one's country, liberty, an ideal, and so on. In some people the same influences produce melancholia instead of mourning and we consequently suspect them of a pathological disposition. It is also well worth notice that, although mourning involves grave departures from the normal attitude to life, it never occurs to us to regard it as a pathological condition and to refer it to medical treatment. We rely on its being overcome after a certain lapse of time, and we look upon any interference with it as useless or even harmful.

[1917e, 3041]

¹ Abraham (1912), to whom we owe the most important of the few analytic studies on this subject, also took this comparison as his starting point.

[1917e, 3041]
The distinguishing mental features of melancholia are a profoundly painful dejection, cessation of interest in the outside world, loss of the capacity to love, inhibition of all activity, and a lowering of the self-regarding feelings to a degree that finds utterance in self-reproaches and self-revilings, and culminates in a delusional expectation of punishment. This picture becomes a little more intelligible when we consider that, with one exception, the same traits are met with in mourning. The disturbance of self-regard is absent in mourning; but otherwise the features are the same. Profound mourning, the reaction to the loss of someone who is loved, contains the same painful frame of mind, the same loss of interest in the outside world - in so far as it does not recall him - the same loss of capacity to adopt any new object of love (which would mean replacing him) and the same turning away from any activity that is not connected with thoughts of him. It is easy to see that this inhibition and circumscription of the ego is the expression of an exclusive devotion to mourning which leaves nothing over for other purposes or other interests. It is really only because we know so well how to explain it that this attitude does not seem to us pathological.

Let us now apply to melancholia what we have learnt about mourning. In one set of cases it is evident that melancholia too may be the reaction to the loss of a loved object. Where the exciting causes are different one can recognize that there is a loss of a more ideal kind. The object has not perhaps actually died, but has been lost as an object of love (e.g. in the case of a betrothed girl who has been jilted). In yet other cases one feels justified in maintaining the belief that a loss of this kind has occurred, but one cannot see clearly what it is that has been lost, and it is all the more reasonable to suppose that the patient cannot consciously perceive what he has lost either. This, indeed, might be so even if the patient is aware of the loss which has given rise to his melancholia, but only in the sense that he knows whom he has lost but not what he has lost in him. This would suggest that melancholia is in some way related to an object-loss which is withdrawn from consciousness, in contradistinction to mourning, in which there is nothing about the loss that is unconscious.

In mourning we found that the inhibition and loss of interest are fully accounted for by the work of mourning in which the ego is absorbed. In melancholia, the unknown loss will result in a similar internal work and will therefore be responsible for the melancholic inhibition. The difference is that the inhibition of the melancholic seems puzzling to us because we cannot see what it is that is absorbing him so entirely. The melancholic displays something else besides which is lacking in mourning - an extraordinary diminution in his self-regard, an impoverishment of his ego on a grand scale. In mourning it is the world which has become poor and empty; in melancholia it is the ego itself. The patient represents his ego to us as worthless, incapable of any achievement and morally despicable; he reproaches himself, vilifies himself and expects to be cast out and punished. He abases himself before everyone and commiserates with his own relatives for being connected with anyone so unworthy. He is not of the opinion that a change has taken place in him, but extends his self-criticism back over the past; he declares that he was never any better. This picture of a delusion of (mainly moral) inferiority is completed by sleeplessness and refusal to take nourishment, and - what is psychologically very remarkable - by an overcoming of the instinct which compels every living thing to cling to life.
Melancholia, therefore, borrows some of its features from mourning, and the others from the process of regression from narcissistic object-choice to narcissism. It is on the one hand, like mourning, a reaction to the real loss of a loved object; but over and above this, it is marked by a determinant which is absent in normal mourning or which, if it is present, transforms the latter into pathological mourning. The loss of a love-object is an excellent opportunity for the ambivalence in love-relationships to make itself effective and come into the open. Where there is a disposition to obsessional neurosis the conflict due to ambivalence gives a pathological cast to mourning and forces it to express itself in the form of self-reproaches to the effect that the mourner himself is to blame for the loss of the loved object, i.e. that he has willed it. These obsessional states of depression following upon the death of a loved person show us what the conflict due to ambivalence can achieve by itself when there is no regressive drawing-in of libido as well. In melancholia, the occasions which give rise to the illness extend for the most part beyond the clear case of a loss by death, and include all those situations of being slighted, neglected or disappointed, which can import opposed feelings of love and hate into the relationship or reinforce an already existing ambivalence. This conflict due to ambivalence, which sometimes arises more from real experiences, sometimes more from constitutional factors, must not be overlooked among the preconditions of melancholia. If the love for the object - a love which cannot be given up though the object itself is given up - takes refuge in narcissistic identification, then the hate comes into operation on this substitutive object, abusing it, debasing it, making it suffer and deriving sadistic satisfaction from its suffering. The self-tormenting in melancholia, which is without doubt enjoyable, signifies, just like the corresponding phenomenon in obsessional neurosis, a satisfaction of trends of sadism and hate which relate to an object, and which have been turned round upon the subject's own self in the ways we have been discussing. In both disorders the patients usually still succeed, by the circuitous path of self-punishment, in taking revenge on the original object and in tormenting their loved one through their illness, having resorted to it in order to avoid the need to express their hostility to him openly. After all, the person who has occasioned the patient's emotional disorder, and on whom his illness is centred, is usually to be found in his immediate environment. The melancholic's erotic cathexis in regard to his object has thus undergone a double vicissitude: part of it has regressed to identification, but the other part, under the influence of the conflict due to ambivalence, has been carried back to the stage of sadism which is nearer to that conflict.

[1917e, 3048]

In the first place, normal mourning, too, overcomes the loss of the object, and it, too, while it lasts, absorbs all the energies of the ego. Why, then, after it has run its course, is there no hint in its case of the economic condition for a phase of triumph? I find it impossible to answer this objection straight away. It also draws our attention to the fact that we do not even know the economic means by which mourning carries out its task. Possibly, however, a conjecture will help us here. Each single one of the memories and situations of expectancy which demonstrate the libido's attachment to the lost object is met by the verdict of reality that the object no longer exists; and the ego, confronted as it were with the question whether it shall share this fate, is persuaded by the sum of the narcissistic satisfactions it derives from being alive to sever its attachment to the object that has been abolished. We may perhaps suppose that this work of severance is so slow and gradual that by the time it has been finished the expenditure of energy necessary for it is also dissipated.¹

[1917e, 3051]
It is tempting to go on from this conjecture about the work of mourning and try to give an account of the work of melancholia. Here we are met at the outset by an uncertainty. So far we have hardly considered melancholia from the topographical point of view, nor asked ourselves in and between what psychical systems the work of melancholia goes on. What part of the mental processes of the disease still takes place in connection with the unconscious object-cathexes that have been given up, and what part in connection with their substitute, by identification, in the ego? [1917e, 3051]

The quick and easy answer is that 'the unconscious (thing-) presentation of the object has been abandoned by the libido'. In reality, however, this presentation is made up of innumerable single impressions (or unconscious traces of them), and this withdrawal of libido is not a process that can be accomplished in a moment, but must certainly, as in mourning, be one in which progress is long-drawn-out and gradual. Whether it begins simultaneously at several points or follows some sort of fixed sequence is not easy to decide; in analyses it often becomes evident that first one and then another memory is activated, and that the laments which always sound the same and are wearisome in their monotony nevertheless take their rise each time in some different unconscious source. If the object does not possess this great significance for the ego - a significance reinforced by a thousand links - then, too, its loss will not be of a kind to cause either mourning or melancholia. This characteristic of detaching the libido bit by bit is therefore to be ascribed alike to mourning and to melancholia; it is probably supported by the same economic situation and serves the same purposes in both. [1917e, 3052]

As we have seen, however, melancholia contains something more than normal mourning. In melancholia the relation to the object is no simple one; it is complicated by the conflict due to ambivalence. The ambivalence is either constitutional, i.e. is an element of every love-relation formed by this particular ego, or else it proceeds precisely from those experiences that involved the threat of losing the object. For this reason the exciting causes of melancholia have a much wider range than those of mourning, which is for the most part occasioned only by a real loss of the object, by its death. In melancholia, accordingly, countless separate struggles are carried on over the object, in which hate and love contend with each other; the one seeks to detach the libido from the object, the other to maintain this position of the libido against the assault. The location of these separate struggles cannot be assigned to any system but the Ucs., the region of the memory-traces of things (as contrasted with word-cathexes). In mourning, too, the efforts to detach the libido are made in this same system; but in it nothing hinders these processes from proceeding along the normal path through the Pcs. to consciousness. This path is blocked for the work of melancholia, owing perhaps to a number of causes or a combination of them. Constitutional ambivalence belongs by its nature to the repressed; traumatic experiences in connection with the object may have activated other repressed material. Thus everything to do with these struggles due to ambivalence remains withdrawn from consciousness, until the outcome characteristic of melancholia has set in. This, as we know, consists in the threatened libidinal cathexis at length abandoning the object, only, however, to draw back to the place in the ego from which it had proceeded. So by taking flight into the ego love escapes extinction. After this regression of the libido the process can become conscious, and it is represented to consciousness as a conflict between one part of the ego and the critical agency. [1917e, 3052]
What consciousness is aware of in the work of melancholia is thus not the essential part of it, nor is it even the part which we may credit with an influence in bringing the ailment to an end. We see that the ego debases itself and rages against itself, and we understand as little as the patient what this can lead to and how it can change. We can more readily attribute such a function to the unconscious part of the work, because it is not difficult to perceive an essential analogy between the work of melancholia and of mourning. Just as mourning impels the ego to give up the object by declaring the object to be dead and offering the ego the inducement of continuing to live, so does each single struggle of ambivalence loosen the fixation of the libido to the object by disparaging it, denigrating it and even as it were killing it. It is possible for the process in the Ucs. to come to an end, either after the fury has spent itself or after the object has been abandoned as valueless. We cannot tell which of these two possibilities is the regular or more usual one in bringing melancholia to an end, nor what influence this termination has on the future course of the case. The ego may enjoy in this the satisfaction of knowing itself as the better of the two, as superior to the object.

Even if we accept this view of the work of melancholia, it still does not supply an explanation of the one point on which we were seeking light. It was our expectation that the economic condition for the emergence of mania after the melancholia has run its course is to be found in the ambivalence which dominates the latter affection; and in this we found support from analogies in various other fields. But there is one fact before which that expectation must bow. Of the three preconditions of melancholia - loss of the object, ambivalence, and regression of libido into the ego - the first two are also found in the obsessional self-reproaches arising after a death has occurred. In those cases it is unquestionably the ambivalence which is the motive force of the conflict, and observation shows that after the conflict has come to an end there is nothing left over in the nature of the triumph of a manic state of mind. We are thus led to the third factor as the only one responsible for the result. The accumulation of cathexis which is at first bound and then, after the work of melancholia is finished, becomes free and makes mania possible must be linked with regression of the libido to narcissism. The conflict within the ego, which melancholia substitutes for the struggle over the object, must act like a painful wound which calls for an extraordinarily high anticathexis. - But here once again, it will be well to call a halt and to postpone any further explanation of mania until we have gained some insight into the economic nature, first, of physical pain, and then of the mental pain which is analogous to it. As we already know, the interdependence of the complicated problems of the mind forces us to break off every enquiry before it is completed - till the outcome of some other enquiry can come to its assistance.¹

Here once more, then, we must break off the course we have started on. For the moment it leads no further and we shall have to learn all kinds of other things before we can find its proper continuation. But on the subject of fixation to a particular phase in the past we may add that such behaviour is far more widespread than neurosis. Every neurosis includes a fixation of that kind, but not every fixation leads to a neurosis, coincides with a neurosis or arises owing to a neurosis. A perfect model of an affective fixation to something that is past is provided by mourning, which actually involves the most complete alienation from the present and the future. But even the judgement of a layman will distinguish sharply between mourning and neurosis. There are, on the other hand, neuroses which may be described as a pathological form of mourning.

¹ [1917e, 3053]
Let us now apply to melancholia what we have learnt about mourning. In one set of cases it is evident that melancholia too may be the reaction to the loss of a loved object. Where the exciting causes are different one can recognize that there is a loss of a more ideal kind. The object has not perhaps actually died, but has been lost as an object of love (e.g. in the case of a betrothed girl who has been jilted). In yet other cases one feels justified in maintaining the belief that a loss of this kind has occurred, but one cannot see clearly what it is that has been lost, and it is all the more reasonable to suppose that the patient cannot consciously perceive what he has lost either. This, indeed, might be so even if the patient is aware of the loss which has given rise to his melancholia, but only in the sense that he knows whom he has lost but not what he has lost in him. This would suggest that melancholia is in some way related to an object-loss which is withdrawn from consciousness, in contradistinction to mourning, in which there is nothing about the loss that is unconscious.

In mourning we found that the inhibition and loss of interest are fully accounted for by the work of mourning in which the ego is absorbed. In melancholia, the unknown loss will result in a similar internal work and will therefore be responsible for the melancholic inhibition. The difference is that the inhibition of the melancholic seems puzzling to us because we cannot see what it is that is absorbing him so entirely. The melancholic displays something else besides which is lacking in mourning - an extraordinary diminution in his self-regard, an impoverishment of his ego on a grand scale. In mourning it is the world which has become poor and empty; in melancholia it is the ego itself. The patient represents his ego to us as worthless, incapable of any achievement and morally despicable; he reproaches himself, vilifies himself and expects to be cast out and punished. He abases himself before everyone and commiserates with his own relatives for being connected with anyone so unworthy. He is not of the opinion that a change has taken place in him, but extends his self-criticism back over the past; he declares that he was never any better. This picture of a delusion of (mainly moral) inferiority is completed by sleeplessness and refusal to take nourishment, and - what is psychologically very remarkable - by an overcoming of the instinct which compels every living thing to cling to life.

[1917e, 3043]
Melancholia, therefore, borrows some of its features from mourning, and the others from the process of regression from narcissistic object-choice to narcissism. It is on the one hand, like mourning, a reaction to the real loss of a loved object; but over and above this, it is marked by a determinant which is absent in normal mourning or which, if it is present, transforms the latter into pathological mourning. The loss of a love-object is an excellent opportunity for the ambivalence in love-relationships to make itself effective and come into the open. Where there is a disposition to obsessional neurosis the conflict due to ambivalence gives a pathological cast to mourning and forces it to express itself in the form of self-reproaches to the effect that the mourner himself is to blame for the loss of the loved object, i.e. that he has willed it. These obsessional states of depression following upon the death of a loved person show us what the conflict due to ambivalence can achieve by itself when there is no regressive drawing-in of libido as well. In melancholia, the occasions which give rise to the illness extend for the most part beyond the clear case of a loss by death, and include all those situations of being slighted, neglected or disappointed, which can import opposed feelings of love and hate into the relationship or reinforce an already existing ambivalence. This conflict due to ambivalence, which sometimes arises more from real experiences, sometimes more from constitutional factors, must not be overlooked among the preconditions of melancholia. If the love for the object - a love which cannot be given up though the object itself is given up - takes refuge in narcissistic identification, then the hate comes into operation on this substitutive object, abusing it, debasing it, making it suffer and deriving sadistic satisfaction from its suffering. The self-tormenting in melancholia, which is without doubt enjoyable, signifies, just like the corresponding phenomenon in obsessional neurosis, a satisfaction of trends of sadism and hate which relate to an object, and which have been turned round upon the subject's own self in the ways we have been discussing. In both disorders the patients usually still succeed, by the circuitous path of self-punishment, in taking revenge on the original object and in tormenting their loved one through their illness, having resorted to it in order to avoid the need to express their hostility to him openly. After all, the person who has occasioned the patient's emotional disorder, and on whom his illness is centred, is usually to be found in his immediate environment. The melancholic's erotic cathectic in regard to his object has thus undergone a double vicissitude: part of it has regressed to identification, but the other part, under the influence of the conflict due to ambivalence, has been carried back to the stage of sadism which is nearer to that conflict.

[1917e, 3048]
Even if we accept this view of the work of melancholia, it still does not supply an explanation of the one point on which we were seeking light. It was our expectation that the economic condition for the emergence of mania after the melancholia has run its course is to be found in the ambivalence which dominates the latter affection; and in this we found support from analogies in various other fields. But there is one fact before which that expectation must bow. Of the three preconditions of melancholia - loss of the object, ambivalence, and regression of libido into the ego - the first two are also found in the obsessional self-reproaches arising after a death has occurred. In those cases it is unquestionably the ambivalence which is the motive force of the conflict, and observation shows that after the conflict has come to an end there is nothing left over in the nature of the triumph of a manic state of mind. We are thus led to the third factor as the only one responsible for the result. The accumulation of cathectes which is at first bound and then, after the work of melancholia is finished, becomes free and makes mania possible must be linked with regression of the libido to narcissism. The conflict within the ego, which melancholia substitutes for the struggle over the object, must act like a painful wound which calls for an extraordinarily high anticathexis. - But here once again, it will be well to call a halt and to postpone any further explanation of mania until we have gained some insight into the economic nature, first, of physical pain, and then of the mental pain which is analogous to it. As we already know, the interdependence of the complicated problems of the mind forces us to break off every enquiry before it is completed - till the outcome of some other enquiry can come to its assistance.¹

As with paranoia, so also with melancholia (of which, incidentally, many different clinical forms have been described) we have found a point at which it has become possible to obtain some insight into the internal structure of the disease. We have discovered that the self-reproaches, with which these melancholic patients torment themselves in the most merciless fashion, in fact apply to another person, the sexual object which they have lost or which has become valueless to them through its own fault. From this we can conclude that the melancholic has, it is true, withdrawn his libido from the object, but that, by a process which we must call 'narcissistic identification', the object has been set up in the ego itself, has been as it were, projected on to the ego. (Here I can only give you a pictorial description and not an ordered account on topographical and dynamic lines.) The subject's own ego is then treated like the object that has been abandoned, and it is subjected to all the acts of aggression and expressions of vengefulness which have been aimed at the object. A melancholic's propensity to suicide is also made more intelligible if we consider that the patient's embitterment strikes with a single blow at his own ego and at the loved and hated object. In melancholia, as well as in other narcissistic disorders, a particular trait in the patient's emotional life emerges with peculiar emphasis - what, since Bleuler, we have been accustomed to describe as 'ambivalence'. By this we mean the direction towards the same person of contrary - affectionate and hostile - feelings. Unluckily I have been unable in the course of these lectures to tell you more about this emotional ambivalence.

Another such instance of introjection of the object has been provided by the analysis of melancholia, an affection which counts among the most notable of its exciting causes the real or emotional loss of a loved object. A leading characteristic of these cases is a cruel self-depreciation of the ego combined with relentless self-criticism and bitter self-reproaches. Analyses have shown that this disparagement and these reproaches apply at bottom to the object and represent the ego's revenge upon it. The shadow of the object has fallen upon the ego, as I have said elsewhere.¹ The introjection of the object is here unmistakably clear. [1921c, 3801]
On the other hand there are melancholias in which the precipitating cause clearly plays an aetiological part. They are those which occur after the loss of a loved object, whether by death or as the result of circumstances which have necessitated the withdrawal of the libido from the object. A psychogenic melancholia of this sort can end in mania, and this cycle can be repeated several times, just as easily as in a case which appears to be spontaneous. Thus the state of things is somewhat obscure, especially as only a few forms and cases of melancholia have been submitted to psycho-analytic investigation.¹ So far we only understand those cases in which the object is given up because it has shown itself unworthy of love. It is then set up again inside the ego, by means of identification, and severely condemned by the ego ideal. The reproaches and attacks directed towards the object come to light in the shape of melancholic self-reproaches.²

I cannot neglect this opportunity of expressing for once my astonishment that human beings can go through such great and important moments of their erotic life without noticing them much, sometimes even, indeed, without having the faintest suspicion of their existence, or else, having become aware of those moments, deceive themselves so thoroughly in their judgement of them. This happens not only under neurotic conditions, where we are familiar with the phenomenon, but seems also to be common enough in ordinary life. In the present case, for example, a girl develops a sentimental adoration for women, which her parents at first find merely vexatious and hardly take seriously; she herself knows quite well that she is very much occupied with these relationships, but still she experiences few of the sensations of intense love until a particular frustration is followed by a quite excessive reaction, which shows everyone concerned that they have to do with a consuming passion of elemental strength. Nor had the girl ever perceived anything of the state of affairs which was a necessary preliminary to the outbreak of this mental storm. In other cases, too, we come across girls or women in a state of severe depression, who on being asked for a possible cause of their condition tell us that they have, it is true, had a slight feeling for a certain person, but that it was nothing deep and that they soon got over it when they had to give it up. And yet it was this renunciation, apparently so easily borne, that became the cause of serious mental disturbance. Again, we come across men who have passed through casual love-affairs and realize only from the subsequent effects that they had been passionately in love with the person whom they had apparently regarded lightly. One is also amazed at the unexpected results that may follow an artificial abortion, the killing of an unborn child, which had been decided upon without remorse and without hesitation. It must be admitted that poets are right in liking to portray people who are in love without knowing it, or uncertain whether they do love, or who think that they hate when in reality they love. It would seem that the information received by our consciousness about our erotic life is especially liable to be incomplete, full of gaps, or falsified. Needless to say, in this discussion I have not omitted to allow for the part played by subsequent forgetting.

At this point we must widen our range a little. We succeeded in explaining the painful disorder of melancholia by supposing that an object which was lost has been set up again inside the ego - that is, that an object-cathexis has been replaced by an identification.³ At that time, however, we did not appreciate the full significance of this process and did not know how common and how typical it is. Since then we have come to understand that this kind of substitution has a great share in determining the form taken by the ego and that it makes an essential contribution towards building up what is called its ‘character’.⁴
It is true that it is by no means easy to demonstrate the traces of this satanic view of the father in the mental life of the individual. When a boy draws grotesque faces and caricatures, we may no doubt be able to show that he is jeering at his father in them; and when a person of either sex is afraid of robbers and burglars at night, it is not hard to recognize these as split off portions of the father.¹ The animals, too, which appear in children’s animal phobias are most often father-substitutes, as were the totem animals of praeval times. But that the Devil is a duplicate of the father and can act as a substitute for him has not been shown so clearly elsewhere as in the demonological neurosis of this seventeenth-century painter. That is why, at the beginning of this paper, I foretold that a demonological case history of this kind would yield in the form of pure metal material which, in the neuroses of a later epoch (no longer superstitious but hypochondriacal instead) has to be laboriously extracted by analytic work from the ore of free associations and symptoms.² A deeper penetration into the analysis of our painter’s illness will probably bring stronger conviction. It is no unusual thing for a man to acquire a melancholic depression and an inhibition in his work as a result of his father’s death. When this happens, we conclude that the man had been attached to his father with an especially strong love, and we remember how often a severe melancholia appears as a neurotic form of mourning.

[1923d, 4011]

In this we are undoubtedly right. But we are not right if we conclude further that this relation has been merely one of love. On the contrary, his mourning over the loss of his father is the more likely to turn into melancholia, the more his attitude to him bore the stamp of ambivalence. This emphasis on ambivalence, however, prepares us for the possibility of the father being subjected to a debasement, as we see happening in the painter’s demonological neurosis. If we were able to learn as much about Christoph Haizmann as about a patient undergoing an analysis with us, it would be an easy matter to elicit this ambivalence, to get him to remember when and under what provocations he was given cause to fear and hate his father; and, above all, to discover what were the accidental factors that were added to the typical motives for a hatred of the father which are necessarily inherent in the natural relationship of son to father. Perhaps we might then find a special explanation for the painter’s inhibition in work. It is possible that his father had opposed his wish to become a painter. If that was so, his inability to practise his art after his father’s death would on the one hand be an expression of the familiar phenomenon of ‘deferred obedience’; and, on the other hand, by making him incapable of earning a livelihood, it would be bound to increase his longing for his father as a protector from the cares of life. In its aspect as deferred obedience it would also be an expression of remorse and a successful self-punishment.

[1923d, 4012]
We also occasionally come across this same fact of the traumas accumulated during sick-nursing being dealt with subsequently, where we get no general impression of illness but where the mechanism of hysteria is nevertheless retained. Thus I am acquainted with a highly-gifted lady who suffers from slight nervous states and whose whole character bears evidence of hysteria, though she has never had to seek medical help or been unable to carry on her duties. She has already nursed to the end three or four of those whom she loved. Each time she reached a state of complete exhaustion; but she did not fall ill after these tragic efforts. Shortly after her patient's death, however, there would begin in her a work of reproduction which once more brought up before her eyes the scenes of the illness and death. Every day she would go through each impression once more, would weep over it and console herself - at her leisure, one might say. This process of dealing with her impressions was dovetailed into her everyday tasks without the two activities interfering with each other. The whole thing would pass through her mind in chronological sequence. I cannot say whether the work of recollection corresponded day by day with the past. I suspect that this depended on the amount of leisure which her current household duties allowed.

Wundt (1906, 129) remarks that 'among the activities attributed by myths all over the world to demons, the harmful predominate, so that in popular belief bad demons are clearly older than good ones'. It is quite possible that the whole concept of demons was derived from the important relation of the living to the dead. The ambivalence inherent in that relation was expressed in the subsequent course of human development by the fact that, from the same root, it gave rise to two completely opposed psychical structures: on the one hand fear of demons and ghosts and on the other hand veneration of ancestors.² The fact that demons are always regarded as the spirits of those who have died recently shows better than anything the influence of mourning on the origin of the belief in demons. Mourning has a quite specific psychical task to perform: its function is to detach the survivors’ memories and hopes from the dead. When this has been achieved, the pain grows less and with it the remorse and self-reproaches and consequently the fear of the demon as well. And the same spirits who to begin with were feared as demons may now expect to meet with friendlier treatment; they are revered as ancestors and appeals are made to them for help.

I propose to avoid (as I have already done elsewhere³) entering into the general problem of the origin of the tendency to project mental processes into the outside. It is, however, safe to assume that that tendency will be intensified when projection promises to bring with it the advantage of mental relief. Such an advantage may be expected with certainty where a conflict has arisen between different impulses all of which are striving towards omnipotence - for they clearly cannot all become omnipotent. The pathological process in paranoia in fact makes use of the mechanism of projection in order to deal with mental conflicts of this kind. The typical case of such a conflict is one between the two members of a pair of opposites - the case of an ambivalent attitude, which we have examined in detail as it appears in someone mourning the death of a loved relative. This kind of case must seem particularly likely to provide a motive for the creation of projections. Here again we are in agreement with the writers who maintain that the first born spirits were evil spirits, and who derive the idea of a soul from the impression made by death upon the survivors. The only difference is that we do not lay stress on the intellectual problem with which death confronts the living; in our view the force which gives the impetus to research is rather to be attributed to the emotional conflict into which the survivors are plunged.

[1895d, 147]
[1912-1913, 2709]
[1912-1913, 2735]
In what, now, does the work which mourning performs consist? I do not think there is anything far-fetched in presenting it in the following way. Reality-testing has shown that the loved object no longer exists, and it proceeds to demand that all libido shall be withdrawn from its attachments to that object. This demand arouses understandable opposition - it is a matter of general observation that people never willingly abandon a libidinal position, not even, indeed, when a substitute is already beckoning to them. This opposition can be so intense that a turning away from reality takes place and a clinging to the object through the medium of a hallucinatory wishful psychosis.¹ Normally, respect for reality gains the day. Nevertheless its orders cannot be obeyed at once. They are carried out bit by bit, at great expense of time and cathectic energy, and in the meantime the existence of the lost object is psychically prolonged. Each single one of the memories and expectations in which the libido is bound to the object is brought up and hypercathected, and detachment of the libido is accomplished in respect of it. Why this compromise by which the command of reality is carried out piecemeal should be so extraordinarily painful is not at all easy to explain in terms of economics. It is remarkable that this painful unpleasure is taken as a matter of course by us. The fact is, however, that when the work of mourning is completed the ego becomes free and uninhibited again.

[1917e, 3042]

It would be equally fruitless from a scientific and a therapeutic point of view to contradict a patient who brings these accusations against his ego. He must surely be right in some way and be describing something that is as it seems to him to be. Indeed, we must at once confirm some of his statements without reservation. He really is as lacking in interest and as incapable of love and achievement as he says. But that, as we know, is secondary; it is the effect of the internal work which is consuming his ego work which is unknown to us but which is comparable to the work of mourning. He also seems to us justified in certain other self-accusations; it is merely that he has a keener eye for the truth than other people who are not melancholic. When in his heightened self-criticism he describes himself as petty, egoistic, dishonest, lacking in independence, one whose sole aim has been to hide the weaknesses of his own nature, it may be, so far as we know, that he has come pretty near to understanding himself; we only wonder why a man has to be ill before he can be accessible to a truth of this kind. For there can be no doubt that if anyone holds and expresses to others an opinion of himself such as this (an opinion which Hamlet held both of himself and of everyone else ¹), he is ill, whether he is speaking the truth or whether he is being more or less unfair to himself. Nor is it difficult to see that there is no correspondence, so far as we can judge, between the degree of self-abasement and its real justification. A good, capable, conscientious woman will speak no better of herself after she develops melancholia than one who is in fact worthless; indeed, the former is perhaps more likely to fall ill of the disease than the latter, of whom we too should have nothing good to say. Finally, it must strike us that after all the melancholic does not behave in quite the same way as a person who is crushed by remorse and self-reproach in a normal fashion. Feelings of shame in front of other people, which would more than anything characterize this latter condition, are lacking in the melancholic, or at least they are not prominent in him. One might emphasize the presence in him of an almost opposite trait of insistent communicativeness which finds satisfaction in self-exposure.

[1917e, 3044]

The essential thing, therefore, is not whether the melancholic's distressing self-denigration is correct, in the sense that his self-criticism agrees with the opinion of other people. The point must rather be that he is giving a correct description of his psychological situation. He has lost his self-respect and he must have good reason for this. It is true that we are then faced with a contradiction that presents a problem which is hard to solve. The analogy with mourning led us to conclude that he had suffered a loss in regard to an object; what he tells us points to a loss in regard to his ego.

[1917e, 3045]
There is no difficulty in reconstructing this process. An object choice, an attachment of the libido to a particular person, had at one time existed; then, owing to a real slight or disappointment coming from this loved person, the relationship was shattered. The result was not the normal one of a withdrawal of the libido from this object and a displacement of it on to a new one, but something different, for whose coming about various conditions seem to be necessary. The object-cathexis proved to have little power of resistance and was brought to an end. But the free libido was not displaced on to another object; it was withdrawn into the ego. There, however, it was not employed in any unspecified way, but served to establish an identification of the ego with the abandoned object. Thus the shadow of the object fell upon the ego, and the latter could henceforth be judged by a special agency, as though it were an object, the forsaken object. In this way an object-loss was transformed into an ego-loss and the conflict between the ego and the loved person into a cleavage between the critical activity of the ego and the ego as altered by identification.

One or two things may be directly inferred with regard to the preconditions and effects of a process such as this. On the one hand, a strong fixation to the loved object must have been present; on the other hand, in contradiction to this, the object-cathexis must have had little power of resistance. As Otto Rank has aptly remarked, this contradiction seems to imply that the object-choice has been effected on a narcissistic basis, so that the object-cathexis, when obstacles come in its way, can regress to narcissism. The narcissistic identification with the object then becomes a substitute for the erotic cathexis, the result of which is that in spite of the conflict with the loved person the love-relation need not be given up. This substitution of identification for object-love is an important mechanism in the narcissistic affections; Karl Landauer (1914) has lately been able to point to it in the process of recovery in a case of schizophrenia. It represents, of course, a regression from one type of object-choice to original narcissism. We have elsewhere shown that identification is a preliminary stage of object-choice, that it is the first way - and one that is expressed in an ambivalent fashion - in which the ego picks out an object. The ego wants to incorporate this object into itself, and, in accordance with the oral or cannibalistic phase of libidinal development in which it is, it wants to do so by devouring it. Abraham is undoubtedly right in attributing to this connection the refusal of nourishment met with in severe forms of melancholia.

The conclusion which our theory would require - namely, that the disposition to fall ill of melancholia (or some part of that disposition) lies in the predominance of the narcissistic type of object-choice - has unfortunately not yet been confirmed by observation. In the opening remarks of this paper, I admitted that the empirical material upon which this study is founded is insufficient for our needs. If we could assume an agreement between the results of observation and what we have inferred, we should not hesitate to include this regression from object-cathexis to the still narcissistic oral phase of the libido in our characterization of melancholia. Identifications with the object are by no means rare in the transference neuroses either; indeed, they are a well-known mechanism of symptom-formation, especially in hysteria. The difference, however, between narcissistic and hysterical identification may be seen in this: that, whereas in the former the object-cathexis is abandoned, in the latter it persists and manifests its influence, though this is usually confined to certain isolated actions and innervations. In any case, in the transference neuroses, too, identification is the expression of there being something in common, which may signify love. Narcissistic identification is the older of the two and it paves the way to an understanding of hysterical identification, which has been less thoroughly studied.
Melancholia confronts us with yet other problems, the answer to which in part eludes us. The fact that it passes off after a certain time has elapsed without leaving traces of any gross changes is a feature it shares with mourning. We found by way of explanation that in mourning time is needed for the command of reality-testing to be carried out in detail, and that when this work has been accomplished the ego will have succeeded in freeing its libido from the lost object. We may imagine that the ego is occupied with analogous work during the course of a melancholia; in neither case have we any insight into the economics of the course of events. The sleeplessness in melancholia testifies to the rigidity of the condition, the impossibility of effecting the general drawing-in of cathexes necessary for sleep. The complex of melancholia behaves like an open wound, drawing to itself cathetic energies - which in the transference neuroses we have called 'anticathexes' - from all directions, and emptying the ego until it is totally impoverished. It can easily prove resistant to the ego’s wish to sleep.

In the first place, normal mourning, too, overcomes the loss of the object, and it, too, while it lasts, absorbs all the energies of the ego. Why, then, after it has run its course, is there no hint in its case of the economic condition for a phase of triumph? I find it impossible to answer this objection straight away. It also draws our attention to the fact that we do not even know the economic means by which mourning carries out its task. Possibly, however, a conjecture will help us here. Each single one of the memories and situations of expectancy which demonstrate the libido’s attachment to the lost object is met by the verdict of reality that the object no longer exists; and the ego, confronted as it were with the question whether it shall share this fate, is persuaded by the sum of the narcissistic satisfactions it derives from being alive to sever its attachment to the object that has been abolished. We may perhaps suppose that this work of severance is so slow and gradual that by the time it has been finished the expenditure of energy necessary for it is also dissipated.¹

It is tempting to go on from this conjecture about the work of mourning and try to give an account of the work of melancholia. Here we are met at the outset by an uncertainty. So far we have hardly considered melancholia from the topographical point of view, nor asked ourselves in and between what psychical systems the work of melancholia goes on. What part of the mental processes of the disease still takes place in connection with the unconscious object-cathexes that have been given up, and what part in connection with their substitute, by identification, in the ego?

The quick and easy answer is that ‘the unconscious (thing-) presentation of the object has been abandoned by the libido’. In reality, however, this presentation is made up of innumerable single impressions (or unconscious traces of them), and this withdrawal of libido is not a process that can be accomplished in a moment, but must certainly, as in mourning, be one in which progress is long-drawn-out and gradual. Whether it begins simultaneously at several points or follows some sort of fixed sequence is not easy to decide; in analyses it often becomes evident that first one and then another memory is activated, and that the laments which always sound the same and are wearisome in their monotony nevertheless take their rise each time in some different unconscious source. If the object does not possess this great significance for the ego - a significance reinforced by a thousand links - then, too, its loss will not be of a kind to cause either mourning or melancholia. This characteristic of detaching the libido bit by bit is therefore to be ascribed alike to mourning and to melancholia; it is probably supported by the same economic situation and serves the same purposes in both.
As we have seen, however, melancholia contains something more than normal mourning. In melancholia the relation to the object is no simple one; it is complicated by the conflict due to ambivalence. The ambivalence is either constitutional, i.e. is an element of every love-relation formed by this particular ego, or else it proceeds precisely from those experiences that involved the threat of losing the object. For this reason the exciting causes of melancholia have a much wider range than those of mourning, which is for the most part occasioned only by a real loss of the object, by its death. In melancholia, accordingly, countless separate struggles are carried on over the object, in which hate and love contend with each other; the one seeks to detach the libido from the object, the other to maintain this position of the libido against the assault. The location of these separate struggles cannot be assigned to any system but the \( Ucs. \), the region of the memory-traces of things (as contrasted with word-cathexes). In mourning, too, the efforts to detach the libido are made in this same system; but in it nothing hinders these processes from proceeding along the normal path through the \( Pcs. \) to consciousness. This path is blocked for the work of melancholia, owing perhaps to a number of causes or a combination of them. Constitutional ambivalence belongs by its nature to the repressed; traumatic experiences in connection with the object may have activated other repressed material. Thus everything to do with these struggles due to ambivalence remains withdrawn from consciousness, until the outcome characteristic of melancholia has set in. This, as we know, consists in the threatened libidinal cathexis at length abandoning the object, only, however, to draw back to the place in the ego from which it had proceeded. So by taking flight into the ego love escapes extinction. After this regression of the libido the process can become conscious, and it is represented to consciousness as a conflict between one part of the ego and the critical agency. [1917e, 3052]

What consciousness is aware of in the work of melancholia is thus not the essential part of it, nor is it even the part which we may credit with an influence in bringing the ailment to an end. We see that the ego debases itself and rages against itself, and we understand as little as the patient what this can lead to and how it can change. We can more readily attribute such a function to the \( unconscious \) part of the work, because it is not difficult to perceive an essential analogy between the work of melancholia and of mourning. Just as mourning impels the ego to give up the object by declaring the object to be dead and offering the ego the inducement of continuing to live, so does each single struggle of ambivalence loosen the fixation of the libido to the object by disparaging it, denigrating it and even as it were killing it. It is possible for the process in the \( Ucs. \) to come to an end, either after the fury has spent itself or after the object has been abandoned as valueless. We cannot tell which of these two possibilities is the regular or more usual one in bringing melancholia to an end, nor what influence this termination has on the future course of the case. The ego may enjoy in this the satisfaction of knowing itself as the better of the two, as superior to the object. [1917e, 3053]

Mourning over the loss of something that we have loved or admired seems so natural to the layman that he regards it as self-evident. But to psychologists mourning is a great riddle, one of those phenomena which cannot themselves be explained but to which other obscurities can be traced back. We possess, as it seems, a certain amount of capacity for love - what we call libido - which in the earliest stages of development is directed towards our own ego. Later, though still at a very early time, this libido is diverted from the ego on to objects, which are thus in a sense taken into our ego. If the objects are destroyed or if they are lost to us, our capacity for love (our libido) is once more liberated; and it can then either take other objects instead or can temporarily return to the ego. But why it is that this detachment of libido from its objects should be such a painful process is a mystery to us and we have not hitherto been able to frame any hypothesis to account for it. We only see that libido clings to its objects and will not renounce those that are lost even when a substitute lies ready to hand. Such then is mourning. [1916a, 3096]
We cannot be surprised that our libido, thus bereft of so many of its objects, has clung with all the greater intensity to what is left to us, that our love of our country, our affection for those nearest us and our pride in what is common to us have suddenly grown stronger. But have those other possessions, which we have now lost, really ceased to have any worth for us because they have proved so perishable and so unresistant? To many of us this seems to be so, but once more wrongly, in my view. I believe that those who think thus, and seem ready to make a permanent renunciation because what was precious has proved not to be lasting, are simply in a state of mourning for what is Lost. Mourning, as we know, however painful it may becomes to a spontaneous end. When it has renounced everything that has been lost, then it has consumed itself, and our libido is once more free (in so far as we are still young and active) to replace the lost objects by fresh ones equally or still more precious. It is to be hoped that the same will be true of the losses caused by this war. When once the mourning is over, it will be found that our high opinion of the riches of civilization has lost nothing from our discovery of their fragility. We shall build up again all that war has destroyed, and perhaps on firmer ground and more lastingly than before.

So little is known about the psychology of emotional processes that the tentative remarks I am about to make on the subject may claim a very lenient judgement. The problem before us arises out of the conclusion we have reached that anxiety comes to be a reaction to the danger of a loss of an object. Now we already know one reaction to the loss of an object, and that is mourning. The question therefore is, when does that loss lead to anxiety and when to mourning? In discussing the subject of mourning on a previous occasion I found that there was one feature about it which remained quite unexplained. This was its peculiar painfulness.¹ And yet it seems self-evident that separation from an object should be painful. Thus the problem becomes more complicated: when does separation from an object produce anxiety, when does it produce mourning and when does it produce, it may be, only pain?

We know of yet another emotional reaction to the loss of an object, and that is mourning. But we have no longer any difficulty in accounting for it. Mourning occurs under the influence of reality-testing; for the latter function demands categorically from the bereaved person that he should separate himself from the object, since it no longer exists. Mourning is entrusted with the task of carrying out this retreat from the object in all those situations in which it was the recipient of a high degree of cathexis. That this separation should be painful fits in with what we have just said, in view of the high and unsatisfiable cathexis of longing which is concentrated on the object by the bereaved person during the reproduction of the situations in which he must undo the ties that bind him to it.
In addition to narcissistic identification, there is a hysterical kind, which has been familiar to us very much longer. I wish it were possible to illustrate for you the differences between the two forms by a few clear specifications. There is something I can tell you about the periodic and cyclical forms of melancholia which I am sure you will be glad to hear. For in favourable circumstances - I have experienced this twice - it is possible by analytic treatment in the lucid intervals to prevent the return of the condition in the same or the opposite emotional mood. We learn from such cases that in melancholia and mania we are concerned once more with a special method of dealing with a conflict whose underlying determinants agree precisely with those of the other neuroses. You can imagine how much more there is for psycho-analysis to learn in this field of knowledge.

[1916-1917, 3472]

It is easy to state in a formula the distinction between an identification with the father and the choice of the father as an object. In the first case one's father is what one would like to be and in the second he is what one would like to have. The distinction, that is, depends upon whether the tie attaches to the subject or to the object of the ego. The former kind of tie is therefore already possible before any sexual object-choice has been made. It is much more difficult to give a clear metapsychological representation of the distinction. We can only see that identification endeavours to mould a person's own ego after the fashion of the one that has been taken as a model.

[1921c, 3798]

Let us disentangle identification as it occurs in the structure of a neurotic symptom from its rather complicated connections. Supposing that a little girl (and we will keep to her for the present) develops the same painful symptom as her mother - for instance, the same tormenting cough. This may come about in various ways. The identification may come from the Oedipus complex; in that case it signifies a hostile desire on the girl's part to take her mother's place, and the symptom expresses her object-love towards her father, and brings about a realization, under the influence of a sense of guilt, of her desire to take her mother's place: 'You wanted to be your mother, and now you are - anyhow so far as your sufferings are concerned.' This is the complete mechanism of the structure of a hysterical symptom. Or, on the other hand, the symptom may be the same as that of the person who is loved; so, for instance, Dora¹ imitated her father's cough. In that case we can only describe the state of things by saying that identification has appeared instead of object-choice, and that object-choice has regressed to identification. We have heard that identification is the earliest and original form of emotional tie; it often happens that under the conditions in which symptoms are constructed, that is, where there is repression and where the mechanisms of the unconscious are dominant, object-choice is turned back into identification - the ego assumes the characteristics of the object. It is noticeable that in these identifications the ego sometimes copies the person who is not loved and sometimes the one who is loved. It must also strike us that in both cases the identification is a partial and extremely limited one and only borrows a single trait from the person who is its object.

[1921c, 3798]
There is a third particularly frequent and important case of symptom formation, in which the identification leaves entirely out of account any object-relation to the person who is being copied. Supposing, for instance, that one of the girls in a boarding school has had a letter from someone with whom she is secretly in love which arouses her jealousy, and that she reacts to it with a fit of hysteric; then some of her friends who know about it will catch the fit, as we say, by mental infection. The mechanism is that of identification based upon the possibility or desire of putting oneself in the same situation. The other girls would like to have a secret love affair too, and under the influence of a sense of guilt they also accept the suffering involved in it. It would be wrong to suppose that they take on the symptom out of sympathy. On the contrary, the sympathy only arises out of the identification, and this is proved by the fact that infection or imitation of this kind takes place in circumstances where even less pre-existing sympathy is to be assumed than usually exists between friends in a girls' school. One ego has perceived a significant analogy with another upon one point - in our example upon openness to a similar emotion; an identification is thereupon constructed on this point, and, under the influence of the pathogenic situation, is displaced on to the symptom which the one ego has produced. The identification by means of the symptom has thus become the mark of a point of coincidence between the two egos which has to be kept repressed.

[1921c, 3799]

What we have learned from these three sources may be summarized as follows. First, identification is the original form of emotional tie with an object; secondly, in a regressive way it becomes a substitute for a libidinal object-tie, as it were by means of introjection of the object into the ego; and thirdly, it may arise with any new perception of a common quality shared with some other person who is not an object of the sexual instinct. The more important this common quality is, the more successful may this partial identification become, and it may thus represent the beginning of a new tie.

[1921c, 3799]

The genesis of male homosexuality in a large class of cases is as follows. A young man has been unusually long and intensely fixated upon his mother in the sense of the Oedipus complex. But at last, after the end of puberty, the time comes for exchanging his mother for some other sexual object. Things take a sudden turn: the young man does not abandon his mother, but identifies himself with her; he transforms himself into her, and now looks about for objects which can replace his ego for him, and on which he can bestow such love and care as he has experienced from his mother. This is a frequent process, which can be confirmed as often as one likes, and which is naturally quite independent of any hypothesis that may be made as to the organic driving force and the motives of the sudden transformation. A striking thing about this identification is its ample scale; it remoulds the ego in one of its important features - in its sexual character - upon the model of what has hitherto been the object. In this process the object itself is renounced - whether entirely or in the sense of being preserved only in the unconscious is a question outside the present discussion. Identification with an object that is renounced or lost, as a substitute for that object - introjection of it into the ego - is indeed no longer a novelty to us. A process of the kind may sometimes be directly observed in small children. A short time ago an observation of this sort was published in the *Internationale Zeitschrift für Psychoanalyse*. A child who was unhappy over the loss of a kitten declared straight out that now he himself was the kitten, and accordingly crawled about on all fours, would not eat at table, etc.¹

[1921c, 3800]
It is now easy to define the difference between identification and such extreme developments of being in love as may be described as 'fascination' or 'bondage'. In the former case the ego has enriched itself with the properties of the object, it has 'introjected' the object into itself, as Ferenczi expresses it. In the second case it is impoverished, it has surrendered itself to the object, it has substituted the object for its own most important constituent. Closer consideration soon makes it plain, however, that this kind of account creates an illusion of contradistinctions that have no real existence. Economically there is no question of impoverishment or enrichment; it is even possible to describe an extreme case of being in love as a state in which the ego has introjected the object into itself. Another distinction is perhaps better calculated to meet the essence of the matter. In the case of identification the object has been lost or given up; it is then set up again inside the ego, and the ego makes a partial alteration in itself after the model of the lost object. In the other case the object is retained, and there is a hypercathexis of it by the ego and at the ego's expense. But here again a difficulty presents itself. Is it quite certain that identification presupposes that object-cathexis has been given up? Can there be no identification while the object is retained? And before we embark upon a discussion of this delicate question, the perception may already be beginning to dawn on us that yet another alternative embraces the real essence of the matter, namely, whether the object is put in the place of the ego or of the ego ideal.

At this point we must widen our range a little. We succeeded in explaining the painful disorder of melancholia by supposing that an object which was lost has been set up again inside the ego - that is, that an object-cathexis has been replaced by an identification.³ At that time, however, we did not appreciate the full significance of this process and did not know how common and how typical it is. Since then we have come to understand that this kind of substitution has a great share in determining the form taken by the ego and that it makes an essential contribution towards building up what is called its 'character'.

When it happens that a person has to give up a sexual object, there quite often ensues an alteration of his ego which can only be described as a setting up of the object inside the ego, as it occurs in melancholia; the exact nature of this substitution is as yet unknown to us. It may be that by this introjection, which is a kind of regression to the mechanism of the oral phase, the ego makes it easier for the object to be given up or renders that process possible. It may be that this identification is the sole condition under which the id can give up its objects. At any rate the process, especially in the early phases of development, is a very frequent one, and it makes it possible to suppose that the character of the ego is a precipitate of abandoned object-cathexes and that it contains the history of those object-choices. It must, of course, be admitted from the outset that there are varying degrees of capacity for resistance, which decide the extent to which a person's character fends off or accepts the influences of the history of his erotic object-choices. In women who have had many experiences in love there seems to be no difficulty in finding vestiges of their object-cathexes in the traits of their character. We must also take into consideration cases of simultaneous object-cathexis and identification - cases, that is, in which the alteration in character occurs before the object has been given up. In such cases the alteration in character has been able to survive the object-relation and in a certain sense to conserve it.
From another point of view it may be said that this transformation of an erotic object-choice into an alteration of the ego is also a method by which the ego can obtain control over the id and deepen its relations with it - at the cost, it is true, of acquiescing to a large extent in the id's experiences. When the ego assumes the features of the object, it is forcing itself, so to speak, upon the id as a love-object and is trying to make good the id's loss by saying: 'Look, you can love me too - I am so like the object.'

[1923b, 3964]

Here we arrive again at the possibility which has already been discussed that sublimation may take place regularly, through the mediation of the ego. The other case will be recollected, in which the ego deals with the first object-cathexes of the id (and certainly with later ones too) by taking over the libido from them into itself and binding it to the alteration of the ego produced by means of identification. The transformation into ego-libido of course involves an abandonment of sexual aims, a desexualization. In any case this throws light upon an important function of the ego in its relation to Eros. By thus getting hold of the libido from the object-cathexes, setting itself up as sole love-object, and desexualizing or sublimating the libido of the id, the ego is working in opposition to the purposes of Eros and placing itself at the service of the opposing instinctual impulses. It has to acquiesce in some of the other object-cathexes of the id; it has, so to speak, to participate in them. We shall come back later to another possible consequence of this activity of the ego.

[1923b, 3979]

Thus we have said repeatedly that the ego is formed to a great extent out of identifications which take the place of abandoned cathexes by the id; that the first of these identifications always behave as a special agency in the ego and stand apart from the ego in the form of a super-ego, while later on, as it grows stronger, the ego may become more resistant to the influences of such identifications. The super-ego owes its special position in the ego, or in relation to the ego, to a factor which must be considered from two sides: on the one hand it was the first identification and one which took place while the ego was still feeble, and on the other hand it is the heir to the Oedipus complex and has thus introduced the most momentous objects into the ego. The super-ego's relation to the later alterations of the ego is roughly similar to that of the primary sexual phase of childhood to later sexual life after puberty. Although it is accessible to all later influences, it nevertheless preserves throughout life the character given to it by its derivation from the father-complex - namely, the capacity to stand apart from the ego and to master it. It is a memorial of the former weakness and dependence of the ego, and the mature ego remains subject to its domination. As the child was once under a compulsion to obey its parents, so the ego submits to the categorical imperative of its super-ego.

[1923b, 3982]
The basis of the process is what is called an 'identification' - that is to say, the assimilation of one ego to another one, as a result of which the first ego behaves like the second in certain respects, imitates it and in a sense takes it up into itself. Identification has been not unsuitably compared with the oral, cannibalistic incorporation of the other person. It is a very important form of attachment to someone else, probably the very first, and not the same thing as the choice of an object. The difference between the two can be expressed in some such way as this. If a boy identifies himself with his father, he wants to be like his father; if he makes him the object of his choice, he wants to have him, to possess him. In the first case his ego is altered on the model of his father; in the second case that is not necessary. Identification and object-choice are to a large extent independent of each other; it is however possible to identify oneself with someone whom, for instance, one has taken as a sexual object, and to alter one's ego on his model. It is said that the influencing of the ego by the sexual object occurs particularly often with women and is characteristic of femininity. I must already have spoken to you in my earlier lectures of what is by far the most instructive relation between identification and object-choice. It can be observed equally easily in children and adults, in normal as in sick people. If one has lost an object or has been obliged to give it up, one often compensates oneself by identifying oneself with it and by setting it up once more in one's ego, so that here object-choice regresses, as it were, to identification.

[1933a, 4672]
The first of these is the oral or, as it might be called, cannibalistic pregenital sexual organization. Here sexual activity has not yet been separated from the ingestion of food; nor are opposite currents within the activity differentiated. The object of both activities is the same; the sexual aim consists in the incorporation of the object - the prototype of a process which, in the form of identification, is later to play such an important psychological part. A relic of this constructed phase of organization, which is forced upon our notice by pathology, may be seen in thumb-sucking, in which the sexual activity, detached from the nutritive activity, has substituted for the extraneous object one situated in the subject's own body.¹

There is no difficulty in reconstructing this process. An object choice, an attachment of the libido to a particular person, had at one time existed; then, owing to a real slight or disappointment coming from this loved person, the relationship was shattered. The result was not the normal one of a withdrawal of the libido from this object and a displacement of it on to a new one, but something different, for whose coming about various conditions seem to be necessary. The object-cathexis proved to have little power of resistance and was brought to an end. But the free libido was not displaced on to another object; it was withdrawn into the ego. There, however, it was not employed in any unspecified way, but served to establish an identification of the ego with the abandoned object. Thus the shadow of the object fell upon the ego, and the latter could henceforth be judged by a special agency, as though it were an object, the forsaken object. In this way an object-loss was transformed into an ego-loss and the conflict between the ego and the loved person into a cleavage between the critical activity of the ego and the ego as altered by identification.

One or two things may be directly inferred with regard to the preconditions and effects of a process such as this. On the one hand, a strong fixation to the loved object must have been present; on the other hand, in contradiction to this, the object-cathexis must have had little power of resistance. As Otto Rank has aptly remarked, this contradiction seems to imply that the object-choice has been effected on a narcissistic basis, so that the object-cathexis, when obstacles come in its way, can regress to narcissism. The narcissistic identification with the object then becomes a substitute for the erotic cathexis, the result of which is that in spite of the conflict with the loved person the love-relation need not be given up. This substitution of identification for object-love is an important mechanism in the narcissistic affections; Karl Landauer (1914) has lately been able to point to it in the process of recovery in a case of schizophrenia. It represents, of course, a regression from one type of object-choice to original narcissism. We have elsewhere shown that identification is a preliminary stage of object-choice, that it is the first way - and one that is expressed in an ambivalent fashion - in which the ego picks out an object. The ego wants to incorporate this object into itself, and, in accordance with the oral or cannibalistic phase of libidinal development in which it is, it wants to do so by devouring it. Abraham is undoubtedly right in attributing to this connection the refusal of nourishment met with in severe forms of melancholia.

¹ [1905d, 1516]

[1917e, 3047]
The conclusion which our theory would require - namely, that the disposition to fall ill of melancholia (or some part of that disposition) lies in the predominance of the narcissistic type of object-choice - has unfortunately not yet been confirmed by observation. In the opening remarks of this paper, I admitted that the empirical material upon which this study is founded is insufficient for our needs. If we could assume an agreement between the results of observation and what we have inferred, we should not hesitate to include this regression from object-cathexis to the still narcissistic oral phase of the libido in our characterization of melancholia. Identifications with the object are by no means rare in the transference neuroses either; indeed, they are a well-known mechanism of symptom-formation, especially in hysteria. The difference, however, between narcissistic and hysterical identification may be seen in this: that, whereas in the former the object-cathexis is abandoned, in the latter it persists and manifests its influence, though this is usually confined to certain isolated actions and innervations. In any case, in the transference neuroses, too, identification is the expression of there being something in common, which may signify love. Narcissistic identification is the older of the two and it paves the way to an understanding of hysterical identification, which has been less thoroughly studied. [1917e, 3048]

Melancholia, therefore, borrows some of its features from mourning, and the others from the process of regression from narcissistic object-choice to narcissism. It is on the one hand, like mourning, a reaction to the real loss of a loved object; but over and above this, it is marked by a determinant which is absent in normal mourning or which, if it is present, transforms the latter into pathological mourning. The loss of a love-object is an excellent opportunity for the ambivalence in love-relationships to make itself effective and come into the open. Where there is a disposition to obsessional neurosis the conflict due to ambivalence gives a pathological cast to mourning and forces it to express itself in the form of self-reproaches to the effect that the mourner himself is to blame for the loss of the loved object, i.e. that he has willed it. These obsessional states of depression following upon the death of a loved person show us what the conflict due to ambivalence can achieve by itself when there is no regressive drawing-in of libido as well. In melancholia, the occasions which give rise to the illness extend for the most part beyond the clear case of a loss by death, and include all those situations of being slighted, neglected or disappointed, which can import opposed feelings of love and hate into the relationship or reinforce an already existing ambivalence. This conflict due to ambivalence, which sometimes arises more from real experiences, sometimes more from constitutional factors, must not be overlooked among the preconditions of melancholia. If the love for the object - a love which cannot be given up though the object itself is given up - takes refuge in narcissistic identification, then the hate comes into operation on this substitutive object, abusing it, debasing it, making it suffer and deriving sadistic satisfaction from its suffering. The self-tormenting in melancholia, which is without doubt enjoyable, signifies, just like the corresponding phenomenon in obsessional neurosis, a satisfaction of trends of sadism and hate¹ which relate to an object, and which have been turned round upon the subject's own self in the ways we have been discussing. In both disorders the patients usually still succeed, by the circuitous path of self-punishment, in taking revenge on the original object and in tormenting their loved one through their illness, having resorted to it in order to avoid the need to express their hostility to him openly. After all, the person who has occasioned the patient's emotional disorder, and on whom his illness is centred, is usually to be found in his immediate environment. The melancholic's erotic cathexis in regard to his object has thus undergone a double vicissitude: part of it has regressed to identification, but the other part, under the influence of the conflict due to 'ambivalence, has been carried back to the stage of sadism which is nearer to that conflict. [1917e, 3048]
It is tempting to go on from this conjecture about the work of mourning and try to give an account of the work of melancholia. Here we are met at the outset by an uncertainty. So far we have hardly considered melancholia from the topographical point of view, nor asked ourselves in and between what psychical systems the work of melancholia goes on. What part of the mental processes of the disease still takes place in connection with the unconscious object-cathexes that have been given up, and what part in connection with their substitute, by identification, in the ego? [1917e, 3051]

As with paranoia, so also with melancholia (of which, incidentally, many different clinical forms have been described) we have found a point at which it has become possible to obtain some insight into the internal structure of the disease. We have discovered that the self-reproaches, with which these melancholic patients torment themselves in the most merciless fashion, in fact apply to another person, the sexual object which they have lost or which has become valueless to them through its own fault. From this we can conclude that the melancholic has, it is true, withdrawn his libido from the object, but that, by a process which we must call 'narcissistic identification', the object has been set up in the ego itself, has been as it were, projected on to the ego. (Here I can only give you a pictorial description and not an ordered account on topographical and dynamic lines.) The subject's own ego is then treated like the object that has been abandoned, and it is subjected to all the acts of aggression and expressions of vengefulness which have been aimed at the object. A melancholic's propensity to suicide is also made more intelligible if we consider that the patient's embitterment strikes with a single blow at his own ego and at the loved and hated object. In melancholia, as well as in other narcissistic disorders, a particular trait in the patient's emotional life emerges with peculiar emphasis - what, since Bleuler, we have been accustomed to describe as 'ambivalence'. By this we mean the direction towards the same person of contrary - affectionate and hostile - feelings. Unluckily I have been unable in the course of these lectures to tell you more about this emotional ambivalence. [1916-1917, 3471]

Another such instance of introjection of the object has been provided by the analysis of melancholia, an affection which counts among the most notable of its exciting causes the real or emotional loss of a loved object. A leading characteristic of these cases is a cruel self-depreciation of the ego combined with relentless self-criticism and bitter self-reproaches. Analyses have shown that this disparagement and these reproaches apply at bottom to the object and represent the ego's revenge upon it. The shadow of the object has fallen upon the ego, as I have said elsewhere.¹ The introjection of the object is here unmistakably clear. [1921c, 3801]
But these melancholias also show us something else, which may be of importance for our later discussions. They show us the ego divided, fallen apart into two pieces, one of which rages against the second. This second piece is the one which has been altered by introjection and which contains the lost object. But the piece which behaves so cruelly is not unknown to us either. It comprises the conscience, a critical agency within the ego, which even in normal times takes up a critical attitude towards the ego, though never so relentlessly and so unjustifiably. On previous occasions⁹ we have been driven to the hypothesis that some such agency develops in our ego which may cut itself off from the rest of the ego and come into conflict with it. We have called it the ‘ego ideal’, and by way of functions we have ascribed to it self-observation, the moral conscience, the censorship of dreams, and the chief influence in repression. We have said that it is the heir to the original narcissism in which the childish ego enjoyed self-sufficiency; it gradually gathers up from the influences of the environment the demands which that environment makes upon the ego and which the ego cannot always rise to; so that a man, when he cannot be satisfied with his ego itself, may nevertheless be able to find satisfaction in the ego ideal which has been differentiated out of the ego. In delusions of observation, as we have further shown, the disintegration of this agency has become patent, and has thus revealed its origin in the influence of superior powers, and above all of parents.³ But we have not forgotten to add that the amount of distance between this ego ideal and the real ego is very variable from one individual to another, and that with many people this differentiation within the ego does not go further than with children.

On the other hand there are melancholias in which the precipitating cause clearly plays an aetiological part. They are those which occur after the loss of a loved object, whether by death or as the result of circumstances which have necessitated the withdrawal of the libido from the object. A psychogenic melancholia of this sort can end in mania, and this cycle can be repeated several times, just as easily as in a case which appears to be spontaneous. Thus the state of things is somewhat obscure, especially as only a few forms and cases of melancholia have been submitted to psycho-analytic investigation.¹ So far we only understand those cases in which the object is given up because it has shown itself unworthy of love. It is then set up again inside the ego, by means of identification, and severely condemned by the ego ideal. The reproaches and attacks directed towards the object come to light in the shape of melancholic self-reproaches.²

Nevertheless I see no difficulty in assigning to the factor of the periodic rebellion of the ego against the ego ideal a share in both kinds of melancholia, the psychogenic as well as the spontaneous. In the spontaneous kind it may be supposed that the ego ideal is inclined to display a peculiar strictness, which then results automatically in its temporary suspension. In the psychogenic kind the ego would be incited to rebellion by ill-treatment on the part of its ideal - an ill-treatment which it encounters when there has been identification with a rejected object.

¹ [1921c, 3801]
² [1921c, 3824]
Neurosis stands outside this series. It also is based upon a peculiarity in the development of the human libido - the twice repeated start made by the directly sexual function, with an intervening period of latency.¹ To this extent it resembles hypnosis and group formation in having the character of a regression, which is absent from being in love. It makes its appearance wherever the advance from directly sexual instincts to those that are inhibited in their aims has not been wholly successful; and it represents a conflict between those portions of the instincts which have been received into the ego after having passed through this development and those portions of them which, springing from the repressed unconscious, strive - as do other, completely repressed, instinctual impulses - to attain direct satisfaction. Neuroses are extraordinarily rich in content, for they embrace all possible relations between the ego and the object - both those in which the object is retained and others in which it is abandoned or erected inside the ego itself - and also the conflicting relations between the ego and its ego ideal.

[1921c, 3834]

At this point we must widen our range a little. We succeeded in explaining the painful disorder of melancholia by supposing that an object which was lost has been set up again inside the ego - that is, that an object-cathexis has been replaced by an identification.³ At that time, however, we did not appreciate the full significance of this process and did not know how common and how typical it is. Since then we have come to understand that this kind of substitution has a great share in determining the form taken by the ego and that it makes an essential contribution towards building up what is called its 'character'.

[1923b, 3962]

When it happens that a person has to give up a sexual object, there quite often ensues an alteration of his ego which can only be described as a setting up of the object inside the ego, as it occurs in melancholia; the exact nature of this substitution is as yet unknown to us. It may be that by this introjection, which is a kind of regression to the mechanism of the oral phase, the ego makes it easier for the object to be given up or renders that process possible. It may be that this identification is the sole condition under which the id can give up its objects. At any rate the process, especially in the early phases of development, is a very frequent one, and it makes it possible to suppose that the character of the ego is a precipitate of abandoned object-cathexes and that it contains the history of those object-choices. It must, of course, be admitted from the outset that there are varying degrees of capacity for resistance, which decide the extent to which a person's character fends off or accepts the influences of the history of his erotic object-choices. In women who have had many experiences in love there seems to be no difficulty in finding vestiges of their object-cathexes in the traits of their character. We must also take into consideration cases of simultaneous object-cathexis and identification - cases, that is, in which the alteration in character occurs before the object has been given up. In such cases the alteration in character has been able to survive the object-relation and in a certain sense to conserve it.

[1923b, 3963]

The description we have given applies to the most extreme instances of this state of affairs, but in a lesser measure this factor has to be reckoned with in very many cases, perhaps in all comparatively severe cases of neurosis. In fact it may be precisely this element in the situation, the attitude of the ego ideal, that determines the severity of a neurotic illness. We shall not hesitate, therefore, to discuss rather more fully the way in which the sense of guilt expresses itself under different conditions.
In melancholia the impression that the super-ego has obtained a hold upon consciousness is even stronger. But here the ego ventures no objection; it admits its guilt and submits to the punishment. We understand the difference. In obsessional neurosis what were in question were objectionable impulses which remained outside the ego, while in melancholic the object to which the super-ego’s wrath applies has been taken into the ego through identification. [1923b, 3985]

Let us again consider obsessional neurosis for a moment. The state of affairs is different here. The defusion of love into aggressiveness has not been effected by the work of the ego, but is the result of a regression which has come about in the id. But this process has extended beyond the id to the super-ego, which now increases its severity towards the innocent ego. It would seem, however, that in this case, no less than in that of melancholia, the ego, having gained control over the libido by means of identification, is punished for doing so by the super-ego through the instrumentality of the aggressiveness which was mixed with the libido. [1923b, 3989]
It would be equally fruitless from a scientific and a therapeutic point of view to contradict a patient who brings these accusations against his ego. He must surely be right in some way and be describing something that is as it seems to him to be. Indeed, we must at once confirm some of his statements without reservation. He really is as lacking in interest and as incapable of love and achievement as he says. But that, as we know, is secondary; it is the effect of the internal work which is consuming his ego work which is unknown to us but which is comparable to the work of mourning. He also seems to us justified in certain other self-accusations; it is merely that he has a keener eye for the truth than other people who are not melancholic. When in his heightened self-criticism he describes himself as petty, egoistic, dishonest, lacking in independence, one whose sole aim has been to hide the weaknesses of his own nature, it may be, so far as we know, that he has come pretty near to understanding himself; we only wonder why a man has to be ill before he can be accessible to a truth of this kind. For there can be no doubt that if anyone holds and expresses to others an opinion of himself such as this (an opinion which Hamlet held both of himself and of everyone else¹), he is ill, whether he is speaking the truth or whether he is being more or less unfair to himself. Nor is it difficult to see that there is no correspondence, so far as we can judge, between the degree of self-abasement and its real justification. A good, capable, conscientious woman will speak no better of herself after she develops melancholia than one who is in fact worthless; indeed, the former is perhaps more likely to fall ill of the disease than the latter, of whom we too should have nothing good to say. Finally, it must strike us that after all the melancholic does not behave in quite the same way as a person who is crushed by remorse and self-reproach in a normal fashion. Feelings of shame in front of other people, which would more than anything characterize this latter condition, are lacking in the melancholic, or at least they are not prominent in him. One might emphasize the presence in him of an almost opposite trait of insistent communicativeness which finds satisfaction in self-exposure.

¹[1917e, 3044]

Before going into this contradiction, let us dwell for a moment on the view which the melancholic's disorder affords of the constitution of the human ego. We see how in him one part of the ego sets itself over against the other, judges it critically, and, as it were, takes it as its object. Our suspicion that the critical agency which is here split off from the ego might also show its independence in other circumstances will be confirmed by every further observation. We shall really find grounds for distinguishing this agency from the rest of the ego. What we are here becoming acquainted with is the agency commonly called 'conscience'; we shall count it, along with the censorship of consciousness and reality-testing, among the major institutions of the ego, and we shall come upon evidence to show that it can become diseased on its own account. In the clinical picture of melancholia, dissatisfaction with the ego on moral grounds is the most outstanding feature. The patient's self-evaluation concerns itself much less frequently with bodily infirmity, ugliness or weakness, or with social inferiority; of this category, it is only his fears and asseverations of becoming poor that occupy a prominent position.

¹[1917e, 3045]
There is no difficulty in reconstructing this process. An object choice, an attachment of the libido to a particular person, had at one time existed; then, owing to a real slight or disappointment coming from this loved person, the relationship was shattered. The result was not the normal one of a withdrawal of the libido from this object and a displacement of it on to a new one, but something different, for whose coming about various conditions seem to be necessary. The object-cathexis proved to have little power of resistance and was brought to an end. But the free libido was not displaced on to another object; it was withdrawn into the ego. There, however, it was not employed in any unspecified way, but served to establish an identification of the ego with the abandoned object. Thus the shadow of the object fell upon the ego, and the latter could henceforth be judged by a special agency, as though it were an object, the forsaken object. In this way an object-loss was transformed into an ego-loss and the conflict between the ego and the loved person into a cleavage between the critical activity of the ego and the ego as altered by identification.

[1917e, 3047]

Melancholia, therefore, borrows some of its features from mourning, and the others from the process of regression from narcissistic object-choice to narcissism. It is on the one hand, like mourning, a reaction to the real loss of a loved object; but over and above this, it is marked by a determinant which is absent in normal mourning or which, if it is present, transforms the latter into pathological mourning. The loss of a love-object is an excellent opportunity for the ambivalence in love-relationships to make itself effective and come into the open. Where there is a disposition to obsessional neurosis the conflict due to ambivalence gives a pathological cast to mourning and forces it to express itself in the form of self-reproaches to the effect that the mourner himself is to blame for the loss of the loved object, i.e. that he has willed it. These obsessional states of depression following upon the death of a loved person show us what the conflict due to ambivalence can achieve by itself when there is no regressive drawing-in of libido as well. In melancholia, the occasions which give rise to the illness extend for the most part beyond the clear case of a loss by death, and include all those situations of being slighted, neglected or disappointed, which can import opposed feelings of love and hate into the relationship or reinforce an already existing ambivalence. This conflict due to ambivalence, which sometimes arises more from real experiences, sometimes more from constitutional factors, must not be overlooked among the preconditions of melancholia. If the love for the object - a love which cannot be given up though the object itself is given up - takes refuge in narcissistic identification, then the hate comes into operation on this substitutive object, abusing it, debasing it, making it suffer and deriving sadistic satisfaction from its suffering. The self-tormenting in melancholia, which is without doubt enjoyable, signifies, just like the corresponding phenomenon in obsessional neurosis, a satisfaction of trends of sadism and hate¹ which relate to an object, and which have been turned round upon the subject's own self in the ways we have been discussing. In both disorders the patients usually still succeed, by the circuitous path of self-punishment, in taking revenge on the original object and in tormenting their loved one through their illness, having resorted to it in order to avoid the need to express their hostility to him openly. After all, the person who has occasioned the patient's emotional disorder, and on whom his illness is centred, is usually to be found in his immediate environment. The melancholic's erotic cathexis in regard to his object has thus undergone a double vicissitude: part of it has regressed to identification, but the other part, under the influence of the conflict due to 'ambivalence, has been carried back to the stage of sadism which is nearer to that conflict.

