Table of Contents

Definitions And Fundamental Tenets Of Psycho-Analysis

Definitions of psycho-analysis <106>
The fundamental tenets/shibboleths/corner-stones of psycho-analytic theory <2708>
The existence of an unconscious portion of the mind. <437>
Division of the mind into conscious and unconscious parts. <437>
Importance of the unconscious. <437>
Division of the mind into agencies <710>
Two primary/basic instincts at work in the mind <543>
Importance of early period of life/childhood <1715>
Importance of sexuality, both in health and in illness. <6>
Infantile sexuality. The Oedipus complex. <1287>
A sexual aetiology for the neuroses <609>
Dynamic view of mental processes. [See topic 589]
Repression and resistance <2709>

The Mental Apparatus

In general <4400>
Origins. As originally being in the nature of a reflex apparatus (arc) <4703>
developed in response to the exigencies of life (external dangers, internal needs). <4703>
Structure
The mind as an apparatus, a compound instrument, extended in space, comprised of several portions. <835>
As being extended in space <1711>
The concept of a stratification of the psyche <3794>
The spatial viewpoint. <4840>
When using the spatial metaphor, don't always necessarily <4840>
mean a different locality but, rather, a different mode of functioning. <4840>
The question of localization of function in the brain (brain 'centres') <5166>
Events within the psychical apparatus as flowing in a given direction. <3883>
As starting out from stimuli and moving (at first) toward hallucination and later in the direction of motor activity. <3883>
Role played by memory in bringing about repetitions of experiences of satisfaction. <3883>
Division of the psychical apparatus into agencies ('systems') [See also under 'The agencies'] <737>

Dynamics
A dynamic view of mental processes <589>
The concept of there being some kind of mobile energy at work in mental life <1201>
The forces at work in the mind - the instincts. [See also under 'The instincts'] <1058>
Importance of the economic viewpoint <590>

Division into conscious and unconscious parts

Introduction
In general <5614>
Existence of an unconscious portion of the mind. Its importance. [See also topic 1049] <1180>
Four possible states for a mental process (conscious, preconscious, unconscious, repressed). <438>

Consciousness
The question of consciousness, in general. <224>
Consciousness as constituting a negligible portion of mental life. <224>
The bulk of our mental activity as being unconscious. <224>
The property of consciousness
How a mental process becomes conscious. <238>
Relationship to perceptual organs. <238>
By coming into association with the word-presentations of things (mnemic residues of speech). <238>
Ideas as representing the instincts <650>
Ideas as becoming conscious through word-presentations/verbal-presentations <4340>
State of consciousness a mobile quantity - may or may not attach to mental processes at any given time. <3980>
Stimuli may arise from two directions - from the external world and from the interior. <4849>
The latter can only be perceived as feelings in the pleasure-unpleasure series. <4849>
Table of Contents

The fact that the system responsible for consciousness has no memory <4852>
The mechanism of attention <4016>
The mechanism behind hallucinations <1093>
The role played by consciousness in mental life in general <4848>
The biological function of consciousness <5550>

The unconscious

Introduction
The existence of an unconscious portion of the mind. <1049>
The concept of unconscious mental processes, unconscious mental activity. <1049>
The bulk of our mind as being unconscious. <237>
The basic unconsciousness of mental life, in general. <237>
Our definition of the unconscious <1060>
The unconscious as being what is truly psychical <1052>
An unconscious portion of the mind as being an unavoidable assumption if we are to <1055>
make any headway in an understanding neurotic symptoms and analogous phenomena <1055>
Refutation of notion that consciousness is all there is. <1183>
Over-estimation of the property of consciousness. <1183>
Overestimation of the role played by consciousness in mental life. <1183>
Consciousness not a necessary accompaniment of mental events. <1183>
Justification for the concept of (the case for) unconscious mental processes. <1183>
How we arrive at a knowledge of unconscious mental processes. <1183>
Knowledge of unconscious mental processes arrived at through inference. <1183>

Types of things (mental processes) that can be unconscious <788>
(emotions, affects, thoughts, impulses, phantasies). <788>
Proofs of the existence of unconscious mental processes <788>
(solutions to problems arrived at without conscious intervention, hypnotic phenomena). <788>
An idea or impulse may be unconscious and yet still be active <3676>
Relevance to the neuroses. Importance of unconscious mental processes in the neuroses. <2521>
How we may become aware of unconscious mental processes <1053>
A problem. Three different types of unconscious. <441>
Sub-division of what is unconscious into preconscious, unconscious and repressed. <441>
General distinctions between them. <441>

Preconscious
In general <225>
Relationship of preconscious state to mnemonic residues of speech (word-presentations) <1194>

The unconscious proper
Characteristics of <1063>
Further sub-division into unconscious and repressed <1050>
The (ordinary) unconscious <1070>
The repressed unconscious <1071>
The repressed unconscious only capable of being made conscious in the face of a resistance <1069>
A mental process' being unconscious not necessarily due to repression <4862>
Conditions under which changes in rules governing states may occur
In general <1082>
In sleep <1083>
In parapraxies <1086>
In jokes <1087>
In the neuroses <1088>
In psychosis (exception to requirement that resistances must be overcome) <1084>

Relationships between the various states
In general <4031>
Distinctions between the various states. What distinguishes conscious, preconscious and unconscious mental processes. <235>
Distinctions between preconscious and unconscious states <1064>
Distinctions not absolute or permanent <1067>
The possibility of there being more than one record of the same material <1068>
Discussion of state prevailing in higher animals <1092>
### Table of Contents

The agencies

The id

Introduction

The very existence of such an agency
Choice of nomenclature for
As the oldest of the provinces
Initially the only agency
Processes within the id as being wholly unconscious
As being far larger than the ego
What it is. What's in it, what goes on in it. Nature and characteristics of.
As having no direct contact with the external world
Content of, in general.
Contains everything that is inherited, present at birth / laid down in the constitution.
As representing the past
As being the representative of the body's needs
As being the point at which the body's needs first make themselves felt
Instincts as finding their first psychical expression here
As being the home of the instincts
As containing the repressed
Relationship between the repressed and the infantile

Characteristics of mental processes in the id

In general
Mental processes within the id as being governed by different rules.
As being governed by the primary process.
Characteristics of the primary process.
Absence of logic in. No conflict in.
No such thing as a 'No' in. No negatives in.
No sense of reality in. No reality testing performed by.
Timelessness of processes in
Absence of anxiety in
As having no concern for self-preservation.
Processes within the id as being governed by considerations of discharge.
Press only for immediate satisfaction of needs.
Processes within the id as being under the sway of / obeying / being governed by the pleasure principle.
The ultimate aim of mental activity being an endeavour to obtain pleasure and avoid unpleasure.
As being unable to do anything but wish

Dependant relationships

Vis-à-vis the ego

Conclusion

As representing the true essence and purpose of our existence.
The unconscious wishful impulses in the id as representing the true core of our being.
The ultimate aim of life is the satisfaction of the instincts in the id.

The ego

Definition of

Origins

In general
The ego and the id as originally having been one
The ego as having developed out of the id, as a sort of cortical layer,
through the modifying influence of the external world.
The ego as being an outgrowth or modified portion of the id

Characteristics and functions of

As being in direct contact with the external world
As being equipped with the organs for reception of stimuli
As serving as a protective shield against stimuli

Table of Contents

By interpolating thought processes <1746>
Use of memories <1822>
How accomplished vis-à-vis the external world (reality) <836>
How accomplished vis-à-vis the id (how the ego gains control over the id) <824>
Anxiety. Role in. Function of. Use of. <1747>
As being dependent on the id for love <602>
Vis-à-vis the super-ego
In general <1739>
The (simple) picture painted above as applying only till the age of +- 5 years <1825>
Super-ego. Existence of. <1950>
The super-ego as a third force which ego has to take into account <1951>
Dependant relationships (summary)
Dependant relationships, in general. <805>
What the ego tries to do, in general. <1952>
An ideal action on the part of the ego <849>
The normal state of affairs. The state of affairs when things are going well. <3245>
The state of affairs when things go wrong <465>
The concept of defence, in general. [See also 'Neurosis In General' > 'Defence mechanisms'] <1767>
Defence by ego, in general. [See also topic 1984] <1753>
Internal reality harder to escape from than external reality <1754>
Sources of energy. Relationship to instincts. As operating on borrowed forces. <761>
As being far smaller than we had thought it to be. Ego not master in its own home. <1205>
Horse and rider analogy for <1224>
Clown in circus analogy for <2074>
The super-ego
Introduction
The existence of such an agency <5804>
General discussion of <234>
As being located within the ego <764>
As occupying intermediate position between id and external world <1835>
Origins
Origins of, in general. <845>
Origins in mastery of Oedipus complex. [See also topic 412] <782>
As a precipitate of the Oedipus complex <850>
As heir to the Oedipus complex <1828>
As representing a prolongation of the parental influence of childhood <852>
Functions and characteristics of
In general <781>
As the critical agency <1808>
Censorship functions <1246>
As being responsible for the limitation of satisfactions <866>
As a punishing agency <3931>
As the home of the ego-ideal <1041>
Dependant relationships
Vis-à-vis the ego
In general <853>
As a third force with which the ego has to contend <854>
Relationship when things are going well <1829>
Relationship when things go wrong <1830>
Vis-à-vis the id <855>
Miscellaneous topics
Further characteristics of the super-ego <1832>
Addition of other figures (relatives, teachers) and influences (social milieu) to those of parents. <851>
As being more severe than original parents. Explanation for. <1826>
Criticisms of ego based not only on deeds but on its thoughts and intentions <1827>
Phylogenetic influences. The super-ego as a representing the influence of the past. <290>
Table of Contents

As uniting the influences of the present and the past <1837>
Sources of energy, in general. <1833>
Role of narcissistic (and more especially homosexual) libido in <490>
Role of the destructive instinct in <303>
Role played by in pathology, in general. <857>
Role played by in the unconscious sense of guilt <537>
Role played by in obsessional neurosis. [See also topic 553] <736>
Role played by in melancholia. [See also topic 478] <846>
Role played by in paranoia. [See also topic 3397] <847>
Relationship to 'conscience' as we know it (as being not quite the same) <1042>
The concept of criminals out of an unconscious sense of guilt. Criminality in general. <766>

Miscellaneous topics
Metapsychology - definition and discussion of term. <2199>
The pleasure and reality principles
The pleasure principle
In general <2239>
Alternative designations for the pleasure principle <2196>
The whole question of pleasure and unpleasure (quantitative and qualitative aspects) <3935>
The mental apparatus as, in general, being governed (regulated) by the pleasure principle. <772>
The pleasure principle as applying in both in the ego and the id <4812>
Apparent contradictions to the above assertion <2215>
The reality principle
Replacement of the pleasure principle by the reality principle. Reasons for. <3413>
The reality principle, in general. <2221>
The reality principle as a modified version of the pleasure principle <2221>
Contrast between the pleasure and reality principles <256>
Relationship of the sexual instincts to the pleasure principle (recalcitrant, hard to educate). <2223>
The primary and secondary processes
Two distinct modes of mental functioning <3958>
Different laws as governing mental processes in the id and ego. Distinctions between them. <1314>
Primary process (condensation, displacement, tendency to discharge). <3280>
Secondary process <3281>
The secondary process as being a later development. <4816>
The secondary process as simply overlaying and inhibiting the primary process. <4816>
The primary process as an integral part of normal mental life <5042>
Role played by primary process in psychopathological structures (dreams, parapraxes, neurotic symptoms). <4878>
The concepts of bound and free energy <4023>
Relationships between the primary process, secondary process, pleasure principle and reality principle. <4024>
Other
Introduction of the economic viewpoint in mental functioning <2201>
The tendency to keep the quantity of excitation in the mind as low as possible, or at least constant. <2209>
Fechner's 'constancy principle', principle of 'the tendency toward stability', the 'Nirvana Principle'. <2209>
Relationships between the three agencies, in general. <423>
Diagrams illustrating the relationships between the three agencies <5842>
The strengths and weaknesses of the ego <3031>
The ability of the ego to influence processes/events in the id <5786>
The ego as representing the present, the id the organic past and the super-ego the cultural past. <1834>
Distinctions between the ego and the id <1144>
How the ego may avoid unpleasure. <2001>
External reality by flight or actively changing it. <2001>
Internal reality by defence (though it cannot ever really escape it). <2001>
Distinctions between the unconscious proper and the repressed <1198>
The ideal situation of the agencies working together in harmony <902>
The state of affairs when things go wrong <1318>
### Table of Contents

Relationship between the agencies not always one of antagonism - often work together toward common goals.  

Use of the term 'unconscious' in its descriptive, dynamic and systematic (topographical) senses.  
Objections to the use of the term 'subconscious'.  
Relationships of the agencies to the various states of consciousness  
Comparison of state of affairs in the individual to whole nations  
Similar psychical organization may be assumed to exist in higher animals  

#### The Instincts

**Introduction**
- The energies or forces at work in the mind  
- Broad definitions of an instinct  
- As holding to a dualistic view of the instincts. [See also topic 2257]  
- Only two basic instincts. Broad definitions of each. Aims of each.  
- Endogenous/somatic origins of. Origin in cells/organs of body. [See topic 774]  
- What do the instincts want?  
- The question of satisfaction - of how satisfaction is achieved.  
- The need to bring about particular changes in the external world for their satisfaction  
- The need for specific objects in the external world for their satisfaction  
- The ability of one instinct to fill in for another  
- Role played by the instincts in mental life, in general.  
- The instincts as the ultimate source of all psychical activity  
- As corresponding to the forces of attraction and repulsion in the inorganic world  

**The sexual instinct**
- In general  
- The popular view of the sexual instinct  
- The popular view as being in error. Facts contradicting the popular view.  
- The perversions  
- Foreplay. [See also topic 5312]  
- The unmistakable presence of the sexual instinct in childhood. [See also topic 1519]  

**The psycho-analytic view of the sexual instinct**
- In general  
- Existence of sexual needs  
- As extending the scope of the term 'sexual'  
- As being present from birth and undergoing development in childhood  
- Extension as called for by the perversions  
- Loosening of tie with reproduction.  
- Embraces the obtaining of pleasure from any suitable area of the body.  
- Distinguishes 'genital' from 'sexual'  
- The sexual instinct as being made up of a number of component instincts  
- Erotogenic zones. Each component instinct as having its origin in a specific area of the body.  
- (Oral erotism, an anal erotism, a urethral erotism).  
- Each component as having a particular aim  
- Each component as requiring a particular object for its satisfaction  
- Each component as seeking pleasure for its own account  
- As only later, after a period of development in childhood, being united toward a common goal  
- (subordination) under the primacy of the genitals.  
- Science as having been scarcely unaware of the presence of sexuality in childhood  
- The presence of sexuality in childhood. [See also topic 315]  
- The libido as undergoing development in early childhood  
- Development as occurring in phases  
- Characteristics of infantile sexuality  
- The concept of organizations of the libido (oral, anal-sadistic, phallic, genital).  
- Development of the ego in childhood  
- Benefits of our enlarged view of sexuality
Table of Contents

Reasons we have gone into infantile sexuality and its development in childhood in such detail. <1517>
Role of infantile sexuality in the neuroses and perversions. <1517>
The sexual instinct as being comprised of both a somatic and a psychical component <3203>

Somatic origins
In general <3205>
The sexual process <3209>
Origins in the organs of the body. [See also topic 774] <307>

Psychical manifestations. The libido.
Origin of the term <2813>
As representing the aims of the sexual instinct <1958>
Correspondence with Eros of the philosophers (Plato) <308>
Aims of, in general. <2814>

Properties and characteristics of the libido
In general <3154>
As being a force <1959>
As being capable of increase, diminution, displacement, satisfaction. <3155>
As being a mobile force, as being fluid. <942>
Primary narcissism. <1188>

The ego as the main reservoir of the libido. <1188>
The concept of auto-erotism <620>

Need for external objects. Early object relationships. <622>
Forms of early sexuality in which an extraneous object is required. The concept of object-choice. <622>

Relationship between object-choice and auto-erotism <2641>
Behaviour of the libido. Vicissitudes the libido may undergo. <1187>
Narcissistic libido (ego-libido), object-libido; distinctions between them. <5315>
Transformation of one into the other. <5315>

Libidinal cathexis <908>
As flowing out to (cathecting) objects. <236>
Hypercathectic. withdrawal of cathectic. <236>
Object love. Object-cathectic. Amoeba analogy. <236>
Attachment to ideas representing its aims. <3207>
Return to the ego. Secondary narcissism. <5323>

Overcoming of object-cathexes through identification with the (lost) object. <940>

Distinction between primary and secondary narcissism. <940>
The concept of there being only a fixed quota of libido available for object-cathexes <2139>
Concept of fixation. Possibility of fixation on particular objects. <306>

Dangers of narcissistic fixation. [See also 'The narcissistic neuroses'] <944>
Behaviour of the libido in the id and super-ego <939>
Knowledge of libido gained from study of the sexual function <309>
(more particularly, from its manifestations as object-libido in the transference neuroses). <309>

Difficult to get to know much about narcissistic libido <5326>
The question of narcissistic satisfaction <938>

Infantile sexuality. Development of the sexual instinct in childhood.
In general <1615>
The primary narcissistic phase
Ego and id as yet poorly differentiated <1644>
Primary narcissism. <1643>
All the libido stored in primitive ego-id. <1643>

The oral phase
In general <2636>
The first erotogenic zone - the mouth. <1606>
Oral erotism <5350>

Sexual manifestations during this phase. Detachment from the need for nourishment. <2648>
Pleasure from the mouth. Thumb-sucking. Auto-erotism. <2648>
Relation to objects. Object-choice. The first object-cathectic - the mother's breast. <1605>
Choice of object attached to a vital need. <1605>
Satisfaction at the breast as prototype for all later forms of sexual satisfaction <5255>
Table of Contents

Psychological development. Ego begins to be differentiated from id. <1597>
The oral organization of the libido <5277>

The anal-sadistic phase
In general <2637>
A new erotogenic zone - the anal orifice. <1607>
Anal erotism <5351>
Return to auto-erotism <5333>
Sexual manifestations during this phase. Holding back stools. <5264>
Manifestations of cruelty/sadism during this phase <5274>
Pity as mental barrier against cruelty <5273>
The anal-sadistic organization of the libido <5278>
Ambivalence as being characteristic of this phase <5279>

Narcissism <5669>

The phallic phase
In general <5280>
A new erotogenic zone - the genitals. <5267>
No distinction made as yet between the sexes <625>
Genital erotism <5352>
Sexual manifestations during this phase. <5268>
Initially associated with micturition. Early infantile masturbation. <5268>
The phallic organization of the libido; subordination to primacy of genitals. <5072>
Infantile sexuality reaches its peak <2054>
Paths of the two sexes begin to diverge <963>

The Oedipus complex
In general <329>
Origin of name <331>
The legend itself <4489>
The concept of aim-inhibited sexual impulses <965>
Choice of object in <5282>
Content of, in general. <1664>
Content, in boys. <332>
The boy's relationship to his mother, in particular. <5130>
The boy's relationship to his father, in particular. <4483>
Content, in girls. <333>
The girl's relationship to her father, in particular. <5131>
The girl's relationship to her mother, in particular. <4484>
As being comprised of both positive and negative aspects <631>
Note on the explicitly sexual nature of the impulses involved <5133>
The Oedipus complex as being a universal complex <4491>
As, under conditions of civilization, being inevitably doomed to come to an end. <1665>
Mastery of the Oedipus complex, in general. <409>
Repression of the Oedipus complex. Reasons for. <1771>
Role played by castration complex in its mastery <995>
Mastery of the Oedipus complex in boys <410>
Mastery of the Oedipus complex in girls. [See also topic 3472] <411>
Role played by its mastery in the formation of the super-ego. [See also topic 782] <412>
The Oedipus complex as a source of the unconscious sense of guilt <5827>
Role of brothers and sisters in (sibling rivalry) <2250>
The concept of death-wishes against loved-ones <2369>
Possible variations in the Oedipus complex <5828>
Role played by the Oedipus complex in neurosis. <632>
The Oedipus complex as the core / kernel / nuclear complex of the neuroses. [See also topic 189] <632>
Importance of the Oedipus complex in other areas (religion, morality). <1702>
The Oedipus complex in creative writing (Hamlet, Macbeth). <4492>

The castration complex
In general <334>
Discovery of the anatomical distinction between the sexes <3891>
Table of Contents

Consequences, in general. <3893>
Content and consequences in boys <335>
Content and consequences in girls (penis envy) [See also topic 3472] <336>
Differing roles of the castration complex vis-à-vis the Oedipus complex in boys and girls <2044>
Castration complex as bringing development to a close and ushering in the latency period in boys <964>
Phylogenetic reinforcement <1680>
Role played by the castration complex in other areas <5529>
(neurosis, myths, legends, fairy tales, men's sense of superiority over women, anti-semitism). <5529>
Circumcision as a symbolic substitute for castration. [See also topic 264] <1681>
Other castration symbols <2840>

Latency period

In general <163>
Certain component instincts need to undergo suppression, as being unserviceable, <2651>
or undergo transformation before being included in final organization. <2651>
Erection of barriers of shame, disgust, pity, morality, reaction-formation, sublimation <4821>
(at cost of perverse components of sexuality). <4821>
Erection of the barrier against incest <5339>
Sexual manifestations during this period <5251>

Puberty. The genital phase.
Concept of diphasic onset of sexuality <322>
The transformations of puberty (physiological, anatomical, changes in aim, object). <5291>
Physiological and anatomical changes in particular <5307>
Sexual instincts reach their full height <2659>
Attainment of a final organization under the primacy of the genital zone. <1610>
The genital organization of the libido. <1610>
Characteristics of this final organization. <1610>
The leading zones in men and women. <3870>
The concept of the vagina taking over the role of the clitoris in females. <3870>
Appearance of new aims <5302>
Aims as differing in the two sexes <5299>
The new sexual aim in males <5300>
The new sexual aim in females <5301>
The sexual development of females as actually undergoing a kind of involution <5303>
Requirement for objects, in general. <5334>
Revival of the Oedipus complex (and associated object-choices) <2660>
The concept of diphasic choice of object. <1532>
The need for new objects to replace the earlier ones. Problems associated therewith. <1532>
Finding of a substitute object <5297>
Note that it actually represents a refinding of the object <5332>
Role played by phantasy in the finding of an object during this phase <5341>
Sexual manifestations during this period (masturbation) <5295>
Distinctions from infantile sexuality <5292>
Directions taken by sexual life in later life determined by sexual development in childhood <2662>
Differentiation between men and women <5329>
Necessity for the convergence of the affective and sensual currents <5304>
Special types of object-choice made by men <5841>
Role of phylogeny in development <5245>

Reasons for having gone into sexual development in childhood in such detail
In general <1633>
Why the importance of infantile sexuality and its development? <1633>
Relevance of this early period of development for later health/neurosis. <1633>
Certain erotogenic zones have been renounced as unserviceable <3801>
What becomes of these perverse components of sexuality? <5100>
Possible outcomes <2624>
(i) suppression. <2624>
(ii) diversion to higher, asexual aims - sublimation. <2624>
(iii) fixation on original aims and objects - perversion. <2624>
(iv) repression - unconscious fixation on original aims and objects - neurosis. <2624>
Table of Contents

Miscellaneous topics relating to the developmental process
Our knowledge of infantile sexuality and its development initially obtained <2612>
from the analyses of the phantasies of adult neurotics <2612>
Development usually proceeds smoothly and goes unnoticed <2614>
The phases do not necessarily always follow each other in strict succession. <337>
Development takes place gradually and a certain degree of overlap may occur. <337>
The possibility of fixation
The process of development as not always proceeding smoothly. <627>
The possibility of fixation on earlier aims and objects. <627>
Factors which may exercise an influence on the developmental process <5354>
  Heredity and constitution <5355>
  Accidental experience <5366>
  Trauma <5502>
  Seduction <5271>
  Temporal factors <5368>
  Sexual precocity <5367>
    Increased pertinacity of early impressions <5369>
Relationship between repression and fixation. [See topic 5684]
Consequences of fixation
In general <1667>
Relationship between fixation and perversion. <345>
  Role played by fixation in the perversions. <345>
The age at which these fixations occur <5196>
The possible outcomes of fixation/inhibition in detail ... <5476>
Analogy for fixation <5831>
Perversion
  Relationship between adult and childhood sexuality <1154>
  Relationship between perversion and childhood sexuality <380>
    Origins of the perversions in childhood sexuality <380>
Neurosis
  Reasons having gone into the perversions in such detail. <628>
  Relationship between neurosis and perversion. <628>
    Neuroses as the negative of the perversions. [See also topics 429 and 5099] <628>
The neuroses as thus, too, having intimate links with childhood sexuality. <5116>
Summary of the above relationships <971>
Role played by particular fixation points in later pathology. <699>
  Relationship between fixation points and particular forms of neurosis. <699>
Fixation at narcissistic phase <700>
Fixation at oral phase <701>
Fixation at anal-sadistic phase <702>
Fixation need not necessarily be an all or none affair. <987>
  Importance of quantitative relations. <987>
  Role played by fixation points in later regression of the libido <990>
Adult sexuality
The perversions
Introduction
  In general <474>
    Earlier theories for the perversions (degeneracy, disease). <5207>
    Attempted definition of normal sexuality <3716>
    Attempted definition of perversion <3859>
    Re-iteration of infantile roots of sexuality <5243>
The disposition to perversion as being present in everyone. <887>
  The presence of perversion in even the most normal sexual life. <887>
  The question of what distinguishes the normal from the abnormal. <887>
Perversions as being traceable to infantile sexuality <3250>
Perversions as being traceable to component instincts <5223>
The sexual instinct as breaking up into its component parts in the perversions

Relationship of the perversions to specific erotogenic zones of the body (oral orifice, anal orifice, the eyes). These zones then behaving like a portion of the sexual apparatus

Factors playing a role in the perversions
In general
Role played by constitutional factors
Role played by accidental factors
Role played by fixation
As representing failures in the developmental process
Role played by frustration in (thereby reinforcing the perverse elements of sexuality)
Role played by regression
Role played by phantasy

Factors opposing the perversions (disgust, shame, pain, morality, aesthetic and moral ideals).

The phenomenon of perversions manifesting themselves as pairs of opposites (active and passive forms)

We are in the habit of regarding the connection between the sexual instinct and sexual object as being closer than it really is

Relationship to neuroses. Neuroses as the negative of the perversions. [See also topics 429 and 628]

Three possible outcomes of the development process - manifest perversion, neurosis or normal sexual life.

Classification of the perversions
In general
Deviations with respect to aim
In general
Anatomical extensions
Sexual use of the mucous membrane of the lips and mouth
Sexual use of the anal orifice
Overvaluation of the sexual object
Fixations on preliminary sexual aims
Touching
Deviations with respect to object
Deviation with respect to both aim and object

Selected perversions
Homosexuality
Introduction
In general
Sexual aims (male and female)
Is homosexuality congenital (inborn) or acquired?
Attempted definitions of 'masculinity' and 'femininity'
Universal bisexuality. Relationship of homosexuality to bisexuality.
All human beings capable of making a homosexual object-choice
Considerable amount of latent homosexuality present in normal people
Presence of homosexuality in childhood
Presence of homosexuality in puberty.
Commonly held views on homosexuality
In general
As being due to degeneracy
As being congenital (inborn)
As being organically determined
Theories of a 'third sex'
‘A woman's brain trapped in man's body’, and vice versa.
The distinguishing of a special homosexual instinct
Not an homogenous group. Get different forms and degrees of homosexuality.
Popular definition of homosexuality far too narrow
Based solely on choice of object
Should also include physical and mental characteristics of the subject
Male homosexuals as at some stage having been susceptible to the charms of women
Factors playing a role in
In general <5172>
Role played by constitutional factors <5174>
Role played by accidental factors <5175>
Frustration <5176>
Forces working against a permanent inversion of the sexual object <5346>

Male homosexuality
Factors playing a role in, in general. <983>
Psychical (developmental, accidental) factors, in general. <2433>
Role played by fixation in <972>
Role played by the mother in <2295>
Identification with a member of the opposite sex in <2261>
Fixation on early homosexual objects in <979>
Narcissism (narcissistic fixation) in. Tendency toward narcissistic object-choice. <523>
Anal erotism in (retention of the erotic significance of anal zone) <2155>
Primacy of phallus in. Retention of high value placed on male organ. <1142>
Inability to tolerate its absence in the sexual object. <1142>
Role played by the castration complex in. <986>
Fear of castration. <986>
Horror of genitals of opposite sex. <986>
Depreciation of women because of discovery of their lack of a penis. <986>
Role played by the father in. <2444>
Fear of the father. Renunciation of aggression/hostility toward the father. <2444>
Retiring in favour of the father. <2444>
Absence of a strong father-figure in childhood to identify with. <2444>
Renunciation of aggression in. Reaction-formation. <2442>
Taken to its extreme, transformation of hate into love. <2442>
Exaggeration of process which leads to birth of social instincts. <2442>
[See also topic 2463] <2442>
Retiring in favour of a brother <2450>
Traumatic factors (early seduction leading to premature fixation of the libido) <2458>

Female homosexuality
In general <5169>
 Constitutional factors <2288>
 Narcissism <2289>
 Castration complex. Penis envy. Unwillingness to renounce desire for penis. <2047>
 Fixation on (revival of the original love for) the mother <2284>
 Therapeutic considerations <2299>

Exhibitionism (being looked at) and voyeurism (looking, scopophilia). <1655>
Sadism and masochism <326>
Fetishism <133>
Sexually immature persons as sexual objects (paedophilia) <5184>
Fellatio <5625>
Animals as sexual objects (bestiality) <5185>
Coprophilia <5198>
Necrophilia <5210>
Other <1658>

Miscellaneous topics
The phenomenon of infantile amnesia. The tendentious nature of memory.
The phenomenon of infantile amnesia. The whole question of memory and remembering. <323>
Mnemonic material as in general being subject to distortion. <323>
Role played by the pleasure principle in. <323>
Nothing ever really forgotten. <323>
Reasons for infantile amnesia. As being due to the sexual content of this early sexual period. <323>
The nature of childhood memories in general. Their unreliability. <323>
The untrustworthiness of our memory, in general. <323>
Table of Contents

Practical applications. <5002>
  Implications, in the light of the above (testimony in courts of law, legends of a people). <5002>

Further characteristics of the sexual instinct
  Diphasic onset of sexual development. <2664>
    As being a biological peculiarity of human species. <2664>
  Other peculiarities of the sexual instinct in the human species. <5496>
    (More strongly developed, constant, no longer periodic.) <5496>
  Diphasic onset as the determining factor in man's predisposition to the neuroses. [See topic 2938]

Further notes on aim
  Aims working independently of each other <2776>
  Possibility of one aim replacing another (displacement) <2777>
  Possibility of aim being replaced by non-sexual one – sublimation. <2779>
  Possibility of activity being replaced by passivity <2773>

Further notes on object-choice
  In general <3861>
    The instinct (the need) as having been there before the object. <910>
      Instinct less closely tied to the object than was formerly thought. <910>
    Objects capable of being exchanged. <910>
    Possibility of choice of self as object - narcissism. <910>
    The significance of early object-choices <1285>
    The after-effects of infantile object-choice <5344>
  Other factors from childhood exercising an influence on object-choice <5345>
  Types of object-choice ('anaclitic' or 'attachment', narcissistic). <1283>

Other
  Resistance to notion of sexuality in children <617>
  The notion of the child being 'polymorphously perverse' <3860>
  Masturbation in childhood <4576>
  Early sexual researches. The sexual theories of children. <328>
    Role played by in symptomatology of later neurotic illness. <328>
  The notion of erotogenic zones serving a dual purpose <5258>
  Ramifications for the neuroses. Pathways of mutual influence. <5289>
  The question of sexual excitation <5308>
  The question of sexual tension <5309>
  Sexual excitation as being of a continuous character <1650>
  Sexuality as an endogenous source of excitation from which the organism cannot escape <3756>
  Sexuality as a recurring need <678>
  Sources of sexual excitation <4495>
    (mechanical agitation, thermal stimuli, contact with the skin of the sexual object, <4495>
      visual stimuli, muscular activity, affective processes, intellectual work). <4495>
  Foreplay. Fore-pleasure. [See also topic 1632] <5312>
  The question of sexual satisfaction; how achieved; factors standing in the way of sexual satisfaction. <806>
  Conditions under which changes in the distribution of the libido may occur (sleep, illness, psychosis). <1230>
  A chemical basis for sexuality. <3753>
    The concept of a specific sexual substance or substances lying behind the sexual process. <3753>
  Constitutional factors <5288>
  Ego vs. id as the great reservoir of the libido <1927>
  The ego-instincts (instincts of self-preservation) as, too, being libidinal in nature. <2791>
  Modification of views required, in the light of the above, <2794>
    as to the nature of the conflict in the transference neuroses. <2794>
  Secondary narcissism - a return of the libido to the ego as implying a desexualization of aims. <2793>

Female sexuality. Female psychology. <3472>

The death instinct
  Existence of <5011>
  In general <41>
    As being opposed to the aims of the sexual instinct <2113>
  Question of nomenclature for <300>
### Table of Contents

Nature and characteristics of, in general. <274>
Originally directed inward <1292>
Silent while it works internally <879>
Later diverted outward <2809>
Only comes to our notice when diverted outward as 'aggression' <880>
Necessity for diversion outward <881>
Association with muscular apparatus <1961>
Certain measure of aggressiveness necessary if aims of libido to be attained <5206>
Vicissitudes of the death instinct. [See also topic 1012] <1116>
Harder to follow vicissitudes of the death instinct than of the libido <1117>
Role in neurosis, in general. <489>
Role in the super-ego. Unconscious sense of guilt. <302>
Mention that some portion of it always remains directed inward <883>
Proofs for the existence of a death instinct <2179>
Aggression as being an intrinsic part of human nature. [See also topic 3157] <2182>
Must manifest itself somewhere <2945>
The problem of masochism. Masochistic trends in mental life. <2249>
Role of the death instinct in strife/war. [See also topic 915] <2151>