[1917e, 3048]
As we have seen, however, melancholia contains something more than normal mourning. In melancholia the relation to the object is no simple one; it is complicated by the conflict due to ambivalence. The ambivalence is either constitutional, i.e. is an element of every love-relation formed by this particular ego, or else it proceeds precisely from those experiences that involved the threat of losing the object. For this reason the exciting causes of melancholia have a much wider range than those of mourning, which is for the most part occasioned only by a real loss of the object, by its death. In melancholia, accordingly, countless separate struggles are carried on over the object, in which hate and love contend with each other; the one seeks to detach the libido from the object, the other to maintain this position of the libido against the assault. The location of these separate struggles cannot be assigned to any system but the Ucs, the region of the memory-traces of things (as contrasted with word-cathexes). In mourning, too, the efforts to detach the libido are made in this same system; but in it nothing hinders these processes from proceeding along the normal path through the Pcs. to consciousness. This path is blocked for the work of melancholia, owing perhaps to a number of causes or a combination of them. Constitutional ambivalence belongs by its nature to the repressed; traumatic experiences in connection with the object may have activated other repressed material. Thus everything to do with these struggles due to ambivalence remains withdrawn from consciousness, until the outcome characteristic of melancholia has set in. This, as we know, consists in the threatened libidinal cathexis at length abandoning the object, only, however, to draw back to the place in the ego from which it had proceeded. So by taking flight into the ego love escapes extinction. After this regression of the libido the process can become conscious, and it is represented to consciousness as a conflict between one part of the ego and the critical agency. [1917e, 3052]

What consciousness is aware of in the work of melancholia is thus not the essential part of it, nor is it even the part which we may credit with an influence in bringing the ailment to an end. We see that the ego debases itself and rages against itself, and we understand as little as the patient what this can lead to and how it can change. We can more readily attribute such a function to the unconscious part of the work, because it is not difficult to perceive an essential analogy between the work of melancholia and of mourning. Just as mourning impels the ego to give up the object by declaring the object to be dead and offering the ego the inducement of continuing to live, so does each single struggle of ambivalence loosen the fixation of the libido to the object by disparaging it, denigrating it and even as it were killing it. It is possible for the process in the Ucs. to come to an end, either after the fury has spent itself or after the object has been abandoned as valueless. We cannot tell which of these two possibilities is the regular or more usual one in bringing melancholia to an end, nor what influence this termination has on the future course of the case. The ego may enjoy in this the satisfaction of knowing itself as the better of the two, as superior to the object. [1917e, 3053]
Even if we accept this view of the work of melancholia, it still does not supply an explanation of the one point on which we were seeking light. It was our expectation that the economic condition for the emergence of mania after the melancholia has run its course is to be found in the ambivalence which dominates the latter affection; and in this we found support from analogies in various other fields. But there is one fact before which that expectation must bow. Of the three preconditions of melancholia—loss of the object, ambivalence, and regression of libido into the ego—the first two are also found in the obsessional self-reproaches arising after a death has occurred. In those cases it is unquestionably the ambivalence which is the motive force of the conflict, and observation shows that after the conflict has come to an end there is nothing left over in the nature of the triumph of a manic state of mind. We are thus led to the third factor as the only one responsible for the result. The accumulation of cathexis which is at first bound and then, after the work of melancholia is finished, becomes free and makes mania possible must be linked with regression of the libido to narcissism. The conflict within the ego, which melancholia substitutes for the struggle over the object, must act like a painful wound which calls for an extraordinarily high anticathexis. - But here once again, it will be well to call a halt and to postpone any further explanation of mania until we have gained some insight into the economic nature, first, of physical pain, and then of the mental pain which is analogous to it. As we already know, the interdependence of the complicated problems of the mind forces us to break off every enquiry before it is completed—till the outcome of some other enquiry can come to its assistance.¹

But these melancholias also show us something else, which may be of importance for our later discussions. They show us the ego divided, fallen apart into two pieces, one of which rages against the second. This second piece is the one which has been altered by introjection and which contains the lost object. But the piece which behaves so cruelly is not unknown to us either. It comprises the conscience, a critical agency within the ego, which even in normal times takes up a critical attitude towards the ego, though never so relentlessly and so unjustifiably. On previous occasions² we have been driven to the hypothesis that some such agency develops in our ego which may cut itself off from the rest of the ego and come into conflict with it. We have called it the ‘ego ideal’, and by way of functions we have ascribed to it self-observation, the moral conscience, the censorship of dreams, and the chief influence in repression. We have said that it is the heir to the original narcissism in which the childish ego enjoyed self-sufficiency; it gradually gathers up from the influences of the environment the demands which that environment makes upon the ego and which the ego cannot always rise to; so that a man, when he cannot be satisfied with his ego itself, may nevertheless be able to find satisfaction in the ego ideal which has been differentiated out of the ego. In delusions of observation, as we have further shown, the disintegration of this agency has become patent, and has thus revealed its origin in the influence of superior powers, and above all of parents.³ But we have not forgotten to add that the amount of distance between this ego ideal and the real ego is very variable from one individual to another, and that with many people this differentiation within the ego does not go further than with children. [1921c, 3801]
We are aware that what we have been able to contribute towards the explanation of the libidinal structure of groups leads back to the distinction between the ego and the ego ideal and to the double kind of tie which this makes possible - identification, and putting the object in the place of the ego ideal. The assumption of this kind of differentiating grade in the ego as a first step in an analysis of the ego must gradually establish its justification in the most various regions of psychology. In my paper on narcissism I have put together all the pathological material that could at the moment be used in support of this differentiation. But it may be expected that when we penetrate deeper into the psychology of the psychoses its significance will be discovered to be far greater. Let us reflect that the ego now enters into the relation of an object to the ego ideal which has been developed out of it, and that all the interplay between an external object and the ego as a whole, with which our study of the neuroses has made us acquainted, may possibly be repeated upon this new scene of action within the ego.

Let us keep to what is clear: On the basis of our analysis of the ego it cannot be doubted that in cases of mania the ego and the ego ideal have fused together, so that the person, in a mood of triumph and self-satisfaction, disturbed by no self-criticism, can enjoy the abolition of his inhibitions, his feelings of consideration for others, and his self-reproaches. It is not so obvious, but nevertheless very probable, that the misery of the melancholic is the expression of a sharp conflict between the two agencies of his ego, a conflict in which the ideal, in an excess of sensitiveness, relentlessly exhibits its condemnation of the ego in delusions of inferiority and in self-deprecation. The only question is whether we are to look for the causes of these altered relations between the ego and the ego ideal in the periodic rebellions, which we have postulated above, against the new institution, or whether we are to make other circumstances responsible for them.

On the other hand there are melancholias in which the precipitating cause clearly plays an aetiological part. They are those which occur after the loss of a loved object, whether by death or as the result of circumstances which have necessitated the withdrawal of the libido from the object. A psychogenic melancholia of this sort can end in mania, and this cycle can be repeated several times, just as easily as in a case which appears to be spontaneous. Thus the state of things is somewhat obscure, especially as only a few forms and cases of melancholia have been submitted to psycho-analytic investigation.¹ So far we only understand those cases in which the object is given up because it has shown itself unworthy of love. It is then set up again inside the ego, by means of identification, and severely condemned by the ego ideal. The reproaches and attacks directed towards the object come to light in the shape of melancholic self-reproaches.²

Nevertheless I see no difficulty in assigning to the factor of the periodic rebellion of the ego against the ego ideal a share in both kinds of melancholia, the psychogenic as well as the spontaneous. In the spontaneous kind it may be supposed that the ego ideal is inclined to display a peculiar strictness, which then results automatically in its temporary suspension. In the psychogenic kind the ego would be incited to rebellion by ill-treatment on the part of its ideal - an ill-treatment which it encounters when there has been identification with a rejected object.

¹ [1921c, 3823]
² [1921c, 3824]
An interpretation of the normal, conscious sense of guilt (conscience) presents no difficulties; it is based on the tension between the ego and the ego ideal and is the expression of a condemnation of the ego by its critical agency. The feelings of inferiority so well known in neurotics are presumably not far removed from it. In two very familiar maladies the sense of guilt is over-strongly conscious; in them the ego ideal displays particular severity and often rages against the ego in a cruel fashion. The attitude of the ego ideal in these two conditions, obsessional neurosis and melancholia, presents, alongside of this similarity, differences that are no less significant.

[1923b, 3985]

In melancholia the impression that the super-ego has obtained a hold upon consciousness is even stronger. But here the ego ventures no objection; it admits its guilt and submits to the punishment. We understand the difference. In obsessional neurosis what were in question were objectionable impulses which remained outside the ego, while in melancholic the object to which the super-ego's wrath applies has been taken into the ego through identification.

[1923b, 3985]

It is certainly not clear why the sense of guilt reaches such an extraordinary strength in these two neurotic disorders; but the main problem presented in this state of affairs lies in another direction. We shall postpone discussion of it until we have dealt with the other cases in which the sense of guilt remains unconscious.

[1923b, 3985]

The question which we put off answering runs as follows: How is it that the super-ego manifests itself essentially as a sense of guilt (or rather, as criticism - for the sense of guilt is the perception in the ego answering to this criticism) and moreover develops such extraordinary harshness and severity towards the ego? If we turn to melancholia first, we find that the excessively strong super-ego which has obtained a hold upon consciousness rages against the ego with merciless violence, as if it had taken possession of the whole of the sadism available in the person concerned. Following our view of sadism, we should say that the destructive component had entrenched itself in the super-ego and turned against the ego. What is now holding sway in the super-ego is, as it were, a pure culture of the death instinct, and in fact it often enough succeds in driving the ego into death, if the latter does not fend off its tyrant in time by the change round into mania.

[1923b, 3987]

Let us again consider obsessional neurosis for a moment. The state of affairs is different here. The defusion of love into aggressiveness has not been effected by the work of the ego, but is the result of a regression which has come about in the id. But this process has extended beyond the id to the super-ego, which now increases its severity towards the innocent ego. It would seem, however, that in this case, no less than in that of melancholia, the ego, having gained control over the libido by means of identification, is punished for doing so by the super-ego through the instrumentality of the aggressiveness which was mixed with the libido.

[1923b, 3989]
The fear of death in melancholia only admits of one explanation: that the ego gives itself up because it feels itself hated and persecuted by the super-ego, instead of loved. To the ego, therefore, living means the same as being loved - being loved by the super-ego, which here again appears as the representative of the id. The super-ego fulfils the same function of protecting and saving that was fulfilled in earlier days by the father and later by Providence or Destiny. But, when the ego finds itself in an excessive real danger which it believes itself unable to overcome by its own strength, it is bound to draw the same conclusion. It sees itself deserted by all protecting forces and lets itself die. Here, moreover, is once again the same situation as that which underlay the first great anxiety-state of birth and the infantile anxiety of longing - the anxiety due to separation from the protecting mother.

[1923b, 3992]

The aetiology common to the onset of a psychoneurosis and of a psychosis always remains the same. It consists in a frustration, a non-fulfilment of one of those childhood wishes which are for ever undefeated and which are so deeply rooted in our phylogenetically determined organization. This frustration is in the last resort always an external one; but in the individual case it may proceed from the internal agency (in the super-ego) which has taken over the representation of the demands of reality. The pathogenic effect depends on whether, in a conflictual tension of this kind, the ego remains true to its dependence on the external world and attempts to silence the id, or whether it lets itself be overcome by the id and thus torn away from reality. A complication is introduced into this apparently simple situation, however, by the existence of the super-ego, which, though a link that is not yet clear to us, unites in itself influences coming from the id as well as from the external world, and is to some extent an ideal model of what the whole endeavour of the ego is aiming at - a reconciliation between its various dependent relationships. The attitude of the super-ego should be taken into account - which has not hitherto been done - in every form of psychical illness. We may provisionally assume that there must also be illnesses which are based on a conflict between the ego and the super-ego. Analysis gives us a right to suppose that melancholia is a typical example of this group; and we would set aside the name of 'narcissistic psychoneuroses' for disorders of that kind. Nor will it clash with our impressions if we find reasons for separating states like melancholia from the other psychoses. We now see that we have been able to make our simple genetic formula more complete, without dropping it. Transference neuroses correspond to a conflict between the ego and the id; narcissistic neuroses, to a conflict between the ego and the super-ego; and psychoses, to one between the ego and the external world. It is true that we cannot tell at once whether we have really gained any new knowledge by this, or have only enriched our store of formulas; but I think that this possible application of the proposed differentiation of the mental apparatus into an ego, a super-ego and an id cannot fail to give us courage to keep that hypothesis steadily in view.

[1924b, 4067]
In order to remain faithful to our customary phraseology, we shall have to speak, not of transposing the psychical accent, but of displacing large amounts of cathexis. The question then is whether we are entitled to picture extensive displacements like this from one agency of the mental apparatus to another. It looks like a new hypothesis constructed *ad hoc*. Yet we may remind ourselves that we have repeatedly (even though not sufficiently often) taken a factor of this kind into account in our attempts at a metapsychological picture of mental events. Thus, for instance, we supposed that the difference between an ordinary erotic object-cathexis and the state of being in love is that in the latter incomparably more cathexis passes over to the object and that the ego empties itself as it were in favour of the object. In studying some cases of paranoia I was able to establish the fact that ideas of persecution are formed early and exist for a long time without any perceptible effect, until, as the result of some particular precipitating event, they receive sufficient amounts of cathexis to cause them to become dominant. The cure, too, of such paranoic attacks would lie not so much in a resolution and correction of the delusional ideas as in a withdrawal from them of the cathexis which has been lent to them. The alternations between melancholia and mania, between a cruel suppression of the ego by the super-ego and a liberation of the ego after that pressure, suggests a shift of cathexis of this kind; such a shift, moreover, would have to be brought in to explain a whole number of phenomena belonging to normal mental life. If this has been done hitherto only to a very limited extent, that is on account of our usual caution - something which deserves only praise. The region in which we feel secure is that of the pathology of mental life; it is here that we make our observations and acquire our convictions. For the present we venture to form a judgement on the normal mind only in so far as we can discern what is normal in the isolations and distortions of the pathological material. When once we have overcome this hesitancy we shall recognize what a large contribution is made to the understanding of mental processes by the static conditions as well as by the dynamic changes in the *quantity* of energetic cathexis. [1927d, 4544]

Hardly have we familiarized ourselves with the idea of a super-ego like this which enjoys a certain degree of autonomy, follows its own intentions and is independent of the ego for its supply of energy, than a clinical picture forces itself on our notice which throws a striking light on the severity of this agency and indeed its cruelty, and on its changing relations to the ego. I am thinking of the condition of melancholia, or, more precisely, of melancholic attacks, which you too will have heard plenty about, even if you are not psychiatrists. The most striking feature of this illness, of whose causation and mechanism we know much too little, is the way in which the super-ego - 'conscience', you may call it, quietly - treats the ego. While a melancholic can, like other people, show a greater or lesser degree of severity to himself in his healthy periods, during a melancholic attack his super-ego becomes over-severe, abuses the poor ego, humiliates it and ill-treats it, threatens it with the direst punishments, reproaches it for actions in the remotest past which had been taken lightly at the time - as though it had spent the whole interval in collecting accusations and had only been waiting for its present access of strength in order to bring them up and make a condemnatory judgement on their basis. The super-ego applies the strictest moral standard to the helpless ego which is at its mercy; in general it represents the claims of morality, and we realize all at once that our moral sense of guilt is the expression of the tension between the ego and the super-ego. It is a most remarkable experience to see morality, which is supposed to have been given us by God and thus deeply implanted in us, functioning as a periodic phenomenon. For after a certain number of months the whole moral fuss is over, the criticism of the super-ego is silent, the ego is rehabilitated and again enjoys all the rights of man till the next attack. In some forms of the disease, indeed, something of a contrary sort occurs in the intervals; the ego finds itself in a blissful state of intoxication, it celebrates a triumph, as though the super-ego had lost all its strength or had melted into the ego; and this liberated, manic ego permits itself a truly uninhibited satisfaction of all its appetites. Here are happenings rich in unsolved riddles! [1933a, 4669]
I then understood that behind the train of thought in which she brought these open accusations against her father there lay concealed as usual a self-accusation. I met her halfway by assuring her that in my view the occurrence of leucorrhoea in young girls pointed primarily to masturbation, and I considered that all the other causes which were commonly assigned to that complaint were put in the background by masturbation.¹ I added that she was now on the way to finding an answer to her own question of why it was that precisely she had fallen ill - by confessing that she had masturbated, probably in childhood. Dora denied flatly that she could remember any such thing. But a few days later she did something which I could not help regarding as a further step towards the confession. For on that day she wore at her waist - a thing she never did on any other occasion before or after - a small reticule of a shape which had just come into fashion; and, as she lay on the sofa and talked, she kept playing with it - opening it, putting a finger into it, shutting it again, and so on. I looked on for some time, and then explained to her the nature of a 'symptomatic act'.² I give the name of symptomatic acts to those acts which people perform, as we say, automatically, unconsciously, without attending to them, or as if in a moment of distraction. They are actions to which people would like to deny any significance, and which, if questioned about them, they would explain as being indifferent and accidental. Closer observation, however, will show that these actions, about which consciousness knows nothing or wishes to know nothing, in fact give expression to unconscious thoughts and impulses, and are therefore most valuable and instructive as being manifestations of the unconscious which have been able to come to the surface. There are two sorts of conscious attitudes possible towards these symptomatic acts. If we can ascribe inconspicuous motives to them we recognize their existence; but if no such pretext can be found for conscious use we usually fail altogether to notice that we have performed them. Dora found no difficulty in producing a motive: 'Why should I not wear a reticule like this, as it is now the fashion to do?' But a justification of this kind does not dismiss the possibility of the action in question having an unconscious origin. Though on the other hand the existence of such an origin and the meaning attributed to the act cannot be conclusively established. We must content ourselves with recording the fact that such a meaning fits in quite extraordinarily well with the situation as a whole and with the programme laid down by the unconscious.

² [1905e, 1413]

It is always a striking thing and deserves special notice when a neurotic is in the habit of speaking ill of himself, expressing a low opinion of himself, and so on. As in the case of self-reproaches, it is often possible to explain it by supposing that he is identifying himself with someone else. But in one patient the attendant circumstances during the session necessitated another explanation of behaviour of this kind. A young lady, who was never tired of declaring that she had very little intelligence, was without gifts, etc., was only trying to indicate by this that she had great physical beauty, and was concealing this boast behind her self-criticism. Nor was a reference to the harmful effects of masturbation - a reference which is to be expected in all such cases - absent in this one.

² [1913h, 2832]

There is one observation, not at all difficult to make, which leads to the explanation of the contradiction mentioned above. If one listens patiently to a melancholic's many and various self-accusations, one cannot in the end avoid the impression that often the most violent of them are hardly at all applicable to the patient himself, but that with insignificant modifications they do fit someone else, someone whom the patient loves or has loved or should love. Every time one examines the facts this conjecture is confirmed. So we find the key to the clinical picture: we perceive that the self-reproaches are reproaches against a loved object which have been shifted away from it on to the patient's own ego.

² [1917e, 3046]
The woman who loudly pities her husband for being tied to such an incapable wife as herself is really accusing her husband of being incapable, in whatever sense she may mean this. There is no need to be greatly surprised that a few genuine self-reproaches are scattered among those that have been transposed back. These are allowed to obtrude themselves, since they help to mask the others and make recognition of the true state of affairs impossible. Moreover, they derive from the pros and cons of the conflict of love that has led to the loss of love. The behaviour of the patients, too, now becomes much more intelligible. Their complaints are really 'plaints' in the old sense of the word. They are not ashamed and do not hide themselves, since everything derogatory that they say about themselves is at bottom said about someone else. Moreover, they are far from evincing towards those around them the attitude of humility and submissiveness that would alone befit such worthless people. On the contrary, they make the greatest nuisance of themselves, and always seem as though they felt slighted and had been treated with great injustice. All this is possible only because the reactions expressed in their behaviour still proceed from a mental constellation of revolt, which has then, by a certain process, passed over into the crushed state of melancholia.

Melancholia, therefore, borrows some of its features from mourning, and the others from the process of regression from narcissistic object-choice to narcissism. It is on the one hand, like mourning, a reaction to the real loss of a loved object; but over and above this, it is marked by a determinant which is absent in normal mourning or which, if it is present, transforms the latter into pathological mourning. The loss of a love-object is an excellent opportunity for the ambivalence in love-relationships to make itself effective and come into the open. Where there is a disposition to obsessional neurosis the conflict due to ambivalence gives a pathological cast to mourning and forces it to express itself in the form of self-reproaches to the effect that the mourner himself is to blame for the loss of the loved object, i.e. that he has willed it. These obsessional states of depression following upon the death of a loved person show us what the conflict due to ambivalence can achieve by itself when there is no regressive drawing-in of libido as well. In melancholia, the occasions which give rise to the illness extend for the most part beyond the clear case of a loss by death, and include all those situations of being slighted, neglected or disappointed, which can import opposed feelings of love and hate into the relationship or reinforce an already existing ambivalence. This conflict due to ambivalence, which sometimes arises more from real experiences, sometimes more from constitutional factors, must not be overlooked among the preconditions of melancholia. If the love for the object - a love which cannot be given up though the object itself is given up - takes refuge in narcissistic identification, then the hate comes into operation on this substitutive object, abusing it, debasing it, making it suffer and deriving sadistic satisfaction from its suffering. The self-tormenting in melancholia, which is without doubt enjoyable, signifies, just like the corresponding phenomenon in obsessional neurosis, a satisfaction of trends of sadism and hate which relate to an object, and which have been turned round upon the subject's own self in the ways we have been discussing. In both disorders the patients usually still succeed, by the circuitous path of self-punishment, in taking revenge on the original object and in tormenting their loved one through their illness, having resorted to it in order to avoid the need to express their hostility to him openly. After all, the person who has occasioned the patient's emotional disorder, and on whom his illness is centred, is usually to be found in his immediate environment. The melancholic's erotic cathexis in regard to his object has thus undergone a double vicissitude: part of it has regressed to identification, but the other part, under the influence of the conflict due to 'ambivalence, has been carried back to the stage of sadism which is nearer to that conflict.
As with paranoia, so also with melancholia (of which, incidentally, many different clinical forms have been described) we have found a point at which it has become possible to obtain some insight into the internal structure of the disease. We have discovered that the self-reproaches, with which these melancholic patients torment themselves in the most merciless fashion, in fact apply to another person, the sexual object which they have lost or which has become valueless to them through its own fault. From this we can conclude that the melancholic has, it is true, withdrawn his libido from the object, but that, by a process which we must call 'narcissistic identification', the object has been set up in the ego itself, has been as it were, projected on to the ego. (Here I can only give you a pictorial description and not an ordered account on topographical and dynamic lines.) The subject's own ego is then treated like the object that has been abandoned, and it is subjected to all the acts of aggression and expressions of vengefulness which have been aimed at the object. A melancholic's propensity to suicide is also made more intelligible if we consider that the patient's embitterment strikes with a single blow at his own ego and at the loved and hated object. In melancholia, as well as in other narcissistic disorders, a particular trait in the patient's emotional life emerges with peculiar emphasis - what, since Bleuler, we have been accustomed to describe as 'ambivalence'. By this we mean the direction towards the same person of contrary - affectionate and hostile - feelings. Unluckily I have been unable in the course of these lectures to tell you more about this emotional ambivalence.¹

Another such instance of introjection of the object has been provided by the analysis of melancholia, an affection which counts among the most notable of its exciting causes the real or emotional loss of a loved object. A leading characteristic of these cases is a cruel self-depreciation of the ego combined with relentless self-criticism and bitter self-reproaches. Analyses have shown that this disparagement and these reproaches apply at bottom to the object and represent the ego's revenge upon it. The shadow of the object has fallen upon the ego, as I have said elsewhere.¹ The introjection of the object is here unmistakably clear.¹

On the other hand there are melancholias in which the precipitating cause clearly plays an aetiologial part. They are those which occur after the loss of a loved object, whether by death or as the result of circumstances which have necessitated the withdrawal of the libido from the object. A psychogenic melancholia of this sort can end in mania, and this cycle can be repeated several times, just as easily as in a case which appears to be spontaneous. Thus the state of things is somewhat obscure, especially as only a few forms and cases of melancholia have been submitted to psycho-analytic investigation.¹ So far we only understand those cases in which the object is given up because it has shown itself unworthy of love. It is then set up again inside the ego, by means of identification, and severely condemned by the ego ideal. The reproaches and attacks directed towards the object come to light in the shape of melancholic self-reproaches.²

To speak more accurately, they conceal themselves behind the reproaches directed towards the subject's own ego, and lend them the fixity, tenacity, and imperativeness which characterize the self-reproaches of a melancholic.²

In melancholia the impression that the super-ego has obtained a hold upon consciousness is even stronger. But here the ego ventures no objection; it admits its guilt and submits to the punishment. We understand the difference. In obsessional neurosis what were in question were objectionable impulses which remained outside the ego, while in melancholic the object to which the super-ego's wrath applies has been taken into the ego through identification.²

¹ To speak more accurately, they conceal themselves behind the reproaches directed towards the subject's own ego, and lend them the fixity, tenacity, and imperativeness which characterize the self-reproaches of a melancholic.

² To speak more accurately, they conceal themselves behind the reproaches directed towards the subject's own ego, and lend them the fixity, tenacity, and imperativeness which characterize the self-reproaches of a melancholic.

³ To speak more accurately, they conceal themselves behind the reproaches directed towards the subject's own ego, and lend them the fixity, tenacity, and imperativeness which characterize the self-reproaches of a melancholic.
When it happens that a person has to give up a sexual object, there quite often ensues an alteration of his ego which can only be described as a setting up of the object inside the ego, as it occurs in melancholia; the exact nature of this substitution is as yet unknown to us. It may be that by this introjection, which is a kind of regression to the mechanism of the oral phase, the ego makes it easier for the object to be given up or renders that process possible. It may be that this identification is the sole condition under which the id can give up its objects. At any rate the process, especially in the early phases of development, is a very frequent one, and it makes it possible to suppose that the character of the ego is a precipitate of abandoned object-cathexes and that it contains the history of those object-choices. It must, of course, be admitted from the outset that there are varying degrees of capacity for resistance, which decide the extent to which a person's character fends off or accepts the influences of the history of his erotic object-choices. In women who have had many experiences in love there seems to be no difficulty in finding vestiges of their object-cathexes in the traits of their character. We must also take into consideration cases of simultaneous object-cathexis and identification - cases, that is, in which the alteration in character occurs before the object has been given up. In such cases the alteration in character has been able to survive the object-relation and in a certain sense to conserve it.

[1923b, 3963]
Melancholia, therefore, borrows some of its features from mourning, and the others from the process of regression from narcissistic object-choice to narcissism. It is on the one hand, like mourning, a reaction to the real loss of a loved object; but over and above this, it is marked by a determinant which is absent in normal mourning or which, if it is present, transforms the latter into pathological mourning. The loss of a love-object is an excellent opportunity for the ambivalence in love-relationships to make itself effective and come into the open. Where there is a disposition to obsessional neurosis the conflict due to ambivalence gives a pathological cast to mourning and forces it to express itself in the form of self-reproaches to the effect that the mourner himself is to blame for the loss of the loved object, i.e. that he has willed it. These obsessional states of depression following upon the death of a loved person show us what the conflict due to ambivalence can achieve by itself when there is no regressive drawing-in of libido as well. In melancholia, the occasions which give rise to the illness extend for the most part beyond the clear case of a loss by death, and include all those situations of being slighted, neglected or disappointed, which can import opposed feelings of love and hate into the relationship or reinforce an already existing ambivalence. This conflict due to ambivalence, which sometimes arises more from real experiences, sometimes more from constitutional factors, must not be overlooked among the preconditions of melancholia. If the love for the object - a love which cannot be given up though the object itself is given up - takes refuge in narcissistic identification, then the hate comes into operation on this substitutive object, abusing it, debasing it, making it suffer and deriving sadistic satisfaction from its suffering. The self-tormenting in melancholia, which is without doubt enjoyable, signifies, just like the corresponding phenomenon in obsessional neurosis, a satisfaction of trends of sadism and hate which relate to an object, and which have been turned round upon the subject's own self in the ways we have been discussing. In both disorders the patients usually still succeed, by the circuitous path of self-punishment, in taking revenge on the original object and in tormenting their loved one through their illness, having resorted to it in order to avoid the need to express their hostility to him openly. After all, the person who has occasioned the patient's emotional disorder, and on whom his illness is centred, is usually to be found in his immediate environment. The melancholic's erotic cathexis in regard to his object has thus undergone a double vicissitude: part of it has regressed to identification, but the other part, under the influence of the conflict due to ambivalence, has been carried back to the stage of sadism which is nearer to that conflict.

[1917e, 3048]

It is this sadism alone that solves the riddle of the tendency to suicide which makes melancholia so interesting - and so dangerous. So immense is the ego's self-love, which we have come to recognize as the primal state from which instinctual life proceeds, and so vast is the amount of narcissistic libido which we see liberated in the fear that emerges at a threat to life, that we cannot conceive how that ego can consent to its own destruction. We have long known, it is true, that no neurotic harbours thoughts of suicide which he has not turned back upon himself from murderous impulses against others, but we have never been able to explain what interplay of forces can carry such a purpose through to execution. The analysis of melancholia now shows that the ego can kill itself only if, owing to the return of the object-cathexis, it can treat itself as an object - if it is able to direct against itself the hostility which relates to an object and which represents the ego's original reaction to objects in the external world. Thus in regression from narcissistic object-choice the object has, it is true, been got rid of, but it has nevertheless proved more powerful than the ego itself. In the two opposed situations of being most intensely in love and of suicide the ego is overwhelmed by the object, though in totally different ways.

[1917e, 3049]
As with paranoia, so also with melancholia (of which, incidentally, many different clinical forms have been described) we have found a point at which it has become possible to obtain some insight into the internal structure of the disease. We have discovered that the self-reproaches, with which these melancholic patients torment themselves in the most merciless fashion, in fact apply to another person, the sexual object which they have lost or which has become valueless to them through its own fault. From this we can conclude that the melancholic has, it is true, withdrawn his libido from the object, but that, by a process which we must call 'narcissistic identification', the object has been set up in the ego itself, has been as it were, projected on to the ego. (Here I can only give you a pictorial description and not an ordered account on topographical and dynamic lines.) The subject's own ego is then treated like the object that has been abandoned, and it is subjected to all the acts of aggression and expressions of vengefulness which have been aimed at the object. A melancholic's propensity to suicide is also made more intelligible if we consider that the patient's embitterment strikes with a single blow at his own ego and at the loved and hated object. In melancholia, as well as in other narcissistic disorders, a particular trait in the patient's emotional life emerges with peculiar emphasis - what, since Bleuler, we have been accustomed to describe as 'ambivalence'. By this we mean the direction towards the same person of contrary - affectionate and hostile - feelings. Unluckily I have been unable in the course of these lectures to tell you more about this emotional ambivalence.

[1916-1917, 3471]

The question which we put off answering runs as follows: How is it that the super-ego manifests itself essentially as a sense of guilt (or rather, as criticism - for the sense of guilt is the perception in the ego answering to this criticism) and moreover develops such extraordinary harshness and severity towards the ego? If we turn to melancholia first, we find that the excessively strong super-ego which has obtained a hold upon consciousness rages against the ego with merciless violence, as if it had taken possession of the whole of the sadism available in the person concerned. Following our view of sadism, we should say that the destructive component had entrenched itself in the super-ego and turned against the ego. What is now holding sway in the super-ego is, as it were, a pure culture of the death instinct, and in fact it often enough succeeds in driving the ego into death, if the latter does not fend off its tyrant in time by the change round into mania.

[1923b, 3987]

The dangerous death instincts are dealt with in the individual in various ways: in part they are rendered harmless by being fused with erotic components, in part they are diverted towards the external world in the form of aggression, while to a large extent they undoubtedly continue their internal work unhindered. How is it then that in melancholia the super-ego can become a kind of gathering-place for the death instincts?

[1923b, 3988]

Let us again consider obsessional neurosis for a moment. The state of affairs is different here. The defusion of love into aggressiveness has not been effected by the work of the ego, but is the result of a regression which has come about in the id. But this process has extended beyond the id to the super-ego, which now increases its severity towards the innocent ego. It would seem, however, that in this case, no less than in that of melancholia, the ego, having gained control over the libido by means of identification, is punished for doing so by the super-ego through the instrumentality of the aggressiveness which was mixed with the libido.

[1923b, 3989]
One or two things may be directly inferred with regard to the preconditions and effects of a process such as this. On the one hand, a strong fixation to the loved object must have been present; on the other hand, in contradiction to this, the object-cathexis must have had little power of resistance. As Otto Rank has aptly remarked, this contradiction seems to imply that the object-choice has been effected on a narcissistic basis, so that the object-cathexis, when obstacles come in its way, can regress to narcissism. The narcissistic identification with the object then becomes a substitute for the erotic cathexis, the result of which is that in spite of the conflict with the loved person the love-relation need not be given up. This substitution of identification for object-love is an important mechanism in the narcissistic affections; Karl Landauer (1914) has lately been able to point to it in the process of recovery in a case of schizophrenia. It represents, of course, a regression from one type of object-choice to original narcissism. We have elsewhere shown that identification is a preliminary stage of object-choice, that it is the first way - and one that is expressed in an ambivalent fashion - in which the ego picks out an object. The ego wants to incorporate this object into itself, and, in accordance with the oral or cannibalistic phase of libidinal development in which it is, it wants to do so by devouring it. Abraham is undoubtedly right in attributing to this connection the refusal of nourishment met with in severe forms of melancholia.

The conclusion which our theory would require - namely, that the disposition to fall ill of melancholia (or some part of that disposition) lies in the predominance of the narcissistic type of object-choice - has unfortunately not yet been confirmed by observation. In the opening remarks of this paper, I admitted that the empirical material upon which this study is founded is insufficient for our needs. If we could assume an agreement between the results of observation and what we have inferred, we should not hesitate to include this regression from object-cathexis to the still narcissistic oral phase of the libido in our characterization of melancholia. Identifications with the object are by no means rare in the transference neuroses either; indeed, they are a well-known mechanism of symptom-formation, especially in hysteria. The difference, however, between narcissistic and hysterical identification may be seen in this: that, whereas in the former the object-cathexis is abandoned, in the latter it persists and manifests its influence, though this is usually confined to certain isolated actions and innervations. In any case, in the transference neuroses, too, identification is the expression of there being something in common, which may signify love. Narcissistic identification is the older of the two and it paves the way to an understanding of hysterical identification, which has been less thoroughly studied.
Melancholia, therefore, borrows some of its features from mourning, and the others from the process of regression from narcissistic object-choice to narcissism. It is on the one hand, like mourning, a reaction to the real loss of a loved object; but over and above this, it is marked by a determinant which is absent in normal mourning or which, if it is present, transforms the latter into pathological mourning. The loss of a love-object is an excellent opportunity for the ambivalence in love-relationships to make itself effective and come into the open. Where there is a disposition to obsessional neurosis the conflict due to ambivalence gives a pathological cast to mourning and forces it to express itself in the form of self-reproaches to the effect that the mourner himself is to blame for the loss of the loved object, i.e. that he has willed it. These obsessional states of depression following upon the death of a loved person show us what the conflict due to ambivalence can achieve by itself when there is no regressive drawing-in of libido as well. In melancholia, the occasions which give rise to the illness extend for the most part beyond the clear case of a loss by death, and include all those situations of being slighted, neglected or disappointed, which can import opposed feelings of love and hate into the relationship or reinforce an already existing ambivalence. This conflict due to ambivalence, which sometimes arises more from real experiences, sometimes more from constitutional factors, must not be overlooked among the preconditions of melancholia. If the love for the object - a love which cannot be given up though the object itself is given up - takes refuge in narcissistic identification, then the hate comes into operation on this substitutive object, abusing it, debasing it, making it suffer and deriving sadistic satisfaction from its suffering. The self-tormenting in melancholia, which is without doubt enjoyable, signifies, just like the corresponding phenomenon in obsessional neurosis, a satisfaction of trends of sadism and hate which relate to an object, and which have been turned round upon the subject's own self in the ways we have been discussing. In both disorders the patients usually still succeed, by the circuitous path of self-punishment, in taking revenge on the original object and in tormenting their loved one through their illness, having resorted to it in order to avoid the need to express their hostility to him openly. After all, the person who has occasioned the patient's emotional disorder, and on whom his illness is centred, is usually to be found in his immediate environment. The melancholic's erotic cathexis in regard to his object has thus undergone a double vicissitude: part of it has regressed to identification, but the other part, under the influence of the conflict due to 'ambivalence, has been carried back to the stage of sadism which is nearer to that conflict.

[1917e, 3048]

It is this sadism alone that solves the riddle of the tendency to suicide which makes melancholia so interesting - and so dangerous. So immense is the ego's self-love, which we have come to recognize as the primal state from which instinctual life proceeds, and so vast is the amount of narcissistic libido which we see liberated in the fear that emerges at a threat to life, that we cannot conceive how that ego can consent to its own destruction. We have long known, it is true, that no neurotic harbours thoughts of suicide which he has not turned back upon himself from murderous impulses against others, but we have never been able to explain what interplay of forces can carry such a purpose through to execution. The analysis of melancholia now shows that the ego can kill itself only if, owing to the return of the object-cathexis, it can treat itself as an object - if it is able to direct against itself the hostility which relates to an object and which represents the ego's original reaction to objects in the external world.¹ Thus in regression from narcissistic object-choice the object has, it is true, been got rid of, but it has nevertheless proved more powerful than the ego itself. In the two opposed situations of being most intensely in love and of suicide the ego is overwhelmed by the object, though in totally different ways.

[1917e, 3049]
Even if we accept this view of the work of melancholia, it still does not supply an explanation of the one point on which we were seeking light. It was our expectation that the economic condition for the emergence of mania after the melancholia has run its course is to be found in the ambivalence which dominates the latter affection; and in this we found support from analogies in various other fields. But there is one fact before which that expectation must bow. Of the three preconditions of melancholia - loss of the object, ambivalence, and regression of libido into the ego - the first two are also found in the obsessional self-reproaches arising after a death has occurred. In those cases it is unquestionably the ambivalence which is the motive force of the conflict, and observation shows that after the conflict has come to an end there is nothing left over in the nature of the triumph of a manic state of mind. We are thus led to the third factor as the only one responsible for the result. The accumulation of cathectic which is at first bound and then, after the work of melancholia is finished, becomes free and makes mania possible must be linked with regression of the libido to narcissism. The conflict within the ego, which melancholia substitutes for the struggle over the object, must act like a painful wound which calls for an extraordinarily high anticathexis. - But here once again, it will be well to call a halt and to postpone any further explanation of mania until we have gained some insight into the economic nature, first, of physical pain, and then of the mental pain which is analogous to it. As we already know, the interdependence of the complicated problems of the mind forces us to break off every enquiry before it is completed - till the outcome of some other enquiry can come to its assistance.¹

[1917e, 3053]

For the moment we will dwell a little longer on regression. After what you have learnt of the development of the libidinal function, you will be prepared to hear that there are regressions of two sorts: a return to the objects first cathected by the libido, which, as we know, are of an incestuous nature, and a return of the sexual organization as a whole to earlier stages. Both sorts are found in the transference neuroses and play a great part in their mechanism. In particular, a return to the first incestuous objects of the libido is a feature that is found in neurotics with positively fatiguing regularity. There is much more to be said about regressions of the libido itself when we take into account as well another group of neuroses, the narcissistic ones, which for the time being we do not intend to do. These disorders give us access to other developmental processes of the libidinal function which we have not yet mentioned, and show us correspondingly new sorts of regression as well. But above all I think I ought to warn you now not to confuse regression with repression and help you to form a clear idea of the relations between the two processes. Repression, as you will recall, is the process by which an act which is admissible to consciousness, one, therefore, which belongs to the system $Pcs.$, is made unconscious - is pushed back, therefore, into the system $Ucs.$ And we equally speak of repression if the unconscious mental act is altogether forbidden access to the neighbouring preconscious system and is turned back at the threshold by the censorship. Thus the concept of repression involves no relation to sexuality: I must ask you to take special note of that. It indicates a purely psychological process, which we can characterize still better if we call it a 'topographical' one. By this we intend to say that it is concerned with the psychical regions which we have assumed to exist, or, if we drop this clumsy working hypothesis, with the construction of the mental apparatus out of distinct psychical systems.

[1916-1917, 3405]
So far all this is trite repetition. And you must not suppose that the many things I have not mentioned this time no longer hold good. This repetition was necessary so that I might use it as the starting-point for a report on the advances in our knowledge. We can boast of having learnt much that is new, particularly about the early organizations of the libido, and of having obtained a clearer grasp of the significance of what is old; and I will give you at least a few examples to demonstrate this. Abraham showed in 1924 that two stages can be distinguished in the sadistic-anal phase. The earlier of these is dominated by the destructive trends of destroying and losing, the later one by trends friendly towards objects - those of keeping and possessing. It is in the middle of this phase, therefore, that consideration for the object makes its first appearance as a precursor of a later erotic cathexis. We are equally justified in making a similar subdivision in the first, oral phase. In the first sub-stage what is in question is only oral incorporation, there is no ambivalence at all in the relation to the object - the mother's breast. The second stage, characterized by the emergence of the biting activity, may be described as the 'oral-sadistic' one; it exhibits for the first time the phenomena of ambivalence, which become so much clearer afterwards, in the following sadistic-anal phase. The value of these new distinctions is to be seen especially if we look for the dispositional points in the development of the libido in the case of particular neuroses, such as obsessional neurosis or melancholia. You must here recall to mind what we have learnt about the connection between fixation of the libido, disposition and regression.

[1933a, 4704]
Melancholia, therefore, borrows some of its features from mourning, and the others from the 
process of regression from narcissistic object-choice to narcissism. It is on the one hand, like 
mourning, a reaction to the real loss of a loved object; but over and above this, it is marked by a 
determinant which is absent in normal mourning or which, if it is present, transforms the latter 
into pathological mourning. The loss of a love-object is an excellent opportunity for the 
ambivalence in love-relationships to make itself effective and come into the open. Where there 
is a disposition to obsessional neurosis the conflict due to ambivalence gives a pathological cast 
to mourning and forces it to express itself in the form of self-reproaches to the effect that the 
mourner himself is to blame for the loss of the loved object, i.e. that he has willed it. These 
obsessional states of depression following upon the death of a loved person show us what the 
conflict due to ambivalence can achieve by itself when there is no regressive drawing-in of libido 
as well. In melancholia, the occasions which give rise to the illness extend for the most part 
beyond the clear case of a loss by death, and include all those situations of being slighted, 
neglected or disappointed, which can import opposed feelings of love and hate into the 
relationship or reinforce an already existing ambivalence. This conflict due to ambivalence, 
which sometimes arises more from real experiences, sometimes more from constitutional 
factors, must not be overlooked among the preconditions of melancholia. If the love for the 
object - a love which cannot be given up though the object itself is given up - takes refuge in 
narcissistic identification, then the hate comes into operation on this substitutive object, abusing 
it, debasing it, making it suffer and deriving sadistic satisfaction from its suffering. The self-
tormenting in melancholia, which is without doubt enjoyable, signifies, just like the 
corresponding phenomenon in obsessional neurosis, a satisfaction of trends of sadism and hate 
which relate to an object, and which have been turned round upon the subject's own self in the 
ways we have been discussing. In both disorders the patients usually still succeed, by the 
circuitous path of self-punishment, in taking revenge on the original object and in tormenting 
their loved one through their illness, having resorted to it in order to avoid the need to express 
their hostility to him openly. After all, the person who has occasioned the patient's emotional 
disorder, and on whom his illness is centred, is usually to be found in his immediate 
environment. The melancholic's erotic cathexis in regard to his object has thus undergone a 
double vicissitude: part of it has regressed to identification, but the other part, under the 
influence of the conflict due to 'ambivalence, has been carried back to the stage of sadism 
which is nearer to that conflict.

[1917e, 3048]
As we have seen, however, melancholia contains something more than normal mourning. In melancholia the relation to the object is no simple one; it is complicated by the conflict due to ambivalence. The ambivalence is either constitutional, i.e. is an element of every love-relation formed by this particular ego, or else it proceeds precisely from those experiences that involved the threat of losing the object. For this reason the exciting causes of melancholia have a much wider range than those of mourning, which is for the most part occasioned only by a real loss of the object, by its death. In melancholia, accordingly, countless separate struggles are carried on over the object, in which hate and love contend with each other; the one seeks to detach the libido from the object, the other to maintain this position of the libido against the assault. The location of these separate struggles cannot be assigned to any system but the Ucs., the region of the memory-traces of things (as contrasted with word-cathexes). In mourning, too, the efforts to detach the libido are made in this same system; but in it nothing hinders these processes from proceeding along the normal path through the Pcs. to consciousness. This path is blocked for the work of melancholia, owing perhaps to a number of causes or a combination of them. Constitutional ambivalence belongs by its nature to the repressed; traumatic experiences in connection with the object may have activated other repressed material. Thus everything to do with these struggles due to ambivalence remains withdrawn from consciousness, until the outcome characteristic of melancholia has set in. This, as we know, consists in the threatened libidinal cathexis at length abandoning the object, only, however, to draw back to the place in the ego from which it had proceeded. So by taking flight into the ego love escapes extinction. After this regression of the libido the process can become conscious, and it is represented to consciousness as a conflict between one part of the ego and the critical agency. [1917e, 3052]

What consciousness is aware of in the work of melancholia is thus not the essential part of it, nor is it even the part which we may credit with an influence in bringing the ailment to an end. We see that the ego debases itself and rages against itself, and we understand as little as the patient what this can lead to and how it can change. We can more readily attribute such a function to the unconscious part of the work, because it is not difficult to perceive an essential analogy between the work of melancholia and of mourning. Just as mourning impels the ego to give up the object by declaring the object to be dead and offering the ego the inducement of continuing to live, so does each single struggle of ambivalence loosen the fixation of the libido to the object by disparaging it, denigrating it and even as it were killing it. It is possible for the process in the Ucs. to come to an end, either after the fury has spent itself or after the object has been abandoned as valueless. We cannot tell which of these two possibilities is the regular or more usual one in bringing melancholia to an end, nor what influence this termination has on the future course of the case. The ego may enjoy in this the satisfaction of knowing itself as the better of the two, as superior to the object. [1917e, 3053]
Even if we accept this view of the work of melancholia, it still does not supply an explanation of the one point on which we were seeking light. It was our expectation that the economic condition for the emergence of mania after the melancholia has run its course is to be found in the ambivalence which dominates the latter affection; and in this we found support from analogies in various other fields. But there is one fact before which that expectation must bow. Of the three preconditions of melancholia - loss of the object, ambivalence, and regression of libido into the ego - the first two are also found in the obsessional self-reproaches arising after a death has occurred. In those cases it is unquestionably the ambivalence which is the motive force of the conflict, and observation shows that after the conflict has come to an end there is nothing left over in the nature of the triumph of a manic state of mind. We are thus led to the third factor as the only one responsible for the result. The accumulation of cathectic which is at first bound and then, after the work of melancholia is finished, becomes free and makes mania possible must be linked with regression of the libido to narcissism. The conflict within the ego, which melancholia substitutes for the struggle over the object, must act like a painful wound which calls for an extraordinarily high anticathexis. - But here once again, it will be well to call a halt and to postpone any further explanation of mania until we have gained some insight into the economic nature, first, of physical pain, and then of the mental pain which is analogous to it. As we already know, the interdependence of the complicated problems of the mind forces us to break off every enquiry before it is completed - till the outcome of some other enquiry can come to its assistance.¹

[1917e, 3053]

As with paranoia, so also with melancholia (of which, incidentally, many different clinical forms have been described) we have found a point at which it has become possible to obtain some insight into the internal structure of the disease. We have discovered that the self-reproaches, with which these melancholic patients torment themselves in the most merciless fashion, in fact apply to another person, the sexual object which they have lost or which has become valueless to them through its own fault. From this we can conclude that the melancholic has, it is true, withdrawn his libido from the object, but that, by a process which we must call 'narcissistic identification', the object has been set up in the ego itself, has been as it were, projected on to the ego. (Here I can only give you a pictorial description and not an ordered account on topographical and dynamic lines.) The subject's own ego is then treated like the object that has been abandoned, and it is subjected to all the acts of aggression and expressions of vengefulness which have been aimed at the object. A melancholic's propensity to suicide is also made more intelligible if we consider that the patient's embitterment strikes with a single blow at his own ego and at the loved and hated object. In melancholia, as well as in other narcissistic disorders, a particular trait in the patient's emotional life emerges with peculiar emphasis - what, since Bleuler, we have been accustomed to describe as 'ambivalence'. By this we mean the direction towards the same person of contrary - affectionate and hostile - feelings. Unluckily I have been unable in the course of these lectures to tell you more about this emotional ambivalence. [1916-1917, 3471]
In this we are undoubtedly right. But we are not right if we conclude further that this relation has been merely one of love. On the contrary, his mourning over the loss of his father is the more likely to turn into melancholia, the more his attitude to him bore the stamp of ambivalence. This emphasis on ambivalence, however, prepares us for the possibility of the father being subjected to a debasement, as we see happening in the painter's demonological neurosis. If we were able to learn as much about Christoph Haizmann as about a patient undergoing an analysis with us, it would be an easy matter to elicit this ambivalence, to get him to remember when and under what provocations he was given cause to fear and hate his father; and, above all, to discover what were the accidental factors that were added to the typical motives for a hatred of the father which are necessarily inherent in the natural relationship of son to father. Perhaps we might then find a special explanation for the painter's inhibition in work. It is possible that his father had opposed his wish to become a painter. If that was so, his inability to practise his art after his father's death would on the one hand be an expression of the familiar phenomenon of 'deferred obedience'; and, on the other hand, by making him incapable of earning a livelihood, it would be bound to increase his longing for his father as a protector from the cares of life. In its aspect as deferred obedience it would also be an expression of remorse and a successful self-punishment.

[1923d, 4012]

So far all this is trite repetition. And you must not suppose that the many things I have not mentioned this time no longer hold good. This repetition was necessary so that I might use it as the starting-point for a report on the advances in our knowledge. We can boast of having learnt much that is new, particularly about the early organizations of the libido, and of having obtained a clearer grasp of the significance of what is old; and I will give you at least a few examples to demonstrate this. Abraham showed in 1924 that two stages can be distinguished in the sadistic-anal phase. The earlier of these is dominated by the destructive trends of destroying and losing, the later one by trends friendly towards objects - those of keeping and possessing. It is in the middle of this phase, therefore, that consideration for the object makes its first appearance as a precursor of a later erotic cathexis. We are equally justified in making a similar subdivision in the first, oral phase. In the first sub-stage what is in question is only oral incorporation, there is no ambivalence at all in the relation to the object - the mother's breast. The second stage, characterized by the emergence of the biting activity, may be described as the 'oral-sadistic' one; it exhibits for the first time the phenomena of ambivalence, which become so much clearer afterwards, in the following sadistic-anal phase. The value of these new distinctions is to be seen especially if we look for the dispositional points in the development of the libido in the case of particular neuroses, such as obsessional neurosis or melancholia. You must here recall to mind what we have learnt about the connection between fixation of the libido, disposition and regression.

[1933a, 4704]
A second form of obsessional neurosis comes about if what has forced its way to representation in conscious psychical life is not the repressed mnemic content but the likewise repressed self-reproach. The affect of self-reproach can, by means of some mental addition, be transformed into any other unpleasurable affect. When this has happened there is no longer anything to prevent the substituted affect from becoming conscious. Thus self-reproach (for carrying out the sexual act in childhood) can easily turn into shame (in case some one else should find out about it), into hypochondriacal anxiety (for the physical injuries resulting from the act involving the self-reproach), into social anxiety (fear of being punished by society for the misdeed), into religious anxiety, into delusions of being noticed (fear of betraying the act to other people), or into fear of temptation (a justified mistrust of one's own moral powers of resistance), and so on. In addition, the mnemic content of the act involving self-reproach may be represented in consciousness as well, or it may remain completely in the background - which makes diagnosis much more difficult. Many cases which, on a superficial examination, seem to be common (neurasthenic hypochondria, belong to this group of obsessive affects; what is known as 'periodic neurasthenia' or 'periodic melancholia' seems in particular to resolve itself with unexpected frequency into obsessional affects and obsessional ideas - a discovery which is not a matter of indifference therapeutically.

[1896b, 391]

In addition to narcissistic identification, there is a hysterical kind, which has been familiar to us very much longer. I wish it were possible to illustrate for you the differences between the two forms by a few clear specifications. There is something I can tell you about the periodic and cyclical forms of melancholia which I am sure you will be glad to hear. For in favourable circumstances - I have experienced this twice - it is possible by analytic treatment in the lucid intervals to prevent the return of the condition in the same or the opposite emotional mood. We learn from such cases that in melancholia and mania we are concerned once more with a special method of dealing with a conflict whose underlying determinants agree precisely with those of the other neuroses. You can imagine how much more there is for psycho-analysis to learn in this field of knowledge.

[1916-1917, 3472]

It is well known that there are people the general color of whose mood oscillates periodically from an excessive depression through some kind of intermediate state to an exalted sense of well-being. These oscillations appear in very different degrees of amplitude, from what is just noticeable to those extreme instances which, in the shape of melancholia and mania, make the most tormenting or disturbing inroads upon the life of the person concerned. In typical cases of this cyclical depression external precipitating causes do not seem to play any decisive part; as regards internal motives, nothing more, or nothing else is to be found in these patients than in all others. It has consequently become the custom to consider these cases as not being psychogenic. We shall refer presently to those other exactly similar cases of cyclical depression which can easily be traced back to mental traumas.

[1921c, 3823]

Thus the foundation of these spontaneous oscillations of mood is unknown; we are without insight into the mechanism of the displacement of a melancholia by a mania. So we are free to suppose that these patients are people in whom our conjecture might find an actual application - their ego ideal might be temporarily resolved into their ego after having previously ruled it with especial strictness.

[1921c, 3823]
Let us keep to what is clear: On the basis of our analysis of the ego it cannot be doubted that in cases of mania the ego and the ego ideal have fused together, so that the person, in a mood of triumph and self-satisfaction, disturbed by no self-criticism, can enjoy the abolition of his inhibitions, his feelings of consideration for others, and his self-reproaches. It is not so obvious, but nevertheless very probable, that the misery of the melancholic is the expression of a sharp conflict between the two agencies of his ego, a conflict in which the ideal, in an excess of sensitiveness, relentlessly exhibits its condemnation of the ego in delusions of inferiority and in self-depreciation. The only question is whether we are to look for the causes of these altered relations between the ego and the ego ideal in the periodic rebellions, which we have postulated above, against the new institution, or whether we are to make other circumstances responsible for them.

A change into mania is not an indispensable feature of the symptomatology of melancholic depression. There are simple melancholias, some in single and some in recurrent attacks, which never show this development.

On the other hand there are melancholias in which the precipitating cause clearly plays an aetiological part. They are those which occur after the loss of a loved object, whether by death or as the result of circumstances which have necessitated the withdrawal of the libido from the object. A psychogenic melancholia of this sort can end in mania, and this cycle can be repeated several times, just as easily as in a case which appears to be spontaneous. Thus the state of things is somewhat obscure, especially as only a few forms and cases of melancholia have been submitted to psycho-analytic investigation.¹ So far we only understand those cases in which the object is given up because it has shown itself unworthy of love. It is then set up again inside the ego, by means of identification, and severely condemned by the ego ideal. The reproaches and attacks directed towards the object come to light in the shape of melancholic self-reproaches.²
In order to remain faithful to our customary phraseology, we shall have to speak, not of transposing the psychical accent, but of displacing large amounts of cathexis. The question then is whether we are entitled to picture extensive displacements like this from one agency of the mental apparatus to another. It looks like a new hypothesis constructed ad hoc. Yet we may remind ourselves that we have repeatedly (even though not sufficiently often) taken a factor of this kind into account in our attempts at a metapsychological picture of mental events. Thus, for instance, we supposed that the difference between an ordinary erotic object-cathexis and the state of being in love is that in the latter incomparably more cathexis passes over to the object and that the ego empties itself as it were in favour of the object. In studying some cases of paranoia I was able to establish the fact that ideas of persecution are formed early and exist for a long time without any perceptible effect, until, as the result of some particular precipitating event, they receive sufficient amounts of cathexis to cause them to become dominant. The cure, too, of such paranoic attacks would lie not so much in a resolution and correction of the delusional ideas as in a withdrawal from them of the cathexis which has been lent to them. The alternations between melancholia and mania, between a cruel suppression of the ego by the super-ego and a liberation of the ego after that pressure, suggests a shift of cathexis of this kind; such a shift, moreover, would have to be brought in to explain a whole number of phenomena belonging to normal mental life. If this has been done hitherto only to a very limited extent, that is on account of our usual caution - something which deserves only praise. The region in which we feel secure is that of the pathology of mental life; it is here that we make our observations and acquire our convictions. For the present we venture to form a judgement on the normal mind only in so far as we can discern what is normal in the isolations and distortions of the pathological material. When once we have overcome this hesitancy we shall recognize what a large contribution is made to the understanding of mental processes by the static conditions as well as by the dynamic changes in the quantity of energetic cathexis.

[1927d, 4544]

Hardly have we familiarized ourselves with the idea of a super-ego like this which enjoys a certain degree of autonomy, follows its own intentions and is independent of the ego for its supply of energy, than a clinical picture forces itself on our notice which throws a striking light on the severity of this agency and indeed its cruelty, and on its changing relations to the ego. I am thinking of the condition of melancholia, or, more precisely, of melancholic attacks, which you too will have heard plenty about, even if you are not psychiatrists. The most striking feature of this illness, of whose causation and mechanism we know much too little, is the way in which the super-ego - 'conscience', you may call it, quietly - treats the ego. While a melancholic can, like other people, show a greater or lesser degree of severity to himself in his healthy periods, during a melancholic attack his super-ego becomes over-severe, abuses the poor ego, humiliates it and ill-treats it, threatens it with the direst punishments, reproaches it for actions in the remotest past which had been taken lightly at the time - as though it had spent the whole interval in collecting accusations and had only been waiting for its present access of strength in order to bring them up and make a condemnatory judgement on their basis. The super-ego applies the strictest moral standard to the helpless ego which is at its mercy; in general it represents the claims of morality, and we realize all at once that our moral sense of guilt is the expression of the tension between the ego and the super-ego. It is a most remarkable experience to see morality, which is supposed to have been given us by God and thus deeply implanted in us, functioning as a periodic phenomenon. For after a certain number of months the whole moral fuss is over, the criticism of the super-ego is silent, the ego is rehabilitated and again enjoys all the rights of man till the next attack. In some forms of the disease, indeed, something of a contrary sort occurs in the intervals; the ego finds itself in a blissful state of intoxication, it celebrates a triumph, as though the super-ego had lost all its strength or had melted into the ego; and this liberated, manic ego permits itself a truly uninhibited satisfaction of all its appetites. Here are happenings rich in unsolved riddles!

[1933a, 4669]
You will no doubt wish to enquire about the possibility of doing harm by undertaking a psycho-analysis. In reply to this I may say that if you are willing to judge impartially, if you will consider this procedure in the same spirit of critical fairness that you show to our other therapeutic methods, you will have to agree with me that no injury to the patient is to be feared when the treatment is conducted with comprehension. Anyone who is accustomed, like the lay public, to blame the treatment for whatever happens during an illness will doubtless judge differently. It is not so very long since the same prejudice was directed against our hydropathic establishments. Many patients who were advised to go into an establishment of that kind hesitated because they had known someone who had entered the place as a nervous invalid and had become insane there. As you may guess, these were cases of early general paralysis that could still in their first stage be sent to a hydropathic establishment; once there, they had run their inevitable course until manifest mental disorder supervened: but the public blamed the water for this disastrous change. When it is a matter of new kinds of therapeutic treatment even physicians are not always free from such errors of judgement. I recall once making an attempt at psychotherapy with a woman who had passed the greater part of her life in a state alternating between mania and melancholia. I took on the case at the close of a period of melancholia and for two weeks things seemed to go smoothly; in the third week we were already at the beginning of the next attack of mania. This was undoubtedly a spontaneous transformation of the clinical picture, since in two weeks analytic psychotherapy cannot accomplish anything. And yet the eminent physician (now deceased) who saw the case with me could not refrain from the remark that psychotherapy was probably to blame for this 'relapse'. I am quite convinced that in other circumstances he would have shown a more critical judgement.

The most remarkable characteristic of melancholia, and the one in most need of explanation, is its tendency to change round into mania - a state which is the opposite of it in its symptoms. As we know, this does not happen to every melancholia. Some cases run their course in periodic relapses, during the intervals between which signs of mania may be entirely absent or only very slight. Others show the regular alternation of melancholic and manic phases which has led to the hypothesis of a circular insanity. One would be tempted to regard these cases as non-psychogenic, if it were not for the fact that the psycho-analytic method has succeeded in arriving at a solution and effecting a therapeutic improvement in several cases precisely of this kind. It is not merely permissible, therefore, but incumbent upon us to extend an analytic explanation of melancholia to mania as well.
I cannot promise that this attempt will prove entirely satisfactory. It hardly carries us much beyond the possibility of taking one's initial bearings. We have two things to go upon: the first is a psycho-analytic impression, and the second what we may perhaps call a matter of general economic experience. The impression which several psycho-analytic investigators have already put into words is that the content of mania is no different from that of melancholia, that both disorders are wrestling with the same 'complex', but that probably in melancholia the ego has succumbed to the complex whereas in mania it has mastered it or pushed it aside. Our second pointer is afforded by the observation that all states such as joy, exultation or triumph, which give us the normal model for mania, depend on the same economic conditions. What has happened here is that, as a result of some influence, a large expenditure of psychical energy, long maintained or habitually occurring, has at last become unnecessary, so that it is available for numerous applications and possibilities of discharge - when, for instance, some poor wretch, by winning a large sum of money, is suddenly relieved from chronic worry about his daily bread, or when a long and arduous struggle is finally crowned with success, or when a man finds himself in a position to throw off at a single blow some oppressive compulsion, some false position which he has long had to keep up, and so on. All such situations are characterized by high spirits, by the signs of discharge of joyful emotion and by increased readiness for all kinds of action - in just the same way as in mania, and in complete contrast to the depression and inhibition of melancholia. We may venture to assert that mania is nothing other than a triumph of this sort, only that here again what the ego has surmounted and what it is triumphing over remain hidden from it. Alcoholic intoxication, which belongs to the same class of states, may (in so far as it is an elated one) be explained in the same way; here there is probably a suspension, produced by toxins, of expenditures of energy in repression. The popular view likes to assume that a person in a manic state of this kind finds such delight in movement and action because he is so 'cheerful'. This false connection must of course be put right. The fact is that the economic condition in the subject's mind referred to above has been fulfilled, and this is the reason why he is in such high spirits on the one hand and so uninhibited in action on the other.

If we put these two indications together, what we find is this. In mania, the ego must have got over the loss of the object (or its mourning over the loss, or perhaps the object itself), and thereupon the whole quota of anticathexis which the painful suffering of melancholia had drawn to itself from the ego and 'bound' will have become available. Moreover, the manic subject plainly demonstrates his liberation from the object which was the cause of his suffering, by seeking like a ravenously hungry man for new object-cathexes.

This explanation certainly sounds plausible, but in the first place it is too indefinite, and, secondly, it gives rise to more new problems and doubts than we can answer. We will not evade a discussion of them, even though we cannot expect it to lead us to a clear understanding.
In the first place, normal mourning, too, overcomes the loss of the object, and it, too, while it lasts, absorbs all the energies of the ego. Why, then, after it has run its course, is there no hint in its case of the economic condition for a phase of triumph? I find it impossible to answer this objection straight away. It also draws our attention to the fact that we do not even know the economic means by which mourning carries out its task. Possibly, however, a conjecture will help us here. Each single one of the memories and situations of expectancy which demonstrate the libido's attachment to the lost object is met by the verdict of reality that the object no longer exists; and the ego, confronted as it were with the question whether it shall share this fate, is persuaded by the sum of the narcissistic satisfactions it derives from being alive to sever its attachment to the object that has been abolished. We may perhaps suppose that this work of severance is so slow and gradual that by the time it has been finished the expenditure of energy necessary for it is also dissipated.

Even if we accept this view of the work of melancholia, it still does not supply an explanation of the one point on which we were seeking light. It was our expectation that the economic condition for the emergence of mania after the melancholia has run its course is to be found in the ambivalence which dominates the latter affection; and in this we found support from analogies in various other fields. But there is one fact before which that expectation must bow. Of the three preconditions of melancholia - loss of the object, ambivalence, and regression of libido into the ego - the first two are also found in the obsessional self-reproaches arising after a death has occurred. In those cases it is unquestionably the ambivalence which is the motive force of the conflict, and observation shows that after the conflict has come to an end there is nothing left over in the nature of the triumph of a manic state of mind. We are thus led to the third factor as the only one responsible for the result. The accumulation of cathexis which is at first bound and then, after the work of melancholia is finished, becomes free and makes mania possible must be linked with regression of the libido to narcissism. The conflict within the ego, which melancholia substitutes for the struggle over the object, must act like a painful wound which calls for an extraordinarily high anticathexis. - But here once again, it will be well to call a halt and to postpone any further explanation of mania until we have gained some insight into the economic nature, first, of physical pain, and then of the mental pain which is analogous to it. As we already know, the interdependence of the complicated problems of the mind forces us to break off every enquiry before it is completed - till the outcome of some other enquiry can come to its assistance.

In addition to narcissistic identification, there is a hysterical kind, which has been familiar to us very much longer. I wish it were possible to illustrate for you the differences between the two forms by a few clear specifications. There is something I can tell you about the periodic and cyclical forms of melancholia which I am sure you will be glad to hear. For in favourable circumstances - I have experienced this twice - it is possible by analytic treatment in the lucid intervals to prevent the return of the condition in the same or the opposite emotional mood. We learn from such cases that in melancholia and mania we are concerned once more with a special method of dealing with a conflict whose underlying determinants agree precisely with those of the other neuroses. You can imagine how much more there is for psycho-analysis to learn in this field of knowledge.

Thus the foundation of these spontaneous oscillations of mood is unknown; we are without insight into the mechanism of the displacement of a melancholia by a mania. So we are free to suppose that these patients are people in whom our conjecture might find an actual application - their ego ideal might be temporarily resolved into their ego after having previously ruled it with especial strictness.
Let us keep to what is clear: On the basis of our analysis of the ego it cannot be doubted that in cases of mania the ego and the ego ideal have fused together, so that the person, in a mood of triumph and self-satisfaction, disturbed by no self-criticism, can enjoy the abolition of his inhibitions, his feelings of consideration for others, and his self-reproaches. It is not so obvious, but nevertheless very probable, that the misery of the melancholic is the expression of a sharp conflict between the two agencies of his ego, a conflict in which the ideal, in an excess of sensitiveness, relentlessly exhibits its condemnation of the ego in delusions of inferiority and in self-deprecation. The only question is whether we are to look for the causes of these altered relations between the ego and the ego ideal in the periodic rebellions, which we have postulated above, against the new institution, or whether we are to make other circumstances responsible for them.

[1921c, 3823]

The question which we put off answering runs as follows: How is it that the super-ego manifests itself essentially as a sense of guilt (or rather, as criticism - for the sense of guilt is the perception in the ego answering to this criticism) and moreover develops such extraordinary harshness and severity towards the ego? If we turn to melancholia first, we find that the excessively strong super-ego which has obtained a hold upon consciousness rages against the ego with merciless violence, as if it had taken possession of the whole of the sadism available in the person concerned. Following our view of sadism, we should say that the destructive component had entrenched itself in the super-ego and turned against the ego. What is now holding sway in the super-ego is, as it were, a pure culture of the death instinct, and in fact it often enough succeeds in driving the ego into death, if the latter does not fend off its tyrant in time by the change round into mania.

[1923b, 3987]

In order to remain faithful to our customary phraseology, we shall have to speak, not of transposing the psychical accent, but of displacing large amounts of cathexis. The question then is whether we are entitled to picture extensive displacements like this from one agency of the mental apparatus to another. It looks like a new hypothesis constructed ad hoc. Yet we may remind ourselves that we have repeatedly (even though not sufficiently often) taken a factor of this kind into account in our attempts at a metapsychological picture of mental events. Thus, for instance, we supposed that the difference between an ordinary erotic object-cathexis and the state of being in love is that in the latter incomparably more cathexis passes over to the object and that the ego empties itself as it were in favour of the object. In studying some cases of paranoia I was able to establish the fact that ideas of persecution are formed early and exist for a long time without any perceptible effect, until, as the result of some particular precipitating event, they receive sufficient amounts of cathexis to cause them to become dominant. Here are happenings rich in unsolved riddles!

[1933a, 4669]
The more generalized inhibitions of the ego obey a different mechanism of a simple kind. When the ego is involved in a particularly difficult psychical task, as occurs in mourning, or when there is some tremendous suppression of affect or when a continual flood of sexual phantasies has to be kept down, it loses so much of the energy at its disposal that it has to cut down the expenditure of it at many points at once. It is in the position of a speculator whose money has become tied up in his various enterprises. I came across an instructive example of this kind of intense, though short-lived, general inhibition. The patient, an obsessional neurotic, used to be overcome by a paralysing fatigue which lasted for one or more days whenever something occurred which should obviously have thrown him into a rage. We have here a point from which it should be possible to reach an understanding of the condition of general inhibition which characterizes states of depression, including the gravest form of them, melancholia. [1926d, 4251]
As we have seen, however, melancholia contains something more than normal mourning. In melancholia the relation to the object is no simple one; it is complicated by the conflict due to ambivalence. The ambivalence is either constitutional, i.e. is an element of every love-relation formed by this particular ego, or else it proceeds precisely from those experiences that involved the threat of losing the object. For this reason the exciting causes of melancholia have a much wider range than those of mourning, which is for the most part occasioned only by a real loss of the object, by its death. In melancholia, accordingly, countless separate struggles are carried on over the object, in which hate and love contend with each other; the one seeks to detach the libido from the object, the other to maintain this position of the libido against the assault. The location of these separate struggles cannot be assigned to any system but the Ucs., the region of the memory-traces of things (as contrasted with word-cathexes). In mourning, too, the efforts to detach the libido are made in this same system; but in it nothing hinders these processes from proceeding along the normal path through the Pcs. to consciousness. This path is blocked for the work of melancholia, owing perhaps to a number of causes or a combination of them. Constitutional ambivalence belongs by its nature to the repressed; traumatic experiences in connection with the object may have activated other repressed material. Thus everything to do with these struggles due to ambivalence remains withdrawn from consciousness, until the outcome characteristic of melancholia has set in. This, as we know, consists in the threatened libidinal cathexis at length abandoning the object, only, however, to draw back to the place in the ego from which it had proceeded. So by taking flight into the ego love escapes extinction. After this regression of the libido the process can become conscious, and it is represented to consciousness as a conflict between one part of the ego and the critical agency.

What consciousness is aware of in the work of melancholia is thus not the essential part of it, nor is it even the part which we may credit with an influence in bringing the ailment to an end. We see that the ego debases itself and rages against itself, and we understand as little as the patient what this can lead to and how it can change. We can more readily attribute such a function to the unconscious part of the work, because it is not difficult to perceive an essential analogy between the work of melancholia and of mourning. Just as mourning impels the ego to give up the object by declaring the object to be dead and offering the ego the inducement of continuing to live, so does each single struggle of ambivalence loosen the fixation of the libido to the object by disparaging it, denigrating it and even as it were killing it. It is possible for the process in the Ucs. to come to an end, either after the fury has spent itself or after the object has been abandoned as valueless. We cannot tell which of these two possibilities is the regular or more usual one in bringing melancholia to an end, nor what influence this termination has on the future course of the case. The ego may enjoy in this the satisfaction of knowing itself as the better of the two, as superior to the object.

[1917e, 3052]

[1917e, 3053]
I have only a few more remarks to add on the subject of affect in dreams from another point of view. A dominating element in a sleeper's mind may be constituted by what we call a 'mood' - or tendency to some affect - and this may then have a determining influence upon his dreams. A mood of this kind may arise from his experiences or thoughts during the preceding day, or its sources may be somatic. In either case it will be accompanied by the trains of thought appropriate to it. From the point of view of dream-construction it is a matter of indifference whether, as sometimes happens, these ideational contents of the dream-thoughts determine the mood in a primary fashion, or whether they are themselves aroused secondarily by the dreamer's emotional disposition which is in its turn to be explained on a somatic basis. In any case the construction of dreams is subject to the condition that it can only represent something which is the fulfilment of a wish and that it is only from wishes that it can derive its psychical motive force. A currently active mood is treated in the same way as a sensation arising and becoming currently active during sleep (cf. p. 714), which can be either disregarded or given a fresh interpretation in the sense of a wish-fulfilment. Distressing moods during sleep can become the motive force of a dream by arousing energetic wishes which the dream is supposed to fulfil. The material to which moods are attached is worked over until it can be used to express the fulfilment of a wish. The more intense and dominating a part is played in the dream-thoughts by the distressing mood, the more certain it becomes that the most strongly suppressed wishful impulses will make use of the opportunity in order to achieve representation. For, since the unpleasure which they would otherwise necessarily produce themselves is already present, they find the harder part of their task - the task of forcing their way through to representation - already accomplished for them. Here once more we are brought up against the problem of anxiety-dreams; and these, as we shall find, form a marginal case in the function of dreaming.

(2) To be quite safe, one should limit one's choice of patients to those who possess a normal mental condition, since in the psycho-analytic method this is used as a foothold from which to obtain control of the morbid manifestations. Psychoses, states of confusion and deeply-rooted (I might say toxic) depression are therefore not suitable for psycho-analysis; at least not for the method as it has been practised up to the present. I do not regard it as by any means impossible that by suitable changes in the method we may succeed in overcoming this contraindication - and so be able to initiate a psychotherapy of the psychoses.

Dreams having served us as the prototype in normal life of narcissistic mental disorders, we will now try to throw some light on the nature of melancholia by comparing it with the normal affect of mourning. This time, however, we must begin by making an admission, as a warning against any over-estimation of the value of our conclusions. Melancholia, whose definition fluctuates even in descriptive psychiatry, takes on various clinical forms the grouping together of which does not seem to be established with certainty; and some of these forms suggest somatic rather than psychogenic affections. Our material, apart from such impressions as are open to every observer, is limited to a small number of cases whose psychogenic nature was indisputable. We shall, therefore, from the outset drop all claim to general validity for our conclusions, and we shall console ourselves by reflecting that, with the means of investigation at our disposal today, we could hardly discover anything that was not typical, if not of a whole class of disorders, at least of a small group of them.
What is probably a somatic factor, and one which cannot be explained psychogenically, makes itself visible in the regular amelioration in the condition that takes place towards evening. These considerations bring up the question whether a loss in the ego irrespectively of the object - a purely narcissistic blow to the ego - may not suffice to produce the picture of melancholia and whether an impoverishment of ego-libido directly due to toxins may not be able to produce certain forms of the disease.

[1917e, 3049]
We find that impulses to suicide in a neurotic turn out regularly to be self-punishments for wishes for someone else's death. [1912-1913, 2794]

It is this sadism alone that solves the riddle of the tendency to suicide which makes melancholia so interesting - and so dangerous. So immense is the ego's self-love, which we have come to recognize as the primal state from which instinctual life proceeds, and so vast is the amount of narcissistic libido which we see liberated in the fear that emerges at a threat to life, that we cannot conceive how that ego can consent to its own destruction. We have long known, it is true, that no neurotic harbours thoughts of suicide which he has not turned back upon himself from murderous impulses against others, but we have never been able to explain what interplay of forces can carry such a purpose through to execution. The analysis of melancholia now shows that the ego can kill itself only if, owing to the return of the object-cathexis, it can treat itself as an object - if it is able to direct against itself the hostility which relates to an object and which represents the ego's original reaction to objects in the external world.¹ Thus in regression from narcissistic object-choice the object has, it is true, been got rid of, but it has nevertheless proved more powerful than the ego itself. In the two opposed situations of being most intensely in love and of suicide the ego is overwhelmed by the object, though in totally different ways. [1917e, 3049]

As with paranoia, so also with melancholia (of which, incidentally, many different clinical forms have been described) we have found a point at which it has become possible to obtain some insight into the internal structure of the disease. We have discovered that the self-reproaches, with which these melancholic patients torment themselves in the most merciless fashion, in fact apply to another person, the sexual object which they have lost or which has become valueless to them through its own fault. From this we can conclude that the melancholic has, it is true, withdrawn his libido from the object, but that, by a process which we must call 'narcissistic identification', the object has been set up in the ego itself, has been as it were, projected on to the ego. (Here I can only give you a pictorial description and not an ordered account on topographical and dynamic lines.) The subject's own ego is then treated like the object that has been abandoned, and it is subjected to all the acts of aggression and expressions of vengefulness which have been aimed at the object. A melancholic's propensity to suicide is also made more intelligible if we consider that the patient's embitterment strikes with a single blow at his own ego and at the loved and hated object. In melancholia, as well as in other narcissistic disorders, a particular trait in the patient's emotional life emerges with peculiar emphasis - what, since Bleuler, we have been accustomed to describe as 'ambivalence'. By this we mean the direction towards the same person of contrary - affectionate and hostile - feelings. Unluckily I have been unable in the course of these lectures to tell you more about this emotional ambivalence. [1916-1917, 3471]
We are led into quite another realm of explanation by the analysis of the attempt at suicide, which I must regard as seriously intended, and which, incidentally, considerably improved her position both with her parents and with the lady she loved. She went for a walk with her one day in a part of the town and at an hour at which she was not unlikely to meet her father on his way from his office. So it turned out. Her father passed them in the street and cast a furious look at her and her companion, about whom he had by that time come to know. A few moments later she flung herself into the railway cutting. The explanation she gave of the immediate reasons determining her decision sounded quite plausible. She had confessed to the lady that the man who had given them such an irate glance was her father, and that he had absolutely forbidden their friendship. The lady became incensed at this and ordered the girl to leave her then and there, and never again to wait for her or to address her - the affair must now come to an end. In her despair at having thus lost her loved one for ever, she wanted to put an end to herself. The analysis, however, was able to disclose another and deeper interpretation behind the one she gave, which was confirmed by the evidence of her own dreams. The attempted suicide was, as might have been expected, determined by two other motives besides the one she gave: it was the fulfilment of a punishment (self-punishment), and the fulfilment of a wish. As the latter it meant the attainment of the very wish which, when frustrated, had driven her into homosexuality - namely, the wish to have a child by her father, for now she 'fell' through her father's fault.¹ The fact that at that moment the lady had spoken in just the same terms as her father, and had uttered the same prohibition, forms the connecting link between this deep interpretation and the superficial one of which the girl herself was conscious. From the point of view of self-punishment the girl's action shows us that she had developed in her unconscious strong death-wishes against one or other of her parents - perhaps against her father, out of revenge for impeding her love, but more probably against her mother too, when she was pregnant with the little brother. For analysis has explained the enigma of suicide in the following way: probably no one finds the mental energy required to kill himself unless, in the first place, in doing so he is at the same time killing an object with whom he has identified himself, and, in the second place, is turning against himself a death-wish which had been directed against someone else. Nor need the regular discovery of these unconscious death-wishes in those who have attempted suicide surprise us (any more than it ought to make us think that it confirms our deductions), since the unconscious of all human beings is full enough of such death-wishes, even against those they love.² Since the girl identified herself with her mother, who should have died at the birth of the child denied to herself, this punishment-fulfilment itself was once again a wish-fulfilment. Finally, the discovery that several quite different motives, all of great strength, must have co-operated to make such a deed possible is only in accordance with what we should expect.

¹ [1920a, 3851]

² The question which we put off answering runs as follows: How is it that the super-ego manifests itself essentially as a sense of guilt (or rather, as criticism - for the sense of guilt is the perception in the ego answering to this criticism) and moreover develops such extraordinary harshness and severity towards the ego? If we turn to melancholia first, we find that the excessively strong super-ego which has obtained a hold upon consciousness rages against the ego with merciless violence, as if it had taken possession of the whole of the sadism available in the person concerned. Following our view of sadism, we should say that the destructive component had entrenched itself in the super-ego and turned against the ego. What is now holding sway in the super-ego is, as it were, a pure culture of the death instinct, and in fact it often enough succeeds in driving the ego into death, if the latter does not fend off its tyrant in time by the change round into mania.

² [1923b, 3987]
The reproaches of conscience in certain forms of obsessional neurosis are as distressing and tormenting, but here the situation is less perspicuous. It is noteworthy that the obsessional neurotic, in contrast to the melancholic, never in fact takes the step of self-destruction; it is as though he were immune against the danger of suicide, and he is far better protected from it than the hysterical. We can see that what guarantees the safety of the ego is the fact that the object has been retained. In obsessional neurosis it has become possible, through a regression to the pregenital organization, for the love-impulses to transform themselves into impulses of aggression against the object. Here again the instinct of destruction has been set free and it seeks to destroy the object, or at least it appears to have that intention. These purposes have not been adopted by the ego and it struggles against them with reaction-formations and precautionary measures; they remain in the id. The super-ego, however, behaves as if the ego were responsible for them and shows at the same time by the seriousness with which it chastises these destructive intentions that they are no mere semblance evoked by regression but an actual substitution of hate for love. Helpless in both directions, the ego defends itself vainly, alike against the instigations of the murderous id and against the reproaches of the punishing conscience. It succeeds in holding in check at least the most brutal actions of both sides; the first outcome is interminable self-torment, and eventually there follows a systematic torturing of the object, in so far as it is within reach.

[1923b, 3987]
(2) To be quite safe, one should limit one's choice of patients to those who possess a normal mental condition, since in the psycho-analytic method this is used as a foothold from which to obtain control of the morbid manifestations. Psychoses, states of confusion and deeply-rooted (I might say toxic) depression are therefore not suitable for psycho-analysis; at least not for the method as it has been practised up to the present. I do not regard it as by any means impossible that by suitable changes in the method we may succeed in overcoming this contraindication - and so be able to initiate a psychotherapy of the psychoses.

[1905a, 1569]

In addition to narcissistic identification, there is a hysterical kind, which has been familiar to us very much longer. I wish it were possible to illustrate for you the differences between the two forms by a few clear specifications. There is something I can tell you about the periodic and cyclical forms of melancholia which I am sure you will be glad to hear. For in favourable circumstances - I have experienced this twice - it is possible by analytic treatment in the lucid intervals to prevent the return of the condition in the same or the opposite emotional mood. We learn from such cases that in melancholia and mania we are concerned once more with a special method of dealing with a conflict whose underlying determinants agree precisely with those of the other neuroses. You can imagine how much more there is for psycho-analysis to learn in this field of knowledge.

[1916-1917, 3472]

There are, however, other forms of illness in which, in spite of the conditions being the same, our therapeutic procedure is never successful. In them, too, it had been a question of an original conflict between the ego and the libido which led to repression - though this may call for a different topographical description; in them, too, it is possible to trace the points in the patient's life at which the repressions occurred; we make use of the same procedure, are ready to make the same promises and give the same help by the offer of anticipatory ideas; and once again the lapse of time between the repressions and the present day favours a different outcome to the conflict. And yet we do not succeed in lifting a single resistance or getting rid of a single repression. These patients, paranoics, melancholics, sufferers from dementia praecox, remain on the whole unaffected and proof against psycho-analytic therapy. What can be the reason for this? Not any lack of intelligence. A certain amount of intellectual capacity is naturally required in our patients; but there is certainly no lack of it in, for instance, the extremely shrewd combinatorics paranoics. Nor do any of the other motives seem to be absent. Thus the melancholics have a very high degree of consciousness, absent in paranoics, that they are ill and that is why they suffer so much; but this does not make them more accessible. We are faced here by a fact which we do not understand and which therefore leads us to doubt whether we have really understood all the determinants of our possible success with the other neuroses.

[1916-1917, 3480]
I have argued elsewhere⁸ that ‘war neuroses’ (in so far as that term implies something more than a reference to the circumstances of the illness's onset) may very well be traumatic neuroses which have been facilitated by a conflict in the ego. The fact to which I have referred in the first paragraph of Chapter II, that a gross physical injury caused simultaneously by the trauma diminishes the chances that a neurosis will develop, becomes intelligible if one bears in mind two facts which have been stressed by psycho-analytic research: firstly, that mechanical agitation must be recognized as one of the sources of sexual excitation,² and secondly, that painful and feverish illnesses exercise a powerful effect, so long as they last, on the distribution of libido. Thus, on the one hand, the mechanical violence of the trauma would liberate a quantity of sexual excitation which, owing to the lack of preparation for anxiety, would have a traumatic effect; but, on the other hand, the simultaneous physical injury, by calling for a narcissistic hypercathexis of the injured organ,³ would bind the excess of excitation. It is also well known, though the libido theory has not yet made sufficient use of the fact, that such severe disorders in the distribution of libido as melancholia are temporarily brought to an end by intercurrent organic illness, and indeed that even a fully developed condition of dementia praecox is capable of a temporary remission in these same circumstances.

[1920g, 3736]

Narcissism. - The most important theoretical advance has certainly been the application of the libido theory to the repressing ego. The ego itself came to be regarded as a reservoir of what was described as narcissistic libido, from which the libidinal catheces of objects flowed out and into which they could be once more withdrawn. By the help of this conception it became possible to embark upon the analysis of the ego and to make a clinical distinction of the psychoneuroses into transference neuroses and narcissistic disorders. In the former (hysteria and obsessional neurosis) the subject has at his disposal a quantity of libido striving to be transferred on to extraneous objects, and use is made of this in carrying out analytic treatment; on the other hand, the narcissistic disorders (dementia praecox, paranoia, melancholia) are characterized by a withdrawal of the libido from objects and they are therefore scarcely accessible to analytic therapy. But their therapeutic inaccessibility has not prevented analysis from making the most fruitful beginnings in the deeper study of these illnesses, which are counted among the psychoses.

[1923a, 3925]
The neuroses were the first subject of analysis, and for a long time they were the only one. No analyst could doubt that medical practice was wrong in separating those disorders from the psychoses and in attaching them to the organic nervous diseases. The theory of the neuroses belongs to psychiatry and is indispensable as an introduction to it. It would seem, however, that the analytic study of the psychoses is impracticable owing to its lack of therapeutic results. Mental patients are as a rule without the capacity for forming a positive transference, so that the principal instrument of analytic technique is inapplicable to them. There are nevertheless a number of methods of approach to be found. Transference is often not so completely absent but that it can be used to a certain extent; and analysis has achieved undoubted successes with cyclical depressions, light paranoic modifications, and partial schizophrenias. It has at least been a benefit to science that in many cases the diagnosis can oscillate for quite a long time between assuming the presence of a psychoneurosis or of a dementia praecox; for therapeutic attempts initiated in such cases have resulted in valuable discoveries before they have had to be broken off. But the chief consideration in this connection is that so many things that in the neuroses have to be laboriously fetched up from the depths are found in the psychoses on the surface, visible to every eye. For that reason the best subjects for the demonstration of many of the assertions of analysis are provided by the psychiatric clinic. It was thus bound to happen before long that analysis would find its way to the objects of psychiatric observation. I was able very early (1896) to establish in a case of paranoid dementia the presence of the same aetiological factors and the same emotional complexes as in the neuroses. Jung explained some most puzzling stereotypies in dements by bringing them into relation with the patients' life-histories; Bleuler demonstrated the existence in various psychoses of mechanisms like those which analysis had discovered in neurotics. Since then analysts have never relaxed their efforts to come to an understanding of the psychoses. Especially since it has been possible to work with the concept of narcissism, they have managed, now in this place and now in that, to get a glimpse beyond the wall. Most of all, no doubt, was achieved by Abraham in his elucidation of the melancholias. It is true that in this sphere all our knowledge is not yet converted into therapeutic power; but the mere theoretical gain is not to be despised, and we may be content to wait for its practical application. In the long run even the psychiatrists cannot resist the convincing force of their own clinical material. At the present time German psychiatry is undergoing a kind of 'peaceful penetration' by analytic views. While they continually declare that they will never be psycho-analysts, that they do not belong to the 'orthodox' school or agree with its exaggerations, and in particular that they do not believe in the predominance of the sexual factor, nevertheless the majority of the younger workers take over one piece or another of analytic theory and apply it in their own fashion to the material. All the signs point to the proximity of further developments in the same direction.

[1925d, 4235]

Psycho-analysis finds a constantly increasing amount of support as a therapeutic procedure, owing to the fact that it can do more for its patients than any other method of treatment. The principle field of its application is in the milder neuroses - hysteria, phobias and obsessional states; and in malformations of character and sexual inhibitions or abnormalities it can also bring about marked improvements or even recoveries. Its influence upon dementia praecox and paranoia is doubtful; on the other hand, in favourable circumstances it can cope with depressive states, even if they are of a severe type.

[1926f, 4402]
Frau P., thirty-two years of age, has been married for three years and is the mother of a child of two. Her parents were not neurotic; but her brother and sister are to my knowledge, like her, neurotic. It is doubtful whether she may not, at one time in her middle twenties, have become temporarily depressed and confused in her judgement. In recent years she was healthy and capable, until, six months after the birth of her child, she showed the first signs if her present illness. She became uncommunicative and distrustful, showed aversion to meeting her husband's brothers and sisters and complained that the neighbours in the small town in which she lived were behaving differently towards her from how they did before and were rude and inconsiderate to her. By degrees these complaints increased in intensity, although not in definiteness. She thought people had something against her, though she had no idea what; but there was no doubt that everyone - relatives and friends - had ceased to respect her and were doing all they could to slight her. She had racked her brains, she said, to find the reason for this, but had no idea. A little time later she complained that she was being watched and that people were reading her thoughts and knew everything that was going on in her house. One afternoon she suddenly had the idea that she was being watched while she was undressing in the evening. From that time on she took the most precautionary measures when she undressed; she got into bed in the dark and did not begin to take off her things till she was under the bedclothes. Since she avoided all contact with other people, ate poorly and was very depressed, she was sent in the summer of 1895 to a hydropathic establishment. There, fresh symptoms appeared and those she already had increased in strength. Already in the spring of that year, when she was alone one day with her housemaid, she had suddenly had a sensation in her lower abdomen, and had thought to herself that the girl had at that moment had an improper idea. This sensation grew more frequent during the summer and became almost continual. She felt her genitals 'as one feels a heavy hand'. Then she began to see images which horrified her - hallucinations of naked women, especially of the lower part of a woman's abdomen with pubic hairs, and occasionally of male genitals as well. The image of the abdomen with hair and the physical sensation in her own abdomen usually occurred together. The images became very tormenting, for they happened regularly when she was in the company of a woman, and it made her think that she was seeing the woman in an indecent state of nakedness, but that simultaneously the woman was having the same picture of her (!). At the same time as these visual hallucinations - which vanished again for several months after their first appearance in the hydropathic establishment - she began to be pestered by voices which she did not recognize and which she could not account for. When she was in the street, they said: 'That's Frau P - There she goes! Where's she going to?' Every one of her movements and actions was commented on; and at times she heard threats and reproaches. All these symptoms became worse when she was in company or in the street. For that reason she refused to go out; she said that eating disgusted her; and her state of health rapidly deteriorated.

[1896b, 396]
What I have to report about this patient concerns the aetiology of the case and the mechanism of the hallucinations. I discovered the aetiology when I applied Breuer's method, exactly as in a case of hysteria - in the first instance for the investigation and removal of the hallucinations. In doing so, I started out from the assumption that in this case of paranoia, just as in the two other defence neuroses with which I was familiar, there must be unconscious thoughts and repressed memories which could be brought into consciousness in the same way as they were in those neuroses, by overcoming a certain resistance. The patient at once confirmed my expectation, for she behaved in analysis exactly like, for instance, a hysterical patient; with her attention on the pressure of my hand,¹ she produced thoughts which she could not remember having had, which at first she did not understand and which were contrary to her expectations. The presence of significant unconscious ideas was thus demonstrated in a case of paranoia as well, and I was able to hope that I might trace the compulsion of paranoia, too, to repression. The only peculiarity was that the thoughts which arose from the unconscious were for the most part heard inwardly or hallucinated by the patient, in the same way as her voices.

My conjecture that we had to do with an affair between children, as is so often found in the aetiology of hysteria, was strengthened by the further progress of the analysis, which at the same time yielded solutions of individual details that frequently recurred in the clinical picture of the paranoia. The patient's depression began at the time of a quarrel between her husband and her brother, as a result of which the latter no longer came to the house. She had always been very fond of this brother and she missed him very much at that time. Besides this she spoke of a certain moment in her illness at which for the first time 'everything became clear to her' - that is, at which she became convinced of the truth of her suspicion that she was despised by everyone and deliberately slighted. This certainty came to her during a visit from her sister-in-law who, in the course of conversation, let fall the words: 'If anything of that sort happens to me, I treat it in a light vein.' At first Frau P. took this remark unsuspectingly; but later, after the visitor had left, it seemed to her that the words had contained a reproach, as if she was in the habit of taking serious things lightly; and from that moment on she was certain that she was the victim of general slander. When I questioned her as to what made her feel justified in applying the words to herself, she answered that it was the tone of voice in which her sister-in-law had spoken that (although, it is true, only subsequently) convinced her of it. This is a detail which is characteristic of paranoia. I now obliged her to remember what her sister-in-law had been saying before the remark she complained of, and it emerged that the sister-in-law had related how in her parents' home there had been all sorts of difficulties with her brothers, and had added the wise comment: 'In every family all sorts of things happen that one would like to draw a veil over. But if anything of the kind happens to me, I take it lightly.' Frau P. now had to admit that her depression was attached to the statements made by her sister-in-law before her last remark. Since she had repressed both the statements which might have awakened a memory of her relations with her brother, and had only retained the insignificant last one, it was with it that she was obliged to connect her feeling that her sister-in-law was making a reproach against her; and since its content offered no basis for this, she turned from the content to the tone in which the words had been spoken. This is probably a typical piece of evidence that the misinterpretations of paranoia are based on a repression.

I now turned to the analysis of the voices. First and foremost what had to be explained was why such an indifferent content as 'Here comes Frau P.', 'She's looking for a house now', and so on, could have been so distressing to her; next, how it was that precisely these innocent phrases had managed to be marked out by hallucinatory reinforcement. From the first it was clear that the 'voices' could not be memories that were being produced in a hallucinatory way, like the images and sensations, but were rather thoughts that were being 'said aloud'.

[1896b, 397]

[1896b, 399]

[1896b, 401]
It only remains for me now to employ what has been learned from this case of paranoia for making a comparison between paranoia and obsessional neurosis. In each of them, repression has been shown to be the nucleus of the psychical mechanism, and in each what has been repressed is a sexual experience in childhood. In this case of paranoia, too, every obsession sprang from repression; the symptoms of paranoia allow of a classification similar to the one which has proved justified for obsessional neurosis. Part of the symptoms, once again, arise from primary defence - namely, all the delusional ideas which are characterized by distrust and suspicion and which are concerned with ideas of being persecuted by others. In obsessional neurosis the initial self-reproach has been repressed by the formation of the primary symptom of defence: self-distrust. With this, the self-reproach is acknowledged as justified; and, to weigh against this, the conscientiousness which the subject has acquired during his healthy interval now protects him from giving credence to the self-reproaches which return in the form of obsessional ideas. In paranoia, the self-reproach is repressed in a manner which may be described as projection. It is repressed by erecting the defensive symptom of distrust of other people. In this way the subject withdraws his acknowledgement of the self-reproach; and, as if to make up for this, he is deprived of a protection against the self-reproaches which return in his delusional ideas.

Other symptoms of my case of paranoia are to be described as symptoms of the return of the repressed, and they, too, like those of obsessional neurosis, bear the traces of the compromise which alone allows them to enter consciousness. Such are, for instance, my patient's delusional idea of being watched while she was undressing, her visual hallucinations, her hallucinations of sensation and her hearing of voices. In the delusional idea which I have just mentioned there is a mnemonic content which is almost unaltered and has only been made indefinite through omission. The return of the repressed in visual images approaches the character of hysteria rather than of obsessional neurosis; but hysteria is in the habit of repeating its mnemonic symbols without modification, whereas mnemonic hallucinations in paranoia undergo a distortion similar to that in obsessional neurosis: an analogous modern image takes the place of the repressed one. (E.g., the abdomen of an adult woman appears instead of a child's, and an abdomen on which the hairs are especially distinct, because they were absent in the original impression.) A thing which is quite peculiar to paranoia and on which no further light can be shed by this comparison, is that the repressed self-reproaches return in the form of thoughts spoken aloud. In the course of this process, they are obliged to submit to twofold distortion: they are subjected to a censorship, which leads to their being replaced by other, associated, thoughts or to their being concealed by an indefinite mode of expression, and they are referred to recent experiences which are no more than analogous to the old ones.
The third group of symptoms that are found in obsessional neurosis, the symptoms of secondary defence, cannot be present as such in paranoia, because no defence can avail against the returning symptoms to which, as we know, belief is attached. In place of this, we find in paranoia another source for the formation of symptoms. The delusional ideas which have arrived in consciousness by means of a compromise (the symptoms of the return) make demands on the thought-activity of the ego until they can be accepted without contradiction. Since they are not themselves open to influence, the ego must adapt itself to them; and thus what corresponds here to the symptoms of secondary defence in obsessional neurosis is a combinatory delusional formation - interpretative delusions which end in an alteration of the ego. In this respect, the case under discussion was not complete; at that time my patient did not as yet exhibit any signs of the attempts at interpretation which appeared later. But I have no doubt that if we apply psycho-analysis to this stage of paranoia as well, we shall be able to arrive at a further important result. It should then turn out that the so-called weakness of memory of paranoics is also a tendentious one - that is to say, that it is based on repression and serves the ends of repression. A subsequent repression and replacement takes place of memories which are not in the least pathogenic, but which are in contradiction to the alteration of the ego which the symptoms of the return of the repressed so insistently demand.

[1896b, 404]

(2) There are the theories which, on the contrary, presuppose that dreams imply a lowering of psychical activity, a loosening of connections, and an impoverishment of the material accessible. These theories must imply the attribution to sleep of characteristics quite different from those suggested, for instance, by Delboeuf. Sleep, according to such theories, has a far reaching influence upon the mind; it does not consist merely in the mind being shut off from the external world; it forces its way, rather, into the mental mechanism and throws it temporarily out of use. If I may venture on a simile from the sphere of psychiatry, the first group of theories construct dreams on the model of paranoia, while the second group make them resemble mental deficiency or confusional states.

[1900a, 583]

The two instances that I have quoted are neither of them entirely devoid of connection with the state of sleep and for that reason are perhaps not well chosen for what I want them to prove. I will therefore refer the reader to my analysis of a woman suffering from hallucinatory paranoia (Freud, 1896b) as well as to the findings in my still unpublished studies on the psychology of the psychoneuroses, for evidence that in such instances of the regressive transformation of thoughts we must not overlook the influence of memories, mostly from childhood, which have been suppressed or have remained unconscious. The thoughts which are connected with a memory of this kind and which are forbidden expression by the censorship are, as it were, attracted by the memory into regression as being the form of representation in which the memory itself is couched. I may also recall that one of the facts arrived at in the Studies on Hysteria was that when it was possible to bring infantile scenes (whether they were memories or phantasies) into consciousness, they were seen like hallucinations and lost that characteristic only in the process of being reported. It is moreover a familiar observation that, even in those whose memory is not normally of a visual type, the earliest recollections of childhood retain far into life the quality of sensory vividness.

[1900a, 978]
(a) A striking and generally observed feature of the behaviour of paranoics is that they attach the greatest significance to the minor details of other people's behaviour which we ordinarily neglect, interpret them and make them the basis of far-reaching conclusions. For example, the last paranoic seen by me concluded that there was a general understanding in his environment, because when his train was moving out of the station the people had made a particular movement with one hand. Another noted the way people walked in the street, how they flourished their walking sticks, and so on.¹

[1901b, 1325]

The category of what is accidental and requires no motivation, in which the normal person includes a part of his own psychical performances and parapraxes, is thus rejected by the paranoic as far as the psychical manifestations of other people are concerned. Everything he observes in other people is full of significance, everything can be interpreted. How does he reach this position? Probably here as in so many similar cases he projects on to the mental life of other people what is unconsciously present in his own. In paranoia many sorts of things force their way through to consciousness whose presence in the unconscious of normal and neurotic people we can demonstrate only through psycho-analysis.² In a certain sense, therefore, the paranoic is justified in this, for he recognizes something that escapes the normal person: he sees more clearly than someone of normal intellectual capacity, but the displacement on to other people of the state of affairs which he recognizes renders his knowledge worthless. I hope I shall not now be expected to justify the various paranoic interpretations. But the partial justification which we concede to paranoia in respect of this view taken by it of chance actions will help us towards a psychological understanding of the sense of conviction that the paranoic attaches to all these interpretations. There is in fact some truth in them; those, too, of our errors of judgement which are not to be counted as pathological acquire their sense of conviction in just the same way. This feeling is justified for a certain part of the erroneous train of thought, or for its source of origin; and it is then extended by us to the rest of the context.

[1901b, 1325]

¹ From other points of view this interpretation of immaterial and accidental indications given by other people has been classed as a 'delusion of reference'.
[1901b, 1325]

² For example, the phantasies of hysterics concerning sexual and cruel maltreatment correspond, at times even down to details, with the complaints of persecuted paranoics. It is curious, but not unintelligible, that we meet the identical content in the form of reality in the contrivances of perverts for the satisfaction of their desires.
[1901b, 1325]
I assume that this conscious ignorance and unconscious knowledge of the motivation of accidental psychical events is one of the psychical roots of superstition. *Because* the superstitious person knows nothing of the motivation of his own chance actions, and *because* the fact of this motivation presses for a place in his field of recognition, he is forced to allocate it, by displacement, to the external world. If such a connection exists, it can hardly be limited to this single application. In point of fact I believe that a large part of the mythological view of the world, which extends a long way into the most modern religions, is *nothing but psychology projected into the external world*. The obscure recognition¹ (the endopsychic perception, as it were) of psychical factors and relations in the unconscious is mirrored - it is difficult to express it in other terms, and here the analogy with paranoia must come to our aid - in the construction of a *supernatural reality*, which is destined to be changed back once more by science into the *psychology of the unconscious*. One could venture to explain in this way the myths of paradise and the fall of man, of God, of good and evil, of immortality, and so on, and to transform *metaphysics* into *metapsychology*. The gap between the paranoic's displacement and that of the superstitious person is less wide than it appears at first sight. When human beings began to think, they were, as is well known, forced to explain the external world anthropomorphically by means of a multitude of personalities in their own image; chance events, which they interpreted superstitiously, were thus actions and manifestations of persons. They behaved, therefore, just like paranics, who draw conclusions from insignificant signs given them by other people, and just like all normal people, who quite rightly base their estimate of their neighbours' characters on their chance and unintentional actions. It is only in our modern, scientific but as yet by no means perfected Weltanschauung that superstition seems so very much out of place; in the Weltanschauung of pre-scientific times and peoples it was justified and consistent.

[1901b, 1328]

¹ In point of fact, the case of N. H. would have to be described as a *hysterical* delusion, not a paranoic one. The indications of paranoia are absent from it.
[1907a, 1844]
Nevertheless, on closer consideration this delusion of Hanold's seems to me to lose the greater part of its improbability. The author, indeed, has made himself responsible for one part of it by basing his story on the premiss that Zoe was in every detail a duplicate of the relief. We must therefore avoid shifting the improbability of this premiss on to its consequence - that Hanold took the girl for Gradiva come to life. Greater value is given to the delusional explanation by the fact that the author has put no rational one at our disposal. Moreover the author has adduced contributory and mitigating circumstances on behalf of his hero's excesses in the shape of the glare of the campagna sunlight and the intoxicating magic of the wine grown on the slopes of Vesuvius. But the most important of all the explanatory and exculpatory factors remains the ease with which our intellect is prepared to accept something absurd provided it satisfies powerful emotional impulses. It is an astonishing fact, and one that is too generally overlooked, how readily and frequently under these psychological conditions people of even the most powerful intelligence react as though they were feeble-minded; and anyone who is not too conceited may see this happening in himself as often as he pleases. And this is far more so if some of the mental processes concerned are linked with unconscious or repressed motives. In this connection I am happy to quote the words of a philosopher, who writes to me: 'I have been noting down the instances I myself experience of striking mistakes and unthinking actions, for which one finds motives afterwards (in a most unreasonable way). It is an alarming thing, but typical, to find how much folly this brings to light.' It must be remembered, too, that the belief in spirits and ghosts and the return of the dead, which finds so much support in the religions to which we have all been attached, at least in our childhood, is far from having disappeared among educated people, and that many who are sensible in other respects find it possible to combine spiritualism with reason. A man who has grown rational and sceptical, even, may be ashamed to discover how easily he may for a moment return to a belief in spirits under the combined impact of strong emotion and perplexity. I know of a doctor who had once lost one of his women patients suffering from Graves' disease, and who could not get rid of a faint suspicion that he might perhaps have contributed to the unhappy outcome by a thoughtless prescription. One day, several years later, a girl entered his consulting-room, who, in spite of all his efforts, he could not help recognizing as the dead one. He could frame only a single thought: 'So after all it's true that the dead can come back to life.' His dread did not give way to shame till the girl introduced herself as the sister of the one who had died of the same disease as she herself was suffering from. The victims of Graves' disease, as has often been observed, have a marked facial resemblance to one another; and in this case this typical likeness was reinforced by a family one. The doctor to whom this occurred was, however, none other than myself; so I have a personal reason for not disputing the clinical possibility of Norbert Hanold's temporary delusion that Gradiva had come back to life. The fact, finally, is familiar to every psychiatrist that in severe cases of chronic delusions (in paranoia) the most extreme examples occur of ingeniously elaborated and well-supported absurdities.

[1907a, 1865]

We are all familiar with the delusional imaginings of the paranoic, which are concerned with the greatness and the sufferings of his own self and which appear in forms that are quite typical and almost monotonous. We have also become acquainted, through numerous accounts, with the strange performances with which certain perverts stage their sexual satisfaction, whether in idea or reality. Nevertheless, it may be new to some readers to hear that quite analogous psychical structures are regularly present in all the psychoneuroses, particularly in hysteria, and that these latter - which are known as hysterical phantasies - can be seen to have important connections with the causation of the neurotic symptoms.

[1908a, 1932]
The analytic investigation of paranoia presents difficulties of a peculiar nature to physicians who, like myself, are not attached to public institutions. We cannot accept patients suffering from this complaint, or, at all events, we cannot keep them for long, since we cannot offer treatment unless there is some prospect of therapeutic success. It is only in exceptional circumstances, therefore, that I succeed in getting more than a superficial view of the structure of paranoia - when, for instance, the diagnosis (which is not always an easy matter) is uncertain enough to justify an attempt at influencing the patient, or when, in spite of an assured diagnosis, I yield to the entreaties of the patient's relatives and undertake to treat him for a time. Apart from this, of course, I see plenty of cases of paranoia and of dementia praecox, and I learn as much about them as other psychiatrists do about their cases; but that is not enough, as a rule, to lead to any analytic conclusions.

"I need not enter any further into the details of the course of the disease. I must, however, draw attention to the manner in which, as time went on, the initial comparatively acute psychosis, which had directly involved the patient's entire mental life and deserved the name of "hallucinatory insanity", developed more and more clearly (one might almost say crystallized out) into the paranoic clinical picture that we have before us to-day." (385.) The fact was that, on the one hand, he had developed an ingenious delusional structure, in which we have every reason to be interested, while, on the other hand, his personality had been reconstructed and now showed itself, except for a few isolated disturbances, capable of meeting the demands of everyday life.

Dr. Weber, in his Report of 1899, makes the following remarks: 'It thus appears that at the present time, apart from certain obvious psychomotor symptoms which cannot fail to strike even the superficial observer as being pathological, Herr Senatspräsident Dr. Schreber shows no signs of confusion or of psychical inhibition, nor is his intelligence noticeably impaired. His mind is collected, his memory is excellent, he has at his disposal a very considerable store of knowledge (not merely upon legal questions, but in many other fields), and he is able to reproduce it in a connected train of thought. He takes an interest in following events in the world of politics, science and art, etc., and is constantly occupied with such matters . . . and an observer who was uninstructed upon his general condition would scarcely notice anything peculiar in these directions. In spite of all this, however, the patient is full of ideas of pathological origin, which have formed themselves into a complete system; they are more or less fixed, and seem to be inaccessible to correction by means of any objective appreciation and judgement of the external facts.' (305-6.)
(a) The medical officer lays stress upon two points as being of chief importance: the patient's assumption of the role of Redeemer, and his transformation into a woman. The Redeemer delusion is a phantasy that is familiar to us through the frequency with which it forms the nucleus of religious paranoia. The additional factor, which makes the redemption dependent upon the man being previously transformed into a woman, is unusual and in itself bewildering, since it shows such a wide divergence from the historical myth which the patient's phantasy is setting out to reproduce. It is natural to follow the medical report in assuming that the motive force of this delusional complex was the patient's ambition to play the part of Redeemer, and that his emasculation was only entitled to be regarded as a means for achieving that end. Even though this may appear to be true of his delusion in its final form, a study of the Denkwürdigkeiten compels us to take a very different view of the matter. For we learn that the idea of being transformed into a woman (that is, of being emasculated) was the primary delusion, that he began by regarding that act as constituting a serious injury and persecution, and that it only became related to his playing the part of Redeemer in a secondary way. There can be no doubt, moreover, that originally he believed that the transformation was to be effected for the purpose of sexual abuse and not so as to serve higher designs. The position may be formulated by saying that a sexual delusion of persecution was later on converted in the patient's mind into a religious delusion of grandeur. The part of persecutor was at first assigned to Professor Flechsig, the physician in whose charge he was; later, his place was taken by God Himself.

These statements are of decisive importance in determining the view we are to take of the delusion of emasculation and in thus giving us a general understanding of the case. It may be added that the 'voices' which the patient heard never treated his transformation into a woman as anything but a sexual disgrace, which gave them an excuse for jeering at him. 'Rays of God¹ not infrequently thought themselves entitled to mock at me by calling me "Miss² Schreber", in allusion to the emasculation which, it was alleged, I was about to undergo.' (127.) Or they would say: 'So this sets up to have been a Senatspräsident, this person who lets himself be f--d!'³ Or again: 'Don't you feel ashamed in front of your wife?'

Of the actual nature of Flechsig's enormity and its motives the patient speaks with the characteristic vagueness and obscurity which may be regarded as marks of an especially intense work of delusion-formation, if it is legitimate to judge paranoia on the model of a far more familiar mental phenomenon - the dream. Flechsig, according to the patient, committed, or attempted to commit, 'soul-murder' upon him - an act which, he thought, was comparable with the effort made by the devil or by demons to gain possession of a soul and may have had its prototype in events which occurred between members of the Flechsig and Schreber families long since deceased (22 ff.). We should be glad to learn more of the meaning of this 'soul-murder', but at this point our sources relapse once more into a tendentious silence: 'As to what constitutes the true essence of soul-murder, and as to its technique, if I may so describe it, I am able to say nothing beyond what has already been indicated. There is only this, perhaps, to be added . . . (The passage which follows is unsuitable for publication.)' (28.) As a result of this omission we are left in the dark on the question of what is meant by 'soul-murder'. We shall refer later on to the only hint upon the subject which has evaded censorship.

[1911c, 2394]

[1911c, 2396]
Since we cannot obtain any insight into the causes of the first illness (a knowledge of which is undoubtedly indispensable for properly elucidating the second and severer illness) we must now plunge at random into an unknown concatenation of circumstances. During the incubation period of his illness, as we are aware (that is, between June 1893, when he was appointed to his new post, and the following October, when he took up his duties), he repeatedly dreamt that his old nervous disorder had returned. Once, moreover, when he was half asleep, he had a feeling that after all it must be nice to be a woman submitting to the act of copulation. The dreams and the phantasy are reported by Schreber in immediate succession; and if we also bring together their subject-matter, we shall be able to infer that, at the same time as his recollection of his illness, a recollection of his doctor was also aroused in his mind, and that the feminine attitude which he assumed in the phantasy was from the first directed towards the doctor. Or it may be that the dream of his illness having returned simply expressed some such longing as: 'I wish I could see Flechsig again!' Our ignorance of the mental content of the first illness bars our way in this direction. Perhaps that illness had left behind in him a feeling of affectionate dependence upon his doctor, which had now, for some unknown reason, become intensified to the pitch of an erotic desire. This feminine phantasy which was still kept impersonal, was met at once by an indignant repudiation - a true 'masculine protest', to use Adler's expression, but in a sense different from his.¹ But in the severe psychosis which broke out soon afterwards the feminine phantasy carried everything before it; and it only requires a slight correction of the characteristic paranoic indefiniteness of Schreber's mode of expression to enable us to divine the fact that the patient was in fear of sexual abuse at the hands of his doctor himself. The exciting cause of his illness, then, was probably from the very first his doctor, Flechsig; and his struggles against the libidinal impulse produced the conflict which gave rise to the symptoms.

Turning once more to the case of Schreber, we are bound to admit that any attempt at throwing light upon the transformation in his delusion brings us up against extraordinary difficulties. In what manner and by what means was the ascent from Flechsig to God brought about? From what source did he derive the megalomania which so fortunately enabled him to become reconciled to his persecution, or, in analytical phraseology, to accept the wishful phantasy which had had to be repressed? The Denkwürdigkeiten give us a first clue; for they show us that in the patient's mind 'Flechsig' and 'God' belonged to the same class. In one of his phantasies he overheard a conversation between Flechsig and his wife, in which the former asserted that he was 'God Flechsig', so that his wife thought he had gone mad (82). But there is another feature in the development of Schreber's delusions which claims our attention. If we take a survey of the delusions as a whole we see that the persecutor is divided into Flechsig and God; in just the same way Flechsig himself subsequently splits up into two personalities, the 'upper' and the 'middle' Flechsig, and God into the 'lower' and the 'upper' God. In the later stages of the illness the decomposition of Flechsig goes further still (193). A process of decomposition of this kind is very characteristic of paranoia. Paranoia decomposes just as hysteria condenses. Or rather, paranoia resolves once more into their elements the products of the condensations and identifications which are effected in the unconscious. The frequent repetition of the decomposing process in Schreber's case would, according to Jung, be an expression of the importance which the person in question possessed for him.¹ All of this dividing up of Flechsig and God into a number of persons thus had the same meaning as the splitting of the persecutor into Flechsig and God. They were all duplications of one and the same important relationship.² But, in order to interpret all these details, we must further draw attention to our view of this decomposition of the persecutor into Flechsig and God as a paranoid reaction to a previously established identification of the two figures or their belonging to the same class. If the persecutor Flechsig was originally a person whom Schreber loved, then God must also simply be the reappearance of some one else whom he loved, and probably some one of greater importance.
We have hitherto been dealing with the father-complex, which was the dominant element in Schreber's case and with the wishful phantasy round which the illness centred. But in all of this there is nothing characteristic of the form of disease known as paranoia, nothing that might not be found (and that has not in fact been found) in other kinds of neuroses. The distinctive character of paranoia (or of dementia paranoides) must be sought for elsewhere - namely, in the particular form assumed by the symptoms; and we shall expect to find that this is determined, not by the nature of the complexes themselves, but by the mechanism by which the symptoms are formed or by which repression is brought about. We should be inclined to say that what was characteristically paranoic about the illness was the fact that the patient, as a means of warding off a homosexual wishful phantasy, reacted precisely with delusions of persecution of this kind.

[1911c, 2429]

These considerations therefore lend an added weight to the circumstance that we are in point of fact driven by experience to attribute to homosexual wishful phantasies an intimate (perhaps an invariable) relation to this particular form of disease. Distrusting my own experience on the subject, I have during the last few years joined with my friends C. G. Jung of Zurich and Sándor Ferenczi of Budapest in investigating upon this single point a number of cases of paranoid disorder which have come under observation. The patients whose histories provided the material for this enquiry included both men and women, and varied in race, occupation, and social standing. Yet we were astonished to find that in all of these cases defence against a homosexual wish was clearly recognizable at the very centre of the conflict which underlay the disease and that it was in an attempt to master an unconsciously reinforced current of homosexuality that they had all of them come to grief.¹ This was certainly not what we had expected. Paranoia is precisely a disorder in which a sexual aetiology is by no means obvious; far from this, the strikingly prominent features in the causation of paranoia, especially among males, are social humiliations and slights. But if we go into the matter only a little more deeply, we shall be able to see that the really operative factor in these social injuries lies in the part played in them by the homosexual components of emotional life. So long as the individual is functioning normally and it is consequently impossible to see into the depths of his mental life, we may doubt whether his emotional relations to his neighbours in society have anything to do with sexuality, either actually or in their genesis. But delusions never fail to uncover these relations and to trace back the social feelings to their roots in a directly sensual erotic wish. So long as he was healthy, Dr. Schreber, too, whose delusions culminated in a wishful phantasy of an unmistakably homosexual nature, had, by all accounts, shown no signs of homosexuality in the ordinary sense of the word.

[1911c, 2429]
In my *Three Essays on the Theory of Sexuality* I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics *endeavour to protect themselves against any such sexualization of their social instinctual cathexes*, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) *schizophrenia*; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.

It is of some importance in connection with other parts of the theory of paranoia to notice that we can detect an element of megalomania in most other forms of paranoic disorder. We are justified in assuming that megalomania is essentially of an infantile nature and that, as development proceeds, it is sacrificed to social considerations. Similarly, an individual's megalomania is never so vehemently suppressed as when he is in the grip of an overpowering love:

And the paranoic builds it again, not more splendid, it is true, but at least so that he can once more live in it. He builds it up by the world of his delusions. The delusional formation, which we take to be the pathological product, is in reality an attempt at recovery, a process of reconstruction. Such a reconstruction after the catastrophe is successful to a greater or lesser extent, but never wholly so; in Schreber's words, there has been a 'profound internal change' in the world. But the human subject has recaptured a relation, and often a very intense one, to the people and things in the world, even though the relation is a hostile one now, where formerly it was hopefully affectionate. We may say, then, that the process of repression proper consists in a detachment of the libido from people - and things - that were previously loved. It happens silently; we receive no intelligence of it, but can only infer it from subsequent events. What forces itself so noisily upon our attention is the process of recovery, which undoes the work of repression and brings back the libido again on to the people it had abandoned. In paranoia this process is carried out by the method of projection. It was incorrect to say that the perception which was suppressed internally is projected outwards; the truth is rather, as we now see, that what was abolished internally returns from without. The thorough examination of the process of projection which we have postponed to another occasion will clear up our remaining doubts on this subject.
(1) Our first reflection will tell us that it cannot be the case that this detachment of the libido occurs exclusively in paranoia; nor can it be that, where it occurs elsewhere, it has such disastrous consequences. It is quite possible that a detachment of the libido is the essential and regular mechanism of every repression. We can have no positive knowledge on that point until the other disorders that are based upon repression have been similarly examined. But it is certain that in normal mental life (and not only in periods of mourning) we are constantly detaching our libido in this way from people or from other objects without falling ill. When Faust freed himself from the world by uttering his curses, the result was not a paranoia or any other neurosis but simply a certain general frame of mind. The detachment of the libido, therefore, cannot in itself be the pathogenic factor in paranoia; there must be some special characteristic which distinguishes a paranoid detachment of the libido from other kinds. It is not difficult to suggest what that characteristic may be. What use is made of the libido after it has been set free by the process of detachment? A normal person will at once begin looking about for a substitute for the lost attachment; and until that substitute has been found the liberated libido will be kept in suspension within his mind, and will there give rise to tensions and colour his mood. In hysteria the liberated libido becomes transformed into somatic innervations or into anxiety. But in paranoia the clinical evidence goes to show that the libido, after it has been withdrawn from the object, is put to a special use. It will be remembered that the majority of cases of paranoia exhibit traces of megalomania, and that megalomania can by itself constitute a paranoia. From this it may be concluded that in paranoia the liberated libido becomes attached to the ego, and is used for the aggrandizement of the ego. A return is thus made to the stage of narcissism (known to us from the development of the libido), in which a person's only sexual object is his own ego. On the basis of this clinical evidence we can suppose that paranoids have brought along with them a fixation at the stage of narcissism, and we can assert that the length of the step back from sublimated homosexuality to narcissism is a measure of the amount of regression characteristic of paranoia.

[1911c, 2438]
A third consideration which arises from the views that have been developed in these pages is as follows. Are we to suppose that a general detachment of the libido from the external world would be an effective enough agent to account for the 'end of the world'? Or would not the ego-cathexes which still remained in existence have been sufficient to maintain rapport with the external world? To meet this difficulty we should either have to assume that what we call libidinal cathexis (that is, interest emanating from erotic sources) coincides with interest in general, or we should have to consider the possibility that a very widespread disturbance in the distribution of libido may bring about a corresponding disturbance in the ego-cathexes. But these are problems which we are still quite helpless and incompetent to solve. It would be otherwise if we could start out from some well-grounded theory of instincts; but in fact we have nothing of the kind at our disposal. We regard instinct as being the concept on the frontier-line between the somatic and the mental, and see in it the psychical representative of organic forces. Further, we accept the popular distinction between ego-instincts and a sexual instinct; for such a distinction seems to agree with the biological conception that the individual has a double orientation, aiming on the one hand at self-preservation and on the other at the preservation of the species. But beyond this are only hypotheses, which we have taken up - and are quite ready to drop again - in order to help us to find our bearings in the chaos of the obscurer processes of the mind. What we expect from psycho-analytic investigations of pathological mental processes is precisely that they shall drive us to some conclusions on questions connected with the theory of instincts. These investigations, however, are in their infancy and are only being carried out by isolated workers, so that the hopes we place in them must still remain unfulfilled. We can no more dismiss the possibility that disturbances of the libido may react upon the ego-cathexes than we can overlook the converse possibility - namely, that a secondary or induced disturbance of the libidinal processes may result from abnormal changes in the ego. Indeed, it is probable that processes of this kind constitute the distinctive characteristic of psychoses. How much of all this may apply to paranoia it is impossible at present to say. There is one consideration, however, on which I should like to lay stress. It cannot be asserted that a paranoic, even at the height of the repression, withdraws his interest from the external world completely - as must be considered to occur in certain other kinds of hallucinatory psychosis (such as Meynert's amentia). The paranoic perceives the external world and takes into account any alterations that may happen in it, and the effect it makes upon him stimulates him to invent explanatory theories (such as Schreber's 'cursorily improvised men'). It therefore appears to me far more probable that the paranoic's altered relation to the world is to be explained entirely or in the main by the loss of his libidinal interest.
Our hypotheses as to the dispositional fixations in paranoia and paraphrenia make it easy to see that a case may begin with paranoic symptoms and may yet develop into a dementia praecox, and that paranoid and schizophrenic phenomena may be combined in any proportion. And we can understand how a clinical picture such as Schreber's can come about, and merit the name of a paranoid dementia, from the fact that in its production of a wishful phantasy and of hallucinations it shows paraphrenic traits, while in its exciting cause, in its use of the mechanism of projection, and in its outcome it exhibits a paranoid character. For it is possible for several fixations to be left behind in the course of development, and each of these in succession may allow an irruption of the libido that has been pushed off - beginning, perhaps, with the later acquired fixations, and going on, as the illness develops, to the original ones that lie nearer the starting-point. We should be glad to know to what conditions the relatively favourable issue of the present case is due; for we cannot willingly attribute the whole responsibility for the outcome to anything so casual as the 'improvement due to change in domicile',¹ which set in after the patient's removal from Flechsig's clinic. But our insufficient acquaintance with the intimate circumstances of the history of the case makes it impossible to give an answer to this interesting question. It may be suspected, however, that what enabled Schreber to reconcile himself to his homosexual phantasy, and so made it possible for his illness to terminate in something approximating to a recovery, may have been the fact that his father-complex was in the main positively toned and that in real life the later years of his relationship with an excellent father had probably been unclouded.

[1911c, 2443]

The secondary revision of the product of the dream-work is an admirable example of the nature and pretensions of a system. There is an intellectual function in us which demands unity, connection and intelligibility from any material, whether of perception or thought, that comes within its grasp; and if, as a result of special circumstances, it is unable to establish a true connection, it does not hesitate to fabricate a false one. Systems constructed in this way are known to us not only from dreams, but also from phobias, from obsessive thinking and from delusions. The construction of systems is seen most strikingly in delusional disorders (in paranoia), where it dominates the symptomatic picture; but its occurrence in other forms of neuro-psychosis must not be overlooked. In all these cases it can be shown that a rearrangement of the psychical material has been made with a fresh aim in view; and the rearrangement may often have to be a drastic one if the outcome is to be made to appear intelligible from the point of view of the system. Thus a system is best characterized by the fact that at least two reasons can be discovered for each of its products: a reason based upon the premises of the system (a reason, then, which may be delusional) and a concealed reason, which we must judge to be the truly operative and the real one.

[1912-1913, 2737]

It would not surprise us if we were to find a special psychical agency which performs the task of seeing that narcissistic satisfaction from the ego ideal is ensured and which, with this end in view, constantly watches the actual ego and measures it by that ideal. If such an agency does exist, we cannot possibly come upon it as a discovery - we can only recognize it; for we may reflect that what we call our 'conscience' has the required characteristics. Recognition of this agency enables us to understand the so-called 'delusions of being noticed' or more correctly, of being watched, which are such striking symptoms in the paranoid diseases and which may also occur as an isolated form of illness, or intercalated in a transference neurosis. Patients of this sort complain that all their thoughts are known and their actions watched and supervised; they are informed of the functioning of this agency by voices which characteristically speak to them in the third person ('Now she's thinking of that again', 'now he's going out'). This complaint is justified; it describes the truth. A power of this kind, watching, discovering and criticizing all our intentions, does really exist. Indeed, it exists in every one of us in normal life.

[1914c, 2949]
In this way large amounts of libido of an essentially homosexual kind are drawn into the formation of the narcissistic ego ideal and find outlet and satisfaction in maintaining it. The institution of conscience was at bottom an embodiment, first of parental criticism, and subsequently of that of society - a process which is repeated in what takes place when a tendency towards repression develops out of a prohibition or obstacle that came in the first instance from without. The voices, as well as the undefined multitude, are brought into the foreground again by the disease, and so the evolution of conscience is reproduced regressively. But the revolt against this 'censoring agency' arises out of the subject's desire (in accordance with the fundamental character of his illness) to liberate himself from all these influences, beginning with the parental one, and out of his withdrawal of homosexual libido from them. His conscience then confronts him in a regressive form as a hostile influence from without.

The complaints made by paranoics also show that at bottom the self-criticism of conscience coincides with the self-observation on which it is based. Thus the activity of the mind which has taken over the function of conscience has also placed itself at the service of internal research, which furnishes philosophy with the material for its intellectual operations. This may have some bearing on the characteristic tendency of paranoics to construct speculative systems.¹

One can go a step further in disproving the accidental nature of the noise. We do not, however, ask our readers to follow us, since the absence of any deeper analytic investigation makes it impossible in this case to go beyond a certain degree of probability. The patient mentioned in her first interview with me that she had immediately demanded an explanation of the noise, and had been told that it was probably the ticking of the small clock on the writing-desk. I venture, however, to explain what she told me as a mistaken memory. It seems to me much more likely that at first she did not react to the noise at all, and that it became significant only after she met the two men on the staircase. Her lover, who had probably not even heard the noise, may have tried, perhaps on some later occasion when she assailed him with her suspicions, to account for it in this way: 'I don't know what noise you can have heard. Perhaps it was the small clock; it sometimes ticks like that.' This deferred use of impressions and this displacement of recollections often occur precisely in paranoia and are characteristic of it. But as I never met the man and could not continue the analysis of the woman, my hypothesis cannot be proved.

[1914c, 2949]

[1915f, 3063]
The form of disease known as paranoia, chronic systematic insanity, occupies an unsettled position in the attempts at classification made by present-day psychiatry. There is, however, no doubt of its close affinity to dementia praecox. I once ventured to suggest that paranoia and dementia praecox should be brought together under the common designation of ‘paraphrenia’. The forms of paranoia are described according to their content as megalomania, persecution mania, erotomania, delusions of jealousy, and so on. We shall not expect anything much in the way of an attempt at an explanation from psychiatry. Here is an example of one, though, it is true, one that is out of date and does not carry much weight - an attempt to derive one symptom from another by means of an intellectual rationalization: it is suggested that the patient, who, owing to a primary disposition, believes that he is being persecuted, infers from his persecution that he must be someone of quite particular importance and so develops megalomania. According to our analytic view the megalomania is the direct result of a magnification of the ego due to the drawing in of the libidinal object-cathexes - a secondary narcissism which is a return of the original early infantile one. We have, however, made a few observations of persecution mania which have induced us to follow a particular track. The first thing that struck us was that in the large majority of cases the persecutor was of the same sex as the persecuted patient. This was still open to an innocent explanation; but in a few cases that were thoroughly studied it was clear that the person of the same sex whom the patient loved most had, since his illness, been turned into his persecutor. This made a further development possible: namely, the replacement of the beloved person, along the line of familiar resemblances, by someone else - for instance, a father by a schoolmaster or by some superior. Experiences of this kind in ever increasing numbers led us to conclude that paranoia persecutoria is the form of the disease in which a person is defending himself against a homosexual impulse which has become too powerful. The change over from affection to hatred, which, it is well known, may become a serious threat to the life of the loved and hated object, corresponds in such cases to the transformation of libidinal impulses into anxiety which is a regular outcome of the process of repression. Listen, for instance, to what is, once again, the most recent instance of my observations in this connection. [1916-1917, 3468]

There are, however, other forms of illness in which, in spite of the conditions being the same, our therapeutic procedure is never successful. In them, too, it had been a question of an original conflict between the ego and the libido which led to repression - though this may call for a different topographical description; in them, too, it is possible to trace the points in the patient's life at which the repressions occurred; we make use of the same procedure, are ready to make the same promises and give the same help by the offer of anticipatory ideas; and once again the lapse of time between the repressions and the present day favours a different outcome to the conflict. And yet we do not succeed in lifting a single resistance or getting rid of a single repression. These patients, paranoics, melancholics, sufferers from dementia praecox, remain on the whole unaffected and proof against psycho-analytic therapy. What can be the reason for this? Not any lack of intelligence. A certain amount of intellectual capacity is naturally required in our patients; but there is certainly no lack of it in, for instance, the extremely shrewd combinatory paranoics. Nor do any of the other motives seem to be absent. Thus the melancholics have a very high degree of consciousness, absent in paranoics, that they are ill and that that is why they suffer so much; but this does not make them more accessible. We are faced here by a fact which we do not understand and which therefore leads us to doubt whether we have really understood all the determinants of our possible success with the other neuroses. [1916-1917, 3480]
As regards the third and apparently sadistic phase of the beating-phantasy, I have already discussed the significance that it gains as the vehicle of the excitation impelling towards masturbation; and I have shown how it arouses activities of the imagination which on the one hand continue the phantasy along the same line, and on the other hand neutralize it through compensation. Nevertheless the second phase, the unconscious and masochistic one, in which the child itself is being beaten by its father, is incomparably the more important. This is not only because it continues to operate through the agency of the phase that takes its place; we can also detect effects upon the character, which are directly derived from its unconscious form. People who harbour phantasies of this kind develop a special sensitiveness and irritability towards anyone whom they can include in the class of fathers. They are easily offended by a person of this kind, and in that way (to their own sorrow and cost) bring about the realization of the imagined situation of being beaten by their father. I should not be surprised if it were one day possible to prove that the same phantasy is the basis of the delusional litigiousness of paranoia.

[1919e, 3655]

In obsessional neurosis and paranoia the forms which the symptoms assume become very valuable to the ego because they obtain for it, not certain advantages, but a narcissistic satisfaction which it would otherwise be without. The systems which the obsessional neurotic constructs flatter his self-love by making him feel that he is better than other people because he is specially cleanly or specially conscientious. The delusional constructions of the paranoic offer to his acute perceptive and imaginative powers a field of activity which he could not easily find elsewhere.

[1926d, 4260]

We shall be glad, then, to know the nature of the girl's libidinal relations to her mother. The answer is that they are of very many different kinds. Since they persist through all three phases of infantile sexuality, they also take on the characteristics of the different phases and express themselves by oral, sadistic-anal and phallic wishes. These wishes represent active as well as passive impulses; if we relate them to the differentiation of the sexes which is to appear later - though we should avoid doing so as far as possible - we may call them masculine and feminine. Besides this, they are completely ambivalent, both affectionate and of a hostile and aggressive nature. The latter often only come to light after being changed into anxiety ideas. It is not always easy to point to a formulation of these early sexual wishes; what is most clearly expressed is a wish to get the mother with child and the corresponding wish to bear her a child - both belonging to the phallic period and sufficiently surprising, but established beyond doubt by analytic observation. The attractiveness of these investigations lies in the surprising detailed findings which they bring us. Thus, for instance, we discover the fear of being murdered or poisoned, which may later form the core of a paranoid illness, already present in this pre-Oedipus period, in relation to the mother. Or another case: you will recall an interesting episode in the history of analytic research which caused me many distressing hours. In the period in which the main interest was directed to discovering infantile sexual traumas, almost all my women patients told me that they had been seduced by their father. I was driven to recognize in the end that these reports were untrue and so came to understand that hysterical symptoms are derived from phantasies and not from real occurrences. It was only later that I was able to recognize in this phantasy of being seduced by the father the expression of the typical Oedipus complex in women. And now we find the phantasy of seduction once more in the pre-Oedipus prehistory of girls; but the seducer is regularly the mother. Here, however, the phantasy touches the ground of reality, for it was really the mother who by her activities over the child's bodily hygiene inevitably stimulated, and perhaps even roused for the first time, pleasurable sensations in her genitals.

[1933a, 4722]
The third group of symptoms that are found in obsessional neurosis, the symptoms of secondary defence, cannot be present as such in paranoia, because no defence can avail against the returning symptoms to which, as we know, belief is attached. In place of this, we find in paranoia another source for the formation of symptoms. The delusional ideas which have arrived in consciousness by means of a compromise (the symptoms of the return) make demands on the thought-activity of the ego until they can be accepted without contradiction. Since they are not themselves open to influence, the ego must adapt itself to them; and thus what corresponds here to the symptoms of secondary defence in obsessional neurosis is a combinatory delusional formation - interpretative delusions which end in an alteration of the ego. In this respect, the case under discussion was not complete; at that time my patient did not as yet exhibit any signs of the attempts at interpretation which appeared later. But I have no doubt that if we apply psycho-analysis to this stage of paranoia as well, we shall be able to arrive at a further important result. It should then turn out that the so-called weakness of memory of paranoics is also a tendentious one - that is to say, that it is based on repression and serves the ends of repression. A subsequent repression and replacement takes place of memories which are not in the least pathogenic, but which are in contradiction to the alteration of the ego which the symptoms of the return of the repressed so insistently demand.

[1896b, 404]

The core of a dream of exhibiting lies in the figure of the dreamer himself (not as he was as a child but as he appears at the present time) and his inadequate clothing (which emerges indistinctly, whether owing to superimposed layers of innumerable later memories of being in undress or as a result of the censorship). Added to these are the figures of the people in whose presence the dreamer feels ashamed. I know of no instance in which the actual spectators of the infantile scene of exhibiting have appeared in the dream; a dream is scarcely ever a simple memory. Curiously enough, the people upon whom our sexual interest was directed in childhood are omitted in all the reproductions which occur in dreams, in hysteria and in obsessional neurosis. It is only in paranoia that these spectators reappear and, though they remain invisible, their presence is inferred with fanatical conviction. What takes their place in dreams - 'a lot of strangers' who take no notice of the spectacle that is offered - is nothing more nor less than the wishful contrary of the single familiar individual before whom the dreamer exposed himself. Incidentally, 'a lot of strangers' frequently appear in dreams in many other connections, and they always stand as the wishful contrary of 'secrecy'. It is to be noticed that even in paranoia, where the original state of things is restored, this reversal into a contrary is observed. The subject feels that he is no longer alone, he has no doubt that he is being observed, but the observers are 'a lot of strangers' whose identity is left curiously vague.

[1900a, 724]

The interest felt by the practical psychiatrist in such delusional formations as these is, as a rule, exhausted when once he has ascertained the character of the products of the delusion and has formed an estimate of their influence on the patient's general behaviour: in his case marvelling is not the beginning of understanding. The psycho-analyst, in the light of his knowledge of the psychoneuroses, approaches the subject with a suspicion that even thought-structures so extraordinary as these and so remote from our common modes of thinking are nevertheless derived from the most general and comprehensible impulses of the human mind; and he would be glad to discover the motives of such a transformation as well as the manner in which it has been accomplished. With this aim in view, he will wish to go more deeply into the details of the delusion and into the history of its development.

[1911c, 2394]
I am quite aware that a psycho-analyst needs no small amount of tact and restraint whenever in the course of his work he goes beyond the typical instances of interpretation and that his listeners or readers will only follow him as far as their own familiarity with analytic technique will allow them. He has every reason, therefore, to guard against the risk that an increased display of acumen on his part may be accompanied by a diminution in the certainty and trustworthiness of his results. It is thus only natural that one analyst will tend too much in the direction of caution and another too much in the direction of boldness. It will not be possible to define the proper limits of justifiable interpretation until many experiments have been made and until the subject has become more familiar. In working upon the case of Schreber I have had a policy of restraint forced on me by the circumstance that the opposition to his publishing the Denkwürdigkeiten was so far effective as to withhold a considerable portion of the material from our knowledge - the portion, too, which would in all probability have thrown the most important light upon the case.¹ Thus, for instance, the third chapter of the book opens with this promising announcement: 'I shall now proceed to describe certain events which occurred to other members of my family and which may conceivably have been connected with the soul-murder I have postulated; for there is at any rate something more or less problematical about all of them, something not easily explicable upon the lines of ordinary human experience.' (33.) But the next sentence, which is also the last of the chapter, is as follows: 'The remainder of this chapter has been withheld from print as being unsuitable for publication.' I shall therefore have to be satisfied if I can succeed in tracing back at any rate the nucleus of the delusional structure with some degree of certainty to familiar human motives.

¹911c, 2411

Turning once more to the case of Schreber, we are bound to admit that any attempt at throwing light upon the transformation in his delusion brings us up against extraordinary difficulties. In what manner and by what means was the ascent from Flechsig to God brought about? From what source did he derive the megalomania which so fortunately enabled him to become reconciled to his persecution, or, in analytical phraseology, to accept the wishful phantasy which had had to be repressed? The Denkwürdigkeiten give us a first clue; for they show us that in the patient's mind 'Flechsig' and 'God' belonged to the same class. In one of his phantasies he overheard a conversation between Flechsig and his wife, in which the former asserted that he was 'God Flechsig', so that his wife thought he had gone mad (82). But there is another feature in the development of Schreber's delusions which claims our attention. If we take a survey of the delusions as a whole we see that the persecutor is divided into Flechsig and God; in just the same way Flechsig himself subsequently splits up into two personalities, the 'upper' and the 'middle' Flechsig, and God into the 'lower' and the 'upper' God. In the later stages of the illness the decomposition of Flechsig goes further still (193). A process of decomposition of this kind is very characteristic of paranoia. Paranoia decomposes just as hysteria condenses. Or rather, paranoia resolves once more into their elements the products of the condensations and identifications which are effected in the unconscious. The frequent repetition of the decomposing process in Schreber's case would, according to Jung, be an expression of the importance which the person in question possessed for him.¹ All of this dividing up of Flechsig and God into a number of persons thus had the same meaning as the splitting of the persecutor into Flechsig and God. They were all duplications of one and the same important relationship.² But, in order to interpret all these details, we must further draw attention to our view of this decomposition of the persecutor into Flechsig and God as a paranoid reaction to a previously established identification of the two figures or their belonging to the same class. If the persecutor Flechsig was originally a person whom Schreber loved, then God must also simply be the reappearance of some one else whom he loved, and probably some one of greater importance.

¹911c, 2421
We have hitherto been dealing with the father-complex, which was the dominant element in Schreber's case and with the wishful phantasy round which the illness centred. But in all of this there is nothing characteristic of the form of disease known as paranoia, nothing that might not be found (and that has not in fact been found) in other kinds of neuroses. The distinctive character of paranoia (or of dementia paranoides) must be sought for elsewhere - namely, in the particular form assumed by the symptoms; and we shall expect to find that this is determined, not by the nature of the complexes themselves, but by the mechanism by which the symptoms are formed or by which repression is brought about. We should be inclined to say that what was characteristically paranoic about the illness was the fact that the patient, as a means of warding off a homosexual wishful phantasy, reacted precisely with delusions of persecution of this kind.

[1911c, 2429]

In my *Three Essays on the Theory of Sexuality* I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics *endeavour to protect themselves against any such sexualization of their social instinctual cathexes*, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) *schizophrenia*; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.

[1911c, 2431]
And the paranoic builds it again, not more splendid, it is true, but at least so that he can once more live in it. He builds it up by the world of his delusions. The delusional formation, which we take to be the pathological product, is in reality an attempt at recovery, a process of reconstruction. Such a reconstruction after the catastrophe is successful to a greater or lesser extent, but never wholly so; in Schreber's words, there has been a 'profound internal change' in the world. But the human subject has recaptured a relation, and often a very intense one, to the people and things in the world, even though the relation is a hostile one now, where formerly it was hopefully affectionate. We may say, then, that the process of repression proper consists in a detachment of the libido from people - and things - that were previously loved. It happens silently; we receive no intelligence of it, but can only infer it from subsequent events. What forces itself so noisily upon our attention is the process of recovery, which undoes the work of repression and brings back the libido again on to the people it had abandoned. In paranoia this process is carried out by the method of projection. It was incorrect to say that the perception which was suppressed internally is projected outwards; the truth is rather, as we now see, that what was abolished internally returns from without. The thorough examination of the process of projection which we have postponed to another occasion will clear up our remaining doubts on this subject.

[1911c, 2437]

(3) A third consideration which arises from the views that have been developed in these pages is as follows. Are we to suppose that a general detachment of the libido from the external world would be an effective enough agent to account for the 'end of the world'? Or would not the ego-cathexes which still remained in existence have been sufficient to maintain rapport with the external world? To meet this difficulty we should either have to assume that what we call libidinal cathexis (that is, interest emanating from erotic sources) coincides with interest in general, or we should have to consider the possibility that a very widespread disturbance in the distribution of libido may bring about a corresponding disturbance in the ego-cathexes. But these are problems which we are still quite helpless and incompetent to solve. It would be otherwise if we could start out from some well-grounded theory of instincts; but in fact we have nothing of the kind at our disposal. We regard instinct as being the concept on the frontier-line between the somatic and the mental, and see in it the psychical representative of organic forces. Further, we accept the popular distinction between ego-instincts and a sexual instinct; for such a distinction seems to agree with the biological conception that the individual has a double orientation, aiming on the one hand at self-preservation and on the other at the preservation of the species. But beyond this are only hypotheses, which we have taken up - and are quite ready to drop again - in order to help us to find our bearings in the chaos of the obscurer processes of the mind. What we expect from psycho-analytic investigations of pathological mental processes is precisely that they shall drive us to some conclusions on questions connected with the theory of instincts. These investigations, however, are in their infancy and are only being carried out by isolated workers, so that the hopes we place in them must still remain unfulfilled. We can no more dismiss the possibility that disturbances of the libido may react upon the ego-cathexes than we can overlook the converse possibility - namely, that a secondary or induced disturbance of the libidinal processes may result from abnormal changes in the ego. Indeed, it is probable that processes of this kind constitute the distinctive characteristic of psychoses. How much of all this may apply to paranoia it is impossible at present to say. There is one consideration, however, on which I should like to lay stress. It cannot be asserted that a paranoic, even at the height of the repression, withdraws his interest from the external world completely - as must be considered to occur in certain other kinds of hallucinatory psychosis (such as Meynert's amentia). The paranoic perceives the external world and takes into account any alterations that may happen in it, and the effect it makes upon him stimulates him to invent explanatory theories (such as Schreber's 'cursorily improvised men'). It therefore appears to me far more probable that the paranoic's altered relation to the world is to be explained entirely or in the main by the loss of his libidinal interest.

[1911c, 2440]
There is another possible mechanism, however, which we have come to know of by analytic investigation of the processes concerned in the change in paranoia. An ambivalent attitude is present from the outset and the transformation is effected by means of a reactive displacement of cathexis, energy being withdrawn from the erotic impulse and added to the hostile one.

Everything in the sphere of this first attachment to the mother seemed to me so difficult to grasp in analysis - so grey with age and shadowy and almost impossible to revivify - that it was as if it had succumbed to an especially inexorable repression. But perhaps I gained this impression because the women who were in analysis with me were able to cling to the very attachment to the father in which they had taken refuge from the early phase that was in question. It does indeed appear that women analysts - as, for instance, Jeanne Lampl-de Groot and Helene Deutsch - have been able to perceive these facts more easily and clearly because they were helped in dealing with those under their treatment by the transference to a suitable mother-substitute. Nor have I succeeded in seeing my way through any case completely, and I shall therefore confine myself to reporting the most general findings and shall give only a few examples of the new ideas which I have arrived at. Among these is a suspicion that this phase of attachment to the mother is especially intimately related to the aetiology of hysteria, which is not surprising when we reflect that both the phase and the neurosis are characteristically feminine, and further, that in this dependence on the mother we have the germ of later paranoia in women.¹ For this germ appears to be the surprising, yet regular, fear of being killed (?) devoured) by the mother. It is plausible to assume that this fear corresponds to a hostility which develops in the child towards her mother in consequence of the manifold restrictions imposed by the latter in the course of training and bodily care and that the mechanism of projection is favoured by the early age of the child's psychical organization.

[1923b, 3977]

[1931b, 4591]
It only remains for me now to employ what has been learned from this case of paranoia for making a comparison between paranoia and obsessional neurosis. In each of them, repression has been shown to be the nucleus of the psychical mechanism, and in each what has been repressed is a sexual experience in childhood. In this case of paranoia, too, every obsession sprang from repression; the symptoms of paranoia allow of a classification similar to the one which has proved justified for obsessional neurosis. Part of the symptoms, once again, arise from primary defence - namely, all the delusional ideas which are characterized by distrust and suspicion and which are concerned with ideas of being persecuted by others. In obsessional neurosis the initial self-reproach has been repressed by the formation of the primary symptom of defence: self-distrust. With this, the self-reproach is acknowledged as justified; and, to weigh against this, the conscientiousness which the subject has acquired during his healthy interval now protects him from giving credence to the self-reproaches which return in the form of obsessional ideas. In paranoia, the self-reproach is repressed in a manner which may be described as projection. It is repressed by erecting the defensive symptom of distrust of other people. In this way the subject withdraws his acknowledgement of the self-reproach; and, as if to make up for this, he is deprived of a protection against the self-reproaches which return in his delusional ideas.

The category of what is accidental and requires no motivation, in which the normal person includes a part of his own psychical performances and parapraxes, is thus rejected by the paranoid as far as the psychical manifestations of other people are concerned. Everything he observes in other people is full of significance, everything can be interpreted. How does he reach this position? Probably here as in so many similar cases he projects on to the mental life of other people what is unconsciously present in his own. In paranoia many sorts of things force their way through to consciousness whose presence in the unconscious of normal and neurotic people we can demonstrate only through psycho-analysis.² In a certain sense, therefore, the paranoid is justified in this, for he recognizes something that escapes the normal person: he sees more clearly than someone of normal intellectual capacity, but the displacement on to other people of the state of affairs which he recognizes renders his knowledge worthless. I hope I shall not now be expected to justify the various paranoid interpretations. But the partial justification which we concede to paranoia in respect of this view taken by it of chance actions will help us towards a psychological understanding of the sense of conviction that the paranoid attaches to all these interpretations. There is in fact some truth in them; those, too, of our errors of judgement which are not to be counted as pathological acquire their sense of conviction in just the same way. This feeling is justified for a certain part of the erroneous train of thought, or for its source of origin; and it is then extended by us to the rest of the context.

[1901b, 1325]
I assume that this conscious ignorance and unconscious knowledge of the motivation of accidental psychical events is one of the psychical roots of superstition. Because the superstitious person knows nothing of the motivation of his own chance actions, and because the fact of this motivation presses for a place in his field of recognition, he is forced to allocate it, by displacement, to the external world. If such a connection exists, it can hardly be limited to this single application. In point of fact I believe that a large part of the mythological view of the world, which extends a long way into the most modern religions, is nothing but psychology projected into the external world. The obscure recognition¹ (the endopsychic perception, as it were) of psychical factors and relations in the unconscious is mirrored - it is difficult to express it in other terms, and here the analogy with paranoia must come to our aid - in the construction of a supernatural reality, which is destined to be changed back once more by science into the psychology of the unconscious. One could venture to explain in this way the myths of paradise and the fall of man, of God, of good and evil, of immortality, and so on, and to transform metaphysics into metapsychology. The gap between the paranoic's displacement and that of the superstitious person is less wide than it appears at first sight. When human beings began to think, they were, as is well known, forced to explain the external world anthropomorphically by means of a multitude of personalities in their own image; chance events, which they interpreted superstitiously, were thus actions and manifestations of persons. They behaved, therefore, just like paranoids, who draw conclusions from insignificant signs given them by other people, and just like all normal people, who quite rightly base their estimate of their neighbours' characters on their chance and unintentional actions. It is only in our modern, scientific but as yet by no means perfected Weltanschauung that superstition seems so very much out of place; in the Weltanschauung of pre-scientific times and peoples it was justified and consistent.