The two instincts as a whole
In general <297>
The aims of the two contrasted <1000>
As only being interested in satisfaction <1722>
Physiological aspects <1962>
Origins in specific organs of the body <774>
Correspondence with physiological processes of anabolism and catabolism <2807>
Not confined to any particular province of the mind. <298>
Both instincts or energies present and active in all three agencies. <298>
Possibility of their fusion/defusion <2150>
Never found in pure form. [See also topic 1595] <1721>
Interaction between the two instincts, in general. <294>
May co-operate or stand in opposition to each other <2149>
The possibility of co-operation between the two instincts <907>
Opposition/conflict between the two instincts <2086>
The one instinct as modifying the effects of the other <2162>
The concept of the libido serving to neutralize the destructive instinct <299>
All the variegated phenomena of life can be explained in terms of <874>
the interaction/interplay of these two basic instincts/forces <874>
The conservative nature of the instincts <868>
Instinct as a compulsion to repeat. The repetition compulsion. [See also topic 167] <2194>
How definition of the libido fits in with the conservative nature of the instincts <873>
How definition of the death instinct fits in with the conservative nature of the instincts <872>

Short summaries of the development of Freud's views on the instincts <2753>
As always having held to a dualistic view of the instincts. <2257>
Distinction between sexual and other non-sexual instincts. <2257>
The ego-instincts. The self-preservation instincts. <2257>
Initially the exact nature of the ego-instincts was unclear <2755>
Initially only the sexual instincts were accessible to investigation <2756>

Neurosis In General

In general <619>
A common model for all the phenomena.
Same mechanisms at work in as in dreams, parapraxes and jokes.
[See topic 2187]
Definitions of neurosis <817>
A psychology for the neuroses <4939>
### Table of Contents

Distinctions between our and other views on neurosis <4194>
The layman's view of neurosis <5087>
The normal state
   - In general. The state of affairs when things are going smoothly. <26>
   - Health as being defined in terms of dynamic relations between the agencies <1868>
The neurotic state
   - In general. The state of affairs when things go wrong. <1425>
   - Characteristics of the neurotic state <27>
   - The unconscious mental life of neurotics, in general. <4567>
Distinction between normal and neurotic state not all that great, nor absolute. <4258>
   - Fine dividing line, no fundamental distinction between the two. <4258>
   - Same mechanisms at work in neurotics as in normal people. <4258>
   - Neurosis as not being due to the operation of pathological influences. <4258>
   - Distinctions quantitative rather than qualitative. <4258>
   - [See also topic 3904] <4258>
Commonness of the neurotic state <2170>
The psycho-analytic view of the neuroses
   - The metapsychological approach. [See also topic 2199] <1897>
   - Overview of factors playing a role in the neuroses <2669>
   - The notion of unconscious mental forces being at work in the neuroses. <3330>
   - The unconsciousness of the whole process. <3330>
   - The unconsciousness of the mental processes at work in the neuroses. <3330>
Neuroses as manifestations of the repressed, in general. <2517>
Our theories of neurosis based on the instincts <3298>
   - Role played by sexuality in the neuroses, in general. <3108>
   - Role played by childhood in the neuroses, in general. <3109>
   - Role played by the infantile factor in the neuroses, in general. <5533>
   - Role played by infantile sexuality in the neuroses, in general. <5536>
   - The neuroses as involving a conflict of sorts <5014>
   - Basic conflict is between the ego and the id (claims of sexuality) <2673>
   - The neuroses as having a hidden meaning <5526>
Defence mechanisms
   - In general
      - Defence mechanisms available to the ego, in general. <1984>
      - Broad comparison of defence mechanisms <1996>
      - Dangers of defence mechanisms. <2006>
         - Damage caused by defence mechanisms. <2006>
         - Defence measures instituted in childhood carried forward and repeated in adult life. <2006>
         - Internal reality cannot ever be completely escaped. <2006>
         - As calling for a constant expenditure of energy (anticathexis) on the part of the ego for their maintenance/upkeep.
            - [See also topic 572] <2006>
            - This expenditure as resulting in a weakening of the ego. <2006>
            - As bringing about a loosening of ego's tie with the external world. <2006>
            - As bringing about alterations in ego. <2006>
         - Relationship between innate strength of instincts and damage done to ego <1847>
         - The unnecessity (superfluity) of early defence mechanisms adopted in later life <2048>
            - (one of the principles on which psycho-analytic treatment is based) <2048>
         - No ego makes use of all the available defence mechanisms <2039>
         - Pathology as lying within the ego rather than within the id <2424>
         - Role played by heredity in determining the defence measures adopted by the ego <2129>
Repression and symptom formation
   - In general <42>
      - A common model for all the phenomena.
         - Same mechanisms at work in neurotic symptoms, dreams, parapraxies and jokes.
            - [See topic 2187]
      - Broad definition of a symptom <744>
Overview of the process of symptom-formation <430>
Unwanted impulse <791>
Impulse made up of two components - its affective cathexis and the idea representing it. <3147>
Defence against unwanted impulse. Repression. <3146>
Attempts by repressed to return <797>
The defensive struggle. <798>
Censorship. Necessity for distortion before entry into consciousness (inadmissibility to consciousness). <816>
Necessity for roundabout paths to satisfaction <2068>
Return of the repressed in distorted form as the symptom <799>

Repression
In general <1588>
The repressed. Its being unconscious (and a particular type of unconscious). <220>
The psychological mechanism of repression, in general. [See also topic 215] <2235>
Repression as being a normal process (as occurring in normal people as well) <4006>
The unconsciousness of the process <745>
Central role played by repression in the neuroses and symptom formation <269>
Reasons for undertaking repression. Motives for defence. <362>
(Unacceptability of impulse to the ego, avoiding unpleasure, <362>
avoiding danger, avoiding conflict, deference to super-ego). <362>
Defence as being tendentious in nature. <1998>
Ego as being under the sway of the pleasure principle. <1998>
A censorship function in mental life. [See also topic 780] <2829>
The ego as the agency responsible for repression. [See also topic 592] <4184>
Role played by the super-ego in repression <1160>
Role played by the pleasure principle in the process of repression <4857>
Unwanted impulses. The nature of the impulses undergoing repression. Reasons for unacceptability. <746>
Surprising frequency of sexual impulses. <746>
As explaining why it is mainly impulses of a sexual nature <4924>
that provide the motive force for neurotic symptoms <4924>

Mechanism of repression
How effected, in general. <215>
(Denial of entry of the idea to consciousness. Dissociation of affect from idea.) <215>
As being internal correlate of flight from dangers in the external world <4809>
Institution of an anticathexis [See also topic 2006] <4830>
Note that it is not only the ‘push’ exercised by the forces of repression <4680>
but also the ‘pull’ (attraction) exercised by previously repressed material <4680>
Relationship between repression and fixation <5684>
Role played by civilization in repression. Phylogenetic reinforcement. ‘Organic’ repression. <5417>
Analogies for repression (the copying of a book, the burial of Pompeii). <1990>

Types of repression
Primary repression. Secondary (after-) repression. Distinctions between them. <3331>
Primary repression. All the primary/decisive repressions take place in early childhood. <3399>
[See also topic 1759] <3399>
Secondary repression <1976>
Only repressed (infantile sexual) impulses can give rise to a symptom <4778>
Impulses, wishes and memories, rather than perceptions, as undergoing repression. <4860>

Latency period
In general <795>

Consequences of repression. Return of the repressed. Symptom formation.
In general <838>
What becomes of the impulse following its repression? <471>
Repression as rendering/keeping the unwanted impulse unconscious <5217>
The repressed impulse as remaining very much alive in the id <567>
The repressed impulse as retaining its upward urge (drive). <216>
As continuing to press for satisfaction in the id. <216>
The repressed impulse has simply been isolated psychically <3639>
Table of Contents

The repressed impulse as acquiring a certain measure of independence <5793>
from the ego in consequence of its repression <5793>
The repressed idea as forming a nucleus or centre of crystallization for <3644>
a second psychical group divorced from the ego <3644>
Dissociation of cathexis (affect) from the idea to which it properly belongs <4026>
Displacement of the cathexis onto a substitute idea <2922>
(an idea with a passport / an \textit{entree} into consciousness and activity) <2922>
Association of the cathexis with / attachment of the cathexis to a substitute idea <2922>
The repressed impulse can only become conscious by coming into association with (through the medium of)
<2922>
a (trivial/nonsensical) preconscious idea which is acceptable to consciousness <2922>
The concept of a 'false connection' <2922>
Attempts on the part of the repressed to return <4827>
Compromise. Return of the repressed in distorted form as the symptom. <2696>
Failure of repression <1691>
Repression as an ongoing process, <572>
requiring a constant expenditure of energy ('anticathexis') on the part of the ego for its maintenance. <572>
Ego now faced with an ongoing defensive struggle with derivatives of the repressed. <572>
Feelings of displeasure now attached to the substitutes. <572>
[See also topic 2006] <572>
Economic considerations. Increase in the strength (reinforcement) of the impulse. Reasons for. <796>
(e.g. repressed impulse/wish receives organic reinforcement.) <796>
The case of successful repression <4825>
Characteristics of the repressed <3661>

Symptoms
In general <5091>
Symptoms as manifestations of the repressed, in general. <2849>
Symptoms as a return of the repressed, in general. <552>
Symptoms as the return of a repressed (unwanted) impulse <2998>
Symptoms as a return of the repressed in distorted form <2071>
Symptoms as distorted representatives of the repressed <5771>
Symptoms as distorted derivatives of the repressed <610>
Symptoms as distorted expressions of the repressed <785>
Symptoms as distorted expressions of repressed impulses <3531>
Symptoms as distorted expressions of repressed wishes <1105>
Symptoms as substitutes, in general. <1112>
Symptoms as substitutes for the repressed <5698>
Symptoms as substitutes for repressed impulses <728>
Symptoms as substitutive satisfactions <600>
Symptoms as products of a conflict between two opposing forces or agencies <721>
Symptoms as the outcome of a conflict between ego and id <3610>
Symptoms as representing part satisfaction for both parties to the conflict. [See also topic 4720] <3001>
Symptoms as providing part satisfaction for a repressed impulse in the id <3434>
Symptoms as representing satisfactions, but in roundabout fashion. <3015>
Symptoms as substitute actions <2918>
Symptoms as wish-fulfilments <3120>
Symptoms as partial fulfilments of repressed wishes <3018>
Symptoms as also representing defensive efforts on the part of the ego. <2065>
Symptoms as also serving purposes of defence. <2065>
Symptom as comprised not only of the repressed impulse but also the ego’s defensive efforts against its return. <2065>
Symptoms as representing, at the same time, partial victory for the impulses in the id <2931>
and partial failure of the ego’s defensive efforts. <2931>
Symptoms must provide satisfaction for both parties to the conflict. [See also topic 3001] <4720>
Symptoms as products of a compromise. Symptoms as compromise-formations. <3000>
Symptoms as compromise structures. <3000>
Symptoms as representing partial failures of repression <521>
Repression in the neuroses as only being partially successful <5454>
Reasons for the unintelligibility of symptoms <2693>
(content as having been subject to the primary process, censorship, distortion before entry into consciousness). <2693>
Role played by the primary process in symptom-formation (displacement, condensation). <3299>
Role played by displacement in symptom formation <4428>
Role played by condensation in symptom-formation <3875>
Role played by the censorship in symptom-formation. Necessity for distortion before entry into consciousness. <573>
Symptoms as psychopathological structures <4940>
Symptoms as being determined <3409>
Symptoms as being overdetermined <2425>
Symptoms as having significance <2069>
Symptoms as having a sense <5721>
Symptoms as having meaning <809>
Symptoms as having a hidden meaning <5702>
Symptoms as being capable of interpretation <5701>
Symptoms as having more than one meaning (and can hence be 'over-interpreted') <4407>
The various meanings of a symptom need not necessarily be compatible with each other <5124>
The intimate nature of the material involved in the formation of symptoms <5447>
The material lying behind symptoms usually being of a sexual nature <5449>
At least one of a symptom’s meanings will be found to be a sexual one <5136>
Sexual origin of symptoms not always easy to see at first <4049>
Symptoms as substitutive (ersatz) sexual satisfactions <520>
Symptoms as constituting the person’s sexual activity <637>
Symptoms as representing the realization of a sexual phantasy <5092>
Symptoms as having a bisexual meaning <5484>
Symptoms as reflections of frustrated libido <784>
Symptoms as possessing a compulsive, daemonic character. <180>
Symptoms as possessing an independence from the ego. <180>
Symptom as being in the nature of unwelcome guests <5085>
Symptoms as, in general, being alien to waking thought. <4869>
Symptoms as distorted (watered-down) expressions/versions of repressed impulses <3016>
Symptoms as distorted substitutes for the original impulses <3017>
The unconsciousness of the processes involved in symptom formation <3137>
Conditions under which the repressed may return <217>
Analogy with pressure of water against a dam wall. <1864>
Arriving at the meaning of symptoms
In general <4559>
Similarity to the procedure adopted in arriving at the meaning of dreams <4663>
Nature and characteristics of the repressed material which emerges. <4191>
(May appear alien to the subject, but no different to normal waking thought.) <4191>
Role played by words in the formation of symptoms <4560>
The concept of a 'language' of the neuroses <5552>
Reaction-formation
In general <98>
Mechanism <1985>
Purpose served by <5361>
Role played by in obsessional neurosis. [See also topic 450] <1988>
Role played by in everyday life <1989>
Role played by in character-formation. [See also topic 2177] <5364>
Conclusions
Repression as resulting in the preservation, rather than the hoped-for annihilation, of the repressed material. <5566>
The indestructibility (immortality) of the repressed <4694>
The timelessness of the repressed <5041>
The material as having become pathogenic precisely on account of its repression <5067>
Table of Contents

Repression as being particularly prone to failure in the case of the sexual instincts <2678>
Repression as being a sine qua non for symptom-formation. [See topic 269]
The importance of the dynamic viewpoint <720>
Repression in early childhood. Dangers faced by the young ego. <3938>
Repression as, at the time, having served a useful purpose but later failing in its function. <4858>
Justification for repression (as being a defence mechanism readily available / on hand to the ego) <3641>

Miscellaneous topics

Affect in the neuroses, in general. <4627>
Relationship between instinct and affect <3094>
The question of why something which should lead to pleasure instead produces / leads to unpleasure <3867>
Relationship between symptoms (neurosis) and gaps in the patient's memory (amnesia). <532>
[See also topic 1713] <532>

Aetiological factors in the neuroses

Aetiology in general
Aetiological factors in the neuroses, in general. <3283>
The requirement for the necessary motive force for the formation of symptoms <4792>
Predisposing factors. Precipitating factors. Distinctions between them. <1511>
Necessary preconditions <3303>
Predisposing factors <1501>
Precipitating factors (releasing causes) <509>
Specific and non-specific aetiological factors <4111>
Requirement for specific aetiological factors <3292>
Non-specific (contributory) factors <4141>
Concurrent (auxiliary) causes. [See also topic 3196] <3308>
Relationship between concurrent factors and specific factors. Relative roles played by each. <3392>
Distinction between preconditions and specific causes <4138>
The question of a specific aetiological factor (or factors) for the neuroses <3362>
Importance of early period of life and sexuality in the neuroses, in general. <1493>

The importance of early childhood
In general <1562>
Importance of the past in, in general. <4996>
Importance of early childhood. Reasons for. <994>
Presence and development of sexuality during this period. <994>
Immortality of wishful impulses dating from this period. <994>
Traumas with greatest effect as occurring during this period. <994>
The neuroses as having their origins in childhood. <994>
The concept of childhood neuroses. <994>
Neuroses can only be acquired in early childhood. <994>
Adult neuroses always a revival of a preceding childhood neurosis. <994>
Repressed impulses playing a role in the neuroses always of an infantile character. <994>
Consequent necessity for an analysis to go back to this early period. <994>
The presence and development of sexuality in childhood <2934>
Role played by repressed infantile sexual impulses in the neuroses, in particular. <4935>
Role played by infantile sexual researches in the neuroses <5512>
Analogies illustrating the importance of this early period of life <4254>
What others put down to heredity we can explain in terms of <3425>
damage done / inhibitions formed / traumas experienced in early childhood <3425>
Dangers faced by young ego (the instincts). Defence mechanisms adopted by the ego (repression). <1768>
The concept of the ego not being able to take flight from certain internal dangers <3910>
(endogenous stimuli - hunger, thirst, respiration, sexuality). <3910>
These endogenous stimuli as arising continuously but only manifesting themselves (psychically) <3910>
periodically through principle of summation. <3910>
Need for a 'specific action' to bring about their satisfaction <3910>
Damage done to ego by early defences mechanisms adopted <1769>
All the primary / most important / decisive repressions are instituted during early childhood. <1759>
[See also topic 3399] <1759>
Repressions instituted during this period cannot be remembered. Reasons for (sexual content). <3483>
Table of Contents

Early repressions later prove to be unsuccessful. Reasons for (resurgence of sexuality at puberty). <1772>
Could neurosis be avoided if the child weren't forced to institute these repressions? <1778>
Necessity for these early repressions (from the point of view of civilization) <1780>
Note that ego sides with reality, even at this early age. <1782>
The concept of the development of the ego lagging behind that of the instincts <1781>
Early development as determining the later course taken by the libido <1600>
Trauma in childhood. Role played by trauma in the neuroses. <355>
Trauma as being comprised of both positive and negative aspects <171>
Fixation to trauma. Role of sexuality in trauma. <177>
The Oedipus complex, as relevant to neurosis. <189>
The Oedipus complex as the core / kernel / nuclear complex of the neuroses. [See also topic 632] <189>
The castration complex, as relevant to neurosis. [See also topic 334] <190>
The father-complex <192>
Ambivalence <284>
Seduction, sexual abuse during childhood. <1599>
Infantile amnesia as being due to early efflorescence of sexuality. [See also topic 323] <158>
Infantilism in mental life, in general. <5017>
The importance of the sexual instinct
In general <383>
Sexuality as an essential need, like any other biological function. <383>
A sexual aetiology (basis) for the neuroses. Always something sexual involved. <383>
Sexuality as the specific aetiological factor for the neuroses. <383>
A libidinal theory for the neuroses. <383>
Psycho-analytic theory of the neuroses based on the libido and its vicissitudes. <383>
Why the sexual instinct and no other? <4594>
Sexuality as the least easily controlled (most unruly) of the instincts <4594>
Sexuality as an imperative need which the ego cannot escape <3115>
Role played by perverse sexuality in <429>
Relationship between neurosis and perversion. <429>
Neuroses as the negative of the perversions. <429>
[See also topics 628 and 5099]
Role played by (latent) homosexuality in <4589>
Accounting for the situation in manifest homosexuals <5220>
Reasons for increased strength of perverse sexuality in the neuroses. Frustration. Regression. <5143>
Analogy with stream of water which, when it meets with an obstacle in its path, <5118>
is dammed up and flows back and fills old channels which had formerly run dry. <5118>
Link with infantile sexuality <2058>
Symptoms as substitutive sexual satisfactions. [Brief. Details at topic 520.] <2671>

Economic considerations
Importance of the economic factor <427>
At the end of the day, quantitative disharmonies to blame. <802>
An economic theory for the neuroses <2543>
Neurosis as being primarily an economic problem <1297>
The economic problem vis-à-vis the ego. Expenditure on repression. <1689>

Frustration
In general. The majority of people fall ill, in some way or other, from frustration. <586>
Sexual frustration, in particular. <814>
Reinforcement of the libido during certain periods of life (puberty, menopause, loss of object/spouse). <2929>
Frustration as leading to a damming up of the libido <44>
Frustration as leading to a reinforcement of the perverse components of sexuality <1965>
Types of frustration, in general. <1692>
External frustration, in general. <45>
Internal frustration, in general. <46>
Factors which may bring about a revival of (stir up) the repressed <3822>
An 'hydraulic model'. <3963>
(Analogies: Interconnecting pipes, pressure on dam wall, filling of subsidiary channels. <3963>
Cathexes in one direction lowering those in another.) <3963>
Table of Contents

Principle of 'collateral reinforcement' <2256>
Principle of summation <3201>
Role played by civilization in frustration of the libido. [See also topic 67] <1596>
The highest achievements of mankind at the expense of the sexual instinct <1784>
The problem with a purely quantitative approach. <1492>
The question of the ability to tolerate frustration. [See also topic 911] <1492>
In the end, a person must love, or else fall ill. <5838>

Regression
The possibility of regression, in general. <5829>
Role played by regression in the neuroses, in general. <5730>
Forms of regression, in general. <1954>
Regression of the libido (e.g. to earlier objects). <1955>
Developmental regression (e.g. of the sexual organization to earlier stages). <1957>
Regression of the ego <1956>
Role played by frustration in regression <2008>
Relationship between repression and regression <4683>
Relationship between fixation and regression. <2009>
Role played by fixation in determining the point to which regression will return <2009>
(and, possibly, the type of illness of which the person will fall ill). <2009>
Regression as leading to a defusion of instinct. Consequences of defusion. <1879>
Analogies for regression <5830>

Anxiety
In general <116>
Neurotic anxiety, in general. <1507>
Infantile anxiety / anxiety in children, in general. <5338>
Views on, in general. <3590>
Relationship to sexuality, in general. <3998>
The original theory. <364>
Anxiety as a straightforward/direct transformation (and discharge) of frustrated (pent-up) (dammed up) libido. <364>
Anxiety as being physiologically similar to processes occurring, and affects experienced, at birth. <3218>
Anxiety attack as being physiologically similar to (as a surrogate for) <3220>
the processes taking place in the act of copulation <3220>
Shift in views. The later amended theory. <365>
Anxiety as a signal generated by the ego in response to a situation of danger. <365>
Dangers faced by the ego, in general. [See also topic 2163] <4749>
External and internal dangers. Distinctions between them. <3225>
Neurotic anxiety as being in response to internal dangers <4100>
Explanation of neurotic anxiety, using the ego's response to external dangers as a starting point. <4099>
Internal dangers, in general. <4097>
The different types of internal danger, and the types of anxiety in relation to these. <1045>
Anxiety in relation to the instincts (neurotic anxiety) <1756>
Anxiety in relation to the super-ego (moral anxiety) <1757>
Castration-anxiety <4759>
Tie up between the two views of anxiety <1046>
Why the particular affective state of anxiety? <3762>
Anxiety as the central problem in the neuroses <4076>
As being an invariable accompaniment of most neuroses <382>
Role played by anxiety in repression, symptom formation and the neuroses, in general. <842>

The death instinct
In general <1564>
Note that the sexual instinct never found in pure form. <1595>
Always found in various alloys with the death instinct. <1595>
[See also topic 1721] <1595>
## The Neuroses

### Classification
- Great division into neuroses and psychoses (narcissistic neuroses) <47>
- Division of neuroses into actual neuroses and transference neuroses (psychoneuroses) <3481>
- Division of actual neuroses into neurasthenia and anxiety neurosis <3486>
- Division of transference neuroses into phobias, conversion hysteria and obsessional neurosis. <3493>
- Distinction between neurosis and psychosis. [See topic 55]
- In practice most neuroses are of mixed aetiology <2185>
- The problem of diagnosis - distinguishing between the various neuroses. <3492>

### The actual neuroses
- In general. Absence of a psychical mechanism. Sexual aetiology for. <1420>
  - Due to specific sexual noxae rather than psychological factors. <1420>
  - The nature of the sexual noxae involved. <1420>
  - Distinction from psychoneuroses. <1420>
- The whole question of harmful sexual practices. <1420>
  - Direct relationship found to exist between specific sexual noxae <1420>
    and the form of actual neurosis of which the person falls ill. <1420>
  - Distinction between neurasthenia and anxiety neurosis. <1420>
  - Often possible to understand fluctuations in the course of illness in terms of <3501>
    changes which have taken place in the sexual life of the person concerned. <3501>

#### Neurasthenia
- In general. The symptomatic picture. <3170>
  - Aetiology. Mechanisms at work in. <3215>
    - An acquired disorder. Specific sexual aetiology for. No psychical mechanisms involved. <3215>
    - Nature of the sexual noxae involved (male and female forms). <3215>
  - The question of masturbation, in general. <3175>
    - Relationship of masturbation to addictions. <3175>
  - Role played by heredity in <3498>
  - Particular symptoms <3184>

#### Anxiety neurosis
- Introduction
  - In general. The symptomatic picture. <3169>
  - Anxiety neurosis as an independent clinical entity. <3228>
    - Reasons for separation off from neurasthenia. <3228>
  - Aetiology. Mechanisms at work in.
    - In general <4060>
      - An acquired disorder. As having a purely physiological basis. <3178>
      - No psychical mechanism involved. <3178>
      - A specific sexual aetiology for. <3178>
    - The sexual noxae involved (male and female forms). <3178>
      - Sexual theory as accounting for periodic nature of attacks <3178>
      - Counter-arguments to sexual aetiology for <3192>
    - Refutations of counter-arguments. Proofs of sexual aetiology. <3192>
    - Mechanism behind anxiety in. [See also topic 364] <4094>
    - Role played by heredity in <3285>
  - Particular symptoms
    - Anxiety attacks <4061>
    - Respiratory (dyspnoea) <3647>
    - Cardiac (angina-like pains, palpitations). <3648>
    - Gastrointestinal disturbances <3183>
    - Glandular (sweating) <4063>
    - Vascular (congestion) <4065>
    - Paraesthesias <3185>
    - Locomotor system (vertigo, fainting). <4064>
      - Pavor nocturnus <4066>
    - Chronic symptoms <4084>
    - Other <3187>
Table of Contents

Relationship to other neuroses
  In general <3227>
  Points in common with neurasthenia <4112>
  Distinctions from neurasthenia <3168>
  Mixed forms. Often found in conjunction with neurasthenia. Reasons for. <4110>
  Relationship to psychoneuroses, in general. <5370>
  Relationship to conversion hysteria <3265>
  Relationship to phobias <3167>
  Relationship to hypochondria <3677>

Therapeutic considerations
  In general. <3505>
    Benefits which flow from recognition of sexual aetiology for neuroses. <3505>
    Neurasthenia, in particular. <3520>
    Anxiety neurosis, in particular. <3514>
    Relationships between actual neurosis and psychoneurosis <3521>
    Importance of sexuality in both <3478>

The transference neuroses
  Introduction
    In general. Distinction from actual neuroses. <2173>
    Psychological basis for <4114>

Phobias
  The symptomatic picture <2959>

Aetiology. Mechanisms at work in.
  In general <176>
  Role played by anxiety in. <3166>
    Relationship to anxiety neurosis. Distinctions from anxiety neurosis. <3166>
    Symptoms in as exaggerations of normal fears <4570>
    Displacement (transposition of affect, 'false connection') in. <4080>
  Role played by condensation in <5535>
  Role played by trauma in <4075>
  Role played by sexuality in <3282>
  Role played by the castration complex (castration anxiety) in <4050>
  Role played by words in <4561>
  Role played by projection (externalization of the danger) in <5781>
  Secondary protective measures. <4081>
    Secondary symptoms (defensive measures) overlaying or replacing the original phobia. <4081>

Typical phobias
  Typical and atypical (specialized) phobias <4068>
  Two distinct classes of phobia - those relating to physiological dangers and those relating to locomotion. <4070>
  Physiological dangers (heights, snakes, vermin). <4072>
    Locomotion <4073>
    Railway phobia <5149>
    Agoraphobia <3195>
    Animal phobias <5774>
    Other phobias <5845>

Relationship to other neuroses
  Place in classificatory system <5542>
  Relationship to obsessional neurosis <4117>
  Relationship to hysteria <5541>
  Hysterical phobias. [See also topic 4747] <5455>

Therapeutic considerations <5525>

Anxiety-hysteria
  In general <5543>
  Mechanisms at work in <5773>
Table of Contents

Role played by constitutional factors in <5546>
Relationship to anxiety neurosis <5655>
Relationship to phobias <5547>
Therapeutic considerations <5548>

Conversion hysteria

Introduction
In general <493>
Characteristics of the hysterical state <3606>
The symptomatic picture. Typical symptoms. <100>
Pre-psycho-analytic views on (medieval times, Charcot). <2871>
Origin of the term 'Hysteria' <5147>

Aetiology. Mechanisms at work in.
In general <5073>
As having little to do with intellect <3719>
A purely psychological theory for <5064>
Psychical meaning behind the symptoms <3668>
Original views on - trauma-based theory for. [See also topic 522] <2191>
Role played by unconscious memories in. Hysteric as suffering from reminiscences. <3408>
Hysterical symptoms as mnemonic symbols from the past. [See also topic 522] <3408>
Role played by early childhood in. <4449>
Timelessness of memories involved in. <4449>
A psychosexual aetiology for <5060>
Role played by sexuality in <5051>
Role played by fixation at the phallic stage in <5593>
Role played by perverse sexuality in <3804>
Role played by the component instincts in <5480>
Role played by the erotogenic zones in. <5226>
These zones behaving as though they were a portion of the sexual apparatus. <5226>
Role played by bisexuality in <5481>
Displacement of sensation in. <4590>
The concept of 'displacement upwards'. <4590>
The concept of hysterogenic zones <5263>
Role played by repression in <5078>
Repression as affecting mainly the genital zones <5262>
Return of the repressed in <4675>
Role played by regression in <5775>
The conversion mechanism <1115>
Reasons for unintelligibility of symptoms <5515>
Role played by the primary process in (condensation, displacement). <5514>
Role played by reaction-formation in <4486>
Transformation of an element into its opposite in <5516>
Reversal of chronological order in <5517>
Role played by phantasy in <2406>
These unconscious phantasies as corresponding in every detail <5121>
with the recorded actions of perverts <5121>
These unconscious phantasies as corresponding with <5374>
the imaginary creations of paranoids (which become conscious as delusions) <5374>
Role played by the Oedipus complex in <3809>
Role played by the aggressive instinct in <5591>
Role played by the super-ego in (guilt-related symptoms) <4718>
Symptoms as self-punishments (self-injury) <5151>
Gaps in memory in <3598>
Role played by symbolization of thoughts in. <3657>
The symbolic content of symptoms. <3657>
Role played by words (and their double meanings) in <5517>
The concept of a language of hysteria <5554>
The concept of hysterical symptoms 'joining in the conversation' <3656>
Table of Contents

Role played by identification in <3833>
Role played by masturbation in <3872>
Affect in <4628>
Precipitating causes, in general. <5574>
Exciting causes in something apparently innocent <5153>
Economic considerations <2407>
 Constitutional factors <5065>
The question of a hysterical disposition <3669>
The concept of ‘somatic compliance’ <5079>
The concept of hysteria exploiting a genuine organic complaint for its own ends <3611>
The unconsciousness of the mental processes at work in. <3670>
   The whole conversion process as being involuntary and unconscious. <3670>

Hysterical symptoms
In general <5216>
As the expression (and realization) of the patient's most secret and repressed (sexual) wishes <5052>
As the realization of an unconscious phantasy <5479>
As having a (hidden) sexual meaning <5137>
As wish-fulfilments <3894>
As compromise formations <5482>

Typical symptoms
Aphonia <5076>
Avoiding company <5074>
*Belle indifference* <3650>
Hysterical amnesia <3556>
Hysterical attacks <3797>
Hysterical blindness. [See also topic 5649] <5650>
Hysterical pains <3607>
Hysterical paralyses <3605>
Hysterical phobias <4747>
Hysterical vomiting <5069>
Loss of appetite <5148>
Motor phenomena (tics) <3608>
Overreactivity <3406>
Visions <4674>

Therapeutic considerations
In general. [See also topic 522] <3721>
Interpretation of the symptoms. Translation of the symptoms into what they really mean. <3649>
Diagnosis. The problem of distinguishing hysterical symptoms from genuine organic illness. <494>
Absence of expected auxiliary signs (e.g. pain) <3654>
Physical manifestations often do not correspond to what would be expected on purely neuro-anatomical grounds <3454>
   The characteristic indefiniteness with which hysterics describe their symptoms <3652>
   Distinction of hysteria from malingering <5081>

Obsessional neurosis
Introduction
A psychical basis for <4203>
The symptomatic picture. Typical symptoms. Characteristics of persons suffering from obsessional neurosis. <99>
 Characteristics of obsessional symptoms <3985>
   (illogical, nonsensical, cannot be suppressed, inamenable to reason/influence, <3985>
   alien, like intruders/unwanted guests). <3985>
   Distinction of obsessional symptoms from the normal (where reasons for the compulsion are known) <3987>

Aetiology. Mechanisms at work in.
In general <1003>
Obsessions with a traumatic aetiology <3150>
Role played by repression in <3992>
## Table of Contents