When a patient brings forward a sound and incontestable train of argument during psychoanalytic treatment, the physician is liable to feel a moment's embarrassment, and the patient may take advantage of it by asking: 'This is all perfectly correct and true, isn't it? What do you want to change in now that I've told it you?' But it soon becomes evident that the patient is using thoughts of this kind, which the analysis cannot attack, for the purpose of cloaking others which are anxious to escape from criticism and from consciousness. A string of reproaches against other people leads one to suspect the existence of a string of self-reproaches with the same content. All that need be done is to turn back each particular reproach on to the speaker himself. There is something undeniably automatic about this method of defending oneself against a self-reproach by making the same reproach against some one else. A model of it is to be found in the tu quoque arguments of children; if one of them is accused of being a liar, he will reply without an instant's hesitation: ‘You're another.’ A grown-up person who wanted to throw back abuse would look for some really exposed spot in his antagonist and would not necessarily lay the chief stress upon the same content being repeated. In paranoia the projection of a reproach on to another person without any alteration in its content and therefore without any consideration for reality becomes manifest as the process of forming delusions.

¹ The contents of the clearly conscious phantasies of perverts (which in favourable circumstances can be transformed into manifest behaviour), of the delusional fears of paranoids (which are projected in a hostile sense on to other people) and of the unconscious phantasies of hysterics (which psycho-analysis reveals behind their symptoms) - all of these coincide with one another even down to their details.
There can be no doubt that the patient felt a need for finding experiences of this kind to act as props for his superstition, and that it was for that reason that he occupied himself so much with the inexplicable coincidences of everyday life with which we are all familiar, and helped out their shortcomings with unconscious activity of his own. I have come across a similar need in many other obsessional patients and have suspected its presence in many more besides. It seems to me easily explicable in view of the psychological characteristics of the obsessional neurosis. In this disorder, as I have already explained (p. 2155), repression is effected not by means of amnesia but by a severance of causal connections brought about by a withdrawal of affect. These repressed connections appear to persist in some kind of shadowy form (which I have elsewhere compared to an endopsychic perception),¹ and they are thus transferred, by a process of projection, into the external world, where they bear witness to what has been effaced from consciousness.

[1909d, 2181]

And when the obsessional patient lays his finger on the weak spot in the security of our mental life - on the untrustworthiness of our memory - the discovery enables him to extend his doubt over everything, even over actions which have already been performed and which have so far had no connection with the love-hatred complex, and over the entire past. I may recall the instance of the woman who had just bought a comb for her little daughter in a shop, and, becoming suspicious of her husband, began to doubt whether she had not as a matter of fact been in possession of the comb for a long time. Was not this woman saying point-blank: 'If I can doubt your love' (and this was only a projection of her doubt of her own love for him), 'then I can doubt this too, then I can doubt everything' - thus revealing to us the hidden meaning of neurotic doubt?

[1909d, 2190]

The study of a number of cases of delusions of persecution has led me as well as other investigators to the view that the relation between the patient and his persecutor can be reduced to a simple formula.¹ It appears that the person to whom the delusion ascribes so much power and influence, in whose hands all the threads of the conspiracy converge, is, if he is definitely named, either identical with some one who played an equally important part in the patient's emotional life before his illness, or is easily recognizable as a substitute for him. The intensity of the emotion is projected in the shape of external power, while its quality is changed into the opposite. The person who is now hated and feared for being a persecutor was at one time loved and honoured. The main purpose of the persecution asserted by the patient's delusion is to justify the change in his emotional attitude.

[1911c, 2415]

In taking the view, then, that what lies at the core of the conflict in cases of paranoia among males is a homosexual wishful phantasy of loving a man, we shall certainly not forget that the confirmation of such an important hypothesis can only follow upon the investigation of a large number of instances of every variety of paranoid disorder. We must therefore be prepared, if need be, to limit our assertion to a single type of paranoia. Nevertheless, it is a remarkable fact that the familiar principal forms of paranoia can all be represented as contradictions of the single proposition: 'I (a man) love him (a man)'; and indeed that they exhaust all the possible ways in which such contradictions could be formulated.

[1911c, 2432]
This contradiction, which must have run thus in the unconscious,¹ cannot, however, become conscious to a paranoiac in this form. The mechanism of symptom-formation in paranoia requires that internal perceptions - feelings - shall be replaced by external perceptions. Consequently the proposition 'I hate him' becomes transformed by projection into another one: 'He hates (persecutes) me, which will justify me in hating him.' And thus the impelling unconscious feeling makes its appearance as though it were the consequence of an external perception:

'I do not love him - I hate him, because HE PERSECUTES ME.'

Observation leaves room for no doubt that the persecutor is some one who was once loved.

And in obedience to the same need for projection, the proposition is transformed into: 'I observe that she loves me.'

Distortion by means of projection is necessarily absent in this instance, since, with the change of the subject who loves, the whole process is in any case thrown outside the self. The fact that the woman loves the men is a matter of external perception to him; whereas the facts that he himself does not love but hates, or that he himself loves not this but that person, are matters of internal perception.

After this discussion of the unexpectedly important part played by homosexual wishful phantasies in paranoia, let us return to the two factors in which we expected from the first to find the distinguishing marks of paranoia, namely, the mechanism by which the symptoms are formed and the mechanism by which repression is brought about.

The most striking characteristic of symptom-formation in paranoia is the process which deserves the name of projection. An internal perception is suppressed, and, instead, its content, after undergoing a certain kind of distortion, enters consciousness in the form of an external perception. In delusions of persecution the distortion consists in a transformation of affect; what should have been felt internally as love is perceived externally as hate. We should feel tempted to regard this remarkable process as the most important element in paranoia and as being absolutely pathognomonic for it, if we were not opportunely reminded of two things. In the first place, projection does not play the same part in all forms of paranoia; and, in the second place, it makes its appearance not only in paranoia but under other psychological conditions as well, and in fact it has a regular share assigned to it in our attitude towards the external world. For when we refer the causes of certain sensations to the external world, instead of looking for them (as we do in the case of others) inside ourselves, this normal proceeding, too, deserves to be called projection. Having thus been made aware that more general psychological problems are involved in the question of the nature of projection, let us make up our minds to postpone the investigation of it (and with it that of the mechanism of paranoic symptom-formation in general) until some other occasion; and let up now turn to consider what ideas we can collect on the subject of the mechanism of repression in paranoia. I should like to say at once, in justification of this temporary renunciation, that we shall find that the manner in which the process of repression occurs is far more intimately connected with the developmental history of the libido and with the disposition to which it gives rise than is the manner in which symptoms are formed.
It is easy to see that this discussion is beginning to trench upon the problem of 'choice of neurosis', which, however, cannot be taken in hand until preliminary work of another kind has been accomplished. Let us bear in mind for the present that we have already dealt with fixation, and that we have postponed the subject of symptom-formation; and let us restrict ourselves to the question of whether the analysis of Schreber's case throws any light upon the mechanism of repression proper which predominates in paranoia.

[1911c, 2436]

And the paranoic builds it again, not more splendid, it is true, but at least so that he can once more live in it. He builds it up by the world of his delusions. The delusional formation, which we take to be the pathological product, is in reality an attempt at recovery, a process of reconstruction. Such a reconstruction after the catastrophe is successful to a greater or lesser extent, but never wholly so; in Schreber's words, there has been a 'profound internal change' in the world. But the human subject has recaptured a relation, and often a very intense one, to the people and things in the world, even though the relation is a hostile one now, where formerly it was hopefully affectionate. We may say, then, that the process of repression proper consists in a detachment of the libido from people - and things - that were previously loved. It happens silently; we receive no intelligence of it, but can only infer it from subsequent events. What forces itself so noisily upon our attention is the process of recovery, which undoes the work of repression and brings back the libido again on to the people it had abandoned. In paranoia this process is carried out by the method of projection. It was incorrect to say that the perception which was suppressed internally is projected outwards; the truth is rather, as we now see, that what was abolished internally returns from without. The thorough examination of the process of projection which we have postponed to another occasion will clear up our remaining doubts on this subject.

[1911c, 2437]

Our hypotheses as to the dispositional fixations in paranoia and paraphrenia make it easy to see that a case may begin with paranoic symptoms and may yet develop into a dementia praecox, and that paranoid and schizophrenic phenomena may be combined in any proportion. And we can understand how a clinical picture such as Schreber's can come about, and merit the name of a paranoid dementia, from the fact that in its production of a wishful phantasy and of hallucinations it shows paraphrenic traits, while in its exciting cause, in its use of the mechanism of projection, and in its outcome it exhibits a paranoid character. For it is possible for several fixations to be left behind in the course of development, and each of these in succession may allow an irruption of the libido that has been pushed off - beginning, perhaps, with the later acquired fixations, and going on, as the illness develops, to the original ones that lie nearer the starting-point. We should be glad to know to what conditions the relatively favourable issue of the present case is due; for we cannot willingly attribute the whole responsibility for the outcome to anything so casual as the 'improvement due to change in domicile,' which set in after the patient's removal from Flechsig's clinic. But our insufficient acquaintance with the intimate circumstances of the history of the case makes it impossible to give an answer to this interesting question. It may be suspected, however, that what enabled Schreber to reconcile himself to his homosexual phantasy, and so made it possible for his illness to terminate in something approximating to a recovery, may have been the fact that his father-complex was in the main positively toned and that in real life the later years of his relationship with an excellent father had probably been unclouded.

[1911c, 2443]
Since I neither fear the criticism of others nor shrink from criticizing myself, I have no motive for avoiding the mention of a similarity which may possibly damage our libido theory in the estimation of many of my readers. Schreber's 'rays of God', which are made up of a condensation of the sun's rays, of nerve fibres, and of spermatozoa, are in reality nothing else than a concrete representation and projection outwards of libidinal cathexes; and they thus lend his delusions a striking conformity with our theory. His belief that the world must come to an end because his ego was attracting all the rays to itself, his anxious concern at a later period, during the process of reconstruction, lest God should sever His ray-connection with him, - these and many other details of Schreber's delusional structure sound almost like endopsychic perceptions of the processes whose existence I have assumed in these pages as the basis of our explanation of paranoia. I can nevertheless call a friend and fellow-specialist to witness that I had developed my theory of paranoia before I became acquainted with the contents of Schreber's book. It remains for the future to decide whether there is more delusion in my theory than I should like to admit, or whether there is more truth in Schreber's delusion than other people are as yet prepared to believe.

We have now discovered a motive which can explain the idea that the souls of those who have just died are transformed into demons and the necessity felt by survivors to protect themselves by taboos against their hostility. Let us suppose that the emotional life of primitive peoples is characterized by an amount of ambivalence as great as that which we are led by the findings of psycho-analysis to attribute to obsessional patients. It then becomes easy to understand how after a painful bereavement savages should be obliged to produce a reaction against the hostility latent in their unconscious similar to that expressed as obsessive self-reproach in the case of neurotics. But this hostility, distressingly felt in the unconscious as satisfaction over the death, is differently dealt with among primitive peoples. The defence against it takes the form of displacing it on to the object of the hostility, on to the dead themselves. This defensive procedure, which is a common one both in normal and in pathological mental life, is known as a 'projection'. The survivor thus denies that he has ever harboured any hostile feelings against the dead loved one; the soul of the dead harbours them instead and seeks to put them into action during the whole period of mourning. In spite of the successful defence which the survivor achieves by means of projection, his emotional reaction shows the characteristics of punishment and remorse, for he is the subject of fears and submits to renunciations and restrictions, though these are in part disguised as measures of protection against the hostile demon. Once again, therefore, we find that the taboo has grown up on the basis of an ambivalent emotional attitude. The taboo upon the dead arises, like the others, from the contrast between conscious pain and unconscious satisfaction over the death that has occurred. Since such is the origin of the ghost's resentment, it follows naturally that the survivors who have the most to fear will be those who were formerly its nearest and dearest.

At the beginning of this essay disagreement was expressed with Wundt's opinion that the essence of taboo was a fear of demons. Yet we have now assented to an explanation that derives the taboo upon the dead from a fear of the soul of the dead person transformed into a demon. The apparent contradiction can easily be resolved. It is true that we have accepted the presence of demons, but not as something ultimate and psychologically unanalysable. We have succeeded, as it were, in getting behind the demons, for we have explained them as projections of hostile feelings harboured by the survivors against the dead.
Both of the two sets of feelings (the affectionate and the hostile), which, as we have good reason to believe, exist towards the dead person, seek to take effect at the time of the bereavement, as mourning and as satisfaction. There is bound to be a conflict between these two contrary feelings; and, since one of the two, the hostility, is wholly or for the greater part unconscious, the outcome of the conflict cannot be to subtract, as it were, the feeling with the lesser intensity from that with the greater and to establish the remainder in consciousness - as occurs, for instance, when one forgives a slight that one has received from someone of whom one is fond. The process is dealt with instead by the special psychical mechanism known in psycho-analysis, as I have said, by the name of 'projection'. The hostility, of which the survivors know nothing and moreover wish to know nothing, is ejected from internal perception into the external world, and thus detached from them and pushed on to someone else. It is no longer true that they are rejoicing to be rid of the dead man; on the contrary, they are mourning for him; but, strange to say, he has turned into a wicked demon ready to gloat over their misfortunes and eager to kill them. It then becomes necessary for them, the survivors, to defend themselves against this evil enemy; they are relieved of pressure from within, but have only exchanged it for oppression from without.

[1912-1913, 2706]

It cannot be disputed that this process of projection, which turns a dead man into a malignant enemy, is able to find support in any real acts of hostility on his part that may be recollected and felt as a grudge against him: his severity, his love of power, his unfairness, or whatever else may form the background of even the tenderest of human relationships. But it cannot be such a simple matter as that. This factor alone cannot explain the creation of demons by projection. The faults of the dead no doubt provide a part of the explanation of the survivors' hostility; but they would not operate in this way unless the survivors had first developed hostility on their own account. The moment of death, moreover, would certainly seem to be a most inappropriate occasion for recalling any justifiable grounds of complaint that might exist. It is impossible to escape the fact that the true determining factor is invariably unconscious hostility. A hostile current of feeling such as this against a person's nearest and dearest relatives may remain latent during their lifetime, that is, its existence may not be betrayed to consciousness either directly or through some substitute. But when they die this is no longer possible and the conflict becomes acute. The mourning which derives from an intensification of the affectionate feelings becomes on the one hand more impatient of the latent hostility and, on the other hand, will not allow it to give rise to any sense of satisfaction. Accordingly, there follow the repression of the unconscious hostility by the method of projection and the construction of the ceremonial which gives expression to the fear of being punished by the demons. When in course of time the mourning runs its course, the conflict grows less acute, so that the taboo upon the dead is able to diminish in severity or sink into oblivion.

[1912-1913, 2707]
The projection of unconscious hostility on to demons in the case of the taboo upon the dead is only a single instance of a number of processes to which the greatest influence must be attributed in the shaping of the primitive mind. In the case we have been dealing with, projection served the purpose of dealing with an emotional conflict; and it is employed in the same way in a large number of psychical situations that lead to neuroses. But projection was not created for the purpose of defence; it also occurs where there is no conflict. The projection outwards of internal perceptions is a primitive mechanism, to which, for instance, our sense perceptions are subject, and which therefore normally plays a very large part in determining the form taken by our external world. Under conditions whose nature has not yet been sufficiently established, internal perceptions of emotional and thought processes can be projected outwards in the same way as sense perceptions; they are thus employed for building up the external world, though they should by rights remain part of the internal world. This may have some genetic connection with the fact that the function of attention was originally directed not towards the internal world but towards the stimuli that stream in from the external world, and that that function's only information upon endopsychic processes was received from feelings of pleasure and unpleasure. It was not until a language of abstract thought had been developed, that is to say, not until the sensory residues of verbal presentations had been linked to the internal processes, that the latter themselves gradually became capable of being perceived. Before that, owing to the projection outwards of internal perceptions, primitive men arrived at a picture of the external world which we, with our intensified conscious perception, have now to translate back into psychology.

[1912-1913, 2708]

The projection of their own evil impulses into demons is only one portion of a system which constituted the Weltanschauung of primitive peoples, and which we shall come to know as 'animism' in the following essay. There we shall have to investigate that system's psychological characteristics, and we shall do so once again by reference to the similar systems which we find constructed by neurotics. For the moment I will only say that the prototype of all such systems is what we have termed the 'secondary revision' of the content of dreams. And we must not forget that, at and after the stage at which systems are constructed, two sets of reasons can be assigned for every psychical event that is consciously judged - one set belonging to the system and the other set real but unconscious.¹

[1912-1913, 2709]

I propose to avoid (as I have already done elsewhere²) entering into the general problem of the origin of the tendency to project mental processes into the outside. It is, however, safe to assume that that tendency will be intensified when projection promises to bring with it the advantage of mental relief. Such an advantage may be expected with certainty where a conflict has arisen between different impulses all of which are striving towards omnipotence - for they clearly cannot all become omnipotent. The pathological process in paranoia in fact makes use of the mechanism of projection in order to deal with mental conflicts of this kind. The typical case of such a conflict is one between the two members of a pair of opposites - the case of an ambivalent attitude, which we have examined in detail as it appears in someone mourning the death of a loved relative. This kind of case must seem particularly likely to provide a motive for the creation of projections. Here again we are in agreement with the writers who maintain that the first born spirits were evil spirits, and who derive the idea of a soul from the impression made by death upon the survivors. The only difference is that we do not lay stress on the intellectual problem with which death confronts the living; in our view the force which gives the impetus to research is rather to be attributed to the emotional conflict into which the survivors are plunged.

[1912-1913, 2735]
When we, no less than primitive man, project something into external reality, what is happening must surely be this: we are recognizing the existence of two states - one in which something is directly given to the senses and to consciousness (that is, is present to them), and alongside it another, in which the same thing is latent but capable of re-appearing. In short, we are recognizing the co-existence of perception and memory, or, putting it more generally, the existence of unconscious mental processes alongside the conscious ones.¹ It might be said that in the last analysis the 'spirit' of persons or things comes down to their capacity to be remembered and imagined after perception of them has ceased.

[1912-1913, 2736]

A dream tells us that something was going on which tended to interrupt sleep, and it enables us to understand in what way it has been possible to fend off this interruption. The final outcome is that the sleeper has dreamt and is able to go on sleeping; the internal demand which was striving to occupy him has been replaced by an external experience, whose demand has been disposed of. A dream is, therefore, among other things, a projection: an externalization of an internal process. We may recall that we have already met with projection elsewhere among the means adopted for defence. The mechanism of a hysterical phobia, too, culminates in the fact that the subject is able to protect himself by attempts at flight against an external danger which has taken the place of an internal instinctual claim. We will, however, defer the full treatment of projection till we come to analyse the narcissistic disorder in which this mechanism plays the most striking part.

[1917d, 3028]

In an earlier passage² we ascribed to the still helpless organism a capacity for making a first orientation in the world by means of its perceptions, distinguishing 'external' and 'internal' according to their relation to its muscular action. A perception which is made to disappear by an action is recognized as external, as reality; where such an action makes no difference, the perception originates within the subject's own body - it is not real. It is of value to the individual to possess a means such as this of recognizing reality, which at the same time helps him to deal with it, and he would be glad to be equipped with a similar power against the often merciless claims of his instincts. That is why he takes such pains to transpose outwards what becomes troublesome to him from within - that is, to project it.

[1917d, 3036]

I might go still further in the analysis of this ostensibly real 'accident'. I do not believe that the clock ever ticked or that there was any noise to be heard at all. The woman's situation justified a sensation of a knock or beat in her clitoris. And it was this that she subsequently projected as a perception of an external object. Just the same sort of thing can occur in dreams. A hysterical woman patient of mine once related to me a short arousal dream to which she could bring no spontaneous associations. She dreamt simply that someone knocked and then she awoke. Nobody had knocked at the door, but during the previous nights she had been awakened by distressing sensations of pollutions: she thus had a motive for awakening as soon as she felt the first sign of genital excitation. There had been a 'knock' in her clitoris. In the case of our paranoic patient, I should substitute for the accidental noise a similar process of projection. I certainly cannot guarantee that in the course of our short acquaintance the patient, who was reluctantly yielding to compulsion, gave me a truthful account of all that had taken place during the two meetings of the lovers. But an isolated contraction of the clitoris would be in keeping with her statement that no contact of the genitals had taken place. In her subsequent rejection of the man, lack of satisfaction undoubtedly played a part as well as 'conscience'.

[1915f, 3063]
Naturally this does not answer all the questions that we might ask in connection with this case. On the contrary, the case bristles with further problems—some that have in general not yet become soluble and others which could not be solved owing to the particular circumstances being unfavourable. For instance, why did this lady who was happily married fall in love with her son-in-law? and why did the relief, which might have been possible in other ways, take the form of this mirror-image this projection of her state on to her husband? You must no: think it is otiose or frivolous to raise such questions. We already have some material at our disposal which might possibly serve to answer them. The lady was at a critical age, at which sexual needs in women suffer a sudden and undesired increase; that alone might account for the event. Or it may further have been that her excellent and faithful husband had for some years no longer enjoyed the sexual capacity which the well-preserved woman required for her satisfaction. Experience has shown us that it is precisely men in this position, whose faithfulness can consequently be taken for granted, who are distinguished by treating their wives with unusual tenderness, and by showing particular forbearance for their nervous troubles. Or, again, it may not be without significance that the object of this pathogenic love was precisely the young husband of one of her daughters. A powerful erotic tie with a daughter, which goes back in the last resort to the mother's sexual constitution, often finds a way of persisting in a transformation of this sort. In this connection I may perhaps remind you that the relation between mother-in-law and son-in-law has been regarded from the earliest times of the human race as a particularly awkward one and that among primitive people it has given rise to very powerful taboo regulations and 'avoidances'. The relation is frequently excessive by civilized standards both in a positive and negative direction. Which of these three factors became operative in our case, or whether two of them or perhaps all three came together, I cannot, it is true, tell you; but that is only because I was not permitted to continue the analysis of the case for more than two sessions.

I told you too that we hoped that the analysis of the narcissistic disorders would give us an insight into the way in which our ego is put together and built up out of different agencies. We have already made a start with this at one point. From the analysis of delusions of observation we have drawn the conclusion that there actually exists in the ego an agency which unceasingly observes, criticizes and compares, and in that way sets itself over against the other part of the ego. We believe, therefore, that the patient is betraying a truth to us which is not yet sufficiently appreciated when he complains that he is spied upon and observed at every step he takes and that every one of his thoughts is reported and criticized. His only mistake is in regarding this uncomfortable power as something alien to him and placing it outside himself. He senses an agency holding sway in his ego which measures his actual ego and each of its activities by an ideal ego that he has created for himself in the course of his development. We believe, too, that this creation was made with the intention of re-establishing the self-satisfaction which was attached to primary infantile narcissism but which since then has suffered so many disturbances and mortifications. We know the self-observing agency as the ego-censor, the conscience; it is this that exercises the dream-censorship during the night, from which the repressions of inadmissible wishful impulses proceed. When in delusions of observation it becomes split up, it reveals to us its origin from the influences of parents, educators and social environment - from an identification with some of these model figures.
We have pointed out how the living vesicle is provided with a shield against stimuli from the external world; and we had previously shown that the cortical layer next to that shield must be differentiated as an organ for receiving stimuli from without. This sensitive cortex, however, which is later to become the system Cs., also receives excitations from within. The situation of the system between the outside and the inside and the difference between the conditions governing the reception of excitations in the two cases have a decisive effect on the functioning of the system and of the whole mental apparatus. Towards the outside it is shielded against stimuli, and the amounts of excitation impinging on it have only a reduced effect. Towards the inside there can be no such shield; the excitations in the deeper layers extend into the system directly and in undiminished amount, in so far as certain of their characteristics give rise to feelings in the pleasure-unpleasure series. The excitations coming from within are, however, in their intensity and in other, qualitative, respects - in their amplitude, perhaps - more commensurate with the system's method of working than the stimuli which stream in from the external world. This state of things produces two definite results. First, the feelings of pleasure and unpleasure (which are an index to what is happening in the interior of the apparatus) predominate over all external stimuli. And secondly, a particular way is adopted of dealing with any internal excitations which produce too great an increase of unpleasure: there is a tendency to treat them as though they were acting, not from the inside, but from the outside, so that it may be possible to bring the shield against stimuli into operation as a means of defence against them. This is the origin of projection, which is destined to play such a large part in the causation of pathological processes.

The jealousy that arises from such a projection has, it is true, an almost delusional character; it is, however, amenable to the analytic work of exposing the unconscious phantasies of the subject's own infidelity. The position is worse as regards jealousy belonging to the third layer, the true delusional type. It too has its origin in repressed impulses towards unfaithfulness; but the object in these cases is of the same sex as the subject. Delusional jealousy is what is left of a homosexuality that has run its course, and it rightly takes its position among the classical forms of paranoia. As an attempt at defence against an unduly strong homosexual impulse it may, in a man, be described in the formula: 'I do not love him, she loves him!' In a delusional case one will be prepared to find jealousy belonging to all three layers, never to the third alone.

We begin to see that we describe the behaviour of both jealous and persecutory paranoics very inadequately by saying that they project outwards on to others what they do not wish to recognize in themselves. Certainly they do this; but they do not project it into the blue, so to speak, where there is nothing of the sort already. They let themselves be guided by their knowledge of the unconscious, and displace to the unconscious minds of others the attention which they have withdrawn from their own. Our jealous husband perceived his wife's unfaithfulness instead of his own; by becoming conscious of hers and magnifying it enormously he succeeded in keeping his own unconscious. If we accept his example as typical, we may infer that the enmity which the persecuted paranoic sees in others is the reflection of his own hostile impulses against them. Since we know that with the paranoic it is precisely the most loved person of his own sex that becomes his persecutor, the question arises where this reversal of affect takes its origin; the answer is not far to seek - the ever-present ambivalence of feeling provides its source and the non-fulfilment of his claim for love strengthens it. This ambivalence thus serves the same purpose for the persecuted paranoic as jealousy served for my patient - that of a defence against homosexuality.
I have nothing to suggest which could have a decisive influence on the solution of this problem. The idea of men's receiving an intimation of their connection with the world around them through an immediate feeling which is from the outset directed to that purpose sounds so strange and fits in so badly with the fabric of our psychology that one is justified in attempting to discover a psycho-analytic - that is, a genetic - explanation of such a feeling. The following line of thought suggests itself. Normally, there is nothing of which we are more certain than the feeling of our self, of our own ego. This ego appears to us as something autonomous and unitary, marked off distinctly from everything else. That such an appearance is deceptive, and that on the contrary the ego is continued inwards, without any sharp delimitation, into an unconscious mental entity which we designate as the id and for which it serves as a kind of façade - this was a discovery first made by psycho-analytic research, which should still have much more to tell us about the relation of the ego to the id. But towards the outside, at any rate, the ego seems to maintain clear and sharp lines of demarcation. There is only one state - admittedly an unusual state, but not one that can be stigmatized as pathological - in which it does not do this. At the height of being in love the boundary between ego and object threatens to melt away. Against all the evidence of his senses, a man who is in love declares that 'I' and 'you' are one, and is prepared to behave as if it were a fact. What can be temporarily done away with by a physiological function must also, of course, be liable to be disturbed by pathological processes. Pathology has made us acquainted with a great number of states in which the boundary lines between the ego and the external world become uncertain or in which they are actually drawn incorrectly. There are cases in which parts of a person's own body, even portions of his own mental life - his perceptions, thoughts and feelings, - appear alien to him and as not belonging to his ego; there are other cases in which he ascribes to the external world things that clearly originate in his own ego and that ought to be acknowledged by it. Thus even the feeling of our own ego is subject to disturbances and the boundaries of the ego are not constant.

[1930a, 4466]

Everything in the sphere of this first attachment to the mother seemed to me so difficult to grasp in analysis - so grey with age and shadowy and almost impossible to revivify - that it was as if it had succumbed to an especially inexorable repression. But perhaps I gained this impression because the women who were in analysis with me were able to cling to the very attachment to the father in which they had taken refuge from the early phase that was in question. It does indeed appear that women analysts - as, for instance, Jeanne Lampl-de Groot and Helene Deutsch - have been able to perceive these facts more easily and clearly because they were helped in dealing with those under their treatment by the transference to a suitable mother-substitute. Nor have I succeeded in seeing my way though any case completely, and I shall therefore confine myself to reporting the most general findings and shall give only a few examples of the new ideas which I have arrived at. Among these is a suspicion that this phase of attachment to the mother is especially intimately related to the aetiology of hysteria, which is not surprising when we reflect that both the phase and the neurosis are characteristically feminine, and further, that in this dependence on the mother we have the germ of later paranoia in women.¹ For this germ appears to be the surprising, yet regular, fear of being killed (?) devoured) by the mother. It is plausible to assume that this fear corresponds to a hostility which develops in the child towards her mother in consequence of the manifold restrictions imposed by the latter in the course of training and bodily care and that the mechanism of projection is favoured by the early age of the child's psychical organization.

[1931b, 4591]
Concerning the origin of the visual hallucinations, or at least of the vivid images, I learned the following. The image of the lower part of a woman's abdomen almost always coincided with the physical sensation in her own abdomen; but the latter was much more constant and often occurred without the image. The first images of a woman's abdomen had appeared in the hydropathic establishment a few hours after she had in fact seen a number of naked women at the baths; so they turned out to be simple reproductions of a real impression. It was therefore to be presumed that these impressions had been repeated only because great interest was attached to them. She told me that she had felt ashamed for these women; she herself had been ashamed to be seen naked as long as she could remember. Since I was obliged to regard the shame as something obsessional, I concluded, in accordance with the mechanism of defence, that an experience must have been repressed here about which she had not felt ashamed. So I requested her to let the memories emerge which belonged to the theme of feeling ashamed. She promptly reproduced a series of scenes going back from her seventeenth to her eighth year, in which she had felt ashamed of being naked in her bath in front of her mother, her sister and the doctor; but the series ended in a scene at the age of six, in which she was undressing in the nursery before going to bed, without feeling any shame in front of her brother who was there. On my questioning her, it transpired that scenes like this had occurred often and that the brother and sister had for years been in the habit of showing themselves to one another naked before going to bed. I now understood the meaning of her sudden idea that she was being watched as she was going to bed. It was an unaltered piece of the old memory which involved self-reproach, and she was now making up for the shame which she had omitted to feel as a child.

[1896b, 398]

The situation is this. Either residues of the previous day have been left over from the activity of waking life and it has not been possible to withdraw the whole cathexis of energy from them; or the activity of waking life during the course of the day has led to the stirring up of an unconscious wish; or these two events have happened to coincide. (We have already discussed the various possibilities in this connection.) The unconscious wish links itself up with the day's residues and effects a transference on to them; this may happen either in the course of the day or not until a state of sleep has been established. A wish now arises which has been transferred on to the recent material; or a recent wish, having been suppressed, gains fresh life by being reinforced from the unconscious. This wish seeks to force its way along the normal path taken by thought processes, though the Pcs. (to which, indeed, it in part belongs) to consciousness. But it comes up against the censorship, which is still functioning and to the influence of which it now submits. At this point it takes on the distortion for which the way has already been paved by the transference of the wish on to recent material. So far it is on the way to becoming an obsessive idea or a delusion or something of the kind - that is, a thought which has been intensified by transference and distorted in its expression by censorship. Its further advance is halted, however, by the sleeping state of the preconscious. (The probability is that that system has protected itself against the invasion by diminishing its own excitations.) The dream-process consequently enters on a regressive path, which lies open to it precisely owing to the peculiar nature of the state of sleep, and it is led along that path by the attraction exercised on it by groups of memories; some of these memories themselves exist only in the form of visual cathexes and not as translations into the terminology of the later systems. In the course of its regressive path the dream-process acquires the attribute of representability. (I shall deal later with the question of compression.) It has now completed the second portion of its zigzag journey. The first portion was a progressive one, leading from the unconscious scenes or phantasies to the preconscious; the second portion led from the frontier of the censorship back again to perceptions. But when the content of the dream process has become perceptual, by that fact it has, as it were, found a way of evading the obstacle put in its way by the censorship and the state of sleep in the Pcs. It succeeds in drawing attention to itself and in being noticed by consciousness.

[1900a, 1002]
The category of what is accidental and requires no motivation, in which the normal person includes a part of his own psychical performances and parapraxes, is thus rejected by the paranoid as far as the psychical manifestations of other people are concerned. Everything he observes in other people is full of significance, everything can be interpreted. How does he reach this position? Probably here as in so many similar cases he projects on to the mental life of other people what is unconsciously present in his own. In paranoia many sorts of things force their way through to consciousness whose presence in the unconscious of normal and neurotic people we can demonstrate only through psycho-analysis.² In a certain sense, therefore, the paranoid is justified in this, for he recognizes something that escapes the normal person: he sees more clearly than someone of normal intellectual capacity, but the displacement on to other people of the state of affairs which he recognizes renders his knowledge worthless. I hope I shall not now be expected to justify the various paranoid interpretations. But the partial justification which we concede to paranoia in respect of this view taken by it of chance actions will help us towards a psychological understanding of the sense of conviction that the paranoid attaches to all these interpretations. There is in fact some truth in them; those, too, of our errors of judgement which are not to be counted as pathological acquire their sense of conviction in just the same way. This feeling is justified for a certain part of the erroneous train of thought, or for its source of origin; and it is then extended by us to the rest of the context.

Let us pause for a moment at this journey, planned for such remarkably uncogent reasons, and take a closer look at our hero's personality and behaviour. He still appears to us as incomprehensible and foolish; we have no idea how his peculiar folly will be linked to human feeling and so arouse our sympathy. It is an author's privilege to be allowed to leave us in such uncertainty. The charm of his language and the ingenuity of his ideas offer us a provisional reward for the reliance we place in him and for the still unearned sympathy which we are ready to feel for his hero. Of this hero we are further told that he was pre-ordained by family tradition to become an archaeologist, that in his later isolation and independence he was wholly absorbed in his studies and had turned completely away from life and its pleasures. Marble and bronze alone were truly alive for him; they alone expressed the purpose and value of human life. But nature, perhaps with benevolent intent, had infused into his blood a corrective of an entirely unscientific sort - an extremely lively imagination, which could show itself not only in his dreams but often in his waking life as well. This division between imagination and intellect destined him to become an artist or a neurotic; he was one of those whose kingdom is not of this world. Thus it was that it could come about that his interest was attached to a relief representing a girl stepping along in a peculiar fashion, that he wove his phantasies around her, imagined a name and origin for her, placed the figure he had created in the setting of the Pompeii that was buried more than eighteen hundred years before, and finally, after a strange anxiety-dream, magnified his phantasy of the existence and death of this girl named Gradiva into a delusion, which gained an influence over his actions. Such products of the imagination would seem to us astonishing and inexplicable if we met them in someone in real life. Since our hero, Norbert Hanold, is a fictitious person, we may perhaps put a timid question to his author, and ask whether his imagination was determined by forces other than its own arbitrary choice.

[1901b, 1325]

[1907a, 1819]
But our hero was not torn from his delusion as quickly as we have been, for, as the author tells us, 'though his belief made him happy, he had to take the acceptance of quite a considerable number of mysteries into the bargain'. (140.) Moreover, this delusion probably had internal roots in him of which we know nothing and which do not exist in ourselves. In his case, no doubt, energetic treatment would seem necessary before he could be brought back to reality. Meanwhile all he could do was to fit his delusion into the wonderful experience he had just had. Gradiva, who had perished with the rest in the destruction of Pompeii, could be nothing other than a mid-day ghost who had returned to life for the brief ghostly hour. But why was it that, after hearing her reply delivered in German, he exclaimed 'I knew your voice sounded like that'? Not only we, but the girl herself was bound to ask the question, and Hanold had to admit that he had never heard it, though he had expected to in his dream, when he called to her as she lay down to sleep on the temple steps. He begged her to do the same thing again as she had then; but now she rose, gave him a strange look, and in a few paces disappeared between the columns of the court. A pretty butterfly had shortly before fluttered round her for a while; and he interpreted it as a messenger from Hades reminding the dead girl that she must return, since the mid-day hour of ghosts was at an end. Hanold still had time to call after the girl as she vanished: 'Will you return here to morrow at the mid-day hour?' To us, however, who can now venture upon more sober interpretations, it looks as though the young lady had seen something improper in the remark addressed to her by Hanold and had left him with a sense of having been insulted; for after all she could have known nothing of his dream. May not her sensibility have detected the erotic nature of his request, whose motive in Hanold's eyes lay in its relation to his dream?

We are beginning to understand now, and to feel some hope. If the young lady in whose form Gradiva had come to life again accepted Hanold's delusion so fully, she was probably doing so in order to set him free from it. There was no other way of doing so; to contradict it would have put an end to any such possibility. Even the serious treatment of a real case of illness of the kind could proceed in no other way than to begin by taking up the same ground as the delusional structure and then investigating it as completely as possible. If Zoe was the right person for the job, we shall soon learn, no doubt, how to cure a delusion like our hero's. We should also be glad to know how such delusions arise. It would be a strange coincidence - but, nevertheless, not without an example or parallel - if the treatment of the delusion were to coincide with its investigation and if the explanation of its origin were to be revealed precisely while it was being dissected. We may suspect, of course, that, if so, our case of illness might end up as a 'commonplace' love-story. But the healing power of love against a delusion is not to be despised - and was not our hero's infatuation for his Gradiva sculpture a complete instance of being in love, though of being in love with something past and lifeless?
Norbert Hanold's condition is often spoken of by the author as a 'delusion', and we have no reason to reject that designation. We can state two chief characteristics of a 'delusion', which do not, it is true, describe it exhaustively, but which distinguish it recognizably from other disorders. In the first place it is one of the group of pathological states which do not produce a direct effect upon the body but are manifested only by mental indications. And secondly it is characterized by the fact that in it 'phantasies' have gained the upper hand - that is, have obtained belief and have acquired an influence on action. If we recall Hanold's journey to Pompeii in order to look for Gradiva's peculiarly formed footprints in the ashes, we shall have a fine example of an action under the dominance of a delusion. A psychiatrist would perhaps place Norbert Hanold's delusion in the great group of 'paranoia' and possibly describe it as 'fetishistic erotomania', because the most striking thing about it was his being in love with the piece of sculpture and because in the psychiatrist's view, with its tendency to coarsen everything, the young archaeologist's interest in feet and the postures of feet would be bound to suggest 'fetishism'. Nevertheless all such systems of nomenclature and classification of the different kinds of delusion according to their subject-matter have something precarious and barren about them.¹

¹ In point of fact, the case of N. H. would have to be described as a hysterical delusion, not a paranoic one. The indications of paranoia are absent from it.

The state of permanently turning away from women produces a personal susceptibility, or, as we are accustomed to say, a 'disposition' to the formation of a delusion. The development of the mental disorder sets in at the moment when a chance impression arouses the childhood experiences which have been forgotten and which have traces, at least, of an erotic colouring. 'Arouses', however, is certainly not the right description, if we take into account what follows. We must repeat the author's accurate account in correct psychological technical terms. When Norbert Hanold saw the relief, he did not remember that he had already seen a similar posture of the foot in his childhood friend; he remembered nothing at all, but all the effects brought about by the relief originated from this link that was made with the impression of his childhood. Thus the childhood impression was stirred up, it became active, so that it began to produce effects, but it did not come into consciousness - it remained 'unconscious', to use a term which has to-day become unavoidable in psychopathology. We are anxious that this unconscious shall not be involved in any of the disputes of philosophers and natural philosophers, which have often no more than an etymological importance. For the time being we possess no better name for psychical processes which behave actively but nevertheless do not reach the consciousness of the person concerned, and that is all we mean by our 'unconsciousness'. When some thinkers try to dispute the existence of an unconscious of this kind, on the ground that it is nonsensical, we can only suppose that they have never had to do with the corresponding mental phenomena, that they are under the spell of the regular experience that everything mental that becomes active and intense becomes at the same time conscious as well, and that they have still to learn (what our author knows very well) that there are most certainly mental processes which, in spite of being intense and producing effects, none the less remain apart from consciousness.

¹ [1907a, 1844]

[1907a, 1846]
Thus in the very first products of Hanold's delusional phantasies and actions we already find a double set of determinants, a derivation from two different sources. One of these is the one that was manifest to Hanold himself, the other is the one which is revealed to us when we examine his mental processes. One of them, looked at from Hanold's point of view, was conscious to him, the other was completely unconscious to him. One of them was derived wholly from the circle of ideas of the science of archaeology, the other arose from the repressed childhood memories that had become active in him and from the emotional instincts attached to them. One might be described as lying on the surface and covering the other, which was, as it were, concealed behind it. The scientific motivation might be said to serve as a pretext for the unconscious erotic one, and science had put itself completely at the service of the delusion. It should not be forgotten, however, that the unconscious determinants could not effect anything that did not simultaneously satisfy the conscious, scientific ones. The symptoms of a delusion - phantasies and actions alike - are in fact the products of compromise between the two mental currents, and in a compromise account is taken of the demands of each of the two parties to it; but each side must also renounce a part of what it wanted to achieve. Where a compromise comes about it must have been preceded by a struggle - in this case it was the conflict we have assumed between suppressed erotism and the forces that were keeping it in repression. In the formation of a delusion this struggle is in fact unending. Assault and resistance are renewed after the construction of each compromise, which is never, so to speak, entirely satisfying. Our author too is aware of this, and that is why he makes a peculiar unrest dominate this stage of his hero's disorder, as a precursor and guarantee of further developments.

[1907a, 1850]

The development of Norbert Hanold's delusion proceeded with a dream which, since it was not occasioned by any new event, seems to have arisen entirely out of his mind, filled as it was by a conflict. But let us pause before we enquire whether, in the construction of his dreams, too, the author meets our expectation that he possesses a deep understanding. Let us ask first what psychiatric science has to say to his hypotheses about the origin of a delusion and what attitude it takes to the part played by repression and the unconscious, to conflict and to the formation of compromises. In short, let us ask whether this imaginative representation of the genesis of a delusion can hold its own before the judgement of science.

[1907a, 1850]
And here we must give what will perhaps be an unexpected answer. In fact the situation is quite the reverse: it is science that cannot hold its own before the achievement of the author. Science allows a gulf to yawn between the hereditary and constitutional preconditions of a delusion and its creations, which seem to emerge ready-made - a gulf which we find that our author has filled. Science does not as yet suspect the importance of repression, it does not recognize that in order to explain the world of psychopathological phenomena the unconscious is absolutely essential, it does not look for the basis of delusions in a psychical conflict, and it does not regard their symptoms as compromises. Does our author stand alone, then, in the face of united science? No, that is not the case (if, that is, I may count my own works as part of science), since for a number of years - and, until recently, more or less alone¹ - I myself have supported all the views that I have here extracted from Jensen's *Gradiva* and stated in technical terms. I indicated, in most detail in connection with the states known as hysteria and obsessions, that the individual determinant of these psychical disorders is the suppression of a part of instinctual life and the repression of the ideas by which the suppressed instinct is represented, and soon afterwards I repeated the same views in relation to some forms of delusion.² The question whether the instincts concerned in this causation are always components of the sexual instinct or may be of another kind as well is a problem which may be regarded as a matter of indifference in the particular case of the analysis of *Gradiva*; for in the instance chosen by our author what was at issue was quite certainly nothing other than the suppression of erotic feelings. The validity of the hypotheses of psychical conflict and of the formation of symptoms by means of compromises between the two mental currents struggling against each other has been demonstrated by me in the case of patients observed and medically treated in real life, just as I have been able to in the imaginary case of Norbert Hanold.³ Even before me, Pierre Janet, a pupil of the great Charcot, and Josef Breuer, in collaboration with me, had traced back the products of neurotic, and especially of hysterical, illness to the power of unconscious thoughts.⁴

[1907a, 1851]

The application of a few of the rules of dream-interpretation to Hanold's first dream has thus resulted in making it intelligible to us in its main features and in inserting it into the nexus of the story. Surely, then, the author must have observed these rules in creating it? We might ask another question, too: why did the author introduce a dream at all to bring about the further development of the delusion? In my opinion it was an ingenious notion and once again true to reality. We have already heard that in real illnesses a delusion very often arises in connection with a dream, and, after what we have learnt about the nature of dreams, there is no need to see a fresh riddle in this fact. Dreams and delusions arise from the same source - from what is repressed. Dreams are, as one might say, the physiological delusions of normal people. Before what is repressed has become strong enough to break through into waking life as a delusion, it may easily have achieved a first success, under the more favourable conditions of the state of sleep, in the form of a dream with persisting effects. For during sleep, along with a general lowering of mental activity, there is a relaxation in the strength of the resistance with which the dominant psychical forces oppose what is repressed. It is this relaxation that makes the formation of dreams possible, and that is why dreams give us our best access to a knowledge of the unconscious part of the mind - except that, as a rule, with the re-establishment of the psychical cathexes of waking life, the dream once more takes to flight and the ground that had been won by the unconscious is evacuated once again.

[1907a, 1858]
This unusually clever girl, then, was determined to win her childhood’s friend for her husband, after she had recognized that the young man’s love for her was the motive force behind the delusion. Our interest in her behaviour, however, will probably yield for the moment to the surprise which we may feel at the delusion itself. The last form taken by it was that Gradiva, who had been buried in 79 A.D., was now able, as a mid-day ghost, to exchange words with him for an hour, at the end of which she must sink into the ground or seek her grave once more. This mental cobweb, which was not brushed away either by his perceiving that the apparition was wearing modern shoes or by her ignorance of the ancient languages and her command of German, which was not in existence in her day, certainly seems to justify the author’s description of his story as a ‘Pompeian phantasy’, but it seems also to exclude any possibility of measuring it by the standards of clinical reality.

[1907a, 1864]

But how did the replacement of the new discovery by the delusion take place? What happened, I think, was that the sense of conviction attaching to the discovery was able to persist and was retained, while the discovery itself, which was inadmissible to consciousness, was replaced by another ideational content connected with it by associations of thought. Thus the sense of conviction became attached to a content which was in fact foreign to it and this, in the form of a delusion, won a recognition which did not apply to it. Hanold transferred his conviction that Gradiva lived in the house to other impressions which he had received in the house; this led to his credulity in regard to the landlord’s remarks, the genuineness of the metal clasp and the truth of the anecdote about the discovery of the embracing lovers - but only through his linking what he heard in the house with Gradiva. The jealousy which was already latent in him seized upon this material and the consequence was the delusion (though it contradicted his first dream) that Gradiva was the girl who had died in her lover’s arms and that the clasp he had bought had belonged to her.

[1907a, 1873]

But it is now time to ask ourselves whether the method of constructing a delusion which we have inferred from our author’s account is one that is known from other sources, or whether, indeed, it is possible at all. From our medical knowledge we can only reply that it is certainly the correct method, and perhaps the sole method, by which a delusion acquires the unshakable conviction which is one of its clinical characteristics. If a patient believes in his delusion so firmly, this is not because his faculty of judgement has been overturned and does not arise from what is false in the delusion. On the contrary, there is a grain of truth concealed in every delusion, there is something in it that really deserves belief, and this is the source of the patient’s conviction, which is therefore to that extent justified. This true element, however, has long been repressed. If eventually it is able to penetrate into consciousness, this time in a distorted form, the sense of conviction attaching to it is over-intensified as though by way of compensation and is now attached to the distorted substitute of the repressed truth, and protects it from any critical attacks. The conviction is displaced, as it were, from the unconscious truth on to the conscious error that is linked to it, and remains fixed there precisely as a result of this displacement. The instance of the formation of a delusion which arose from Hanold’s first dream is no more than a similar, though not identical, example of such a displacement. Indeed, the method described here by which conviction arises in the case of a delusion does not differ fundamentally from the method by which a conviction is formed in normal cases, where repression does not come into the picture. We all attach our conviction to thought-contents in which truth is combined with error, and let it extend from the former over the latter. It becomes diffused, as it were, from the truth over the error associated with it and protects the latter, though not so unalterably as in the case of a delusion, against deserved criticism. In normal psychology, too, being well-connected - ‘having influence’, so to speak - can take the place of true worth.

[1907a, 1874]
The emergence of Zoe as a physician, as I have already remarked, arouses a new interest in us. We shall be anxious to learn whether a cure of the kind she performed upon Hanold is conceivable or even possible, and whether the author has taken as correct a view of the conditions for the disappearance of a delusion as he has of those for its genesis.
[1907a, 1880]

Thus the author has drawn the closest link between the clearing up of the delusion and the outbreak of a craving for love, and he has paved the way for the inevitable outcome in a courtship. He knows the essential nature of the delusion better than his critics: he knows that a component of loving desire had combined with a component of resistance to it in bringing about the delusion, and he makes the girl who undertakes the cure sensitive to the element in Hanold's delusion which is agreeable to her. It was only this knowledge which could decide her to devote herself to the treatment; it was only the certainty of being loved by him that could induce her to admit her love to him. The treatment consisted in giving him back from outside the repressed memories which he could not set free from inside; but it would have had no effect if in the course of it the therapist had not taken his feelings into account and if her ultimate translation of the delusion had not been: 'Look, all this only means that you love me.'
[1907a, 1881]

And now for the final question, whose answer we have already evaded more than once. Our views on repression, on the genesis of delusions and allied disorders, on the formation and solution of dreams, on the part played by erotic life, and on the method by which such disorders are cured, are far from being the common property of science, let alone the assured possession of educated people. If the insight which has enabled the author to construct his 'phantasy' in such a way that we have been able to dissect it like a real case history is in the nature of knowledge, we should be curious to learn what were the sources of that knowledge. One of our circle - the one who, as I said at the beginning, was interested in the dreams in Gradiva and their possible interpretation - approached the author with the direct question whether he knew anything of such scientific theories as these. The author replied, as was to be expected, in the negative, and, indeed, somewhat brusquely. His imagination, he said, had inspired Gradiva, and he had enjoyed it; if there was anyone whom it did not please, let him simply leave it alone. He had no suspicion of how greatly it had in fact pleased his readers.
[1907a, 1882]
It is quite possible that the author's disavowal does not stop at this. He may perhaps altogether deny any knowledge of the rules which we have shown that he has followed, and he may repudiate all the purposes we have recognized in his work. I do not regard this as improbable; but if it is so, there are only two possible explanations. It may be that we have produced a complete caricature of an interpretation by introducing into an innocent work of art purposes of which its creator had no notion, and by so doing have shown once more how easy it is to find what one is looking for and what is occupying one's own mind - a possibility of which the strangest examples are to be found in the history of literature. Let every reader now make up his mind whether he is able to accept this explanation. We ourselves, of course, hold to the other view, the remaining alternative. Our opinion is that the author need have known nothing of these rules and purposes, so that he could disavow them in good faith, but that nevertheless we have not discovered anything in his work that is not already in it. We probably draw from the same source and work upon the same object, each of us by another method. And the agreement of our results seems to guarantee that we have both worked correctly. Our procedure consists in the conscious observation of abnormal mental processes in other people so as to be able to elicit and announce their laws. The author no doubt proceeds differently. He directs his attention to the unconscious in his own mind, he listens to its possible developments and lends them artistic expression instead of suppressing them by conscious criticism. Thus he experiences from himself what we learn from others - the laws which the activities of this unconscious must obey. But he need not state these laws, nor even be clearly aware of them; as a result of the tolerance of his intelligence, they are incorporated within his creations. We discover these laws by analysing his writings just as we find them from cases of real illness; but the conclusion seems inescapable that either both of us, the writer and the doctor, have misunderstood the unconscious in the same way, or we have both understood it correctly. This conclusion is of great value to us, and it is on its account that it has been worth while to investigate by the methods of medical psycho-analysis the way in which the formation and the cure of the delusions as well as the dreams are represented in Jensen's *Gradiva*. [1907a, 1883]

¹ The words in which Schreber states this theory are italicized by him, and he adds a footnote, in which he insists that it can be used as an explanation of heredity: 'The male semen', he declares, 'contains a nerve belonging to the father, and it unites with a nerve taken from the mother's body to form a new entity.' (7.) Here, therefore, we find a quality properly belonging to the spermatozoon transferred on to the nerves, which makes it probable that Schreber's 'nerves' are derived from the sphere of ideas connected with sexuality. It not infrequently happens in the *Denkwürdigkeiten* that an incidental note upon some piece of delusional theory gives us the desired indication of the genesis of the delusion and so of its meaning. [1911c, 2398]
One such change was the replacement of Flechsig by the superior figure of God. This seems at first as though it were a sign of aggravation of the conflict, an intensification of the unbearable persecution, but it soon becomes evident that it was preparing the way for the second change and, with it, the solution of the conflict. It was impossible for Schreber to become reconciled to playing the part of a female wanton towards his doctor; but the task of providing God Himself with the voluptuous sensations that He required called up no such resistance on the part of his ego. Emasculation was now no longer a disgrace; it became 'consonant with the Order of Things', it took its place in a great cosmic chain of events, and was instrumental in the recreation of humanity after its extinction. 'A new race of men, born from the spirit of Schreber' would, so he thought, revere as their ancestor this man who believed himself the victim of persecution. By this means an outlet was provided which would satisfy both of the contending forces. His ego found compensation in his megalomania, while his feminine wishful phantasy made its way through and became acceptable. The struggle and the illness could cease. The patient's sense of reality, however, which had in the meantime become stronger, compelled him to postpone the solution from the present to the remote future, and to content himself with what might be described as an asymptotic wish-fulfilment.¹ Some time or other, he anticipated, his transformation into a woman would come about; until then the personality of Dr. Schreber would remain indestructible.
[1911c, 2420]

In taking the view, then, that what lies at the core of the conflict in cases of paranoia among males is a homosexual wishful phantasy of loving a man, we shall certainly not forget that the confirmation of such an important hypothesis can only follow upon the investigation of a large number of instances of every variety of paranoid disorder. We must therefore be prepared, if need be, to limit our assertion to a single type of paranoia. Nevertheless, it is a remarkable fact that the familiar principal forms of paranoia can all be represented as contradictions of the single proposition: 'I (a man) love him (a man)'; and indeed that they exhaust all the possible ways in which such contradictions could be formulated.
[1911c, 2432]

The neuroses exhibit on the one hand striking and far-reaching points of agreement with those great social institutions, art, religion and philosophy. But on the other hand they seem like distortions of them. It might be maintained that a case of hysteria is a caricature of a work of art, that an obsessional neurosis is a caricature of a religion and that a paranoid delusion is a caricature of a philosophical system. The divergence resolves itself ultimately into the fact that the neuroses are asocial structures; they endeavour to achieve by private means what is effected in society by collective effort. If we analyse the instincts at work in the neuroses, we find that the determining influence in them is exercised by instinctual forces of sexual origin; the corresponding cultural formations, on the other hand, are based upon social instincts, originating from the combination of egoistic and erotic elements. Sexual needs are not capable of uniting men in the same way as are the demands of self-preservation. Sexual satisfaction is essentially the private affair of each individual.
[1912-1913, 2717]
The secondary revision of the product of the dream-work is an admirable example of the nature and pretensions of a system. There is an intellectual function in us which demands unity, connection and intelligibility from any material, whether of perception or thought, that comes within its grasp; and if, as a result of special circumstances, it is unable to establish a true connection, it does not hesitate to fabricate a false one. Systems constructed in this way are known to us not only from dreams, but also from phobias, from obsessive thinking and from delusions. The construction of systems is seen most strikingly in delusional disorders (in paranoia), where it dominates the symptomatic picture; but its occurrence in other forms of neuro-psychosis must not be overlooked. In all these cases it can be shown that a rearrangement of the psychical material has been made with a fresh aim in view; and the rearrangement may often have to be a drastic one if the outcome is to be made to appear intelligible from the point of view of the system. Thus a system is best characterized by the fact that at least two reasons can be discovered for each of its products: a reason based upon the premises of the system (a reason, then, which may be delusional) and a concealed reason, which we must judge to be the truly operative and the real one.

Similar considerations apply to the deliria and hallucinations, as well as to the delusional systems, exhibited by various psychotic patients. Where hitherto nothing but the most freakish capriciousness has seemed to prevail, psycho-analytic research has introduced law, order and connection, or has at least allowed us to suspect their presence where its work is still incomplete. The most heterogeneous forms of mental disorder are revealed as the results of processes which are at bottom identical and which can be understood and described by means of psychological concepts. What had already been discovered in the formation of dreams is operative everywhere - psychical conflict, the repression of certain instinctual impulses which have been pushed back into the unconscious by other mental forces, reaction formations set up by the repressing forces, and substitutes constructed by the instincts which have been repressed but have not been robbed of all their energy. The accompanying processes of condensation and displacement, so familiar to us in dreams, are also to be found everywhere. The multiplicity of clinical pictures observed by psychiatrists depends upon two other things: the multiplicity of the psychical mechanisms at the disposal of the repressive process and the multiplicity of developmental dispositions which give the repressed impulses an opportunity for breaking through into substitutive structures.

It is to these phenomena, then, that I now propose to draw your attention. But you will protest with some annoyance: 'There are so many vast problems in the wide universe, as well as within the narrower confines of our minds, so many marvels in the field of mental disorders, which require and deserve to have light thrown upon them, that it does really seem gratuitous to waste labour and interest on such trivialities. If you could make us understand why a person with sound eyes and ears can see and hear in broad daylight things that are not there, why another person suddenly thinks he is being persecuted by the people of whom he has hitherto been most fond, or puts forward the cleverest arguments in support of delusional beliefs which any child could see were nonsensical, then we should have some opinion of psycho-analysis. But if it can do no more than ask us to consider why a speaker at a banquet uses one word instead of another or why a housewife has mislaid her keys, and similar futilities, then we shall know how to put our time and interest to better uses.'
After this first point has been established our psychiatric interest will become even livelier. If a delusion is not to be got rid of by a reference to reality, no doubt it did not originate from reality either. Where else did it originate? There are delusions of the most varied content: why in our case is the content of the delusion jealousy in particular? In what kind of people do delusions, and especially delusions of jealousy, come about? We should like to hear what the psychiatrist has to say about this; but at this point he leaves us in the lurch. He enters into only a single one of our enquiries. He will investigate the woman's family history and will perhaps give us this reply: 'Delusions come about in people in whose families similar and other psychical disorders have repeatedly occurred.' In other words, if this woman developed a delusion she was predisposed to it by hereditary transmission. No doubt that is something; but is it all we want to know? Was this the only thing that contributed to the causation of the illness? Must we be content to suppose that it is a matter of indifference or caprice or is inexplicable whether a delusion of jealousy arises rather than any other sort? And ought we to understand the assertion of the predominance of the hereditary influence in a negative sense as well - that no matter what experiences this woman's mind encountered she was destined some time or other to produce a delusion? You will want to know why it is that scientific psychiatry will give us no further information. But my reply to you is: 'he is a rogue who gives more than he has.' The psychiatrist knows no way of throwing more light on a case like this one. He must content himself with a diagnosis and a prognosis - uncertain in spite of a wealth of experience - of its future course.

You will recall that at our first meeting of the present academic year I described a case to you of a woman suffering from delusions of jealousy. Now that we are so near its end you would no doubt like to hear how delusions are explained by psycho-analysis. But I have less to tell you about that than you expect. The fact that a delusion cannot be shaken by logical arguments or real experiences is explained in the same way as in the case of an obsession - by its relation to the unconscious, which is represented and held down by the delusion or by the obsession. The difference between the two is based on the difference between the topography and dynamics of the two illnesses. You will recall that at our first meeting of the present academic year I described a case to you of a woman suffering from delusions of jealousy. Now that we are so near its end you would no doubt like to hear how delusions are explained by psycho-analysis. But I have less to tell you about that than you expect. The fact that a delusion cannot be shaken by logical arguments or real experiences is explained in the same way as in the case of an obsession - by its relation to the unconscious, which is represented and held down by the delusion or by the obsession. The difference between the two is based on the difference between the topography and dynamics of the two illnesses.

I told you too that we hoped that the analysis of the narcissistic disorders would give us an insight into the way in which our ego is put together and built up out of different agencies. We have already made a start with this at one point. From the analysis of delusions of observation we have drawn the conclusion that there actually exists in the ego an agency which unceasingly observes, criticizes and compares, and in that way sets itself over against the other part of the ego. We believe, therefore, that the patient is betraying a truth to us which is not yet sufficiently appreciated when he complains that he is spied upon and observed at every step he takes and that every one of his thoughts is reported and criticized. His only mistake is in regarding this uncomfortable power as something alien to him and placing it outside himself. He senses an agency holding sway in his ego which measures his actual ego and each of its activities by an ideal ego that he has created for himself in the course of his development. We believe, too, that this creation was made with the intention of re-establishing the self-satisfaction which was attached to primary infantile narcissism but which since then has suffered so many disturbances and mortifications. We know the self-observing agency as the ego-censor, the conscience; it is this that exercises the dream-censorship during the night, from which the repressions of inadmissible wishful impulses proceed. When in delusions of observation it becomes split up, it reveals to us its origin from the influences of parents, educators and social environment - from an identification with some of these model figures.
As regards the third and apparently sadistic phase of the beating-phantasy, I have already discussed the significance that it gains as the vehicle of the excitation impelling towards masturbation; and I have shown how it arouses activities of the imagination which on the one hand continue the phantasy along the same line, and on the other hand neutralize it through compensation. Nevertheless the second phase, the unconscious and masochistic one, in which the child itself is being beaten by its father, is incomparably the more important. This is not only because it continues to operate through the agency of the phase that takes its place; we can also detect effects upon the character, which are directly derived from its unconscious form. People who harbour phantasies of this kind develop a special sensitiveness and irritability towards anyone whom they can include in the class of fathers. They are easily offended by a person of this kind, and in that way (to their own sorrow and cost) bring about the realization of the imagined situation of being beaten by their father. I should not be surprised if it were one day possible to prove that the same phantasy is the basis of the delusional litigiousness of paranoia.

[1919e, 3655]

It cannot be proved, but also cannot be disproved, that instead of this, what happened was the following. Her mother told her one day that her son had sent a telepathic message; whereupon the conviction at once arose in her mind that she had had the same experience at the same time. Such illusions of memory arise in the mind with a compelling force which they draw from real sources; but they turn psychical reality into material reality. The strength of the illusion lies in its being an excellent way of expressing the sister's proneness to identify herself with her mother. 'You are anxious about the boy, but I am really his mother, and his cry was meant for me; I had this telepathic message.' The sister would naturally firmly reject our attempt at explanation and would hold to her belief in the authenticity of her experience. But she could not do otherwise. She would be bound to believe in the reality of the pathological effect so long as the reality of its unconscious premises were unknown to her. Every such delusion derives its strength and its unassailable character from having a source in unconscious psychical reality. I note in passing that it is not incumbent on us here to explain the mother's experience or to investigate its authenticity.

[1922a, 3895]

In a psychosis, the transforming of reality is carried out upon the psychical precipitates of former relations to it - that is, upon the memory-traces, ideas and judgements which have been previously derived from reality and by which reality was represented in the mind. But this relation was never a closed one; it was continually being enriched and altered by fresh perceptions. Thus the psychosis is also faced with the task of procuring for itself perceptions of a kind which shall correspond to the new reality; and this is most radically effected by means of hallucination. The fact that, in so many forms and cases of psychosis, the paramnesias, the delusions and the hallucinations that occur are of a most distressing character and are bound up with a generation of anxiety - this fact is without doubt a sign that the whole process of remodelling is carried through against forces which oppose it violently. We may construct the process on the model of a neurosis, with which we are more familiar. There we see that a reaction of anxiety sets in whenever the repressed instinct makes a thrust forward, and that the outcome of the conflict is only a compromise and does not provide complete satisfaction. Probably in a psychosis the rejected piece of reality constantly forces itself upon the mind, just as the repressed instinct does in a neurosis, and that is why in both cases the consequences too are the same. The elucidation of the various mechanisms which are designed, in the psychoses, to turn the subject away from reality and to reconstruct reality - this is a task for specialized psychiatric study which has not yet been taken in hand.

[1924e, 4096]
In obsessional neurosis and paranoia the forms which the symptoms assume become very valuable to the ego because they obtain for it, not certain advantages, but a narcissistic satisfaction which it would otherwise be without. The systems which the obsessional neurotic constructs flatter his self-love by making him feel that he is better than other people because he is specially cleanly or specially conscientious. The delusional constructions of the paranoic offer to his acute perceptive and imaginative powers a field of activity which he could not easily find elsewhere.
[1926d, 4260]

When I say that these things are all illusions, I must define the meaning of the word. An illusion is not the same thing as an error; nor is it necessarily an error. Aristotle’s belief that vermin are developed out of dung (a belief to which ignorant people still cling) was an error; so was the belief of a former generation of doctors that tabes dorsalis is the result of sexual excess. It would be incorrect to call these errors illusions. On the other hand, it was an illusion of Columbus’s that he had discovered a new sea-route to the Indies. The part played by his wish in this error is very clear. One may describe as an illusion the assertion made by certain nationalists that the Indo-Germanic race is the only one capable of civilization; or the belief, which was only destroyed by psycho-analysis, that children are creatures without sexuality. What is characteristic of illusions is that they are derived from human wishes. In this respect they come near to psychiatric delusions. But they differ from them, too, apart from the more complicated structure of delusions. In the case of delusions, we emphasize as essential their being in contradiction with reality. Illusions need not necessarily be false - that is to say, unrealizable or in contradiction to reality. For instance, a middle-class girl may have the illusion that a prince will come and marry her. This is possible; and a few such cases have occurred. That the Messiah will come and found a golden age is much less likely. Whether one classifies this belief as an illusion or as something analogous to a delusion will depend on one’s personal attitude. Examples of illusions which have proved true are not easy to find, but the illusion of the alchemists that all metals can be turned into gold might be one of them. The wish to have a great deal of gold, as much gold as possible, has, it is true, been a good deal damped by our present-day knowledge of the determinants of wealth, but chemistry no longer regards the transmutation of metals into gold as impossible. Thus we call a belief an illusion when a wish-fulfilment is a prominent factor in its motivation, and in doing so we disregard its relations to reality, just as the illusion itself sets no store by verification.
[1927c, 4441]

Another procedure operates more energetically and more thoroughly. It regards reality as the sole enemy and as the source of all suffering, with which it is impossible to live, so that one must break off all relations with it if one is to be in any way happy. The hermit turns his back on the world and will have no truck with it. But one can do more than that; one can try to re-create the world, to build up in its stead another world in which its most unbearable features are eliminated and replaced by others that are in conformity with one’s own wishes. But whoever, in desperate defiance, sets out upon this path to happiness will as a rule attain nothing. Reality is too strong for him. He becomes a madman, who for the most part finds no one to help him in carrying through his delusion. It is asserted, however, that each one of us behaves in some one respect like a paranoic, corrects some aspect of the world which is unbearable to him by the construction of a wish and introduces this delusion into reality. A special importance attaches to the case in which this attempt to procure a certainty of happiness and a protection against suffering through a delusional remoulding of reality is made by a considerable number of people in common. The religions of mankind must be classed among the mass delusions of this kind. No one, needless to say, who shares a delusion ever recognizes it as such.
[1930a, 4480]
It is worth specially stressing the fact that each portion which returns from oblivion asserts itself with peculiar force, exercises an incomparably powerful influence on people in the mass, and raises an irresistible claim to truth against which logical objections remain powerless: a kind of 'credo quia absurdum'. This remarkable feature can only be understood on the pattern of the delusions of psychotics. We have long understood that a portion of forgotten truth lies hidden in delusional ideas, that when this returns it has to put up with distortions and misunderstandings, and that the compulsive conviction which attaches to the delusion arises from this core of truth and spreads out on to the errors that wrap it round. We must grant an ingredient such as this of what may be called historical truth to the dogmas of religion as well, which, it is true, bear the character of psychotic symptoms but which, as group phenomena, escape the curse of isolation.

[1939a, 4909]

This view of delusions is not, I think, entirely new, but it nevertheless emphasizes a point of view which is not usually brought into the foreground. The essence of it is that there is not only method in madness, as the poet has already perceived, but also a fragment of historical truth; and it is plausible to suppose that the compulsive belief attaching to delusions derives its strength precisely from infantile sources of this kind. All that I can produce to-day in support of this theory are reminiscences, not fresh impressions. It would probably be worth while to make an attempt to study cases of the disorder in question on the basis of the hypotheses that have been here put forward and also to carry out their treatment on those same lines. The vain effort would be abandoned of convincing the patient of the error of his delusion and of its contradiction of reality; and, on the contrary, the recognition of its kernel of truth would afford common ground upon which the therapeutic work could develop. That work would consist in liberating the fragment of historical truth from its distortions and its attachments to the actual present day and in leading it back to the point in the past to which it belongs. The transposing of material from a forgotten past on to the present or on to an expectation of the future is indeed a habitual occurrence in neurotics no less than in psychotics. Often enough, when a neurotic is led by an anxiety-state to expect the occurrence of some terrible event, he is in fact merely under the influence of a repressed memory (which is seeking to enter consciousness but cannot become conscious) that something which was at that time terrifying did really happen. I believe that we should gain a great deal of valuable knowledge from work of this kind upon psychotics even if it led to no therapeutic success.

[1937d, 5058]
Since we cannot obtain any insight into the causes of the first illness (a knowledge of which is undoubtedly indispensable for properly elucidating the second and severer illness) we must now plunge at random into an unknown concatenation of circumstances. During the incubation period of his illness, as we are aware (that is, between June 1893, when he was appointed to his new post, and the following October, when he took up his duties), he repeatedly dreamt that his old nervous disorder had returned. Once, moreover, when he was half asleep, he had a feeling that after all it must be nice to be a woman submitting to the act of copulation. The dreams and the phantasy are reported by Schreber in immediate succession; and if we also bring together their subject-matter, we shall be able to infer that, at the same time as his recollection of his illness, a recollection of his doctor was also aroused in his mind, and that the feminine attitude which he assumed in the phantasy was from the first directed towards the doctor. Or it may be that the dream of his illness having returned simply expressed some such longing as: 'I wish I could see Flechsig again!' Our ignorance of the mental content of the first illness bars our way in this direction. Perhaps that illness had left behind in him a feeling of affectionate dependence upon his doctor, which had now, for some unknown reason, become intensified to the pitch of an erotic desire. This feminine phantasy which was still kept impersonal, was met at once by an indignant repudiation - a true 'masculine protest', to use Adler's expression, but in a sense different from his.¹ But in the severe psychosis which broke out soon afterwards the feminine phantasy carried everything before it; and it only requires a slight correction of the characteristic paranoic indefiniteness of Schreber's mode of expression to enable us to divine the fact that the patient was in fear of sexual abuse at the hands of his doctor himself. The exciting cause of his illness, then, was an outburst of homosexual libido; the object of this libido was probably from the very first his doctor, Flechsig; and his struggles against the libidinal impulse produced the conflict which gave rise to the symptoms.

Perhaps I may be allowed to add a few words with a view to establishing the causes of this conflict that broke out in relation to the feminine wishful phantasy. As we know, when a wishful phantasy makes its appearance, our business is to bring it into connection with some frustration, some privation in real life. Now Schreber admits having suffered a privation of the kind. His marriage, which he describes as being in other respects a happy one, brought him no children; and in particular it brought him no son who might have consoled him for the loss of his father and brother and upon whom he might have drained off his unsatisfied homosexual affections.¹ His family line threatened to die out, and it seems that he felt no little pride in his birth and lineage. 'Both the Flechsigs and the Schrebers were members of "the highest nobility of Heaven", as the phrase went. The Schrebers in particular bore the title of "Margraves of Tuscany and Tasmania"; for souls, urged by some sort of personal vanity, have a custom of adorning themselves with somewhat high-sounding titles borrowed from this world.'² (24.) The great Napoleon obtained a divorce from Josephine (though only after severe internal struggles) because she could not propagate the dynasty.³ Dr. Schreber may have formed a phantasy that if he were a woman he would manage the business of having children more successfully; and he may thus have found his way back into the feminine attitude towards his father which he had exhibited in the earliest years of his childhood. If that were so, then his delusion that as a result of his emasculation the world was to be peopled with 'a new race of men, born from the spirit of Schreber' (288) - a delusion the realization of which he was continually postponing to a more and more remote future - would also be designed to offer him an escape from his childlessness. If the 'little men' whom Schreber himself finds so puzzling were children, then we should have no difficulty in understanding why they were collected in such great numbers on his head (158): they were in truth the 'children of his spirit'.⁴

¹[1911c, 2416]
²[1911c, 2428]
In my *Three Essays on the Theory of Sexuality* I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoids **endeavour to protect themselves against any such sexualization of their social instinctual cathexes**, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) *schizophrenia*; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.