Role played by displacement (transposition) in. The 'false connection'. &lt;3398&gt;  
Role played by substitution in &lt;3766&gt;  
Role played by objects in &lt;3901&gt;  
Role played by sexuality in &lt;4043&gt;  
Role played by the component instincts in &lt;5559&gt;  
Role played by perverse sexuality in &lt;5558&gt;  
Role played by latent (repressed) homosexuality in &lt;5557&gt;  
Role played by the scopophilic and epistemophilic instincts in &lt;5600&gt;  
Role played by childhood in &lt;5372&gt;  
Role played by the infantile in &lt;5565&gt;  
Role played by the aggressive instinct (sadism) in &lt;118&gt;  
Regression to anal-sadistic phase in &lt;119&gt;  
Role played by fixation at the anal-sadistic stage in &lt;3173&gt;  
Role played by (repressed) anal erotism / anal-sadism in &lt;3173&gt;  
Role played by defusion of instinct in &lt;5590&gt;  
Transformation of love into hate in &lt;5221&gt;  
Role played by hostile/death-wishes against loved ones (parents, siblings, spouse) in. &lt;3831&gt;  
Role played by the super-ego in. [See also topic 736] &lt;553&gt;  
Role played by the unconscious sense of guilt in &lt;554&gt;  
Role played by the censorship and distortion in &lt;4227&gt;  
Secondary defensive symptoms (measures) in, in general. &lt;3340&gt;  
Role played by reaction-formation in. [See also topic 1988] &lt;450&gt;  
Role played by the affects in, in general. &lt;4186&gt;  
Role played by reversal/transformation of affect in &lt;2400&gt;  
Role played by ambivalence in &lt;568&gt;  
Role played by anxiety in. Relationship to anxiety neurosis. &lt;451&gt;  
Role played by the castration complex in &lt;4579&gt;  
Role played by phantasy in &lt;5569&gt;  
Role played by (infantile) masturbation in &lt;3851&gt;  
Role played by words in (double meanings, ambiguity) ('verbal bridges'). &lt;3921&gt;  
Use of external associations in. Looseness of these associations. &lt;5570&gt;  
Role played by symbolism in &lt;5446&gt;  
Diphasic nature of certain symptoms in &lt;5572&gt;  
Precipitating causes in &lt;5575&gt;  

### Typical symptoms

Categories of obsessional symptoms, in general. &lt;4059&gt;  
Avoidances &lt;4167&gt;  
Compulsive collecting (hoarding) &lt;4207&gt;  
Conscientiousness &lt;3343&gt;  
Excessively intense (supervalent) trains of thought &lt;5126&gt;  
Guilt-related symptoms, in general. &lt;4205&gt;  
Hindrances. Inhibitions (abulias). &lt;5442&gt;  
Isolation &lt;5598&gt;  
Measures undertaken to prevent betrayal &lt;4211&gt;  
Obsession for protecting &lt;5607&gt;  
Obsession for understanding &lt;5605&gt;  
Obsessional (self-)prohibitions &lt;5146&gt;  
Obsessional actions &lt;2370&gt;  
Obsessional brooding and speculating ('brooding mania') &lt;4055&gt;  
Obsessional cleanliness (fear of dirt, mysophobia). Obsessional washing. Hand-ceremonials. &lt;4057&gt;  
Obsessional commands &lt;5582&gt;  
Obsessional counting (arithmomania) &lt;4056&gt;  
Obsessional deliria &lt;5581&gt;  
Obsessional doubt (folie du doute, 'doubting mania'). &lt;3182&gt;  
Uncertainty. Self-distrust. Hesitation. Indecision. &lt;3182&gt;  
Checking. Repeating. &lt;3182&gt;  
Obsessional fears &lt;5562&gt;  
Obsessional ideas (idees fixes) &lt;3152&gt;
Table of Contents

Obsessional impulses <5441>
Obsessional reflections <5585>
Obsessional rituals/ceremonials <3153>
Obsessional temptations <5584>
Obsessional thinking <3240>
Obsessional thoughts <5127>
Obsessional touching (and not touching) of objects <3714>
Obsessional wishes <5583>
'Omnipotence of thoughts' <248>
Penances <5471>
Penitential measures/acts <4208>
Phobias <4215>
Precautionary measures <4210>
Preventative measures <3432>
Protective measures <3581>
Renunciations <4168>
Self-punishments <3932>
Self-reproaches <4175>
Tics <3582>
Undoing what has already been done <3241>
Other <4214>

Miscellaneous topics
The phenomenon of two kinds of knowledge in <5578>
Reason why obsessional ideas do not meet with belief <3344>
The fact that obsessional ideas, and everything derived from them, <4217>
meet with belief in obsessional neurosis. <4217>
Reasons for the obsessional/compulsive character of the symptoms. <4185>
(Reasons for inamenability to influence of symptoms. <4185>
(Due to origins in, and hence reinforcement received from, the repressed.) <4185>
Reasons for persistence of the emotional state (affect) in <4058>
Reasons for absurdity, unintelligibility of the symptoms in. <4054>
Relationship between primary and secondary symptoms (defensive measures) in <4216>
The symptoms as, after interpretation, possessing a meaning. <5445>
The intimate nature of the material finding expression in the symptoms <5450>
The concept of a language of obsessional neurosis <5553>
Return of the repressed in. <5510>
The tendency to failure of the repressions/reaction-formations in. <5510>
The neurosis as eventually attaining its goals in a roundabout manner. <5510>
The unconsciousness of the mental processes at work in the neurosis <4772>
Relationship to religion. Obsesssional neurosis as a private religion. [See also topic 11] <2985>

Therapeutic considerations <3347>

Relationships between the various neuroses
Similarities and distinctions, in general. <3235>
What the various neuroses share in common. <3232>
All the neuroses as sharing a common mechanism up to a certain point. <3232>
Differences <3233>
Distinctions between the actual neuroses and the psychoneuroses <2841>
Relation between anxiety neurosis and hysteria <3238>
Points in common between obsessional neurosis and hysteria <4113>
Distinctions between obsessional neurosis and hysteria <2698>
Relationship between obsessional neurosis and phobias <3073>
Distinctions between hysteria and phobias <5540>
The Narcissistic Neuroses (Psychoses)

The narcissistic neuroses, in general

Introduction
- In general <5835>
- The theory of narcissism <2785>
- The narcissistic nature of these disorders <479>
- Distinction from transference neuroses <3244>
- Difficulties presented by the narcissistic nature of these disorders <5320>
- Characteristics of, in general. <54>

Aetiology. Mechanisms at work in.

In general <1437>
- Withdrawal from external reality in <1227>
- Withdrawal of the libido into the ego in. Megalomania in. <4149>
- Kinship with the state of sleep and dreams. [See also topic 1419] <2980>
- Suspension of reality-testing in <5800>
- Disintegration of the psyche in <3088>
- Ego as approximating to the id in. <1794>
  - Presence of primary process near the surface. <1794>
- Inroads made by the id into the ego in <4774>
- Id as overpowering the ego in <4710>
- Role played by wish-fulfilment in <4362>
- Hallucinatory (wish-fulfilling) psychosis (delusional insanity). <3134>
  - Commonness of this type of disorder. <3134>
- Remodelling of reality in <4247>
- Role played by phantasy in <5432>
- Weakening of ego in <4713>
- Role played by the super-ego in <3777>
- Role played by censorship in ('Russian censorship') <3880>
- Role played by repression in <4678>
- Return of the repressed in <4673>
- Regression in <1688>
- Role played by childhood in <4677>
- Role played by secondary revision in <5836>
- Predisposing factors. <2971>
  - Fixation at primary narcissistic stage of libidinal development. <2971>
- Precipitating factors (painful reality, increase in strength of instincts, relative weakening of ego). <1798>
- Economic considerations. Importance of the economic factor. <4711>
  - A question of the relative strengths of the various forces at the time. <4711>
- Alterations of the ego in, in general. <1903>

Splitting of the ego
- Splitting of the ego in the process of defence, in general. <5849>
- Splitting of the ego in the psychoses <1800>
- Role played by disavowal of reality in splitting of the ego <1815>
  - The possibility of an abnormal ego co-existing alongside a normal one <1853>
- Splitting of the ego found elsewhere <1807>
- Splitting of the ego in fetishism <1814>
- Splitting of the ego in religion <1818>
- The unconsciousness of the whole process <3132>

Typical symptoms
- Delusions. Delusions as always having a core of truth to them. <2975>
- Hallucinations (auditory, visual). <2977>
  - Conditions required for formation of. <2977>
  - Connection with the state of sleep and dreams. <2977>
- Role played by memories in. <2977>
- Peculiarities of speech. [See also topic 3667] <3055>
- Negativism <5844>
Table of Contents

Miscellaneous topics
- The symptomatic picture / symptomatology easily explained in terms of our theories <3053>
- The concept of 'psychosis of defence' <3140>
- The concept of 'flight into psychosis' <3127>
- The concept of 'psychosis of overwhelming' <3098>
- Acute hallucinatory confusion (Meynert's 'amentia') <3771>
- The ego's break with reality never really complete <1799>
- Symptoms as representing an attempt at reconstruction / restitution / recovery <387>
- Multiple personalities. Role played by identification in. <3816>
- Distinction between neurosis and psychosis. Distinction not absolute. <55>
- A certain amount of resistance as a sine qua non of normalacy <1080>
- What was learnt from the narcissistic neuroses <2787>
  (behaviour of the libido in the ego, the ego-instincts as being libidinal in nature). <2787>
- Therapeutic considerations <4018>

Melancholia
- In general <278>
- Early theories for (including relationship to neurasthenia) <3754>
- Mechanisms at work in <408>
- The concept of normal prototypes of the pathological <3929>
- Mourning as the normal prototype for melancholia <3930>
- Melancholia as involving the loss of an object <3370>
- The work of mourning <3660>
- The mechanism of identification <3045>
- Identification with the lost object in melancholia <593>
- Role played by the super-ego in. [See also topic 846] <478>
- Super-ego's criticisms as in fact applying to the lost object <3042>
- Mechanism at work in melancholia as possibly the only way in which an object-attachment <3043>
  can be overcome <3043>
- Role played by the aggressive instinct in <4315>
- Role played by regression in <5808>
- Role played by ambivalence in <5809>
- Periodic/cyclical forms of the disorder <3339>
- Turnaround into mania. Explanations for. <507>
- Melancholic attacks following the suppression of a large amount of affect <1278>
- The unconscionness of the whole process <5812>
- A possible organic basis in certain cases <506>
- Suicide in <5811>
- Therapeutic considerations <5392>

Paranoia
- Introduction
  - In general. Typical symptoms. <1254>
- Aetiology. Mechanisms at work in.
  - In general <3355>
  - Projection in <640>
  - Delusions in <198>
    - Delusions as serving the purposes of defence. <198>
    - Delusions as serving the purposes of wish-fulfilment. <198>
    - Reasons for strength of delusions ('false connection'). <198>
    - A core of truth in every delusion. <198>
  - Economic factors in <759>
  - Withdrawal libido from objects in. Narcissism in. <2876>
  - Predisposing factors. Fixation at the stage of narcissism in. <5737>
  - Regression in. Regression to stage of narcissism in. <5739>
  - Forward surge of auto-erotic current in <3900>
  - Role played by the super-ego in. [See also topic 847] <3397>
  - Hypercathexis of the super-ego in <2879>
Table of Contents

Role played by repression in <4231>
Return of the repressed (in distorted form) in. <4226>
Role played by censorship in <4222>
Paramnesia in <5005>
Over-attention to (hyercathexis of) manifestations of the unconscious in other people <2379>
Role played by sexuality in <3785>
Important role played by (latent, repressed) homosexuality in. <657>
Reversal of affect in. [See also topic 2400] <2389>
Role played by the aggressive instinct in <3786>
Role played by reaction-formation in <5592>
The transformation of love into hate in. [See also topic 2442] <2469>
Role played by the Oedipus complex in <3810>
Role played by the father-complex in <5663>
Role played by phantasy in (alienation of parentage, exaltation of parentage, systematic nature of). <3826>
Role played by identifications (and their dissolution) in <3899>
Precipitating causes <1803>
Certain symptoms as representing attempts at reconstruction/restitution/recovery <5752>

Typical symptoms
Jealousy, in general (different grades of, role played by projection in). <1801>
Delusions of jealousy (delusional jealousy, jealous paranoia). <2382>
Delusions of reference <2380>
Delusions of being followed, watched, observed, criticized. <3193>
Delusions of persecution (persecutory paranoia) <2365>
Delusions of grandeur. Megalomania. <1255>
Delusions of world-catastrophe. Delusions of 'the end of the world'. <5731>
Religious delusions. <5659>
Erotomania <5679>
Eating disorders. Delusions of being poisoned. <3846>
Auditory hallucinations. Voices. <2386>
Visual hallucinations. <2387>
Hypochondriacal symptoms <5667>

Miscellaneous topics
Further notes on delusions
In general <2398>
The work of delusion-formation <5660>
Certain delusions as representing a return of the repressed, but in distorted form. <4228>
The content of delusions as being determined <5666>
Delusions as having a meaning <5668>
Alterations undergone by the ego in order to accommodate the primary delusions <3356>
Secondary delusions as being designed to fit in with the primary delusions <3357>
The concept that the delusion may have been present in the unconscious <2396>
long before its emergence / irruption into consciousness <2396>
The uninfluencibility of delusions. Reasons for. <4232>
Distinctions between obsessional ideas and delusions <3131>

Further notes on hallucinations
In general <4652>
Content as being determined <4653>
The concept of 'organ-speech' (hypochondriacal speech) <5788>
Weakness of memory in <3358>
Absurdity in as expressing ridicule and derision <5664>
Splitting of the ego in. [See also topic 1800] <1806>
Presence of the same (repressed) material in normal and neurotic people <5027>

Therapeutic considerations <2376>
## Table of Contents

### Schizophrenia

**Introduction**
- In general. Typical symptoms. <444>
- Usual period of onset at puberty or early adult life. Reasons for. <3191>

**Aetiology. Mechanisms at work in.**
- In general <3224>
  - Narcissistic nature of the disorder. <2962>
  - Turning away from the external world in. <2962>
  - Withdrawal of the libido from objects in. <2962>
  - Fixation at the stage of narcissism in <5673>
  - Role played by regression in. Regression to stage of narcissism in. <2963>
  - Role played by repression in <5749>
  - Return of the repressed in distorted form in <5748>
  - Delusional formations as representing attempts at reconstruction/restitution/recovery. <426>
- The predominance of what has to do with words over what has to do with things in <5789>
- Role played by identification in <5807>

**Typical symptoms**
- In general <3666>
- Peculiarities of speech (neologisms). <3667>
  - Words, rather than the thing-presentations themselves, as being subjected to primary process. <3667>
  - [See also topic 3055] <3667>
- Hallucinations <5750>

**Miscellaneous topics**
- Resemblance of some philosophical writings to those of schizophrenics <1261>
- Relationship between schizophrenia and paranoia <5674>
- Origins of the designations for <5744>
  - Suggestion of the alternative designation 'paraphrenia' for paranoid schizophrenia <3881>

**Therapeutic considerations** <5751>

### Miscellaneous Disorders

**Traumatic neurosis <1502>**
**Inhibitions <2722>**
**Hypochondria <3179>**

**Disorders of the sexual function**
- In general <357>
  - Anaesthesia (frigidity) in females <5330>
  - Impotence, *ejaculatio praecox* in males. <4967>

**Character formation**
- Character in general <5008>
- Factors playing a role in formation of, in general. <265>
- Role of defence mechanisms in <2042>
- Role played by the super-ego in <2043>
- Role played by sexual instinct in <5623>
- Role played by identification in <1410>
- Role played by sublimation in <5493>
- Role played by repression in <5637>
- Role played by reaction-formation in. [See also topic 5364] <2177>
  - The perverse sexual disposition of childhood as, through the reaction-formation it stimulates, being the source of a number of our virtues. <5362>
- Role played by fixation in <5636>
- Role played by trauma, especially negative reaction to, in. <172>
- Role played by repetition compulsion in <169>
- Character types <3239>
- Relationships between particular erotogenic zones (component instincts) <5359>
  - and certain character traits, in general. <5359>
  - Character traits having their origin in (repressed) anal erotism <5630>
Table of Contents

Relationship between anal erotism and money (gold) <3805>
The triad of orderliness, miserliness (parsimony, thrift) and obstinacy often being found together. <1809>
The relationship between urethral erotism (micturition, bed-wetting, nocturnal enuresis) and ambition. <4446>
The concept of a man's attitude in sexual matters acting as a template for his attitude in other areas <5595>
Libidinal types <5846>
Other
'Housewife's psychosis' <5066>
Feeling of derealization. Depersonalization. <5847>

Practical Applications. The Unconscious In Everyday Life.

In general
General introduction <582>
The common model. <2187>
Same mechanisms at work in and responsible for dreams, parapraxes, jokes and neurotic symptoms. <2187>
Determinism in mental life <581>

Dreams

Introduction
Introduction <2573>
Freud's early views on the nature of dreams; attempts at interpretation; use of in treatment; <3596>
realization of their importance. <3596>
How Freud came upon dream-interpretation. <3596>
The state of sleep <288>
Why conditions prevailing during the state of sleep allow for the formation of dreams <1306>
Broad definition of dreams <341>
Earlier literature dealing with dreams <2422>
The layman's view of dreams <680>
The creative writer's view of dreams <5431>
Various questions relating to dreams. <1210>

Why the need to dream? Do they have any value? What purpose do they serve? <1210>

General characteristics of dreams
The psychological characteristics of dreams <110>
(nonsensical, absurd, childish, long/fleeting, alien, strange). <110>
Suspension of reality-testing in. <110>
Belief attaching to dream-content. <110>
Hallucinatory nature of. <110>
Lack of moral sense in. <110>
Tendency to condensation, displacement; replacement of one element by another. <110>
Generally forgotten soon after waking. <110>
Suspension of reality-testing in, in particular. <4301>
Egoistic nature of <4494>
The looseness of the basis on which associations are formed <4513>

Preliminary findings and conclusions
In general. <2563>
Broad descriptions of what dreams are and the mechanisms behind them <2272>
Concept of the dream being the dreamer's response to certain external or internal disturbing stimuli <4916>
Unconscious mental processes at work in <4845>
Distinction between manifest and latent content <128>
Manifest content as being only a facade <1218>

Manifest dream as being negligible portion of total dream content <2325>
Dreams as having a disguised/hidden/concealed meaning <4344>
As adhering to a dynamic theory of dream-formation <2569>
Dreams as having the same underlying basis as neurotic symptoms. <445>
As, too, representing a return of the repressed, but whose form is determined by <445>
the psychical conditions prevailing during the state of sleep. <445>
Distinction between dreams and neurotic symptoms. [See also topic 1300] <445>
Nature of the psychical forces at work in the formation of dreams <4276>
As constituting a return of the repressed, but in distorted form. <113>
A note that all psychical activity set in motion by a wish <4708>
Dreams as wish-fulfillments. [See also topic 1638] <111>
Wish-fulfilment not always clear or obvious. Dreams as disguised wish-fulfilments. <3983>
Dreams as valid psychical phenomena <4382>
Dreams as being significant mental acts <2601>
As being capable of interpretation. [See also topic 122] <4274>
As, after interpretation, being seen to occupy an assignable place in the person's mental life. <4275>
Factors contributing to the dream's strangeness/unintelligibility. <585>
(Nature of underlying material, censorship, distortion, primary process, pictorial form of representation.) <585>
The notion of an object evading the censorship under cover of something else <4645>

Types of dreams
Division of dreams into those where wish-fulfilment is clear and those where it is not <4685>
Simple dreams. Dreams in which the wish-fulfilment is relatively clear (undisguised wish-fulfilments). <4387>
Children's dreams (dreams of the simple infantile type) (frank wish-fulfilments) <595>
Reasons why this is so (no great distinction yet between id and ego) <4693>
Transition from children's dreams to adult dreams. <4392>
(Further development of psyche, censorship, necessity for distortion.) <4392>

Dream instigators. Potential disturbers of sleep.
In general. Possible sources of disturbance to sleep. <1302>
Non-psychical stimuli <4334>
External stimuli, in general. <1304>
External (objective) sensory stimuli <4320>
Internal stimuli, in general. <4330>
Internal somatic (organic) stimuli. <1305>
(Natural bodily functions and needs; hunger, thirst, voiding of bladder, <1305>
need for warmth, sexual needs.) <1305>
Internal (subjective) sensory stimuli <4321>
Internal psychical stimuli <2392>
Recent events and experiences, in general. <4425>
Waking interests, events, preconscious wishes carried over from waking life. <4378>
Previous day's residues. [See also topic 344] <4378>
Non-wishful instigators in particular <4695>
(thoughts, worries, intentions, unsolved problems, distressing anticipations). <4695>
Note on whether it must be events and experiences from the preceding day <4418>
Events and experiences from the recent past <4424>
Wishes as dream-instigators <5823>
Types of wishes seeking fulfilment in adult dreams <4687>
Repressed wishes as dream-instigators, in general. <4439>
Repressed wishes as providing the major motive force for the formation of dreams <1308>
Repressed sexual wishes as dream-instigators, in particular. <4538>
Role played by perverse sexual wishes, in particular. <4921>
Role played by repressed homosexual impulses, in particular. <4539>
Repressed wishes generally from the past <4482>
Role played by repressed infantile sexual wishes, in particular. <4932>
Repressed infantile wishes as constituting the main dream-instigators. <4452>
(Indestructibility of these wishes.) <4452>

The formation of dreams. The dream-work.
Definition of. Function of. Aims and goals. <604>
Mechanisms involved in the formation dreams, in general. <695>
Overview of the process of dream-formation. <695>
Components of the dream-work (condensation, displacement). <695>
[See also topic 2580] <695>

Role played by the ego in the formation of dreams
In general <1332>
The state of the ego during sleep <3971>
(withdrawal of perceptual cathexes) <3971>
Withdrawal of cathexis never complete <4912>
Table of Contents

The ego's wish to go on sleeping <1414>
Other wishes on the part of the ego which may exercise an influence over the direction taken by the dream <4724>
Partial relaxation of censorship during sleep <4909>
Censorship. Distortion. Why the need for distortion? <1335>
Censorship and distortion as expression of the same forces which, during the day, <1335>
were responsible for the complete repression of the unconscious wish. <1335>
Methods used by the dream-work to evade the censorship. <3083>
(Use of acceptable preconscious material, condensation, displacement, reversal into the opposite.) <3083>
Secondary revision <109>

Role played by the primary process in the formation of dreams
In general <1325>
Characteristics of the primary process <1339>
Condensation (the marked tendency to condensation in dreams). <343>
(Identifications, creation of composite figures/structures, compromise formations.) <343>
Condensation involving words, in particular. <4514>
(Similarity of sound, use of verbal ambiguity, neologisms.) <4514>
Displacement <342>
Combined condensation and displacement <4893>
Substitution. Replacement of one object with another. <1150>
Representation through the opposite. [See topic 3570]

Role played by the id in the formation of dreams
In general <3996>
The question of a necessary motive force for the formation of dream. <2570>
Requirement for reinforcement from a repressed wish for the formation of a dream. <2570>
Relationship between preconscious material and the repressed wish <4701>
Analogy with entrepreneur <3854>

Further discussion of certain topics.
Question of where the dream actually gets formed <1323>
Logical links holding the material together as being lost in the course of the transformation process <4896>
Passage of id material into the preconscious ego accompanied by a passage of the primary process into the ego <1319>

The content of dreams
In general <126>
Relationship to waking life. Material from the present. <4280>
Material provided by external and internal sensory stimuli <4455>
Preconscious material, in general. <2430>
Recent material (including requirements of), in general. <4303>
The previous day's residues, in particular. <344>
(Inevitable appearance of residues from the previous day in dreams.)
[See also topic 4378] <344>
Memory and knowledge <4285>
Material from the past, in general. <4415>
Memory far more extensive in dreams than in waking life. (Dreams as being hypermnestic.) <1310>
(Dream-work as having access to material from early childhood.) <1310>
Material from childhood (infantile material), in particular. <268>
Representation of events from childhood in dreams <4608>
Role played by infantile sexual researches in dreams <5342>
Repressed material in dreams. <1311>
The emergence in dreams of impulses and desires we didn't know we harboured. <1311>
Sexual material in dreams. <4512>
The great majority (but not necessarily all) dreams as having an underlying sexual content. <4512>
Bisexuality in dreams. Satisfaction of homosexual impulses in dreams. <4596>
Seemingly innocent dreams may contain crudely sexual content. <4597>
Sexual content not always obvious or apparent. <4597>
The castration complex in dreams <5840>
Death-wishes in dreams. [See also topic 4481] <4403>
Use of symbols in dreams [See also topic 2335] <127>
Prehistoric material in dreams. <1312>
   Dream-work as having access to archaic/phylogenetic material. <1312>
Words, speeches in dreams. <4431>
Intellectual activity in dreams <4530>
Numbers and calculations in dreams <4613>
Periods of time in dreams <5152>
Judgements in dreams <4621>
The drawing of conclusions in dreams <4630>
The expression of astonishment/surprise in dreams <4626>
Expressions of criticism in dreams (annoyance, repulsion). <4637>
Interpolations in dreams <4638>
Absurdity, nonsense in dreams. <4615>
Dead people coming alive again in dreams <4617>
Proper names in dreams <4616>
Affects in dreams <4351>
Mood in dreams <4636>
Phantasy in dreams <4510>
Feeling of satisfaction in dreams <4631>
The feeling of reality in dreams <4580>
Doubt and uncertainty in dreams <4656>
The 'either-or' relationship in dreams (both in the text of the dream and in reporting the dream) <4899>
Repetition in dreams. Significance thereof. <4581>
Variations in the degree of intensity in various portions of the dream. Reasons for. <4543>
Choice of material, and the way in which it is chosen. <4299>
   Apparent preference for indifferent material. Reasons for. <4299>
   Content of dreams as being overdetermined. <4299>
   Relationship between manifest and latent content of dreams. <4299>
Dreams in which part of the content (and often the most important part) is only remembered later <4657>
Dreams which are forgotten, or cannot be recalled in their entirety, <4659>
   but can be recalled after certain resistances have been overcome. <4659>
Pathological material in dreams. [See also topic 2393] <2429>
Considerations of representability. The means of representation.
In general <4564>
   The move over from an essentially verbal form of expression to a pictorial (hallucinatory) one. <4548>
      Modes of expression at the dream-work's disposal. <4548>
Symbolism in dreams. <2335>
   Knowledge and use of symbolism as being something primitive and inborn rather than learned. <2335>
   Used from an early age. <2335>
   Symbols used - male (phallic) and female. <2335>
      (Including typical dreams - birth dreams, dreams of falling, flying, being naked, glued to the spot, tooth dreams.) <2335>
      Male symbols, in particular. <3824>
      Female symbols, in particular. <3825>
   Experiments involving symbolism in dreams <4586>
      Use of symbolism elsewhere <2515>
         (myths, legends, fairy-tales, folklore, popular customs, superstition, jokes, psychoneuroses, <2515>
            fetishism, in unconscious mental life in general). <2515>
Archaic modes of thought in dreams, in general. <5489>
   (As found in ancient civilizations, myths, fairy tales, superstitions, <5489>
      unconscious thinking, dreams and the neuroses.) <5489>
Regression in dreams. As providing an explanation for the hallucinatory character of dreams. <4668>
Use of indirect modes of representation in, in general. <4936>
Use of allusion in <4441>
Representation through the opposite. <3570>
   Reversal into its opposite. <3570>
   Reversal of chronological relations in dreams <5518>
Table of Contents

Representation of time in dreams <4531>
Representation of logical relations in dreams <4527>
Representation of causal relations in dreams <4532>
Representation of similarity in dreams <4535>
Representation of contraries in dreams <4533>
A note on 'the antithetical meaning of primal words' (K Abel) <4534>
Linguistic expression, verbal transformations in dreams <4366>
(Play on words, use of puns, similar-sounding words, verb ambiguity). <4366>
Replacement of a thought expressed in the optative by representation in the present tense <4885>
Analogy with the task faced by the painter/sculptor <4529>

Typical dreams
In general <4475>
Dreams of the infantile type in adults <4880>
Dreams of convenience (e.g. as prompted by internal organic stimuli). <4384>
(as undisguised wish-fulfilments / simple satisfactions of the need) <4384>
Dreams with an intestinal stimulus <4603>
Dreams with a urinary stimulus <4602>
Arousal dreams <4723>
Dreams of being naked / in a partial state of undress <4473>
Dreams of being inhibited, glued to the spot, paralysed. <4471>
Dreams of flying, falling through the air, floating, swimming. <4472>
Oedipus dreams <4578>
Dreams of the death of persons of whom the dreamer is fond. [See also topic 4403] <4481>
Examination dreams <4496>
Dreams of missing a train <4587>
Dreams with a dental stimulus (tooth-dreams) <4588>
Dreams of fire <4592>
Dreams of passing through narrow spaces or of being in water (birth dreams) <4600>
Rescue dreams <4604>
Lying dreams <2270>
Hypocritical dreams <4402>
Dreams of impatience <4437>
'Biographical' dreams <4571>
Dreams in which one has a feeling of having been there once before (deja vu) <4599>
Dreams in which robbers, burglars, ghosts play a part. <4606>
Dreams of paranoiacs (persecutory dreams) <2393>
(including the topic of the inclusion of pathological thought-material in the dream-content in general). <2393>
[See also topic 2429] <2393>
Dreams during analytic treatment. The ability of analysis to influence a dream's content. <4610>
Transference-dreams. <4610>
Recurrent dreams (which may undergo distortion over time) <2343>

Technique of interpretation
Aims/goals of dream interpretation. What dream interpretation sets out to achieve. Its task. Dream interpretation technique. <122>
Approaches to dream interpretation (including older/earlier methods). <122>
Our approach - free association to each of the elements of the dream. <122>
Justification for free association. <122>
General technical rules. <122>
The dream's manifest content as being strictly determined by the latent content. <122>
Necessity for dreamer's own associations (except where symbols are employed). <122>
Note on the quantity of material which emerges relative to the sparsity of the manifest dream. <122>
Significance of glosses, comments, judgements passed by the dreamer regarding the dream. <122>
The possibility of interpreting one's own dreams <3886>
Interpretation of dreams as the counterpart to the dream-work. <4873>
As proceeding in the reverse direction and undoing the transformations bought about by the dream-work. <4873>
The concept of a language of dreams <5580>
Analysis vs. synthesis <4524>
Further discussion of certain topics

Dreams as being simply another form of thinking <2414>
The dream as being a substitute for a rational process of thought <4871>
The concept of a preconscious thought-process being 'drawn down into' <4777>
and being subject to the workings of the unconscious' <4777>
Dream-work as being an unconscious working-over of preconscious thought processes. <1330>
Strangeness/unintelligibility of dreams explainable in terms of this. <1330>
The concept of the manifest and latent content being two different versions <4497>
(a transcript) of the same material <4497>
Motives for censorship <4426>
Distortion in dreams, in general. <2346>

Analogies for distortion in dreams taken from everyday life. <4398>
(Need for distortion, censorship, need to adopt indirect mode of expression.) <4398>
Characteristics of the latent dream-content (the dream-thoughts arrived at by interpretation). <598>
As being completely logical and rational. As being no different to our waking thoughts. <598>
Although some may seem alien, we are forced to acknowledge them as our own. <598>
The forgetting of dreams. Most dreams as being forgotten soon after waking. Explanations for. <3978>
Doubts as to accuracy of what is remembered after waking. <3978>
Role played by external and internal sensory stimuli in the content of dreams <4459>
(as providing material for the dream-work, how woven into the dream, <4459>
the way in which it is deliberately misinterpreted in the interests of preserving sleep). <4459>
Dreams as representing a regression to earlier, more primitive, infantile <4705>
modes of operation of the psychical apparatus. <4705>

Miscellaneous technical questions

How dreams instigated by external sensory stimuli are created in so short a space of time. <4323>
The ingenuity which the dream-work displays, considering how quickly the dream was formed. <4323>
Possibility of the dream having already been partially formed in the day-time. <4323>
Use of phantasies by the dream work. <4323>
Miscellaneous questions relating to external sensory dream-instigators <4326>
Miscellaneous questions relating to internal somatic dream-instigators <4328>
Detailed discussions of what constitutes a wish <4801>
How the dream succeeds in doing away with the disturbing wish, seeing that the wish <4729>
retains its cathexis, and hence its upward drive, throughout the night. <4729>
The concept that it is far more expedient for the ego to relax its repressions during sleep and allow dreams to be
formed than to maintain a high level of expenditure on repression <4732>
Reasons why the sleeping ego feels safe in lowering its expenditure on repression. <4732>
(ACCESS TO CONSCIOUSNESS AND VOLUNTARY MOVEMENT CUT OFF DURING SLEEP.) <4732>
Other ways in which the dreamer could have reacted to a dream-instigator (e.g. woke up). <4457>
The question of whether the material which emerges in association to the dream-elements <4503>
was present at the time of the formation of the dream <4503>
All the processes involved in the formation of dreams as being unconscious <4506>
Dreams occurring on successive nights, <4620>
successive dreams on the same night as working over the same material. <4620>
The possibility of there being two or more meanings for a dream (the possibility of 'over-interpretation') <2352>
More than one wish may be fulfilled in a dream <4422>
Can a dream ever be completely interpreted? <4499>

Problem areas

In general <1260>
Types of dreams apparently running counter to the wish-fulfilment theory of dreams, in general. <2245>
Dreams that appear to be the reverse of a wish-fulfilment <4405>
Anxiety-dreams <123>
Analogical role of ego with that of the town's night-watchman <1418>
Masochistic dreams (including role played by super-ego in) <4411>
Role played by super-ego in the formation of dreams <4696>
Dreams occurring in the traumatic neuroses <2247>
Role played by the repetition compulsion in dreams <4434>
Replies to criticisms of wish-fulfilment theory of dreams <4393>
Necessary distinction hasn't been made between manifest and latent content of dream <4394>
What is pleasurable for one agency need not necessarily represent pleasure for the other <4462>
Table of Contents

Need for slight revision of wish-fulfilment theory of dreams <1417>
   in the light of anxiety and masochistic dreams <1417>
The question of the distinction, if any, between dreams of normal people and neurotics. <4583>
A note that the censorship function is also the guardian of mental health <4709>
Difficulties facing the expositor <4375>
   (underlying material usually of an extremely intimate nature, volume of material involved). <4375>
A note on the fact that dreams with an obviously sexual content noticeably absent from <4834>
   early editions of The Interpretation of Dreams. Reasons for. <4834>
Significance of our findings in relation to dreams, in general. <4867>
Ethical/moral significance of our findings in relation to dreams <4866>
Other possible functions of dreams (e.g. biological) <4868>
Refutation of notion that dreams may have other 'secondary' functions <4743>

Summary. Conclusions reached.
Recap of what dreams are <1341>
Overviews of the process of dream-formation <2580>
   (unwanted impulse > repression > partial failure of repression > compromise > <2580>
   return of the repressed in distorted form). <2580>
   [See also topic 695] <2580>
Dreams as wish-fulfillments. [See also topic 111] <1638>
The function of dreams is to preserve sleep. <405>
   Dreams are the guardians of sleep. <405>
As binding unconscious excitations by allowing them to become preconscious <4740>
Dreams as significant mental acts (no insignificant dreams) <4430>
Dreams as giving expression to repressed material <5024>
Dream as being in the nature of a compromise <1333>
As being compromise-formations <4742>
Relationship of dreams to mental processes in infants (wishful-cathexes, hallucinatory wish-fulfilment). <3973>
Summary of factors responsible for the unintelligibility of dreams <3248>
Summary of factors giving dreams their final form (condensation, displacement, censorship, secondary revision). <4517>

The value of dreams (both from a theoretical and practical point of view). <472>
Theoretical: Dreams as falling into the category of psychopathological structures. <472>
   Their understanding as helping to explain the neuroses/psychoses. <472>
Because dreams occur in normal people as well, <472>
   their understanding throws light on unconscious mental processes in general. <472>
An understanding of dreams throws light on other <472>
   structurally-related psychical phenomena - parapraxes and jokes. <472>
Dreams as the royal road to a knowledge of unconscious mental processes. <472>
   Practical: Their interpretation as giving access to unconscious psychical material. <472>
   Serves as a useful analytic tool. [See also topic 102] <472>
Possible diagnostic value - may serve as premonitors of physical or mental illness. <4327>
Summary of distinctions between our and other views on dreams <2560>
   (the ancients, scientific, lay views). <2560>
Reasons why dreams are held in such low esteem (e.g. by the scientific community). <4890>
   Apparently deal with trivialities. <4890>
The purported ability of dreams to foretell the future (premonitory dreams, prophetic dreams). <4346>

Relationship of dreams to other phenomena
   Relationship to neurotic symptoms <726>
   Distinctions from neurotic symptoms <1300>
   Relationship to psychosis. Dream as a brief psychosis. [See also topic 2980] <1419>
   Relationship to day-dreams <4342>
   Relationship to jokes <4515>
   Relationship to myths, legends, creative writing. <1313>
Table of Contents

Parapraxes

Introduction
   Introduction of concept. <120>
   Broad listing of phenomena in this category. Enumeration of phenomena in question. <120>

Mechanisms at work in
   In general <4940>
   Relationship to neurotic symptoms.
      Same mechanisms at work in as in dreams, jokes and neurotic symptoms. [See topic 2187]
   Role played by repression in <3553>
   Role played by the primary process in (displacement, condensation). <4974>
   Role played by displacement in, in particular. <4976>
   Role played by condensation in, in particular. <4977>
   The unconsciousness of the mental processes at work in <4950>
   As, too, being disguised wish-fulfilments. <4803>
   As, too, representing a return of the repressed in distorted form. <4953>
   As, too, representing partial failures of repression. <5044>
   As, too, being compromise formations. <4782>
   As being valid psychical acts <5822>
   As having a sense. As having a hidden content and meaning. <3095>
   As being significant <1262>
   As being relevant in the context of the person's unconscious mental life <2081>
   As being motivated <937>
   The motivation as being unconscious <1001>
   As having a hidden intent <3276>
   As having a hidden purpose <3968>
      (as serving an unconscious purpose, as being purposive acts). <3968>
   As betraying our innermost thoughts, feelings, intentions and wishes. <2166>
   As representing part satisfactions for repressed impulses <3266>
   As being a manifestation of the interfering influence of the repressed <1040>
   As arising from the mutual interference of two intentions <5821>
   Their nature and content as being strictly determined <1225>
   As representing the outcome of a conflict between two opposing forces or agencies <3529>
   As being capable of interpretation <3096>
   Distinction from neurotic symptoms <5047>

Categories/classes of parapraxis
   General examples <1405>
   Slips of the tongue <389>
      More general disturbances of speech (in rhythm, execution of whole speech). <4992>
      Perseverations <5631>
   Slips of the pen <400>
   Misreading <466>
   Mishearing <390>

Failures (lapses) of memory <468>
   The mechanism of forgetting (inability to recall things) in general. Psychological basis for. <1228>
   The forgetting of words <4960>
   Forgetting of proper names, names of places with which one is familiar. <467>
      Related phenomenon of paramnesia - remembering names incorrectly. <467>
   Other parapraxes relating to proper names. <4540>
      Deliberate or unintentional distortion (mutilation) of proper names. Significance of. <4540>
   The disagreeable feeling when one comes across someone with the same name as oneself <4966>
   The contagiousness of name-forgetting <4968>
   The forgetting of words of a foreign language <4957>
   The forgetting of impressions and experiences (knowledge) <4997>
   Paramnesias in relation to impressions and experiences <5004>
   The forgetting of intentions (forgetting to carry out intended actions) <391>
   Errors of memory (unaccompanied by paramnesia) <5022>
Table of Contents

Mislaying of objects <433>
Losing objects <434>
Leaving objects behind <2021>
Unintentionally carrying off objects <5016>
Bungled actions (breaking of objects) <469>
    Bungled actions with potentially serious consequences <5012>
        (as seriously endangering the health or lives of others) <5012>
Self-injuries (including suicide) <2692>
Errors, in general. <5021>
Errors of judgement <5023>
Misprints (compositor errors) <5820>
Disowning (disavowal) <5001>
Combined parapraxes <1004>
Same motive as finding expression in different parapraxes <1005>

Technique of interpretation
    In general <436>
        Role played by symbolism in <5141>
        Role played by 'verbal bridges' (switch-words, associative bridges) in. <4993>
        The looseness (superficiality) of the basis on which verbal associations are formed <4955>
            (but there usually being a deeper connection) <4955>

Symptomatic acts. Chance actions.
    In general <435>

Further discussion of certain topics
    The phenomenon of an element undergoing intensification, being ultra-clear. <4959>
    Role played by secondary factors in parapraxes (tiredness, lack of attention, distraction, etc.) <4964>
    The concept that actions which are performed automatically are performed better than <5035>
        those to which attention is paid <5035>
    Analogies for role played by secondary factors in <4965>
    The nature of the repressed material lying behind parapraxes <4994>
    Problems facing the expositor (intimate nature of the underlying material) <2691>
        As being common, both in normal people and in neurotics. <2183>
    The popular view of parapraxes and symptomatic acts. <917>
        As being generally overlooked. <917>
    People as generally being reluctant to acknowledge the significance of their own parapraxes. <4982>
        As experiencing distress when their attention is drawn to their parapraxes. <4982>
    Role played by in inter-personal relations, in general. <1>
        All human beings as possessing the ability to interpret manifestations of the unconscious in other persons <3329>
        As attaching psychological significance to the parapraxes of others <4990>
        As being an important source of information of what is going on in the unconscious mind of the other person <1011>
    Parapraxes (and their interpretation) as an important source of misunderstandings in human relations <5019>
    The study of one's own parapraxes and symptomatic acts as the road to self-knowledge <5018>
    As serving as a warning for the future. As a forerunner of things to come. <996>
    The meaning and significance of a parapraxis may only become clear months or years later <2172>
    The value of parapraxes, in general (theoretical and practical). <2557>

Employment as a therapeutic tool. [See also topic 103] <1265>
Possible objections to theory for <5033>
Relationship between parapraxes and dreams <5026>
Relationship between parapraxes and jokes <4980>
Employment of parapraxes by creative writers <4987>
Superstition <4614>
Deja vu <5031>
Deja raconte <5032>
Table of Contents

Jokes
  In general <2>
  Characteristics, typical features of. <5395>
  The tendency to economy in <5404>
  Same mechanisms at work in as in neurotic symptoms <371>
  Joke techniques <5397>
  Mechanisms at work in, in general. <819>
  The joke-work. Analogy with the dream-work. <498>
  Role played by the primary process in (condensation, displacement). <4784>
  Role played by condensation in, in particular. <4954>
  Role played by displacement in, in particular. <5405>
  Role played by repression in <5416>
  Role played by the censorship in <3429>
  Necessity for distortion before entry into consciousness. <5410>
    Necessity for indirect forms of expression in. <5410>
    The various forms of indirect expression used. <5410>
    Explanations for the pleasure derived from jokes, in general. <5400>
    Explanation of the pleasure derived from jokes along economic lines, in general. <4833>
    Explanation of the pleasure derived from innocent jokes <5425>
    Explanation of the pleasure derived from tendentious jokes along purely economic lines <5413>
    Return of the repressed in <5409>
    Jokes as allowing for a temporary lifting of repression <5396>
    Jokes as enabling a circumvention of the censorship <5419>
    The joke as a facade for something deeper behind it <5421>
  Categories of joke, in general. <497>
    Jokes characterized by condensation <5399>
      (either via the formation of composite words or accompanied by modification) (condensation jokes) <5399>
    Role played by words, verbal transformations in, in general <4556>
      (play on words, use of double meanings of words, puns). <4556>
    Role played by allusion in <4726>
    Role played by symbolism in <4938>
    Purposes served by jokes, in general. <5412>
    Tendentious jokes. Purposes served by. <5414>
    The psychogenesis of jokes <5427>
    Role played by subjective determinants in appreciating a joke (having a ‘sense of humour’) <5428>
  Laughter. Mechanism behind. <5429>
  Humour <5430>
    The comic <5406>
    Relationship between jokes and the comic <5407>
    Relationship of jokes to repartee <5403>
    Relationship of jokes to irony <5408>
    Relationship between jokes and riddles <5402>
    Analogy of jokes with dreams <372>

Psycho-Analytic Treatment

  Introduction
    Psychotherapy, in general. <3691>
    Psycho-analytic treatment, in general. The approach. What goes on. [See also topic 3699] <647>
      Distinction from conventional psychiatry (makes no use of medication). <1877>
        Distinction from other therapeutic approaches. [Brief. Main discussion at topic 2404.] <1877>
  Theoretical background
    Review of fundamental premisses <1168>
      (unconscious mental processes, importance of childhood, <1168>
        important role played by instincts, importance of sexuality, dynamic view of mental functioning). <1168>
    Review of aetiological factors <1666>
    Possibility of mixed neurosis (actual neurosis along with a psychoneurosis) <1845>
    The normal state of affairs <1427>
Table of Contents

The state of affairs when things have gone wrong <1428>
Cognisance of the fact that it is only acquired (accidental, sexual) factors that we can exercise an influence over. <3494>
   Cannot influence heredity, disposition, demands of civilization. <3494>
Suitability for treatment. <1461>
   Only transference neuroses suitable. <1461>
   Requirement for a relatively normal ego with which one can deal. <1461>
Cases not suitable. Reasons for. <1899>

Aims and goals of treatment
   Aims and goals of treatment, in general. <1432>
   Strengthening the patient's ego. <512>
      Extending the ego's domain of control over the id. To replace id with ego. <512>
   To arrive at a knowledge of the unconscious material <1280>
   The insufficiency of anamnestic methods for arriving at a knowledge of such material <3414>
      Distinction of psycho-analysis from anamnestic methods <3414>
   The material we are looking for <1444>
   Making the patient aware of his repressions <3114>
   The undoing of repressions. Making the repressed material (pre-)conscious. <1161>
   Making the patient aware of, and overcoming, his resistances. <1926>

Implications
   The necessity for an analysis to go back to early childhood. <1841>
   The necessity to analyse the childhood neurosis upon which the later adult neurosis is based. <1841>
   The necessity for going into the patient's sexual life. <2480>
      As being almost impossible to understand a neurosis <2480>
      without going into the sexual life of the person concerned. <2480>
      As, in fact, being the physician's obligation and duty to do so. <2480>
   Tendencies to secretiveness, prudery and hypocrisy when it comes to matters in sexual life. <3476>
   The fact that there are things which one keeps hidden not only from others but also from oneself <4443>

The therapeutic task
   The technique, in general. <2078>
   The concept of the analyst as an ally. As forming a pact with the patient's ego. <1426>
   The intellectual task <1442>
   How treatment proceeds, in general. <3699>
   The nature and volume of the material which emerges <3365>
   The way in which the material emerges <3696>
   The order in which the material emerges <4246>
   The ego's attitude toward the emerging material <3700>
   Note that we don't overlook the role played by the ego in the pathological process. <2091>
   Work equally divided between ego-analysis and id-analysis. <2091>

Tools at the analyst's disposal
   In general <614>

Free association
   The method, in general. <455>
      Theoretical basis of. Justification for. Rationale behind. <455>
      Determinism in mental life. <455>
      All mental events determined (or even over-determined). <455>
      Necessary preconditions. The psycho-analytic pact. <455>
      The fundamental rule of psycho-analysis. <455>
      The attitude required on the part of the patient. <455>
      Technical aspects and rules. <455>
   Demands made on the analyst <5521>
      Attitude required of the analyst while employing the free association technique <2547>
      As the most important of the tools <2558>
   Interpretation of dreams <102>
   Interpretation of parapraxes, symptomatic acts, chance actions. <103>
Interpretations and constructions
In general <1445>
  The question of timing. The need for correct timing in imparting our knowledge to the patient. <1445>
  The need to distinguish between our knowledge and the patient's knowledge. <1445>
  Not sufficient to make content known to patient. <1445>
  Patient must accept and work through it for it to become his knowledge. <1445>
  The question of incorrect constructions. <1445>

The transference
In general <2706>
  Its inevitable appearance in the course of psycho-analytic treatment <3693>
  (or any other form of medical treatment, for that matter). <3693>
  The positive transference. [See also topics 1539 and 3705] <1542>
  The negative transference. [See also topic 2707] <1543>
  Distinction between the positive and negative transference <5767>
  Role played by the transference in treatment. Handling of, in general. <1843>
    As constituting an indispensable therapeutic tool. <1843>
    Cure as being obtained through resolution (mastery) of the transference neurosis <4143>
  Transference phenomenon as constituting proof of the role played by the sexual instinct in the neuroses <2703>
  The counter-transference <1577>

Other
Screen memories (childhood memories) <2324>
Corroboration of interpretations by close family members, relatives. <5817>
The concept of 'acting out' (instead of remembering) <203>

Factors affecting the outcome
Relative factors
In general <1546>
  Suitability for treatment. Patient's capacity to form a transference. [See also topic 1461] <86>
    Patient doesn't initially come to us with a conviction of the truth of psycho-analytic theories <2115>
    or of the curative powers, of psycho-analysis. <2115>
  The patient's intellectual capacity <1483>
  Ability to arouse intellectual interest in the theories of psycho-analysis in the patient <1536>
    Condition of the patient's ego (alterations in, split in). <1579>
      The fiction of a normal ego. <1579>
    The extent to which the aetiology is a traumatic one <1856>
    Constitutional factors. Innate strength of the instincts. Genetic predisposition. <1578>
    Quantitative relations. [See topic 911]
    The possibility of actual satisfaction of the instincts in real life <1547>
    Capacity for sublimation <1482>

Factors working in our favour
In general <2117>
  Upward drive of the repressed <1537>
  The positive transference <1539>
    Any intellectual interest in psycho-analysis which we may have aroused in the patient <3690>

Factors opposing our efforts
In general <3702>
Resistances
Resistance, in general. <616>
Reasons for resistance. <2675>
  Forms the resistance may assume. <2675>
  Relationship of resistance to repression. <2675>
  Resistances as being an expression of the self-same forces which initially instituted the repressions. <2675>
    Same forces responsible for repression and resistance. <2675>
  Distortion of the material coming forward as being due to the resistance <5385>
  Resistance as a quantifiable force. <1073>
    Resistance as being measured by the amount of effort required to make the repressed material conscious. <1073>
Treatment as proceeding in the face of a resistance, in general. Patient meets us with a resistance. <2157>
The resistances as opposing our efforts <1450>
The concept of resistance to recovery <638>
The resistances as opposing the patient's own recovery <5390>
The sources of resistance as being unconscious <1462>
Role played by the repressing ego, the forces of repression in the neuroses. <1925>
The uncovering and overcoming of resistances as at least half the work, if not the primary task, of analysis. <1925>
Handling of the resistances. <1925>
Factors affecting the strength of the resistances <3953>
The resistances as being more easily recognized than material in the id <2114>
The concept of resistance to the uncovering of the resistances <2105>
Role of resistances in the therapeutic outcome <2122>
Analogies for resistance <5617>

Forms of resistance
In general. <1451>
Sources of resistance other than those emanating from the ego. <1451>
Resistances emanating from the patient's ego (ego-resistances). <1476>
Resistances emanating from the ego's wish to maintain (hold on to) <1476>
(the ego's clinging to) its repressions. <1476>
Resistances emanating from the super-ego (unconscious sense of guilt). <2492>
[See also topic 3100] <2492>
Resistances emanating from the patient's need to suffer, the patient's need to remain ill. <1464>
Resistances attributable to the death instinct. [See also topic 1983] <1466>
Resistances attributable to fundamental characteristics of the instincts themselves. <2133>
Resistances attributable to masochistic trends within ego. <2133>
The transference as a source of resistance, in general. <1555>
The positive transference as a source of resistance <3705>
The negative transference as a source of resistance <2707>
The counter-transference as a source of resistance <104>
The castration complex as a source of resistance / as the mental structure least subject to influence in males <1677>
Penis envy as a source of resistance / as the mental structure least subject to influence in females <1704>
Remembering, repeating, working through. The patient repeats instead of remembering. <5826>
The relative absence of resistances, up to a certain point, in the psychoses. <3593>
Their absence as being pathognomic for the psychoses. <3593>

Economic considerations
Importance of the economic factor. <911>
Neurosis as being first and foremost an economic problem. <911>
All a question of quantitative relations - <911>
the relative strengths of the various forces playing a role in the neurosis. <911>
Need for satisfaction of the instincts in real life. <911>
Importance, in particular, of the sexual instinct. <911>
The ego's ability to tolerate frustration. <911>
The ego's capacity for sublimation. <911>
[See also 'Neurosis In General' > 'Aetiological factors in the neuroses' > 'Economic considerations'] <911>
A note on the libido's reluctance to give up a form of satisfaction it has once enjoyed <3507>

Motives for illness. Primary gain from illness. Secondary gain from illness. [See topic 5082]

Other factors
Constitutional factors. Innate strength of instincts. <515>
Relative strength of the instincts at the time of falling ill. <515>
Reinforcement of the instincts at certain times of life (puberty, menopause, loss of sexual object). [See also topic 2929] <515>
Role played by Fate (marriage, loss of spouse). <5142>
Unfavourable fixations of the libido. <1002>
Unsuitability of the narcissistic disorders for treatment. <1002>
Age. Psychical inertia. Adhesiveness of the libido. <513>
Table of Contents
Secondary factors which may cause a relative weakening of the ego. [See also topic 3196] <1866>
Notion that in certain cases, for a conflict to end in neurosis may be the most harmless and socially tolerable solution. <5837>
Analysis as . . .
In general <5387>
The concept of neurosis being due to lack of insight <3595>
Analysis as involving the elucidation of symptoms <5057>
Analysis as a form of after-education, as an extension of self-knowledge. <1438>
Analysis as the making conscious of what is pathogenically unconscious / repressed in the patient <3322>
Analysis as the undoing of repressions, in general. <1714>
Analysis as the undoing of repressions instituted (and hence damage done) in early childhood. <1760>
Analysis as the undoing of infantile (and now unnecessary) repressions. <1760>
Analysis as replacing repression with something better - with suppression (a condemning judgement) or sublimation. <4644>
Analysis as enabling / bringing about the resolution of the patient's conflicts <5013>
Analysis as the overcoming of resistances <1453>
Analysis as the filling in of gaps in the patient's memory (removing amnesias). <1713>
As the making conscious of what has been forgotten. [See also topic 532] <1713>
Analysis as the uncovering, and working through, of past traumas. <1712>
(The material emerges, symptoms are analysed, in the reverse order to which the traumas occurred.) <1712>
Analysis as a taming of the instincts. <1859>
(Note that we don't aim to do away with the instincts - merely to tame them.) <1859>
Achievements of an analysis
What a successful analysis achieves and how it achieves it. <267>
Possible outcomes of treatment. <267>
The undoing of repressions. Makes repressed material (pre-)conscious. <1226>
Brings processes in the id under the domination of the ego <4731>
Broadens of the compass of the ego <1454>
Frees the patient from the reigns of sexuality <2743>
Overcomes resistances. Benefits thereof. <1457>
Enables sublimation of the instincts <576>
Enables direct satisfaction for the instincts <649>
The distinction between 'repression' and 'suppression' <3882>
Relationship between sublimation and repression. Distinction from reaction-formation. <2394>
Analogy for analysis achieves <5618>
Analogy with the finding of the solution to a parapraxis <3555>
Technical matters
When may an analysis be considered complete? <517>
Is there any natural end to the treatment? <517>
Bringing the treatment to an end <2156>
Is a complete cure possible? <3845>
When may a treatment be considered to have been successful? <2154>
Variability of results obtained. Reasons for. <1872>
Spontaneous cures. Is a spontaneous cure possible? Explanations for. <1296>
The concept of one neurosis (or symptom) (or form of suffering) being replaced another <3300>
Limitations of analytic treatment, in general. <5154>
People's expectations in relation to an analysis <3680>
(underestimation of the severity and depth of the neuroses) <3680>
The value of an analysis, in general. <3681>
Prophylactic value of an analysis. Permanency of the cure. <1855>
Can a successful treatment prevent a person from falling ill later? <1855>
Is it possible to stir up, and hence influence, a conflict which is not currently active? <1882>
Ways of making a latent conflict active <1886>
The problem of inaccurate amanuenses <3269>
Attempts at speeding up / shortening the length of the treatment (e.g. setting a time limit). <1839>
The dangers of getting results too soon <1840>
## Table of Contents

Modifications in technique called for by the various neuroses

Problems associated with making case histories public / facing the expositor

(medical confidentiality, intimate nature of material involved, mass of material involved).

Problems people may have with the free association technique (adopting of the required psychical attitude)

Miscellaneous technical rules

In general

Anything which interrupts / interferes with the progress of analytic work should be regarded as a resistance

Negation

Analysis / analytic treatment should be carried out / through, as far as is possible, in a state of frustration /

abstinence / under privation.

We do not concern ourselves with individual symptoms per se.

Their resolution comes about as a by-product of the analysis.

The taking of notes during an analytic session

Pros and cons of psycho-analytic therapy

Pros

As being powerful, and possibly dangerous, in the wrong hands. Analogy with surgery.

As the most thorough-going of the therapeutic modalities

Distinctions from other forms of therapy

(Simple anamnestic, hypnotic, suggestive.)

Psycho-analysis as a deep therapy.

As being the only means of arriving at a knowledge of the unconscious material.

Analyses for, in general.

Analyses illustrating distinction from other forms of therapy.

Archaeological analogy for

Cons

Shortcomings, in general.

Analysis as lengthy, time-consuming (and thus expensive) procedure.

Psycho-analysis as being only for the rich.

Attempts at making analysis accessible to the broad population.

The practice of psycho-analysis

Who shall practice psycho-analysis? The question of lay analysis. Requirement for a training analysis.

Qualities required of the analyst

The analyst's own resistances

The analyst's individuality

Analysis as not allowing the presence of a third person

The question of sexual relations between patient and analyst

Note that we respect the patient's individuality - we don't try and mould him in accordance with our ideals.

Miscellaneous topics

The question of the role played by suggestion in analytic treatment

Doubts as to the believability of the material which emerges

(the analyst forces material on the patient; the patient himself invents the material)

Synthesis vs. analysis (unsatisfactory nature of the former)

The question of self-analysis

Psycho-analysis of children

Freud's own views as to psycho-analytic therapy, in general.

Late therapeutic pessimism. Increased emphasis on the economic factor.

Therapies in the future

Civilization And Society

Introduction

Definition of

Civilization and society as founded upon repression and renunciation of instinct. [Brief. See topic 65.]

Origins

In general

The civilization process

Adoption of the upright posture. Atrophy of sense of smell.

Abolition of the periodicity of the libido
Table of Contents

Early civilization
- Origins in the darkest past. Father-murder (patricide). [See also topic 12] <66>
- The sexual lives of primitives <5644>
- Taboo observances, in general. <5645>
- Taboo on incest and the injunction to exogamy. [See also topic 263] <195>
- Origins of the sense of morality. [See also topic 262] <3827>

Civilization in relation to the instincts, in general.
- Civilization and society are founded upon repression and renunciation of instinct <65>

Civilization in relation to the sexual instinct
- Society's suppression of the sexual instinct, in general. <3533>
- Civilization at the expense of the sexual instinct, in particular. <368>
- Civilization as requiring the renunciation of certain erotogenic zones as unserviceable <3803>
- As a result of repression, the sexual instinct is forced to find alternative sources of satisfaction, <1787>
  to take detours, roundabout paths to satisfaction. <1787>
- Desexualization of the sexual instinct <1786>
- The possibility of its sublimation <5499>
- The sexual instinct as making a contribution to mankind's highest achievements <1785>
- Society's reasons for enforcing sexual repression. [See also topic 2864] <475>
- Monogamous marriage - general discussion of; problems associated therewith. <2375>

Civilization in relation to the aggressive instinct
- The inborn human tendency toward aggression. [See also topic 2182] <3157>
- Civilization as requiring / being based on a renunciation of aggression <2866>
- Our relations with our fellow man. Role of the aggressive instinct in inter-personal relations. <2463>
  Development of the social instincts through reaction-formation/transformation. <2463>
- Dangers the aggressive instinct poses to society. <2864>
  As being the main reason why society imposes such heavy restrictions on the sexual instinct. <2864>
  [See also topic 475] <2864>
- Role played by religion in the civilization process <5472>

The problem with society. Reasons for unhappiness in society.
- In general <539>
- Unhappiness in relation to the sexual instinct <2290>
- Unhappiness in relation to the aggressive instinct
  - In general. <915>
    - The inevitability of strife and war. <915>
    - The aggressive instinct as the main source of human unhappiness. <915>
    - Dangers suppression of the aggressive instinct poses for the individual. <915>
    - Relationships between virtue, turning inward of the aggressive instinct <915>
    - and the unconscious sense of guilt. <915>
    - Need for the aggressive instinct to be turned outward to avoid falling ill. <915>
    - The aggressive instinct as possible source of all internal conflict. <915>
  - [See also under 'Neurosis In General' > 'Aetiological factors in the neuroses' > 'The death instinct'] <915>
- Other sources of human suffering <1918>

Paths to happiness
- In general <2965>
- Active pursuit of pleasure <1914>
- Avoidance of unpleasure <1915>
- The chemical approach. Altered states of consciousness (e.g. alcohol). <1913>
- Religion <1920>
- Retreat into psychosis <2070>

Society's role in the aetiology/causationgenesis of neurosis
- Society and the individual - general discussion of needs of each. <1044>
- Society and its cultural demands as being ultimately responsible for neurosis. <67>
  - Neurosis as a by-product of the civilization process. <67>
  - Neurotics as those / that class/group of people who founder on the civilization process. <67>
- Normal person as, too, being a product of repression, sublimation and reaction-formation. <2014>
- The role played by the repressed in mental life, in general. <4995>
- Relationship between the father and other / higher / later forms of authority <4448>
- Relationship between neurosis and higher productions of human mind <642>
### Table of Contents

#### Group Psychology

In general <652>
Critique of the concept of a 'herd instinct' <2797>
Man as a horde, rather than a herd, animal. <282>
Group formation, in general. <2798>
The simple case of two lovers <1617>
Role played by aim-inhibited libido in ordinary friendships <2801>
Role played by the libido in groups. <546>
    Groups as being based on libidinal ties. <546>
Group as being based on (sublimated) homosexual ties, in particular. <2499>
Role played by the aggressive instinct in groups, in general. <3040>
Role played by reaction-formation against hostile impulses dating from the nursery <2799>
The group's management of internal aggression. <207>
    Need for an external minority on whom to direct the aggression. <207>
The 'narcissism of minor differences' <208>
Role played by the leader in the group. <247>
    Man's need for a powerful figure in authority (father-figure). <247>
The group as being based on a common love (and fear) of the leader <457>
Role played by identification in <547>
Role played by the super-ego in <276>
Role played by the ego ideal in <5769>
Effect of the group on the intellectual capacity of its members <3740>
Nations as a whole as following the same dynamics as the individual <914>
Nations as a whole may be neurotic <834>

#### Religion

Religion in general
In general <2023>
Characteristics of all religions <420>
(moral injunctions, calls for renunciation, penances, promised rewards). <420>
Religion as a psychological problem in need of an explanation <4052>

Viewpoints
In general <393>
Role played by the past in
    In general. <5460>
        Origins of religion in the prehistory, the childhood, of mankind. <5460>
        The core of truth / the historical truth in religion. <5460>
    Role played by trauma in, in general. <936>
Infantile aspects of religion <271>
    (man's weakness, need for a strong, all-powerful father-figure and protector). <271>
    Role played by the father-complex in. <271>
Religion as an illusion <96>

Religion as a neurosis
In general <4048>
Renunciation of instinct in <5457>
Role played by repression in <4045>
Return of the repressed in <5461>
Role played by wish-fulfilment in <4819>
Role played by displacement in <5468>
Role played by unconscious sense of guilt in <4047>
Role played by super-ego in <1282>
Role played by anxiety in (fear of divine punishment) <5458>
Role played by projection in <4278>
Religion as psychology projected into the external world <5029>
Role played by the compulsion to repeat in <4773>
## Table of Contents

Religion as an obsessional neurosis, in particular. [See also topic 2985] <11>  
Differences between religion and obsessional neurosis <5443>  
Religion as offering protection against neurotic illness <5635>  
Role played by civilization in <1037>  
Religion as the neurosis of mankind <151>  
Religion as a delusion <13>  
Splitting of the ego in religion. [See topic 1818]  

### The religions

#### Primitive religion

Ancient origins of religion, in general. <5754>  
The mental lives of primitive people, in general. <5589>  
Animistic view of the universe <5646>  
Characteristics of primitive religions, in general. <558>  

#### Totemism

Totemism, in general. <5753>  
Precepts of, in general. <2016>  
Role played by the Oedipus complex in, in general. <2748>  
Prohibition on incest in. [See also topic 195] <263>  
The father-complex in. Patricide. [See also topic 66] <12>  
The sense of guilt in reaction to father-murder <285>  
Projection in <5647>  
God as a sublimation (elevation to a higher sphere) of the father <2828>  
Its two main precepts as constituting the origins of mankind's moral and social order. [See also topic 3827] <262>  
Evolution of later religions from totemism <197>  

The ancient religions <5473>  

#### Judaism

In general <395>  
Monotheism <131>  
The man Moses  
In general <115>  
Moses, an Egyptian … <70>  
Facts pointing in favour of this theory, in general. <396>  
His Egyptian name <107>  
Interpretation of the myth of his birth <108>  
Was said to have been 'slow of speech' <144>  
The Exodus from Egypt <418>  
The murder of Moses <140>  
Disavowal of the murder. Latency period. Later return of the repressed. <141>  
Sense of guilt in reaction to the murder <1402>  
Moses' murder as reinforcing in the Jews the universal sense of guilt from earlier patricide <2017>  
If Moses was an Egyptian. Ramifications. <71>  
Monotheism as being of Egyptian origin <1936>  
Religions prevalent in Egypt at the time <132>  
The Egyptian religion which Moses passed on to his followers <142>  
Distinctions between Egyptian religions and monotheism <143>  
Circumcision as being of Egyptian origin. <264>  
Circumcision as a symbolic substitute for castration. [See also topic 1681] <264>  
Moses' motives for doing what he did <130>  
The Jewish nation, in general. <5463>  
The Jewish nation as being assembled out of a number of different tribes <146>  
The Levites as originally being Egyptian <147>  
Moses' role in stamping the Jews with their unique character <246>  
Summary <145>
Table of Contents

Christianity
In general <73>
As an offshoot from Judaism, in general. <199>
The figure of Christ <3850>
Role played by disciples (the Apostles) in the establishment of Christianity <419>
The psychological logic behind Christianity <202>
Role of sense of guilt in <201>
Symbolic significance of communion <283>
The philosophy of universal love <2306>
Distinctions from Judaism <421>

Other religions
Mahommedanism <210>
Rationalistic religions of the East <5848>

Miscellaneous topics
The archaic heritage
The question of phylogenetic memory. [See also topic 580] <213>
Symbolism as an example of <239>
The child's reaction to trauma (the Oedipus and castration complexes) as examples of <240>
Instinctual (unlearned) behaviour of animals as justification for <242>
Importance for group psychology <241>
Role played by inherited memory traces in religion <243>
Role played by inherited memory traces in the neuroses <245>
How acquired, passed on, later re-activated. <244>
The notion of ontogeny repeating phylogeny <4684>
Other religious beliefs and their origin (belief in life after death) <4601>
The Jews and anti-semitism <204>
The role of religion in society <651>