[1911c, 2431]

In order to remain faithful to our customary phraseology, we shall have to speak, not of transposing the psychical accent, but of displacing large amounts of catheysis. The question then is whether we are entitled to picture extensive displacements like this from one agency of the mental apparatus to another. It looks like a new hypothesis constructed *ad hoc*. Yet we may remind ourselves that we have repeatedly (even though not sufficiently often) taken a factor of this kind into account in our attempts at a metapsychological picture of mental events. Thus, for instance, we supposed that the difference between an ordinary erotic object-cathexis and the state of being in love is that in the latter incomparably more cathexis passes over to the object and that the ego empties itself as it were in favour of the object. In studying some cases of paranoia I was able to establish the fact that ideas of persecution are formed early and exist for a long time without any perceptible effect, until, as the result of some particular precipitating event, they receive sufficient amounts of catheysis to cause them to become dominant. The cure, too, of such paranoic attacks would lie not so much in a resolution and correction of the delusional ideas as in a withdrawal from them of the cathexis which has been lent to them. The alternations between melancholia and mania, between a cruel suppression of the ego by the super-ego and a liberation of the ego after that pressure, suggests a shift of cathexis of this kind; such a shift, moreover, would have to be brought in to explain a whole number of phenomena belonging to normal mental life. If this has been done hitherto only to a very limited extent, that is on account of our usual caution - something which deserves only praise. The region in which we feel secure is that of the pathology of mental life; it is here that we make our observations and acquire our convictions. For the present we venture to form a judgement on the normal mind only in so far as we can discern what is normal in the isolations and distortions of the pathological material. When once we have overcome this hesitancy we shall recognize what a large contribution is made to the understanding of mental processes by the static conditions as well as by the dynamic changes in the *quantity* of energetic cathexis.

[1927d, 4544]
We have repeatedly had to insist on the fact that the ego owes its origin as well as the most important of its acquired characteristics to its relation to the real external world. We are thus prepared to assume that the ego's pathological states, in which it most approximates once again to the id, are founded on a cessation or slackening of that relation to the external world. This tallies very well with what we learn from clinical experience - namely, that the precipitating cause of the outbreak of a psychosis is either that reality has become intolerably painful or that the instincts have become extraordinarily intensified - both of which, in view of the rival claims made on the ego by the id and the external world, must lead to the same result. The problem of psychoses would be simple and perspicuous if the ego's detachment from reality could be carried through completely. But that seems to happen only rarely or perhaps never. Even in a state so far removed from the reality of the external world as one of hallucinatory confusion, one learns from patients after their recovery that at the time in some corner of their mind (as they put it) there was a normal person hidden, who, like a detached spectator, watched the hubbub of illness go past him. I do not know if we may assume that this is so in general, but I can report the same of other psychoses with a less tempestuous course. I call to mind a case of chronic paranoia in which after each attack of jealousy a dream conveyed to the analyst a correct picture of the precipitating cause, free from any delusion. An interesting contrast was thus brought to light: while we are accustomed to discover from the dreams of neurotics jealousies which are alien to their waking lives, in this psychotic case the delusion which dominated the patient in the day-time was corrected by his dream. We may probably take it as being generally true that what occurs in all these cases is a psychical split. Two psychical attitudes have been formed instead of a single one - one, the normal one, which takes account of reality, and another which under the influence of the instincts detaches the ego from reality. The two exist alongside of each other. The issue depends on their relative strength. If the second is or becomes the stronger, the necessary precondition for a psychosis is present. If the relation is reversed, then there is an apparent cure of the delusional disorder. Actually it has only retreated into the unconscious - just as numerous observations lead us to believe that the delusion existed ready-made for a long time before its manifest irruption.

[1940a [1938], 5007]
One such change was the replacement of Flechsig by the superior figure of God. This seems at first as though it were a sign of aggravation of the conflict, an intensification of the unbearable persecution, but it soon becomes evident that it was preparing the way for the second change and, with it, the solution of the conflict. It was impossible for Schreber to become reconciled to playing the part of a female wanton towards his doctor; but the task of providing God Himself with the voluptuous sensations that He required called up no such resistance on the part of his ego. Emasculation was now no longer a disgrace; it became 'consonant with the Order of Things', it took its place in a great cosmic chain of events, and was instrumental in the re-creation of humanity after its extinction. 'A new race of men, born from the spirit of Schreber' would, so he thought, revere as their ancestor this man who believed himself the victim of persecution. By this means an outlet was provided which would satisfy both of the contending forces. His ego found compensation in his megalomania, while his feminine wishful phantasy made its way through and became acceptable. The struggle and the illness could cease. The patient's sense of reality, however, which had in the meantime become stronger, compelled him to postpone the solution from the present to the remote future, and to content himself with what might be described as an asymptotic wish-fulfilment.¹ Some time or other, he anticipated, his transformation into a woman would come about; until then the personality of Dr. Schreber would remain indestructible.

[1911c, 2420]

In my Three Essays on the Theory of Sexuality I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics endeavour to protect themselves against any such sexualization of their social instinctual cathexes, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) schizophrenia; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.

[1911c, 2431]

A world-catastrophe of this kind is not infrequent during the agitated stage in other cases of paranoia.¹ If we base ourselves on our theory of libidinal cathexis, and if we follow the hint given by Schreber's view of other people as being 'cursorily improvised men', we shall not find it difficult to explain these catastrophes.² The patient has withdrawn from the people in his environment and from the external world generally the libidinal cathexis which he has hitherto directed on to them. Thus everything has become indifferent and irrelevant to him, and has to be explained by means of a secondary rationalization as being 'miracled up, cursorily improvised'. The end of the world is the projection of this internal catastrophe; his subjective world has come to an end since his withdrawal of his love from it.³

[1911c, 2437]
And the paranoic builds it again, not more splendid, it is true, but at least so that he can once more live in it. He builds it up by the world of his delusions. The delusional formation, which we take to be the pathological product, is in reality an attempt at recovery, a process of reconstruction. Such a reconstruction after the catastrophe is successful to a greater or lesser extent, but never wholly so; in Schreber's words, there has been a 'profound internal change' in the world. But the human subject has recaptured a relation, and often a very intense one, to the people and things in the world, even though the relation is a hostile one now, where formerly it was hopefully affectionate. We may say, then, that the process of repression proper consists in a detachment of the libido from people - and things - that were previously loved. It happens silently; we receive no intelligence of it, but can only infer it from subsequent events. What forces itself so noisily upon our attention is the process of recovery, which undoes the work of repression and brings back the libido again on to the people it had abandoned. In paranoia this process is carried out by the method of projection. It was incorrect to say that the perception which was suppressed internally is projected outwards; the truth is rather, as we now see, that what was abolished internally returns from without. The thorough examination of the process of projection which we have postponed to another occasion will clear up our remaining doubts on this subject.

¹ An 'end of the world' based upon other motives is to be found at the climax of the ecstasy of love (cf. Wagner's Tristan und Isolde); in this case it is not the ego but the single love-object which absorbs all the cathexes directed upon the external world.

³ He has perhaps withdrawn from it not only his libidinal cathexis, but his interest in general - that is, the cathexes that proceed from his ego as well. This question is discussed below.

(1) Our first reflection will tell us that it cannot be the case that this detachment of the libido occurs exclusively in paranoia; nor can it be that, where it occurs elsewhere, it has such disastrous consequences. It is quite possible that a detachment of the libido is the essential and regular mechanism of every repression. We can have no positive knowledge on that point until the other disorders that are based upon repression have been similarly examined. But it is certain that in normal mental life (and not only in periods of mourning) we are constantly detaching our libido in this way from people or from other objects without falling ill. When Faust freed himself from the world by uttering his curses, the result was not a paranoia or any other neurosis but simply a certain general frame of mind. The detachment of the libido, therefore, cannot in itself be the pathogenic factor in paranoia; there must be some special characteristic which distinguishes a paranoic detachment of the libido from other kinds. It is not difficult to suggest what that characteristic may be. What use is made of the libido after it has been set free by the process of detachment? A normal person will at once begin looking about for a substitute for the lost attachment; and until that substitute has been found the liberated libido will be kept in suspension within his mind, and will there give rise to tensions and colour his mood. In hysteria the liberated libido becomes transformed into somatic innervations or into anxiety. But in paranoia the clinical evidence goes to show that the libido, after it has been withdrawn from the object, is put to a special use. It will be remembered that the majority of cases of paranoia exhibit traces of megalomania, and that megalomania can by itself constitute a paranoia. From this it may be concluded that in paranoia the liberated libido becomes attached to the ego, and is used for the aggrandizement of the ego. A return is thus made to the stage of narcissism (known to us from the development of the libido), in which a person's only sexual object is his own ego. On the basis of this clinical evidence we can suppose that paranoids have brought along with them a fixation at the stage of narcissism, and we can assert that the length of the step back from sublimated homosexuality to narcissism is a measure of the amount of regression characteristic of paranoia.

[1911c, 2437]

[1911c, 2437]

[1911c, 2437]
(2) An equally plausible objection can be based upon Schreber's case history, as well as upon many others. For it can be urged that the delusions of persecution (which were directed against Flechsig) unquestionably made their appearance at an earlier date than the phantasy of the end of the world; so that what is supposed to have been a return of the repressed actually preceded the repression itself - and this is patent nonsense. In order to meet this objection we must leave the high ground of generalization and descend to the detailed consideration of actual circumstances, which are undoubtedly very much more complicated. We must admit the possibility that a detachment of the libido such as we are discussing might just as easily be a partial one, a drawing back from some single complex, as a general one. A partial detachment should be by far the commoner of the two, and should precede a general one, since to begin with it is only for a partial detachment that the influences of life provide a motive. The process may then stop at the stage of a partial detachment or it may spread to a general one, which will loudly proclaim its presence in the symptoms of megalomania. Thus the detachment of the libido from the figure of Flechsig may nevertheless have been what was primary in the case of Schreber; it was immediately followed by the appearance of the delusion, which brought back the libido on to Flechsig again (though with a negative sign to mark the fact that repression had taken place) and thus annulled the work of repression. And now the battle of repression broke out anew, but this time with more powerful weapons. In proportion as the object of contention became the most important thing in the external world, trying on the one hand to draw the whole of the libido on to itself, and on the other hand mobilizing all the resistances against itself, so the struggle raging around this single object became more and more comparable to a general engagement; till at length a victory for the forces of repression found expression in a conviction that the world had come to an end and that the self alone survived. If we review the ingenious constructions which were raised by Schreber's delusion in the domain of religion - the hierarchy of God, the proved souls, the fore-courts of Heaven, the lower and the upper God - we can gauge in retrospect the wealth of sublimations which were brought down in ruin by the catastrophe of the general detachment of his libido.

[1911c, 2439]
A third consideration which arises from the views that have been developed in these pages is as follows. Are we to suppose that a general detachment of the libido from the external world would be an effective enough agent to account for the 'end of the world'? Or would not the ego-cathexes which still remained in existence have been sufficient to maintain rapport with the external world? To meet this difficulty we should either have to assume that what we call libidinal cathexis (that is, interest emanating from erotic sources) coincides with interest in general, or we should have to consider the possibility that a very widespread disturbance in the distribution of libido may bring about a corresponding disturbance in the ego-cathexes. But these are problems which we are still quite helpless and incompetent to solve. It would be otherwise if we could start out from some well-grounded theory of instincts; but in fact we have nothing of the kind at our disposal. We regard instinct as being the concept on the frontier-line between the somatic and the mental, and see in it the psychical representative of organic forces. Further, we accept the popular distinction between ego-instincts and a sexual instinct; for such a distinction seems to agree with the biological conception that the individual has a double orientation, aiming on the one hand at self-preservation and on the other at the preservation of the species. But beyond this are only hypotheses, which we have taken up - and are quite ready to drop again - in order to help us to find our bearings in the chaos of the obscurer processes of the mind. What we expect from psycho-analytic investigations of pathological mental processes is precisely that they shall drive us to some conclusions on questions connected with the theory of instincts. These investigations, however, are in their infancy and are only being carried out by isolated workers, so that the hopes we place in them must still remain unfulfilled. We can no more dismiss the possibility that disturbances of the libido may react upon the ego-cathexes than we can overlook the converse possibility - namely, that a secondary or induced disturbance of the libidinal processes may result from abnormal changes in the ego. Indeed, it is probable that processes of this kind constitute the distinctive characteristic of psychoses. How much of all this may apply to paranoia it is impossible at present to say. There is one consideration, however, on which I should like to lay stress. It cannot be asserted that a paranoic, even at the height of the repression, withdraws his interest from the external world completely - as must be considered to occur in certain other kinds of hallucinatory psychosis (such a Meynert's amentia). The paranoic perceives the external world and takes into account any alterations that may happen in it, and the effect it makes upon him stimulates him to invent explanatory theories (such as Schreber's 'cursorily improvised men'). It therefore appears to me far more probable that the paranoic's altered relation to the world is to be explained entirely or in the main by the loss of his libidinal interest.

[1911c, 2440]
(4) It is impossible to avoid asking, in view of the close connection between the two disorders, how far this conception of paranoia will affect our conception of dementia praecox. I am of opinion that Kraepelin was entirely justified in taking the step of separating off a large part of what had hitherto been called paranoia and merging it, together with catatonia and certain other forms of disease, into a new clinical unit - though 'dementia praecox' was a particularly unhappy name to choose for it. The designation chosen by Bleuler for the same group of forms - 'schizophrenia' - is also open to the objection that the name appears appropriate only so long as we forget its literal meaning. For otherwise it prejudices the issue, since it is based on a characteristic of the disease which is theoretically postulated - a characteristic, moreover, which does not belong exclusively to that disease, and which, in the light of other considerations, cannot be regarded as the essential one. However, it is not on the whole of very great importance what names we give to clinical pictures. What seems to me more essential is that paranoia should be maintained as an independent clinical type, however frequently the picture it offers may be complicated by the presence of schizophrenic features. For, from the standpoint of the libido theory, while it would resemble dementia praecox in so far as the repression proper would in both disorders have the same principal feature - detachment of the libido, together with its regression on to the ego - it would be distinguished from dementia praecox by having its dispositional fixation differently located and by having a different mechanism for the return of the repressed (that is, for the formation of symptoms). It would seem to me the most convenient plan to give dementia praecox the name of **paraphrenia**. This term has no special connotation, and it would serve to indicate a relationship with paranoia (a name which cannot be changed) and would further recall hebephrenia, an entity which is now merged in dementia praecox. It is true that the name has already been proposed for other purposes; but this need not concern us, since the alternative applications have not passed into general use.

[1911c, 2441]

Since I neither fear the criticism of others nor shrink from criticizing myself, I have no motive for avoiding the mention of a similarity which may possibly damage our libido theory in the estimation of many of my readers. Schreber's 'rays of God', which are made up of a condensation of the sun's rays, of nerve fibres, and of spermatozoa, are in reality nothing else than a concrete representation and projection outwards of libidinal cathexes; and they thus lend his delusions a striking conformity with our theory. His belief that the world must come to an end because his ego was attracting all the rays to itself, his anxious concern at a later period, during the process of reconstruction, lest God should sever His ray-connection with him, - these and many other details of Schreber's delusional structure sound almost like endopsychic perceptions of the processes whose existence I have assumed in these page as the basis of our explanation of paranoia. I can nevertheless call a friend and fellow-specialist to witness that I had developed my theory of paranoia before I became acquainted with the contents of Schreber's book. It remains for the future to decide whether there is more delusion in my theory than I should like to admit, or whether there is more truth in Schreber's delusion than other people are as yet prepared to believe.

[1911c, 2444]
In the case of schizophrenia, on the other hand, we have been driven to the assumption that after the process of repression the libido that has been withdrawn does not seek a new object, but retreats into the ego; that is to say, that here the object-cathexes are given up and a primitive objectless condition of narcissism is re-established. The incapacity of these patients for transference (so far as the pathological process extends), their consequent inaccessibility to therapeutic efforts, their characteristic repudiation of the external world, the appearance of signs of a hypercathexis of their own ego, the final outcome in complete apathy - all these clinical features seem to agree excellently with the assumption that their object-cathexes have been given up. As regards the relation of the two psychical systems to each other, all observers have been struck by the fact that in schizophrenia a great deal is expressed as being conscious which in the transference neuroses can only be shown to be present in the Ucs. by psychoanalysis. But to begin with we were not able to establish any intelligible connection between the ego-object relation and the relationships of consciousness.

If now we put this finding alongside the hypothesis that in schizophrenia object-cathexes are given up, we shall be obliged to modify the hypothesis by adding that the cathexis of the word-presentations of objects is retained. What we have permissibly called the conscious presentation of the object can now be split up into the presentation of the word and the presentation of the thing; the latter consists in the cathexis, if not of the direct memory-images of the thing, at least of remoter memory-traces derived from these. We now seem to know all at once what the difference is between a conscious and an unconscious presentation. The two are not, as we supposed, different registrations of the same content in different psychical localities, nor yet different functional states of cathexis in the same locality; but the conscious presentation comprises the presentation of the thing plus the presentation of the word belonging to it, while the unconscious presentation is the presentation of the thing alone. The system Ucs. contains the thing-cathexes of the objects, the first and true object-cathexes; the system Pcs. comes about by this thing-presentation being hypercathected through being linked with the word-presentations corresponding to it. It is these hypercathexes, we may suppose, that bring about a higher psychical organization and make it possible for the primary process to be succeeded by the secondary process which is dominant in the Pcs. Now, too, we are in a position to state precisely what it is that repression denies to the rejected presentation in the transference neuroses: what it denies to the presentation is translation into words which shall remain attached to the object. A presentation which is not put into words, or a psychical act which is not hypercathected, remains thereafter in the Ucs. in a state of repression.

On the basis of our clinical impressions we maintained that these patients' object-cathexes must have been given up and that their object-libido must have been transformed into ego-libido. Through this characteristic we distinguished them from the first group of neurotics (sufferers from hysteria, anxiety-hysteria and obsessional neurosis). This suspicion is now confirmed by their behaviour in our attempts at therapy. They manifest no transference and for that reason are inaccessible to our efforts and cannot be cured by us.
The acceptance of suggestions on individual points is no doubt discouraged by the fact that during the treatment we are struggling unceasingly against resistances which are able to transform themselves into negative (hostile) transferences. Nor must we fail to point out that a large number of the individual findings of analysis, which might otherwise be suspected to being products of suggestion, are confirmed from another and irreproachable source. Our guarantors in this case are the sufferers from dementia praecox and paranoia, who are of course far above any suspicion of being influenced by suggestion. The translations of symbols and the phantasies, which these patients produce for us and which in them have forced their way through into consciousness, coincide faithfully with the results of our investigations into the unconscious of transference neurotics and thus confirm the objective correctness of our interpretations, on which doubt is so often thrown. You will not, I think, be going astray if you trust analysis on these points.
[1916-1917, 3493]
In my *Three Essays on the Theory of Sexuality* I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics *endeavour to protect themselves against any such sexualization of their social instinctual cathexes*, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) *schizophrenia*; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.

(1) Our first reflection will tell us that it cannot be the case that this detachment of the libido occurs exclusively in paranoia; nor can it be that, where it occurs elsewhere, it has such disastrous consequences. It is quite possible that a detachment of the libido is the essential and regular mechanism of every repression. We can have no positive knowledge on that point until the other disorders that are based upon repression have been similarly examined. But it is certain that in normal mental life (and not only in periods of mourning) we are constantly detaching our libido in this way from people or from other objects without falling ill. When Faust freed himself from the world by uttering his curses, the result was not a paranoia or any other neurosis but simply a certain general frame of mind. The detachment of the libido, therefore, cannot in itself be the pathogenic factor in paranoia; there must be some special characteristic which distinguishes a paranoic detachment of the libido from other kinds. It is not difficult to suggest what that characteristic may be. What use is made of the libido after it has been set free by the process of detachment? A normal person will at once begin looking about for a substitute for the lost attachment; and until that substitute has been found the liberated libido will be kept in suspension within his mind, and will there give rise to tensions and colour his mood. In hysteria the liberated libido becomes transformed into somatic innervations or into anxiety. But in paranoia the clinical evidence goes to show that the libido, after it has been withdrawn from the object, is put to a special use. It will be remembered that the majority of cases of paranoia exhibit traces of megalomania, and that megalomania can by itself constitute a paranoia. From this it may be concluded that in paranoia the liberated libido becomes attached to the ego, and is used for the aggrandizement of the ego. A return is thus made to the stage of narcissism (known to us from the development of the libido), in which a person's only sexual object is his own ego. On the basis of this clinical evidence we can suppose that paranoics have brought along with them *a fixation at the stage of narcissism*, and we can assert that the length of the *step back from sublimated homosexuality to narcissism* is a measure of the amount of *regression* characteristic of paranoia.
(4) It is impossible to avoid asking, in view of the close connection between the two disorders, how far this conception of paranoia will affect our conception of dementia praecox. I am of opinion that Kraepelin was entirely justified in taking the step of separating off a large part of what had hitherto been called paranoia and merging it, together with catatonia and certain other forms of disease, into a new clinical unit - though 'dementia praecox' was a particularly unhappy name to choose for it. The designation chosen by Bleuler for the same group of forms - 'schizophrenia' - is also open to the objection that the name appears appropriate only so long as we forget its literal meaning. For otherwise it prejudices the issue, since it is based on a characteristic of the disease which is theoretically postulated - a characteristic, moreover, which does not belong exclusively to that disease, and which, in the light of other considerations, cannot be regarded as the essential one. However, it is not on the whole of very great importance what names we give to clinical pictures. What seems to me more essential is that paranoia should be maintained as an independent clinical type, however frequently the picture it offers may be complicated by the presence of schizophrenic features. For, from the standpoint of the libido theory, while it would resemble dementia praecox in so far as the repression proper would in both disorders have the same principal feature - detachment of the libido, together with its regression on to the ego - it would be distinguished from dementia praecox by having its dispositional fixation differently located and by having a different mechanism for the return of the repressed (that is, for the formation of symptoms). It would seem to me the most convenient plan to give dementia praecox the name of paraphrenia. This term has no special connotation, and it would serve to indicate a relationship with paranoia (a name which cannot be changed) and would further recall hebephrenia, an entity which is now merged in dementia praecox. It is true that the name has already been proposed for other purposes; but this need not concern us, since the alternative applications have not passed into general use.

Our hypotheses as to the dispositional fixations in paranoia and paraphrenia make it easy to see that a case may begin with paranoic symptoms and may yet develop into a dementia praecox, and that paranoid and schizophrenic phenomena may be combined in any proportion. And we can understand how a clinical picture such as Schreber's can come about, and merit the name of a paranoid dementia, from the fact that in its production of a wishful phantasy and of hallucinations it shows paraphrenic traits, while in its exciting cause, in its use of the mechanism of projection, and in its outcome it exhibits a paranoid character. For it is possible for several fixations to be left behind in the course of development, and each of these in succession may allow an irruption of the libido that has been pushed off - beginning, perhaps, with the later acquired fixations, and going on, as the illness develops, to the original ones that lie nearer the starting-point. We should be glad to know to what conditions the relatively favourable issue of the present case is due; for we cannot willingly attribute the whole responsibility for the outcome to anything so casual as the 'improvement due to change in domicile',¹ which set in after the patient's removal from Flechsig's clinic. But our insufficient acquaintance with the intimate circumstances of the history of the case makes it impossible to give an answer to this interesting question. It may be suspected, however, that what enabled Schreber to reconcile himself to his homosexual phantasy, and so made it possible for his illness to terminate in something approximating to a recovery, may have been the fact that his father-complex was in the main positively toned and that in real life the later years of his relationship with an excellent father had probably been unclouded.

¹[1911c, 2443]
Further study has shown that it is expedient and indeed indispensable to insert a third stage between these two, or, putting it in another way, to divide the first stage, that of auto-erotism, into two. At this intermediate stage, the importance of which is being made more and more evident by research, the hitherto isolated sexual instincts have already come together into a single whole and have also found an object. But this object is not an external one, extraneous to the subject, but it is his own ego, which has been constituted at about this same time. Bearing in mind pathological fixations of this new stage, which become observable later, we have given it the name of 'narcissism'. The subject behaves as though he were in love with himself; his egoistic instincts and his libidinal wishes are not yet separable under our analysis. [1912-1913, 2731]

When educators have become familiar with the findings of psycho-analysis, it will be easier for them to reconcile themselves to certain phases of infantile development and they will, among other things, not be in danger of over-estimating the importance of the socially unserviceable or perverse instinctual impulses which emerge in children. On the contrary they will refrain from any attempt at forcibly suppressing such impulses, when they learn that efforts of this kind often produce no less undesirable results than the alternative, which is so much dreaded by educators, of giving free play to children's naughtiness. The forcible suppression of strong instincts by external means never has the effect in a child of these instincts being extinguished or brought under control; it leads to repression, which establishes a predisposition to later nervous illness. Psycho-analysis has frequent opportunities of observing the part played by inopportune and undiscerning severity of upbringing in the production of neuroses, or the price, in loss of efficiency and of capacity for enjoyment, which has to be paid for the normality upon which the educator insists. And psycho-analysis can also show what precious contributions to the formation of character are made by these asocial and perverse instincts in the child, if they are not subjected to repression but are diverted from their original aims to more valuable ones by the process known as 'sublimation'. Our highest virtues have grown up, as reaction formations and sublimations, out of our worst dispositions. Education should scrupulously refrain from burying these precious springs of action and should restrict itself to encouraging the processes by which these energies are led along safe paths. Whatever we can expect in the way of prophylaxis against neurosis in the individual lies in the hands of a psycho-analytically enlightened education.¹ [1913], 2825

Homosexual object-choice originally lies closer to narcissism than does the heterosexual kind. When it is a question, therefore, of repelling an undesirably strong homosexual impulse, the path back to narcissism is made particularly easy. Hitherto I have had very little opportunity of talking to you about the foundations of erotic life so far as we have discovered them, and it is too late now to catch up on the omission. This much, however, I can emphasize to you. Object-choice, the step forward in the development of the libido which is made after the narcissistic stage, can take place according to two different types: either according to the narcissistic type, where the subject's own ego is replaced by another one that is as similar as possible, or according to the attachment type, where people who have become precious through satisfying the other vital needs are chosen as objects by the libido as well. A strong libidinal fixation to the narcissistic type of object-choice is to be included in the predisposition to manifest homosexuality. [1916-1917, 3470]
(1) Our first reflection will tell us that it cannot be the case that this detachment of the libido occurs exclusively in paranoia; nor can it be that, where it occurs elsewhere, it has such disastrous consequences. It is quite possible that a detachment of the libido is the essential and regular mechanism of every repression. We can have no positive knowledge on that point until the other disorders that are based upon repression have been similarly examined. But it is certain that in normal mental life (and not only in periods of mourning) we are constantly detaching our libido in this way from people or from other objects without falling ill. When Faust freed himself from the world by uttering his curses, the result was not a paranoia or any other neurosis but simply a certain general frame of mind. The detachment of the libido, therefore, cannot in itself be the pathogenic factor in paranoia; there must be some special characteristic which distinguishes a paranoid detachment of the libido from other kinds. It is not difficult to suggest what that characteristic may be. What use is made of the libido after it has been set free by the process of detachment? A normal person will at once begin looking about for a substitute for the lost attachment; and until that substitute has been found the liberated libido will be kept in suspension within his mind, and will there give rise to tensions and colour his mood. In hysteria the liberated libido becomes transformed into somatic innervations or into anxiety. But in paranoia the clinical evidence goes to show that the libido, after it has been withdrawn from the object, is put to a special use. It will be remembered that the majority of cases of paranoia exhibit traces of megalomania, and that megalomania can by itself constitute a paranoia. From this it may be concluded that in paranoia the liberated libido becomes attached to the ego, and is used for the aggrandizement of the ego. A return is thus made to the stage of narcissism (known to us from the development of the libido), in which a person's only sexual object is his own ego. On the basis of this clinical evidence we can suppose that paranoics have brought along with them a fixation at the stage of narcissism, and we can assert that the length of the step back from sublimated homosexuality to narcissism is a measure of the amount of regression characteristic of paranoia.

(4) It is impossible to avoid asking, in view of the close connection between the two disorders, how far this conception of paranoia will affect our conception of dementia praecox. I am of opinion that Kraepelin was entirely justified in taking the step of separating off a large part of what had hitherto been called paranoia and merging it, together with catatonia and certain other forms of disease, into a new clinical unit - though 'dementia praecox' was a particularly unhappy name to choose for it. The designation chosen by Bleuler for the same group of forms - 'schizophrenia' - is also open to the objection that the name appears appropriate only so long as we forget its literal meaning. For otherwise it prejudices the issue, since it is based on a characteristic of the disease which is theoretically postulated - a characteristic, moreover, which does not belong exclusively to that disease, and which, in the light of other considerations, cannot be regarded as the essential one. However, it is not on the whole of very great importance what names we give to clinical pictures. What seems to me more essential is that paranoia should be maintained as an independent clinical type, however frequently the picture it offers may be complicated by the presence of schizophrenic features. For, from the standpoint of the libido theory, while it would resemble dementia praecox in so far as the repression proper would in both disorders have the same principal feature - detachment of the libido, together with its regression on to the ego - it would be distinguished from dementia praecox by having its dispositional fixation differently located and by having a different mechanism for the return of the repressed (that is, for the formation of symptoms). It would seem to me the most convenient plan to give dementia praecox the name of paraphrenia. This term has no special connotation, and it would serve to indicate a relationship with paranoia (a name which cannot be changed) and would further recall hebephrenia, an entity which is now merged in dementia praecox. It is true that the name has already been proposed for other purposes; but this need not concern us, since the alternative applications have not passed into general use.

[1911c, 2438]

[1911c, 2441]
For the moment we will dwell a little longer on regression. After what you have learnt of the development of the libidinal function, you will be prepared to hear that there are regressions of two sorts: a return to the objects first cathected by the libido, which, as we know, are of an incestuous nature, and a return of the sexual organization as a whole to earlier stages. Both sorts are found in the transference neuroses and play a great part in their mechanism. In particular, a return to the first incestuous objects of the libido is a feature that is found in neurotics with positively fatiguing regularity. There is much more to be said about regressions of the libido itself when we take into account as well another group of neuroses, the narcissistic ones, which for the time being we do not intend to do. These disorders give us access to other developmental processes of the libidinal function which we have not yet mentioned, and show us correspondingly new sorts of regression as well. But above all I think I ought to warn you now not to confuse regression with repression and help you to form a clear idea of the relations between the two processes. Repression, as you will recall, is the process by which an act which is admissible to consciousness, one, therefore, which belongs to the system Pcs., is made unconscious - is pushed back, therefore, into the system Ucs. And we equally speak of repression if the unconscious mental act is altogether forbidden access to the neighbouring preconscious system and is turned back at the threshold by the censorship. Thus the concept of repression involves no relation to sexuality: I must ask you to take special note of that. It indicates a purely psychological process, which we can characterize still better if we call it a 'topographical' one. By this we intend to say that it is concerned with the psychical regions which we have assumed to exist, or, if we drop this clumsy working hypothesis, with the construction of the mental apparatus out of distinct psychical systems.

[1916-1917, 3405]
This confession to a pleasure in the excretory processes, which we have learnt to recognize as one of the auto-erotic components of infantile sexuality, may be compared with the remarks made by little Hans in my 'Analysis of a Phobia in a Five-year-old Boy'. [1911c, 2402]
We are ready to recognize the fact that Silberer’s phenomena constitute a second contribution on the part of waking thought to the construction of dreams; though it is less regularly present and less significant than the first one, which has already been introduced under the name of ‘secondary revision.’ It has been shown that a part of the attention which operates during the day continues to be directed towards dreams during the state of sleep, that it keeps a check on them and criticizes them and reserves the power to interrupt them. It has seemed plausible to recognize in the mental agency which thus remains awake the censor to whom we have had to attribute such a powerful restricting influence upon the form taken by dreams. What Silberer’s observations have added to this is the fact that in certain circumstances a species of self-observation plays a part in this and makes a contribution to the content of the dream. The probable relations of this self-observing agency, which may be particularly prominent in philosophical minds, to endopsychic perception, to delusions of observation, to conscience and to the censor of dreams can be more appropriately treated elsewhere.¹

Before going into this contradiction, let us dwell for a moment on the view which the melancholic’s disorder affords of the constitution of the human ego. We see how in him one part of the ego sets itself over against the other, judges it critically, and, as it were, takes it as its object. Our suspicion that the critical agency which is here split off from the ego might also show its independence in other circumstances will be confirmed by every further observation. We shall really find grounds for distinguishing this agency from the rest of the ego. What we are here becoming acquainted with is the agency commonly called ‘conscience’; we shall count it, along with the censorship of consciousness and reality-testing, among the major institutions of the ego, and we shall come upon evidence to show that it can become diseased on its own account. In the clinical picture of melancholia, dissatisfaction with the ego on moral grounds is the most outstanding feature. The patient’s self-evaluation concerns itself much less frequently with bodily infirmity, ugliness or weakness, or with social inferiority; of this category, it is only his fears and asseverations of becoming poor that occupy a prominent position.

I told you too that we hoped that the analysis of the narcissistic disorders would give us an insight into the way in which our ego is put together and built up out of different agencies. We have already made a start with this at one point. From the analysis of delusions of observation we have drawn the conclusion that there actually exists in the ego an agency which unceasingly observes, criticizes and compares, and in that way sets itself over against the other part of the ego. We believe, therefore, that the patient is betraying a truth to us which is not yet sufficiently appreciated when he complains that he is spied upon and observed at every step he takes and that every one of his thoughts is reported and criticized. His only mistake is in regarding this uncomfortable power as something alien to him and placing it outside himself. He senses an agency holding sway in his ego which measures his actual ego and each of its activities by an ideal ego that he has created for himself in the course of his development. We believe, too, that this creation was made with the intention of re-establishing the self-satisfaction which was attached to primary infantile narcissism but which since then has suffered so many disturbances and mortifications. We know the self-observing agency as the ego-censor, the conscience; it is this that exercises the dream-censorship during the night, from which the repressions of inadmissible wishful impulses proceed. When in delusions of observation it becomes split up, it reveals to us its origin from the influences of parents, educators and social environment - from an identification with some of these model figures.

¹ [1900a, 943]

[1917e, 3045]

[1916-1917, 3472]
Little light is thrown upon the genesis of masochism by our discussion of the beating-phantasy. To begin with, there seems to be a confirmation of the view that masochism is not the manifestation of a primary instinct, but originates from sadism which has been turned round upon the self - that is to say, by means of regression from an object to the ego.¹ Instincts with a passive aim must be taken for granted as existing, especially among women. But passivity is not the whole of masochism. The characteristic of unpleasure belongs to it as well, - a bewildering accompaniment to the satisfaction of an instinct. The transformation of sadism into masochism appears to be due to the influence of the sense of guilt which takes part in the act of repression. Thus repression is operative here in three ways: it renders the consequences of the genital organization unconscious, it compels that organization itself to regress to the earlier sadistic-anal stage, and it transforms the sadism of this stage into masochism, which is passive and again in a certain sense narcissistic. The second of these three effects is made possible by the weakness of the genital organization, which must be presupposed in these cases. The third becomes necessary because the sense of guilt takes as much objection to sadism as to incestuous object-choice genitally conceived. Again, the analyses do not tell us the origin of the sense of guilt itself. It seems to be brought along by the new phase upon which the child is entering, and, if it afterwards persists, it seems to correspond to a scar-like formation which is similar to the sense of inferiority. According to our present orientation in the structure of the ego, which is as yet uncertain, we should assign it to the agency in the mind which sets itself up as a critical conscience over against the rest of the ego, which produces Silberer's functional phenomenon in dreams, and which cuts itself loose from the ego in delusions of being watched. [1919e, 3654]

The idea of the 'double' does not necessarily disappear with the passing of primary narcissism, for it can receive fresh meaning from the later stages of the ego's development. A special agency is slowly formed there, which is able to stand over against the rest of the ego, which has the function of observing and criticizing the self and of exercising a censorship within the mind, and which we become aware of as our 'conscience'. In the pathological case of delusions of being watched, this mental agency becomes isolated, dissociated from the ego, and discernible to the physician's eye. The fact that an agency of this kind exists, which is able to treat the rest of the ego like an object - the fact, that is, that man is capable of self-observation - renders it possible to invest the old idea of a 'double' with a new meaning and to ascribe a number of things to it - above all, those things which seem to self-criticism to belong to the old surmounted narcissism of earliest times.¹ [1919h, 3687]
But these melancholias also show us something else, which may be of importance for our later discussions. They show us the ego divided, fallen apart into two pieces, one of which rages against the second. This second piece is the one which has been altered by introjection and which contains the lost object. But the piece which behaves so cruelly is not unknown to us either. It comprises the conscience, a critical agency within the ego, which even in normal times takes up a critical attitude towards the ego, though never so relentlessly and so unjustifiably. On previous occasions² we have been driven to the hypothesis that some such agency develops in our ego which may cut itself off from the rest of the ego and come into conflict with it. We have called it the ‘ego ideal’, and by way of functions we have ascribed to it self-observation, the moral conscience, the censorship of dreams, and the chief influence in repression. We have said that it is the heir to the original narcissism in which the childish ego enjoyed self-sufficiency; it gradually gathers up from the influences of the environment the demands which that environment makes upon the ego and which the ego cannot always rise to; so that a man, when he cannot be satisfied with his ego itself, may nevertheless be able to find satisfaction in the ego ideal which has been differentiated out of the ego. In delusions of observation, as we have further shown, the disintegration of this agency has become patent, and has thus revealed its origin in the influence of superior powers, and above all of parents.³ But we have not forgotten to add that the amount of distance between this ego ideal and the real ego is very variable from one individual to another, and that with many people this differentiation within the ego does not go further than with children.

[1921c, 3801]

We are aware that what we have been able to contribute towards the explanation of the libidinal structure of groups leads back to the distinction between the ego and the ego ideal and to the double kind of tie which this makes possible - identification, and putting the object in the place of the ego ideal. The assumption of this kind of differentiating grade in the ego as a first step in an analysis of the ego must gradually establish its justification in the most various regions of psychology. In my paper on narcissism I have put together all the pathological material that could at the moment be used in support of this differentiation. But it may be expected that when we penetrate deeper into the psychology of the psychoses its significance will be discovered to be far greater. Let us reflect that the ego now enters into the relation of an object to the ego ideal which has been developed out of it, and that all the interplay between an external object and the ego as a whole, with which our study of the neuroses has made us acquainted, may possibly be repeated upon this new scene of action within the ego.

[1921c, 3821]
The aetiology common to the onset of a psychoneurosis and of a psychosis always remains the same. It consists in a frustration, a non-fulfilment of one of those childhood wishes which are for ever undefeated and which are so deeply rooted in our phylogenetically determined organization. This frustration is in the last resort always an external one; but in the individual case it may proceed from the internal agency (in the super-ego) which has taken over the representation of the demands of reality. The pathogenic effect depends on whether, in a conflictual tension of this kind, the ego remains true to its dependence on the external world and attempts to silence the id, or whether it lets itself be overcome by the id and thus torn away from reality. A complication is introduced into this apparently simple situation, however, by the existence of the super-ego, which, though a link that is not yet clear to us, unites in itself influences coming from the id as well as from the external world, and is to some extent an ideal model of what the whole endeavour of the ego is aiming at - a reconciliatiion between its various dependent relationships. The attitude of the super-ego should be taken into account - which has not hitherto been done - in every form of psychical illness. We may provisionally assume that there must also be illnesses which are based on a conflict between the ego and the super-ego. Analysis gives us a right to suppose that melancholia is a typical example of this group; and we would set aside the name of 'narcissistic psychoneuroses' for disorders of that kind. Nor will it clash with our impressions if we find reasons for separating states like melancholia from the other psychoses. We now see that we have been able to make our simple genetic formula more complete, without dropping it. Transference neuroses correspond to a conflict between the ego and the id; narcissistic neuroses, to a conflict between the ego and the super-ego; and psychoses, to one between the ego and the external world. It is true that we cannot tell at once whether we have really gained any new knowledge by this, or have only enriched our store of formulas; but I think that this possible application of the proposed differentiation of the mental apparatus into an ego, a super-ego and an id cannot fail to give us courage to keep that hypothesis steadily in view.

We describe one group of these patients as suffering from delusions of being observed. They complain to us that perpetually, and down to their most intimate actions, they are being molested by the observation of unknown powers - presumably persons - and that in hallucinations they hear these persons reporting the outcome of their observation: 'now he's going to say this, now he's dressing to go out' and so on. Observation of this sort is not yet the same thing as persecution, but it is not far from it; it presupposes that people distrust them, and expect to catch them carrying out forbidden actions for which they would be punished. How would it be if these insane people were right, if in each of us there is present in his ego an agency like this which observes and threatens to punish, and which in them has merely become sharply divided from their ego and mistakenly displaced into external reality?
And here is another warning, to conclude these remarks, which have certainly been exacting and not, perhaps, very illuminating. In thinking of this division of the personality into an ego, a super-ego and an id, you will not, of course, have pictured sharp frontiers like the artificial ones drawn in political geography. We cannot do justice to the characteristics of the mind by linear outlines like those in a drawing or in primitive painting, but rather by areas of colour melting into one another as they are presented by modern artists. After making the separation we must allow what we have separated to merge together once more. You must not judge too harshly a first attempt at giving a pictorial representations of something so intangible as psychical processes. It is highly probable that the development of these divisions is subject to great variations in different individuals; it is possible that in the course of actual functioning they may change and go through a temporary phase of involution. Particularly in the case of what is phylogenetically the last and most delicate of these divisions - the differentiation between the ego and the super-ego - something of the sort seems to be true. There is no question but that the same thing results from psychical illness. It is easy to imagine, too, that certain mystical practices may succeed in upsetting the normal relations between the different regions of the mind, so that, for instance, perception may be able to grasp happenings in the depths of the ego and in the id which were otherwise inaccessible to it. It may safely be doubted, however, whether this road will lead us to the ultimate truths from which salvation is to be expected. Nevertheless it may be admitted that the therapeutic efforts of psycho-analysis have chosen a similar line of approach. Its intention is, indeed, to strengthen the ego, to make it more independent of the super-ego, to widen its field of perception and enlarge its organization, so that it can appropriate fresh portions of the id. Where id was, there ego shall be. It is a work of culture - not unlike the draining of the Zuider Zee.

[1933a, 4687]
In order to remain faithful to our customary phraseology, we shall have to speak, not of transposing the psychical accent, but of displacing large amounts of cathexis. The question then is whether we are entitled to picture extensive displacements like this from one agency of the mental apparatus to another. It looks like a new hypothesis constructed ad hoc. Yet we may remind ourselves that we have repeatedly (even though not sufficiently often) taken a factor of this kind into account in our attempts at a metapsychological picture of mental events. Thus, for instance, we supposed that the difference between an ordinary erotic object-cathexis and the state of being in love is that in the latter incomparably more cathexis passes over to the object and that the ego empties itself as it were in favour of the object. In studying some cases of paranoia I was able to establish the fact that ideas of persecution are formed early and exist for a long time without any perceptible effect, until, as the result of some particular precipitating event, they receive sufficient amounts of cathexis to cause them to become dominant. The cure, too, of such paranoid attacks would lie not so much in a resolution and correction of the delusional ideas as in a withdrawal from them of the cathexis which has been lent to them. The alternations between melancholia and mania, between a cruel suppression of the ego by the super-ego and a liberation of the ego after that pressure, suggests a shift of cathexis of this kind; such a shift, moreover, would have to be brought in to explain a whole number of phenomena belonging to normal mental life. If this has been done hitherto only to a very limited extent, that is on account of our usual caution - something which deserves only praise. The region in which we feel secure is that of the pathology of mental life; it is here that we make our observations and acquire our convictions. For the present we venture to form a judgement on the normal mind only in so far as we can discern what is normal in the isolations and distortions of the pathological material. When once we have overcome this hesitancy we shall recognize what a large contribution is made to the understanding of mental processes by the static conditions as well as by the dynamic changes in the quantity of energetic cathexis.

[1927d, 4544]
Turning once more to the case of Schreber, we are bound to admit that any attempt at throwing light upon the transformation in his delusion brings us up against extraordinary difficulties. In what manner and by what means was the ascent from Flechsig to God brought about? From what source did he derive the megalomania which so fortunately enabled him to become reconciled to his persecution, or, in analytical phraseology, to accept the wishful phantasy which had had to be repressed? The Denkwürdigkeiten give us a first clue; for they show us that in the patient's mind 'Flechsig' and 'God' belonged to the same class. In one of his phantasies he overheard a conversation between Flechsig and his wife, in which the former asserted that he was 'God Flechsig', so that his wife thought he had gone mad (82). But there is another feature in the development of Schreber's delusions which claims our attention. If we take a survey of the delusions as a whole we see that the persecutor is divided into Flechsig and God; in just the same way Flechsig himself subsequently splits up into two personalities, the 'upper' and the 'middle' Flechsig, and God into the 'lower' and the 'upper' God. In the later stages of the illness the decomposition of Flechsig goes further still (193). A process of decomposition of this kind is very characteristic of paranoia. Paranoia decomposes just as hysteria condenses. Or rather, paranoia resolves once more into their elements the products of the condensations and identifications which are effected in the unconscious. The frequent repetition of the decomposing process in Schreber's case would, according to Jung, be an expression of the importance which the person in question possessed for him.¹ All of this dividing up of Flechsig and God into a number of persons thus had the same meaning as the splitting of the persecutor into Flechsig and God. They were all duplications of one and the same important relationship.² But, in order to interpret all these details, we must further draw attention to our view of this decomposition of the persecutor into Flechsig and God as a paranoid reaction to a previously established identification of the two figures or their belonging to the same class. If the persecutor Flechsig was originally a person whom Schreber loved, then God must also simply be the reappearance of some one else whom he loved, and probably some one of greater importance.

In taking the view, then, that what lies at the core of the conflict in cases of paranoia among males is a homosexual wishful phantasy of loving a man, we shall certainly not forget that the confirmation of such an important hypothesis can only follow upon the investigation of a large number of instances of every variety of paranoic disorder. We must therefore be prepared, if need be, to limit our assertion to a single type of paranoia. Nevertheless, it is a remarkable fact that the familiar principal forms of paranoia can all be represented as contradictions of the single proposition: 'I (a man) love him (a man)'; and indeed that they exhaust all the possible ways in which such contradictions could be formulated.

After this discussion of the unexpectedly important part played by homosexual wishful phantasies in paranoia, let us return to the two factors in which we expected from the first to find the distinguishing marks of paranoia, namely, the mechanism by which the symptoms are formed and the mechanism by which repression is brought about.
The most striking characteristic of symptom-formation in paranoia is the process which deserves the name of projection. An internal perception is suppressed, and, instead, its content, after undergoing a certain kind of distortion, enters consciousness in the form of an external perception. In delusions of persecution the distortion consists in a transformation of affect; what should have been felt internally as love is perceived externally as hate. We should feel tempted to regard this remarkable process as the most important element in paranoia and as being absolutely pathognomonic for it, if we were not opportunely reminded of two things. In the first place, projection does not play the same part in all forms of paranoia; and, in the second place, it makes its appearance not only in paranoia but under other psychological conditions as well, and in fact it has a regular share assigned to it in our attitude towards the external world. For when we refer the causes of certain sensations to the external world, instead of looking for them (as we do in the case of others) inside ourselves, this normal proceeding, too, deserves to be called projection. Having thus been made aware that more general psychological problems are involved in the question of the nature of projection, let us make up our minds to postpone the investigation of it (and with it that of the mechanism of paranoic symptom-formation in general) until some other occasion; and let us now turn to consider what ideas we can collect on the subject of the mechanism of repression in paranoia. I should like to say at once, in justification of this temporary renunciation, that we shall find that the manner in which the process of repression occurs is far more intimately connected with the developmental history of the libido and with the disposition to which it gives rise than is the manner in which symptoms are formed.

[1911c, 2434]

And the paranoic builds it again, not more splendid, it is true, but at least so that he can once more live in it. He builds it up by the world of his delusions. The delusional formation, which we take to be the pathological product, is in reality an attempt at recovery, a process of reconstruction. Such a reconstruction after the catastrophe is successful to a greater or lesser extent, but never wholly so; in Schreber's words, there has been a 'profound internal change' in the world. But the human subject has recaptured a relation, and often a very intense one, to the people and things in the world, even though the relation is a hostile one now, where formerly it was hopefully affectionate. We may say, then, that the process of repression proper consists in a detachment of the libido from people - and things - that were previously loved. It happens silently; we receive no intelligence of it, but can only infer it from subsequent events. What forces itself so noisily upon our attention is the process of recovery, which undoes the work of repression and brings back the libido again on to the people it had abandoned. In paranoia this process is carried out by the method of projection. It was incorrect to say that the perception which was suppressed internally is projected outwards; the truth is rather, as we now see, that what was abolished internally returns from without. The thorough examination of the process of projection which we have postponed to another occasion will clear up our remaining doubts on this subject.

[1911c, 2437]
(2) An equally plausible objection can be based upon Schreber's case history, as well as upon many others. For it can be urged that the delusions of persecution (which were directed against Flechsig) unquestionably made their appearance at an earlier date than the phantasy of the end of the world; so that what is supposed to have been a return of the repressed actually preceded the repression itself - and this is patent nonsense. In order to meet this objection we must leave the high ground of generalization and descend to the detailed consideration of actual circumstances, which are undoubtedly very much more complicated. We must admit the possibility that a detachment of the libido such as we are discussing might just as easily be a partial one, a drawing back from some single complex, as a general one. A partial detachment should be by far the commoner of the two, and should precede a general one, since to begin with it is only for a partial detachment that the influences of life provide a motive. The process may then stop at the stage of a partial detachment or it may spread to a general one, which will loudly proclaim its presence in the symptoms of megalomania. Thus the detachment of the libido from the figure of Flechsig may nevertheless have been what was primary in the case of Schreber; it was immediately followed by the appearance of the delusion, which brought back the libido on to Flechsig again (though with a negative sign to mark the fact that repression had taken place) and thus annulled the work of repression. And now the battle of repression broke out anew, but this time with more powerful weapons. In proportion as the object of contention became the most important thing in the external world, trying on the one hand to draw the whole of the libido on to itself, and on the other hand mobilizing all the resistances against itself, so the struggle raging around this single object became more and more comparable to a general engagement; till at length a victory for the forces of repression found expression in a conviction that the world had come to an end and that the self alone survived. If we review the ingenious constructions which were raised by Schreber's delusion in the domain of religion - the hierarchy of God, the proved souls, the fore-courts of Heaven, the lower and the upper God - we can gauge in retrospect the wealth of sublimations which were brought down in ruin by the catastrophe of the general detachment of his libido.

[1911c, 2439]
Other symptoms of my case of paranoia are to be described as symptoms of the return of the repressed, and they, too, like those of obsessional neurosis, bear the traces of the compromise which alone allows them to enter consciousness. Such are, for instance, my patient's delusional idea of being watched while she was undressing, her visual hallucinations, her hallucinations of sensation and her hearing of voices. In the delusional idea which I have just mentioned there is a mnemonic content which is almost unaltered and has only been made indefinite through omission. The return of the repressed in visual images approaches the character of hysteria rather than of obsessional neurosis; but hysteria is in the habit of repeating its mnemonic symbols without modification, whereas mnemonic hallucinations in paranoia undergo a distortion similar to that in obsessional neurosis: an analogous modern image takes the place of the repressed one. (E.g., the abdomen of an adult woman appears instead of a child's, and an abdomen on which the hairs are especially distinct, because they were absent in the original impression.) A thing which is quite peculiar to paranoia and on which no further light can be shed by this comparison, is that the repressed self-reproaches return in the form of thoughts spoken aloud. In the course of this process, they are obliged to submit to twofold distortion: they are subjected to a censorship, which leads to their being replaced by other, associated, thoughts or to their being concealed by an indefinite mode of expression, and they are referred to recent experiences which are no more than analogous to the old ones.

[1896b, 403]

In taking the view, then, that what lies at the core of the conflict in cases of paranoia among males is a homosexual wishful phantasy of *loving a man*, we shall certainly not forget that the confirmation of such an important hypothesis can only follow upon the investigation of a large number of instances of every variety of paranoic disorder. We must therefore be prepared, if need be, to limit our assertion to a single type of paranoia. Nevertheless, it is a remarkable fact that the familiar principal forms of paranoia can all be represented as contradictions of the single proposition: 'I (a man) love him (a man)'; and indeed that they exhaust all the possible ways in which such contradictions could be formulated.

[1911c, 2432]
(2) An equally plausible objection can be based upon Schreber’s case history, as well as upon many others. For it can be urged that the delusions of persecution (which were directed against Flechsig) unquestionably made their appearance at an earlier date than the phantasy of the end of the world; so that what is supposed to have been a return of the repressed actually preceded the repression itself - and this is patent nonsense. In order to meet this objection we must leave the high ground of generalization and descend to the detailed consideration of actual circumstances, which are undoubtedly very much more complicated. We must admit the possibility that a detachment of the libido such as we are discussing might just as easily be a partial one, a drawing back from some single complex, as a general one. A partial detachment should be by far the commoner of the two, and should precede a general one, since to begin with it is only for a partial detachment that the influences of life provide a motive. The process may then stop at the stage of a partial detachment or it may spread to a general one, which will loudly proclaim its presence in the symptoms of megalomania. Thus the detachment of the libido from the figure of Flechsig may nevertheless have been what was primary in the case of Schreber; it was immediately followed by the appearance of the delusion, which brought back the libido on to Flechsig again (though with a negative sign to mark the fact that repression had taken place) and thus annulled the work of repression. And now the battle of repression broke out anew, but this time with more powerful weapons. In proportion as the object of contention became the most important thing in the external world, trying on the one hand to draw the whole of the libido on to itself, and on the other hand mobilizing all the resistances against itself, so the struggle raging around this single object became more and more comparable to a general engagement; till at length a victory for the forces of repression found expression in a conviction that the world had come to an end and that the self alone survived. If we review the ingenious constructions which were raised by Schreber’s delusion in the domain of religion - the hierarchy of God, the proved souls, the fore-courts of Heaven, the lower and the upper God - we can gauge in retrospect the wealth of sublimations which were brought down in ruin by the catastrophe of the general detachment of his libido.

(4) It is impossible to avoid asking, in view of the close connection between the two disorders, how far this conception of paranoia will affect our conception of dementia praecox. I am of opinion that Kraepelin was entirely justified in taking the step of separating off a large part of what had hitherto been called paranoia and merging it, together with catatonia and certain other forms of disease, into a new clinical unit - though ‘dementia praecox’ was a particularly unhappy name to choose for it. The designation chosen by Bleuler for the same group of forms - ‘schizophrenia’ - is also open to the objection that the name appears appropriate only so long as we forget its literal meaning. For otherwise it prejudices the issue, since it is based on a characteristic of the disease which is theoretically postulated - a characteristic, moreover, which does not belong exclusively to that disease, and which, in the light of other considerations, cannot be regarded as the essential one. However, it is not on the whole of very great importance what names we give to clinical pictures. What seems to me more essential is that paranoia should be maintained as an independent clinical type, however frequently the picture it offers may be complicated by the presence of schizophrenic features. For, from the standpoint of the libido theory, while it would resemble dementia praecox in so far as the repression proper would in both disorders have the same principal feature - detachment of the libido, together with its regression on to the ego - it would be distinguished from dementia praecox by having its dispositional fixation differently located and by having a different mechanism for the return of the repressed (that is, for the formation of symptoms). It would seem to me the most convenient plan to give dementia praecox the name of paraphrenia. This term has no special connotation, and it would serve to indicate a relationship with paranoia (a name which cannot be changed) and would further recall hebephrenia, an entity which is now merged in dementia praecox. It is true that the name has already been proposed for other purposes; but this need not concern us, since the alternative applications have not passed into general use.
Thus the voices owed their origin to the repression of thoughts which, in the last analysis, were in fact self-reproaches about experiences that were analogous to her childhood trauma. The voices were accordingly symptoms of the return of the repressed. But they were at the same time consequences of a compromise between the resistance of the ego and the power of the returning repressed - a compromise which in this instance had brought about a distortion that went beyond recognition. In other instances in which I had occasion to analyse Frau P.'s voices, the distortion was less great. Nevertheless, the words she heard always had a quality of diplomatic indefiniteness: the insulting allusion was generally deeply hidden; the connection between the separate sentences was disguised by a strange mode of expression, unusual forms of speech and so on - characteristics which are common to the auditory hallucinations of paranoics in general and in which I see the traces of distortion through compromise. For instance, the remark, 'there goes Frau P.; she's looking for a house in the street', meant a threat that she would never recover; for I had promised her that after her treatment she would be able to go back to the small town in which her husband worked. (She had provisionally taken rooms in Vienna for a few months.)

In isolated instances Frau P. also received more definite threats - for example, in regard to her husband's relatives; yet there was still a contrast between the reserved manner in which they were expressed and the torment which the voices caused her. In view of what is known of paranoia apart from this, I am inclined to suppose that there is a gradual impairment of the resistances which weaken the self-reproaches; so that finally the defence fails altogether and the original self-reproach, the actual term of abuse, from which the subject was trying to spare himself, returns in its unaltered form. I do not know, however, whether this course of events is a constant one, or whether the censorship of the words involving the self-reproach may be absent from the beginning or may persist to the end.

Other symptoms of my case of paranoia are to be described as symptoms of the return of the repressed, and they, too, like those of obsessional neurosis, bear the traces of the compromise which alone allows them to enter consciousness. Such are, for instance, my patient's delusional idea of being watched while she was undressing, her visual hallucinations, her hallucinations of sensation and her hearing of voices. In the delusional idea which I have just mentioned there is a mnemonic content which is almost unaltered and has only been made indefinite through omission. The return of the repressed in visual images approaches the character of hysteria rather than of obsessional neurosis; but hysteria is in the habit of repeating its mnemonic symbols without modification, whereas mnemonic hallucinations in paranoia undergo a distortion similar to that in obsessional neurosis: an analogous modern image takes the place of the repressed one. (E.g., the abdomen of an adult woman appears instead of a child's, and an abdomen on which the hairs are especially distinct, because they were absent in the original impression.) A thing which is quite peculiar to paranoia and on which no further light can be shed by this comparison, is that the repressed self-reproaches return in the form of thoughts spoken aloud. In the course of this process, they are obliged to submit to twofold distortion: they are subjected to a censorship, which leads to their being replaced by other, associated, thoughts or to their being concealed by an indefinite mode of expression, and they are referred to recent experiences which are no more than analogous to the old ones.
Of the actual nature of Flechsig's enormity and its motives the patient speaks with the characteristic vagueness and obscurity which may be regarded as marks of an especially intense work of delusion-formation, if it is legitimate to judge paranoia on the model of a far more familiar mental phenomenon - the dream. Flechsig, according to the patient, committed, or attempted to commit, 'soul-murder' upon him - an act which, he thought, was comparable with the effort made by the devil or by demons to gain possession of a soul and may have had its prototype in events which occurred between members of the Flechsig and Schreber families long since deceased (22 ff.). We should be glad to learn more of the meaning of this 'soul-murder', but at this point our sources relapse once more into a tendentious silence: 'As to what constitutes the true essence of soul-murder, and as to its technique, if I may so describe it, I am able to say nothing beyond what has already been indicated. There is only this, perhaps, to be added . . . (The passage which follows is unsuitable for publication.)' (28.) As a result of this omission we are left in the dark on the question of what is meant by 'soul-murder'. We shall refer later on to the only hint upon the subject which has evaded censorship.

'But it is nowhere expressly stated that the transformation into a woman which he so much dreaded was to be carried out for the benefit of Flechsig.' - That is true; and it is not difficult to understand why, in preparing his memoirs for publication, since he was anxious not to insult the 'man Flechsig', he should have avoided so gross an accusation. But the toning-down of his language owing to these considerations did not go so far as to be able to conceal the true meaning of his accusation. Indeed, it may be maintained that after all it is expressed openly in such a passage as the following: 'In this way a conspiracy against me was brought to a head (in about March or April, 1894). Its object was to contrive that, when once my nervous complaint had been recognized as incurable or assumed to be so, I should be handed over to a certain person in such a manner that my soul should be delivered up to him, but my body . . . should be transformed into a female body, and as such surrendered to the person in question with a view to sexual abuse . . ."¹ (56). It is unnecessary to remark that no other individual is ever named who could be put in Flechsig's place. Towards the end of Schreber's stay in the clinic at Leipzig, a fear occurred to his mind that he 'was to be thrown to the attendants' for the purpose of sexual abuse (98). Any remaining doubts that we have upon the nature of the part originally attributed to the doctor are dispelled when, in the later stages of his delusion, we find Schreber outspokenly admitting his feminine attitude towards God. The other accusation against Flechsig echoes over-loudly through the book. Flechsig, he says, tried to commit soul-murder upon him. As we already know, the patient was himself not clear as to the actual nature of that crime, but it was connected with matters of discretion which precluded their publication (as we see from the suppressed third chapter). From this point a single thread takes us further. Schreber illustrates the nature of soul-murder by referring to the legends embodied in Goethe's Faust, Byron's Manfred, Weber's Freischütz, etc. (22), and one of these instances is further cited in another passage. In discussing the division of God into two persons, Schreber identifies his 'lower God' and 'upper God' with Ahriman andOrmuzd respectively (19); and a little later a casual footnote occurs: 'Moreover, the name of Ahriman also appears in connection with a soul-murder in, for example, Lord Byron's Manfred.' (20.) In the play which is thus referred to there is scarcely anything comparable to the bartering of Faust's soul, and I have searched it in vain for the expression 'soul-murder'. But the essence and the secret of the whole work lies in - an incestuous relation between a brother and a sister. And here our thread breaks off short.²

¹[1911c, 2412]
²[1911c, 2417]
One such change was the replacement of Flechsig by the superior figure of God. This seems at first as though it were a sign of aggravation of the conflict, an intensification of the unbearable persecution, but it soon becomes evident that it was preparing the way for the second change and, with it, the solution of the conflict. It was impossible for Schreber to become reconciled to playing the part of a female wanton towards his doctor; but the task of providing God Himself with the voluptuous sensations that He required called up no such resistance on the part of his ego. Emasculation was now no longer a disgrace; it became 'consonant with the Order of Things', it took its place in a great cosmic chain of events, and was instrumental in the re-creation of humanity after its extinction. 'A new race of men, born from the spirit of Schreber' would, so he thought, revere as their ancestor this man who believed himself the victim of persecution. By this means an outlet was provided which would satisfy both of the contending forces. His ego found compensation in his megalomania, while his feminine wishful phantasy made its way through and became acceptable. The struggle and the illness could cease. The patient's sense of reality, however, which had in the meantime become stronger, compelled him to postpone the solution from the present to the remote future, and to content himself with what might be described as an asymptotic wish-fulfilment.¹ Some time or other, he anticipated, his transformation into a woman would come about; until then the personality of Dr. Schreber would remain indestructible.

[1911c, 2420]
In a very similar way to the forgetting of names, the forgetting of impressions can be accompanied by faulty recollection; and this, where it finds credence, is described as paramnesia. Paramnesia in pathological cases - in paranoia it actually plays the part of a constituent factor in the formation of the delusion - has brought forth an extensive literature in which I have entirely failed to find any hint whatever as to its motivation. As this is also a subject which belongs to the psychology of the neuroses it is inappropriate to consider it in the present context. Instead, I shall describe a singular paramnesia of my own, in which the motivation provided by unconscious, repressed material and the manner and nature of the connection with this material can be recognized clearly enough. [1901b, 1230]

In a psychosis, the transforming of reality is carried out upon the psychical precipitates of former relations to it - that is, upon the memory-traces, ideas and judgements which have been previously derived from reality and by which reality was represented in the mind. But this relation was never a closed one; it was continually being enriched and altered by fresh perceptions. Thus the psychosis is also faced with the task of procuring for itself perceptions of a kind which shall correspond to the new reality; and this is most radically effected by means of hallucination. The fact that, in so many forms and cases of psychosis, the paramnesias, the delusions and the hallucinations that occur are of a most distressing character and are bound up with a generation of anxiety - this fact is without doubt a sign that the whole process of remodelling is carried through against forces which oppose it violently. We may construct the process on the model of a neurosis, with which we are more familiar. There we see that a reaction of anxiety sets in whenever the repressed instinct makes a thrust forward, and that the outcome of the conflict is only a compromise and does not provide complete satisfaction. Probably in a psychosis the rejected piece of reality constantly forces itself upon the mind, just as the repressed instinct does in a neurosis, and that is why in both cases the consequences too are the same. The elucidation of the various mechanisms which are designed, in the psychoses, to turn the subject away from reality and to reconstruct reality - this is a task for specialized psychiatric study which has not yet been taken in hand. [1924e, 4096]
(a) A striking and generally observed feature of the behaviour of paranoics is that they attach the greatest significance to the minor details of other people's behaviour which we ordinarily neglect, interpret them and make them the basis of far-reaching conclusions. For example, the last paranoic seen by me concluded that there was a general understanding in his environment, because when his train was moving out of the station the people had made a particular movement with one hand. Another noted the way people walked in the street, how they flourished their walking sticks, and so on.¹

The category of what is accidental and requires no motivation, in which the normal person includes a part of his own psychical performances and parapraxes, is thus rejected by the paranoic as far as the psychical manifestations of other people are concerned. Everything he observes in other people is full of significance, everything can be interpreted. How does he reach this position? Probably here as in so many similar cases he projects on to the mental life of other people what is unconsciously present in his own. In paranoia many sorts of things force their way through to consciousness whose presence in the unconscious of normal and neurotic people we can demonstrate only through psycho-analysis.² In a certain sense, therefore, the paranoic is justified in this, for he recognizes something that escapes the normal person: he sees more clearly than someone of normal intellectual capacity, but the displacement on to other people of the state of affairs which he recognizes renders his knowledge worthless. I hope I shall not now be expected to justify the various paranoic interpretations. But the partial justification which we concede to paranoia in respect of this view taken by it of chance actions will help us towards a psychological understanding of the sense of conviction that the paranoic attaches to all these interpretations. There is in fact some truth in them; those, too, of our errors of judgement which are not to be counted as pathological acquire their sense of conviction in just the same way. This feeling is justified for a certain part of the erroneous train of thought, or for its source of origin; and it is then extended by us to the rest of the context.

¹ From other points of view this interpretation of immaterial and accidental indications given by other people has been classed as a 'delusion of reference'.

² [1901b, 1325]
I assume that this conscious ignorance and unconscious knowledge of the motivation of accidental psychical events is one of the psychical roots of superstition. Because the superstitious person knows nothing of the motivation of his own chance actions, and because the fact of this motivation presses for a place in his field of recognition, he is forced to allocate it, by displacement, to the external world. If such a connection exists, it can hardly be limited to this single application. In point of fact I believe that a large part of the mythological view of the world, which extends a long way into the most modern religions, is nothing but psychology projected into the external world. The obscure recognition¹ (the endopsychic perception, as it were) of psychical factors and relations in the unconscious is mirrored - it is difficult to express it in other terms, and here the analogy with paranoia must come to our aid - in the construction of a supernatural reality, which is destined to be changed back once more by science into the psychology of the unconscious. One could venture to explain in this way the myths of paradise and the fall of man, of God, of good and evil, of immortality, and so on, and to transform metaphysics into metapsychology. The gap between the paranoic's displacement and that of the superstitious person is less wide than it appears at first sight. When human beings began to think, they were, as is well known, forced to explain the external world anthropomorphically by means of a multitude of personalities in their own image; chance events, which they interpreted superstitiously, were thus actions and manifestations of persons. They behaved, therefore, just like paranics, who draw conclusions from insignificant signs given them by other people, and just like all normal people, who quite rightly base their estimate of their neighbours' characters on their chance and unintentional actions. It is only in our modern, scientific but as yet by no means perfected Weltanschauung that superstition seems so very much out of place; in the Weltanschauung of pre-scientific times and peoples it was justified and consistent.

We may now claim to have made further advances in our understanding of parapraxes. We know not only that they are mental acts, in which we can detect sense and intention, not only that they come about through mutual interference between two different intentions, but beyond this we know that one of these intentions must have been in some way forced back from being put into effect before it can manifest itself as a disturbance of the other intention. It must itself have been disturbed before it can become a disturber. This does not mean, of course, that we have yet achieved a complete explanation of the phenomena which we call parapraxes. We see further questions immediately cropping up, and we suspect in general that the further our understanding goes the more occasions there will be for raising fresh questions. We may ask, for instance, why things should not be much simpler. If the intention is to force back a particular purpose instead of carrying it into effect, the forcing back should be successful, so that the purpose does not manifest itself at all; or on the other hand the forcing back might fail, so that the purpose that was to have been forced back would manifest itself completely. But parapraxes are the outcome of a compromise: they constitute a half-success and a half-failure for each of the two intentions; the intention which is being challenged is neither completely suppressed nor, apart from special cases, carried through quite unscathed. We may conclude that special conditions must prevail in order that an interference or compromise of this kind shall come about, but we can form no conception of what they can be. Nor do I think that we could discover these unknown factors by going deeper into the study of parapraxes. It will be necessary, rather, to examine first yet other obscure regions of mental life: it is only from analogies which we shall meet with there that we shall find the courage to set up the hypotheses necessary for throwing a more penetrating light upon parapraxes. And one thing more. Working from small indications, as we are constantly in the habit of doing in the present field, brings its own dangers. There is a mental disease, 'combinatory paranoia', in which the exploitation of small indications like these is carried to unlimited lengths; and I will not of course claim that conclusions built on such foundations are invariably correct. We can only be guarded against these risks by the broad basis of our observations, the repetition of similar impressions from the most varied spheres of mental life.

[1901b, 1328]

[1916-1917, 3173]
These attacks drew their material from his observation of minute indications, by which his wife's quite unconscious coquetry, unnoticeable to any one else, had betrayed itself to him. She had unintentionally touched the man sitting next her with her hand; she had turned too much towards him, or she had smiled more pleasantly than when alone with her husband. He was extraordinarily observant of all these manifestations of her unconscious, and always knew how to interpret them correctly, so that he really was always in the right about it, and could furthermore call in analysis to justify his jealousy. His abnormality really reduced itself to this, that he watched his wife's unconscious mind much more closely and then regarded it as far more important than anyone else would have thought of doing.

[1922b, 3902]

We are reminded that sufferers from persecutory paranoia act in just the same way. They, too, cannot regard anything in other people as indifferent, and they, too, take up minute indications with which these other, unknown, people present them, and use them in their delusions of reference. The meaning of their delusion of reference is that they expect from all strangers something like love. But these people show them nothing of the kind; they laugh to themselves, flourish their sticks, even spit on the ground as they go by - and one really does not do such things while a person in whom one takes a friendly interest is near. One does them only when one feels quite indifferent to the passer-by, when one can treat him like air; and, considering, too, the fundamental kinship of the concepts of 'stranger' and 'enemy', the paranoid is not so far wrong in regarding this indifference as hate, in contrast to his claim for love.

[1922b, 3903]

We begin to see that we describe the behaviour of both jealous and persecutory paranoids very inadequately by saying that they project outwards on to others what they do not wish to recognize in themselves. Certainly they do this; but they do not project it into the blue, so to speak, where there is nothing of the sort already. They let themselves be guided by their knowledge of the unconscious, and displace to the unconscious minds of others the attention which they have withdrawn from their own. Our jealous husband perceived his wife's unfaithfulness instead of his own; by becoming conscious of hers and magnifying it enormously he succeeded in keeping his own unconscious. If we accept his example as typical, we may infer that the enmity which the persecuted paranoid sees in others is the reflection of his own hostile impulses against them. Since we know that with the paranoid it is precisely the most loved person of his own sex that becomes his persecutor, the question arises where this reversal of affect takes its origin; the answer is not far to seek - the ever-present ambivalence of feeling provides its source and the non-fulfilment of his claim for love strengthens it. This ambivalence thus serves the same purpose for the persecuted paranoid as jealousy served for my patient - that of a defence against homosexuality.

[1922b, 3903]
It seems to me that we have here an important discovery - namely, that the qualitative factor, the presence of certain neurotic formations, has less practical significance than the quantitative factor, the degree of attention or, more correctly, the amount of cathexis that these structures are able to attract to themselves. Our consideration of the first case, the jealous paranoia, led to a similar estimate of the importance of the quantitative factor, by showing that there also the abnormality essentially consisted in the hypercathexis of the interpretations of someone else's unconscious. We have long known of an analogous fact in the analysis of hysteria. The pathogenic phantasies, derivatives of repressed instinctual impulses, are for a long time tolerated alongside the normal life of the mind, and have no pathogenic effect until by a revolution in the libidinal economy they receive a hypercathexis; not till then does the conflict which leads to the formation of symptoms break out. Thus as our knowledge grows we are increasingly impelled to bring the economic point of view into the foreground. I should also like to throw out the question whether this quantitative factor that I am now dwelling on does not suffice to cover the phenomena which Bleuler and others have lately proposed to name 'switching'. One need only assume that an increase in resistance in the course taken by the psychical current in one direction results in a hypercathexis of another path and thus causes the flow to be switched into that path.

[1922b, 3905]
This surprising sexualization of the state of heavenly bliss suggests the possibility that Schreber's concept of the state of bliss is derived from a condensation of the two principal meanings of the German word 'selig' - namely, 'dead' and 'sensually happy'.¹ But this instance of sexualization will also give us occasion to examine the patient's general attitude to the erotic side of life and to questions of sexual indulgence. For we psycho-analysts have hitherto supported the view that the roots of every nervous and mental disorder are chiefly to be found in the patient's sexual life - some of us merely upon empirical grounds, others influenced in addition by theoretical considerations.