Historical
Freud
Personal <2313>
Early pre-psychoanalytic influences. Charcot, Brucke, Bernheim. <2317>
Visits to Salpetriere, Nancy. What was learnt. <2317>
Wilhelm Fliess <612>
Other figures who exercised an influence on Freud's thought. Opponents (e.g. Meynert). <3739>
Persons admired by Freud. Goethe. Schopenhauer. Lichtenberg. <2824>
Works regarded by Freud as being important <2844>

Early views on the mental apparatus
The Project. Lines of thought, theories emanating from it. <3675>
The brain as the scene of action of our mental processes <286>
(Neurones, contact-barriers, facilitations, memory, pain, <286>
role of quantity and quality in, the property of consciousness). <286>
The concept of already cathected neurones/systems being <3943>
more susceptible to cathectic than uncathected ones <3943>

Psycho-analysis
Overview of development of views, theories and techniques
In general <366>
Pre-psychoanalytic views on neurosis (Medieval times, Middle Ages, Charcot). <2858>
Everything put down to heredity. <2858>
Other views on neurosis (Janet). <2858>
Over-emphasis on role played by heredity, degeneracy, chemical factors. Critique thereof. <2858>
Freud's early views on the role played by heredity. <2858>
The possibility of the neuroses having an acquired basis. <2858>
Breuer and the case history of Anna O.
   In general <1277>
   Case history <492>
   Breuer's method <2893>
   What Breuer's method made possible <4155>
   Breuer's findings <500>

Freud enters the scene <2898>
   Freud's early employment of Breuer's method. <2900>
   A new technique for arriving at a knowledge of unconscious material. <2900>
   Freud's extensions of the technique. <2900>
   The goal of treatment at this stage <4157>
   Freud's findings <511>
   Subsequent confirmation of findings on other patients <2478>

Original joint statement of findings
   Hysteria as an acquired disorder, having a psychical basis with a traumatic aetiology. <522>
   Unconscious mental processes at work in. <522>
   Defence on the part of the patient's ego. <522>
   Suppression of affect. Strangulated affect finds employment in symptom through conversion. <522>
   Causal link between trauma and symptom. <522>
   Aims/goals of therapy. <522>
   Therapy aimed at re-establishing causal link between trauma and symptom, <522>
   thereby allowing abreaction of strangulated affect. <522>
   Treatment essentially of a cathartic nature. <522>
   Use of hypnosis as a therapeutic tool. <522>
   Analogy with 'traumatic neuroses'. <522>
   Traumas must have occurred in early childhood. <522>
   Role played by memories in. Hysteric as suffering mainly from reminiscences. <522>
   Role played by sexuality in. Traumatic experiences usually of a sexual nature. <522>
   Nature of the sexual traumas (seduction). <522>
   Mechanism of symptom formation. The conversion process. <522>
   Symptoms as a return of the repressed. <522>

Technical matters
   In general <3348>
   Similarities/differences between hysteria and obsessional neurosis <3319>
   Early views on obsessional neurosis. <3316>
   Also traumatic aetiology, but event experienced is of an active/aggressive nature. <3316>
   Explanation of symptoms in terms of a 'counter-will' <3586>
   The concept of 'the putting into effect of antithetic ideas' <3609>
   Reasons for the perseveration of memories long after the event. <2956>
   The question of an adequate reaction to a psychical trauma. <2956>
   Adequate reaction not occurring in hysterics. As reason for retention and consequent <2982>
   pathogenicity of their memories. Hysteric as suffering from reminiscences. <2982>
   Explanation for the deferred action of early traumas. <3337>
   How early experiences of a sexual nature are able to exert their pathogenic effect. <3337>
   Through the re-activation of their memory-traces in later life. <3337>
   Deferred action of memories. <3337>
   Distinction of views from other earlier views on the aetiology of the neuroses <2904>
   (acquired, psychical mechanism, traumatic aetiology, defence, the sexual factor). <2904>

Parting of the ways
   Breuer's theory of hypnoid states. Freud's criticisms thereof. <533>
   Other differences in views. <533>
   Acknowledgements to Breuer. Later retractions of these. <2490>
   Breuer's theoretical contribution <3671>
   The question of how much of the theoretical contribution is due to Breuer and how much due to Freud <3673>
   The value of Breuer's findings <3312>
Table of Contents

Importance of the case history of Anna O. <2897>
Value of Breuer's method. <2897>
Reasons for Breuer's abrupt withdrawal from the case and cessation of all further involvement in psycho-analysis <3579>

Freud's early views on the neuroses
In general. <3003>
The neuroses as having an acquired basis. <3003>
The actual neuroses as having a discrete physical mechanism. <3003>
The psychoneuroses as having a psychical basis. <3003>
Dynamic mechanism, based on conflict between opposing forces. <3003>
Defence-based theory for the neuroses, with the mechanism of repression as its nucleus. <3003>
Repression not necessarily a pathological phenomenon. <3003>
Found in healthy people as well. <3003>
Distinction of normal defence from pathological defence. <3003>
A common mechanism for the psychoneuroses. <3003>
Paths taken by repressed material in the formation of the symptom. <3003>
Dissociation of affect from idea. <3003>
Conversion in hysteria, attachment to surrogate idea in obsessional neurosis. <3003>
The concept of a 'false connection'. <3003>
Symptoms as representing a return of the repressed. <3003>
Symptoms as representing failures of repression. <3003>
Mechanism of repression. <3003>
Greater appreciation of the role played by the instincts in the neuroses. <3003>
A sexual aetiology for the neuroses. [See also topic 383] <3003>
Ideas of a sexual nature as being main motive for defence. <3003>
Importance of childhood. <3003>
Relationship between sexuality and childhood. <3003>
Presence of sexuality in childhood. <3003>
The relationship of symptoms to sexuality not always obvious. <3003>
The unconsciousness of the mental processes at work in the neuroses. <3003>

What treatment called for at this stage <4221>
Differences in the aetiology of the various neuroses <3022>
Differing chronological requirements <3790>
Conversion mechanism in hysteria. [See also topic 1115] <3026>
Displacement of affect of anxiety on to surrogate object in phobias <3027>
Attachment of affect to wrong/surrogate object in obsessional neurosis <3028>
The concept of the process which takes place in hysteria being more advantageous <3090>

than that occurring in the other neuroses <3090>
Early views on paranoia - as, too, being based on defence. <3349>
Symptoms as representing a return of the repressed in distorted form. <3349>
Comparison between symptom formation in paranoia and obsessional neurosis <3353>
Comparison between symptom formation in paranoia and hysteria <3354>

Modification of views
Abandonment of traumatic theory for the neuroses. Reasons for. <2169>
Shift to dynamic aetiology for neuroses <2111>
Greater appreciation of role played by sexuality in the neuroses. <2583>
Greater appreciation of role played by perverse sexuality in the neuroses. <2583>
Neuroses as the negative of the perversions. <2583>
Appreciation of importance of childhood in <2584>
Greater appreciation of role played by ego in. <2717>
Greater appreciation of role played by 'defence' in. <2717>
Focus shifted away from the repressed to the resistances. <2717>

Intimation of notion of repression <540>
Analogy for repression - rowdy man in hall. <542>
Notion of a censorship function in mental life <2537>
The resistance. [See also 'Psycho-Analytic Treatment' > 'Factors opposing our efforts' > 'Resistances'] <1043>

Analogy with extracting the pure metal from the ore <5386>
Summary of changes undergone in therapeutic technique <2736>

The movement
In general <377>
As working alone in the first few years <2710>
Begins to build up a band of followers around him <2711>
The Vienna Psychoanalytic Society <139>
Cool reception received in Germany. Rejection from scientific world. <2701>
The breakaway movements <894>
Freud's definitions of what is and isn't psycho-analysis <2713>
Persons whom Freud credits with having made a contribution to psycho-analysis and its theories <2825>
Translations and the translators of Freud's works <2846>

Psycho-Analysis In General

Resistances to psycho-analysis and its theories
In general. <607>
Reasons for. Sources of. Guises under which these resistances may manifest themselves. <607>
Criticisms usually based on ignorance <607>
(criticisms usually made by people not qualified to do so). <607>
Resistances often based on prudery i.e. on ethical/moral rather than on valid scientific grounds. <607>
Resistances arise mainly in response to the emphasis psycho-analysis lays on sexuality. <607>
Resistance to a sexual aetiology for the neuroses <3374>
Resistance to assertion of an unconscious portion of the mind <3451>
Resistance to assertion of a death instinct (even within psycho-analytic circles) <3130>
Fears of the dangers posed by psycho-analysis to society as a whole <3463>

Criticisms commonly applied to psycho-analysis and its theories
Criticisms of the method itself (validity, credibility of its findings). <1216>
Believability/genuineness of what patient tells us. <1216>
That we may perhaps have forced our own ideas on the patient. <1216>
That all our findings based on studies of the abnormal. <1216>
Over-concern with sexuality. That we put everything down to sexuality. <1216>
(Note that we don't lose sight of the organic factor.) <1216>
That psycho-analysis seeks to cure the neuroses by giving free reign to sexuality. <1216>
That our notions of sexuality in children are derived from analyses of adults. <1216>
That every dream is the fulfilment of a sexual wish. <1216>
Dualistic view of the instincts. <1216>
Objections to psycho-analysis as a whole. <1216>
That psycho-analysis is a threat to all that is best and highest in society. <1216>
That we put all criticism down to resistances. <1216>

Replies to criticisms
Refutation of criticisms, clearing up of misconceptions, in general. <5839>
Replies to / refutations of criticisms relating to psycho-analysis as a form of treatment, in particular. <1888>
Fear of the dangers posed by psycho-analytic treatment <1888>
(may cause break-up of marriages, cause people to lose jobs). <1888>
("Better to let sleeping dogs lie' - the problem is the dogs aren't sleeping.) <1888>
Distinction from philosophy. <2195>
Theories arrived at from observation rather than speculation. <2195>
Driven by practical necessity. <2195>

Origins of the name 'psycho-analysis' given to the science/procedure <2542>
Freud as having had very little to retract in later years <2494>
Freud's initial aversion to a sexual aetiology for the neuroses <3678>
Freud as never having wavered from his sexual theory for the neuroses <3122>
Psycho-analysis as not being a static science - its theories open to change and modification. <2845>
Application of psycho-analysis in other fields. <2836>
Its value from a broader perspective. <2836>
Psycho-analysis and its findings not confined to field of psychopathology. <2836>
Understanding of mental life in general. <2836>
Understanding of human failings; improvement of humanity. <2836>
Table of Contents

Future prospects of psycho-analysis. <4302>
  Psycho-analysis unlikely to ever become popular or find widespread acceptance. <4302>
Prospects for the future (therapy) <654>
Psycho-analysis as Weltanschauung (philosophy of life) <2839>

Using This Edition
About This Edition
Extracts, Arranged by Topic and Ordered by Date
In a short paper published in 1894, I grouped together hysteria, obsessions and certain cases of acute hallucinatory confusion under the name of 'neuro-psychoses of defence', because those affections turned out to have one aspect in common. This was that their symptoms arose through the psychical mechanism of (unconscious) defence - that is, in an attempt to repress an incompatible idea which had come into distressing opposition to the patient's ego. In some passages in a book which has since appeared by Dr. J. Breuer and myself (Studies on Hysteria) I have been able to elucidate, and to illustrate from clinical observations, the sense in which this psychical process of 'defence' or 'repression' is to be understood. There, too, some information is to be found about the laborious but completely reliable method of psycho-analysis used by me in making those investigations - investigations which also constitute a therapeutic procedure.

My observations during my last two years of work have strengthened me in the inclination to look on defence as the nuclear point in the psychical mechanism of the neuroses in question; and they have also enabled me to give this psychological theory a clinical foundation. To my own surprise, I have come upon a few simple, though narrowly circumscribed, solutions of the problems of neurosis, and in the following pages I shall give a preliminary and brief account of them. In this kind of communication it is not possible to bring forward the evidence needful to support my assertions, but I hope to be able to fulfil this obligation later in a detailed presentation.

The most immediate objections to this conclusion will probably be that sexual assaults on small children happen too often for them to have any aetiological importance, or that these sorts of experiences are bound to be without effect precisely because they happen to a person who is sexually undeveloped; and further, that one must beware of forcing on patients supposed reminiscences of this kind by questioning them, or of believing in the romances which they themselves invent. In reply to the latter objections we may ask that no one should form too certain judgements in this obscure field until he has made use of the only method which can throw light on it - of psycho-analysis for the purpose of making conscious what has so far been unconscious.¹ What is essential in the first objections can be disposed of by pointing out that it is not the experiences themselves which act traumatically their revival as a memory after the subject has entered on sexual maturity.

You will readily admit that it would be a good thing to have a second method of arriving at the aetiology of hysteria, one in which we should feel less dependent on the assertions of the patients themselves. A dermatologist, for instance, is able to recognize a sore as luetic from the character of its margins, or the crust on it and of its shape, without being misled by the protestations of his patient, who denies any source of infection for it; and a forensic physician can arrive at the cause of an injury, even if he has to do without any information from the injured person. In hysteria, too, there exists a similar possibility of penetrating from the symptoms to a knowledge of their causes. But in order to explain the relationship between the method which we have to employ for this purpose and the older method of anamnestic enquiry, I should like to bring before you an analogy taken from an advance that has in fact been made in another field of work.

Moreover, Gentlemen, this first disappointment we meet with in following Breuer's method is immediately succeeded by another, and one that must be especially painful to us as physicians. When our procedure leads, as in the cases described above, to findings which are insufficient as an explanation both in respect to their suitability as determinants and to their traumatic effectiveness, we also fail to secure any therapeutic gain; the patient retains his symptoms unaltered, in spite of the initial result yielded by the analysis. You can understand how great the temptation is at this point to proceed no further with what is in any case a laborious piece of work.
I have now come to the end of what I have to say to-day. Prepared as I am to meet with contradiction and disbelief, I should like to say one thing more in support of my position. Whatever you may think about the conclusions I have come to, I must ask you not to regard them as the fruit of idle speculation. They are based on a laborious individual examination of patients which in most cases taken up a hundred or more hours of work. What is even more important to me than the value you put on my results is the attention you give to the procedure I have employed. This procedure is new and difficult to handle, but it is nevertheless irreplaceable for scientific and therapeutic purposes. You will realize, I am sure, that one cannot properly deny the findings which follow from this modification of Breuer's procedure so long as one puts it aside and uses only the customary method of questioning patients. To do so would be like trying to refute the findings of histological technique by relying upon macroscopic examination. The new method of research gives wide access to a new element in the psychical field of events, namely, to processes of thought which have remained unconscious - which, to use Breuer's expression, are 'inadmissible to consciousness'. Thus it inspires us with the hope of a new and better understanding of all functional psychical disturbances. I cannot believe that psychiatry will long hold back from making use of this new pathway to knowledge.

A large number of dreams have been published and analysed in accordance with my directions in papers by physicians who have decided to adopt the psycho-analytic therapeutic procedure, as well as by other authors. In so far as these writings have gone beyond a mere confirmation of my views I have included their findings in the course of my exposition. I have added a second bibliography at the end of the volume containing a list of the most important works that have appeared since this book was first published. The extensive monograph on dreams by Sante de Sanctis (1899), of which a German translation appeared soon after its issue, was published almost simultaneously with my Interpretation of Dreams, so that neither I nor the Italian author was able to comment upon each other's work. I have unfortunately been unable to escape the conclusion that his painstaking volume is totally deficient in ideas- so much so, in fact, that it would not even lead one to suspect the existence of the problems with which I have dealt.

One day I discovered to my great astonishment that the view of dreams which came nearest to the truth was not the medical but the popular one, half-involved though it still was in superstition. For I had been led to fresh conclusions on the subject of dreams by applying to them a new method of psychological investigation which had done excellent service in the solution of phobias, obsessions and delusions, etc. Since then, under the name of 'psycho-analysis', it has found acceptance by a whole school of research workers. The numerous analogies that exist between dream-life and a great variety of conditions of psychical illness in waking life have indeed been correctly observed by many medical investigators. There seemed, therefore, good ground for hoping that a method of investigation which had given satisfactory results in the case of psychopathic structures would also be of use in throwing light upon dreams. Phobias and obsessions are as alien to normal consciousness as dreams are to waking consciousness; their origin is as unknown to consciousness as that of dreams. In the case of these psychopathic structures practical considerations led to an investigation of their origin and mode of development; for experience had shown that the discovery of the trains of thought which, concealed from consciousness, connect the pathological ideas with the remaining contents of the mind is equivalent to a resolution of the symptoms and has as its consequence the mastering of ideas which till then could not be inhibited. Thus psychotherapy was the starting-point of the procedure of which I made use for the explanation of dreams.
I will now show what results follow if I apply this method of investigation to dreams. Any example of a dream should in fact be equally appropriate for the purpose; but for particular reasons I will choose some dream of my own, one which seems obscure and meaningless as I remember it, and one which has the advantage of brevity. A dream which I actually had last night will perhaps meet these requirements. Its content, as I noted it down immediately after waking up, was as follows:

In the psychotherapeutic procedure which I employ for resolving and removing neurotic symptoms I am very often faced with the task of discovering, from the patient's apparently casual utterances and associations, a thought-content which is at pains to remain concealed but which cannot nevertheless avoid unintentionally betraying its existence in a whole variety of ways. Slips of the tongue often perform a most valuable service here, as I could show by some highly convincing and at the same time very singular examples. Thus, for instance, a patient will be speaking of his aunt and, without noticing the slip, will consistently call her 'my mother'; or another will refer to her husband as her 'brother'. In this way they draw my attention to the fact that they have 'identified' these persons with one another - that they have put them into a series which implies a recurrence of the same type in their emotional life. To give another example: a young man of twenty introduced himself to me during my consulting hours in these words: 'I am the father of So-and-so who came to you for treatment. I beg your pardon, I meant to say I am his brother: he is four years older than I am.' I inferred that he intended this slip to express the view that, like his brother, he had fallen ill through the fault of his father; that, like his brother, he wished to be cured; but that his father was the one who most needed to be cured. - At other times an arrangement of words that sounds unusual, or an expression that seems forced, is enough to reveal that a repressed thought is participating in the patient's remarks, which had a different end in view..

Chance actions and symptomatic acts occurring in matrimonial matters often have the most serious significance and might induce people who disregard the psychology of the unconscious to believe in omens. It is not a happy beginning when a young bride loses her wedding-ring on the honeymoon; but after all it is usually only mislaid and is soon found again. - I know a lady, now divorced from her husband, who in managing her money affairs frequently signed documents in her maiden name, many years before she in fact resumed it. - I was once the guest of a young married couple and heard the young woman laughingly describe her latest experience. The day after her return from the honeymoon she had called for her unmarried sister to go shopping with her as she used to do, while her husband went to his business. Suddenly she noticed a gentleman on the other side of the street, and nudging her sister had cried: 'Look, there goes Herr L.' She had forgotten that this gentleman had been her husband for some weeks. I felt a cold chill as I heard the story, but I did not dare to draw the inference. The little incident only occurred to my mind some years later when the marriage had come to a most unhappy end.

The general conclusion that emerges from the previous individual discussions may be stated in the following terms. Certain shortcomings in our psychical functioning - whose common characteristics will in a moment be defined more closely - and certain seemingly unintentional performances prove, if psycho-analytic methods of investigation are applied to them, to have valid motives and to be determined by motives unknown to consciousness.
There is a great deal of symbolism of this kind in life, but as a rule we pass it by without heeding it. When I set myself the task of bringing to light what human beings keep hidden within them, not by the compelling power of hypnosis, but by observing what they say and what they show, I thought the task was a harder one than it really is. He that has eyes to see and ears to hear may convince himself that no mortal can keep a secret. If his lips are silent, he chatters with his fingers; betrayal oozes out of him at every pore. And thus the task of making conscious the most hidden recesses of the mind is one which it is quite possible to accomplish.

Nevertheless, in publishing this paper, incomplete though it is, I had two objects in view. In the first place, I wished to supplement my book on the interpretation of dreams by showing how an art, which would otherwise be useless, can be turned to account for the discovery of the hidden and repressed parts of mental life. (Incidentally, in the process of analysing the two dreams dealt with in the paper, the technique of dream-interpretation, which is similar to that of psycho-analysis, has come under consideration.) In the second place, I wished to stimulate interest in a whole group of phenomena of which science is still in complete ignorance to-day because they can only be brought to light by the use of this particular method. No one, I believe, can have had any true conception of the complexity of the psychological events in a case of hysteria - the juxtaposition of the most dissimilar tendencies, the mutual dependence of contrary ideas, the repressions and displacements, and so on. The emphasis laid by Janet upon the 'idée fixe' which becomes transformed into a symptom amounts to no more than an extremely meagre attempt at schematization. Moreover, it is impossible to avoid the suspicion that, when the ideas attaching to certain excitations are incapable of becoming conscious, those excitations must act upon one another differently, run a different course, and manifest themselves differently from those other excitations which we describe as 'normal' and which have ideas attaching to them of which we become conscious. When once things have been made clear up to this point, no obstacle can remain in the way of an understanding of a therapeutic method which removes neurotic symptoms by transforming ideas of the former kind into normal ones.
Some people may feel inclined to look upon it as a serious objection to a method which is in any case troublesome enough that it itself should multiply the labours of the physician by creating a new species of pathological mental products. They may even be tempted to infer from the existence of transferences that the patient will be injured by analytic treatment. Both these suppositions would be mistaken. The physician's labours are not multiplied by transference; it need make no difference to him whether he has to overcome any particular impulse of the patient's in connection with himself or with some one else. Nor does the treatment force upon the patient, in the shape of transference, any new task which he would not other wise have performed. It is true that neuroses may be cured in institutions from which psycho-analytic treatment is excluded, that hysteria may be said to be cured not by the method but by the physician, and that there is usually a sort of blind dependence and a permanent bond between a patient and the physician who has removed his symptoms by hypnotic suggestion; but the scientific explanation of all these facts is to be found in the existence of 'transferences' such as are regularly directed by patients on to their physicians. Psycho-analytic treatment does not create transferences, it merely brings them to light, like so many other hidden psychical factors. The only difference is this - that spontaneously a patient will only call up affectionate and friendly transferences to help towards his recovery; if they cannot be called up, he feels the physician is 'antipathetic' to him, and breaks away from him as fast as possible and without having been influenced by him. In psycho-analysis, on the other hand, since the play of motives is different, all the patient's tendencies, including hostile ones, are aroused; they are then turned to account for the purposes of the analysis by being made conscious, and in this way the transference is constantly being destroyed. Transference, which seems ordained to be the greatest obstacle to psycho-analysis, becomes its most powerful ally, if its presence can be detected each time and explained to the patient.¹

I must, however, emphasize that the present work is characterized not only by being completely based upon psycho-analytic research, but also by being deliberately independent of the findings of biology. I have carefully avoided introducing my preconceptions, whether derived from general sexual biology or from that of particular animal species, into this study - a study which is concerned with the sexual functions of human beings and which is made possible through the technique of psycho-analysis. Indeed, my aim has rather been to discover how far psychological investigation can throw light upon the biology of the sexual life of man. It was legitimate for me to indicate points of contact and agreement which came to light during my investigation, but there was no need for me to be diverted from my course if the psycho-analytic method led in a number of important respects to opinions and findings which differed largely from those based on biological considerations.

Nevertheless I cannot bring myself to accept the idea that this part of psycho-analytic theory can be very much more distant than the rest from the reality which it is its business to discover. My recollections, as well as a constant re-examination of the material, assure me that this part of the theory is based upon equally careful and impartial observation. There is, moreover, no difficulty in finding an explanation of this discrepancy in the general acceptance of my views. In the first place, the beginnings of human sexual life which are here described can only be confirmed by investigators who have enough patience and technical skill to trace back an analysis to the first years of a patient's childhood. And there is often no possibility of doing this, since medical treatment demands that an illness should, at least in appearance, be dealt with more rapidly. None, however, but physicians who practise psycho-analysis can have any access whatever to this sphere of knowledge or any possibility of forming a judgement that is uninfluenced by their own dislikes and prejudices. If mankind had been able to learn from a direct observation of children, these three essays could have remained unwritten.
Footnote added 1910: When the account which I have given above of infantile sexuality was first published in 1905, it was founded for the most part on the results of psycho-analytic research upon adults. At that time it was impossible to make full use of direct observation on children: only isolated hints and some valuable pieces of confirmation came from that source. Since then it has become possible to gain direct insight into infantile psycho-sexuality by the analysis of some cases of neurotic illness during the early years of childhood. It is gratifying to be able to report that direct observation has fully confirmed the conclusions arrived at by psycho-analysis - which is incidentally good evidence of the trustworthiness of that method of research. In addition to this, the 'Analysis of a Phobia in a Five-Year-Old Boy' (1909b) has taught us much that is new for which we have not been prepared by psycho-analysis: for instance, the fact that sexual symbolism - the representation of what is sexual by non-sexual objects and relations - extends back into the first years of possession of the power of speech.

[1905d, 1512]

The time has arrived for me to attempt to summarize what I have said. We started out from the aberrations of the sexual instinct in respect of its object and of its aim and we were faced by the question of whether these arise from an innate disposition or are acquired as a result of experiences in life. We arrived at an answer to this question from an understanding, derived from psycho-analytic investigation, of the workings of the sexual instinct in psychoneurotics, a numerous class of people and one not far removed from the healthy. We found that in them tendencies to every kind of perversion can be shown to exist as unconscious forces and betray their presence as factors leading to the formation of symptoms. It was thus possible to say that neurosis is, as it were, the negative of perversion. In view of what was now seen to be the wide dissemination of tendencies to perversion we were driven to the conclusion that a disposition to perversions is an original and universal disposition of the human sexual instinct and that normal sexual behaviour is developed out of it as a result of organic changes and psychical inhibitions occurring in the course of maturation; we hoped to be able to show the presence of this original disposition in childhood. Among the forces restricting the direction taken by the sexual instinct we laid emphasis upon shame, disgust, pity and the structures of morality and authority erected by society. We were thus led to regard any established aberration from normal sexuality as an instance of developmental inhibition and infantilism. Though it was necessary to place in the foreground the importance of the variations in the original disposition, a co-operative and not an opposing relation was to be assumed as existing between them and the influences of actual life. It appeared, on the other hand, that since the original disposition is necessarily a complex one, the sexual instinct itself must be something put together from various factors, and that in the perversions it falls apart, as it were, into its components. The perversions were thus seen to be on the one hand inhibitions, and on the other hand dissociations, of normal development. Both these aspects were brought together in the supposition that the sexual instinct of adults arises from a combination of a number of impulses of childhood into a unity, an impulsion with a single aim.

[1905d, 1542]
(b) It seems to me that there is a widespread and erroneous impression among my colleagues that this technique of searching for the origins of an illness and removing its manifestations by that means is an easy one which can be practised off-hand, as it were. I conclude this from the fact that not one of all the people who have shown an interest in my therapy and passed definite judgements upon it has ever asked me how I actually go about it. There can be only one reason for this: that they think there is nothing to enquire about, that the thing is perfectly self-evident. Again, I am now and then astonished to hear that in this or that department of a hospital a young assistant has received an order from his chief to undertake a 'psycho-analysis' of a hysterical patient. I am sure he would not be allowed to examine an extirpated tumour unless he had convinced his chiefs that he was conversant with histological technique. Similarly, reports reach my ears that this or that colleague has arranged appointments with a patient in order to undertake a mental treatment of the case, though I am certain he knows nothing of the technique of any such therapy. His expectation must be therefore that the patient will make him a present of his secrets, or perhaps that he is looking for salvation in some sort of confession or confidence. I should not be surprised if a patient were injured rather than benefited by being treated in such a fashion. For it is not so easy to play upon the instrument of the mind. I am reminded on such occasions of the words of a world-famous neurotic - though it is true that he was never treated by a physician but existed only in a poet's imagination - Hamlet, Prince of Denmark. The King has ordered two courtiers, Rosenkranz and Guildenstern, to follow him, to question him and drag the secret of his depression out of him. He wards them off. Then some recorders are brought on the stage and Hamlet, taking one of them, begs one of his tormentors to play upon it, telling him that it is as easy as lying. The courtier excuses himself, for he knows no touch of the instrument, and when he cannot be persuaded to try it, Hamlet finally breaks out with these words: 'Why, look you now, how unworthy a thing you make of me! You would play upon me; . . . you would pluck out the heart of my mystery; you would sound me from my lowest note to the top of my compass; and there is much music, excellent voice, in this little organ; yet you cannot make it speak. 'Sblood, do you think I am easier to be played on than a pipe? Call me what instrument you will, though you can fret me, you cannot play upon me.' (Act III, Scene 2.)

[1905a, 1567]
I think it is worth emphasizing the fact that, whatever modifications my views on the aetiology of the psychoneuroses have passed through, there are two positions which I have never repudiated or abandoned - the importance of sexuality and of infantilism. Apart from this, accidental influences have been replaced by constitutional factors and 'defence' in the purely psychological sense has been replaced by organic 'sexual repression'. The question may, however, be raised of where convincing evidence is to be found in favour of the alleged aetiological importance of sexual factors in the psychoneuroses, in view of the fact that the onset of these illnesses may be observed in response to the most commonplace emotions or even to somatic precipitating causes, and since I have had to abandon a specific aetiology depending on the particular form of the childhood experiences concerned. To such a question I would reply that the psycho-analytic examination of neurotics is the source from which this disputed conviction of mine is derived. If we make use of that irreplaceable method of research, we discover that the patient's symptoms constitute his sexual activity (whether wholly or in part), which arises from the sources of the normal or perverse component instincts of sexuality. Not only is a large part of the symptomatology of hysteria derived directly from expressions of sexual excitement, not only do a number of erotogenic zones attain the significance of genitals during neuroses owing to an intensification of infantile characteristics, but the most complicated symptoms are themselves revealed as representing, by means of 'conversion', phantasies which have a sexual situation as their subject-matter. Anyone who knows how to interpret the language of hysteria will recognize that the neurosis is concerned only with the patient's repressed sexuality. The sexual function must, however, be understood in its true extent, as it is laid down by disposition in infancy. Wherever some commonplace emotion must be included among the determinants of the onset of the illness, analysis invariably shows that it is the sexual component of the traumatic experience - a component that is never lacking which has produced the pathogenic result.

[1906a, 1582]

It is quite possible that the author's disavowal does not stop at this. He may perhaps altogether deny any knowledge of the rules which we have shown that he has followed, and he may repudiate all the purposes we have recognized in his work. I do not regard this as improbable; but if it is so, there are only two possible explanations. It may be that we have produced a complete caricature of an interpretation by introducing into an innocent work of art purposes of which its creator had no notion, and by so doing have shown once more how easy it is to find what one is looking for and what is occupying one's own mind - a possibility of which the strangest examples are to be found in the history of literature. Let every reader now make up his mind whether he is able to accept this explanation. We ourselves, of course, hold to the other view, the remaining alternative. Our opinion is that the author need have known nothing of these rules and purposes, so that he could disavow them in good faith, but that nevertheless we have not discovered anything in his work that is not already in it. We probably draw from the same source and work upon the same object, each of us by another method. And the agreement of our results seems to guarantee that we have both worked correctly. Our procedure consists in the conscious observation of abnormal mental processes in other people so as to be able to elicit and announce their laws. The author no doubt proceeds differently. He directs his attention to the unconscious in his own mind, he listens to its possible developments and lends them artistic expression instead of suppressing them by conscious criticism. Thus he experiences from himself what we learn from others - the laws which the activities of this unconscious must obey. But he need not state these laws, nor even be clearly aware of them; as a result of the tolerance of his intelligence, they are incorporated within his creations. We discover these laws by analysing his writings just as we find them from cases of real illness; but the conclusion seems inescapable that either both of us, the writer and the doctor, have misunderstood the unconscious in the same way, or we have both understood it correctly. This conclusion is of great value to us, and it is on its account that it has been worth while to investigate by the methods of medical psycho-analysis the way in which the formation and the cure of the delusions as well as the dreams are represented in Jensen's Gradiva.

[1907a, 1883]
I know that you are at the moment concerned with the potentialities and difficulties of this procedure, whose aim is to lead the accused into an objective self-betrayal. I should therefore like to bring to your notice the fact that an exactly similar method of disclosing psychical material which is buried away or kept secret has been practised for more than a decade in another field. My purpose is to lay before you the resemblances and differences between conditions in the two fields.

[1906c, 1891]

The field I have in mind is indeed very different from yours. I am referring to the therapy employed for certain 'nervous diseases' - what are known as the psychoneuroses - of which hysteria and obsessional ideas may be taken as samples. The method is called 'psycho-analysis'; it was evolved by me from the 'cathartic' method of therapy first practised by Josef Breuer in Vienna.¹ To combat your surprise, I must draw an analogy between the criminal and the hysteric. In both we are concerned with a secret, with something hidden. But in order not to be paradoxical I must at once point out the difference. In the case of the criminal it is a secret which he knows and hides from you, whereas in the case of the hysteric it is a secret which he himself does not know either, which is hidden even from himself. How is this possible? Now we know, through laborious research, that all these illnesses are the result of the patient's having succeeded in repressing certain ideas and memories that are strongly cathected with affect, together with the wishes that arise from them, in such a way that they play no part in his thinking - do not enter into his consciousness - and thus remain unknown to him. But from this repressed psychical material (these 'complexes') are generated the somatic and psychical symptoms which plague the patient in just the same way as a guilty conscience does. In this one respect, therefore, the difference between the criminal and the hysteric is fundamental.

[1906c, 1892]

If you look more deeply into the comparison between the two situations it will become clear to you in general that psycho-analysis is concerned with a simpler, special, form of the task of uncovering what is hidden in the mind; whereas in your work the task is a more comprehensive one. That the case of the psychoneurotic is invariably concerned with a repressed sexual complex (in the widest sense) is a difference which you need not take into account. But there is something else that you must. The aim of psycho-analysis is absolutely uniform in every case: complexes have to be uncovered which have been repressed because of feelings of unpleasure and which produce signs of resistance if an attempt is made to bring them into consciousness. This resistance is as it were localized; it arises at the frontier between unconscious and conscious. In your cases what is concerned is a resistance which comes entirely from consciousness. You cannot dismiss this difference out of hand. You will first have to determine experimentally whether conscious resistance is betrayed by exactly the same indications as unconscious resistance. Further, you cannot yet be certain, in my opinion, whether you may interpret your objective indications of a complex as a 'resistance', as we psycho-therapists do. It may happen with your experimental subjects - even though not very frequently with criminals - that the complex you touch on is pleasurably toned; and the question then arises whether such a complex will produce the same reaction as a complex that is unpleasurably toned.

[1906c, 1896]
It is easy to see where the resemblances lie between neurotic ceremonials and the sacred acts of religious ritual: in the qualms of conscience brought on by their neglect, in their complete isolation from all other actions (shown in the prohibition against interruption) and in the conscientiousness with which they are carried out in every detail. But the differences are equally obvious, and a few of them are so glaring that they make the comparison a sacrilege: the greater individual variability of ceremonial actions in contrast to the stereotyped character of rituals (prayer, turning to the East, etc.), their private nature as opposed to the public and communal character of religious observances, above all, however, the fact that, while the minutiae of religious ceremonial are full of significance and have a symbolic meaning, those of neurotics seem foolish and senseless. In this respect an obsessional neurosis presents a travesty, half comic and half tragic, of a private religion. But it is precisely this sharpest difference between neurotic and religious ceremonial which disappears when, with the help of the psycho-analytic technique of investigation, one penetrates to the true meaning of obsessive actions.¹ In the course of such an investigation the appearance which obsessive actions afford of being foolish and senseless is completely effaced, and the reason for their having that appearance is explained. It is found that the obsessive actions are perfectly significant in every detail, that they serve important interests of the personality and that they give expression to experiences that are still operative and to thoughts that are cathected with affect. They do this in two ways, either by direct or by symbolic representation; and they are consequently to be interpreted either historically or symbolically.

Anyone who studies hysteria, therefore, soon finds his interest turned away from its symptoms to the phantasies from which they proceed. The technique of psycho-analysis enables us in the first place to infer from the symptoms what those unconscious phantasies are and then to make them conscious to the patient. By this means it has been found that the content of the hysteric's unconscious phantasies corresponds completely to the situations in which satisfaction is consciously obtained by perverts; and if anyone is at a loss for examples of such situations he has only to recall the world-famous performances of the Roman Emperors, the wild excesses of which were, of course, determined only by the enormous and unrestrained power possessed by the authors of the phantasies. The delusions of paranoics are phantasies of the same nature, though they are phantasies which have become directly conscious. They rest on the sadomasochistic components of the sexual instinct, and they, too, may find their complete counterpart in certain unconscious phantasies of hysterical subjects. We also know of cases - cases which have their practical importance as well - in which hysterics do not give expression to their phantasies in the form of symptoms but as conscious realizations, and in that way devise and stage assaults, attacks or acts of sexual aggression.

This method of psycho-analytic investigation, which leads from the conspicuous symptoms to the hidden unconscious phantasies, tells us everything that can be known about the sexuality of psychoneurotics, including the fact which is to be the main subject-matter of this short preliminary publication.

[1907b, 1903]

[1908a, 1935]
This connection between symptoms and phantasies makes it easy to arrive from a psycho-analysis of the former at a knowledge of the components of the sexual instincts which dominate the individual, as I have demonstrated in my *Three Essays on the Theory of Sexuality*. In some cases, however, investigation by this means yields an unexpected result. It shows that there are many symptoms where the uncovering of a sexual phantasy (or of a number of phantasies, one of which, the most significant and the earliest, is of a sexual nature) is not enough to bring about a resolution of the symptoms. To resolve it one has to have two sexual phantasies, of which one has a masculine and the other a feminine character. Thus one of these phantasies springs from a homosexual impulse. This new finding does not alter our seventh formula. It remains true that a hysterical symptom must necessarily represent a compromise between a libidinal and a repressing impulse; but it may also represent a union of two libidinal phantasies of an opposite sexual character.
[1908a, 1937]

Among those whom we try to help by our psycho-analytic efforts we often come across a type of person who is marked by the possession of a certain set of character-traits, while at the same time our attention is drawn to the behaviour in his childhood of one of his bodily functions and the organ concerned in it. I cannot say at this date what particular occasions began to give me an impression that there was some organic connection between this type of character and this behaviour of an organ, but I can assure the reader that no theoretical expectation played any part in that impression.
[1908b, 1942]

With the psychoneuroses, the influence of heredity is more marked and the causation less transparent. A peculiar method of investigation known as psycho-analysis has, however, enabled us to recognize that the symptoms of these disorders (hysteria, obsessional neurosis, etc.) are *psychogenic* and depend upon the operation of unconscious (repressed) ideational complexes. This same method has also taught us what those unconscious complexes are and has shown that, quite generally speaking, they have a sexual content. They spring from the sexual needs of people who are unsatisfied and represent for them a kind of substitutive satisfaction. We must therefore view all factors which impair sexual life, suppress its activity or distort its aims as being pathogenic factors in the psychoneuroses as well.
[1908d, 1951]

My investigations into the aetiology and psychical mechanism of neurotic illnesses, which I have pursued since 1893, attracted little notice to begin with among my fellow specialists. At length, however, those investigations have met with recognition from a number of medical research workers and have also drawn attention to the psycho-analytic methods of examination and treatment to which I owe my findings. Dr. Wilhelm Stekel, who was one of the first of the colleagues to whom I was able to impart a knowledge of psycho-analysis, and who has himself become familiar with its technique through many years of practice in it, has now undertaken the task of working over one topic in the clinical aspect of these neuroses on the basis of my views and of presenting medical readers with the experiences he has obtained through the psycho-analytic method. If I am glad to take the responsibility for his work in the sense which I have just indicated, I think it is only right to declare explicitly that my direct influence upon the volume on nervous states of anxiety which lies before us has been a very slight one. The observations and all the detailed opinions and interpretations are the author's own. My share has been limited to proposing the use of the term 'anxiety hysteria'.
[1908f, 1994]
Psycho-analytic research into the neuroses (the various forms of nervous illness with a mental causation) has endeavoured to trace their connection with instinctual life and the restrictions imposed on it by the claims of civilization, with the activities of the normal individual in phantasies and dreams, and with the creations of the popular mind in religion, myths and fairy tales. The psycho-analytic treatment of neurotic patients, based on this method of research, makes far higher demands on doctor and patient than the methods hitherto in common use, which operate through medicaments, diet, hydropathy and suggestion. But it brings the patients so much more relief and permanent strengthening in the face of life's problems, that there is no cause for surprise at the continual advances made by this therapeutic method in spite of violent opposition. [1910b, 1995]

It is true that during the analysis Hans had to be told many things that he could not say himself, that he had to be presented with thoughts which he had so far shown no signs of possessing, and that his attention had to be turned in the direction from which his father was expecting something to come. This detracts from the evidential value of the analysis; but the procedure is the same in every case. For a psycho-analysis is not an impartial scientific investigation, but a therapeutic measure. Its essence is not to prove anything, but merely to alter something. In a psycho-analysis the physician always gives his patient (sometimes to a greater and some times to a less extent) the conscious anticipatory ideas by the help of which he is put in a position to recognize and to grasp the unconscious material. For there are some patients who need more of such assistance and some who need less; but there are none who get through without some of it. Slight disorders may perhaps be brought to an end by the subject's unaided efforts, but never a neurosis - a thing which has set itself up against the ego as an element alien to it. To get the better of such an element another person must be brought in, and in so far as that other person can be of assistance the neurosis will be curable. If it is in the very nature of any neurosis to turn away from the 'other person' - and this seems to be one of the characteristics of the states grouped together under the name of dementia praecox - then for that very reason such a state will be incurable by any efforts of ours. It is true that a child, on account of the small development of his intellectual systems, requires especially energetic assistance. But, after all, the information which the physician gives his patient is itself derived in its turn from analytical experience; and indeed it is sufficiently convincing if, at the cost of this intervention by the physician, we are enabled to discover the structure of the pathogenic material and simultaneously to dissipate it. [1909b, 2089]

You must forgive me if I have not succeeded in giving you a more clearly intelligible account of these basic positions adopted by the method of treatment that is now described as 'psycho-analysis'. The difficulties have not lain only in the novelty of the subject. The nature of the incompatible wishes which, in spite of repression, succeed in making their existence in the unconscious perceptible, and the subjective and constitutional determinants which must be present in anyone before a failure of repression can occur and a substitute or symptom be formed - on all this I shall have more light to throw in some of my later observations. [1910a, 2216]

You must not suppose, Ladies and Gentlemen, that these discussions on sexual life and the psychosexual development of children have led us too far from psycho-analysis and the problem of curing nervous disorders. You can, if you like, regard psycho-analytic treatment as no more than a prolongation of education for the purpose of overcoming the residues of childhood. [1910a, 2233]

I hope you will have formed an impression that, when we know all that we now only suspect and when we have carried out all the improvements in technique to which deeper observation of our patients is bound to lead us, our medical procedure will reach a degree of precision and certainty of success which is not to be found in every specialized field of medicine. [1910d, 2310]
In view of the strenuous efforts being made in the civilized world to-day to reform sexual life, it will not be superfluous to give a reminder that psycho-analytic research is as remote from tendentiousness as any other kind of research. It has no other end in view than to throw light on things by tracing what is manifest back to what is hidden. It is quite satisfied if reforms make use of its findings to replace what is injurious by something more advantageous; but it cannot predict whether other institutions may not result in other, and perhaps graver, sacrifices.

I cannot advise my colleagues too urgently to model themselves during psycho-analytic treatment on the surgeon, who puts aside all his feelings, even his human sympathy, and concentrates his mental forces on the simple aim of performing the operation as skilfully as possible. Under present-day conditions the feeling that is most dangerous to a psycho-analyst is the therapeutic ambition to achieve by this novel and much disputed method something that will produce a convincing effect upon other people. This will not only put him into a state of mind which is unfavourable for his work, but will make him helpless against certain resistances of the patient, whose recovery, as we know, primarily depends on the interplay of forces in him. The justification for requiring this emotional coldness in the analyst is that it creates the most advantageous conditions for both parties: for the doctor a desirable protection for his own emotional life and for the patient the largest amount of help that we can give him to-day. A surgeon of earlier times took as his motto the words: 'Je le pansai, Dieu le guérit.'¹ The analyst should be content with something similar.

Psycho-analysis is a remarkable combination, for it comprises not only a method of research into the neuroses but also a method of treatment based on the aetiology thus discovered. I may begin by saying that psycho-analysis is not a child of speculation, but the outcome of experience; and for that reason, like every new product of science, is unfinished. It is open to anyone to convince himself by his own investigations of the correctness of the theses embodied in it, and to help in the further development of the study.

It has been our purpose on this occasion to show the direction into which the study of the problem of masturbation has been forced by the emergence of the psycho-analytic method of approach. How far we have succeeded in that purpose will appear from our readers' applause, or perhaps still more clearly from their disapproval.

Psycho-analysis had its origin on medical soil, as a therapeutic procedure for the treatment of certain nervous illnesses which were termed 'functional' and which were considered with increasing certainty to be consequences of disturbances in emotional life. It attains its end - of removing the manifestations of these disturbances, the symptoms - by assuming that they are not the only possible and final outcome of particular psychical processes. It therefore uncovers the history of the development of these symptoms in the patient's memory, it revivifies the processes underlying them, and then conducts them, under the doctor's guidance, to a more favourable outlet. Psycho-analysis has set itself the same therapeutic aims as treatment by hypnotism, which was introduced by Liébeault and Bernheim and after lengthy and severe struggles achieved a place in the technique of nerve specialists. But it goes far deeper into the structure of the mechanism of the mind, and seeks to bring about permanent results and viable changes in its subjects.
But we are able to bring forward other motives than these, thanks to the knowledge of concealed mental impulses which we have acquired from the psycho-analytic examination of individual human beings. A woman whose psychosexual needs should find satisfaction in her marriage and her family life is often threatened with the danger of being left unsatisfied, because her marriage relation has come to a premature end and because of the uneventfulness of her emotional life. A mother, as she grows older, saves herself from this by putting herself in her children's place, by identifying herself with them; and this she does by making their emotional experiences her own. Parents are said to stay young with their children, and that is indeed one of the most precious psychological gains that parents derive from their children. Where a marriage is childless, the wife has lost one of the things which might be of most help to her in tolerating the resignation that her own marriage demands from her. A mother's sympathetic identification with her daughter can easily go so far that she herself falls in love with the man her daughter loves; and in glaring instances this may lead to severe forms of neurotic illness as a result of her violent mental struggles against this emotional situation. In any case, it very frequently happens that a mother-in-law is subject to an impulse to fall in love in this way, and this impulse itself or an opposing trend are added to the tumult of conflicting forces in her mind. And very often the unkind, sadistic components of her love are directed on to her son-in-law in order that the forbidden, affectionate ones may be the more severely suppressed.

Anyone approaching the problem of taboo from the angle of psycho-analysis, that is to say, of the investigation of the unconscious portion of the individual mind, will recognize, after a moment's reflection, that these phenomena are far from unfamiliar to him. He has come across people who have created for themselves individual taboo prohibitions of this very kind and who obey them just as strictly as savages obey the communal taboos of their tribe or society. If he were not already accustomed to describing such people as 'obsessional' patients, he would find 'taboo sickness' a most appropriate name for their condition. Having learnt so much, however, about this obsessional sickness from psycho-analytic examination - its clinical aetiology and the essence of its psychical mechanism - he can scarcely refrain from applying the knowledge he has thus acquired to the parallel sociological phenomenon.

Psycho-analysis is a medical procedure which aims at the cure of certain forms of nervous disease (the neuroses) by a psychological technique. In a small volume published in 1910.¹ I described the evolution of psycho-analysis from Josef Breuer's cathartic procedure and its relation to the theories of Charcot and Pierre Janet.

It may safely be said that the psycho-analytic study of dreams has given us our first insight into a 'depth-psychology' whose existence had not hitherto been suspected.¹ Fundamental changes will have to be introduced into normal psychology if it is to be brought into harmony with these new findings.

The comparison between the childhood of individual men and the early history of societies has already proved its fruitfulness in several directions, even though the study has scarcely more than begun. In this connection the psycho-analytic mode of thought acts like a new instrument of research. The application of its hypotheses to social psychology enables us both to raise fresh problems and to see old ones in a fresh light and contribute towards their solution.
It is true that psycho-analysis has taken the individual mind as its subject, but in investigating the individual it could not avoid dealing with the emotional basis of the relation of the individual to society. It has found that the social feelings invariably contain an erotic element - an element which, if it is over-emphasized and then repressed, becomes one of the marks of a particular group of mental disorders. Psycho-analysis has recognized that in general the neuroses are asocial in their nature and that they always aim at driving the individual out of society and at replacing the safe monastic seclusion of earlier days by the isolation of illness. The intense feeling of guilt which dominates so many neuroses has been shown to be a social modification of neurotic anxiety.

[1913j, 2824]

Long before I had any opportunity of hearing about psycho-analysis, I learnt that a Russian art-connoisseur, Ivan Lermolieff,¹ had caused a revolution in the art galleries of Europe by questioning the authorship of many pictures, showing how to distinguish copies from originals with certainty, and constructing hypothetical artists for those works whose former supposed authorship had been discredited. He achieved this by insisting that attention should be diverted from the general impression and main features of a picture, and by laying stress on the significance of minor details, of things like the drawing of the fingernails, of the lobe of an ear, of halos and such unconsidered trifles which the copyist neglects to imitate and yet which every artist executes in his own characteristic way. I was then greatly interested to learn that the Russian pseudonym concealed the identity of an Italian physician called Morelli, who died in 1891 with the rank of Senator of the Kingdom of Italy. It seems to me that his method of inquiry is closely related to the technique of psycho-analysis. It, too, is accustomed to divine secret and concealed things from despised or unnoticed features, from the rubbish-heap, as it were, of our observations.

[1914b, 2854]

As a psycho-analyst I am bound to be concerned more with emotional than intellectual processes, with unconscious than with conscious mental life. My emotion at meeting my old schoolmaster warns me to make a first admission: it is hard to decide whether what affected us more and was of greater importance to us was our concern with the sciences that we were taught or with the personalities of our teachers. It is true, at least, that this second concern was a perpetual undercurrent in all of us, and that in many of us the path to the sciences led only through our teachers. Some of us stopped half-way along that path, and for a few - why not admit as much? - it was on that account blocked for good and all.

[1914f, 2872]

No one need be surprised at the subjective character of the contribution I propose to make here to the history of the psycho-analytic movement, nor need anyone wonder at the part I play in it. For psycho-analysis is my creation; for ten years I was the only person who concerned himself with it, and all the dissatisfaction which the new phenomenon aroused in my contemporaries has been poured out in the form of criticisms on my head. Although it is a long time now since I was the only psycho-analyst, I consider myself justified in maintaining that even to-day no one can know better than I do what psycho-analysis is, how it differs from other ways of investigating the life of the mind, and precisely what should be called psycho-analysis and what would better be described by some other name. In thus repudiating what seems to me a cool act of usurpation, I am indirectly informing the readers of this Jahrbuch the events that have led to the changes in its editorship and format.

[1914d, 2877]

Since by 'depth-psychology' he means nothing else but psycho-analysis, we may for the present be content with this acknowledgement.

[1914d, 2906]
It is no easy or enviable task to write the history of these two secessions, partly because I am without any strong personal motive for doing so - I had not expected gratitude nor am I revengeful to any effective degree - and partly because I know that by doing so I shall lay myself open to the invectives of my not too scrupulous opponents and offer the enemies of analysis the spectacle they so heartily desire - of 'the psycho-analysts tearing one another limb from limb'. After exercising so much self-restraint in not coming to blows with opponents outside of analysis, I now see myself compelled to take up arms against its former followers or people who still like to call themselves its followers. I have no choice in the matter, however; only indolence or cowardice could lead one to keep silence, and silence would cause more harm than a frank revelation of the harms that already exist. Anyone who has followed the growth of other scientific movements will know that the same upheavals and dissensions commonly occur in them as well. It may be that elsewhere they are more carefully concealed; but psycho-analysis, which repudiates so many conventional ideals, is more honest in these matters too.

[1914d, 2912]

The first task confronting psycho-analysis was to explain the neuroses; it used the two facts of resistance and transference as starting-points, and, taking into consideration the third fact of amnesia, accounted for them with its theories of repression, of the sexual motive forces in neurosis and of the unconscious. Psycho-analysis has never claimed to provide a complete theory of human mentality in general, but only expected that what it offered should be applied to supplement and correct the knowledge acquired by other means. Adler's theory, however, goes far beyond this point; it seeks at one stroke to explain the behaviour and character of human beings as well as their neurotic and psychotic illnesses. It is actually more suited to any other field than that of neurosis, although for reasons connected with the history of its development it still places this in the foreground. For many years I had opportunities of studying Dr. Adler and have never refused to recognize his unusual ability, combined with a particularly speculative disposition. As an instance of the 'persecution' to which he asserts he has been subjected by me, I can point to the fact that after the Association was founded I made over to him the leadership of the Vienna group. It was not until urgent demands were put forward by all the members of the society that I let myself be persuaded to take the chair again at its scientific meetings. When I perceived how little gift Adler had precisely for judging unconscious material, my view changed to an expectation that he would succeed in discovering the connections of psycho-analysis with psychology and with the biological foundations of instinctual processes - an expectation which was in some sense justified by the valuable work he had done on 'organ-inferiority'. And he did in fact effect something of the kind; but his work conveys an impression 'as if' - to speak in his own 'jargon' - it was intended to prove that psycho-analysis was wrong in everything and that it had only attributed so much importance to sexual motive forces because of its credulity in accepting the assertions of neurotics. I may even speak publicly of the personal motive for his work, since he himself announced it in the presence of a small circle of members of the Vienna group: - 'Do you think it gives me such great pleasure to stand in your shadow my whole life long?' To be sure, I see nothing reprehensible in a younger man freely admitting his ambition, which one would in any case guess was among the incentives for his work. But even though a man is dominated by a motive of this kind he should know how to avoid being what the English, with their fine social tact, call 'unfair' - which in German can only be expressed by a much cruder word. How little Adler has succeeded in this is shown by the profusion of petty outbursts of malice which disfigure his writings and by the indications they contain of an uncontrolled craving for priority. At the Vienna Psycho-Analytical Society we once actually heard him claim priority for the conception of the 'unity of the neuroses' and for the 'dynamic view' of them. This came as a great surprise to me, for I had always believed that these two principles were stated by me before I ever made Adler's acquaintance.

[1914d, 2913]
Men are strong so long as they represent a strong idea; they become powerless when they oppose it. Psycho-analysis will survive this loss and gain new adherents in place of these. In conclusion, I can only express a wish that fortune may grant an agreeable upward journey to all those who have found their stay in the underworld of psycho-analysis too uncomfortable for their taste. The rest of us, I hope, will be permitted without hindrance to carry through to their conclusion our labours in the depths.
[1914d, 2928]

Since a study of instinctual life from the direction of consciousness presents almost insuperable difficulties, the principal source of our knowledge remains the psycho-analytic investigation of mental disturbances. Psycho-analysis, however, in consequence of the course taken by its development, has hitherto been able to give us information of a fairly satisfactory nature only about the sexual instincts; for it is precisely that group which alone can be observed in isolation, as it were, in the psychoneuroses. With the extension of psycho-analysis to the other neurotic affections, we shall no doubt find a basis for our knowledge of the ego-instincts as well, though it would be rash to expect equally favourable conditions for observation in this further field of research.
[1915c, 2963]

By accepting the existence of these two (or three) psychical systems, psycho-analysis has departed a step further from the descriptive 'psychology of consciousness' and has raised new problems and acquired a new content. Up till now, it has differed from that psychology mainly by reason of its dynamic view of mental processes; now in addition it seems to take account of psychical topography as well, and to indicate in respect of any given mental act within what system or between what systems it takes place. On account of this attempt, too, it has been given the name of 'depth-psychology'. We shall hear that it can be further enriched by taking yet another point of view into account.
[1915e, 2997]

The most remarkable characteristic of melancholia, and the one in most need of explanation, is its tendency to change round into mania - a state which is the opposite of it in its symptoms. As we know, this does not happen to every melancholia. Some cases run their course in periodic relapses, during the intervals between which signs of mania may be entirely absent or only very slight. Others show the regular alternation of melancholic and manic phases which has led to the hypothesis of a circular insanity. One would be tempted to regard these cases as non-psychogenic, if it were not for the fact that the psycho-analytic method has succeeded in arriving at a solution and effecting a therapeutic improvement in several cases precisely of this kind. It is not merely permissible, therefore, but incumbent upon us to extend an analytic explanation of melancholia to mania as well.
[1917e, 3050]
Let us now leave primaeval man, and turn to the unconscious in our own mental life. Here we depend entirely upon the psycho-analytic method of investigation, the only one which reaches to such depths. What, we ask, is the attitude of our unconscious towards the problem of death? The answer must be: almost exactly the same as that of primaeval man. In this respect, as in many others, the man of prehistoric times survives unchanged in our unconscious. Our unconscious, then, does not believe in its own death; it behaves as if it were immortal. What we call our 'unconscious' - the deepest strata of our minds, made up of instinctual impulses - knows nothing that is negative, and no negation; in it contradictories coincide. For that reason it does not know its own death, for to that we can give only a negative content. Thus there is nothing instinctual in us which responds to a belief in death. This may even be the secret of heroism. The rational grounds for heroism rest on a judgement that the subject's own life cannot be so precious as certain abstract and general goods. But more frequent, in my view, is the instinctive and impulsive heroism which knows no such reasons, and flouts danger in the spirit of Anzengruber's *Steinklopferhans*: 'Nothing can happen to me'. Or else those reasons only serve to clear away the hesitations which might hold back the heroic reaction that corresponds to the unconscious. The fear of death, which dominates us oftener than we know, is on the other hand something secondary, and is usually the outcome of a sense of guilt.

Psycho-analytic work is continually confronted with the task of inducing the patient to renounce an immediate and directly attainable yield of pleasure. He is not asked to renounce all pleasure; that could not, perhaps, be expected of any human being, and even religion is obliged to support its demand that earthly pleasure shall be set aside by promising that it will provide instead an incomparably greater amount of superior pleasure in another world. No, the patient is only asked to renounce such satisfactions as will inevitably have detrimental consequences. His privation is only to be temporary; he has only to learn to exchange an immediate yield of pleasure for a better assured, even though a postponed one. Or, in other words, under the doctor's guidance he is asked to make the advance from the pleasure principle to the reality principle by which the mature human being is distinguished from the child. In this educative process, the doctor's clearer insight can hardly be said to play a decisive part; as a rule, he can only tell his patient what the latter's own reason can tell him. But it is not the same to know a thing in one's own mind and to hear it from someone outside. The doctor plays the part of this effective outsider; he makes use of the influence which one human being exercises over another. Or - recalling that it is the habit of psycho-analysis to replace what is derivative and etiolated by what is original and basic - let us say that the doctor, in his educative work, makes use of one of the components of love. In this work of after-education, he is probably doing no more than repeat the process which made education of any kind possible in the first instance. Side by side with the exigencies of life, love is the great educator; and it is by the love of those nearest him that the incomplete human being is induced to respect the decrees of necessity and to spare himself the punishment that follows any infringement of them.

[1915b, 3088]

[1916d, 3100]
I can, however, assume this much - that you know that psycho-analysis is a procedure for the medical treatment of neurotic patients. And here I can at once give you an instance of how in this field a number of things take place in a different way - often, indeed, in an opposite way - from what they do elsewhere in medical practice. When elsewhere we introduce a patient to a medical technique which is new to him, we usually minimize its inconveniences and give him confident assurances of the success of the treatment. I think we are justified in this, since by doing so we are increasing the probability of success. But when we take a neurotic patient into psycho-analytic treatment, we act differently. We point out the difficulties of the method to him, its long duration, the efforts and sacrifices it calls for; and as regards its success, we tell him we cannot promise it with certainty, that it depends on his own conduct, his understanding, his adaptability and his perseverance. We have good reasons, of course, for such apparently wrong-headed behaviour, as you will perhaps come to appreciate later on.

[1916-1917, 3129]

Incidentally, I have said nothing at all to you yet as to the circumstances in which we can obtain our deepest insight into the hypothetical ‘primal language’ and as to the field in which most of it has survived. Until you know this you cannot form an opinion of its whole significance. For this field is that of the neuroses and its material is the symptoms and other manifestations of neurotic patients, for the explanation and treatment of which psycho-analysis was, indeed, created.

[1916-1917, 3261]

I notice now, Gentlemen, that I have been talking to you about a number of things which you are not yet prepared to understand. I did so in order to carry out the comparison between psychiatry and psycho-analysis. But there is one thing that I can ask you now. Have you observed any sign of a contradiction between them? Psychiatry does not employ the technical methods of psycho-analysis; it omits to make any inferences from the content of the delusion, and, in pointing to heredity, it gives us a very general and remote aetiology instead of indicating first the more special and proximate causes. But is there a contradiction, an opposition in this? Is it not rather a case of one supplementing the other? Does the hereditary factor contradict the importance of experience? Do not the two things rather combine in the most effective manner? You will grant that there is nothing in the nature of psychiatric work which could be opposed to psycho-analytic research. What is opposed to psycho-analysis is not psychiatry but psychiatrists. Psycho-analysis is related to psychiatry approximately as histology is to anatomy: the one studies the external forms of the organs, the other studies their construction out of tissues and cells. It is not easy to imagine a contradiction between these two species of study, of which one is a continuation of the other. To-day, as you know, anatomy is regarded by us as the foundation of scientific medicine. But there was a time when it was as much forbidden to dissect the human cadaver in order to discover the internal structure of the body as it now seems to be to practise psycho-analysis in order to learn about the internal mechanism of the mind. It is to be expected that in the not too distant future it will be realized that a scientifically based psychiatry is not possible without a sound knowledge of the deeper-lying unconscious processes in mental life.

[1916-1917, 3336]
Perhaps, however, the much-abused psycho-analysis has friends among you who will be pleased if it can be justified from another direction - from the therapeutic side. As you know, our psychiatric therapy is not hitherto able to influence delusions. Is it possible, perhaps, that psycho-analysis can do so, thanks to its insight into the mechanism of these symptoms? No, Gentlemen, it cannot. It is as powerless (for the time being at least) against these ailments as any other form of therapy. We can understand, indeed, what has happened in the patient, but we have no means of making the patient himself understand it. You have heard how I was unable to pursue the analysis of this delusion beyond a first beginning. Will you be inclined to maintain on that account that an analysis of such cases is to be rejected because it is fruitless? I think not. We have a right, or rather a duty, to carry on our research without consideration of any immediate beneficial effect. In the end - we cannot tell where or when - every little fragment of knowledge will be transformed into power, and into therapeutic power as well. Even if psycho-analysis showed itself as unsuccessful in every other form of nervous and psychical disease as it does in delusions, it would still remain completely justified as an irreplaceable instrument of scientific research. It is true that in that case we should not be in a position to practise it. The human material on which we seek to learn, which lives, has its own will and needs its motives for co-operating in our work, would hold back from us. Let me therefore end my remarks to-day by informing you that there are extensive groups of nervous disorders in which the transformation of our better understanding into therapeutic power has actually taken place, and that in these illnesses, which are difficult of access by other means, we achieve, under favourable conditions, successes which are second to no others in the field of internal medicine.

[1916-1917, 3337]

One reason is probably that the title 'Introduction to Psycho-Analysis' is no longer applicable to the present section, which is supposed to deal with the neuroses. An introduction to psycho-analysis is provided by the study of parapraxes and dreams; the theory of the neuroses is psycho-analysis itself. It would not, I believe, have been possible to give you a knowledge of the subject-matter of the theory of the neuroses in so short a time except in this concentrated form. It was a question of presenting you with a connected account of the sense and significance of symptoms and of the external and internal determinants and mechanism of their formation. That is what I have tried to do; it is more or less the nucleus of what psycho-analysis has to teach to-day. It involved saying a great deal about the libido and its development and a little, too, about that of the ego. Our introduction had already prepared you in advance for the premisses of our technique and for the major considerations of the unconscious and of repression (of resistance). You will discover from one of the next lectures the points from which the work of psycho-analysis makes its further organic advance. For the time being I have made no secret of the fact that everything I have said is derived from the study of a single group of nervous disorders what are termed the 'transference neuroses'. Indeed, I have traced the mechanism of symptom-formation in the case only of the hysterical neurosis. Even if you have acquired no thorough knowledge and have not retained every detail, yet I hope that you have formed some picture of the methods by which psycho-analysis works, of the problems which it attacks and of the results at which it has arrived.

[1916-1917, 3432]

What characterizes psycho-analysis as a science is not the material which it handles but the technique with which it works. It can be applied to the history of civilization, to the science of religion and to mythology, no less than to the theory of the neuroses, without doing violence to its essential nature. What it aims at and achieves is nothing other than the uncovering of what is unconscious in mental life. The problems of the 'actual' neuroses, whose symptoms are probably generated by direct toxic damage, offer psycho-analysis no points of attack. It can do little towards throwing light on them and must leave the task to biologico-medical research.

[1916-1917, 3440]
My present readers, I take it, have not so far had anything to do with the subject and I shall be obliged, therefore, to go back some distance. Out of a great number of individual observations and impressions something in the nature of a theory has at last shaped itself in psycho-analysis, and this is known by the name of the 'libido theory'. As is well known, psycho-analysis is concerned with the elucidation and removal of what are called nervous disorders. A starting-point had to be found from which to approach this problem, and it was decided to look for it in the instinctual life of the mind. Hypotheses about the instincts in man came to form the basis, therefore, of our conception of nervous disease.

[1917a, 3608]

With this as a starting-point we go on to make our first important discovery. We learn that, when we try to understand neurotic disorders, by far the greater significance attaches to the sexual instincts; that in fact neuroses are the specific disorders, so to speak, of the sexual function; that in general whether or not a person develops a neurosis depends on the quantity of his libido, and on the possibility of satisfying it and of discharging it through satisfaction; that the form taken by the disease is determined by the way in which the individual passes through the course of development of his sexual function, or, as we put it, by the fixations his libido has undergone in the course of its development; and, further, that by a special, not very simple technique for influencing the mind we are able to throw light on the nature of some groups of neuroses and at the same time to do away with them. Our therapeutic efforts have their greatest success with a certain class of neuroses which proceed from a conflict between the ego-instincts and the sexual instincts. For in human beings it may happen that the demands of the sexual instincts, whose reach of course extends far beyond the individual, seem to the ego to constitute a danger which threatens its self-preservation or its self-esteem. The ego then assumes the defensive, denies the sexual instincts the satisfaction they desire and forces them into those by-paths of substitutive satisfaction which become manifest as nervous symptoms.

[1917a, 3609]

The work by which we bring the repressed mental material into the patient's consciousness has been called by us psycho-analysis. Why 'analysis' - which means breaking up or separating out, and suggests an analogy with the work carried out by chemists on substances which they find in nature and bring into their laboratories? Because in an important respect there really is an analogy between the two. The patient's symptoms and pathological manifestations, like all his mental activities, are of a highly composite kind; the elements of this compound are at bottom motives, instinctual impulses. But the patient knows nothing of these elementary motives or not nearly enough. We teach him to understand the way in which these highly complicated mental formations are compounded; we trace the symptoms back to the instinctual impulses which motivate them; we point out to the patient these instinctual motives, which are present in his symptoms and of which he has hitherto been unaware, - just as a chemist isolates the fundamental substance, the chemical 'element', out of the salt in which it had been combined with other elements and in which it was unrecognizable. In the same way, as regards those of the patient's mental manifestations that were not considered pathological, we show him that he was only to a certain extent conscious of their motivation - that other instinctual impulses of which he had remained in ignorance had co-operated in producing them.