[1911c, 2405]

The samples of Schreber's delusions that have already been given enable us without more ado to dismiss the suspicion that it might be precisely this paranoid disorder which would turn out to be the 'negative case' which has so long been sought for - a case in which sexuality plays only a very minor part. Schreber himself speaks again and again as though he shared our prejudice. He is constantly talking in the same breath of 'nervous disorder' and erotic lapses, as though the two things were inseparable.¹

[1911c, 2406]

These considerations therefore lend an added weight to the circumstance that we are in point of fact driven by experience to attribute to homosexual wishful phantasies an intimate (perhaps an invariable) relation to this particular form of disease. Distrusting my own experience on the subject, I have during the last few years joined with my friends C. G. Jung of Zurich and Sándor Ferenczi of Budapest in investigating upon this single point a number of cases of paranoid disorder which have come under observation. The patients whose histories provided the material for this enquiry included both men and women, and varied in race, occupation, and social standing. Yet we were astonished to find that in all of these cases defence against a homosexual wish was clearly recognizable at the very centre of the conflict which underlay the disease and that it was in an attempt to master an unconsciously reinforced current of homosexuality that they had all of them come to grief.¹ This was certainly not what we had expected. Paranoia is precisely a disorder in which a sexual aetiology is by no means obvious; far from this, the strikingly prominent features in the causation of paranoia, especially among males, are social humiliations and slights. But if we go into the matter only a little more deeply, we shall be able to see that the really operative factor in these social injuries lies in the part played in them by the homosexual components of emotional life. So long as the individual is functioning normally and it is consequently impossible to see into the depths of his mental life, we may doubt whether his emotional relations to his neighbours in society have anything to do with sexuality, either actually or in their genesis. But delusions never fail to uncover these relations and to trace back the social feelings to their roots in a directly sensual erotic wish. So long as he was healthy, Dr. Schreber, too, whose delusions culminated in a wishful phantasy of an unmistakably homosexual nature, had, by all accounts, shown no signs of homosexuality in the ordinary sense of the word.

[1911c, 2429]

In taking the view, then, that what lies at the core of the conflict in cases of paranoia among males is a homosexual wishful phantasy of loving a man, we shall certainly not forget that the confirmation of such an important hypothesis can only follow upon the investigation of a large number of instances of every variety of paranoid disorder. We must therefore be prepared, if need be, to limit our assertion to a single type of paranoia. Nevertheless, it is a remarkable fact that the familiar principal forms of paranoia can all be represented as contradictions of the single proposition: 'I (a man) love him (a man)'; and indeed that they exhaust all the possible ways in which such contradictions could be formulated.

[1911c, 2432]
Concerning the origin of the visual hallucinations, or at least of the vivid images, I learned the following. The image of the lower part of a woman's abdomen almost always coincided with the physical sensation in her own abdomen; but the latter was much more constant and often occurred without the image. The first images of a woman's abdomen had appeared in the hydropathic establishment a few hours after she had in fact seen a number of naked women at the baths; so they turned out to be simple reproductions of a real impression. It was therefore to be presumed that these impressions had been repeated only because great interest was attached to them. She told me that she had felt ashamed for these women; she herself had been ashamed to be seen naked for as long as she could remember. Since I was obliged to regard the shame as something obsessional, I concluded, in accordance with the mechanism of defence, that an experience must have been repressed here about which she had not felt ashamed. So I requested her to let the memories emerge which belonged to the theme of feeling ashamed. She promptly reproduced a series of scenes going back from her seventeenth to her eighth year, in which she had felt ashamed of being naked in her bath in front of her mother, her sister and the doctor; but the series ended in a scene at the age of six, in which she was undressing in the nursery before going to bed, without feeling any shame in front of her brother who was there. On my questioning her, it transpired that scenes like this had occurred often and that the brother and sister had for years been in the habit of showing themselves to one another naked before going to bed. I now understood the meaning of her sudden idea that she was being watched as she was going to bed. It was an unaltered piece of the old memory which involved self-reproach, and she was now making up for the shame which she had omitted to feel as a child.

[1896b, 398]

The state of permanently turning away from women produces a personal susceptibility, or, as we are accustomed to say, a 'disposition' to the formation of a delusion. The development of the mental disorder sets in at the moment when a chance impression arouses the childhood experiences which have been forgotten and which have traces, at least, of an erotic colouring. 'Arouses', however, is certainly not the right description, if we take into account what follows. We must repeat the author's accurate account in correct psychological technical terms. When Norbert Hanold saw the relief, he did not remember that he had already seen a similar posture of the foot in his childhood friend; he remembered nothing at all, but all the effects brought about by the relief originated from this link that was made with the impression of his childhood. Thus the childhood impression was stirred up, it became active, so that it began to produce effects, but it did not come into consciousness - it remained 'unconscious', to use a term which has to-day become unavoidable in psychopathology. We are anxious that this unconscious shall not be involved in any of the disputes of philosophers and natural philosophers, which have often no more than an etymological importance. For the time being we possess no better name for psychical processes which behave actively but nevertheless do not reach the consciousness of the person concerned, and that is all we mean by our 'unconsciousness'. When some thinkers try to dispute the existence of an unconscious of this kind, on the ground that it is nonsensical, we can only suppose that they have never had to do with the corresponding mental phenomena, that they are under the spell of the regular experience that everything mental that becomes active and intense becomes at the same time conscious as well, and that they have still to learn (what our author knows very well) that there are most certainly mental processes which, in spite of being intense and producing effects, none the less remain apart from consciousness.

[1907a, 1846]
The idea of being transformed into a woman was the salient feature and the earliest germ of his delusional system. It also proved to be the one part of it that persisted after his cure, and the one part that was able to retain a place in his behaviour in real life after he had recovered. 'The only thing which could appear unreasonable in the eyes of other people is the fact, already touched upon in the expert's report, that I am sometimes to be found standing before the mirror or elsewhere with the upper portion of my body bared, and wearing sundry feminine adornments, such as ribbons, false necklaces, and the like. This only occurs, I may add, when I am by myself; and never, at least so far as I am able to avoid it, in the presence of other people.' (429.) The Herr Senatspräsident confesses to this frivolity at a date (July, 1901) at which he was already in a position to express very aptly the completeness of his recovery in the region of practical life: 'I have now long been aware that the persons I see about me are not "cursorily improvised men" but real people, and that I must therefore behave towards them as a reasonable man is used to behave towards his fellows.' (409.) In contrast to the way in which he put his emasculation phantasy into action, the patient never took any steps towards inducing people to recognize his mission as Redeemer, beyond the publication of his *Denkwürdigkeiten.* [1911c, 2397]

Such then, was the result of the changes produced in Schreber by his illness, as we find them expressed in the two main features of his delusional system. Before it he had been inclined to sexual asceticism and had been a doubter in regard to God; while after it he was a believer in God and a devotee of voluptuousness. But just as his re-conquered belief in God was of a peculiar kind, so too the sexual enjoyment which he had won for himself was of a most unusual character. It was not the sexual liberty of a man, but the sexual feelings of a woman. He took up a feminine attitude towards God; he felt that he was God's wife.¹ [1911c, 2407]

No other part of his delusions is treated by the patient so exhaustively, one might almost say so insistently, as his alleged transformation into a woman. The nerves absorbed by him have, so he says, assumed in his body the character of female nerves of voluptuousness, and have given to his body a more or less female stamp, and more particularly to his skin a softness peculiar to the female sex (87). If he presses lightly with his fingers upon any part of his body, he can feel these nerves, under the surface of the skin, as a tissue of a thread-like or stringy texture; they are especially present in the region of the chest, where, in a woman, her breasts would be. 'By applying pressure to this tissue, I am able to evoke a sensation of voluptuousness such as women experience, and especially in I think of something feminine at the same time.' (277.) He knows with certainty that this tissue was originally nothing else than nerves of God, which could hardly have lost the character of nerves merely through having passed over into his body (279). By means of what he calls 'drawing' (that is, by calling up visual images) he is able to give both himself and the rays an impression that his body is fitted out with female breasts and genitals: 'It has become so much a habit with me to draw female buttocks on to my body - *honi soit qui mal y pense* - that I do it almost involuntarily every time I stoop.' (233.) He is 'bold enough to assert that anyone who should happen to see me before the mirror with the upper portion of my torso bared - especially if the illusion is assisted by my wearing a little feminine finery - would receive an unmistakable impression of a *female bust*.' (280.) He calls for a medical examination, in order to establish the fact that his whole body has nerves of voluptuousness dispersed over it from head to foot, a state of things which is only to be found, in his opinion, in the female body, whereas, in the male, to the best of his knowledge, nerves of voluptuousness exist only in the sexual organs and their immediate vicinity (274). The spiritual voluptuousness which has been developed owing to this accumulation of nerves in his body is so intense that it only requires a slight effort of his imagination (especially when he is lying in bed) to procure him a feeling of sensual well-being that affords a tolerably clear adumbration of the sexual pleasure enjoyed by a woman during copulation (269). [1911c, 2407]
If we now recall the dream which the patient had during the incubation period of his illness, before he had moved to Dresden, it will become clear beyond a doubt that his delusion of being transformed into a woman was nothing else than a realization of the content of that dream. At that time he had rebelled against the dream with masculine indignation, and in the same way he began by striving against its fulfilment in his illness and looked upon his transformation into a woman as a disgrace with which he was threatened with hostile intention. But there came a time (it was in November, 1895) when he began to reconcile himself to the transformation and bring it into harmony with the higher purposes of God: 'Since then, and with a full consciousness of what I did, I have inscribed upon my banner the cultivation of femaleness.' (177-8.)

He then arrived at the firm conviction that it was God Himself who, for His own satisfaction, was demanding femaleness from him:

In Schreber's system the two principal elements of his delusions (his transformation into a woman and his favoured relation to God) are linked in his assumption of a feminine attitude towards God. It will be an unavoidable part of our task to show that there is an essential genetic relation between these two elements. Otherwise our attempts at elucidating Schreber's delusions will leave us in the absurd position described in Kant's famous simile in the *Critique of Pure Reason* - we shall be like a man holding a sieve under a he-goat while some one else milks it.

With this object in view I shall now mention a further small piece of the case history to which sufficient weight is not given in the reports, although the patient himself has done all he can to put it in the foreground. I refer to Schreber's relations to his first physician, Geheimrat Prof. Flechsig of Leipzig.

As we already know, Schreber's case at first took the form of delusions of persecution, and did not begin to lose it until the turning-point of his illness (the time of his 'reconciliation'). From that time onwards the persecutions became less and less intolerable, and the ignominious purpose which at first underlay his threatened emasculation began to be superseded by a purpose in consonance with the Order of Things. But the first author of all these acts of persecution was Flechsig, and he remains their instigator throughout the whole course of the illness.¹

Of the actual nature of Flechsig's enormity and its motives the patient speaks with the characteristic vagueness and obscurity which may be regarded as marks of an especially intense work of delusion-formation, if it is legitimate to judge paranoia on the model of a far more familiar mental phenomenon - the dream. Flechsig, according to the patient, committed, or attempted to commit, 'soul-murder' upon him - an act which, he thought, was comparable with the effort made by the devil or by demons to gain possession of a soul and may have had its prototype in events which occurred between members of the Flechsig and Schreber families long since deceased (22 ff.). We should be glad to learn more of the meaning of this 'soul-murder', but at this point our sources relapse once more into a tendentious silence: 'As to what constitutes the true essence of soul-murder, and as to its technique, if I may so describe it, I am able to say nothing beyond what has already been indicated. There is only this, perhaps, to be added . . . (The passage which follows is unsuitable for publication.)¹ (28.) As a result of this omission we are left in the dark on the question of what is meant by 'soul-murder'. We shall refer later on to the only hint upon the subject which has evaded censorship.

¹[1911c, 2408]

[1911c, 2409]

[1911c, 2412]
Even now the voices that talk with me call out your name to me hundreds of times each day. They 
name you in certain constantly recurring connections, and especially as being the first author of the injuries 
I have suffered. And yet the personal relations which existed between us for a time have, so far as I am 
concerned, long since faded into the background; so that I myself could have little enough reason to be for 
ever recalling you to my mind, and still less for doing so with any feelings of resentment.’ (‘Open Letter to 
Professor Flechsig’, viii.)

The study of a number of cases of delusions of persecution has led me as well as other 
investigators to the view that the relation between the patient and his persecutor can be 
reduced to a simple formula.¹ It appears that the person to whom the delusion ascribes so much 
power and influence, in whose hands all the threads of the conspiracy converge, is, if he is 
definitely named, either identical with some one who played an equally important part in the 
patient's emotional life before his illness, or is easily recognizable as a substitute for him. The 
intensity of the emotion is projected in the shape of external power, while its quality is changed 
into the opposite. The person who is now hated and feared for being a persecutor was at one 
time loved and honoured. The main purpose of the persecution asserted by the patient's 
delusion is to justify the change in his emotional attitude.

Since we cannot obtain any insight into the causes of the first illness (a knowledge of which is 
undoubtedly indispensable for properly elucidating the second and severer illness) we must now 
plunge at random into an unknown concatenation of circumstances. During the incubation 
period of his illness, as we are aware (that is, between June 1893, when he was appointed to 
his new post, and the following October, when he took up his duties), he repeatedly dreamt that 
his old nervous disorder had returned. Once, moreover, when he was half asleep, he had a 
feeling that after all it must be nice to be a woman submitting to the act of copulation. The 
dreams and the phantasy are reported by Schreber in immediate succession; and if we also 
bring together their subject-matter, we shall be able to infer that, at the same time as his 
recollection of his illness, a recollection of his doctor was also aroused in his mind, and that the 
feminine attitude which he assumed in the phantasy was from the first directed towards the 
doctor. Or it may be that the dream of his illness having returned simply expressed some such 
longing as: 'I wish I could see Flechsig again!' Our ignorance of the mental content of the first 
illness bars our way in this direction. Perhaps that illness had left behind in him a feeling of 
affectonate dependence upon his doctor, which had now, for some unknown reason, become 
 intensified to the pitch of an erotic desire. This feminine phantasy which was still kept 
 impersonal, was met at once by an indignant repudiation - a true 'masculine protest', to use 
Adler's expression, but in a sense different from his.¹ But in the severe psychosis which broke 
out soon afterwards the feminine phantasy carried everything before it; and it only requires a 
slight correction of the characteristic paranoic indefiniteness of Schreber's mode of expression 
to enable us to divine the fact that the patient was in fear of sexual abuse at the hands of his 
doctor himself. The exciting cause of his illness, then, was an outburst of homosexual libido; the 
object of this libido was probably from the very first his doctor, Flechsig; and his struggles 
against the libidinal impulse produced the conflict which gave rise to the symptoms.

'Is it not an act of irresponsible levity, an indiscretion and a calumny, to charge a man of such 
high ethical standing as the former Senatspräsident Schreber with homosexuality?' - No. The 
patient has himself informed the world at large of his phantasy of being transformed into a 
woman, and he has allowed all personal considerations to be outweighed by interests of a 
higher nature. Thus he has himself given us the right to occupy ourselves with his phantasy, 
and in translating it into the technical terminology of medicine we have not made the slightest 
addition to its content.
'Yes, but he was not in his right mind when he did it. His delusion that he was being transformed into a woman was a pathological idea.' - We have not forgotten that. Indeed our only concern is with the meaning and origin of this pathological idea. We will appeal to the distinction he himself draws between the man Flechsig and the 'Flechsig soul'. We are not making reproaches of any kind against him - whether for having had homosexual impulses or for having endeavoured to suppress them. Psychiatrists should at last take a lesson from this patient, when they see him trying, in spite of his delusions, not to confuse the world of the unconscious with the world of reality.

[1911c, 2417]

'But it is nowhere expressly stated that the transformation into a woman which he so much dreaded was to be carried out for the benefit of Flechsig.' - That is true; and it is not difficult to understand why, in preparing his memoirs for publication, since he was anxious not to insult the 'man Flechsig', he should have avoided so gross an accusation. But the toning-down of his language owing to these considerations did not go so far as to be able to conceal the true meaning of his accusation. Indeed, it may be maintained that after all it is expressed openly in such a passage as the following: 'In this way a conspiracy against me was brought to a head (in about March or April, 1894). Its object was to contrive that, when once my nervous complaint had been recognized as incurable or assumed to be so, I should be handed over to a certain person in such a manner that my soul should be delivered up to him, but my body . . . should be transformed into a female body, and as such surrendered to the person in question with a view to sexual abuse . . .!" (56). It is unnecessary to remark that no other individual is ever named who could be put in Flechsig's place. Towards the end of Schreber's stay in the clinic at Leipzig, a fear occurred to his mind that he 'was to be thrown to the attendants' for the purpose of sexual abuse (98). Any remaining doubts that we have upon the nature of the part originally attributed to the doctor are dispelled when, in the later stages of his delusion, we find Schreber outspokenly admitting his feminine attitude towards God. The other accusation against Flechsig echoes over-loudly through the book. Flechsig, he says, tried to commit soul-murder upon him. As we already know, the patient was himself not clear as to the actual nature of that crime, but it was connected with matters of discretion which precluded their publication (as we see from the suppressed third chapter). From this point a single thread takes us further. Schreber illustrates the nature of soul-murder by referring to the legends embodied in Goethe's Faust, Byron's Manfred, Weber's Freischütz, etc. (22), and one of these instances is further cited in another passage. In discussing the division of God into two persons, Schreber identifies his 'lower God' and 'upper God' with Ahriman and Ormuzd respectively (19); and a little later a casual footnote occurs: 'Moreover, the name of Ahriman also appears in connection with a soul-murder in, for example, Lord Byron's Manfred.' (20.) In the play which is thus referred to there is scarcely anything comparable to the bartering of Faust's soul, and I have searched it in vain for the expression 'soul-murder'. But the essence and the secret of the whole work lies in - an incestuous relation between a brother and a sister. And here our thread breaks off short.² [1911c, 2417]
At a later stage in this paper I intend to return to a discussion of some further objections; but in the meantime I shall consider myself justified in maintaining the view that the basis of Schreber's illness was the outburst of a homosexual impulse. This hypothesis harmonizes with a noteworthy detail of the case history, which remains otherwise inexplicable. The patient had a fresh 'nervous collapse', which exercised a decisive effect upon the course of his illness, at a time when his wife was taking a short holiday on account of her own health. Up till then she had spent several hours with him every day and had taken her mid-day meal with him. But when she returned after an absence of four days, she found him most sadly altered: so much so, indeed, that he himself no longer wished to see her. 'What especially determined my mental breakdown was a particular night, during which I had a quite extraordinary number of emissions - quite half a dozen, all in that one night.' (44.) It is easy to understand that the mere presence of his wife must have acted as a protection against the attractive power of the men about him; and if we are prepared to admit that an emission cannot occur in an adult without some mental concomitant, we shall be able to supplement the patient's emissions that night by assuming that they were accompanied by homosexual phantasies which remained unconscious.

The question of why this outburst of homosexual libido overtook the patient precisely at this period (that is, between the dates of his appointment and of his move to Dresden) cannot be answered in the absence of more precise knowledge of the story of his life. Generally speaking, every human being oscillates all through his life between heterosexual and homosexual feelings, and any frustration or disappointment in the one direction is apt to drive him over into the other. We know nothing of these factors in Schreber's case, but we must not omit to draw attention to a somatic factor which may very well have been relevant. At the time of this illness Dr. Schreber was fifty-one years old, and he had therefore reached an age which is of critical importance in sexual life. It is a period at which in women the sexual function, after a phase of intensified activity, enters upon a process of far-reaching involution; nor do men appear to be exempt from its influence, for men as well as women are subject to a 'climacteric' and to the susceptibilities to disease which go along with it.¹

I can well imagine what a dubious hypothesis it must appear to be to suppose that a man's friendly feeling towards his doctor can suddenly break out in an intensified form after a lapse of eight years¹ and become the occasion of such a severe mental disorder. But I do not think we should be justified in dismissing such a hypothesis merely on account of its inherent improbability, if it recommends itself to us on other grounds; we ought rather to inquire how far we shall get if we follow it up. For the improbability may be of a passing kind and may be due to the fact that the doubtful hypothesis has not as yet been brought into relation with any other pieces of knowledge and that it is the first hypothesis with which the problem has been approached. But for the benefit of those who are unable to hold their judgement in suspense and who regard our hypothesis as altogether untenable, it is easy to suggest a possibility which would rob it of its bewildering character. The patient's friendly feeling towards his doctor may very well have been due to a process of 'transference', by means of which an emotional cathexis became transposed from some person who was important to him on to the doctor who was in reality indifferent to him; so that the doctor will have been chosen as a deputy or surrogate for some one much closer to him. To put the matter in a more concrete form: the patient was reminded of his brother or father by the figure of the doctor, he rediscovered them in him; there will then be nothing to wonder at if, in certain circumstances, a longing for the surrogate figure reappeared in him and operated with a violence that is only to be explained in the light of its origin and primary significance.
We shall therefore, I think, raise no further objections to the hypothesis that the exciting cause of the illness was the appearance in him of a feminine (that is, a passive homosexual) wishful phantasy, which took as its object the figure of his doctor. An intense resistance to this phantasy arose on the part of Schreber's personality, and the ensuing defensive struggle, which might perhaps just as well have assumed some other shape, took on, for reasons unknown to us, that of a delusion of persecution. The person he longed for now became his persecutor, and the content of his wishful phantasy became the content of his persecution. It may be presumed that the same schematic outline will turn out to be applicable to other cases of delusions of persecution. What distinguishes Schreber's case from others, however, is its further development and the transformation it underwent in the course of it.

[1911c, 2419]

One such change was the replacement of Flechsig by the superior figure of God. This seems at first as though it were a sign of aggravation of the conflict, an intensification of the unbearable persecution, but it soon becomes evident that it was preparing the way for the second change and, with it, the solution of the conflict. It was impossible for Schreber to become reconciled to playing the part of a female wanton towards his doctor; but the task of providing God Himself with the voluptuous sensations that He required called up no such resistance on the part of his ego. Emasculation was now no longer a disgrace; it became 'consonant with the Order of Things', it took its place in a great cosmic chain of events, and was instrumental in the re-creation of humanity after its extinction. 'A new race of men, born from the spirit of Schreber' would, so he thought, revere as their ancestor this man who believed himself the victim of persecution. By this means an outlet was provided which would satisfy both of the contending forces. His ego found compensation in his megalomania, while his feminine wishful phantasy made its way through and became acceptable. The struggle and the illness could cease. The patient's sense of reality, however, which had in the meantime become stronger, compelled him to postpone the solution from the present to the remote future, and to content himself with what might be described as an asymptotic wish-fulfilment.¹ Some time or other, he anticipated, his transformation into a woman would come about; until then the personality of Dr. Schreber would remain indestructible.

[1911c, 2420]

If we pursue this train of thought, which seems to be a legitimate one, we shall be driven to the conclusion that the other person must have been his father; this makes it all the clearer that Flechsig must have stood for his brother - who, let us hope, may have been older than himself.¹ The feminine phantasy, which aroused such violent opposition in the patient, thus had its root in a longing, intensified to an erotic pitch, for his father and brother. This feeling, so far as it referred to his brother, passed, by a process of transference, on to his doctor, Flechsig; and when it was carried back on to his father a settlement of the conflict was reached.

[1911c, 2422]
Thus in the case of Schreber we find ourselves once again on the familiar ground of the father-complex.¹ The patient's struggle with Flechsig became revealed to him as a conflict with God, and we must therefore construe it as an infantile conflict with the father whom he loved; the details of that conflict (of which we know nothing) are what determined the content of his delusions. None of the material which in other cases of the sort is brought to light by analysis is absent in the present one: every element is hinted at in one way or another. In infantile experiences such as this the father appears as an interferer with the satisfaction which the child is trying to obtain; this is usually of an auto-erotic character, though at a later date it is often replaced in phantasy by some other satisfaction of a less inglorious kind.² In the final stage of Schreber's delusion a magnificent victory was scored by the infantile sexual urge; for voluptuousness became God-fearing, and God Himself (his father) never tired of demanding it from him. His father's most dreaded threat, castration, actually provided the material for his wishful phantasy (at first resisted but later accepted) of being transformed into a woman. His allusion to an offence covered by the surrogate idea 'soul-murder' could not be more transparent. The chief attendant was discovered to be identical with his neighbour von W., who, according to the voices, had falsely accused him of masturbation (108). The voices said, as though giving grounds for the threat of castration: 'For you are to be represented as being given over to voluptuous excesses.'³ (127-8.) Finally, we come to the enforced thinking (47) to which the patient submitted himself because he supposed that God would believe he had become an idiot and would withdraw from him if he ceased thinking for a moment. This is a reaction (with which we are also familiar in other connections) to the threat or fear of losing one's reason� as a result of indulging in sexual practices and especially in masturbation. Considering the enormous number of delusional ideas of a hypochondriacal nature which the patient developed, no great importance should perhaps be attached to the fact that some of them coincide word for word with the hypochondriacal fears of masturbators.⁵

Perhaps I may be allowed to add a few words with a view to establishing the causes of this conflict that broke out in relation to the feminine wishful phantasy. As we know, when a wishful phantasy makes its appearance, our business is to bring it into connection with some frustration, some privation in real life. Now Schreber admits having suffered a privation of the kind. His marriage, which he describes as being in other respects a happy one, brought him no children; and in particular it brought him no son who might have consoled him for the loss of his father and brother and upon whom he might have drained off his unsatisfied homosexual affections.¹ His family line threatened to die out, and it seems that he felt no little pride in his birth and lineage. 'Both the Flechsigs and the Schrebers were members of "the highest nobility of Heaven", as the phrase went. The Schrebers in particular bore the title of "Margraves of Tuscany and Tasmania"; for souls, urged by some sort of personal vanity, have a custom of adorning themselves with somewhat high-sounding titles borrowed from this world."¹⁹ (24.) The great Napoleon obtained a divorce from Josephine (though only after severe internal struggles) because she could not propagate the dynasty.³ Dr. Schreber may have formed a phantasy that if he were a woman he would manage the business of having children more successfully; and he may thus have found his way back into the feminine attitude towards his father which he had exhibited in the earliest years of his childhood. If that were so, then his delusion that as a result of his emasculation the world was to be peopled with 'a new race of men, born from the spirit of Schreber' (288) - a delusion the realization of which he was continually postponing to a more and more remote future - would also be designed to offer him an escape from his childlessness. If the 'little men' whom Schreber himself finds so puzzling were children, then we should have no difficulty in understanding why they were collected in such great numbers on his head (158): they were in truth the 'children of his spirit'.⁴
These considerations therefore lend an added weight to the circumstance that we are in point of fact driven by experience to attribute to homosexual wishful phantasies an intimate (perhaps an invariable) relation to this particular form of disease. Distrusting my own experience on the subject, I have during the last few years joined with my friends C. G. Jung of Zurich and Sándor Ferenczi of Budapest in investigating upon this single point a number of cases of paranoid disorder which have come under observation. The patients whose histories provided the material for this enquiry included both men and women, and varied in race, occupation, and social standing. Yet we were astonished to find that in all of these cases defence against a homosexual wish was clearly recognizable at the very centre of the conflict which underlay the disease and that it was in an attempt to master an unconsciously reinforced current of homosexuality that they had all of them come to grief.¹ This was certainly not what we had expected. Paranoia is precisely a disorder in which a sexual aetiology is by no means obvious; far from this, the strikingly prominent features in the causation of paranoia, especially among males, are social humiliations and slights. But if we go into the matter only a little more deeply, we shall be able to see that the really operative factor in these social injuries lies in the part played in them by the homosexual components of emotional life. So long as the individual is functioning normally and it is consequently impossible to see into the depths of his mental life, we may doubt whether his emotional relations to his neighbours in society have anything to do with sexuality, either actually or in their genesis. But delusions never fail to uncover these relations and to trace back the social feelings to their roots in a directly sensual erotic wish. So long as he was healthy, Dr. Schreber, too, whose delusions culminated in a wishful phantasy of an unmistakably homosexual nature, had, by all accounts, shown no signs of homosexuality in the ordinary sense of the word.

¹ [1911c, 2429]

I shall now endeavour (and I think the attempt is neither unnecessary nor unjustifiable) to show that the knowledge of psychological processes, which, thanks to psycho-analysis, we now possess, already enables us to understand the part played by a homosexual wish in the development of paranoia. Recent investigations¹ have directed our attention to a stage in the development of the libido which it passes through on the way from auto-eroticism to object-love.² This stage has been given the name of narcissism. What happens is this. There comes a time in the development of the individual at which he unifies his sexual instincts (which have hitherto been engaged in auto-erotic activities) in order to obtain a love-object; and he begins by taking himself, his own body, as his love-object, and only subsequently proceeds from this to the choice of some person other than himself as his object. This half-way phase between auto-erotism and object-love may perhaps be indispensable normally; but it appears that many people linger unusually long in this condition, and that many of its features are carried over by them into the later stages of their development. What is of chief importance in the subject's self thus chosen as a love object may already be the genitals. The line of development then leads on to the choice of an external object with similar genitals - that is, to homosexual object-choice - and thence to heterosexuality. People who are manifest homosexuals in later life have, it may be presumed, never emancipated themselves from the binding condition that the object of their choice must possess genitals like their own; and in this connection the infantile sexual theories which attribute the same kind of genitals to both sexes exert much influence.

² [1911c, 2430]
In my Three Essays on the Theory of Sexuality I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoids endeavour to protect themselves against any such sexualization of their social instinctual cathexes, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) schizophrenia; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.

[1911c, 2431]

In taking the view, then, that what lies at the core of the conflict in cases of paranoia among males is a homosexual wishful phantasy of loving a man, we shall certainly not forget that the confirmation of such an important hypothesis can only follow upon the investigation of a large number of instances of every variety of paranoic disorder. We must therefore be prepared, if need be, to limit our assertion to a single type of paranoia. Nevertheless, it is a remarkable fact that the familiar principal forms of paranoia can all be represented as contradictions of the single proposition: 'I (a man) love him (a man)'; and indeed that they exhaust all the possible ways in which such contradictions could be formulated.

[1911c, 2432]

After this discussion of the unexpectedly important part played by homosexual wishful phantasies in paranoia, let us return to the two factors in which we expected from the first to find the distinguishing marks of paranoia, namely, the mechanism by which the symptoms are formed and the mechanism by which repression is brought about.

[1911c, 2433]
(1) Our first reflection will tell us that it cannot be the case that this detachment of the libido occurs exclusively in paranoia; nor can it be that, where it occurs elsewhere, it has such disastrous consequences. It is quite possible that a detachment of the libido is the essential and regular mechanism of every repression. We can have no positive knowledge on that point until the other disorders that are based upon repression have been similarly examined. But it is certain that in normal mental life (and not only in periods of mourning) we are constantly detaching our libido in this way from people or from other objects without falling ill. When Faust freed himself from the world by uttering his curses, the result was not a paranoia or any other neurosis but simply a certain general frame of mind. The detachment of the libido, therefore, cannot in itself be the pathogenic factor in paranoia; there must be some special characteristic which distinguishes a paranoic detachment of the libido from other kinds. It is not difficult to suggest what that characteristic may be. What use is made of the libido after it has been set free by the process of detachment? A normal person will at once begin looking about for a substitute for the lost attachment; and until that substitute has been found the liberated libido will be kept in suspension within his mind, and will there give rise to tensions and colour his mood. In hysteria the liberated libido becomes transformed into somatic innervations or into anxiety. But in paranoia the clinical evidence goes to show that the libido, after it has been withdrawn from the object, is put to a special use. It will be remembered that the majority of cases of paranoia exhibit traces of megalomania, and that megalomania can by itself constitute a paranoia. From this it may be concluded that in paranoia the liberated libido becomes attached to the ego, and is used for the aggrandizement of the ego. A return is thus made to the stage of narcissism (known to us from the development of the libido), in which a person’s only sexual object is his own ego. On the basis of this clinical evidence we can suppose that paranoics have brought along with them a fixation at the stage of narcissism, and we can assert that the length of the step back from sublimated homosexuality to narcissism is a measure of the amount of regression characteristic of paranoia.

[1911c, 2438]

Abraham has very convincingly shown¹ that the turning away of the libido from the external world is a particularly clearly-marked feature in dementia praecox. From this feature we infer that the repression is effected by means of detachment of the libido. Here once more we may regard the phase of violent hallucinations as a struggle between repression and an attempt at recovery by bringing the libido back again on to its objects. Jung, with extraordinary analytic acumen, has perceived that the deliria² and motor stereotypes occurring in this disorder are the residues of former object-cathexes, clung to with great persistence. This attempt at recovery, which observers mistake for the disease itself, does not, as in paranoia, make use of projection, but employs a hallucinatory (hysterical) mechanism. This is one of the two major respects in which dementia praecox differs from paranoia; and this difference can be explained genetically from another direction. The second difference is shown by the outcome of the disease in those cases where the process has not remained too restricted. The prognosis is on the whole more unfavourable than in paranoia. The victory lies with repression and not, as in the former, with reconstruction. The regression extends not merely to narcissism (manifesting itself in the shape of megalomania) but to a complete abandonment of object-love and a return to infantile auto-erotism. The dispositional fixation must therefore be situated further back than in paranoia, and must lie some where at the beginning of the course of development from auto-erotism to object-love. Moreover, it is not at all likely that homosexual impulsions, which are so frequently - perhaps invariably - to be found in paranoia, play an equally important part in the aetiology of that far more comprehensive disorder, dementia praecox.

[1911c, 2442]
Our hypotheses as to the dispositional fixations in paranoia and paraphrenia make it easy to see that a case may begin with paranoic symptoms and may yet develop into a dementia praecox, and that paranoid and schizophrenic phenomena may be combined in any proportion. And we can understand how a clinical picture such as Schreber's can come about, and merit the name of a paranoid dementia, from the fact that in its production of a wishful phantasy and of hallucinations it shows paraphrenic traits, while in its exciting cause, in its use of the mechanism of projection, and in its outcome it exhibits a paranoid character. For it is possible for several fixations to be left behind in the course of development, and each of these in succession may allow an irruption of the libido that has been pushed off - beginning, perhaps, with the later acquired fixations, and going on, as the illness develops, to the original ones that lie nearer the starting-point. We should be glad to know to what conditions the relatively favourable issue of the present case is due; for we cannot willingly attribute the whole responsibility for the outcome to anything so casual as the 'improvement due to change in domicile',¹ which set in after the patient's removal from Flechsig's clinic. But our insufficient acquaintance with the intimate circumstances of the history of the case makes it impossible to give an answer to this interesting question. It may be suspected, however, that what enabled Schreber to reconcile himself to his homosexual phantasy, and so made it possible for his illness to terminate in something approximating to a recovery, may have been the fact that his father-complex was in the main positively toned and that in real life the later years of his relationship with an excellent father had probably been unclouded.

[1911c, 2443]

The eagle, then, who makes his young look into the sun and requires of them that they shall not be dazzled by its light, is behaving as though he were himself a descendant of the sun and were submitting his children to a test of their ancestry. And when Schreber boasts that he can look into the sun unscathed and undazzled, he has rediscovered the mythological method of expressing his filial relation to the sun, and has confirmed us once again in our view that the sun is a symbol of the father. It will be remembered that during his illness Schreber gave free expression to his family pride,² and that we discovered in the fact of his childlessness a human motive for his having fallen ill with a feminine wishful phantasy. Thus the connection between his delusional privilege and the basis of his illness becomes evident.

[1911c, 2446]

It is true that psycho-analysis has taken the individual mind as its subject, but in investigating the individual it could not avoid dealing with the emotional basis of the relation of the individual to society. It has found that the social feelings invariably contain an erotic element - an element which, if it is over-emphasized and then repressed, becomes one of the marks of a particular group of mental disorders. Psycho-analysis has recognized that in general the neuroses are asocial in their nature and that they always aim at driving the individual out of society and at replacing the safe monastic seclusion of earlier days by the isolation of illness. The intense feeling of guilt which dominates so many neuroses has been shown to be a social modification of neurotic anxiety.

[1913j, 2824]
The ego ideal opens up an important avenue for the understanding of group psychology. In addition to its individual side, this ideal has a social side; it is also the common ideal of a family, a class or a nation. It binds not only a person's narcissistic libido, but also a considerable amount of his homosexual libido, which is in this way turned back into the ego. The want of satisfaction which arises from the non-fulfilment of this ideal liberates homosexual libido, and this is transformed into a sense of guilt (social anxiety). Originally this sense of guilt was a fear of punishment by the parents, or, more correctly, the fear of losing their love; later the parents are replaced by an indefinite number of fellow-men. The frequent causation of paranoia by an injury to the ego, by a frustration of satisfaction within the sphere of the ego ideal, is thus made more intelligible, as is the convergence of ideal-formation and sublimation in the ego ideal, as well as the involution of sublimations and the possible transformation of ideals in paraphrenic disorders.

[1914c, 2954]

I need hardly justify my agreement with this judgement. But the case had a special interest for me other than a merely diagnostic one. The view had already been put forward in psycho-analytic literature that patients suffering from paranoia are struggling against an intensification of their homosexual trends - a fact pointing back to a narcissistic object-choice. And a further interpretation had been made: that the persecutor is at bottom someone whom the patient loves or has loved in the past. A synthesis of the two propositions would lead us to the necessary conclusion that the persecutor must be of the same sex as the person persecuted. We did not maintain, it is true, as universally and without exception valid the thesis that paranoia is determined by homosexuality; but this was only because our observations were not sufficiently numerous; the thesis was one of those which in view of certain considerations become important only when universal application can be claimed for them. In psychiatric literature there is certainly no lack of cases in which the patient imagines himself persecuted by a person of the opposite sex. It is one thing, however, to read of such cases, and quite a different thing to come into personal contact with one of them. My own observations and analyses and those of my friends had so far confirmed the relation between paranoia and homosexuality without any difficulty. But the present case emphatically contradicted it. The girl seemed to be defending herself against love for a man by directly transforming the lover into a persecutor: there was no sign of the influence of a woman, no trace of a struggle against a homosexual attachment.

[1915f, 3058]

In these circumstances the simplest thing would have been to abandon the theory that the delusion of persecution invariably depends on homosexuality, and at the same time to abandon everything that followed from that theory. Either the theory must be given up or else, in view of this departure from our expectations, we must side with the lawyer and assume that this was no paranoic combination but an actual experience which had been correctly interpreted. But I saw another way out, by which a final verdict could for the moment be postponed. I recollected how often wrong views have been taken about people who are ill psychically, simply because the physician has not studied them thoroughly enough and has thus not learnt enough about them. I therefore said that I could not form an immediate opinion, and asked the patient to call on me a second time, when she could relate her story again at greater length and add any subsidiary details that might have been omitted. Thanks to the lawyer's influence I secured this promise from the reluctant patient; and he helped me in another way by saying that at our second meeting his presence would be unnecessary.

[1915f, 3059]
In the first place, this new information removes any doubts as to the pathological nature of her suspicion. It is easy to see that the white-haired elderly superior was a substitute for her mother, that in spite of his youth her lover had been put in the place of her father, and that it was the strength of her mother-complex which had driven the patient to suspect a love-relationship between these ill-matched partners, however unlikely such a relation might be. Moreover, this disposes of the apparent contradiction to the expectation, based on psycho-analytic theory, that the development of a delusion of persecution will turn out to be determined by an over-powerful homosexual attachment. The original persecutor - the agency whose influence the patient wishes to escape - is here again not a man but a woman. The superior knew about the girl's love affairs, disapproved of them, and showed her disapproval by mysterious hints. The patient's attachment to her own sex opposed her attempts to adopt a person of the other sex as a love-object. Her love for her mother had become the spokesman of all those tendencies which, playing the part of a 'conscience', seek to arrest a girl's first step along the new road to normal sexual satisfaction - in many respects a dangerous one; and indeed it succeeded in disturbing her relation with men.

One would think that the resistance was now definitely overcome, that the girl who until now had been bound to her mother had succeeded in coming to love a man. But after the second visit a new delusion appeared, which, by making ingenious use of some accidental circumstances, destroyed this love and thus successfully carried through the purpose of the mother-complex. It still seems strange that a woman should protect herself against loving a man by means of a paranoic delusion; but before examining this state of things more closely, let us glance at the accidental circumstances that formed the basis of this second delusion, the one aimed exclusively against the man.
Lying partly undressed on the sofa beside her lover, she heard a noise like a click or beat. She did not know its cause, but she arrived at an interpretation of it after meeting two men on the staircase, one of whom was carrying something that looked like a covered box. She became convinced that someone acting on instructions from her lover had watched and photographed her during their intimate tête à tête. I do not for a moment imagine, of course, that if the unlucky noise had not occurred the delusion would not have been formed; on the contrary, something inevitable is to be seen behind this accidental circumstance, something which was bound to assert itself compulsively in the patient, just as when she supposed that there was a liaison between her lover and the elderly superior, her mother-substitute. Among the store of unconscious phantasies of all neurotics, and probably of all human beings, there is one which is seldom absent and which can be disclosed by analysis: this is the phantasy of watching sexual intercourse between the parents. I call such phantasies - of the observation of sexual intercourse between the parents, of seduction, of castration, and others - ‘primal phantasies’; and I shall discuss in detail elsewhere their origin and their relation to individual experience. The accidental noise was thus merely playing the part of a provoking factor which activated the typical phantasy of overhearing which is a component of the parental complex. Indeed, it is doubtful whether we can rightly call the noise ‘accidental’. As Otto Rank has remarked to me, such noises are on the contrary an indispensable part of the phantasy of listening, and they reproduce either the sounds which betray parental intercourse or those by which the listening child fears to betray itself. But now we know at once where we stand. The patient’s lover was still her father, but she herself had taken her mother’s place. The part of the listener had then to be allotted to a third person. We can see by what means the girl had freed herself from her homosexual dependence on her mother. It was by means of a small piece of regression: instead of choosing her mother as a love-object, she identified herself with her - she herself became her mother. The possibility of this regression points to the narcissistic origin of her homosexual object-choice and thus to the paranoic disposition in her. One might sketch a train of thought which would bring about the same result as this identification: ‘If my mother does it, I may do it too; I’ve just as good a right as she has.’

Let us consider again the outstanding fact that the patient protected herself against her love for a man by means of a paranoic delusion. The key to the understanding of this is to be found in the history of the development of the delusion. As we might have expected, the latter was at first aimed against the woman. But now, on this paranoic basis, the advance from a female to a male object was accomplished. Such an advance is unusual in paranoia; as a rule we find that the victim of persecution remains fixated to the same persons, and therefore to the same sex to which his love-objects belonged before the paranoic transformation took place. But neurotic disorder does not preclude an advance of this kind, and our observation may be typical of many others. There are many similar processes occurring outside paranoia which have not yet been looked at from this point of view, amongst them some which are very familiar. For instance, the so-called neurasthenic’s unconscious attachment to incestuous love-objects prevents him from choosing a strange woman as his object and restricts his sexual activity to phantasy. But within the limits of phantasy he achieves the progress which is denied him, and he succeeds in replacing mother and sister by extraneous objects. Since the veto of the censorship does not come into action with these objects, he can become conscious in his phantasies of his choice of these substitute-figures.
I have said that neurotic symptoms are substitutes for sexual satisfaction, and I indicated to you that the confirmation of this assertion by the analysis of symptoms would come up against a number of difficulties. For it can only be justified if under 'sexual satisfaction' we include the satisfaction of what are called perverse sexual needs, since an interpretation of symptoms of that kind is forced upon us with surprising frequency. The claim made by homosexuals or invertors to being exceptions collapses at once when we learn that homosexual impulses are invariably discovered in every single neurotic, and that a fair number of symptoms give expression to this latent inversion. Those who call themselves homosexuals are only the conscious and manifest invertors, whose number is nothing compared to that of the latent homosexuals. We are compelled, however, to regard choice of an object of one's own sex as a divergence in erotic life which is of positively habitual occurrence, and we are learning more and more to ascribe an especially high importance to it. No doubt this does not do away with the differences between manifest homosexuality and a normal attitude; their practical significance remains, but their theoretical value is greatly diminished. We have even found that a particular disease, paranoia, which is not to be counted among the transference neuroses, regularly arises from an attempt to fend off excessively strong homosexual impulses. You will perhaps recall that one of our patients (p. 3343) behaved in her obsessional action like a man, her own husband whom she had left; neurotic women very commonly produce symptoms in this way in the character of a man. Even if this is not actually to be regarded as homosexuality, it is closely related to its preconditions.

[1916-1917, 3379]

The form of disease known as paranoia, chronic systemic insanity, occupies an unsettled position in the attempts at classification made by present-day psychiatry. There is, however, no doubt of its close affinity to dementia praecox. I once ventured to suggest that paranoia and dementia praecox should be brought together under the common designation of 'paraphrenia'. The forms of paranoia are described according to their content as megalomania, persecution mania, erotomania, delusions of jealousy, and so on. We shall not expect anything much in the way of an attempt at an explanation from psychiatry. Here is an example of one, though, it is true, one that is out of date and does not carry much weight - an attempt to derive one symptom from another by means of an intellectual rationalization: it is suggested that the patient, who, owing to a primary disposition, believes that he is being persecuted, infers from his persecution that he must be someone of quite particular importance and so develops megalomania. According to our analytic view the megalomania is the direct result of a magnification of the ego due to the drawing in of the libidinal object-cathexes - a secondary narcissism which is a return of the original early infantile one. We have, however, made a few observations of persecution mania which have induced us to follow a particular track. The first thing that struck us was that in the large majority of cases the persecutor was of the same sex as the persecuted patient. This was still open to an innocent explanation; but in a few cases that were thoroughly studied it was clear that the person of the same sex whom the patient loved most had, since his illness, been turned into his persecutor. This made a further development possible: namely, the replacement of the beloved person, along the line of familiar resemblances, by someone else - for instance, a father by a schoolmaster or by some superior. Experiences of this kind in ever increasing numbers led us to conclude that paranoia persecutoria is the form of the disease in which a person is defending himself against a homosexual impulse which has become too powerful. The change over from affection to hatred, which, it is well known, may become a serious threat to the life of the loved and hated object, corresponds in such cases to the transformation of libidinal impulses into anxiety which is a regular outcome of the process of repression. Listen, for instance, to what is, once again, the most recent instance of my observations in this connection.

[1916-1917, 3468]
A young doctor had to be expelled from the town in which he lived because he had threatened the life of the son of a university professor residing there, who had up till then been his greatest friend. He attributed really fiendish intentions and demonic power to this former friend, whom he regarded as responsible for all the misfortunes that had befallen his family in recent years, for every piece of ill-luck whether in his home or in his social life. But that was not all. He believed that this bad friend and the friend’s father, the Professor, had caused the war, too, and brought the Russians into the country. His friend had forfeited his life a thousand times, and our patient was convinced that the criminal’s death would put an end to every evil. Yet his affection for him was still so strong that it had paralysed his hand when, on one occasion, he had an opportunity of shooting down his enemy at close range. In the course of the short conversations I had with the patient, it came to light that their friendship went back far into their schooldays. Once at least it had overstepped the bounds of friendship: a night which they had spent together had been an occasion for complete sexual intercourse. Our patient had never acquired the emotional relation to women which would have corresponded to his age and his attractive personality. He had once been engaged to a beautiful young girl of good social position; but she had broken off the engagement because she found that her fiancé was without any affection. Years later, his illness broke out just at the moment when he had succeeded for the first time in satisfying a woman completely. When this woman embraced him in gratitude and devotion, he suddenly had a mysterious pain that went round the top of his head like a sharp cut. Later on he interpreted this sensation as though an incision were being made at an autopsy for exposing the brain. And as his friend had become a pathological anatomist, it slowly dawned on him that he alone could have sent this last woman to him to seduce him. From that point onwards his eyes were opened to the other persecutions to which he believed he had been made a victim by the machinations of his one-time friend.

[1916-1917, 3469]

But what about the cases in which the persecutor is not of the same sex as the patient and which appear, therefore, to contradict our explanation of their being a defence against homosexual libido? A little time ago I had an opportunity of examining such a case and was able to derive a confirmation from the apparent contradiction. A girl, who believed she was being persecuted by a man with whom she had had affectionate assignations on two occasions, had in fact first had a delusion that was directed against a woman who could be looked on as a substitute for her mother. It was only after her second assignation that she took the step of detaching the delusion from the woman and transferring it to the man. To begin with, therefore, the precondition of the persecutor being of the same sex as the patient was fulfilled in this case too. In making a complaint to a lawyer and to a doctor, the patient made no mention of this preliminary stage of her delusion and thus gave rise to an appearance of there being a contradiction of our explanation of paranoia.

[1916-1917, 3470]

Homosexual object-choice originally lies closer to narcissism than does the heterosexual kind. When it is a question, therefore, of repelling an undesirably strong homosexual impulse, the path back to narcissism is made particularly easy. Hitherto I have had very little opportunity of talking to you about the foundations of erotic life so far as we have discovered them, and it is too late now to catch up on the omission. This much, however, I can emphasize to you. Object-choice, the step forward in the development of the libido which is made after the narcissistic stage, can take place according to two different types: either according to the narcissistic type, where the subject’s own ego is replaced by another one that is as similar as possible, or according to the attachment type, where people who have become precious through satisfying the other vital needs are chosen as objects by the libido as well. A strong libidinal fixation to the narcissistic type of object-choice is to be included in the predisposition to manifest homosexuality.

[1916-1917, 3470]
The jealousy that arises from such a projection has, it is true, an almost delusional character; it is, however, amenable to the analytic work of exposing the unconscious phantasies of the subject's own infidelity. The position is worse as regards jealousy belonging to the third layer, the true delusional type. It too has its origin in repressed impulses towards unfaithfulness; but the object in these cases is of the same sex as the subject. Delusional jealousy is what is left of a homosexuality that has run its course, and it rightly takes its position among the classical forms of paranoia. As an attempt at defence against an unduly strong homosexual impulse it may, in a man, be described in the formula: "I do not love him, she loves him!"¹ In a delusional case one will be prepared to find jealousy belonging to all three layers, never to the third alone. [1922b, 3902]

The first case was that of a youngish man with a fully developed paranoia of jealousy, the object of which was his impeccably faithful wife. A stormy period in which the delusion had possessed him uninterruptedly already lay behind him. When I saw him he was only subject to clearly separated attacks, which lasted for several days and which, curiously enough, regularly appeared on the day after he had had sexual intercourse with his wife, which was, incidentally, satisfying to both of them. The inference is justified that after every satiation of the heterosexual libido the homosexual component, likewise stimulated by the act, forced an outlet for itself in the attack of jealousy. [1922b, 3902]

We begin to see that we describe the behaviour of both jealous and persecutory paranoics very inadequately by saying that they project outwards on to others what they do not wish to recognize in themselves. Certainly they do this; but they do not project it into the blue, so to speak, where there is nothing of the sort already. They let themselves be guided by their knowledge of the unconscious, and displace to the unconscious minds of others the attention which they have withdrawn from their own. Our jealous husband perceived his wife's unfaithfulness instead of his own; by becoming conscious of hers and magnifying it enormously he succeeded in keeping his own unconscious. If we accept his example as typical, we may infer that the enmity which the persecuted paranoic sees in others is the reflection of his own hostile impulses against them. Since we know that with the paranoic it is precisely the most loved person of his own sex that becomes his persecutor, the question arises where this reversal of affect takes its origin; the answer is not far to seek - the ever-present ambivalence of feeling provides its source and the non-fulfilment of his claim for love strengthens it. This ambivalence thus serves the same purpose for the persecuted paranoic as jealousy served for my patient - that of a defence against homosexuality. [1922b, 3903]

The dreams of my jealous patient presented me with a great surprise. They were not simultaneous with the outbreaks of the attacks, it is true, but they occurred within the period which was under the dominance of the delusion; yet they were completely free from delusion and they revealed the underlying homosexual impulses with no more than the usual degree of disguise. Since I had had little experience of the dreams of paranoics, it seemed plausible at the time to suppose that it was true in general that paranoia does not penetrate into dreams. [1922b, 3904]
This patient's homosexual position was easily surveyed. He had made no friendships and
developed no social interests; one had the impression that only the delusion had carried forward
the development of his relations with men, as if it had taken over some of the arrears that had
been neglected. The fact that his father was of no great importance in the family, combined with
a humiliating homosexual trauma in early boyhood, had forced his homosexuality into
repression and barred the way to its sublimation. The whole of his youth was governed by a
strong attachment to his mother. Of all her many sons he was her declared favourite, and he
developed marked jealousy of the normal type in regard to her. When later he made his choice
of a wife - mainly prompted by an impulse to enrich his mother - his longing for a virgin mother
expressed itself in obsessive doubts about his fiancée's virginity. The first years of his marriage
were free from jealousy. Then he became unfaithful to his wife and entered upon an intimate
relationship with another woman that lasted for a considerable time. Frightened by a certain
suspicion, he at length made an end of this love affair, and not until then did jealousy of the
second, projected type break out, by means of which he was able to assuage his self-
reproaches about his own unfaithfulness. It was soon complicated by an accession of
homosexual impulses, of which his father-in-law was the object, and became a fully formed
jealous paranoia.

My two cases of paranoia showed an instructive contrast in the behaviour of their dreams.
Whereas those of the first case were free from delusion, as has already been said, the other
patient produced great numbers of persecutory dreams, which may be regarded as forerunners
of or substitutes for the delusional ideas. The pursuer, whom he only managed to escape with
great fear, was usually a powerful bull or some other male symbol which even in the dream
itself he sometimes recognized as representing his father. One day he produced a very
characteristic paranoid transference-dream. He saw me shaving in front of him, and from the
scent he realized that I was using the same soap as his father had used. I was doing this in
order to oblige him to make a father-transference on to me. The choice of this incident for his
dream quite unmistakably betrays the patient's depreciatory attitude to his paranoic phantasies
and his disbelief in them; for his own eyes could tell him every day that I was never in a position
to make use of shaving-soap and that therefore there was in this respect nothing to which a
father-transference could attach itself.

Now the case in which someone first loves and then hates the same person (or the reverse)
because that person has given him cause for doing so, has obviously nothing to do with our
problem. Nor has the other case, in which feelings of love that have not yet become manifest
express themselves to begin with by hostility and aggressive tendencies; for it may be that here
the destructive component in the object-cathexis has hurried on ahead and is only later on
joined by the erotic one. But we know of several instances in the psychology of the neuroses in
which it is more plausible to suppose that a transformation does take place. In persecutory
paranoia the patient fends off an excessively strong homosexual attachment to some particular
person in a special way; and as a result this person whom he loved most becomes a
persecutor, against whom the patient directs an often dangerous aggressiveness. Here we have
a right to interpolate a previous phase which has transformed the love into hate. In the case of
the origin of homosexuality, and of desexualized social feelings as well, analytic investigation
has only recently taught us to recognize that violent feelings of rivalry are present which lead to
aggressive inclinations, and that it is only after these have been surmounted that the formerly
hated object becomes the loved one or gives rise to an identification. The question arises
whether in these instances we are to assume a direct transformation of hate into love. It is clear
that here the changes are purely internal and an alteration in the behaviour of the object plays
no part in them.

[1922b, 3904]
[1922b, 3906]
[1923b, 3977]
Among the observations made by psycho-analysis of the mental life of children there is scarcely one which sounds so repugnant and unbelievable to a normal adult as that of a boy's feminine attitude to his father and the phantasy of pregnancy that arises from it. It is only since Senatspräsident Daniel Paul Schreber, a judge presiding over a division of the Appeal Court of Saxony, published the history of his psychotic illness and his extensive recovery from it,¹ that we can discuss the subject without trepidation or apology. We learn from this invaluable book that, somewhere about the age of fifty, the Senatspräsident became firmly convinced that God - who, incidentally, exhibited distinct traits of his father, the worthy physician, Dr. Schreber - had decided to emasculate him, to use him as a woman, and to beget from him 'a new race of men born from the spirit of Schreber'. (His own marriage was childless.) In his revolt against this intention of God's, which seemed to him highly unjust and 'contrary to the Order of Things', he fell ill with symptoms of paranoia, which, however, underwent a process of involution in the course of years, leaving only a small residue behind. The gifted author of his own case history could not have guessed that in it he had uncovered a typical pathogenic factor.

[1923d, 4015]

Senatspräsident Schreber found the way to recovery when he decided to give up his resistance to castration and to accommodate himself to the feminine role cast for him by God. After this, he became lucid and calm, was able to put through his own discharge from the asylum and led a normal life - with the one exception that he devoted some hours every day to the cultivation of his femaleness, of whose gradual advance towards the goal determined by God he remained convinced.

[1923d, 4016]
The form of disease known as paranoia, chronic systematic insanity, occupies an unsettled position in the attempts at classification made by present-day psychiatry. There is, however, no doubt of its close affinity to dementia praecox. I once ventured to suggest that paranoia and dementia praecox should be brought together under the common designation of 'paraphrenia'. Listen, for instance, to what is, once again, the most recent instance of my observations in this connection.

[1916-1917, 3468]

We begin to see that we describe the behaviour of both jealous and persecutory paranoics very inadequately by saying that they project outwards on to others what they do not wish to recognize in themselves. Certainly they do this; but they do not project it into the blue, so to speak, where there is nothing of the sort already. They let themselves be guided by their knowledge of the unconscious, and displace to the unconscious minds of others the attention which they have withdrawn from their own. Our jealous husband perceived his wife's unfaithfulness instead of his own; by becoming conscious of hers and magnifying it enormously he succeeded in keeping his own unconscious. If we accept his example as typical, we may infer that the enmity which the persecuted paranoic sees in others is the reflection of his own hostile impulses against them. Since we know that with the paranoic it is precisely the most loved person of his own sex that becomes his persecutor, the question arises where this reversal of affect takes its origin; the answer is not far to seek - the ever-present ambivalence of feeling provides its source and the non-fulfilment of his claim for love strengthens it. This ambivalence thus serves the same purpose for the persecuted paranoic as jealousy served for my patient - that of a defence against homosexuality.

[1922b, 3903]
If we consider a number of analyses of obsessional neurotics we shall find it impossible to escape the impression that a relation between love and hatred such as we have found in our present patient is among the most frequent, the most marked, and probably, therefore, the most important characteristics of obsessional neurosis. But however tempting it may be to bring the problem of the 'choice of neurosis' into connection with instinctual life, there are reasons enough for avoiding such a course. For we must remember that in every neurosis we come upon the same suppressed instincts behind the symptoms. After all, hatred, kept suppressed in the unconscious by love, plays a great part in the pathogenesis of hysteria and paranoia. We know too little of the nature of love to be able to arrive at any definite conclusion here; and, in particular, the relation between the negative factor¹ in love and the sadistic components of the libido remains completely obscure. What follows is therefore to be regarded as no more than a provisional explanation. We may suppose, then, that in the cases of unconscious hatred with which we are concerned the sadistic components of love have, from constitutional causes, been exceptionally strongly developed, and have consequently undergone a premature and all too thorough suppression, and that the neurotic phenomena we have observed arise on the one hand from conscious feelings of affection which have become exaggerated as a reaction, and on the other hand from sadism persisting in the unconscious in the form of hatred.

[1909d, 2187]

We begin to see that we describe the behaviour of both jealous and persecutory paranoics very inadequately by saying that they project outwards on to others what they do not wish to recognize in themselves. Certainly they do this; but they do not project it into the blue, so to speak, where there is nothing of the sort already. They let themselves be guided by their knowledge of the unconscious, and displace to the unconscious minds of others the attention which they have withdrawn from their own. Our jealous husband perceived his wife's unfaithfulness instead of his own; by becoming conscious of hers and magnifying it enormously he succeeded in keeping his own unconscious. This ambivalence thus serves the same purpose for the persecuted paranoic as jealousy served for my patient - that of a defence against homosexuality.

[1922b, 3903]
If we consider a number of analyses of obsessional neurotics we shall find it impossible to escape the impression that a relation between love and hatred such as we have found in our present patient is among the most frequent, the most marked, and probably, therefore, the most important characteristics of obsessional neurosis. But however tempting it may be to bring the problem of the 'choice of neurosis' into connection with instinctual life, there are reasons enough for avoiding such a course. For we must remember that in every neurosis we come upon the same suppressed instincts behind the symptoms. After all, hatred, kept suppressed in the unconscious by love, plays a great part in the pathogenesis of hysteria and paranoia. We know too little of the nature of love to be able to arrive at any definite conclusion here; and, in particular, the relation between the negative factor¹ in love and the sadistic components of the libido remains completely obscure. What follows is therefore to be regarded as no more than a provisional explanation. We may suppose, then, that in the cases of unconscious hatred with which we are concerned the sadistic components of love have, from constitutional causes, been exceptionally strongly developed, and have consequently undergone a premature and all too thorough suppression, and that the neurotic phenomena we have observed arise on the one hand from conscious feelings of affection which have become exaggerated as a reaction, and on the other hand from sadism persisting in the unconscious in the form of hatred.

[1909d, 2187]

There is another possible mechanism, however, which we have come to know of by analytic investigation of the processes concerned in the change in paranoia. An ambivalent attitude is present from the outset and the transformation is effected by means of a reactive displacement of cathexis, energy being withdrawn from the erotic impulse and added to the hostile one.

[1923b, 3977]
(c) An especially prominent part is played as factors in the formation of symptoms in psychoneuroses by the component instincts, which emerge for the most part as pairs of opposites and which we have met with as introducing new sexual aims - the scopophilic instinct and exhibitionism and the active and passive forms of the instinct for cruelty. The contribution made by the last of these is essential to the understanding of the fact that symptoms involve suffering, and it almost invariably dominates a part of the patient's social behaviour. It is also through the medium of this connection between libido and cruelty that the transformation of love into hate takes place, the transformation of affectionate into hostile impulses, which is characteristic of a great number of cases of neurosis, and indeed, it would seem, of paranoia in general.

[1905d, 1491]

The form of disease known as paranoia, chronic systematic insanity, occupies an unsettled position in the attempts at classification made by present-day psychiatry. There is, however, no doubt of its close affinity to dementia praecox. I once ventured to suggest that paranoia and dementia praecox should be brought together under the common designation of 'paraphrenia'. The forms of paranoia are described according to their content as megalomania, persecution mania, erotomania, delusions of jealousy, and so on. We shall not expect anything much in the way of an attempt at an explanation from psychiatry. Here is an example of one, though, it is true, one that is out of date and does not carry much weight - an attempt to derive one symptom from another by means of an intellectual rationalization: it is suggested that the patient, who, owing to a primary disposition, believes that he is being persecuted, infers from his persecution that he must be someone of quite particular importance and so develops megalomania.

According to our analytic view the megalomania is the direct result of a magnification of the ego due to the drawing in of the libidinal object-cathexes - a secondary narcissism which is a return of the original early infantile one. We have, however, made a few observations of persecution mania which have induced us to follow a particular track. The first thing that struck us was that in the large majority of cases the persecutor was of the same sex as the persecuted patient. This was still open to an innocent explanation; but in a few cases that were thoroughly studied it was clear that the person of the same sex whom the patient loved most had, since his illness, been turned into his persecutor. This made a further development possible: namely, the replacement of the beloved person, along the line of familiar resemblances, by someone else - for instance, a father by a schoolmaster or by some superior. Experiences of this kind in ever increasing numbers led us to conclude that paranoia persecutoria is the form of the disease in which a person is defending himself against a homosexual impulse which has become too powerful. The change over from affection to hatred, which, it is well known, may become a serious threat to the life of the loved and hated object, corresponds in such cases to the transformation of libidinal impulses into anxiety which is a regular outcome of the process of repression. Listen, for instance, to what is, once again, the most recent instance of my observations in this connection.

[1916-1917, 3468]
Now the case in which someone first loves and then hates the same person (or the reverse) because that person has given him cause for doing so, has obviously nothing to do with our problem. Nor has the other case, in which feelings of love that have not yet become manifest express themselves to begin with by hostility and aggressive tendencies; for it may be that here the destructive component in the object-cathexis has hurried on ahead and is only later on joined by the erotic one. But we know of several instances in the psychology of the neuroses in which it is more plausible to suppose that a transformation does take place. In persecutory paranoia the patient fends off an excessively strong homosexual attachment to some particular person in a special way; and as a result this person whom he loved most becomes a persecutor, against whom the patient directs an often dangerous aggressiveness. Here we have a right to interpolate a previous phase which has transformed the love into hate. In the case of the origin of homosexuality, and of desexualized social feelings as well, analytic investigation has only recently taught us to recognize that violent feelings of rivalry are present which lead to aggressive inclinations, and that it is only after these have been surmounted that the formerly hated object becomes the loved one or gives rise to an identification. The question arises whether in these instances we are to assume a direct transformation of hate into love. It is clear that here the changes are purely internal and an alteration in the behaviour of the object plays no part in them.
[1923b, 3977]

There is another possible mechanism, however, which we have come to know of by analytic investigation of the processes concerned in the change in paranoia. An ambivalent attitude is present from the outset and the transformation is effected by means of a reactive displacement of cathexis, energy being withdrawn from the erotic impulse and added to the hostile one. [1923b, 3977]
We shall be glad, then, to know the nature of the girl's libidinal relations to her mother. The answer is that they are of very many different kinds. Since they persist through all three phases of infantile sexuality, they also take on the characteristics of the different phases and express themselves by oral, sadistic-anal and phallic wishes. These wishes represent active as well as passive impulses; if we relate them to the differentiation of the sexes which is to appear later - though we should avoid doing so as far as possible - we may call them masculine and feminine. Besides this, they are completely ambivalent, both affectionate and of a hostile and aggressive nature. The latter often only come to light after being changed into anxiety ideas. It is not always easy to point to a formulation of these early sexual wishes; what is most clearly expressed is a wish to get the mother with child and the corresponding wish to bear her a child - both belonging to the phallic period and sufficiently surprising, but established beyond doubt by analytic observation. The attractiveness of these investigations lies in the surprising detailed findings which they bring us. Thus, for instance, we discover the fear of being murdered or poisoned, which may later form the core of a paranoic illness, already present in this pre-Oedipus period, in relation to the mother. Or another case: you will recall an interesting episode in the history of analytic research which caused me many distressing hours. In the period in which the main interest was directed to discovering infantile sexual traumas, almost all my women patients told me that they had been seduced by their father. I was driven to recognize in the end that these reports were untrue and so came to understand that hysterical symptoms are derived from phantasies and not from real occurrences. It was only later that I was able to recognize in this phantasy of being seduced by the father the expression of the typical Oedipus complex in women. And now we find the phantasy of seduction once more in the pre-Oedipus prehistory of girls; but the seducer is regularly the mother. Here, however, the phantasy touches the ground of reality, for it was really the mother who by her activities over the child's bodily hygiene inevitably stimulated, and perhaps even roused for the first time, pleasurable sensations in her genitals.

[1933a, 4722]
If we pursue this train of thought, which seems to be a legitimate one, we shall be driven to the conclusion that the other person must have been his father; this makes it all the clearer that Flechsig must have stood for his brother - who, let us hope, may have been older than himself.¹ The feminine phantasy, which aroused such violent opposition in the patient, thus had its root in a longing, intensified to an erotic pitch, for his father and brother. This feeling, so far as it referred to his brother, passed, by a process of transference, on to his doctor, Flechsig; and when it was carried back on to his father a settlement of the conflict was reached. [1911c, 2422]

We shall not feel that we have been justified in thus introducing Schreber's father into his delusions, unless the new hypothesis shows itself of some use to us in understanding the case and in elucidating details of the delusions which are as yet unintelligible. It will be recalled that Schreber's God and his relations to Him exhibited the most curious features: how they showed the strangest mixture of blasphemous criticism and mutinous insubordination on the one hand and of reverent devotion on the other. God, according to him, had succumbed to the misleading influence of Flechsig: He was incapable of learning anything by experience, and did not understand living men because He only knew how to deal with corpses; and He manifested His power in a succession of miracles which, striking though they might be, were none the less futile and silly. [1911c, 2422]

Now the father of Senatspräsident Dr. Schreber was no insignificant person. He was the Dr. Daniel Gottlob Moritz Schreber whose memory is kept green to this day by the numerous Schreber Associations which flourish especially in Saxony; and, moreover, he was a physician. His activities in favour of promoting the harmonious upbringing of the young, of securing co-ordination between education in the home and in the school, of introducing physical culture and manual work with a view to raising the standards of health - all this exerted a lasting influence upon his contemporaries.¹ His great reputation as the founder of therapeutic gymnastics in Germany is still shown by the wide circulation of his Ärtzliche Zimmergymnastik in medical circles and the numerous editions through which it has passed. [1911c, 2423]

Such a father as this was by no means unsuitable for transfiguration into a God in the affectionate memory of the son from whom he had been so early separated by death. It is true that we cannot help feeling that there is an impassable gulf between the personality of God and that of any human being, however eminent he may be. But we must remember that this has not always been so. The gods of the peoples of antiquity stood in a closer human relationship to them. The Romans used to deify their dead emperors as a matter of routine; and the Emperor Vespasian, a sensible and competent man, exclaimed when he was first taken ill: 'Alas! Methinks I am becoming a God!'² [1911c, 2423]
We are perfectly familiar with the infantile attitude of boys towards their father; it is composed of the same mixture of reverent submission and mutinous insubordination that we have found in Schreber's relation to his God, and is the unmistakable prototype of that relation, which is faithfully copied from it. But the circumstance that Schreber's father was a physician, and a most eminent physician, and one who was no doubt highly respected by his patients, is what explains the most striking characteristics of his God and those upon which he dwells in such a critical fashion. Could more bitter scorn be shown for such a physician than by declaring that he understands nothing about living men and only knows how to deal with corpses? No doubt it is an essential attribute of God to perform miracles; but a physician performs miracles too; he effects miraculous cures, as his enthusiastic clients proclaim. So that when we see that these very miracles (the material for which was provided by the patient's hypochondria) turn out to be incredible, absurd, and to some extent positively silly, we are reminded of the assertion in my Interpretation of Dreams that absurdity in dreams expresses ridicule and derision.¹ Evidently, therefore, it is used for the same purposes in paranoia. As regards some of the other reproaches which he levelled against God, such, for instance, as that He learned nothing by experience, it is natural to suppose that they are examples of the *tu quoque* mechanism used by children,² which, when they receive a reproof, flings it back unchanged upon the person who originated it. Similarly, the voices give us grounds for suspecting that the accusation of soul-murder brought against Flechsig was in the first instance a self-accusation.³

[1911c, 2424]

Emboldened by the discovery that his father's profession helps to explain the peculiarities of Schreber's God, we shall now venture upon an interpretation which may throw some light upon the remarkable structure of that Being. The heavenly world consisted, as we know, of the 'anterior realms of God' which were also called the 'fore-courts of Heaven' and which contained the souls of the dead, and of the 'lower' and the 'upper' God, who together constituted the 'posterior realms of God' (19). Although we must be prepared to find that there is a condensation here which we shall not be able to resolve, it is nevertheless worth while referring to a clue that is already in our hands. If the 'miracled' birds, which have been shown to be girls, were originally fore-courts of Heaven, may it not be that the *anterior* realms of God and the fore-courts ¹ of Heaven are to be regarded as a symbol of what is female, and the *posterior* realms of God as a symbol of what is male? If we knew for certain that Schreber's dead brother was older than himself, we might suppose that the decomposition of God into the lower and the upper God gave expression to the patient's recollection that after his father's early death his elder brother had stepped into his place.

[1911c, 2425]
Thus in the case of Schreber we find ourselves once again on the familiar ground of the father-complex.¹ The patient's struggle with Flechsig became revealed to him as a conflict with God, and we must therefore construe it as an infantile conflict with the father whom he loved; the details of that conflict (of which we know nothing) are what determined the content of his delusions. None of the material which in other cases of the sort is brought to light by analysis is absent in the present one: every element is hinted at in one way or another. In infantile experiences such as this the father appears as an interferer with the satisfaction which the child is trying to obtain; this is usually of an auto-erotic character, though at a later date it is often replaced in phantasy by some other satisfaction of a less inglorious kind.² In the final stage of Schreber's delusion a magnificent victory was scored by the infantile sexual urge; for voluptuousness became God-fearing, and God Himself (his father) never tired of demanding it from him. His father's most dreaded threat, castration, actually provided the material for his wishful phantasy (at first resisted but later accepted) of being transformed into a woman. His allusion to an offence covered by the surrogate idea 'soul-murder' could not be more transparent. The chief attendant was discovered to be identical with his neighbour von W., who, according to the voices, had falsely accused him of masturbation (108). The voices said, as though giving grounds for the threat of castration: 'For you are to be represented as being given over to voluptuous excesses.'³ (127-8.) Finally, we come to the enforced thinking (47) to which the patient submitted himself because he supposed that God would believe he had become an idiot and would withdraw from him if he ceased thinking for a moment. This is a reaction (with which we are also familiar in other connections) to the threat or fear of losing one's reason⁴ as a result of indulging in sexual practices and especially in masturbation. Considering the enormous number of delusional ideas of a hypochondriacal nature which the patient developed, no great importance should perhaps be attached to the fact that some of them coincide word for word with the hypochondriacal fears of masturbators.⁶

We have hitherto been dealing with the father-complex, which was the dominant element in Schreber's case and with the wishful phantasy round which the illness centred. But in all of this there is nothing characteristic of the form of disease known as paranoia, nothing that might not be found (and that has not in fact been found) in other kinds of neuroses. The distinctive character of paranoia (or of dementia paranoicae) must be sought for elsewhere - namely, in the particular form assumed by the symptoms; and we shall expect to find that this is determined, not by the nature of the complexes themselves, but by the mechanism by which the symptoms are formed or by which repression is brought about. We should be inclined to say that what was characteristically paranoic about the illness was the fact that the patient, as a means of warding off a homosexual wishful phantasy, reacted precisely with delusions of persecution of this kind.⁷

¹ [1911c, 2427]
² [1911c, 2427]
³ [1911c, 2427]
⁴ [1911c, 2427]
⁵ [1911c, 2427]
⁶ [1911c, 2427]
⁷ [1911c, 2427]
Another side of the attitude of primitive peoples towards their rulers recalls a procedure which is common in neuroses generally but comes into the open in what are known as delusions of persecution. The importance of one particular person is immensely exaggerated and his absolute power is magnified to the most improbable degree, in order that it may be easier to make him responsible for everything disagreeable that the patient may experience. Savages are really behaving in just the same way with their kings when they ascribe to them power over rain and sunshine, wind and weather, and then depose them or kill them because Nature disappoints their hopes of a successful hunt or a rich harvest. The model upon which paranotics base their delusions of persecution is the relation of a child to his father. A son's picture of his father is habitually clothed with excessive powers of this kind, and it is found that distrust of the father is intimately linked with admiration for him. When a paranoic turns the figure of one of his associates into a 'persecutor', he is raising him to the rank of a father: he is putting him into a position in which he can blame him for all his misfortunes. Thus this second analogy between savages and neurotics gives us a glimpse of the truth that much of a savage's attitude to his ruler is derived from a child's infantile attitude to his father.