[1919a, 3629]

In America, according to the best of my information, it has already been recognized that psycho-analysis (the first attempt at a depth-psychology) has made successful inroads into this unexplored region of psychiatry. Many medical schools in that country, accordingly, have already organized courses of psycho-analysis as an introduction to psychiatry.

[1919j, 3639]
The uncanny effect of epilepsy and of madness has the same origin. The layman sees in them the working of forces hitherto unsuspected in his fellow-men, but at the same time he is dimly aware of them in remote corners of his own being. The Middle Ages quite consistently ascribed all such maladies to the influence of demons, and in this their psychology was almost correct. Indeed, I should not be surprised to hear that psycho-analysis, which is concerned with laying bare these hidden forces, has itself become uncanny to many people for that very reason. In one case, after I had succeeded - though none too rapidly - in effecting a cure in a girl who had been an invalid for many years, I myself heard this view expressed by the patient's mother long after her recovery.

Psycho-analysis was born out of medical necessity. It sprang from the need for bringing help to neurotic patients, who had found no relief through rest-cures, through the arts of hydropathy or through electricity. A most remarkable observation made by Josef Breuer had excited a hope that the more one understood of the hitherto unexplored origin of their symptoms the more extensive would be the help one could afford them. Thus it came about that psycho-analysis, being originally a purely medical technique, was from the first directed towards research, towards the discovery of causal chains at once far-reaching and recondite.

What strikes us in this is the unexpected analogy with our own view, which was arrived at along such a different path. Weismann, regarding living substance morphologically, sees in it one portion which is destined to die - the soma, the body apart from the substance concerned with sex and inheritance - and an immortal portion - the germ-plasm, which is concerned with the survival of the species, with reproduction. We, on the other hand, dealing not with the living substance but with the forces operating in it, have been led to distinguish two kinds of instincts: those which seek to lead what is living to death, and others, the sexual instincts, which are perpetually attempting and achieving a renewal of life. This sounds like a dynamic corollary to Weismann's morphological theory.

Although group psychology is only in its infancy, it embraces an immense number of separate issues and offers to investigators countless problems which have hitherto not even been properly distinguished from one another. The mere classification of the different forms of group formation and the description of the mental phenomena produced by them require a great expenditure of observation and exposition, and have already given rise to a copious literature. Anyone who compares the narrow dimensions of this little book with the wide extent of group psychology will at once be able to guess that only a few points chosen from the whole material are to be dealt with here. And they will in fact only be a few questions with which the depth-psychology of psycho-analysis is specially concerned.

We shall take the liberty of interrupting Le Bon's exposition with glosses of our own, and shall accordingly insert an observation at this point. If the individuals in the group are combined into a unity, there must surely be something to unite them, and this bond might be precisely the thing that is characteristic of a group. But Le Bon does not answer this question; he goes on to consider the alteration which the individual undergoes when in a group and describes it in terms which harmonize well with the fundamental postulates of our own depth-psychology.
This first configuration of the child's love, which in typical cases takes the shape of the Oedipus complex, succumbs, as we know, from the beginning of the period of latency onwards to a wave of repression. Such of it as is left over shows itself as a purely affectionate emotional tie, relating to the same people, but no longer to be described as 'sexual'. Psycho-analysis, which illuminates the depths of mental life, has no difficulty in showing that the sexual ties of the earliest years of childhood also persist, though repressed and unconscious. It gives us courage to assert that wherever we come across an affectionate feeling it is successor to a completely 'sensual' object-tie with the person in question or rather with that person's prototype (or *imago*). It cannot indeed disclose to us without a special investigation whether in a given case this former complete sexual current still exists under repression or whether it has already been exhausted. To speak still more precisely: it is quite certain that this current is still there as a form and possibility, and can always be cathected and put into activity again by means of regression; the only question is (and it cannot always be answered) what degree of cathexis and operative force it still has at the present moment. Equal care must be taken in this connection to avoid two sources of error - the Scylla of underestimating the importance of the repressed unconscious, and the Charybdis of judging the normal entirely by the standards of the pathological.

In view of this difference between their mental attitudes co-operation between analysts and occultists offers small prospect of gain. The analyst has his own province of work, which he must not abandon: the unconscious element of mental life. If in the course of his work he were to be on the watch for occult phenomena, he would be in danger of overlooking everything that more nearly concerned him. He would be surrendering the impartiality, the lack of prejudices and prepossessions, which have formed an essential part of his analytic armour and equipment. If occult phenomena force themselves on him in the same way in which others do, he will evade them no more than he evades the others. This would appear to be the only plan of behaviour consistent with the activity of an analyst.

It is a vain hope to suppose that analytic work, precisely because it relates to the mysterious unconscious, will be able to escape such a collapse in values as this. If spiritual beings who are the intimate friends of human enquirers can supply ultimate explanations of everything, no interest can be left over for the laborious approaches to unknown mental forces made by analytic research. So, too, the methods of analytic technique will be abandoned if there is a hope of getting into direct touch with the operative spirits by means of occult procedures, just as habits of patient humdrum work are abandoned if there is a hope of growing rich at a single blow by means of a successful speculation. We have heard during the war of people who stood half-way between two hostile nations, belonging to one by birth and to the other by choice and domicile; it was their fate to be treated as enemies first by one side and then, if they were lucky enough to escape, by the other. Such might equally be the fate of psycho-analysis. However, one must put up with one's fate whatever it may be; and psycho-analysis will somehow or other come to terms with hers.

Psycho-analysis is the name (1) of a procedure for the investigation of mental processes which are almost inaccessible in any other way, (2) of a method (based upon that investigation) for the treatment of neurotic disorders and (3) of a collection of psychological information obtained along those lines, which is gradually being accumulated into a new scientific discipline.
Psycho-Analysis as a Therapeutic Procedure. - Psycho-analysis has never set itself up as a panacea and has never claimed to perform miracles. In one of the most difficult spheres of medical activity it is the only possible method of treatment for certain illnesses and for others it is the method which yields the best or the most permanent results - though never without a corresponding expenditure of time and trouble. A physician who is not wholly absorbed in the work of giving help will find his labours amply repaid by obtaining an unhoped-for insight into the complications of mental life and the interrelations between the mental and the physical. Where at present it cannot offer help but only theoretical understanding, it may perhaps be preparing the way for some later, more direct means of influencing neurotic disorders. Its province is above all the two transference neuroses, hysteria and obsessional neurosis, in which it has contributed to the discovery of their internal structure and operative mechanisms; and, beyond them, all kinds of phobias, inhibitions, deformities of character, sexual perversions and difficulties in erotic life. Some analysts (Jelliffe, Groddeck, Felix Deutsch) have reported too that the analytic treatment of gross organic diseases is not unpromising, since a mental factor not infrequently contributes to the origin and continuance of such illnesses. Since psycho-analysis demands a certain amount of psychical plasticity from its patients, some kind of age-limit must be laid down in their selection; and since it necessitates the devotion of long and intense attention to the individual patient, it would be uneconomical to squander such expenditure upon completely worthless persons who happen to be neurotic. Experience upon material in clinics can alone show what modifications may be necessary in order to make psycho-analytic treatment accessible to wider strata of the population or to adapt it to weaker intelligences.
[1923a, 3926]

Its Relation to Psychiatry. - Psychiatry is at present essentially a descriptive and classificatory science whose orientation is still towards the somatic rather than the psychological and which is without the possibility of giving explanations of the phenomena which it observes. Psycho-analysis does not, however, stand in opposition to it, as the almost unanimous behaviour of the psychiatrists might lead one to believe. On the contrary, as a depth-psychology, a psychology of those processes in mental life which are withdrawn from consciousness, it is called upon to provide psychiatry with an indispensable groundwork and to free it from its present limitations. We can foresee that the future will give birth to a scientific psychiatry, to which psycho-analysis has served as an introduction.
[1923a, 3927]
Criticisms and Misunderstandings of Psycho-Analysis. - Most of what is brought up against psycho-analysis, even in scientific works, is based upon insufficient information which in its turn seems to be determined by emotional resistances. Thus it is a mistake to accuse psycho-analysis of 'pan-sexualism' and to allege that it derives all mental occurrences from sexuality and traces them all back to it. On the contrary, psycho-analysis has from the very first distinguished the sexual instincts from others which it has provisionally termed 'ego instincts'. It has never dreamt of trying to explain 'everything', and even the neuroses it has traced back not to sexuality alone but to the conflict between the sexual impulses and the ego. In psycho-analysis (unlike the works of C. G. Jung) the term 'libido' does not mean psychical energy in general but the motive force of the sexual instincts. Some assertions, such as that every dream is the fulfilment of a sexual wish, have never been maintained by it at all. The charge of one-sidedness made against psycho-analysis, which, as the science of the unconscious mind, has its own definite and restricted field of work, is as inapplicable as it would be if it were made against chemistry. To believe that psycho-analysis seeks a cure for neurotic disorders by giving a free rein to sexuality is a serious misunderstanding which can only be excused by ignorance. The making conscious of repressed sexual desires in analysis makes it possible, on the contrary, to obtain a mastery over them which the previous repression had been unable to achieve. It can more truly be said that analysis sets the neurotic free from the chains of his sexuality. Moreover, it is quite unscientific to judge analysis by whether it is calculated to undermine religion, authority and morals; for, like all sciences, it is entirely non-tendentious and has only a single aim - namely to arrive at a consistent view of one portion of reality. Finally, one can only characterize as simple-minded the fear which is sometimes expressed that all the highest goods of humanity, as they are called - research, art, love, ethical and social sense - will lose their value or their dignity because psycho-analysis is in a position to demonstrate their origin in elementary and animal instinctual impulses.

The Non-Medical Applications and Correlations of Psycho-analysis. - Any estimate of psycho-analysis would be incomplete if it failed to make clear that, alone among the medical disciplines, it has the most extensive relations with the mental sciences, and that it is in a position to play a part of the same importance in the studies of religious and cultural history and in the sciences of mythology and literature as it is in psychiatry. This may seem strange when we reflect that originally its only object was the understanding and improvement of neurotic symptoms. But it is easy to indicate the starting-point of the bridge that leads over to the mental sciences. The analysis of dreams gave us an insight into the unconscious processes of the mind and showed us that the mechanisms which produce pathological symptoms are also operative in the normal mind. Thus psychoanalysis became a depth-psychology and capable as such of being applied to the mental sciences, and it was able to answer a good number of questions with which the academic psychology of consciousness was helpless to deal. At quite an early stage problems of human phylogenesis arose. It became clear that pathological function was often nothing more than a regression to an earlier stage in the development of normal function. C. G. Jung was the first to draw explicit attention to the striking similarity between the disordered phantasies of sufferers from dementia praecox and the myths of primitive peoples; while the present writer pointed out that the two wishes which combine to form the Oedipus complex coincide precisely with the two principal prohibitions imposed by totemism (not to kill the tribal ancestor and not to marry any woman belonging to one's own clan) and drew far-reaching conclusions from this fact. The significance of the Oedipus complex began to grow to gigantic proportions and it looked as though social order, morals, justice and religion had arisen together in the primaeval ages of mankind as reaction-formations against the Oedipus complex. Otto Rank threw a brilliant light upon mythology and the history of literature by the application of psycho-analytic views, as did Theodor Reik upon the history of morals and religions, while Dr. Pfister, of Zurich, aroused the interest of religious and secular teachers and demonstrated the importance of the psycho-analytic standpoint for education. Further discussion of these applications of psycho-analysis would be out of place here, and it is enough to say that the limits of their influence are not yet in sight.

[1923a, 3928]
Psycho-analysis has been reproached time after time with ignoring the higher, moral, supra-personal side of human nature. The reproach is doubly unjust, both historically and methodologically. For, in the first place, we have from the very beginning attributed the function of instigating repression to the moral and aesthetic trends in the ego, and secondly, there has been a general refusal to recognize that psycho-analytic research could not, like a philosophical system, produce a complete and ready-made theoretical structure, but had to find its way step by step along the path towards understanding the intricacies of the mind by making an analytic dissection of both normal and abnormal phenomena. So long as we had to concern ourselves with the study of what is repressed in mental life, there was no need for us to share in any agitated apprehensions as to the whereabouts of the higher side of man. But now that we have embarked upon the analysis of the ego we can give an answer to all those whose moral sense has been shocked and who have complained that there must surely be a higher nature in man: 'Very true,' we can say, 'and here we have that higher nature, in this ego ideal or super-ego, the representative of our relation to our parents. When we were little children we knew these higher natures, we admired them and feared them; and later we took them into ourselves.'

[1923b, 3969]

There are two paths by which the contents of the id can penetrate into the ego. The one is direct, the other leads by way of the ego ideal; which of these two paths they take may, for some mental activities, be of decisive importance. The ego develops from perceiving instincts to controlling them, from obeying instincts to inhibiting them. In this achievement a large share is taken by the ego ideal, which indeed is partly a reaction-formation against the instinctual processes of the id. Psycho-analysis is an instrument to enable the ego to achieve a progressive conquest of the id.

[1923b, 3989]

It does indeed sound strange that the Devil should be chosen as a substitute for a loved father. But this is only so at first sight, for we know a good many things which lessen our surprise. To begin with, we know that God is a father-substitute; or, more correctly, that he is an exalted father; or, yet again, that he is a copy of a father as he is seen and experienced in childhood - by individuals in their own childhood and by mankind in its prehistory as the father of the primitive and primal horde. Later on in life the individual sees his father as something different and lesser. But the ideational image belonging to his childhood is preserved and becomes merged with the inherited memory-traces of the primal father to form the individual's idea of God. We also know, from the secret life of the individual which analysis uncovers, that his relation to his father was perhaps ambivalent from the outset, or, at any rate, soon became so. That is to say, it contained two sets of emotional impulses that were opposed to each other: it contained not only impulses of an affectionate and submissive nature, but also hostile and defiant ones. It is our view that the same ambivalence governs the relations of mankind to its Deity. The unresolved conflict between, on the one hand, a longing for the father and, on the other, a fear of him and a son's defiance of him, has furnished us with an explanation of important characteristics of religion and decisive vicissitudes in it.

[1923d, 4009]
Now a dream is not a morbid symptom but a product of the normal mind. The wishes which it represents as fulfilled are the same as those which are repressed in neuroses. Dreams owe the possibility of their genesis merely to the favourable circumstance that during the state of sleep, which paralyses man's power of movement, repression is mitigated into the dream-censorship. If, however, the process of dream-formation oversteps certain limits, the dreamer brings it to a stop and wakes up in a fright. Thus it is proved that the same forces and the same processes taking place between them operate in normal as in pathological mental life. From the date of "The Interpretation of Dreams" psycho-analysis had a twofold significance. It was not only a new method of treating the neuroses but it was also a new psychology; it claimed the attention not only of nerve-specialists but also of all those who were students of a mental science.

The noisy rejection of psycho-analysis by the medical world could not deter its supporters from developing it, to begin with, along its original lines into a specialized pathology and treatment of the neuroses - a task which has not been completely accomplished even to-day. Its undeniable therapeutic success, which far exceeded any that had previously been achieved, constantly spurred them on to fresh efforts; while the difficulties which came to light as the material was examined more deeply led to profound alterations in the technique of analysis and to important corrections in its theoretical hypotheses and postulates.

In this way psychiatry became the first field to which psycho-analysis was applied and it has remained so ever since. The same research workers who have done most to deepen analytic knowledge of the neuroses, such as Karl Abraham in Berlin and Sándor Ferenczi in Budapest (to name only the most prominent), have also played a leading part in throwing analytic light on the psychoses. The conviction of the unity and intimate connection of all the disorders that present themselves as neurotic and psychotic phenomena is becoming more and more firmly established despite all the efforts of the psychiatrists. People are beginning to understand - best of all, perhaps, in America - that the psycho-analytic study of the neuroses is the only preparation for an understanding of the psychoses, and that psycho-analysis is destined to make possible a scientific psychiatry of the future which will not need to content itself with describing curious clinical pictures and unintelligible sequences of events and with tracing the influence of gross anatomical and toxic traumas upon a mental apparatus which is inaccessible to our knowledge.

But the importance of psycho-analysis for psychiatry would never have drawn the attention of the intellectual world to it or won it a place in "The History of our Times". This result was brought about by the relation of psycho-analysis to normal, not to pathological, mental life. Originally, analytic research had indeed no other aim than to establish the determinants of the onset (the genesis) of a few morbid mental states. In the course of its efforts, however, it succeeded in bringing to light facts of fundamental importance, in actually creating a new psychology, so that it became obvious that the validity of such findings could not possibly be restricted to the sphere of pathology. We have seen already when it was that the decisive proof was produced of the correctness of this conclusion. It was when dreams were successfully interpreted by analytic technique - dreams, which are a part of the mental life of normal people and which yet may in fact be regarded as pathological products that can regularly appear under healthy conditions.
If the psychological discoveries gained from the study of dreams were firmly kept in view, only one further step was needed before psycho-analysis could be proclaimed as the theory of the deeper mental processes not directly accessible to consciousness - as a ‘depth-psychology’ - and before it could be applied to almost all the mental sciences. This step lay in the transition from the mental activity of individual men to the psychical functions of human communities and peoples - that is, from individual to group psychology; and many surprising analogies forced this transition upon us. It had been found, for instance, that in the deep strata of unconscious mental activity contraries are not distinguished from each other but are expressed by the same element. But already in 1884 Karl Abel the philologist had put forward the view (in his ‘Über den Gegensinn der Urworte’) that the oldest languages known to us treat contraries in the same way. Thus Ancient Egyptian, for example, had in the first instance only one word for ‘strong’ and ‘weak’, and not till later were the two sides of the antithesis distinguished by slight modifications. Even in the most modern languages clear relics of such antithetical meanings are to be found. So in German ‘Boden’ means the highest as well as the lowest thing in the house; similarly in Latin ‘altus’ means ‘high’ and ‘deep’. Thus the equivalence of contraries in dreams is a universal archaic trait in human thinking.

[1924f, 4115]

If we may assume that the most general features of unconscious mental life (conflicts between instinctual impulses, repressions and substitutive satisfactions) are present everywhere, and if there is a depth-psychology which leads to a knowledge of those features, then we may reasonably expect that the application of psycho-analysis to the most varied spheres of human mental activity will everywhere bring to light important and hitherto unattainable results. In an exceedingly valuable study, Otto Rank and Hanns Sachs (1913) have tried to bring together what the work of psycho-analysts had been able to achieve up to that time towards fulfilling these expectations. Lack of space prevents me from attempting to complete their enumeration here. I can only select for mention the most important findings with the addition of a few details.

[1924f, 4116]

Thus we may express our expectation that psycho-analysis, whose development and achievements hitherto have been briefly and inadequately related in these pages, will enter into the cultural development of the next decades as a significant ferment, and will help to deepen our understanding of the world and to fight against some things in life which are recognized as injurious. It must not be forgotten, however, that psycho-analysis alone cannot offer a complete picture of the world. If we accept the distinction which I have recently proposed of dividing the mental apparatus into an ego, turned towards the external world and equipped with consciousness, and an unconscious id, dominated by its instinctual needs, then psycho-analysis is to be described as a psychology of the id (and of its effects upon the ego). In each field of knowledge, therefore, it can make only contributions, which require to be completed from the psychology of the ego. If these contributions often contain the essence of the facts, this only corresponds to the important part which, it may be claimed, is played in our lives by the mental unconscious that has so long remained unknown.

[1924f, 4118]
A particularly bad reception was accorded to psycho-analysis, which the present writer began to develop nearly thirty years ago from the discoveries of Josef Breuer (of Vienna) on the origin of neurotic symptoms. It cannot be disputed that it possessed the quality of novelty, even though it made use of plenty of material which was well known from other sources (quite apart from Breuer's discoveries), such as the lessons from the teachings of Charcot, the great neuropathologist, and impressions derived from the sphere of hypnotic phenomena. Its original significance was purely therapeutic: it aimed at creating a new and efficient method for treating neurotic illnesses. But connections which could not be foreseen in the beginning caused psycho-analysis to reach out far beyond its original aim. It ended by claiming to have set our whole view of mental life upon a new basis and therefore to be of importance for every field of knowledge that is founded on psychology. After a decade of complete neglect it suddenly became a subject of general interest - and set loose a storm of indignant opposition.

The forms in which the resistance to psycho-analysis found expression need not now be considered. It is enough to say that the struggle over this innovation is by no means at an end, though it is already possible to see what direction it will take. Its opponents have not succeeded in suppressing the movement. Psycho-analysis, of which twenty years ago I was the only spokesman, has since attracted the support of numerous valuable and active workers, medical and non-medical, who make use of it as a procedure for the treatment of nervous diseases, as a method of psychological research and as an auxiliary instrument for scientific work in the most various departments of intellectual life. In the following pages our interest will be directed only to the motives of the resistance to psycho-analysis, with particular stress upon the composite character of that resistance and upon the differing amount of weight carried by its components.

My friend Max Eitingon, who created the Berlin Psycho-Analytical Policlinic and has hitherto supported it out of his own resources, has in the following pages made public his reasons for founding it and has also given an account of the Institute's organization and functions. I can only add to what he has written my wish that individuals or societies may be found elsewhere to follow Eitingon's example and bring similar institutions into existence. If psycho-analysis, alongside of its scientific significance, has a value as a therapeutic procedure, if it is capable of giving help to sufferers in their struggle to fulfil the demands of civilization, this help should be accessible as well to the great multitude who are too poor themselves to repay an analyst for his laborious work. This seems to be a social necessity particularly in our times, when the intellectual strata of the population, which are especially prone to neurosis, are sinking irresistibly into poverty. Institutes such as the Berlin Policlinic are also alone in a position to overcome the difficulties which otherwise stand in the way of thorough instruction in psycho-analysis. They make possible the education of a considerable number of trained analysts, whose activity must be regarded as the sole possible protection against injury to patients by ignorant and unqualified persons, whether they are laymen or doctors.

The theory of repression became the corner-stone of our understanding of the neuroses. A different view had now to be taken of the task of therapy. Its aim was no longer to 'abreact' an affect which had got on to the wrong lines but to uncover repressions and replace them by acts of judgement which might result either in the accepting or in the condemning of what had formerly been repudiated. I showed my recognition of the new situation by no longer calling my method of investigation and treatment catharsis but psycho-analysis.
In the same way that psycho-analysis makes use of dream-interpretation, it also profits by the study of the numerous little slips and mistakes which people make - symptomatic actions, as they are called. I investigated this subject in a series of papers which were published for the first time in book form in 1904 under the title of *The Psychopathology of Everyday Life*. In this widely circulated work I have pointed out that these phenomena are not accidental, that they require more than physiological explanations, that they have a meaning and can be interpreted, and that one is justified in inferring from them the presence of restrained or repressed impulses and intentions. But what constitutes the enormous importance of dream-interpretation, as well as of this latter study, is not the assistance they give to the work of analysis but another of their attributes. Previously psycho-analysis had only been concerned with solving pathological phenomena and in order to explain them it had often been driven into making assumptions whose comprehensiveness was out of all proportion to the importance of the actual material under consideration. But when it came to dreams, it was no longer dealing with a pathological symptom, but with a phenomenon of normal mental life which might occur in any healthy person. If dreams turned out to be constructed like symptoms, if their explanation required the same assumptions - the repression of impulses, substitutive formation, compromise-formation, the dividing of the conscious and the unconscious into various psychical systems - then psycho-analysis was no longer an auxiliary science in the field of psychopathology, it was rather the starting-point of a new and deeper science of the mind which would be equally indispensable for the understanding of the normal. Its postulates and findings could be carried over to other regions of mental happening; a path lay open to it that led far afield, into spheres of universal interest.

[1925d, 4222]

By a process of development against which it would have been useless to struggle, the word 'psycho-analysis' has itself become ambiguous. While it was originally the name of a particular therapeutic method, it has now also become the name of a science - the science of unconscious mental processes. By itself this science is seldom able to deal with a problem completely, but it seems destined to give valuable contributory help in the most varied regions of knowledge. The sphere of application of psycho-analysis extends as far as that of psychology, to which it forms a complement of the greatest moment.

[1925d, 4243]
Shortly before I wrote this study it seemed as though my life would soon be brought to an end by the recurrence of a malignant disease; but surgical skill saved me in 1923 and I was able to continue my life and my work, though no longer in freedom from pain. In the period of more than ten years that has passed since then, I have never ceased my analytic work nor my writing - as is proved by the completion of the twelfth volume of the German edition of my collected works. But I myself find that a significant change has come about. Threads which in the course of my development had become intertangled have now begun to separate; interests which I had acquired in the later part of my life have receded, while the older and original ones become prominent once more. It is true that in this last decade I have carried out some important pieces of analytic work, such as the revision of the problem of anxiety in my book Inhibitions, Symptoms and Anxiety (1926d) or the simple explanation of sexual ‘fetishism’ which I was able to make a year later (1927e). Nevertheless it would be true to say that, since I put forward my hypothesis of the existence of two classes of instinct (Eros and the death instinct) and since I proposed a division of the mental personality into an ego, a super-ego, and an id (1923b), I have made no further decisive contributions to psycho-analysis: what I have written on the subject since then has been either unessential or would soon have been supplied by someone else. This circumstance is connected with an alteration in myself, with what might be described as a phase of regressive development. My interest, after making a lifelong détour through the natural sciences, medicine and psychotherapy, returned to the cultural problems which had fascinated me long before, when I was a youth scarcely old enough for thinking. At the very climax of my psycho-analytic work, in 1912, I had already attempted in Totem and Taboo to make use of the newly discovered findings of analysis in order to investigate the origins of religion and morality. I now carried this work a stage further in two later essays, The Future of an Illusion (1927c) and Civilization and its Discontents (1930a). I perceived ever more clearly that the events of human history, the interactions between human nature, cultural development and the precipitates of primaeval experiences (the most prominent example of which is religion) are no more than a reflection of the dynamic conflicts between the ego, the id and the super-ego, which psycho-analysis studies in the individual - are the very same processes repeated upon a wider stage. In The Future of an Illusion I expressed an essentially negative valuation of religion. Later, I found a formula which did better justice to it: while granting that its power lies in the truth which it contains, I showed that that truth was not a material but a historical truth.

[1925d, 4244]

The question is limited in place because it does not arise in all countries with equal significance. In Germany and America it would be no more than an academic discussion; for in those countries every patient can have himself treated how and by whom he chooses, and anyone who chooses can, as a ‘quack’, handle any patients, provided only that he undertakes the responsibility for his actions. The law does not intervene until it is called in to expiate some injury done to the patient. But in Austria, in which and for which I am writing, there is a preventive law, which forbids non-doctors from undertaking the treatment of patients, without waiting for its outcome.¹ So here the question whether laymen (= non-doctors) may treat patients by psycho-analysis has a practical sense. As soon as it is raised, however, it appears to be settled by the wording of the law. Neurotics are patients, laymen are non-doctors, psycho-analysis is a procedure for curing or improving nervous disorders, and all such treatments are reserved to doctors. It follows that laymen are not permitted to practise analysis on neurotics, and are punishable if they nevertheless do so. The position being so simple, one hardly ventures to take up the question of lay analysis. All the same, there are some complications, which the law does not trouble about, but which nevertheless call for consideration. It may perhaps turn out that in this instance the patients are not like other patients, that the laymen are not really laymen, and that the doctors have not exactly the qualities which one has a right to expect of doctors and on which their claims should be based. If this can be proved, there will be justifiable grounds for demanding that the law shall not be applied without modification to the instance before us.

[1926e, 4327]
All these people recognize that they are ill and go to doctors, by whom people expect nervous
disorders like these to be removed. The doctors, too, lay down the categories into which these
complaints are divided. They diagnose them, each according to his own standpoint, under
different names: neurasthenia, psychasthenia, phobias, obsessional neurosis, hysteria. They
examine the organs which produce the symptoms, the heart, the stomach, the bowels, the
genitals, and find them healthy. They recommend interruptions in the patient's accustomed mode
of life, holidays, strengthening exercises, tonics, and by these means bring about temporary
improvements - or no result at all. Eventually the patients hear that there are people who are
concerned quite specially with the treatment of such complaints and start an analysis with them.
[1926e, 4329]

So you feel that a consideration both of what is lowest and of what is highest has been missing
from our discussions up till now? The reason for that is that we have not yet considered the
contents of mental life at all. But allow me now for once myself to play the part of an interrupter
who holds up the progress of the conversation. I have talked so much psychology to you because
I wanted you to get the impression that the work of analysis is a part of applied psychology - and,
moreover, of a psychology that is unknown outside analysis. An analyst must therefore first and
foremost have learnt this psychology, this depth-psychology or psychology of the unconscious, or
as much of it at least as is known to-day. We shall need this as a basis for our later conclusions.
But now, what was it you meant by your allusion to 'purity'?
[1926e, 4349]

There are at the moment two Institutes at which instruction in psycho-analysis is given. The first
has been founded in Berlin by Dr. Max Eitingon, who is a member of the Society there. The
second is maintained by the Vienna Psycho-Analytical Society at its own expense and at
considerable sacrifice. The part played by the authorities is at present limited to the many
difficulties which they put in the way of the young undertaking. A third training Institute is at this
moment being opened in London by the Society there, under the direction of Dr. Ernest Jones. At
these Institutes the candidates themselves are taken into analysis, receive theoretical instruction
by lectures on all the subjects that are important for them, and enjoy the supervision of older and
more experienced analysts when they are allowed to make their first trials with comparatively
slight cases. A period of some two years is calculated for this training. Even after this period, of
course, the candidate is only a beginner and not yet a master. What is still needed must be
acquired by practice and by an exchange of ideas in the psycho-analytical societies in which
young and old members meet together. Preparation for analytic activity is by no means so easy
and simple. The work is hard, the responsibility great. But anyone who has passed through such
a course of instruction, who has been analysed himself, who has mastered what can be taught to-
day of the psychology of the unconscious, who is at home in the science of sexual life, who has
learnt the delicate technique of psycho-analysis, the art of interpretation, of fighting resistances
and of handling the transference - anyone who has accomplished all this is no longer a layman in
the field of psycho-analysis. He is capable of undertaking the treatment of neurotic disorders, and
will be able in time to achieve in that field whatever can be required from this form of therapy.
[1926e, 4370]
'You have expended a great deal of effort on showing me what psycho-analysis is and what sort of knowledge is needed in order to practise it with some prospect of success. Very well. Listening to you can have done me no harm. But I do not know what influence on my judgement you expect your explanations to have. I see before me a case which has nothing unusual about it. The neuroses are a particular kind of illness and analysis is a particular method of treating them - a specialized branch of medicine. It is the rule in other cases as well for a doctor who has chosen a special branch of medicine not to be satisfied with the education that is confirmed by his diploma: particularly if he intends to set up in a fairly large town, such as can alone offer a livelihood to specialists. Anyone who wants to be a surgeon tries to work for a few years at a surgical clinic, and similarly with oculists, laryngologists and so on - to say nothing of psychiatrists, who are perhaps never able to get away from a state institution or a sanatorium. And the same will happen in the case of psycho-analysts: anyone who decides in favour of this new specialized branch of medicine will, when his studies are completed, take on the two years' training you spoke of in a training institute, if it really requires so much time. He will realize afterwards, too, that it is to his advantage to keep up his contact with his colleagues in a psycho-analytical society, and everything will go along swimmingly. I cannot see where there is a place in this for the question of lay analysis.'

[1926e, 4371]

Psychiatry is right to do so and medical education is clearly excellent. If it is described as one-sided, one must first discover the standpoint from which one is making that characteristic into a reproach. In itself every science is one-sided. It must be so, since it restricts itself to particular subjects, points of view and methods. It is a piece of nonsense in which I would take no part to play off one science against another. After all, physics does not diminish the value of chemistry; it cannot take its place but on the other hand cannot be replaced by it. Psycho-analysis is certainly quite particularly one-sided, as being the science of the mental unconscious. We must not therefore dispute to the medical sciences their right to be one-sided.

[1926e, 4373]

For we do not consider it at all desirable for psycho-analysis to be swallowed up by medicine and to find its last resting-place in a text-book of psychiatry under the heading 'Methods of Treatment', alongside of procedures such as hypnotic suggestion, autosuggestion, and persuasion, which, born from our ignorance, have to thank the laziness and cowardice of mankind for their short-lived effects. It deserves a better fate and, it may be hoped, will meet with one. As a 'depth-psychology', a theory of the mental unconscious, it can become indispensable to all the sciences which are concerned with the evolution of human civilization and its major institutions such as art, religion and the social order. It has already, in my opinion, afforded these sciences considerable help in solving their problems. But these are only small contributions compared with what might be achieved if historians of civilization, psychologists of religion, philologists and so on would agree themselves to handle the new instrument of research which is at their service. The use of analysis for the treatment of the neuroses is only one of its applications; the future will perhaps show that it is not the most important one. In any case it would be wrong to sacrifice all the other applications to this single one, just because it touches on the circle of medical interests.