[1912-1913, 2696]

As regards the third and apparently sadistic phase of the beating-phantasy, I have already discussed the significance that it gains as the vehicle of the excitation impelling towards masturbation; and I have shown how it arouses activities of the imagination which on the one hand continue the phantasy along the same line, and on the other hand neutralize it through compensation. Nevertheless the second phase, the unconscious and masochistic one, in which the child itself is being beaten by its father, is incomparably the more important. This is not only because it continues to operate through the agency of the phase that takes its place; we can also detect effects upon the character, which are directly derived from its unconscious form. People who harbour phantasies of this kind develop a special sensitiveness and irritability towards anyone whom they can include in the class of fathers. They are easily offended by a person of this kind, and in that way (to their own sorrow and cost) bring about the realization of the imagined situation of being beaten by their father. I should not be surprised if it were one day possible to prove that the same phantasy is the basis of the delusional litigiousness of paranoia.

[1919e, 3655]

Among the observations made by psycho-analysis of the mental life of children there is scarcely one which sounds so repugnant and unbelievable to a normal adult as that of a boy's feminine attitude to his father and the phantasy of pregnancy that arises from it. It is only since Senatspräsident Daniel Paul Schreber, a judge presiding over a division of the Appeal Court of Saxony, published the history of his psychotic illness and his extensive recovery from it,¹ that we can discuss the subject without trepidation or apology. We learn from this invaluable book that, somewhere about the age of fifty, the Senatspräsident became firmly convinced that God - who, incidentally, exhibited distinct traits of his father, the worthy physician, Dr. Schreber - had decided to emasculate him, to use him as a woman, and to beget from him 'a new race of men born from the spirit of Schreber'. (His own marriage was childless.) In his revolt against this intention of God's, which seemed to him highly unjust and 'contrary to the Order of Things', he fell ill with symptoms of paranoia, which, however, underwent a process of involution in the course of years, leaving only a small residue behind. The gifted author of his own case history could not have guessed that in it he had uncovered a typical pathogenic factor.

[1923d, 4015]
The interest taken by the hero of the story in this relief is the basic psychological fact in the narrative. It was not immediately explicable. 'Dr. Norbert Hanold, Lecturer in Archaeology, did not in fact find in the relief anything calling for special notice from the point of view of his branch of science.' (3.)¹ 'He could not explain to himself what there was in it that had provoked his attention. He only knew that he had been attracted by something and that the effect had continued unchanged ever since.' But his imagination was occupied with the sculpture without ceasing. He found something 'of to-day' about it, as though the artist had had a glimpse in the street and captured it 'from the life'. He gave the girl thus pictured as she stepped along the name of 'Gradiva' - 'the girl who steps along'. He made up a story that she was no doubt the daughter of an aristocratic family, perhaps 'of a patrician aedile, who carried out his office in the service of Ceres', and that she was on her way to the goddess's temple. Then he found it hard to fit her quiet, calm nature into the busy life of a capital city. He convinced himself, rather, that she must be transported to Pompeii, and that somewhere there she was stepping across the curious stepping-stones which have been dug up and which made it possible to cross dry-foot from one side of the street to the other in rainy weather, though allowing carriage-wheels to pass between them as well. Her features struck him as having a Greek look and he had no doubt that she was of Hellenic origin. Little by little he brought the whole of his archaeological learning into the service of these and other phantasies relating to the original who had been the model for the relief.
[1907a, 1816]

Anyone who studies hysteria, therefore, soon finds his interest turned away from its symptoms to the phantasies from which they proceed. The technique of psycho-analysis enables us in the first place to infer from the symptoms what those unconscious phantasies are and then to make them conscious to the patient. By this means it has been found that the content of the hysteric's unconscious phantasies corresponds completely to the situations in which satisfaction is consciously obtained by perverts; and if anyone is at a loss for examples of such situations he has only to recall the world-famous performances of the Roman Emperors, the wild excesses of which were, of course, determined only by the enormous and unrestrained power possessed by the authors of the phantasies. The delusions of paranoics are phantasies of the same nature, though they are phantasies which have become directly conscious. They rest on the sadomasochistic components of the sexual instinct, and they, too, may find their complete counterpart in certain unconscious phantasies of hysterical subjects. We also know of cases - cases which have their practical importance as well - in which hysterics do not give expression to their phantasies in the form of symptoms but as conscious realizations, and in that way devise and stage assaults, attacks or acts of sexual aggression.
[1908a, 1935]
Turning once more to the case of Schreber, we are bound to admit that any attempt at throwing light upon the transformation in his delusion brings us up against extraordinary difficulties. In what manner and by what means was the ascent from Flechsig to God brought about? From what source did he derive the megalomania which so fortunately enabled him to become reconciled to his persecution, or, in analytical phraseology, to accept the wishful phantasy which had had to be repressed? The Denkwürdigkeiten give us a first clue; for they show us that in the patient's mind 'Flechsig' and 'God' belonged to the same class. In one of his phantasies he overheard a conversation between Flechsig and his wife, in which the former asserted that he was 'God Flechsig', so that his wife thought he had gone mad. But there is another feature in the development of Schreber's delusions which claims our attention. If we take a survey of the delusions as a whole we see that the persecutor is divided into Flechsig and God; in just the same way Flechsig himself subsequently splits up into two personalities, the 'upper' and the 'middle' Flechsig, and God into the 'lower' and the 'upper' God. In the later stages of the illness the decomposition of Flechsig goes further still. A process of decomposition of this kind is very characteristic of paranoia. Paranoia decomposes just as hysteria condenses. Or rather, paranoia resolves once more into their elements the products of the condensations and identifications which are effected in the unconscious. The frequent repetition of the decomposing process in Schreber's case would, according to Jung, be an expression of the importance which the person in question possessed for him. All of this dividing up of Flechsig and God into a number of persons thus had the same meaning as the splitting of the persecutor into Flechsig and God. They were all duplications of one and the same important relationship. But, in order to interpret all these details, we must further draw attention to our view of this decomposition of the persecutor into Flechsig and God as a paranoid reaction to a previously established identification of the two figures or their belonging to the same class. If the persecutor Flechsig was originally a person whom Schreber loved, then God must also simply be the reappearance of some one else whom he loved, and probably some one of greater importance.

If we pursue this train of thought, which seems to be a legitimate one, we shall be driven to the conclusion that the other person must have been his father; this makes it all the clearer that Flechsig must have stood for his brother - who, let us hope, may have been older than himself. The feminine phantasy, which aroused such violent opposition in the patient, thus had its root in a longing, intensified to an erotic pitch, for his father and brother. This feeling, so far as it referred to his brother, passed, by a process of transference, on to his doctor, Flechsig; and when it was carried back on to his father a settlement of the conflict was reached.
Perhaps I may be allowed to add a few words with a view to establishing the causes of this conflict that broke out in relation to the feminine wishful phantasy. As we know, when a wishful phantasy makes its appearance, our business is to bring it into connection with some frustration, some privation in real life. Now Schreber admits having suffered a privation of the kind. His marriage, which he describes as being in other respects a happy one, brought him no children; and in particular it brought him no son who might have consoled him for the loss of his father and brother and upon whom he might have drained off his unsatisfied homosexual affections.¹ His family line threatened to die out, and it seems that he felt no little pride in his birth and lineage. "Both the Flechtsigs and the Schrebers were members of "the highest nobility of Heaven", as the phrase went. The Schrebers in particular bore the title of "Margraves of Tuscany and Tasmania"; for souls, urged by some sort of personal vanity, have a custom of adorning themselves with somewhat high-sounding titles borrowed from this world."² The great Napoleon obtained a divorce from Josephine (though only after severe internal struggles) because she could not propagate the dynasty.³ Dr. Schreber may have formed a phantasy that if he were a woman he would manage the business of having children more successfully; and he may thus have found his way back into the feminine attitude towards his father which he had exhibited in the earliest years of his childhood. If that were so, then his delusion that as a result of his emasculation the world was to be peopled with 'a new race of men, born from the spirit of Schreber' (288) - a delusion the realization of which he was continually postponing to a more and more remote future - would also be designed to offer him an escape from his childlessness. If the 'little men' whom Schreber himself finds so puzzling were children, then we should have no difficulty in understanding why they were collected in such great numbers on his head (158): they were in truth the 'children of his spirit'.⁴

The eagle, then, who makes his young look into the sun and requires of them that they shall not be dazzled by its light, is behaving as though he were himself a descendant of the sun and were submitting his children to a test of their ancestry. And when Schreber boasts that he can look into the sun unscathed and undazzled, he has rediscovered the mythological method of expressing his filial relation to the sun, and has confirmed us once again in our view that the sun is a symbol of the father. It will be remembered that during his illness Schreber gave free expression to his family pride,² and that we discovered in the fact of his childlessness a human motive for his having fallen ill with a feminine wishful phantasy. Thus the connection between his delusional privilege and the basis of his illness becomes evident.

As regards the third and apparently sadistic phase of the beating-phantasy, I have already discussed the significance that it gains as the vehicle of the excitation impelling towards masturbation; and I have shown how it arouses activities of the imagination which on the one hand continue the phantasy along the same line, and on the other hand neutralize it through compensation. Nevertheless the second phase, the unconscious and masochistic one, in which the child itself is being beaten by its father, is incomparably the more important. This is not only because it continues to operate through the agency of the phase that takes its place; we can also detect effects upon the character, which are directly derived from its unconscious form. People who harbour phantasies of this kind develop a special sensitiveness and irritability towards anyone whom they can include in the class of fathers. They are easily offended by a person of this kind, and in that way (to their own sorrow and cost) bring about the realization of the imagined situation of being beaten by their father. I should not be surprised if it were one day possible to prove that the same phantasy is the basis of the delusional litigiousness of paranoia.

¹[1911c, 2428]
²[1919e, 3655]
Turning once more to the case of Schreber, we are bound to admit that any attempt at throwing light upon the transformation in his delusion brings us up against extraordinary difficulties. In what manner and by what means was the ascent from Flechsig to God brought about? From what source did he derive the megalomania which so fortunately enabled him to become reconciled to his persecution, or, in analytical phraseology, to accept the wishful phantasy which had had to be repressed? The Denkwürdigkeiten give us a first clue; for they show us that in the patient's mind 'Flechsig' and 'God' belonged to the same class. In one of his phantasies he overheard a conversation between Flechsig and his wife, in which the former asserted that he was 'God Flechsig', so that his wife thought he had gone mad (82). But there is another feature in the development of Schreber's delusions which claims our attention. If we take a survey of the delusions as a whole we see that the persecutor is divided into Flechsig and God; in just the same way Flechsig himself subsequently splits up into two personalities, the 'upper' and the 'middle' Flechsig, and God into the 'lower' and the 'upper' God. In the later stages of the illness the decomposition of Flechsig goes further still (193). A process of decomposition of this kind is very characteristic of paranoia. Paranoia decomposes just as hysteria condenses. Or rather, paranoia resolves once more into their elements the products of the condensations and identifications which are effected in the unconscious. The frequent repetition of the decomposing process in Schreber's case would, according to Jung, be an expression of the importance which the person in question possessed for him.¹ All of this dividing up of Flechsig and God into a number of persons thus had the same meaning as the splitting of the persecutor into Flechsig and God. They were all duplications of one and the same important relationship.² But, in order to interpret all these details, we must further draw attention to our view of this decomposition of the persecutor into Flechsig and God as a paranoid reaction to a previously established identification of the two figures or their belonging to the same class. If the persecutor Flechsig was originally a person whom Schreber loved, then God must also simply be the reappearance of some one else whom he loved, and probably some one of greater importance.

[1911c, 2421]
Since we cannot obtain any insight into the causes of the first illness (a knowledge of which is undoubtedly indispensable for properly elucidating the second and severer illness) we must now plunge at random into an unknown concatenation of circumstances. During the incubation period of his illness, as we are aware (that is, between June 1893, when he was appointed to his new post, and the following October, when he took up his duties), he repeatedly dreamt that his old nervous disorder had returned. Once, moreover, when he was half asleep, he had a feeling that after all it must be nice to be a woman submitting to the act of copulation. The dreams and the phantasy are reported by Schreber in immediate succession; and if we also bring together their subject-matter, we shall be able to infer that, at the same time as his recollection of his illness, a recollection of his doctor was also aroused in his mind, and that the feminine attitude which he assumed in the phantasy was from the first directed towards the doctor. Or it may be that the dream of his illness having returned simply expressed some such longing as: 'I wish I could see Flechsig again!' Our ignorance of the mental content of the first illness bars our way in this direction. Perhaps that illness had left behind in him a feeling of affectionate dependence upon his doctor, which had now, for some unknown reason, become intensified to the pitch of an erotic desire. This feminine phantasy which was still kept impersonal, was met at once by an indignant repudiation - a true 'masculine protest', to use Adler's expression, but in a sense different from his.¹ But in the severe psychosis which broke out soon afterwards the feminine phantasy carried everything before it; and it only requires a slight correction of the characteristic paranoic indefiniteness of Schreber's mode of expression to enable us to divine the fact that the patient was in fear of sexual abuse at the hands of his doctor himself. The exciting cause of his illness, then, was an outburst of homosexual libido; the object of this libido was probably from the very first his doctor, Flechsig; and his struggles against the libidinal impulse produced the conflict which gave rise to the symptoms.

[1911c, 2416]

Our hypotheses as to the dispositional fixations in paranoia and paraphrenia make it easy to see that a case may begin with paranoic symptoms and may yet develop into a dementia praecox, and that paranoid and schizophrenic phenomena may be combined in any proportion. And we can understand how a clinical picture such as Schreber's can come about, and merit the name of a paranoid dementia, from the fact that in its production of a wishful phantasy and of hallucinations it shows paraphrenic traits, while in its exciting cause, in its use of the mechanism of projection, and in its outcome it exhibits a paranoid character. For it is possible for several fixations to be left behind in the course of development, and each of these in succession may allow an irruption of the libido that has been pushed off - beginning, perhaps, with the later acquired fixations, and going on, as the illness develops, to the original ones that lie nearer the starting-point. We should be glad to know to what conditions the relatively favourable issue of the present case is due; for we cannot willingly attribute the whole responsibility for the outcome to anything so casual as the 'improvement due to change in domicile',¹ which set in after the patient's removal from Flechsig's clinic. But our insufficient acquaintance with the intimate circumstances of the history of the case makes it impossible to give an answer to this interesting question. It may be suspected, however, that what enabled Schreber to reconcile himself to his homosexual phantasy, and so made it possible for his illness to terminate in something approximating to a recovery, may have been the fact that his father-complex was in the main positively toned and that in real life the later years of his relationship with an excellent father had probably been unclouded.

[1911c, 2443]
The ego ideal opens up an important avenue for the understanding of group psychology. In addition to its individual side, this ideal has a social side; it is also the common ideal of a family, a class or a nation. It binds not only a person's narcissistic libido, but also a considerable amount of his homosexual libido, which is in this way turned back into the ego. The want of satisfaction which arises from the non-fulfilment of this ideal liberates homosexual libido, and this is transformed into a sense of guilt (social anxiety). Originally this sense of guilt was a fear of punishment by the parents, or, more correctly, the fear of losing their love; later the parents are replaced by an indefinite number of fellow-men. The frequent causation of paranoia by an injury to the ego, by a frustration of satisfaction within the sphere of the ego ideal, is thus made more intelligible, as is the convergence of ideal-formation and sublimation in the ego ideal, as well as the involution of sublimations and the possible transformation of ideals in paraphrenic disorders.

[1914c, 2954]
Abraham has very convincingly shown⁴ that the turning away of the libido from the external world is a particularly clearly-marked feature in dementia praecox. From this feature we infer that the repression is effected by means of detachment of the libido. Here once more we may regard the phase of violent hallucinations as a struggle between repression and an attempt at recovery by bringing the libido back again on to its objects. Jung, with extraordinary analytic acumen, has perceived that the deliria² and motor stereotypes occurring in this disorder are the residues of former object-cathexes, clung to with great persistence. This attempt at recovery, which observers mistake for the disease itself, does not, as in paranoia, make use of projection, but employs a hallucinatory (hysterical) mechanism. This is one of the two major respects in which dementia praecox differs from paranoia; and this difference can be explained genetically from another direction. The second difference is shown by the outcome of the disease in those cases where the process has not remained too restricted. The prognosis is on the whole more unfavourable than in paranoia. The victory lies with repression and not, as in the former, with reconstruction. The regression extends not merely to narcissism (manifesting itself in the shape of megalomania) but to a complete abandonment of object-love and a return to infantile auto-erotism. The dispositional fixation must therefore be situated further back than in paranoia, and must lie some where at the beginning of the course of development from auto-erotism to object-love. Moreover, it is not at all likely that homosexual impulses, which are so frequently - perhaps invariably - to be found in paranoia, play an equally important part in the aetiology of that far more comprehensive disorder, dementia praecox.

[1911c, 2442]

We have recognized our mental apparatus as being first and foremost a device designed for mastering excitations which would otherwise be felt as distressing or would have pathogenic effects. Working them over in the mind helps remarkably towards an internal draining away of excitations which are incapable of direct discharge outwards, or for which such a discharge is for the moment undesirable. In the first instance, however, it is a matter of indifference whether this internal process of working-over is carried out upon real or imaginary objects. The difference does not appear till later - if the turning of the libido on to unreal objects (introversion) has led to its being dammed up. In paraphrenics, megalomania allows of a similar internal working-over of libido which has returned to the ego; perhaps it is only when the megalomania fails that the damming-up of libido in the ego becomes pathogenic and starts the process of recovery which gives us the impression of being a disease.

[1914c, 2940]
I shall try here to penetrate a little further into the mechanism of paraphrenia and shall bring together those views which already seem to me to deserve consideration. The difference between paraphrenic affections and the transference neuroses appears to me to lie in the circumstance that, in the former, the libido that is liberated by frustration does not remain attached to objects in phantasy, but withdraws on to the ego. Megalomania would accordingly correspond to the psychical mastering of this latter amount of libido, and would thus be the counterpart of the introversion on to phantasies that is found in the transference neuroses; a failure of this psychical function gives rise to the hypochondria of paraphrenia and this is homologous to the anxiety of the transference neuroses. We know that this anxiety can be resolved by further psychical working over, i.e. by conversion, reaction-formation or the construction of protections (phobias). The corresponding process in paraphrenics is an attempt at restoration, to which the striking manifestations of the disease are due. Since paraphrenia frequently, if not usually, brings about only a partial detachment of the libido from objects, we can distinguish three groups of phenomena in the clinical picture: (1) those representing what remains of a normal state or of neurosis (residual phenomena); (2) those representing the morbid process (detachment of libido from its objects and, further, megalomania, hypochondria, affective disturbance and every kind of regression); (3) those representing restoration, in which the libido is once more attached to objects, after the manner of a hysteria (in dementia praecox or paraphrenia proper), or of an obsessional neurosis (in paranoia). This fresh libidinal cathexis differs from the primary one in that it starts from another level and under other conditions. The difference between the transference neuroses brought about in the case of this fresh kind of libidinal cathexis and the corresponding formations where the ego is normal should be able to afford us the deepest insight into the structure of our mental apparatus.

The clinical picture of dementia praecox (which, incidentally, is very changeable) is not determined exclusively by the symptoms arising from the forcing away of the libido on objects and its accumulation in the ego as narcissistic libido. A large part, rather, is played by other phenomena, which are derived from efforts of the libido to attain objects once more and which thus correspond to an attempt at restitution or recovery. These latter symptoms are indeed the more striking and noisy; they exhibit an undeniable resemblance to those of hysteria or, less frequently, of obsessional neurosis, but nevertheless differ from them in every respect. It seems as though in dementia praecox the libido, in its efforts once more to reach objects (that is, the presentations of objects), does in fact snatch hold something of them, but, as it were, only their shadows - I mean the word-presentations belonging to them. I cannot say more about this now, but I believe that this behaviour of the libido as it strives to find its way back has enabled us to obtain an insight into what really constitutes the difference between a conscious and an unconscious idea.

I can do so in a few words, and you will see how simply the riddle can be solved and how well everything fits together. Observation shows that sufferers from narcissistic neuroses have no capacity for transference or only insufficient residues of it. They reject the doctor, not with hostility but with indifference. For that reason they cannot be influenced by him either; what he says leaves them cold, makes no impression on them; consequently the mechanism of cure which we carry through with other people - the revival of the pathogenic conflict and the overcoming of the resistance due to repression - cannot be operated with them. They remain as they are. Often they have already undertaken attempts at recovery on their own account which have led to pathological results. We cannot alter this in any way.
Narcissism. - A decisive advance was made when the analysis of dementia praecox and other psychotic disorders was ventured upon and thus the examination was begun of the ego itself, which had so far been known only as the agency of repression and opposition. It was found that the pathogenic process in dementia praecox is the withdrawal of the libido from objects and its introduction into the ego, while the clamorous symptoms of the disease arise from the vain struggles of the libido to find a pathway back to objects. It thus turned out to be possible for object-libido to change into cathexis of the ego and vice versa. Further reflection showed that this process must be presumed to occur on the largest scale and that the ego is to be regarded as a great reservoir of libido from which libido is sent out to objects and which is always ready to absorb libido flowing back from objects. Thus the instincts of self-preservation were also of a libidinal nature: they were sexual instincts which, instead of external objects, had taken the subject's own ego as an object. Clinical experience had made us familiar with people who behaved in a striking fashion as though they were in love with themselves and this perversion had been given the name of narcissism. The libido of the self-preservative instincts was now described as narcissistic libido and it was recognized that a high degree of this self-love constituted the primary and normal state of things. The earlier formula laid down for the transference neuroses consequently required to be modified, though not corrected. It was better, instead of speaking of a conflict between sexual instincts and ego instincts, to speak of a conflict between object-libido and ego-libido, or, since the nature of these instincts was the same, between the object-cathexes and the ego.

[1923a, 3933]

We know that other forms of psychosis, the schizophrenias, are inclined to end in affective hebetude - that is, in a loss of all participation in the external world. In regard to the genesis of delusions, a fair number of analyses have taught us that the delusion is found applied like a patch over the place where originally a rent had appeared in the ego's relation to the external world. If this precondition of a conflict with the external world is not much more noticeable to us than it now is, that is because, in the clinical picture of the psychosis, the manifestations of the pathogenic process are often overlaid by manifestations of an attempt at a cure or a reconstruction.

[1924b, 4067]
I did my best to get rid of this 'retention hysteria' by getting her to reproduce all her agitating experiences and to abreact them after the event. I made her abuse her uncle, lecture him, tell him the unvarnished truth, and so on, and this treatment did her good. Unfortunately, however, she was living in Vienna under very unfavourable conditions. She had no luck with her relatives. She was being put up by another uncle, who treated her in a friendly way; but for that very reason her aunt took a dislike to her. This woman suspected that her husband had a deeper interest in his niece, and therefore chose to make her stay in Vienna as disagreeable as possible. The aunt herself in her youth had been obliged to give up a desire for an artistic career and envied her niece for being able to cultivate her talent, though in the girl's case it was not her desire but her need for independence that had determined her decision. Rosalie felt so constrained in the house that she did not venture, for instance, to sing or play the piano while her aunt was within earshot and carefully avoided singing or playing to her uncle (who, incidentally, was an old man, her mother's brother) when there was a possibility of her aunt coming in. While I was trying to wipe out the traces of old agitations, new ones arose out of these relations with her host and hostess, which eventually interfered with the success of my treatment as well as bringing it to a premature end.

AFTER-EFFECTS OF INFANTILE OBJECT-CHOICE

Even a person who has been fortunate enough to avoid an incestuous fixation of his libido does not entirely escape its influence. It often happens that a young man falls in love seriously for the first time with a mature woman, or a girl with an elderly man in a position of authority; this is clearly an echo of the phase of development that we have been discussing, since these figures are able to re-animate pictures of their mother or father.¹ There can be no doubt that every object-choice whatever is based, though less closely, on these prototypes. A man, especially, looks for someone who can represent his picture of his mother, as it has dominated his mind from his earliest childhood; and accordingly, if his mother is still alive, she may well resent this new version of herself and meet her with hostility. In view of the importance of a child's relations to his parents in determining his later choice of a sexual object, it can easily be understood that any disturbance of those relations will produce the gravest effects upon his adult sexual life. Jealousy in a lover is never without an infantile root or at least an infantile reinforcement. If there are quarrels between the parents or if their marriage is unhappy, the ground will be prepared in their children for the severest predisposition to a disturbance of sexual development or to a neurotic illness.
The technique of distortion by ellipsis seems to be typical of obsessional neuroses; I have come across it in the obsessional thoughts of other patients as well. One example, a particularly transparent one, is of especial interest on account of a certain structural similarity with the rat idea. It was a case of doubting, and occurred in a lady who suffers principally from obsessional acts. This lady was going for a walk with her husband in Nuremberg, and made him take her into a shop, where she purchased various objects for her child and amongst them a comb. Her husband, finding that the shopping was too long a business for his taste, said that he had noticed some coins in an antique shop on the way which he was anxious to secure, adding that after he had made his purchase he would come and fetch her in the shop in which they at present were. But he stayed away, as she thought, far too long. When he came back she accordingly asked him where he had been. 'Why,' he replied, 'at the antique shop I told you about.' At the same instant she was seized by a tormenting doubt whether she had not as a matter of fact always possessed the comb which she had just bought for her child. She was naturally quite unable to discover the simple mental link that was involved. There is nothing for it but to regard the doubt as having become displaced, and to reconstruct the complete chain of unconscious thoughts as follows: 'If it is true that you were only at the antique shop, if I am really to believe that, then I may just as well believe that this comb that I bought a moment ago has been in my possession for years.' Here, therefore, the lady was drawing a derisive and ironical parallel, just as when our patient thought: 'Oh yes, as sure as those two' (his father and the lady) 'will have children, I shall pay back the money to A.' In the lady's case the doubt was dependent upon her unconscious jealousy, which led her to suppose that her husband had spent the interval of his absence in paying a visit of gallantry.

[1909d, 2177]

You will recall that at our first meeting of the present academic year I described a case to you of a woman suffering from delusions of jealousy. Now that we are so near its end you would no doubt like to hear how delusions are explained by psycho-analysis. But I have less to tell you about that than you expect. The fact that a delusion cannot be shaken by logical arguments or real experiences is explained in the same way as in the case of an obsession - by its relation to the unconscious, which is represented and held down by the delusion or by the obsession. The difference between the two is based on the difference between the topography and dynamics of the two illnesses.

[1916-1917, 3471]

Jealousy is one of those affective states, like grief, that may be described as normal. If anyone appears to be without it, the inference is justified that it has undergone severe repression and consequently plays all the greater part in his unconscious mental life. The instances of abnormally intense jealousy met with in analytic work reveal themselves as constructed of three layers. The three layers or grades of jealousy may be described as (1) competitive or normal, (2) projected, and (3) delusional jealousy.

[1922b, 3900]
There is not much to be said from the analytic point of view. It is easy to see that essentially it
is compounded of grief, the pain caused by the thought of losing the loved object, and of the
narcissistic wound, in so far as this is distinguishable from the other wound; further, of feelings
of enmity against the successful rival, and of a greater or lesser amount of self-criticism which
tries to hold the subject's own ego accountable for his loss. Although we may call it normal, this
jealousy is by no means completely rational, that is, derived from the actual situation,
proportionate to the real circumstances and under the complete control of the conscious ego;
for it is rooted deep in the unconscious, it is a continuation of the earliest stirrings of the child's
affective life, and it originates in the Oedipus or brother-and-sister complex of the first sexual
period. Moreover, it is noteworthy that in some people it is experienced bisexually. That is to
say, a man will not only feel pain about the woman he loves and hatred of the man who is his
rival, but also grief about the man, whom he loves unconsciously, and hatred of the woman as
his rival; and this latter set of feelings will add to the intensity of his jealousy. I even know of a
man who suffered exceedingly during his attacks of jealousy and who, according to his own
account, went through unendurable torments by consciously imagining himself in the position of
the faithless woman. The sensation of helplessness which then came over him and the images
he used to describe his condition - exposed to the vulture's beak like Prometheus, or thrown
bound into a nest of serpents - were referred by him to impressions received during several
homosexual acts of aggression to which he had been subjected as a boy.

The jealousy of the second layer, projected jealousy, is derived in both men and women either
from their own actual unfaithfulness in real life or from impulses towards it which have
succumbed to repression. It is a matter of everyday experience that fidelity, especially that
degree of it required in marriage, is only maintained in the face of continual temptations. Anyone
who denies these temptations in himself will nevertheless feel their pressure so strongly that he
will be glad enough to make use of an unconscious mechanism to alleviate his situation. He can
obtain this alleviation - and, indeed, acquittal by his conscience - if he projects his own impulses
to faithlessness on to the partner to whom he owes faith. This strong motive can then make use
of the perceptual material which betrays unconscious impulses of the same kind in the partner,
and the subject can justify himself with the reflection that the other is probably not much better
than he is himself.¹

Social conventions have wisely taken this universal state of things into account, by granting a
certain amount of latitude to the married woman's craving to attract and the married man's thirst
to make conquests, in the expectation that this inevitable tendency to unfaithfulness will thus
find a safety valve and be rendered innocuous. Convention has laid down that neither partner is
to hold the other accountable for these little excursions in the direction of unfaithfulness, and
they usually result in the desire that has been awakened by the new object finding satisfaction
in some kind of return to faithfulness to the original object. A jealous person, however, does not
recognize this convention of tolerance; he does not believe in any such thing as a halt or a
turning-back once the path has been trodden, nor that a flirtation may be a safeguard against
actual infidelity. In the treatment of a jealous person like this, one must refrain from disputing
with him the material on which he bases his suspicions; one can only aim at bringing him to
regard the matter in a different light.

¹[1922b, 3901]
The jealousy that arises from such a projection has, it is true, an almost delusional character; it is, however, amenable to the analytic work of exposing the unconscious phantasies of the subject's own infidelity. The position is worse as regards jealousy belonging to the third layer, the true delusional type. It too has its origin in repressed impulses towards unfaithfulness; but the object in these cases is of the same sex as the subject. Delusional jealousy is what is left of a homosexuality that has run its course, and it rightly takes its position among the classical forms of paranoia. As an attempt at defence against an unduly strong homosexual impulse it may, in a man, be described in the formula: 'I do not love him, she loves him!' In a delusional case one will be prepared to find jealousy belonging to all three layers, never to the third alone. [1922b, 3902]

This patient's homosexual position was easily surveyed. He had made no friendships and developed no social interests; one had the impression that only the delusion had carried forward the development of his relations with men, as if it had taken over some of the arrears that had been neglected. The fact that his father was of no great importance in the family, combined with a humiliating homosexual trauma in early boyhood, had forced his homosexuality into repression and barred the way to its sublimation. The whole of his youth was governed by a strong attachment to his mother. Of all her many sons he was her declared favourite, and he developed marked jealousy of the normal type in regard to her. When later he made his choice of a wife - mainly prompted by an impulse to enrich his mother - his longing for a virgin mother expressed itself in obsessive doubts about his fiancée's virginity. The first years of his marriage were free from jealousy. Then he became unfaithful to his wife and entered upon an intimate relationship with another woman that lasted for a considerable time. Frightened by a certain suspicion, he at length made an end of this love affair, and not until then did jealousy of the second, projected type break out, by means of which he was able to assuage his self-reproaches about his own unfaithfulness. It was soon complicated by an accession of homosexual impulses, of which his father-in-law was the object, and became a fully formed jealous paranoia. [1922b, 3904]
(c) The third way in which the original proposition can be contradicted would be by delusions of jealousy, which we can study in the characteristic forms in which they appear in each sex. [1911c, 2433]

(a) Alcoholic delusions of jealousy. The part played by alcohol in this disorder is intelligible in every way. We know that that source of pleasure removes inhibitions and undoes sublimations. It is not infrequently disappointment over a woman that drives a man to drink - but this means, as a rule, that he resorts to the public-house and to the company of men, who afford him the emotional satisfaction which he has failed to get from his wife at home. If now these men become the objects of a strong libidinal cathexis in his unconscious, he will ward it off with the third kind of contradiction:

'[It is not I who love the man - she loves him'], and he suspects the woman in relation to all the men whom he himself is tempted to love.

Distortion by means of projection is necessarily absent in this instance, since, with the change of the subject who loves, the whole process is in any case thrown outside the self. The fact that the woman loves the men is a matter of external perception to him; whereas the facts that he himself does not love but hates, or that he himself loves not this but that person, are matters of internal perception.

(β) Delusions of jealousy in women are exactly analogous.

'[It is not I who love the women - he loves them].' The jealous woman suspects her husband in relation to all the women by whom she is herself attracted owing to her homosexuality and the dispositional effect of her excessive narcissism. The influence of the time of life at which her fixation occurred is clearly shown by the selection of the love-objects which she imputes to her husband; they are often old and quite inappropriate for a real love relation - revivals of the nurses and servants and girls who were her friends in childhood, or sisters who were her actual rivals.

[(d)] Now it might be supposed that a proposition consisting of three terms, such as 'I love him', could only be contradicted in three different ways. Delusions of jealousy contradict the subject, delusions of persecution contradict the verb, and erotomania contradicts the object. But in fact a fourth kind of contradiction is possible - namely, one which rejects the proposition as a whole:

[1911c, 2433]
What attitude, then, will a psychiatrist adopt in a case of illness like this? We know already how he would behave to the symptomatic action of the patient who fails to shut the consulting-room door. He pronounces it to be a chance event of no psychological interest with which he has no further concern. But this procedure cannot be carried over to the illness of the jealous woman. The symptomatic action seems to be a matter of indifference; but the symptom forces itself on our attention as a matter of importance. It is accompanied by intense subjective suffering and, as an objective fact, it threatens the communal life of a family; it is thus an undeniable subject of psychiatric interest. The psychiatrist will start by endeavouring to characterize the symptom by some essential feature. The idea with which the woman torments herself cannot in itself be called absurd; it does, indeed, happen that elderly gentlemen have love affairs with young girls. But there is something else about it which is absurd and hard to understand. The patient had no other reason at all for believing that her affectionate and loyal husband belonged to this otherwise not so rare class of husbands except what was asserted in the anonymous letter. She knew that this document had no evidential value and she was able to give a satisfying explanation of its origin. She ought therefore to have been able to tell herself that she had no ground whatever for her jealousy, and she did tell herself so. But in spite of this she suffered as much as if she regarded this jealousy as completely justified. Ideas of this kind, which are inaccessible to logical arguments based on reality, are by general agreement described as delusions. The good lady, then, was suffering from delusions of jealousy. This is no doubt the essential feature of this case of illness.

[1916-1917, 3332]

After this first point has been established our psychiatric interest will become even livelier. If a delusion is not to be got rid of by a reference to reality, no doubt it did not originate from reality either. Where else did it originate? There are delusions of the most varied content: why in our case is the content of the delusion jealousy in particular? In what kind of people do delusions, and especially delusions of jealousy, come about? We should like to hear what the psychiatrist has to say about this; but at this point he leaves us in the lurch. He enters into only a single one of our enquiries. He will investigate the woman's family history and will perhaps give us this reply: 'Delusions come about in people in whose families similar and other psychical disorders have repeatedly occurred.' In other words, if this woman developed a delusion she was predisposed to it by hereditary transmission. No doubt that is something; but is it all we want to know? Was this the only thing that contributed to the causation of the illness? Must we be content to suppose that it is a matter of indifference or caprice or is inexplicable whether a delusion of jealousy arises rather than any other sort? And ought we to understand the assertion of the predominance of the hereditary influence in a negative sense as well - that no matter what experiences this woman's mind encountered she was destined some time or other to produce a delusion? You will want to know why it is that scientific psychiatry will give us no further information. But my reply to you is: 'he is a rogue who gives more than he has.' The psychiatrist knows no way of throwing more light on a case like this one. He must content himself with a diagnosis and a prognosis - uncertain in spite of a wealth of experience - of its future course.

[1916-1917, 3333]
But can psycho-analysis do more here? Yes, it actually can. I hope to be able to show you that, even in a case so hard of access as this, it can discover something which makes a first understanding possible. And to begin with I would draw your attention to the inconspicuous detail that the patient herself positively provoked the anonymous letter, which now gave support to her delusion, by informing the scheming housemaid on the previous day that it would cause her the greatest unhappiness if her husband had a love affair with a young girl. In this way she first put the notion of sending the anonymous Letter into the housemaid's head. Thus the delusion acquires a certain independence of the letter; it had been present already in the patient as a fear - or was it as a wish? Let us now add to this the small further indications yielded by only two analytic sessions. The patient, indeed, behaved in a very unco-operative way when, after telling me her story, she was asked for her further thoughts, ideas and memories. She said that nothing occurred to her, that she had told me everything already, and after two sessions the experiment with me had in fact to be broken off because she announced that she already felt well and that she was sure the pathological idea would not come back. She only said this, of course, from resistance and from dread of the continuation of the analysis. Nevertheless, during these two sessions she let fall a few remarks which allowed of, and indeed necessitated, a particular interpretation; and this interpretation threw a clear light on the genesis of her delusion of jealousy. She herself was intensely in love with a young man, with the same son-in-law who had persuaded her to come to me as a patient. She herself knew nothing, or perhaps only a very little, of this love; in the family relationship that existed between them it was easy for this passionate liking to disguise itself as innocent affection. After all our experiences elsewhere, it is not hard for us to feel our way into the mental life of this upright wife and worthy mother, of the age of fifty-three. Being in love like this, a monstrous and impossible thing, could not become conscious; but it remained in existence and, even though it was unconscious, it exercised a severe pressure. Something had to become of it, some relief had to be looked for; and the easiest mitigation was offered, no doubt, by the mechanism of displacement which plays a part so regularly in the generating of delusional jealousy. If not only were she, the old woman, in love with a young man, but if also her old husband were having a love affair with a young girl, then her conscience would be relieved of the weight of her unfaithfulness. The phantasy of her husband's unfaithfulness thus acted as a cooling compress on her burning wound. Her own love had not become conscious to her, but its mirror-reflection, which brought her such an advantage, now became conscious as an obsession and delusion. No arguments against it could, of course, have any effect, for they were only directed against the mirror-image and not against the original which gave the other its strength and which lay hidden, inviolable, in the unconscious.

[1916-1917, 3334]

You will recall that at our first meeting of the present academic year I described a case to you of a woman suffering from delusions of jealousy. Now that we are so near its end you would no doubt like to hear how delusions are explained by psycho-analysis. But I have less to tell you about that than you expect. The fact that a delusion cannot be shaken by logical arguments or real experiences is explained in the same way as in the case of an obsession - by its relation to the unconscious, which is represented and held down by the delusion or by the obsession. The difference between the two is based on the difference between the topography and dynamics of the two illnesses.

[1916-1917, 3471]
The jealousy that arises from such a projection has, it is true, an almost delusional character; it is, however, amenable to the analytic work of exposing the unconscious phantasies of the subject's own infidelity. The position is worse as regards jealousy belonging to the third layer, the true delusional type. It too has its origin in repressed impulses towards unfaithfulness; but the object in these cases is of the same sex as the subject. Delusional jealousy is what is left of a homosexuality that has run its course, and it rightly takes its position among the classical forms of paranoia. As an attempt at defence against an unduly strong homosexual impulse it may, in a man, be described in the formula: 'I do not love him, she loves him!'¹ In a delusional case one will be prepared to find jealousy belonging to all three layers, never to the third alone.

[1922b, 3902]

The first case was that of a youngish man with a fully developed paranoia of jealousy, the object of which was his impeccably faithful wife. A stormy period in which the delusion had possessed him uninterruptedly already lay behind him. When I saw him he was only subject to clearly separated attacks, which lasted for several days and which, curiously enough, regularly appeared on the day after he had had sexual intercourse with his wife, which was, incidentally, satisfying to both of them. The inference is justified that after every satiation of the heterosexual libido the homosexual component, likewise stimulated by the act, forced an outlet for itself in the attack of jealousy.

[1922b, 3902]

These attacks drew their material from his observation of minute indications, by which his wife's quite unconscious coquetry, unnoticeable to any one else, had betrayed itself to him. She had unintentionally touched the man sitting next her with her hand; she had turned too much towards him, or she had smiled more pleasantly than when alone with her husband. He was extraordinarily observant of all these manifestations of her unconscious, and always knew how to interpret them correctly, so that he really was always in the right about it, and could furthermore call in analysis to justify his jealousy. His abnormality really reduced itself to this, that he watched his wife's unconscious mind much more closely and then regarded it as far more important than anyone else would have thought of doing.

[1922b, 3902]

We begin to see that we describe the behaviour of both jealous and persecutory paranoics very inadequately by saying that they project outwards on to others what they do not wish to recognize in themselves. Certainly they do this; but they do not project it into the blue, so to speak, where there is nothing of the sort already. They let themselves be guided by their knowledge of the unconscious, and displace to the unconscious minds of others the attention which they have withdrawn from their own. Our jealous husband perceived his wife's unfaithfulness instead of his own; by becoming conscious of hers and magnifying it enormously he succeeded in keeping his own unconscious. If we accept his example as typical, we may infer that the enmity which the persecuted paranoic sees in others is the reflection of his own hostile impulses against them. Since we know that with the paranoic it is precisely the most loved person of his own sex that becomes his persecutor, the question arises where this reversal of affect takes its origin; the answer is not far to seek - the ever-present ambivalence of feeling provides its source and the non-fulfilment of his claim for love strengthens it. This ambivalence thus serves the same purpose for the persecuted paranoic as jealousy served for my patient - that of a defence against homosexuality.

[1922b, 3903]
This patient's homosexual position was easily surveyed. He had made no friendships and developed no social interests; one had the impression that only the delusion had carried forward the development of his relations with men, as if it had taken over some of the arrears that had been neglected. The fact that his father was of no great importance in the family, combined with a humiliating homosexual trauma in early boyhood, had forced his homosexuality into repression and barred the way to its sublimation. The whole of his youth was governed by a strong attachment to his mother. Of all her many sons he was her declared favourite, and he developed marked jealousy of the normal type in regard to her. When later he made his choice of a wife - mainly prompted by an impulse to enrich his mother - his longing for a virgin mother expressed itself in obsessive doubts about his fiancée's virginity. The first years of his marriage were free from jealousy. Then he became unfaithful to his wife and entered upon an intimate relationship with another woman that lasted for a considerable time. Frightened by a certain suspicion, he at length made an end of this love affair, and not until then did jealousy of the second, projected type break out, by means of which he was able to assuage his self-reproaches about his own unfaithfulness. It was soon complicated by an accession of homosexual impulses, of which his father-in-law was the object, and became a fully formed jealous paranoia.

It seems to me that we have here an important discovery - namely, that the qualitative factor, the presence of certain neurotic formations, has less practical significance than the quantitative factor, the degree of attention or, more correctly, the amount of cathexis that these structures are able to attract to themselves. Our consideration of the first case, the jealous paranoia, led to a similar estimate of the importance of the quantitative factor, by showing that there also the abnormality essentially consisted in the hypercathexis of the interpretations of someone else's unconscious. We have long known of an analogous fact in the analysis of hysteria. The pathogenic phantasies, derivatives of repressed instinctual impulses, are for a long time tolerated alongside the normal life of the mind, and have no pathogenic effect until by a revolution in the libidinal economy they receive a hypercathexis; not till then does the conflict which leads to the formation of symptoms break out. Thus as our knowledge grows we are increasingly impelled to bring the economic point of view into the foreground. I should also like to throw out the question whether this quantitative factor that I am now dwelling on does not suffice to cover the phenomena which Bleuler and others have lately proposed to name 'switching'. One need only assume that an increase in resistance in the course taken by the psychical current in one direction results in a hypercathexis of another path and thus causes the flow to be switched into that path.

¹ In the well-known case of delusional jealousy reported by Ruth Mack Brunswick (1928), the direct source of the disorder was the patient's pre-Oedipus fixation (to her sister).

[1922b, 3904]

[1922b, 3905]
¹ From other points of view this interpretation of immaterial and accidental indications given by other people has been classed as a 'delusion of reference'.
[1901b, 1325]

We are reminded that sufferers from persecutory paranoia act in just the same way. They, too, cannot regard anything in other people as indifferent, and they, too, take up minute indications with which these other, unknown, people present them, and use them in their delusions of reference. The meaning of their delusion of reference is that they expect from all strangers something like love. But these people show them nothing of the kind; they laugh to themselves, flourish their sticks, even spit on the ground as they go by - and one really does not do such things while a person in whom one takes a friendly interest is near. One does them only when one feels quite indifferent to the passer-by, when one can treat him like air; and, considering, too, the fundamental kinship of the concepts of 'stranger' and 'enemy', the paranoic is not so far wrong in regarding this indifference as hate, in contrast to his claim for love.
[1922b, 3903]
In the case of our dream we are in a position to indicate the material upon which the misinterpretation is based. The impostor is the dream and the Emperor is the dreamer himself; the moralizing purpose of the dream reveals an obscure knowledge of the fact that the latent dream-content is concerned with forbidden wishes that have fallen victim to repression. For the context in which dreams of this sort appear during my analyses of neurotics leaves no doubt that they are based upon memories from earliest childhood. It is only in our childhood that we are seen in inadequate clothing both by members of our family and by strangers - nurses, maidservants, and visitors; and it is only then that we feel no shame at our nakedness.¹ We can observe how undressing has an almost intoxicating effect on many children even in their later years, instead of making them feel ashamed. They laugh and jump about and slap themselves, while their mother, or whoever else may be there, reproves them and says: 'Ugh! Shocking! You mustn't ever do that!' Children frequently manifest a desire to exhibit. One can scarcely pass through a country village in our part of the world without meeting some child of two or three who lifts up his little shirt in front of one - in one's honour, perhaps. One of my patients has a conscious memory of a scene in his eighth year, when at bed-time he wanted to dance into the next room where his little sister slept, dressed in his night-shirt, but was prevented by his nurse. In the early history of neurotics an important part is played by exposure to children of the opposite sex; in paranoia delusions of being observed while dressing and undressing are to be traced back to experiences of this kind; while among persons who have remained at the stage of perversion there is one class in which this infantile impulse has reached the pitch of a symptom - the class of 'exhibitionists'.¹

[1900a, 723]

We are ready to recognize the fact that Silberer's phenomena constitute a second contribution on the part of waking thought to the construction of dreams; though it is less regularly present and less significant than the first one, which has already been introduced under the name of 'secondary revision.'¹ It has been shown that a part of the attention which operates during the day continues to be directed towards dreams during the state of sleep, that it keeps a check on them and criticizes them and reserves the power to interrupt them. It has seemed plausible to recognize in the mental agency which thus remains awake the censor to whom we have had to attribute such a powerful restricting influence upon the form taken by dreams. What Silberer's observations have added to this is the fact that in certain circumstances a species of self-observation plays a part in this and makes a contribution to the content of the dream. The probable relations of this self-observing agency, which may be particularly prominent in philosophical minds, to endopsychic perception, to delusions of observation, to conscience and to the censor of dreams can be more appropriately treated elsewhere.¹

[1900a, 943]

It would not surprise us if we were to find a special psychical agency which performs the task of seeing that narcissistic satisfaction from the ego ideal is ensured and which, with this end in view, constantly watches the actual ego and measures it by that ideal. If such an agency does exist, we cannot possibly come upon it as a discovery - we can only recognize it; for we may reflect that what we call our 'conscience' has the required characteristics. Recognition of this agency enables us to understand the so-called 'delusions of being noticed' or more correctly, of being watched, which are such striking symptoms in the paranoid diseases and which may also occur as an isolated form of illness, or intercalated in a transference neurosis. Patients of this sort complain that all their thoughts are known and their actions watched and supervised; they are informed of the functioning of this agency by voices which characteristically speak to them in the third person ('Now she's thinking of that again', 'now he's going out'). This complaint is justified; it describes the truth. A power of this kind, watching, discovering and criticizing all our intentions, does really exist. Indeed, it exists in every one of us in normal life.

[1914c, 2949]
Delusions of being watched present this power in a regressive form, thus revealing its genesis and the reason why the patient is in revolt against it. For what prompted the subject to form an ego ideal, on whose behalf his conscience acts as watchman, arose from the critical influence of his parents (conveyed to him by the medium of the voice), to whom were added, as time went on, those who trained and taught him and the innumerable and indefinable host of all the other people in his environment - his fellow-men - and public opinion.

[1914c, 2949]

The complaints made by paranoics also show that at bottom the self-criticism of conscience coincides with the self-observation on which it is based. Thus the activity of the mind which has taken over the function of conscience has also placed itself at the service of internal research, which furnishes philosophy with the material for its intellectual operations. This may have some bearing on the characteristic tendency of paranoics to construct speculative systems.¹

[1914c, 2949]

It will certainly be of importance to us if evidence of the activity of this critically observing agency - which becomes heightened into conscience and philosophic introspection - can be found in other fields as well. I will mention here what Herbert Silberer has called the 'functional phenomenon', one of the few indisputably valuable additions to the theory of dreams. Silberer, as we know, has shown that in states between sleeping and waking we can directly observe the translation of thoughts into visual images, but that in these circumstances we frequently have a representation, not of a thought-content, but of the actual state (willingness, fatigue, etc.) of the person who is struggling against sleep. Similarly, he has shown that the conclusions of some dreams or some divisions in their content merely signify the dreamer's own perception of his sleeping and waking. Silberer has thus demonstrated the part played by observation - in the sense of the paranoic's delusions of being watched - in the formation of dreams. This part is not a constant one. Probably the reason why I overlooked it is because it does not play any great part in my own dreams; in persons who are gifted philosophically and accustomed to introspection it may become very evident.

[1914c, 2950]

I told you too that we hoped that the analysis of the narcissistic disorders would give us an insight into the way in which our ego is put together and built up out of different agencies. We have already made a start with this at one point. From the analysis of delusions of observation we have drawn the conclusion that there actually exists in the ego an agency which unceasingly observes, criticizes and compares, and in that way sets itself over against the other part of the ego. We believe, therefore, that the patient is betraying a truth to us which is not yet sufficiently appreciated when he complains that he is spied upon and observed at every step he takes and that every one of his thoughts is reported and criticized. His only mistake is in regarding this uncomfortable power as something alien to him and placing it outside himself. He senses an agency holding sway in his ego which measures his actual ego and each of its activities by an ideal ego that he has created for himself in the course of his development. We believe, too, that this creation was made with the intention of re-establishing the self-satisfaction which was attached to primary infantile narcissism but which since then has suffered so many disturbances and mortifications. We know the self-observing agency as the ego-censor, the conscience; it is this that exercises the dream-censorship during the night, from which the repressions of inadmissible wishful impulses proceed. When in delusions of observation it becomes split up, it reveals to us its origin from the influences of parents, educators and social environment - from an identification with some of these model figures.

[1916-1917, 3472]
Little light is thrown upon the genesis of masochism by our discussion of the beating-phantasy. To begin with, there seems to be a confirmation of the view that masochism is not the manifestation of a primary instinct, but originates from sadism which has been turned round upon the self - that is to say, by means of regression from an object to the ego.¹ Instincts with a passive aim must be taken for granted as existing, especially among women. But passivity is not the whole of masochism. The characteristic of displeasure belongs to it as well, - a bewildering accompaniment to the satisfaction of an instinct. The transformation of sadism into masochism appears to be due to the influence of the sense of guilt which takes part in the act of repression. Thus repression is operative here in three ways: it renders the consequences of the genital organization unconscious, it compels that organization itself to regress to the earlier sadistic-anal stage, and it transforms the sadism of this stage into masochism, which is passive and again in a certain sense narcissistic. The second of these three effects is made possible by the weakness of the genital organization, which must be presupposed in these cases. The third becomes necessary because the sense of guilt takes as much objection to sadism as to incestuous object-choice genitally conceived. Again, the analyses do not tell us the origin of the sense of guilt itself. It seems to be brought along by the new phase upon which the child is entering, and, if it afterwards persists, it seems to correspond to a scar-like formation which is similar to the sense of inferiority. According to our present orientation in the structure of the ego, which is as yet uncertain, we should assign it to the agency in the mind which sets itself up as a critical conscience over against the rest of the ego, which produces Silberer's functional phenomenon in dreams, and which cuts itself loose from the ego in delusions of being watched.

The idea of the 'double' does not necessarily disappear with the passing of primary narcissism, for it can receive fresh meaning from the later stages of the ego's development. A special agency is slowly formed there, which is able to stand over against the rest of the ego, which has the function of observing and criticizing the self and of exercising a censorship within the mind, and which we become aware of as our 'conscience'. In the pathological case of delusions of being watched, this mental agency becomes isolated, dissociated from the ego, and discernible to the physician's eye. The fact that an agency of this kind exists, which is able to treat the rest of the ego like an object - the fact, that is, that man is capable of self-observation - renders it possible to invest the old idea of a 'double' with a new meaning and to ascribe a number of things to it - above all, those things which seem to self-criticism to belong to the old surmounted narcissism of earliest times.¹
But these melancholias also show us something else, which may be of importance for our later discussions. They show us the ego divided, fallen apart into two pieces, one of which rages against the second. This second piece is the one which has been altered by introjection and which contains the lost object. But the piece which behaves so cruelly is not unknown to us either. It comprises the conscience, a critical agency within the ego, which even in normal times takes up a critical attitude towards the ego, though never so relentlessly and so unjustifiably. On previous occasions we have been driven to the hypothesis that some such agency develops in our ego which may cut itself off from the rest of the ego and come into conflict with it. We have called it the ‘ego ideal’, and by way of functions we have ascribed to it self-observation, the moral conscience, the censorship of dreams, and the chief influence in repression. We have said that it is the heir to the original narcissism in which the childish ego enjoyed self-sufficiency; it gradually gathers up from the influences of the environment the demands which that environment makes upon the ego and which the ego cannot always rise to; so that a man, when he cannot be satisfied with his ego itself, may nevertheless be able to find satisfaction in the ego ideal which has been differentiated out of the ego. In delusions of observation, as we have further shown, the disintegration of this agency has become patent, and has thus revealed its origin in the influence of superior powers, and above all of parents. But we have not forgotten to add that the amount of distance between this ego ideal and the real ego is very variable from one individual to another, and that with many people this differentiation within the ego does not go further than with children.

We describe one group of these patients as suffering from delusions of being observed. They complain to us that perpetually, and down to their most intimate actions, they are being molested by the observation of unknown powers - presumably persons - and that in hallucinations they hear these persons reporting the outcome of their observation: ‘now he’s going to say this, now he’s dressing to go out’ and so on. Observation of this sort is not yet the same thing as persecution, but it is not far from it; it presupposes that people distrust them, and expect to catch them carrying out forbidden actions for which they would be punished. How would it be if these insane people were right, if in each of us there is present in his ego an agency like this which observes and threatens to punish, and which in them has merely become sharply divided from their ego and mistakenly displaced into external reality?

I cannot tell whether the same thing will happen to you as to me. Ever since, under the powerful impression of this clinical picture, I formed the idea that the separation of the observing agency from the rest of the ego might be a regular feature of the ego’s structure, that idea has never left me, and I was driven to investigate the further characteristics and connections of the agency which was thus separated off. The next step is quickly taken. The content of the delusions of being observed already suggests that the observing is only a preparation for judging and punishing, and we accordingly guess that another function of this agency must be what we call our conscience. There is scarcely anything else in us that we so regularly separate from our ego and so easily set over against it as precisely our conscience. I feel an inclination to do something that I think will give me pleasure, but I abandon it on the ground that my conscience does not allow it. Or I have let myself be persuaded by too great an expectation of pleasure into doing something to which the voice of conscience has objected and after the deed my conscience punishes me with distressing reproaches and causes me to feel remorse for the deed. I might simply say that the special agency which I am beginning to distinguish in the ego is conscience. But it is more prudent to keep the agency as something independent and to suppose that conscience is one of its functions and that self-observation, which is an essential preliminary to the judging activity of conscience, is another of them. And since when we recognize that something has a separate existence we give it a name of its own, from this time forward I will describe this agency in the ego as the ‘super-ego’.
We are ready to recognize the fact that Silberer's phenomena constitute a second contribution on the part of waking thought to the construction of dreams; though it is less regularly present and less significant than the first one, which has already been introduced under the name of 'secondary revision.' It has been shown that a part of the attention which operates during the day continues to be directed towards dreams during the state of sleep, that it keeps a check on them and criticizes them and reserves the power to interrupt them. It has seemed plausible to recognize in the mental agency which thus remains awake the censor to whom we have had to attribute such a powerful restricting influence upon the form taken by dreams. What Silberer's observations have added to this is the fact that in certain circumstances a species of self-observation plays a part in this and makes a contribution to the content of the dream. The probable relations of this self-observing agency, which may be particularly prominent in philosophical minds, to endopsychic perception, to delusions of observation, to conscience and to the censor of dreams can be more appropriately treated elsewhere.¹

² For example, the phantasies of hysterics concerning sexual and cruel maltreatment correspond, at times even down to details, with the complaints of persecuted paranoics. It is curious, but not unintelligible, that we meet the identical content in the form of reality in the contrivances of perverts for the satisfaction of their desires.

(a) The medical officer lays stress upon two points as being of chief importance: the patient's assumption of the role of Redeemer, and his transformation into a woman. The Redeemer delusion is a phantasy that is familiar to us through the frequency with which it forms the nucleus of religious paranoia. The additional factor, which makes the redemption dependent upon the man being previously transformed into a woman, is unusual and in itself bewildering, since it shows such a wide divergence from the historical myth which the patient's phantasy is setting out to reproduce. It is natural to follow the medical report in assuming that the motive force of this delusional complex was the patient's ambition to play the part of Redeemer, and that his emasculation was only entitled to be regarded as a means for achieving that end. Even though this may appear to be true of his delusion in its final form, a study of the Denkwürdigkeiten compels us to take a very different view of the matter. For we learn that the idea of being transformed into a woman (that is, of being emasculated) was the primary delusion, that he began by regarding that act as constituting a serious injury and persecution, and that it only became related to his playing the part of Redeemer in a secondary way. There can be no doubt, moreover, that originally he believed that the transformation was to be effected for the purpose of sexual abuse and not so as to serve higher designs. The position may be formulated by saying that a sexual delusion of persecution was later on converted in the patient's mind into a religious delusion of grandeur. The part of persecutor was at first assigned to Professor Flechsig, the physician in whose charge he was; later, his place was taken by God Himself.

¹ [1900a, 943]

² [1901b, 1325]

[1911c, 2394]
'But now what follows reveals the full perfidy¹ of the policy that has been pursued towards me. Almost every time the need for evacuation was miracled up in me, some other person in my vicinity was sent (by having his nerves stimulate for that purpose) to the lavatory, in order to prevent my evacuating. This is a phenomenon which I have observed for years and upon such countless occasions - thousands of them - and with such regularity, as to exclude any possibility of its being attributable to chance. And thereupon comes the question: "Why don't you sh--?" to which the brilliant repartee is made that I am "so stupid or something". The pen well-nigh shrinks from recording so monumental a piece of absurdity as that God, blinded by His ignorance of human nature, can positively go to such lengths as to suppose that there can exist a man too stupid to do what every animal can do - too stupid to be able to sh--. When, upon the occasion of such an urge, I actually succeed in evacuating - and as a rule, since I nearly always find the lavatory engaged, I use a pail for the purpose - the process is always accompanied by the generation of an exceedingly strong feeling of spiritual voluptuousness. For the relief from the pressure caused by the presence of the faeces in the intestines produces a sense of intense well-being in the nerves of voluptuousness; and the same is equally true of making water. For this reason, even down to the present day, while I am passing stool or making water, all the rays are always without exception united; for this very reason, whenever I address myself to these natural functions, an attempt is invariably made, though as a rule in vain, to miracle backwards the urge to pass stool and to make water.'² (225-7.)

[1911c, 2402]

It is perhaps worth giving a more detailed illustration of this procedure. Schreber complains of the nuisance created by the so-called 'miracled birds' or 'talking birds', to which he ascribes a number of very remarkable qualities (208-14). It is his belief that they are composed of former 'fore-courts of Heaven', that is, of human souls which have entered into a state of bliss, and that they have been loaded with ptomaine¹ poison and set on to him. They have been brought to the condition of repeating 'meaningless phrases which they have learnt by heart' and which have been 'dinned into them'. Each time that they have discharged their load of ptomaine poison on to him - that is each time that they have 'reeled off the phrases which have been dinned into them', as it were - they become to some extent absorbed into his soul, with the words 'The deuce of a fellow!' or 'Deuce take it!' which are the only words they are still capable of using to express a genuine feeling. They cannot understand the meaning of the words they speak, but they are by nature susceptible to similarity of sounds, though the similarity need not necessarily be a complete one. Thus it is immaterial to them whether one says:

[1911c, 2410]

As we already know, Schreber's case at first took the form of delusions of persecution, and did not begin to lose it until the turning-point of his illness (the time of his 'reconciliation'). From that time onwards the persecutions became less and less intolerable, and the ignominious purpose which at first underlay his threatened emasculation began to be superseded by a purpose in consonance with the Order of Things. But the first author of all these acts of persecution was Flechsig, and he remains their instigator throughout the whole course of the illness.¹

[1911c, 2412]
The study of a number of cases of delusions of persecution has led me as well as other investigators to the view that the relation between the patient and his persecutor can be reduced to a simple formula.¹ It appears that the person to whom the delusion ascribes so much power and influence, in whose hands all the threads of the conspiracy converge, is, if he is definitely named, either identical with some one who played an equally important part in the patient's emotional life before his illness, or is easily recognizable as a substitute for him. The intensity of the emotion is projected in the shape of external power, while its quality is changed into the opposite. The person who is now hated and feared for being a persecutor was at one time loved and honoured. The main purpose of the persecution asserted by the patient's delusion is to justify the change in his emotional attitude.

[1911c, 2415]

We shall therefore, I think, raise no further objections to the hypothesis that the exciting cause of the illness was the appearance in him of a feminine (that is, a passive homosexual) wishful phantasy, which took as its object the figure of his doctor. An intense resistance to this phantasy arose on the part of Schreber's personality, and the ensuing defensive struggle, which might perhaps just as well have assumed some other shape, took on, for reasons unknown to us, that of a delusion of persecution. The person he longed for now became his persecutor, and the content of his wishful phantasy became the content of his persecution. It may be presumed that the same schematic outline will turn out to be applicable to other cases of delusions of persecution. What distinguishes Schreber's case from others, however, is its further development and the transformation it underwent in the course of it.

[1911c, 2419]

In textbooks of psychiatry we frequently come across statements to the effect that megalomania can develop out of delusions of persecution. The process is supposed to be as follows. The patient is primarily the victim of a delusion that he is being persecuted by powers of the greatest might. He then feels a need to account to himself for this, and in that way hits on the idea that he himself is a very exalted personage and worthy of such persecution. The development of megalomania is thus attributed by the textbooks to a process which (borrowing a useful word from Ernest Jones) we may describe as 'rationalization'. But to ascribe such important affective consequences to a rationalization is, as it seems to us, an entirely unpsychological proceeding; and we would consequently draw a sharp distinction between our opinion and the one which we have quoted from the textbooks. We are making no claim, for the moment, to knowing the origin of the megalomania.

[1911c, 2420]
Turning once more to the case of Schreber, we are bound to admit that any attempt at throwing light upon the transformation in his delusion brings us up against extraordinary difficulties. In what manner and by what means was the ascent from Flechsig to God brought about? From what source did he derive the megalomania which so fortunately enabled him to become reconciled to his persecution, or, in analytical phraseology, to accept the wishful phantasy which had had to be repressed? The Denkwürdigkeiten give us a first clue; for they show us that in the patient's mind 'Flechsig' and 'God' belonged to the same class. In one of his phantasies he overheard a conversation between Flechsig and his wife, in which the former asserted that he was 'God Flechsig', so that his wife thought he had gone mad (82). But there is another feature in the development of Schreber's delusions which claims our attention. If we take a survey of the delusions as a whole we see that the persecutor is divided into Flechsig and God; in just the same way Flechsig himself subsequently splits up into two personalities, the 'upper' and the 'middle' Flechsig, and God into the 'lower' and the 'upper' God. In the later stages of the illness the decomposition of Flechsig goes further still (193). A process of decomposition of this kind is very characteristic of paranoia. Paranoia decomposes just as hysteria condenses. Or rather, paranoia resolves once more into their elements the products of the condensations and identifications which are effected in the unconscious. The frequent repetition of the decomposing process in Schreber's case would, according to Jung, be an expression of the importance which the person in question possessed for him.⁹ All of this dividing up of Flechsig and God into a number of persons thus had the same meaning as the splitting of the persecutor into Flechsig and God. They were all duplications of one and the same important relationship.² But, in order to interpret all these details, we must further draw attention to our view of this decomposition of the persecutor into Flechsig and God as a paranoid reaction to a previously established identification of the two figures or their belonging to the same class. If the persecutor Flechsig was originally a person whom Schreber loved, then God must also simply be the reappearance of some one else whom he loved, and probably some one of greater importance.

[1911c, 2421]

We have hitherto been dealing with the father-complex, which was the dominant element in Schreber's case and with the wishful phantasy round which the illness centred. But in all of this there is nothing characteristic of the form of disease known as paranoia, nothing that might not be found (and that has not in fact been found) in other kinds of neuroses. The distinctive character of paranoia (or of dementia paranoides) must be sought for elsewhere - namely, in the particular form assumed by the symptoms; and we shall expect to find that this is determined, not by the nature of the complexes themselves, but by the mechanism by which the symptoms are formed or by which repression is brought about. We should be inclined to say that what was characteristically paranoic about the illness was the fact that the patient, as a means of warding off a homosexual wishful phantasy, reacted precisely with delusions of persecution of this kind.

[1911c, 2429]
The proposition 'I (a man) love him' is contradicted by:
(a) Delusions of persecution; for they loudly assert:
'I do not love him - I hate him.'
This contradiction, which must have run thus in the unconscious, cannot, however, become conscious to a paranoiac in this form. The mechanism of symptom-formation in paranoia requires that internal perceptions - feelings - shall be replaced by external perceptions. Consequently the proposition 'I hate him' becomes transformed by projection into another one: 'He hates (persecutes) me, which will justify me in hating him.' And thus the impelling unconscious feeling makes its appearance as though it were the consequence of an external perception:
'I do not love him - I hate him, because HE PERSECUTES ME.'
Observation leaves room for no doubt that the persecutor is some one who was once loved.
[1911c, 2432]

Distortion by means of projection is necessarily absent in this instance, since, with the change of the subject who loves, the whole process is in any case thrown outside the self. The fact that the woman loves the men is a matter of external perception to him; whereas the facts that he himself does not love but hates, or that he himself loves not this but that person, are matters of internal perception.
[1911c, 2433]

Now it might be supposed that a proposition consisting of three terms, such as 'I love him', could only be contradicted in three different ways. Delusions of jealousy contradict the subject, delusions of persecution contradict the verb, and erotomania contradicts the object. But in fact a fourth kind of contradiction is possible - namely, one which rejects the proposition as a whole:
[1911c, 2433]

The most striking characteristic of symptom-formation in paranoia is the process which deserves the name of projection. An internal perception is suppressed, and, instead, its content, after undergoing a certain kind of distortion, enters consciousness in the form of an external perception. In delusions of persecution the distortion consists in a transformation of affect; what should have been felt internally as love is perceived externally as hate. We should feel tempted to regard this remarkable process as the most important element in paranoia and as being absolutely pathognomonic for it, if we were not opportune reminded of two things. In the first place, projection does not play the same part in all forms of paranoia; and, in the second place, it makes its appearance not only in paranoia but under other psychological conditions as well, and in fact it has a regular share assigned to it in our attitude towards the external world. For when we refer the causes of certain sensations to the external world, instead of looking for them (as we do in the case of others) inside ourselves, this normal proceeding, too, deserves to be called projection. Having thus been made aware that more general psychological problems are involved in the question of the nature of projection, let us make up our minds to postpone the investigation of it (and with it that of the mechanism of paranoic symptom-formation in general) until some other occasion; and let us now turn to consider what ideas we can collect on the subject of the mechanism of repression in paranoia. I should like to say at once, in justification of this temporary renunciation, that we shall find that the manner in which the process of repression occurs is far more intimately connected with the developmental history of the libido and with the disposition to which it gives rise than is the manner in which symptoms are formed. [1911c, 2434]
(2) An equally plausible objection can be based upon Schreber's case history, as well as upon many others. For it can be urged that the delusions of persecution (which were directed against Flechsig) unquestionably made their appearance at an earlier date than the phantasy of the end of the world; so that what is supposed to have been a return of the repressed actually preceded the repression itself - and this is patent nonsense. In order to meet this objection we must leave the high ground of generalization and descend to the detailed consideration of actual circumstances, which are undoubtedly very much more complicated. We must admit the possibility that a detachment of the libido such as we are discussing might just as easily be a partial one, a drawing back from some single complex, as a general one. A partial detachment should be by far the commoner of the two, and should precede a general one, since to begin with it is only for a partial detachment that the influences of life provide a motive. The process may then stop at the stage of a partial detachment or it may spread to a general one, which will loudly proclaim its presence in the symptoms of megalomania. Thus the detachment of the libido from the figure of Flechsig may nevertheless have been what was primary in the case of Schreber; it was immediately followed by the appearance of the delusion, which brought back the libido on to Flechsig again (though with a negative sign to mark the fact that repression had taken place) and thus annulled the work of repression. And now the battle of repression broke out anew, but this time with more powerful weapons. In proportion as the object of contention became the most important thing in the external world, trying on the one hand to draw the whole of the libido on to itself, and on the other hand mobilizing all the resistances against itself, so the struggle raging around this single object became more and more comparable to a general engagement; till at length a victory for the forces of repression found expression in a conviction that the world had come to an end and that the self alone survived. If we review the ingenious constructions which were raised by Schreber's delusion in the domain of religion - the hierarchy of God, the proved souls, the fore-courts of Heaven, the lower and the upper God - we can gauge in retrospect the wealth of sublimations which were brought down in ruin by the catastrophe of the general detachment of his libido.

[1911c, 2439]

Another side of the attitude of primitive peoples towards their rulers recalls a procedure which is common in neuroses generally but comes into the open in what are known as delusions of persecution. The importance of one particular person is immensely exaggerated and his absolute power is magnified to the most improbable degree, in order that it may be easier to make him responsible for everything disagreeable that the patient may experience. Savages are really behaving in just the same way with their kings when they ascribe to them power over rain and sunshine, wind and weather, and then depose them or kill them because Nature disappoints their hopes of a successful hunt or a rich harvest. The model upon which paranoics base their delusions of persecution is the relation of a child to his father. A son's picture of his father is habitually clothed with excessive powers of this kind, and it is found that distrust of the father is intimately linked with admiration for him. When a paranoic turns the figure of one of his associates into a 'persecutor', he is raising him to the rank of a father: he is putting him into a position in which he can blame him for all his misfortunes. Thus this second analogy between savages and neurotics gives us a glimpse of the truth that much of a savage's attitude to his ruler is derived from a child's infantile attitude to his father.

[1912-1913, 2696]
It is to these phenomena, then, that I now propose to draw your attention. But you will protest with some annoyance: 'There are so many vast problems in the wide universe, as well as within the narrower confines of our minds, so many marvels in the field of mental disorders, which require and deserve to have light thrown upon them, that it does really seem gratuitous to waste labour and interest on such trivialities. If you could make us understand why a person with sound eyes and ears can see and hear in broad daylight things that are not there, why another person suddenly thinks he is being persecuted by the people of whom he has hitherto been most fond, or puts forward the cleverest arguments in support of delusional beliefs which any child could see were nonsensical, then we should have some opinion of psycho-analysis. But if it can do no more than ask us to consider why a speaker at a banquet uses one word instead of another or why a housewife has mislaid her keys, and similar futilities, then we shall know how to put our time and interest to better uses.'

The form of disease known as paranoia, chronic systematic insanity, occupies an unsettled position in the attempts at classification made by present-day psychiatry. There is, however, no doubt of its close affinity to dementia praecox. I once ventured to suggest that paranoia and dementia praecox should be brought together under the common designation of 'paraphrenia'. The forms of paranoia are described according to their content as megalomania, persecution mania, erotomania, delusions of jealousy, and so on. We shall not expect anything much in the way of an attempt at an explanation from psychiatry. Here is an example of one, though, it is true, one that is out of date and does not carry much weight - an attempt to derive one symptom from another by means of an intellectual rationalization: it is suggested that the patient, who, owing to a primary disposition, believes that he is being persecuted, infers from his persecution that he must be someone of quite particular importance and so develops megalomania. According to our analytic view the megalomania is the direct result of a magnification of the ego due to the drawing in of the libidinal object-cathexes - a secondary narcissism which is a return of the original early infantile one. We have, however, made a few observations of persecution mania which have induced us to follow a particular track. The first thing that struck us was that in the large majority of cases the persecutor was of the same sex as the persecuted patient. This was still open to an innocent explanation; but in a few cases that were thoroughly studied it was clear that the person of the same sex whom the patient loved most had, since his illness, been turned into his persecutor. This made a further development possible: namely, the replacement of the beloved person, along the line of familiar resemblances, by someone else - for instance, a father by a schoolmaster or by some superior. Experiences of this kind in ever increasing numbers led us to conclude that paranoia persecutoria is the form of the disease in which a person is defending himself against a homosexual impulse which has become too powerful. The change over from affection to hatred, which, it is well known, may become a serious threat to the life of the loved and hated object, corresponds in such cases to the transformation of libidinal impulses into anxiety which is a regular outcome of the process of repression. Listen, for instance, to what is, once again, the most recent instance of my observations in this connection.

[1916-1917, 3468]
We are reminded that sufferers from persecutory paranoia act in just the same way. They, too, cannot regard anything in other people as indifferent, and they, too, take up minute indications with which these other, unknown, people present them, and use them in their delusions of reference. The meaning of their delusion of reference is that they expect from all strangers something like love. But these people show them nothing of the kind; they laugh to themselves, flourish their sticks, even spit on the ground as they go by - and one really does not do such things while a person in whom one takes a friendly interest is near. One does them only when one feels quite indifferent to the passer-by, when one can treat him like air; and, considering, too, the fundamental kinship of the concepts of 'stranger' and 'enemy', the paranoic is not so far wrong in regarding this indifference as hate, in contrast to his claim for love.

We begin to see that we describe the behaviour of both jealous and persecutory paranoics very inadequately by saying that they project outwards on to others what they do not wish to recognize in themselves. Certainly they do this; but they do not project it into the blue, so to speak, where there is nothing of the sort already. They let themselves be guided by their knowledge of the unconscious, and displace to the unconscious minds of others the attention which they have withdrawn from their own. Our jealous husband perceived his wife's unfaithfulness instead of his own; by becoming conscious of hers and magnifying it enormously he succeeded in keeping his own unconscious. If we accept his example as typical, we may infer that the enmity which the persecuted paranoic sees in others is the reflection of his own hostile impulses against them. Since we know that with the paranoic it is precisely the most loved person of his own sex that becomes his persecutor, the question arises where this reversal of affect takes its origin; the answer is not far to seek - the ever-present ambivalence of feeling provides its source and the non-fulfilment of his claim for love strengthens it. This ambivalence thus serves the same purpose for the persecuted paranoic as jealousy served for my patient - that of a defence against homosexuality.

My second case would probably not have been classified as persecutory paranoia, apart from analysis; but I had to recognize the young man as a candidate for a terminal illness of that kind. In his attitude to his father there existed an ambivalence which in its range was quite extraordinary. On the one hand, he was the most pronounced rebel imaginable, and had developed manifestly in every direction in opposition to his father's wishes and ideals; on the other hand, at a deeper level he was still the most submissive of sons, who after his father's death denied himself all enjoyment of women out of a tender sense of guilt. His actual relations with men were clearly dominated by suspiciousness; his keen intellect easily rationalized this attitude; and he knew how to bring it about that both friends and acquaintances deceived and exploited him. The new thing I learned from studying him was that classical persecutory ideas may be present without finding belief or acceptance. They flashed up occasionally during the analysis, but he regarded them as unimportant and invariably scoffed at them. This may occur in many cases of paranoia; it may be that the delusions which we regard as new formations when the disease breaks out have already long been in existence.
My two cases of paranoia showed an instructive contrast in the behaviour of their dreams. Whereas those of the first case were free from delusion, as has already been said, the other patient produced great numbers of persecutory dreams, which may be regarded as forerunners of or substitutes for the delusional ideas. The pursuer, whom he only managed to escape with great fear, was usually a powerful bull or some other male symbol which even in the dream itself he sometimes recognized as representing his father. One day he produced a very characteristic paranoid transference-dream. He saw me shaving in front of him, and from the scent he realized that I was using the same soap as his father had used. I was doing this in order to oblige him to make a father-transference on to me. The choice of this incident for his dream quite unmistakably betrays the patient's depreciatory attitude to his paranoic phantasies and his disbelief in them; for his own eyes could tell him every day that I was never in a position to make use of shaving-soap and that therefore there was in this respect nothing to which a father-transference could attach itself.

[1922b, 3906]

Now the case in which someone first loves and then hates the same person (or the reverse) because that person has given him cause for doing so, has obviously nothing to do with our problem. Nor has the other case, in which feelings of love that have not yet become manifest express themselves to begin with by hostility and aggressive tendencies; for it may be that here the destructive component in the object-cathexis has hurried on ahead and is only later on joined by the erotic one. But we know of several instances in the psychology of the neuroses in which it is more plausible to suppose that a transformation does take place. In persecutory paranoia the patient fends off an excessively strong homosexual attachment to some particular person in a special way; and as a result this person whom he loved most becomes a persecutor, against whom the patient directs an often dangerous aggressiveness. Here we have a right to interpolate a previous phase which has transformed the love into hate. In the case of the origin of homosexuality, and of desexualized social feelings as well, analytic investigation has only recently taught us to recognize that violent feelings of rivalry are present which lead to aggressive inclinations, and that it is only after these have been surmounted that the formerly hated object becomes the loved one or gives rise to an identification. The question arises whether in these instances we are to assume a direct transformation of hate into love. It is clear that here the changes are purely internal and an alteration in the behaviour of the object plays no part in them.

[1923b, 3977]
In order to remain faithful to our customary phraseology, we shall have to speak, not of transposing the psychical accent, but of displacing large amounts of cathexis. The question then is whether we are entitled to picture extensive displacements like this from one agency of the mental apparatus to another. It looks like a new hypothesis constructed *ad hoc.* Yet we may remind ourselves that we have repeatedly (even though not sufficiently often) taken a factor of this kind into account in our attempts at a metapsychological picture of mental events. Thus, for instance, we supposed that the difference between an ordinary erotic object-cathexis and the state of being in love is that in the latter incomparably more cathexis passes over to the object and that the ego empties itself as it were in favour of the object. In studying some cases of paranoia I was able to establish the fact that ideas of persecution are formed early and exist for a long time without any perceptible effect, until, as the result of some particular precipitating event, they receive sufficient amounts of cathexis to cause them to become dominant. The cure, too, of such paranoic attacks would lie not so much in a resolution and correction of the delusional ideas as in a withdrawal from them of the cathexis which has been lent to them. The alternations between melancholia and mania, between a cruel suppression of the ego by the super-ego and a liberation of the ego after that pressure, suggests a shift of cathexis of this kind; such a shift, moreover, would have to be brought in to explain a whole number of phenomena belonging to normal mental life. If this has been done hitherto only to a very limited extent, that is on account of our usual caution - something which deserves only praise. The region in which we feel secure is that of the pathology of mental life; it is here that we make our observations and acquire our convictions. For the present we venture to form a judgement on the normal mind only in so far as we can discern what is normal in the isolations and distortions of the pathological material. When once we have overcome this hesitancy we shall recognize what a large contribution is made to the understanding of mental processes by the static conditions as well as by the dynamic changes in the *quantity* of energetic cathexis.

[1927d, 4544]

We describe one group of these patients as suffering from delusions of being observed. They complain to us that perpetually, and down to their most intimate actions, they are being molested by the observation of unknown powers - presumably persons - and that in hallucinations they hear these persons reporting the outcome of their observation: 'now he's going to say this, now he's dressing to go out' and so on. Observation of this sort is not yet the same thing as persecution, but it is not far from it; it presupposes that people distrust them, and expect to catch them carrying out forbidden actions for which they would be punished. How would it be if these insane people were right, if in each of us there is present in his ego an agency like this which observes and threatens to punish, and which in them has merely become sharply divided from their ego and mistakenly displaced into external reality?

[1933a, 4668]
One such change was the replacement of Flechsig by the superior figure of God. This seems at first as though it were a sign of aggravation of the conflict, an intensification of the unbearable persecution, but it soon becomes evident that it was preparing the way for the second change and, with it, the solution of the conflict. It was impossible for Schreber to become reconciled to playing the part of a female wanton towards his doctor; but the task of providing God Himself with the voluptuous sensations that He required called up no such resistance on the part of his ego. Emasculation was now no longer a disgrace; it became 'consonant with the Order of Things', it took its place in a great cosmic chain of events, and was instrumental in the re-creation of humanity after its extinction. 'A new race of men, born from the spirit of Schreber' would, so he thought, revere as their ancestor this man who believed himself the victim of persecution. By this means an outlet was provided which would satisfy both of the contending forces. His ego found compensation in his megalomania, while his feminine wishful phantasy made its way through and became acceptable. The struggle and the illness could cease. The patient's sense of reality, however, which had in the meantime become stronger, compelled him to postpone the solution from the present to the remote future, and to content himself with what might be described as an asymptotic wish-fulfilment.¹ Some time or other, he anticipated, his transformation into a woman would come about; until then the personality of Dr. Schreber would remain indestructible. [1911c, 2420]

In textbooks of psychiatry we frequently come across statements to the effect that megalomania can develop out of delusions of persecution. The process is supposed to be as follows. The patient is primarily the victim of a delusion that he is being persecuted by powers of the greatest might. He then feels a need to account to himself for this, and in that way hits on the idea that he himself is a very exalted personage and worthy of such persecution. The development of megalomania is thus attributed by the textbooks to a process which (borrowing a useful word from Ernest Jones) we may describe as 'rationalization'. But to ascribe such important affective consequences to a rationalization is, as it seems to us, an entirely unpsychological proceeding; and we would consequently draw a sharp distinction between our opinion and the one which we have quoted from the textbooks. We are making no claim, for the moment, to knowing the origin of the megalomania. [1911c, 2420]
Turning once more to the case of Schreber, we are bound to admit that any attempt at throwing light upon the transformation in his delusion brings us up against extraordinary difficulties. In what manner and by what means was the ascent from Flechsig to God brought about? From what source did he derive the megalomania which so fortunately enabled him to become reconciled to his persecution, or, in analytical phraseology, to accept the wishful phantasy which had had to be repressed? The *Denkwürdigkeiten* give us a first clue; for they show us that in the patient's mind 'Flechsig' and 'God' belonged to the same class. In one of his phantasies he overheard a conversation between Flechsig and his wife, in which the former asserted that he was 'God Flechsig', so that his wife thought he had gone mad (82). But there is another feature in the development of Schreber's delusions which claims our attention. If we take a survey of the delusions as a whole we see that the persecutor is divided into Flechsig and God; in just the same way Flechsig himself subsequently splits up into two personalities, the 'upper' and the 'middle' Flechsig, and God into the 'lower' and the 'upper' God. In the later stages of the illness the decomposition of Flechsig goes further still (193). A process of decomposition of this kind is very characteristic of paranoia. Paranoia decomposes just as hysteria condenses. Or rather, paranoia resolves once more into their elements the products of the condensations and identifications which are effected in the unconscious. The frequent repetition of the decomposing process in Schreber's case would, according to Jung, be an expression of the importance which the person in question possessed for him.¹ All of this dividing up of Flechsig and God into a number of persons thus had the same meaning as the splitting of the persecutor into Flechsig and God. They were all duplications of one and the same important relationship.² But, in order to interpret all these details, we must further draw attention to our view of this decomposition of the persecutor into Flechsig and God as a paranoid reaction to a previously established identification of the two figures or their belonging to the same class. If the persecutor Flechsig was originally a person whom Schreber loved, then God must also simply be the reappearance of some one else whom he loved, and probably some one of greater importance.

¹[1911c, 2421]

[(d)] Now it might be supposed that a proposition consisting of three terms, such as 'I love him', could only be contradicted in three different ways. Delusions of jealousy contradict the subject, delusions of persecution contradict the verb, and erotomania contradicts the object. But in fact a fourth kind of contradiction is possible - namely, one which rejects the proposition as a whole:

[1911c, 2433]

'I do not love at all - I do not love any one.' And since, after all, one's libido must go somewhere, this proposition seems to be the psychological equivalent of the proposition: 'I love only myself.' So that this kind of contradiction would give us megalomania, which we may regard as a *sexual overvaluation of the ego* and may thus set beside the overvaluation of the love-object with which we are already familiar.¹

[1911c, 2433]

It is of some importance in connection with other parts of the theory of paranoia to notice that we can detect an element of megalomania in most other forms of paranoic disorder. We are justified in assuming that megalomania is essentially of an infantile nature and that, as development proceeds, it is sacrificed to social considerations. Similarly, an individual's megalomania is never so vehemently suppressed as when he is in the grip of an overpowering love:

[1911c, 2433]
(1) Our first reflection will tell us that it cannot be the case that this detachment of the libido occurs exclusively in paranoia; nor can it be that, where it occurs elsewhere, it has such disastrous consequences. It is quite possible that a detachment of the libido is the essential and regular mechanism of every repression. We can have no positive knowledge on that point until the other disorders that are based upon repression have been similarly examined. But it is certain that in normal mental life (and not only in periods of mourning) we are constantly detaching our libido in this way from people or from other objects without falling ill. When Faust freed himself from the world by uttering his curses, the result was not a paranoia or any other neurosis but simply a certain general frame of mind. The detachment of the libido, therefore, cannot in itself be the pathogenic factor in paranoia; there must be some special characteristic which distinguishes a paranoid detachment of the libido from other kinds. It is not difficult to suggest what that characteristic may be. What use is made of the libido after it has been set free by the process of detachment? A normal person will at once begin looking about for a substitute for the lost attachment; and until that substitute has been found the liberated libido will be kept in suspension within his mind, and will there give rise to tensions and colour his mood. In hysteria the liberated libido becomes transformed into somatic innervations or into anxiety. But in paranoia the clinical evidence goes to show that the libido, after it has been withdrawn from the object, is put to a special use. It will be remembered that the majority of cases of paranoia exhibit traces of megalomania, and that megalomania can by itself constitute a paranoia. From this it may be concluded that in paranoia the liberated libido becomes attached to the ego, and is used for the aggrandizement of the ego. A return is thus made to the stage of narcissism (known to us from the development of the libido), in which a person's only sexual object is his own ego. On the basis of this clinical evidence we can suppose that paranoics have brought along with them a fixation at the stage of narcissism, and we can assert that the length of the step back from sublimated homosexuality to narcissism is a measure of the amount of regression characteristic of paranoia.

[1911c, 2438]
An equally plausible objection can be based upon Schreber's case history, as well as upon many others. For it can be urged that the delusions of persecution (which were directed against Flechsig) unquestionably made their appearance at an earlier date than the phantasy of the end of the world; so that what is supposed to have been a return of the repressed actually preceded the repression itself - and this is patent nonsense. In order to meet this objection we must leave the high ground of generalization and descend to the detailed consideration of actual circumstances, which are undoubtedly very much more complicated. We must admit the possibility that a detachment of the libido such as we are discussing might just as easily be a partial one, a drawing back from some single complex, as a general one. A partial detachment should be by far the commoner of the two, and should precede a general one, since to begin with it is only for a partial detachment that the influences of life provide a motive. The process may then stop at the stage of a partial detachment or it may spread to a general one, which will loudly proclaim its presence in the symptoms of megalomania. Thus the detachment of the libido from the figure of Flechsig may nevertheless have been what was primary in the case of Schreber; it was immediately followed by the appearance of the delusion, which brought back the libido on to Flechsig again (though with a negative sign to mark the fact that repression had taken place) and thus annulled the work of repression. And now the battle of repression broke out anew, but this time with more powerful weapons. In proportion as the object of contention became the most important thing in the external world, trying on the one hand to draw the whole of the libido on to itself, and on the other hand mobilizing all the resistances against itself, so the struggle raging around this single object became more and more comparable to a general engagement; till at length a victory for the forces of repression found expression in a conviction that the world had come to an end and that the self alone survived. If we review the ingenious constructions which were raised by Schreber's delusion in the domain of religion - the hierarchy of God, the proved souls, the fore-courts of Heaven, the lower and the upper God - we can gauge in retrospect the wealth of sublimations which were brought down in ruin by the catastrophe of the general detachment of his libido.

A pressing motive for occupying ourselves with the conception of a primary and normal narcissism arose when the attempt was made to subsume what we know of dementia praecox (Kraepelin) or schizophrenia (Bleuler) under the hypothesis of the libido theory. Patients of this kind, whom I have proposed to term paraphrenics, display two fundamental characteristics: megalomania and diversion of their interest from the external world - from people and things. In consequence of the latter change, they become inaccessible to the influence of psychoanalysis and cannot be cured by our efforts. But the paraphrenic's turning away from the external world needs to be more precisely characterized. A patient suffering from hysteria or obsessional neurosis has also, as far as his illness extends, given up his relation to reality. But analysis shows that he has by no means broken off his erotic relations to people and things. He still retains them in phantasy; i.e. he has, on the one hand, substituted for real objects imaginary ones from his memory, or has mixed the latter with the former; and on the other hand, he has renounced the initiation of motor activities for the attainment of his aims in connection with those objects. Only to this condition of the libido may we legitimately apply the term 'introversion' of the libido which is used by Jung indiscriminately. It is otherwise with the paraphrenic. He seems really to have withdrawn his libido from people and things in the external world, without replacing them by others in phantasy. When he does so replace them, the process seems to be a secondary one and to be part of an attempt at recovery, designed to lead the libido back to objects.
We began at an early date to extend psycho-analytic observations to these other illnesses. Already in 1908 Karl Abraham, after an exchange of thoughts with me, pronounced the main characteristic of dementia praecox (which was reckoned among the psychoses) to be that in it the libidinal cathexis of objects was lacking. But the question then arose of what happened to the libido of dementia praecox patients which was turned away from objects. Abraham did not hesitate to give the answer: it is turned back on to the ego and this reflexive turning-back is the source of the megalomania in dementia praecox. Megalomania is in every way comparable to the familiar sexual overvaluation of the object in erotic life. In this way for the first time we learnt to understand a trait in a psychotic illness by relating it to normal erotic life.

[1916-1917, 3461]

The form of disease known as paranoia, chronic systematic insanity, occupies an unsettled position in the attempts at classification made by present-day psychiatry. There is, however, no doubt of its close affinity to dementia praecox. I once ventured to suggest that paranoia and dementia praecox should be brought together under the common designation of 'paraphrenia'. The forms of paranoia are described according to their content as megalomania, persecution mania, erotomania, delusions of jealousy, and so on. We shall not expect anything much in the way of an attempt at an explanation from psychiatry. Here is an example of one, though, it is true, one that is out of date and does not carry much weight - an attempt to derive one symptom from another by means of an intellectual rationalization: it is suggested that the patient, who, owing to a primary disposition, believes that he is being persecuted, infers from his persecution that he must be someone of quite particular importance and so develops megalomania. According to our analytic view the megalomania is the direct result of a magnification of the ego due to the drawing in of the libidinal object-cathexes - a secondary narcissism which is a return of the original early infantile one. We have, however, made a few observations of persecution mania which have induced us to follow a particular track. The first thing that struck us was that in the large majority of cases the persecutor was of the same sex as the persecuted patient. This was still open to an innocent explanation; but in a few cases that were thoroughly studied it was clear that the person of the same sex whom the patient loved most had, since his illness, been turned into his persecutor. This made a further development possible: namely, the replacement of the beloved person, along the line of familiar resemblances, by someone else - for instance, a father by a schoolmaster or by some superior. Experiences of this kind in ever increasing numbers led us to conclude that paranoia persecutoria is the form of the disease in which a person is defending himself against a homosexual impulse which has become too powerful. The change over from affection to hatred, which, it is well known, may become a serious threat to the life of the loved and hated object, corresponds in such cases to the transformation of libidinal impulses into anxiety which is a regular outcome of the process of repression. Listen, for instance, to what is, once again, the most recent instance of my observations in this connection.

[1916-1917, 3468]
At the climax of his illness, under the influence of visions which were 'partly of a terrifying character, but partly, too, of an indescribable grandeur' (73), Schreber became convinced of the imminence of a great catastrophe, of the end of the world. Voices told him that the work of the past 14,000 years had now come to nothing, and that the earth's allotted span was only 212 years more (71); and during the last part of his stay in Flechsig's clinic he believed that that period had already elapsed. He himself was 'the only real man left alive', and the few human shapes that he still saw - the doctor, the attendants, the other patients - he explained as being 'miracled up, cursorily improvised men'. Occasionally the converse current of feeling also made itself apparent: a newspaper was put into his hands in which there was a report of his own death (81); he himself existed in a second, inferior shape, and in this second shape he one day quietly passed away (73). But the form of his delusion in which his ego was retained and the world sacrificed proved itself by far the more powerful. He had various theories of the cause of the catastrophe. At one time he had in mind a process of glaciation owing to the withdrawal of the sun; at another it was to be destruction by an earthquake, in the occurrence of which he, in his capacity of 'seer of spirits', was to act a leading part, just as another seer was alleged to have done in the Lisbon earthquake of 1755 (91). Or again, Flechsig was the culprit, since through his magic arts he had sown fear and terror among men, had wrecked the foundations of religion, and spread abroad general nervous disorders and immorality, so that devastating pestilences had descended upon mankind (91). In any case the end of the world was the consequence of the conflict which had broken out between him and Flechsig, or, according to the aetiology adopted in the second phase of his delusion, of the indissoluble bond which had been formed between him and God; it was, in fact, the inevitable result of his illness. Years afterwards, when Dr. Schreber had returned to human society, and could find no trace in the books, the musical scores, or the other articles of daily use which fell into his hands once more, of anything to bear out his theory that there had been a gap of vast duration in the history of mankind, he admitted that his view was no longer tenable: '. . . I can no longer avoid recognizing that, externally considered, everything is as it used to be. Whether, nevertheless, there may not have been a profound internal change is a question to which I shall recur later.' (84-5.) He could not bring himself to doubt that during his illness the world had come to an end and that, in spite of everything, the one that he now saw before him was a different one. [1911c, 2436]

A world-catastrophe of this kind is not infrequent during the agitated stage in other cases of paranoia.¹ If we base ourselves on our theory of libidinal cathexis, and if we follow the hint given by Schreber's view of other people as being 'cursorily improvised men', we shall not find it difficult to explain these catastrophes.² The patient has withdrawn from the people in his environment and from the external world generally the libidinal cathexis which he has hitherto directed on to them. Thus everything has become indifferent and irrelevant to him, and has to be explained by means of a secondary rationalization as being 'miracled up, cursorily improvised'. The end of the world is the projection of this internal catastrophe; his subjective world has come to an end since his withdrawal of his love from it.³ [1911c, 2437]

¹ An 'end of the world' based upon other motives is to be found at the climax of the ecstasy of love (cf. Wagner's Tristan und Isolde); in this case it is not the ego but the single love-object which absorbs all the cathexes directed upon the external world. [1911c, 2437]

³ He has perhaps withdrawn from it not only his libidinal cathexis, but his interest in general - that is, the cathexes that proceed from his ego as well. This question is discussed below. [1911c, 2437]
(2) An equally plausible objection can be based upon Schreber's case history, as well as upon many others. For it can be urged that the delusions of persecution (which were directed against Flechsig) unquestionably made their appearance at an earlier date than the phantasy of the end of the world; so that what is supposed to have been a return of the repressed actually preceded the repression itself - and this is patent nonsense. In order to meet this objection we must leave the high ground of generalization and descend to the detailed consideration of actual circumstances, which are undoubtedly very much more complicated. We must admit the possibility that a detachment of the libido such as we are discussing might just as easily be a partial one, a drawing back from some single complex, as a general one. A partial detachment should be by far the commoner of the two, and should precede a general one, since to begin with it is only for a partial detachment that the influences of life provide a motive. The process may then stop at the stage of a partial detachment or it may spread to a general one, which will loudly proclaim its presence in the symptoms of megalomania. Thus the detachment of the libido from the figure of Flechsig may nevertheless have been what was primary in the case of Schreber; it was immediately followed by the appearance of the delusion, which brought back the libido on to Flechsig again (though with a negative sign to mark the fact that repression had taken place) and thus annulled the work of repression. And now the battle of repression broke out anew, but this time with more powerful weapons. In proportion as the object of contention became the most important thing in the external world, trying on the one hand to draw the whole of the libido on to itself, and on the other hand mobilizing all the resistances against itself, so the struggle raging around this single object became more and more comparable to a general engagement; till at length a victory for the forces of repression found expression in a conviction that the world had come to an end and that the self alone survived. If we review the ingenious constructions which were raised by Schreber's delusion in the domain of religion - the hierarchy of God, the proved souls, the fore-courts of Heaven, the lower and the upper God - we can gauge in retrospect the wealth of sublimations which were brought down in ruin by the catastrophe of the general detachment of his libido.

[1911c, 2439]
A third consideration which arises from the views that have been developed in these pages is as follows. Are we to suppose that a general detachment of the libido from the external world would be an effective enough agent to account for the "end of the world"? Or would not the ego-cathexes which still remained in existence have been sufficient to maintain rapport with the external world? To meet this difficulty we should either have to assume that what we call libidinal cathexis (that is, interest emanating from erotic sources) coincides with interest in general, or we should have to consider the possibility that a very widespread disturbance in the distribution of libido may bring about a corresponding disturbance in the ego-cathexes. But these are problems which we are still quite helpless and incompetent to solve. It would be otherwise if we could start out from some well-grounded theory of instincts; but in fact we have nothing of the kind at our disposal. We regard instinct as being the concept on the frontier-line between the somatic and the mental, and see in it the psychical representative of organic forces. Further, we accept the popular distinction between ego-instincts and a sexual instinct; for such a distinction seems to agree with the biological conception that the individual has a double orientation, aiming on the one hand at self-preservation and on the other at the preservation of the species. But beyond this are only hypotheses, which we have taken up - and are quite ready to drop again - in order to help us to find our bearings in the chaos of the obscurer processes of the mind. What we expect from psycho-analytic investigations of pathological mental processes is precisely that they shall drive us to some conclusions on questions connected with the theory of instincts. These investigations, however, are in their infancy and are only being carried out by isolated workers, so that the hopes we place in them must still remain unfulfilled. We can no more dismiss the possibility that disturbances of the libido may react upon the ego-cathexes than we can overlook the converse possibility - namely, that a secondary or induced disturbance of the libidinal processes may result from abnormal changes in the ego. Indeed, it is probable that processes of this kind constitute the distinctive characteristic of psychoses. How much of all this may apply to paranoia it is impossible at present to say. There is one consideration, however, on which I should like to lay stress. It cannot be asserted that a paranoic, even at the height of the repression, withdraws his interest from the external world completely - as must be considered to occur in certain other kinds of hallucinatory psychosis (such a Meynert's amentia). The paranoic perceives the external world and takes into account any alterations that may happen in it, and the effect it makes upon him stimulates him to invent explanatory theories (such as Schreber's 'cursorily improvised men'). It therefore appears to me far more probable that the paranoic's altered relation to the world is to be explained entirely or in the main by the loss of his libidinal interest.

Since I neither fear the criticism of others nor shrink from criticizing myself, I have no motive for avoiding the mention of a similarity which may possibly damage our libido theory in the estimation of many of my readers. Schreber's 'rays of God', which are made up of a condensation of the sun's rays, of nerve fibres, and of spermatozoa, are in reality nothing else than a concrete representation and projection outwards of libidinal cathexes; and they thus lend his delusions a striking conformity with our theory. His belief that the world must come to an end because his ego was attracting all the rays to itself, his anxious concern at a later period, during the process of reconstruction, lest God should sever His ray-connection with him, - these and many other details of Schreber's delusional structure sound almost like endopsychic perceptions of the processes whose existence I have assumed in these page as the basis of our explanation of paranoia. I can nevertheless call a friend and fellow-specialist to witness that I had developed my theory of paranoia before I became acquainted with the contents of Schreber's book. It remains for the future to decide whether there is more delusion in my theory than I should like to admit, or whether there is more truth in Schreber's delusion than other people are as yet prepared to believe.
This extension of the libido theory - in my opinion, a legitimate one - receives reinforcement from a third quarter, namely, from our observations and views on the mental life of children and primitive peoples. In the latter we find characteristics which, if they occurred singly, might be put down to megalomania: an over-estimation of the power of their wishes and mental acts, the 'omnipotence of thoughts', a belief in the thaumaturgic force of words, and a technique for dealing with the external world - 'magic' - which appears to be a logical application of these grandiose premisses.¹ In the children of to-day, whose development is much more obscure to us, we expect to find an exactly analogous attitude towards the external world.² Thus we form the idea of there being an original libidinal cathexis of the ego, from which some is later given off to objects, but which fundamentally persists and is related to the object-cathexes much as the body of an amoeba is related to the pseudopodia which it puts out. In our researches, taking, as they did, neurotic symptoms for their starting-point, this part of the allocation of libido necessarily remained hidden from us at the outset. All that we noticed were the emanations of this libido - the object-cathexes, which can be sent out and drawn back again. We see also, broadly speaking, an antithesis between ego-libido and object-libido. The more of the one is employed, the more the other becomes depleted. The highest phase of development of which object-libido is capable is seen in the state of being in love, when the subject seems to give up his own personality in favour of an object-cathexis; while we have the opposite condition in the paranoid’s phantasy (or self-perception) of the 'end of the world'.³ Finally, as regards the differentiation of psychical energies, we are led to the conclusion that to begin with, during the state of narcissism, they exist together and that our analysis is too coarse to distinguish between them; not until there is object-cathexis is it possible to discriminate a sexual energy - the libido - from an energy of the ego-instincts.

[1914c, 2933]
(a) The medical officer lays stress upon two points as being of chief importance: the patient's assumption of the role of Redeemer, and his transformation into a woman. The Redeemer delusion is a phantasy that is familiar to us through the frequency with which it forms the nucleus of religious paranoia. The additional factor, which makes the redemption dependent upon the man being previously transformed into a woman, is unusual and in itself bewildering, since it shows such a wide divergence from the historical myth which the patient's phantasy is setting out to reproduce. It is natural to follow the medical report in assuming that the motive force of this delusional complex was the patient's ambition to play the part of Redeemer, and that his emasculation was only entitled to be regarded as a means for achieving that end. Even though this may appear to be true of his delusion in its final form, a study of the Denkwürdigkeiten compels us to take a very different view of the matter. For we learn that the idea of being transformed into a woman (that is, of being emasculated) was the primary delusion, that he began by regarding that act as constituting a serious injury and persecution, and that it only became related to his playing the part of Redeemer in a secondary way. There can be no doubt, moreover, that originally he believed that the transformation was to be effected for the purpose of sexual abuse and not so as to serve higher designs. The position may be formulated by saying that a sexual delusion of persecution was later on converted in the patient's mind into a religious delusion of grandeur. The part of persecutor was at first assigned to Professor Flechsig, the physician in whose charge he was; later, his place was taken by God Himself.

[1911c, 2394]

The medical report might easily lead us to suppose that Schreber exhibited the everyday form of Redeemer phantasy, in which the patient believes he is the son of God, destined to save the world from its misery or from the destruction that is threatening it, and so on. It is for this reason that I have been careful to present in detail the peculiarities of Schreber's relation to God. The significance of this relation for the rest of mankind is only rarely alluded to in the Denkwürdigkeiten and not until the last phase of his delusional formation. It consists essentially in the fact that no one who dies can enter the state of bliss so long as the greater part of the rays of God are absorbed in his (Schreber's) person, owing to his powers of attraction (32). It is only at a very late stage, too, that his identification with Jesus Christ makes an undisguised appearance (338 and 431).

[1911c, 2403]
(b) Another element is chosen for contradiction in *erotomania*, which remains totally unintelligible on any other view:
'I do not love *him* - I love *her*.'
[1911c, 2432]

'I do not love *him* - I love *her*, because SHE LOVES ME.'
[1911c, 2432]

Distortion by means of projection is necessarily absent in this instance, since, with the change of the subject who loves, the whole process is in any case thrown outside the self. The fact that the woman loves the men is a matter of external perception to him; whereas the facts that he himself does not love but hates, or that he himself loves not this but that person, are matters of internal perception.
[1911c, 2433]

[(d)] Now it might be supposed that a proposition consisting of three terms, such as '*I love him*', could only be contradicted in three different ways. Delusions of jealousy contradict the subject, delusions of persecution contradict the verb, and erotomania contradicts the object. But in fact a fourth kind of contradiction is possible - namely, one which rejects the proposition as a whole:
[1911c, 2433]
I then succeeded in getting her to reproduce the various scenes in which her sexual relationship with her brother (which had certainly lasted at least from her sixth to her tenth year) had culminated. During this work of reproduction, the physical sensation in her abdomen 'joined in the conversation' as it were, as is regularly observed to happen in the analysis of hysterical mnemonic residues. The image of the lower part of a woman's naked abdomen (but now reduced to childish proportions and without hair on it) appeared with the sensation or stayed away, according as the scene in question had occurred in full light or in the dark. Her disgust at eating, too, found an explanation in a repulsive detail of these proceedings. After we had gone through this series of scenes, the hallucinatory sensations and images had disappeared, and (up to the present, at any rate) they have not returned.¹

The language of dreams may be looked upon as the method by which unconscious mental activity expresses itself. But the unconscious speaks more than one dialect. According to the differing psychological conditions governing and distinguishing the various forms of neurosis, we find regular modifications in the way in which unconscious mental impulses are expressed. While the gesture-language of hysteria agrees on the whole with the picture-language of dreams and visions, etc., the thought-language of obsessional neurosis and of the paraphrenias (dementia praecox and paranoia) exhibits special idiomatic peculiarities which, in a number of instances, we have been able to understand and interrelate. For instance, what a hysteric expresses by vomiting an obsessional will express by painstaking protective measures against infection, while a paraphrenic will be led to complaints or suspicions that he is being poisoned. These are all of them different representations of the patient's wish to become pregnant which have been repressed into the unconscious, or of his defensive reaction against that wish.

(b) The function of nutrition is most frequently disturbed by a disinclination to eat, brought about by a withdrawal of libido. An increase in the desire to eat is also a not uncommon thing. The compulsion to eat is attributed to a fear of starving; but this is a subject which has been but little studied. The symptom of vomiting is known to us as a hysterical defence against eating. Refusal to eat owing to anxiety is a concomitant of psychotic states (delusions of being poisoned).

¹ [1896b, 400]
We shall be glad, then, to know the nature of the girl's libidinal relations to her mother. The answer is that they are of very many different kinds. Since they persist through all three phases of infantile sexuality, they also take on the characteristics of the different phases and express themselves by oral, sadistic-anal and phallic wishes. These wishes represent active as well as passive impulses; if we relate them to the differentiation of the sexes which is to appear later - though we should avoid doing so as far as possible - we may call them masculine and feminine. Besides this, they are completely ambivalent, both affectionate and of a hostile and aggressive nature. The latter often only come to light after being changed into anxiety ideas. It is not always easy to point to a formulation of these early sexual wishes; what is most clearly expressed is a wish to get the mother with child and the corresponding wish to bear her a child - both belonging to the phallic period and sufficiently surprising, but established beyond doubt by analytic observation. The attractiveness of these investigations lies in the surprising detailed findings which they bring us. Thus, for instance, we discover the fear of being murdered or poisoned, which may later form the core of a paranoic illness, already present in this pre-Oedipus period, in relation to the mother. Or another case: you will recall an interesting episode in the history of analytic research which caused me many distressing hours. In the period in which the main interest was directed to discovering infantile sexual traumas, almost all my women patients told me that they had been seduced by their father. I was driven to recognize in the end that these reports were untrue and so came to understand that hysterical symptoms are derived from phantasies and not from real occurrences. It was only later that I was able to recognize in this phantasy of being seduced by the father the expression of the typical Oedipus complex in women. And now we find the phantasy of seduction once more in the pre-Oedipus prehistory of girls; but the seducer is regularly the mother. Here, however, the phantasy touches the ground of reality, for it was really the mother who by her activities over the child's bodily hygiene inevitably stimulated, and perhaps even roused for the first time, pleasurable sensations in her genitals.

[1933a, 4722]

The reproach against the mother which goes back furthest is that she gave the child too little milk - which is construed against her as lack of love. Now there is some justification for this reproach in our families. Mothers often have insufficient nourishment to give their children and are content to suckle them for a few months, for half or three-quarters of a year. Among primitive peoples children are fed at their mother's breast for two or three years. The figure of the wet-nurse who suckles the child is as a rule merged into the mother; when this has not happened, the reproach is turned into another one - that the nurse, who fed the child so willingly, was sent away by the mother too early. But whatever the true state of affairs may have been, it is impossible that the child's reproach can be justified as often as it is met with. It seems, rather, that the child's avidity for its earliest nourishment is altogether insatiable, that it never gets over the pain of losing its mother's breast. I should not be surprised if the analysis of a primitive child, who could still suck at its mother's breast when it was already able to run about and talk, were to bring the same reproach to light. The fear of being poisoned is also probably connected with the withdrawal of the breast. Poison is nourishment that makes one ill. Perhaps children trace back their early illnesses too to this frustration. A fair amount of intellectual education is a prerequisite for believing in chance; primitive people and uneducated ones, and no doubt children as well, are able to assign a ground for everything that happens. Perhaps originally it was a reason on animistic lines. Even to-day in some strata of our population no one can die without having been killed by someone else - preferably by the doctor. And the regular reaction of a neurotic to the death of someone closely connected with him is to put the blame on himself for having caused the death.

[1933a, 4724]
I now turned to the analysis of the voices. First and foremost what had to be explained was why such an indifferent content as 'Here comes Frau P.', 'She's looking for a house now', and so on, could have been so distressing to her; next, how it was that precisely these innocent phrases had managed to be marked out by hallucinatory reinforcement. From the first it was clear that the 'voices' could not be memories that were being produced in a hallucinatory way, like the images and sensations, but were rather thoughts that were being 'said aloud'.

[1896b, 401]

These statements are of decisive importance in determining the view we are to take of the delusion of emasculation and in thus giving us a general understanding of the case. It may be added that the 'voices' which the patient heard never treated his transformation into a woman as anything but a sexual disgrace, which gave them an excuse for jeering at him. 'Rays of God¹ not infrequently thought themselves entitled to mock at me by calling me "Miss² Schreber", in allusion to the emasculation which, it was alleged, I was about to undergo.' (127.) Or they would say: 'So this sets up to have been a Senatspräsident, this person who lets himself be f--d!'³ Or again: 'Don't you feel ashamed in front of your wife?'

[1911c, 2396]

¹ 'Even now the voices that talk with me call out your name to me hundreds of times each day. They name you in certain constantly recurring connections, and especially as being the first author of the injuries I have suffered. And yet the personal relations which existed between us for a time have, so far as I am concerned, long since faded into the background; so that I myself could have little enough reason to be for ever recalling you to my mind, and still less for doing so with any feelings of resentment.' ('Open Letter to Professor Flechsig', viii.)

[1911c, 2412]

We are perfectly familiar with the infantile attitude of boys towards their father; it is composed of the same mixture of reverent submission and mutinous insubordination that we have found in Schreber's relation to his God, and is the unmistakable prototype of that relation, which is faithfully copied from it. But the circumstance that Schreber's father was a physician, and a most eminent physician, and one who was no doubt highly respected by his patients, is what explains the most striking characteristics of his God and those upon which he dwells in such a critical fashion. Could more bitter scorn be shown for such a physician than by declaring that he understands nothing about living men and only knows how to deal with corpses? No doubt it is an essential attribute of God to perform miracles; but a physician performs miracles too; he effects miraculous cures, as his enthusiastic clients proclaim. So that when we see that these very miracles (the material for which was provided by the patient's hypochondria) turn out to be incredible, absurd, and to some extent positively silly, we are reminded of the assertion in my Interpretation of Dreams that absurdity in dreams expresses ridicule and derision.¹ Evidently, therefore, it is used for the same purposes in paranoia. As regards some of the other reproaches which he levelled against God, such, for instance, as that He learned nothing by experience, it is natural to suppose that they are examples of the tu quoque mechanism used by children,² which, when they receive a reproof, flings it back unchanged upon the person who originated it. Similarly, the voices give us grounds for suspecting that the accusation of soul-murder brought against Flechsig was in the first instance a self-accusation.³
Thus in the case of Schreber we find ourselves once again on the familiar ground of the father-complex.¹ The patient's struggle with Flechsig became revealed to him as a conflict with God, and we must therefore construe it as an infantile conflict with the father whom he loved; the details of that conflict (of which we know nothing) are what determined the content of his delusions. None of the material which in other cases of the sort is brought to light by analysis is absent in the present one: every element is hinted at in one way or another. In infantile experiences such as this the father appears as an interferer with the satisfaction which the child is trying to obtain; this is usually of an auto-erotic character, though at a later date it is often replaced in phantasy by some other satisfaction of a less inglorious kind.² In the final stage of Schreber's delusion a magnificent victory was scored by the infantile sexual urge; for voluptuousness became God-fearing, and God Himself (his father) never tired of demanding it from him. His father's most dreaded threat, castration, actually provided the material for his wishful phantasy (at first resisted but later accepted) of being transformed into a woman. His allusion to an offence covered by the surrogate idea 'soul-murder' could not be more transparent. The chief attendant was discovered to be identical with his neighbour von W., who, according to the voices, had falsely accused him of masturbation (108). The voices said, as though giving grounds for the threat of castration: 'For you are to be represented as being given over to voluptuous excesses.'³ (127-8.) Finally, we come to the enforced thinking (47) to which the patient submitted himself because he supposed that God would believe he had become an idiot and would withdraw from him if he ceased thinking for a moment. This is a reaction (with which we are also familiar in other connections) to the threat or fear of losing one's reason as a result of indulging in sexual practices and especially in masturbation. Considering the enormous number of delusional ideas of a hypochondriacal nature which the patient developed, no great importance should perhaps be attached to the fact that some of them coincide word for word with the hypochondriacal fears of masturbators.²

6 'For this reason attempts were made to pump out my spinal cord. This was done by means of so-called "little men" who were placed in my feet. I shall have more to say presently on the subject of these "little men", who showed some resemblance to the phenomena of the same name which I have already discussed in Chapter VI. There used as a rule to be two of them - a "little Flechsig" and a "little von W." - And I used to hear their voices, too, in my feet.' (154.) Von W. was the man who was supposed to have accused Schreber of masturbation. The 'little men' are described by Schreber himself as being among the most remarkable and, in some respects, the most puzzling phenomena of his illness (157). It looks as though they were the product of a condensation of children and - spermatozoa.

It would not surprise us if we were to find a special psychical agency which performs the task of seeing that narcissistic satisfaction from the ego ideal is ensured and which, with this end in view, constantly watches the actual ego and measures it by that ideal. If such an agency does exist, we cannot possibly come upon it as a discovery - we can only recognize it; for we may reflect that what we call our 'conscience' has the required characteristics. Recognition of this agency enables us to understand the so-called 'delusions of being noticed' or more correctly, of being watched, which are such striking symptoms in the paranoid diseases and which may also occur as an isolated form of illness, or intercalated in a transference neurosis. Patients of this sort complain that all their thoughts are known and their actions watched and supervised; they are informed of the functioning of this agency by voices which characteristically speak to them in the third person ('Now she's thinking of that again', 'now he's going out'). This complaint is justified; it describes the truth. A power of this kind, watching, discovering and criticizing all our intentions, does really exist. Indeed, it exists in every one of us in normal life.
In this way large amounts of libido of an essentially homosexual kind are drawn into the formation of the narcissistic ego ideal and find outlet and satisfaction in maintaining it. The institution of conscience was at bottom an embodiment, first of parental criticism, and subsequently of that of society - a process which is repeated in what takes place when a tendency towards repression develops out of a prohibition or obstacle that came in the first instance from without. The voices, as well as the undefined multitude, are brought into the foreground again by the disease, and so the evolution of conscience is reproduced regressively. But the revolt against this 'censoring agency' arises out of the subject's desire (in accordance with the fundamental character of his illness) to liberate himself from all these influences, beginning with the parental one, and out of his withdrawal of homosexual libido from them. His conscience then confronts him in a regressive form as a hostile influence from without.

[1914c, 2949]

We describe one group of these patients as suffering from delusions of being observed. They complain to us that perpetually, and down to their most intimate actions, they are being molested by the observation of unknown powers - presumably persons - and that in hallucinations they hear these persons reporting the outcome of their observation: 'now he's going to say this, now he's dressing to go out' and so on. Observation of this sort is not yet the same thing as persecution, but it is not far from it; it presupposes that people distrust them, and expect to catch them carrying out forbidden actions for which they would be punished. How would it be if these insane people were right, if in each of us there is present in his ego an agency like this which observes and threatens to punish, and which in them has merely become sharply divided from their ego and mistakenly displaced into external reality?

[1933a, 4668]
Other symptoms of my case of paranoia are to be described as symptoms of the return of the repressed, and they, too, like those of obsessional neurosis, bear the traces of the compromise which alone allows them to enter consciousness. Such are, for instance, my patient's delusional idea of being watched while she was undressing, her visual hallucinations, her hallucinations of sensation and her hearing of voices. In the delusional idea which I have just mentioned there is a mnemonic content which is almost unaltered and has only been made indefinite through omission. The return of the repressed in visual images approaches the character of hysteria rather than of obsessional neurosis; but hysteria is in the habit of repeating its mnemonic symbols without modification, whereas mnemonic hallucinations in paranoia undergo a distortion similar to that in obsessional neurosis: an analogous modern image takes the place of the repressed one. (E.g., the abdomen of an adult woman appears instead of a child's, and an abdomen on which the hairs are especially distinct, because they were absent in the original impression.) A thing which is quite peculiar to paranoia and on which no further light can be shed by this comparison, is that the repressed self-reproaches return in the form of thoughts spoken aloud. In the course of this process, they are obliged to submit to twofold distortion: they are subjected to a censorship, which leads to their being replaced by other, associated, thoughts or to their being concealed by an indefinite mode of expression, and they are referred to recent experiences which are no more than analogous to the old ones.

[1896b, 403]
Thus in the case of Schreber we find ourselves once again on the familiar ground of the father-complex.¹ The patient's struggle with Flechsig became revealed to him as a conflict with God, and we must therefore construe it as an infantile conflict with the father whom he loved; the details of that conflict (of which we know nothing) are what determined the content of his delusions. None of the material which in other cases of the sort is brought to light by analysis is absent in the present one: every element is hinted at in one way or another. In infantile experiences such as this the father appears as an interferer with the satisfaction which the child is trying to obtain; this is usually of an auto-erotic character, though at a later date it is often replaced in phantasy by some other satisfaction of a less inglorious kind.² In the final stage of Schreber's delusion a magnificent victory was scored by the infantile sexual urge; for voluptuousness became God-fearing, and God Himself (his father) never tired of demanding it from him. His father's most dreaded threat, castration, actually provided the material for his wishful phantasy (at first resisted but later accepted) of being transformed into a woman. His allusion to an offence covered by the surrogate idea 'soul-murder' could not be more transparent. The chief attendant was discovered to be identical with his neighbour von W., who, according to the voices, had falsely accused him of masturbation (108). The voices said, as though giving grounds for the threat of castration: 'For you are to be represented as being given over to voluptuous excesses.'³ (127-8.) Finally, we come to the enforced thinking (47) to which the patient submitted himself because he supposed that God would believe he had become an idiot and would withdraw from him if he ceased thinking for a moment. This is a reaction (with which we are also familiar in other connections) to the threat or fear of losing one's reason⁴ as a result of indulging in sexual practices and especially in masturbation. Considering the enormous number of delusional ideas of a hypochondriacal nature which the patient developed, no great importance should perhaps be attached to the fact that some of them coincide word for word with the hypochondriacal fears of masturbators.⁵

¹ I must not omit to remark at this point that I shall not consider any theory of paranoia trustworthy unless it also covers the hypochondriacal symptoms by which that disorder is almost invariably accompanied. It seems to me that hypochondria stands in the same relation to paranoia as anxiety neurosis does to hysteria.

[1911c, 2427]
I shall try here to penetrate a little further into the mechanism of paraphrenia and shall bring together those views which already seem to me to deserve consideration. The difference between paraphrenic affections and the transference neuroses appears to me to lie in the circumstance that, in the former, the libido that is liberated by frustration does not remain attached to objects in phantasy, but withdraws on to the ego. Megalomania would accordingly correspond to the psychical mastering of this latter amount of libido, and would thus be the counterpart of the introversion on to phantasies that is found in the transference neuroses; a failure of this psychical function gives rise to the hypochondria of paraphrenia and this is homologous to the anxiety of the transference neuroses. We know that this anxiety can be resolved by further psychical working over, i.e. by conversion, reaction-formation or the construction of protections (phobias). The corresponding process in paraphrenics is an attempt at restoration, to which the striking manifestations of the disease are due. Since paraphrenia frequently, if not usually, brings about only a partial detachment of the libido from objects, we can distinguish three groups of phenomena in the clinical picture: (1) those representing what remains of a normal state or of neurosis (residual phenomena); (2) those representing the morbid process (detachment of libido from its objects and, further, megalomania, hypochondria, affective disturbance and every kind of regression); (3) those representing restoration, in which the libido is once more attached to objects, after the manner of a hysteria (in dementia praecox or paraphrenia proper), or of an obsessional neurosis (in paranoia). This fresh libidinal cathexis differs from the primary one in that it starts from another level and under other conditions. The difference between the transference neuroses brought about in the case of this fresh kind of libidinal cathexis and the corresponding formations where the ego is normal should be able to afford us the deepest insight into the structure of our mental apparatus.

[1914c, 2941]

The patient's comments on her unintelligible remark have the value of an analysis, for they contain the equivalent of the remark expressed in a generally comprehensible form. They throw light at the same time on the meaning and the genesis of schizophrenic word-formation. I agree with Tausk in stressing in this example the point that the patient's relation to a bodily organ (the eye) has arrogated to itself the representation of the whole content. Here the schizophrenic utterance exhibits a hypochondriac trait: it has become 'organ-speech'.

[1915e, 3020]
Before we draw any conclusion from impressions such as these, let us consider further the
distinctions between the formation of substitutes in schizophrenia on the one hand, and in
hysteria and obsessional neurosis on the other - subtle distinctions which nevertheless make a
strange impression. A patient whom I have at present under observation has allowed himself to
be withdrawn from all the interests of life on account of a bad condition of the skin of his face.
He declares that he has black heads and deep holes in his face which everyone notices.
Analysis shows that he is playing out his castration complex upon his skin. At first he worked at
these blackheads remorselessly; and it gave him great satisfaction to squeeze them out,
because, as he said, something spat out when he did so. Then he began to think that a deep
cavity appeared wherever he had got rid of a blackhead, and he reproached himself most
vehemence with having ruined his skin for ever by 'constantly fiddling about with his hand'.
Pressing out the content of the blackheads is clearly to him a substitute for masturbation. The
cavity which then appears owing to his fault is the female genital, i.e. the fulfillment of the threat
of castration (or the phantasy representing that threat) provoked by his masturbatting. This
substitutive formation has, in spite of its hypochondriacal character, considerable resemblance
to a hysterical conversion; and yet we have a feeling that something different must be going on
here, that a substitutive formation such as this cannot be attributed to hystera, even before we
can say in what the difference consists. A tiny little cavity such as a pore of the skin would
hardly be used by a hysteric as a symbol for the vagina, which he is otherwise ready to
compare with every imaginable object that encloses a hollow space. Besides, we should expect
the multiplicity of these little cavities to prevent him from using them as a substitute for the
female genital. The same applies to the case of a young patient reported by Tausk some years
ago to the Vienna Psycho-Analytical Society. This patient behaved in other respects exactly as
though he were suffering from an obsessional neurosis; he took hours to wash and dress, and
so on. It was noticeable, however, that he was able to give the meaning of his inhibitions without
any resistance. In putting on his stockings, for instance, he was disturbed by the idea that he
must pull apart the stitches in the knitting, i.e. the holes, and to him every hole was a symbol of
the female genital aperture. This again is a thing which we cannot attribute to an obsessional
neurotic. Reitler observed a patient of the latter sort, who also suffered from having to take a
long time over putting on his stockings; this man, after overcoming his resistances, found as the
explanation that his foot symbolized a penis, that putting on the stocking stood for a
masturbatory act, and that he had to keep on pulling the stocking on and off, partly in order to
complete the picture of masturbation, and partly in order to undo that act.
[1915e, 3021]

A noteworthy relation between the symptoms of the 'actual' neuroses and of the
psychoneuroses makes a further important contribution to our knowledge of the formation of
symptoms in the latter. For a symptom of an 'actual' neurosis is often the nucleus and first stage
of a psychoneurotic symptom. A relation of this kind can be most clearly observed between
neurasthenia and the transference neurosis known as 'conversion hysteria', between anxiety
neurosis and anxiety hysteria, but also between hypochondria and the forms of disorder which
will be mentioned later under the name of paraphrenia (dementia praecox and paranoia). Let us
take as an example a case of hysterical headache or lumbar pain. Analysis shows us that, by
condensation and displacement, it has become a substitutive satisfaction for a whole number of
libidinal phantasies or memories. But this pain was also at one time a real one and it was then a
direct sexual-toxic symptom, the somatic expression of a libidinal excitation. We are far from
asserting that all hysterical symptoms contain a nucleus of this kind. But it remains a fact that
this is especially often the case and that whatever somatic influences (whether normal or
pathological) are brought about by libidinal excitation are preferred for the construction of
hysterical symptoms. In such cases they play the part of the grain of sand which a mollusc
coats with layers of mother-of-pearl. In the same way, the passing indications of sexual
excitation which accompany the sexual act are employed by the psychoneurosis as the most
convenient and appropriate material for the construction of symptoms.
[1916-1917, 3441]
What attitude, then, will a psychiatrist adopt in a case of illness like this? We know already how he would behave to the symptomatic action of the patient who fails to shut the consulting-room door. He pronounces it to be a chance event of no psychological interest with which he has no further concern. But this procedure cannot be carried over to the illness of the jealous woman. The symptomatic action seems to be a matter of indifference; but the symptom forces itself on our attention as a matter of importance. It is accompanied by intense subjective suffering and, as an objective fact, it threatens the communal life of a family; it is thus an undeniable subject of psychiatric interest. The psychiatrist will start by endeavouring to characterize the symptom by some essential feature. The idea with which the woman torments herself cannot in itself be called absurd; it does, indeed, happen that elderly gentlemen have love affairs with young girls. But there is something else about it which is absurd and hard to understand. The patient had no other reason at all for believing that her affectionate and loyal husband belonged to this otherwise not so rare class of husbands except what was asserted in the anonymous letter. She knew that this document had no evidential value and she was able to give a satisfying explanation of its origin. She ought therefore to have been able to tell herself that she had no ground whatever for her jealousy, and she did tell herself so. But in spite of this she suffered as much as if she regarded this jealousy as completely justified. Ideas of this kind, which are inaccessible to logical arguments based on reality, are by general agreement described as delusions. The good lady, then, was suffering from delusions of jealousy. This is no doubt the essential feature of this case of illness.

[1916-1917, 3332]

You will recall that at our first meeting of the present academic year I described a case to you of a woman suffering from delusions of jealousy. Now that we are so near its end you would no doubt like to hear how delusions are explained by psycho-analysis. But I have less to tell you about that than you expect. The fact that a delusion cannot be shaken by logical arguments or real experiences is explained in the same way as in the case of an obsession - by its relation to the unconscious, which is represented and held down by the delusion or by the obsession. The difference between the two is based on the difference between the topography and dynamics of the two illnesses.

[1916-1917, 3471]

As regards the third and apparently sadistic phase of the beating-phantasy, I have already discussed the significance that it gains as the vehicle of the excitation impelling towards masturbation; and I have shown how it arouses activities of the imagination which on the one hand continue the phantasy along the same line, and on the other hand neutralize it through compensation. Nevertheless the second phase, the unconscious and masochistic one, in which the child itself is being beaten by its father, is incomparably the more important. This is not only because it continues to operate through the agency of the phase that takes its place; we can also detect effects upon the character, which are directly derived from its unconscious form. People who harbour phantasies of this kind develop a special sensitiveness and irritability towards anyone whom they can include in the class of fathers. They are easily offended by a person of this kind, and in that way (to their own sorrow and cost) bring about the realization of the imagined situation of being beaten by their father. I should not be surprised if it were one day possible to prove that the same phantasy is the basis of the delusional litigiousness of paranoia.

[1919e, 3655]
In a psychosis, the transforming of reality is carried out upon the psychical precipitates of former relations to it - that is, upon the memory-traces, ideas and judgements which have been previously derived from reality and by which reality was represented in the mind. But this relation was never a closed one; it was continually being enriched and altered by fresh perceptions. Thus the psychosis is also faced with the task of procuring for itself perceptions of a kind which shall correspond to the new reality; and this is most radically effected by means of hallucination. The fact that, in so many forms and cases of psychosis, the paramnesias, the delusions and the hallucinations that occur are of a most distressing character and are bound up with a generation of anxiety - this fact is without doubt a sign that the whole process of remodelling is carried through against forces which oppose it violently. We may construct the process on the model of a neurosis, with which we are more familiar. There we see that a reaction of anxiety sets in whenever the repressed instinct makes a thrust forward, and that the outcome of the conflict is only a compromise and does not provide complete satisfaction. Probably in a psychosis the rejected piece of reality constantly forces itself upon the mind, just as the repressed instinct does in a neurosis, and that is why in both cases the consequences too are the same. The elucidation of the various mechanisms which are designed, in the psychoses, to turn the subject away from reality and to reconstruct reality - this is a task for specialized psychiatric study which has not yet been taken in hand.

[1924e, 4096]

Another procedure operates more energetically and more thoroughly. It regards reality as the sole enemy and as the source of all suffering, with which it is impossible to live, so that one must break off all relations with it if one is to be in any way happy. The hermit turns his back on the world and will have no truck with it. But one can do more than that; one can try to re-create the world, to build up in its stead another world in which its most unbearable features are eliminated and replaced by others that are in conformity with one's own wishes. But whoever, in desperate defiance, sets out upon this path to happiness will as a rule attain nothing. Reality is too strong for him. He becomes a madman, who for the most part finds no one to help him in carrying through his delusion. It is asserted, however, that each one of us behaves in some one respect like a paranoic, corrects some aspect of the world which is unbearable to him by the construction of a wish and introduces this delusion into reality. A special importance attaches to the case in which this attempt to procure a certainty of happiness and a protection against suffering through a delusional remoulding of reality is made by a considerable number of people in common. The religions of mankind must be classed among the mass delusions of this kind. No one, needless to say, who shares a delusion ever recognizes it as such.

[1930a, 4480]
We have repeatedly had to insist on the fact that the ego owes its origin as well as the most important of its acquired characteristics to its relation to the real external world. We are thus prepared to assume that the ego's pathological states, in which it most approximates once again to the id, are founded on a cessation or slackening of that relation to the external world. This tallies very well with what we learn from clinical experience - namely, that the precipitating cause of the outbreak of a psychosis is either that reality has become intolerably painful or that the instincts have become extraordinarily intensified - both of which, in view of the rival claims made on the ego by the id and the external world, must lead to the same result. The problem of psychoses would be simple and perspicuous if the ego's detachment from reality could be carried through completely. But that seems to happen only rarely or perhaps never. Even in a state so far removed from the reality of the external world as one of hallucinatory confusion, one learns from patients after their recovery that at the time in some corner of their mind (as they put it) there was a normal person hidden, who, like a detached spectator, watched the hubbub of illness go past him. I do not know if we may assume that this is so in general, but I can report the same of other psychoses with a less tempestuous course. I call to mind a case of chronic paranoia in which after each attack of jealousy a dream conveyed to the analyst a correct picture of the precipitating cause, free from any delusion. An interesting contrast was thus brought to light: while we are accustomed to discover from the dreams of neurotics jealousies which are alien to their waking lives, in this psychotic case the delusion which dominated the patient in the day-time was corrected by his dream. We may probably take it as being generally true that what occurs in all these cases is a psychical split. Two psychical attitudes have been formed instead of a single one - one, the normal one, which takes account of reality, and another which under the influence of the instincts detaches the ego from reality. The two exist alongside of each other. The issue depends on their relative strength. If the second is or becomes the stronger, the necessary precondition for a psychosis is present. If the relation is reversed, then there is an apparent cure of the delusional disorder. Actually it has only retreated into the unconscious - just as numerous observations lead us to believe that the delusion existed ready-made for a long time before its manifest irruption.

[1940a [1938], 5007]

These recollections might have been described as hallucinations if a belief in their actual presence had been added to their clearness. The importance of this analogy seemed greater when I noticed that true hallucinations occasionally occurred in the case of other patients who were certainly not psychotic. My line of thought proceeded as follows. Perhaps it may be a general characteristic of hallucinations to which sufficient attention has not hitherto been paid that in them something that has been experienced in infancy and then forgotten returns - something that the child has seen or heard at a time when he could still hardly speak and that now forces its way into consciousness, probably distorted and displaced owing to the operation of forces that are opposed to this return. And, in view of the close relation between hallucinations and particular forms of psychosis, our line of thought may be carried still further. It may be that the delusions into which these hallucinations are so constantly incorporated may themselves be less independent of the upward drive of the unconscious and the return of the repressed than we usually assume. In the mechanism of a delusion we stress as a rule only two factors: the turning away from the real world and its motive forces on the one hand, and the influence exercised by wish-fulfilment on the content of the delusion on the other. But may it not be that the dynamic process is rather that the turning away from reality is exploited by the upward drive of the repressed in order to force its content into consciousness, while the resistances stirred up by this process and the trend to wish-fulfilment share the responsibility for the distortion and displacement of what is recollected? This is after all the familiar mechanism of dreams, which intuition has equated with madness from time immemorial.

[1937d, 5058]
This view of delusions is not, I think, entirely new, but it nevertheless emphasizes a point of view which is not usually brought into the foreground. The essence of it is that there is not only method in madness, as the poet has already perceived, but also a fragment of historical truth; and it is plausible to suppose that the compulsive belief attaching to delusions derives its strength precisely from infantile sources of this kind. All that I can produce to-day in support of this theory are reminiscences, not fresh impressions. It would probably be worth while to make an attempt to study cases of the disorder in question on the basis of the hypotheses that have been here put forward and also to carry out their treatment on those same lines. The vain effort would be abandoned of convincing the patient of the error of his delusion and of its contradiction of reality; and, on the contrary, the recognition of its kernel of truth would afford common ground upon which the therapeutic work could develop. That work would consist in liberating the fragment of historical truth from its distortions and its attachments to the actual present day and in leading it back to the point in the past to which it belongs. The transposing of material from a forgotten past on to the present or on to an expectation of the future is indeed a habitual occurrence in neurotics no less than in psychotics. Often enough, when a neurotic is led by an anxiety-state to expect the occurrence of some terrible event, he is in fact merely under the influence of a repressed memory (which is seeking to enter consciousness but cannot become conscious) that something which was at that time terrifying did really happen. I believe that we should gain a great deal of valuable knowledge from work of this kind upon psychotics even if it led to no therapeutic success.

I am aware that it is of small service to handle so important a subject in the cursory fashion that I have here employed. But none the less I have not been able to resist the seduction of an analogy. The delusions of patients appear to me to be the equivalents of the constructions which we build up in the course of an analytic treatment - attempts at explanation and cure, though it is true that these, under the conditions of a psychosis, can do no more than replace the fragment of reality that is being disavowed in the present by another fragment that had already been disavowed in the remote past. It will be the task of each individual investigation to reveal the intimate connections between the material of the present disavowal and that of the original repression. Just as our construction is only effective because it recovers a fragment of lost experience, so the delusion owes its convincing power to the element of historical truth which it inserts in the place of the rejected reality. In this way a proposition which I originally asserted only of hysteria would apply also to delusions - namely, that those who are subject to them are suffering from their own reminiscences. I never intended by this short formula to dispute the complexity of the causation of the illness or to exclude the operation of many other factors.
Of the actual nature of Flechsig’s enormity and its motives the patient speaks with the characteristic vagueness and obscurity which may be regarded as marks of an especially intense work of delusion-formation, if it is legitimate to judge paranoia on the model of a far more familiar mental phenomenon - the dream. Flechsig, according to the patient, committed, or attempted to commit, ‘soul-murder’ upon him - an act which, he thought, was comparable with the effort made by the devil or by demons to gain possession of a soul and may have had its prototype in events which occurred between members of the Flechsig and Schreber families long since deceased (22 ff.). We should be glad to learn more of the meaning of this ‘soul-murder’, but at this point our sources relapse once more into a tendentious silence: ‘As to what constitutes the true essence of soul-murder, and as to its technique, if I may so describe it, I am able to say nothing beyond what has already been indicated. There is only this, perhaps, to be added . . . (The passage which follows is unsuitable for publication.)’ (28.) As a result of this omission we are left in the dark on the question of what is meant by ‘soul-murder’. We shall refer later on to the only hint upon the subject which has evaded censorship. [1911c, 2412]
It is worth specially stressing the fact that each portion which returns from oblivion asserts itself with peculiar force, exercises an incomparably powerful influence on people in the mass, and raises an irresistible claim to truth against which logical objections remain powerless: a kind of 'credo quia absurdum'. This remarkable feature can only be understood on the pattern of the delusions of psychotics. We have long understood that a portion of forgotten truth lies hidden in delusional ideas, that when this returns it has to put up with distortions and misunderstandings, and that the compulsive conviction which attaches to the delusion arises from this core of truth and spreads out on to the errors that wrap it round. We must grant an ingredient such as this of what may be called historical truth to the dogmas of religion as well, which, it is true, bear the character of psychotic symptoms but which, as group phenomena, escape the curse of isolation. [1939a, 4909]

These recollections might have been described as hallucinations if a belief in their actual presence had been added to their clearness. The importance of this analogy seemed greater when I noticed that true hallucinations occasionally occurred in the case of other patients who were certainly not psychotic. My line of thought proceeded as follows. Perhaps it may be a general characteristic of hallucinations to which sufficient attention has not hitherto been paid that in them something that has been experienced in infancy and then forgotten returns - something that the child has seen or heard at a time when he could still hardly speak and that now forces its way into consciousness, probably distorted and displaced owing to the operation of forces that are opposed to this return. And, in view of the close relation between hallucinations and particular forms of psychosis, our line of thought may be carried still further. It may be that the delusions into which these hallucinations are so constantly incorporated may themselves be less independent of the upward drive of the unconscious and the return of the repressed than we usually assume. In the mechanism of a delusion we stress as a rule only two factors: the turning away from the real world and its motive forces on the one hand, and the influence exercised by wish-fulfilment on the content of the delusion on the other. But may it not be that the dynamic process is rather that the turning away from reality is exploited by the upward drive of the repressed in order to force its content into consciousness, while the resistances stirred up by this process and the trend to wish-fulfilment share the responsibility for the distortion and displacement of what is recollected? This is after all the familiar mechanism of dreams, which intuition has equated with madness from time immemorial. [1937d, 5058]
We are perfectly familiar with the infantile attitude of boys towards their father; it is composed of the same mixture of reverent submission and mutinous insubordination that we have found in Schreber's relation to his God, and is the unmistakable prototype of that relation, which is faithfully copied from it. But the circumstance that Schreber's father was a physician, and a most eminent physician, and one who was no doubt highly respected by his patients, is what explains the most striking characteristics of his God and those upon which he dwells in such a critical fashion. Could more bitter scorn be shown for such a physician than by declaring that he understands nothing about living men and only knows how to deal with corpses? No doubt it is an essential attribute of God to perform miracles; but a physician performs miracles too; he effects miraculous cures, as his enthusiastic clients proclaim. So that when we see that these very miracles (the material for which was provided by the patient's hypochondria) turn out to be incredible, absurd, and to some extent positively silly, we are reminded of the assertion in my *Interpretation of Dreams* that absurdity in dreams expresses ridicule and derision.¹ Evidently, therefore, it is used for the same purposes in paranoia. As regards some of the other reproaches which he levelled against God, such, for instance, as that He learned nothing by experience, it is natural to suppose that they are examples of the *tu quoque* mechanism used by children,² which, when they receive a reproof, flings it back unchanged upon the person who originated it. Similarly, the voices give us grounds for suspecting that the accusation of soul-murder brought against Flechsig was in the first instance a self-accusation.³

[1911c, 2424]

Emboldened by the discovery that his father's profession helps to explain the peculiarities of Schreber's God, we shall now venture upon an interpretation which may throw some light upon the remarkable structure of that Being. The heavenly world consisted, as we know, of the 'anterior realms of God' which were also called the 'fore-courts of Heaven' and which contained the souls of the dead, and of the 'lower' and the 'upper' God, who together constituted the 'posterior realms of God' (19). Although we must be prepared to find that there is a condensation here which we shall not be able to resolve, it is nevertheless worth while referring to a clue that is already in our hands. If the 'miracled' birds, which have been shown to be girls, were originally fore-courts of Heaven, may it not be that the *anterior* realms of God and the fore-courts *of Heaven are to be regarded as a symbol of what is female, and the *posterior realms of God as a symbol of what is male? If we knew for certain that Schreber's dead brother was older than himself, we might suppose that the decomposition of God into the lower and the upper God gave expression to the patient's recollection that after his father's early death his elder brother had stepped into his place.

[1911c, 2425]
Thus in the case of Schreber we find ourselves once again on the familiar ground of the father-complex.¹ The patient's struggle with Flechsig became revealed to him as a conflict with God, and we must therefore construe it as an infantile conflict with the father whom he loved; the details of that conflict (of which we know nothing) are what determined the content of his delusions. None of the material which in other cases of the sort is brought to light by analysis is absent in the present one: every element is hinted at in one way or another. In infantile experiences such as this the father appears as an interferer with the satisfaction which the child is trying to obtain; this is usually of an auto-erotic character, though at a later date it is often replaced in phantasy by some other satisfaction of a less inglorious kind.² In the final stage of Schreber's delusion a magnificent victory was scored by the infantile sexual urge; for voluptuousness became God-fearing, and God Himself (his father) never tired of demanding it from him. His father's most dreaded threat, castration, actually provided the material for his wishful phantasy (at first resisted but later accepted) of being transformed into a woman. His allusion to an offence covered by the surrogate idea 'soul-murder' could not be more transparent. The chief attendant was discovered to be identical with his neighbour von W., who, according to the voices, had falsely accused him of masturbation (108). The voices said, as though giving grounds for the threat of castration: 'For you are to be represented as being given over to voluptuous excesses.'³ (127-8.) Finally, we come to the enforced thinking (47) to which the patient submitted himself because he supposed that God would believe he had become an idiot and would withdraw from him if he ceased thinking for a moment. This is a reaction (with which we are also familiar in other connections) to the threat or fear of losing one's reason⁴ as a result of indulging in sexual practices and especially in masturbation. Considering the enormous number of delusional ideas of a hypochondriacal nature⁵ which the patient developed, no great importance should perhaps be attached to the fact that some of them coincide word for word with the hypochondriacal fears of masturbators.⁶

Any one who was more daring than I am in making interpretations, or who was in touch with Schreber's family and consequently better acquainted with the society in which he moved and the small events of his life, would find it an easy matter to trace back innumerable details of his delusions to their sources and so discover their meaning, and this in spite of the censorship to which the Denkwürdigkeiten have been subjected. But as it is, we must necessarily content ourselves with this shadowy sketch of the infantile material which was used by the paranoic disorder in portraying the current conflict.

Let us now bring together what this effort at a psycho-analysis, short and impeded as it was, has brought to light for an understanding of this case - assuming, of course, that our enquiries were correctly carried out, which I cannot here submit to your judgement. Firstly, the delusion has ceased to be absurd or unintelligible; it had a sense, it had good motives and it fitted into the context of an emotional experience of the patient's. Secondly, the delusion was necessary, as a reaction to an unconscious mental process which we have inferred from other indications, and it was precisely to this connection that it owed its delusional character and its resistance to every logical and realistic attack. It itself was something desired, a kind of consolation. Thirdly, the fact that the delusion turned out to be precisely a jealous one and not one of another kind was unambiguously determined by the experience that lay behind the illness. You recall of course that, the day before, she had told the scheming maid that the most dreadful thing that could happen to her would be her husband's unfaithfulness. Nor will you have overlooked the two important analogies between this case and the symptomatic action which we analysed - the explanation of its sense or intention and its relation to something unconscious that was involved in the situation.
Any one who was more daring than I am in making interpretations, or who was in touch with Schreber's family and consequently better acquainted with the society in which he moved and the small events of his life, would find it an easy matter to trace back innumerable details of his delusions to their sources and so discover their meaning, and this in spite of the censorship to which the *Denkwürdigkeiten* have been subjected. But as it is, we must necessarily content ourselves with this shadowy sketch of the infantile material which was used by the paranoid disorder in portraying the current conflict.

[1911c, 2428]
The third group of symptoms that are found in obsessional neurosis, the symptoms of secondary defence, cannot be present as such in paranoia, because no defence can avail against the returning symptoms to which, as we know, belief is attached. In place of this, we find in paranoia another source for the formation of symptoms. The delusional ideas which have arrived in consciousness by means of a compromise (the symptoms of the return) make demands on the thought-activity of the ego until they can be accepted without contradiction. Since they are not themselves open to influence, the ego must adapt itself to them; and thus what corresponds here to the symptoms of secondary defence in obsessional neurosis is a combinatory delusional formation - interpretative delusions which end in an alteration of the ego. In this respect, the case under discussion was not complete; at that time my patient did not as yet exhibit any signs of the attempts at interpretation which appeared later. But I have no doubt that if we apply psycho-analysis to this stage of paranoia as well, we shall be able to arrive at a further important result. It should then turn out that the so-called weakness of memory of paranoics is also a tenacious one - that is to say, that it is based on repression and serves the ends of repression. A subsequent repression and replacement takes place of memories which are not in the least pathogenic, but which are in contradiction to the alteration of the ego which the symptoms of the return of the repressed so insistently demand.