[1926e, 4389]
It will not have escaped my readers that in what I have said I have assumed as axiomatic something that is still violently disputed in the discussion. I have assumed, that is to say, that psycho-analysis is not a specialized branch of medicine. I cannot see how it is possible to dispute this. Psycho-analysis is a part of psychology; not of medical psychology in the old sense, not of the psychology of morbid processes, but simply of psychology. It is certainly not the whole of psychology, but its sub-structure and perhaps even its entire foundation. The possibility of its application to medical purposes must not lead us astray. Electricity and radiology also have their medical application, but the science to which they both belong is none the less physics. Nor can their situation be affected by historical arguments. The whole theory of electricity had its origin in an observation of a nerve-muscle preparation; yet no one would dream to-day of regarding it as a part of physiology. It is argued that psycho-analysis was after all discovered by a physician in the course of his efforts to assist his patients. But that is clearly neither here nor there. Moreover, the historical argument is double-edged. We might pursue the story and recall the unfriendliness and indeed the animosity with which the medical profession treated analysis from the very first. That would seem to imply that it can have no claims over analysis to-day. And though I do not accept that implication, I still feel some doubts as to whether the present wooing of psycho-analysis by the doctors is based, from the point of view of the libido theory, upon the first or upon the second of Abraham's sub-stages - whether they wish to take possession of their object for the purpose of destroying or of preserving it.

No doubt what I have just said throws little light on the problem of lay analysis; it was only intended to exhibit my personal credentials as being myself a supporter of the inherent value of psycho-analysis and of its independence of its application to medicine. But it will be objected at this point that whether psycho-analysis, regarded as a science, is a subdivision of medicine or of psychology is a purely academic question and of no practical interest. The real point at issue, it will be said, is a different one, namely the application of analysis to the treatment of patients; in so far as it claims to do this it must be content, the argument will run, to be accepted as a specialized branch of medicine, like radiology, for instance, and to submit to the rules laid down for all therapeutic methods. I recognize that that is so; I admit it. I only want to feel assured that the therapy will not destroy the science. Unluckily analogies never carry one more than a certain distance; a point is soon reached at which the subjects of the comparison take divergent paths. The case of analysis differs from that of radiology. A physicist does not require to have a patient in order to study the laws that govern X-rays. But the only subject-matter of psycho-analysis is the mental processes of human beings and it is only in human beings that it can be studied. For reasons which can easily be understood, neurotic human beings offer far more instructive and accessible material than normal ones, and to withhold that material from anyone who wishes to study and apply analysis is to dock him of a good half of his training possibilities. I have, of course, no intention of asking that the interests of neurotic patients should be sacrificed to those of instruction and scientific research. The aim of my small volume on the question of lay analysis was precisely to show that, if certain precautions are observed, the two interests can quite easily be brought into harmony and that the interests of medicine, as rightly understood, will not be the last to profit by such a solution.

[1926e, 4393]
This was at a date before the investigations of Charcot and Pierre Janet into the origin of hysterical symptoms, and Breuer's discovery was thus entirely uninfluenced by them. But he did not pursue the matter any further at the time, and it was not until some ten years later that he took it up again in collaboration with Sigmund Freud. In 1895 they published a book, *Studies on Hysteria*, in which Breuer's discoveries were described and an attempt was made to explain them by the theory of 'catharsis'. According to that hypothesis, hysterical symptoms originate through the energy of a mental process being withheld from conscious influence and being diverted into bodily innervation ('conversion'). A hysterical symptom would thus be a substitute for an omitted mental act and a reminiscence of the occasion which should have given rise to that act. And, on this view, recovery would be a result of the liberation of the affect that had gone astray and of its discharge along a normal path ('abreaction'). Cathartic treatment gave excellent therapeutic results, but it was found that they were not permanent and that they were not independent of the personal relation between the patient and the physician. Freud, who later proceeded with these investigations by himself, made an alteration in their technique, by replacing hypnosis by the method of free association. He invented the term 'psycho-analysis', which in the course of time came to have two meanings: (1) a particular method of treating nervous disorders and (2) the science of unconscious mental processes, which has also been appropriately described as 'depth-psychology'.

Psycho-analysis finds a constantly increasing amount of support as a therapeutic procedure, owing to the fact that it can do more for its patients than any other method of treatment. The principle field of its application is in the milder neuroses - hysteria, phobias and obsessional states; and in malformations of character and sexual inhibitions or abnormalities it can also bring about marked improvements or even recoveries. Its influence upon dementia praecox and paranoia is doubtful; on the other hand, in favourable circumstances it can cope with depressive states, even if they are of a severe type.

The therapeutic influence of psycho-analysis depends on the replacement of unconscious mental acts by conscious ones and is effective within the limits of that factor. The replacement is effected by overcoming internal resistances in the patient's mind. The future will probably attribute far greater importance to psycho-analysis as the science of the unconscious than as a therapeutic procedure.

Psycho-analysis, in its character of depth-psychology, considers mental life from three points of view: the dynamic, the economic and the topographical.

At this point two observations may be in place. It must not be supposed that these very general ideas are presuppositions upon which the work of psycho-analysis depends. On the contrary, they are its latest conclusions and are 'open to revision'. Psycho-analysis is founded securely upon the observation of the facts of mental life; and for that very reason its theoretical superstructure is still incomplete and subject to constant alteration. Secondly, there is no reason for surprise that psycho-analysis, which was originally no more than an attempt at explaining pathological mental phenomena, should have developed into a psychology of normal mental life. The justification for this arose with the discovery that the dreams and mistakes of normal men have the same mechanism as neurotic symptoms.
Within this narrow compass it has been impossible to mention many matters of the greatest interest, such as the 'sublimation' of instincts, the part played by symbolism, the problem of 'ambivalence', etc. Nor has there been space to allude to the applications of psycho-analysis, which originated, as we have seen, in the sphere of medicine, to other departments of knowledge (such as Social Anthropology, the Study of Religion, Literary History and Education) where its influence is constantly increasing. It is enough to say that psycho-analysis, in its character of the psychology of the deepest, unconscious mental acts, promises to become the link between psychiatry and all of these other branches of mental science.
[1926f, 4406]

An outcry of this kind will really be disagreeable to me on account of my many fellow-workers, some of whom do not by any means share my attitude to the problems of religion. But psycho-analysis has already weathered many storms and now it must brave this fresh one. In point of fact psycho-analysis is a method of research, an impartial instrument, like the infinitesimal calculus, as it were. If a physicist were to discover with the latter's help that after a certain time the earth would be destroyed, we would nevertheless hesitate to attribute destructive tendencies to the calculus itself and therefore to proscribe it. Nothing that I have said here against the truth-value of religions needed the support of psycho-analysis; it had been said by others long before analysis came into existence. If the application of the psycho-analytic method makes it possible to find a new argument against the truths of religion, tant pis for religion; but defenders of religion will by the same right make use of psycho-analysis in order to give full value to the affective significance of religious doctrines.
[1927c, 4445]

My life's work has been directed to a single aim. I have observed the more subtle disturbances of mental function in healthy and sick people and have sought to infer - or, if you prefer it, to guess - from signs of this kind how the apparatus which serves these functions is constructed and what concurrent and mutually opposing forces are at work in it. What we - I, my friends and collaborators - have managed to learn in following this path has seemed to us of importance for the construction of a mental science which makes it possible to understand both normal and pathological processes as parts of the same natural course of events.
[1930, 4578]

The first piece of work that it fell to psycho-analysis to perform was the discovery of the instincts that are common to all men living to-day - and not only to those living to-day but to those of ancient and of prehistoric times. It called for no great effort, therefore, for psycho-analysis to ignore the differences that arise among the inhabitants of the earth owing to the multiplicity of races, languages and countries. From the start it was international, and it is well known that its followers overcame the dividing effects of the Great War sooner than any others.
[1929a, 4609]
LADIES AND GENTLEMEN, - If, after an interval of more than fifteen years, I have brought you together again to discuss with you what novelties, and what improvements it may be, the intervening time has introduced into psycho-analysis, it is right and fitting from more than one point of view that we should turn our attention first to the position of the theory of dreams. It occupies a special place in the history of psycho-analysis and marks a turning-point; it was with it that analysis took the step from being a psychotherapeutic procedure to being a depth-psychology. Since then, too, the theory of dreams has remained what is most characteristic and peculiar about the young science, something to which there is no counterpart in the rest of our knowledge, a stretch of new country, which has been reclaimed from popular beliefs and mysticism. The strangeness of the assertions it was obliged to put forward has made it play the part of a shibboleth, the use of which decided who could become a follower of psycho-analysis and to whom it remained forever incomprehensible. I myself found it a sheet-anchor during those difficult times when the unrecognized facts of the neuroses used to confuse my inexperienced judgement. Whenever I began to have doubts of the correctness of my wavering conclusions, the successful transformation of a senseless and muddled dream into a logical and intelligible mental process in the dreamer would renew my confidence of being on the right track.

[1933a, 4621]

You may perhaps expect an introduction to psycho-analysis to give you instructions, too, on what arguments you should use to correct these obvious errors about analysis, what books you should recommend to give more accurate information, or even what examples you should bring up in the discussion from your reading or experience in order to alter the company's attitude. I must beg you to do none of this. It would be useless. The best plan would be for you to conceal your superior knowledge altogether. If that is no longer possible, limit yourself to saying that, so far as you can make out, psycho-analysis is a special branch of knowledge, very hard to understand and to form an opinion on, which is concerned with very serious things, so that a few jokes will not bring one to close quarters with it - and that it would be better to find some other plaything for social entertainment. Nor, of course, will you join in attempts at interpretation, if unwary people repeat their dreams; and you will resist the temptation to curry favour for analysis by retailing reports of its cures.

[1933a, 4739]
One of the first applications of psycho-analysis was to teach us to understand the opposition offered to us by our contemporaries because we practised psycho-analysis. Other applications, of an objective nature, may claim a more general interest. Our first purpose, of course, was to understand the disorders of the human mind, because a remarkable experience had shown that here understanding and cure almost coincide, that a traversable road leads from the one to the other. And for a long time it was our only purpose. Then, however, we perceived the close relations, the internal identity indeed, between pathological processes and what are known as normal ones. Psycho-analysis became a depth-psychology; and, since nothing that men make or do is understandable without the co-operation of psychology, the applications of psycho-analysis to numerous fields of knowledge, in particular to those of the mental sciences, came about of their own accord, pushed their way to the front and called for ventilation. These tasks unfortunately came up against obstacles which, rooted as they were in the circumstances, have not yet been overcome even to-day. An application of this kind presupposes specialized knowledge which an analyst does not possess, while those who possess it, the specialists, know nothing of analysis and perhaps want to know nothing. The result has been that analysts, as amateurs with an equipment of greater or less adequacy, often hastily scraped together, have made excursions into such fields of knowledge as mythology, the history of civilization, ethnology, the science of religion and so on. They were no better treated by the experts resident in those fields than are trespassers in general: their methods and their findings, in so far as they attracted attention, were in the first instance rejected. But these conditions are constantly improving, and in every region there is a growing number of people who study psycho-analysis in order to make use of it in their special subject, and in order, as colonists, to replace the pioneers. Here we may expect a rich harvest of new discoveries. Applications of analysis are always confirmations of it as well. There, too, where scientific work is further removed from practical activity, the inevitable differences of opinion will no doubt take a less embittered form.

[1933a, 4745]

I propose further, Ladies and Gentlemen, to say a few words to you about psycho-analysis as a form of therapy. I discussed the theoretical side of this question fifteen years ago and I cannot formulate it in any other manner to-day; I have now to tell you of our experience during this interval. As you know, psycho-analysis originated as a method of treatment; it has far outgrown this, but it has not abandoned its home-ground and it is still linked to its contact with patients for increasing its depth and for its further development. The accumulated impressions from which we derive our theories could be arrived at in no other way. The failures we meet with as therapists are constantly setting us new tasks and the demands of real life are an effective guard against an overgrowth of the speculation which we cannot after all do without in our work. I have already discussed long ago the means used by psycho-analysis in helping patients, when it does help them, and the method by which it does so; to-day I shall enquire how much it achieves.

[1933a, 4750]
You are perhaps aware that I have never been a therapeutic enthusiast; there is no danger of
my misusing this lecture by indulging in eulogies. I would rather say too little than too much.
During the period at which I was the only analyst, people who were ostensibly friendly to my ideas
used to say to me: 'That's all very nice and clever; but show me a case that you have cured by
analysis.' This was one of the many formulas which in the course of time have succeeded one
another in performing the function of pushing the uncomfortable novelty aside. To-day it is as out
date as many others: the analyst, too, has a heap of letters in his files from grateful patients
who have been cured. The analogy does not stop at that. Psycho-analysis is really a method of
treatment like others. It has its triumphs and its defeats, its difficulties, its limitations, its
indications. At one time a complaint was made against analysis that it was not to be taken
seriously as a treatment since it did not dare to issue any statistics of its successes. Since then,
the Psycho-Analytic Institute in Berlin, which was founded by Dr. Max Eitingon, has published a
statement of its results during its first ten years. Its therapeutic successes give grounds neither for
boasting nor for being ashamed. But statistics of that kind are in general uninstructive; the
material worked upon is so heterogeneous that only very large numbers would show anything. It
is wiser to examine one's individual experiences. And here I should like to add that I do not think
our cures can compete with those of Lourdes. There are so many more people who believe in the
miracles of the Blessed Virgin than in the existence of the unconscious. If we turn to mundane
competitors, we must compare psycho-analytic treatment with other kinds of psychotherapy. To-
day organic physical methods of treating neurotic states need scarcely be mentioned. Analysis as
a psycho-therapeutic procedure does not stand in opposition to other methods used in this
specialized branch of medicine; it does not diminish their value nor exclude them. There is no
theoretical inconsistency in a doctor who likes to call himself a psychotherapist using analysis on
his patients alongside of any other method of treatment according to the peculiarities of the case
and the favourable or unfavourable external circumstances. It is in fact technique that
necessitates the specialization in medical practice. Thus in the same way surgery and
orthopaedics were obliged to separate. Psycho-analytic activity is arduous and exacting; it cannot
well be handled like a pair of glasses that one puts on for reading and takes off when one goes
for a walk. As a rule psycho-analysis possesses a doctor either entirely or not at all. Those
psychotherapists who make use of analysis among other methods, occasionally, do not to my
knowledge stand on firm analytic ground; they have not accepted the whole of analysis but have
watered it down - have drawn its fangs, perhaps; they cannot be counted as analysts. This is, I
think, to be regretted. But co-operation in medical practice between an analyst and a
psychotherapist who restricts himself to other techniques would serve quite a useful purpose.
[1933a, 4751]

I have told you that psycho-analysis began as a method of treatment; but I did not want to
commend it to your interest as a method of treatment but on account of the truths it contains, on
account of the information it gives us about what concerns human beings most of all - their own
nature - and on account of the connections it discloses between the most different of their
activities. As a method of treatment it is one among many, though, to be sure, primus inter pares.
If it was without therapeutic value it would not have been discovered, as it was, in connection with
sick people and would not have gone on developing for more than thirty years.
[1933a, 4756]
If that is the nature of a Weltanschauung, the answer as regards psycho-analysis is made easy. As a specialist science, a branch of psychology - a depth-psychology or psychology of the unconscious - it is quite unfit to construct a Weltanschauung of its own: it must accept the scientific one. But the Weltanschauung of science already departs noticeably from our definition. It is true that it too assumes the uniformity of the explanation of the universe; but it does so only as a programme, the fulfilment of which is relegated to the future. Apart from this it is marked by negative characteristics, by its limitation to what is at the moment knowable and by its sharp rejection of certain elements that are alien to it. It asserts that there are no sources of knowledge of the universe other than the intellectual working-over of carefully scrutinized observations - in other words, what we call research - and alongside of it no knowledge derived from revelation, intuition or divination. It seems as though this view came very near to being generally recognized in the course of the last few centuries that have passed; and it has been left to our century to discover the presumptuous objection that a Weltanschauung like this is alike paltry and cheerless, that it overlooks the claims of the human intellect and the needs of the human mind. [1933a, 4757]

This objection cannot be too energetically repudiated. It is quite without a basis, since the intellect and the mind are objects for scientific research in exactly the same way as any non-human things. Psycho-analysis has a special right to speak for the scientific Weltanschauung at this point, since it cannot be reproached with having neglected what is mental in the picture of the universe. Its contribution to science lies precisely in having extended research to the mental field. And, incidentally, without such a psychology science would be very incomplete. If, however, the investigation of the intellectual and emotional functions of men (and of animals) is included in science, then it will be seen that nothing is altered in the attitude of science as a whole, that no new sources of knowledge or methods of research have come into being. Intuition and divination would be such, if they existed; but they may safely be reckoned as illusions, the fulfilments of wishful impulses. It is easy to see, too, that these demands upon a Weltanschauung are only based on emotion. Science takes notice of the fact that the human mind produces these demands and is ready to examine their sources; but it has not the slightest reason to regard them as justified. On the contrary it sees this as a warning carefully to separate from knowledge everything that is illusion and an outcome of emotional demands like these. [1933a, 4758]

Psycho-analysis is a part of the mental science of psychology. It is also described as 'depth psychology' - we shall later discover why. If someone asks what 'the psychical' really means, it is easy to reply by enumerating its constituents: our perceptions, ideas, memories, feelings and acts of volition - all these form part of what is psychical. But if the questioner goes further and asks whether there is not some common quality possessed by all these processes which makes it possible to get nearer to the nature, or, as people sometimes say, the essence of the psychical, then it is harder to give an answer. [1940b [1938], 5068]
Nor need it be supposed that this alternative view of the psychical is an innovation due to psycho-analysis. A German philosopher, Theodor Lipps, asserted with the greatest explicitness that the psychical is in itself unconscious and that the unconscious is the truly psychical. The concept of the unconscious has long been knocking at the gates of psychology and asking to be let in. Philosophy and literature have often toyed with it, but science could find no use for it. Psycho-analysis has seized upon the concept, has taken it seriously and has given it a fresh content. By its researches it has led to a knowledge of characteristics of the unconscious psychical which have hitherto been unsuspected, and it has discovered some of the laws which govern it. But none of this implies that the quality of being conscious has lost its importance for us. It remains the one light which illuminates our path and leads us through the darkness of mental life. In consequence of the special character of our discoveries, our scientific work in psychology will consist in translating unconscious processes into conscious ones, and thus filling in the gaps in conscious perception. . . .

[1940b [1938], 5071]
As regards my share of the book, too, the only possible decision has been that the text of the first edition shall be reprinted without alteration. The developments and changes in my views during the course of thirteen years of work have been too far-reaching for it to be possible to attach them to my earlier exposition without entirely destroying its essential character. Nor have I any reason for wishing to eliminate this evidence of my initial views. Even to-day I regard them not as errors but as valuable first approximations to knowledge which could only be fully acquired after long and continuous efforts. The attentive reader will be able to detect in the present book the germs of all that has since been added to the theory of catharsis: for instance, the part played by psychosexual factors and infantilism, the importance of dreams and of unconscious symbolism. And I can give no better advice to any one interested in the development of catharsis into psycho-analysis than to begin with *Studies on Hysteria* and thus follow the path which I myself have trodden.

[1895d, 4]

'I have propounded a little theory of my own. I have noticed that people who have a talent for painting have no feeling for music, and vice versa. Some time ago I had a conversation with someone on this point, in which I remarked: "So far my observation has always held good, with the exception of only one person." When I wanted to recall that person's name, I found it had been irretrievably forgotten, even though I knew that the owner of it was one of my closest friends. When I heard the name mentioned quite by chance a few days later, I knew at once, of course, that it was the destroyer of my theory who was being spoken of. The grudge I unconsciously bore against him was expressed by my forgetting his name, which, apart from that, I knew so well.'

[1901b, 1121]

(D) Anyone who has had the opportunity of studying the hidden mental impulses of human beings by means of psycho-analysis can also say something new about the *quality* of the unconscious motives that find expression in superstition. It can be recognized most clearly in neurotics suffering from obsessional thinking or obsessional states - people who are often of high intelligence - that superstition derives from suppressed hostile and cruel impulses. Superstition is in large part the expectation of trouble; and a person who has harboured frequent evil wishes against others, but has been brought up to be good and has therefore repressed such wishes into the unconscious, will be especially ready to expect punishment for his unconscious wickedness in the form of trouble threatening him from without.

[1901b, 1330]
Some people may feel inclined to look upon it as a serious objection to a method which is in any case troublesome enough that it itself should multiply the labours of the physician by creating a new species of pathological mental products. They may even be tempted to infer from the existence of transferences that the patient will be injured by analytic treatment. Both these suppositions would be mistaken. The physician's labours are not multiplied by transference; it need make no difference to him whether he has to overcome any particular impulse of the patient's in connection with himself or with some one else. Nor does the treatment force upon the patient, in the shape of transference, any new task which he would not other wise have performed. It is true that neuroses may be cured in institutions from which psycho-analytic treatment is excluded, that hysteria may be said to be cured not by the method but by the physician, and that there is usually a sort of blind dependence and a permanent bond between a patient and the physician who has removed his symptoms by hypnotic suggestion; but the scientific explanation of all these facts is to be found in the existence of 'transferences' such as are regularly directed by patients on to their physicians. Psycho-analytic treatment does not create transferences, it merely brings them to light, like so many other hidden psychical factors. The only difference is this - that spontaneously a patient will only call up affectionate and friendly transferences to help towards his recovery; if they cannot be called up, he feels the physician is 'antipathetic' to him, and breaks away from him as fast as possible and without having been influenced by him. In psycho-analysis, on the other hand, since the play of motives is different, all the patient's tendencies, including hostile ones, are aroused; they are then turned to account for the purposes of the analysis by being made conscious, and in this way the transference is constantly being destroyed. Transference, which seems ordained to be the greatest obstacle to psycho-analysis, becomes its most powerful ally, if its presence can be detected each time and explained to the patient.¹

Now that the flood-waters of war have subsided, it is satisfactory to be able to record the fact that interest in psycho-analytic research remains unimpaired in the world at large. But the different parts of the theory have not all had the same history. The purely psychological theses and findings of psycho-analysis on the unconscious, repression, conflict as a cause of illness, the advantage accruing from illness, the mechanisms of the formation of symptoms, etc., have come to enjoy increasing recognition and have won notice even from those who are in general opposed to our views. That part of the theory, however, which lies on the frontiers of biology and the foundations of which are contained in this little work is still faced with undiminished contradiction. It has even led some who for a time took a very active interest in psycho-analysis to abandon it and to adopt fresh views which were intended to restrict once more the part played by the factor of sexuality in normal and pathological mental life.

It has justly been said that the Oedipus complex is the nuclear complex of the neuroses, and constitutes the essential part of their content. It represents the peak of infantile sexuality, which, through its after-effects, exercises a decisive influence on the sexuality of adults. Every new arrival on this planet is faced by the task of mastering the Oedipus complex; anyone who fails to do so falls a victim to neurosis. With the progress of psycho-analytic studies the importance of the Oedipus complex has became more and more clearly evident; its recognition has become the shibboleth that distinguishes the adherents of psycho-analysis from its opponents.

¹ [1905e, 1451]

[1905d, 1462]
The factor of resistance has become one of the corner-stones of his theory. The ideas which are normally pushed aside on every sort of excuse - such as those mentioned above - are regarded by him as derivatives of the repressed psychical phenomena (thoughts and impulses), distorted owing to the resistance against their reproduction. Ideas which are normally pushed aside on every sort of excuse - such as those mentioned above - are regarded by him as derivatives of the repressed psychical phenomena (thoughts and impulses), distorted owing to the resistance against their reproduction.

[1904a, 1557]

But in view of the close connections between the psychoneuroses and the simple neuroses, which go so far, indeed, that a differential diagnosis is not always easy for inexperienced observers, it could not be long before the knowledge arrived at in the one field was extended to the other. Moreover, apart from this consideration, a deeper investigation of the psychical mechanism of hysterical symptoms led to the same result. For if the psychical traumas from which the hysterical symptoms were derived were pursued further and further by means of the 'cathartic' procedure initiated by Breuer and me, experiences were eventually reached which belonged to the patient's childhood and related to his sexual life. And this was so, even in cases in which the onset of the illness had been brought about by some commonplace emotion of a non-sexual kind. Unless these sexual traumas of childhood were taken into account it was impossible either to elucidate the symptoms (to understand the way in which they were determined) or to prevent their recurrence. In this way the unique significance of sexual experiences in the aetiology of the psychoneuroses seemed to be established beyond a doubt; and this fact remains to this day one of the corner-stones of my theory.

[1906a, 1576]

I think it is worth emphasizing the fact that, whatever modifications my views on the aetiology of the psychoneuroses have passed through, there are two positions which I have never repudiated or abandoned - the importance of sexuality and of infantilism. Apart from this, accidental influences have been replaced by constitutional factors and 'defence' in the purely psychological sense has been replaced by organic 'sexual repression'. The question may, however, be raised of where convincing evidence is to be found in favour of the alleged aetiological importance of sexual factors in the psychoneuroses, in view of the fact that the onset of these illnesses may be observed in response to the most commonplace emotions or even to somatic precipitating causes, and since I have had to abandon a specific aetiology depending on the particular form of the childhood experiences concerned. To such a question I would reply that the psycho- analytic examination of neurotics is the source from which this disputed conviction of mine is derived. If we make use of that irreplaceable method of research, we discover that the patient's symptoms constitute his sexual activity (whether wholly or in part), which arises from the sources of the normal or perverse component instincts of sexuality. Not only is a large part of the symptomatology of hysteria derived directly from expressions of sexual excitement, not only do a number of erotogenic zones attain the significance of genitals during neuroses owing to an intensification of infantile characteristics, but the most complicated symptoms are themselves revealed as representing, by means of 'conversion', phantasies which have a sexual situation as their subject-matter. Anyone who knows how to interpret the language of hysteria will recognize that the neurosis is concerned only with the patient's repressed sexuality. The sexual function must, however, be understood in its true extent, as it is laid down by disposition in infancy. Wherever some commonplace emotion must be included among the determinants of the onset of the illness, analysis invariably shows that it is the sexual component of the traumatic experience - a component that is never lacking which has produced the pathogenic result.

[1906a, 1582]
Recognition of the simultaneous presence of the three factors of 'infantilism', 'sexuality' and 'repression' constitutes the main characteristic of the psycho-analytic theory, and marks its distinction from other views of pathological mental life. At the same time, psycho-analysis has demonstrated that there is no fundamental difference, but only one of degree, between the mental life of normal people, of neurotics and of psychotics. A normal person has to pass through the same repressions and has to struggle with the same substitutive structures; the only difference is that he deals with these events with less trouble and better success. The psycho-analytic method of investigation can accordingly be applied equally to the explanation of normal psychical phenomena, and has made it possible to discover the close relationship between pathological psychical products and normal structures such as dreams, the small blunders of everyday life, and such valuable phenomena as jokes, myths and imaginative works. The explanation of these has been carried furthest in the case of dreams, and has resulted here in the following general formula: 'A dream is a disguised fulfillment of a repressed wish.' The interpretation of dreams has as its object the removal of the disguise to which the dreamer's thoughts have been subjected. It is, moreover, a highly valuable aid to psycho-analytic technique, for it constitutes the most convenient method of obtaining insight into unconscious psychical life.

I devoted a volume published in 1900 to the important subject of dream-interpretation and have had the satisfaction of seeing the theories put forward in it confirmed and amplified by contributions from almost every worker in the field of psycho-analysis.¹ It is generally agreed that dream-interpretation is the foundation stone of psycho-analytic work and that its findings constitute the most important contribution made by psycho-analysis to psychology.

The overmastering interest which must be felt in psycho-analysis by the theory of education is based upon a fact which has become evident. Only someone who can feel his way into the minds of children can be capable of educating them; and we grown-up people cannot understand children because we no longer understand our own childhood. Our infantile amnesia proves that we have grown estranged from our childhood. Psycho-analysis has brought to light the wishes, the thought structures and the developmental processes of childhood. All earlier attempts in this direction have been in the highest degree incomplete and misleading because they have entirely overlooked the inestimably important factor of sexuality in its physical and mental manifestations. The incredulous astonishment which meets the most certainly established findings of psycho-analysis on the subject of childhood - the Oedipus complex, self-love (or 'narcissism'), the disposition to perversions, anal erotism, sexual curiosity - is a measure of the gulf which separates our mental life, our judgements of value and, indeed, our processes of thought from those of even normal children.

Among the other new factors which were added to the cathartic procedure as a result of my work and which transformed it into psycho-analysis, I may mention in particular the theory of repression and resistance, the recognition of infantile sexuality, and the interpreting and exploiting of dreams as a source of knowledge of the unconscious.
The theory of repression is the corner-stone on which the whole structure of psycho-analysis rests. It is the most essential part of it; and yet it is nothing but a theoretical formulation of a phenomenon which may be observed as often as one pleases if one undertakes an analysis of a neurotic without resorting to hypnosis. In such cases one comes across a resistance which opposes the work of analysis and in order to frustrate it pleads a failure of memory. The use of hypnosis was bound to hide this resistance; the history of psycho-analysis proper, therefore, only begins with the new technique that dispenses with hypnosis. The theoretical consideration of the fact that this resistance coincides with an amnesia leads inevitably to the view of unconscious mental activity which is peculiar to psycho-analysis and which, too, distinguishes it quite clearly from philosophical speculations about the unconscious. It may thus be said that the theory of psycho-analysis is an attempt to account for two striking and unexpected facts of observation which emerge whenever an attempt is made to trace the symptoms of a neurotic back to their sources in his past life: the facts of transference and of resistance. Any line of investigation which recognizes these two facts and takes them as the starting-point of its work has a right to call itself psycho-analysis, even though it arrives at results other than my own. But anyone who takes up other sides of the problem while avoiding these two hypotheses will hardly escape a charge of misappropriation of property by attempted impersonation, if he persists in calling himself a psycho-analyst.

[1914d, 2885]

If anyone sought to place the theory of repression and resistance among the premisses instead of the findings of psycho-analysis, I should oppose him most emphatically. Such premisses of a general psychological and biological nature do exist, and it would be useful to consider them on some other occasion; but the theory of repression is a product of psycho-analytic work, a theoretical inference legitimately drawn from innumerable observations.

[1914d, 2885]
The first task confronting psycho-analysis was to explain the neuroses; it used the two facts of resistance and transference as starting-points, and, taking into consideration the third fact of amnesia, accounted for them with its theories of repression, of the sexual motive forces in neurosis and of the unconscious. Psycho-analysis has never claimed to provide a complete theory of human mentality in general, but only expected that what it offered should be applied to supplement and correct the knowledge acquired by other means. Adler's theory, however, goes far beyond this point; it seeks at one stroke to explain the behaviour and character of human beings as well as their neurotic and psychotic illnesses. It is actually more suited to any other field than that of neurosis, although for reasons connected with the history of its development it still places this in the foreground. For many years I had opportunities of studying Dr. Adler and have never refused to recognize his unusual ability, combined with a particularly speculative disposition. As an instance of the 'persecution' to which he asserts he has been subjected by me, I can point to the fact that after the Association was founded I made over to him the leadership of the Vienna group. It was not until urgent demands were put forward by all the members of the society that I let myself be persuaded to take the chair again at its scientific meetings. When I perceived how little gift Adler had precisely for judging unconscious material, my view changed to an expectation that he would succeed in discovering the connections of psycho-analysis with psychology and with the biological foundations of instinctual processes - an expectation which was in some sense justified by the valuable work he had done on 'organ-inferiority'. And he did in fact effect something of the kind; but his work conveys an impression 'as if' - to speak in his own 'jargon' - it was intended to prove that psycho-analysis was wrong in everything and that it had only attributed so much importance to sexual motive forces because of its credulity in accepting the assertions of neurotics. I may even speak publicly of the personal motive for his work, since he himself announced it in the presence of a small circle of members of the Vienna group: - 'Do you think it gives me such great pleasure to stand in your shadow my whole life long?' To be sure, I see nothing reprehensible in a younger man freely admitting his ambition, which one would in any case guess was among the incentives for his work. But even though a man is dominated by a motive of this kind he should know how to avoid being what the English, with their fine social tact, call 'unfair' - which in German can only be expressed by a much cruder word. How little Adler has succeeded in this is shown by the profusion of petty outbursts of malice which disfigure his writings and by the indications they contain of an uncontrolled craving for priority. At the Vienna Psycho-Analytical Society we once actually heard him claim priority for the conception of the 'unity of the neuroses' and for the 'dynamic view' of them. This came as a great surprise to me, for I had always believed that these two principles were stated by me before I ever made Adler's acquaintance.

[1914d, 2913]
I will not dwell any longer on the biological aspect of the Adlerian theory nor discuss whether either actual "organ-inferiority" or the subjective feeling of it - one does not know which - is really capable of serving as the foundation of Adler's system. I will merely remark in passing that if it were so neurosis would appear as a by-product of every kind of physical decrepitude, whereas observation shows that an impressive majority of ugly, misshapen, crippled and miserable people fail to react to their defects by neurosis. Nor will I deal with the interesting assertion according to which inferiority is to be traced back to the feeling of being a child. It shows the disguise under which the factor of infantilism, which is so strongly emphasized by psycho-analysis, re-appears in 'Individual Psychology'. On the other hand, I must point out how all the psychological acquisitions of psycho-analysis have been thrown to the winds by Adler. In his book Über den nervösen Charakter the unconscious is still mentioned as a psychological peculiarity, without, however, any relation to his system. Later, he has consistently declared that it is a matter of indifference to him whether an idea is conscious or unconscious. Adler has never from the first shown any understanding of repression. In an abstract of a paper read by him at the Vienna Society (February, 1911) he wrote that it must be pointed out that the evidence in a particular case showed that the patient had never repressed his libido, but had been continually 'safeguarding' himself against it. Soon afterwards, in a discussion at the Vienna Society, he said: 'If you ask where repression comes from, you are told, "from civilization"; but if you go on to ask where civilization comes from, you are told "from repression". So you see it is all simply playing with words.' A tithe of the acuteness and ingenuity with which Adler has unmasked the defensive devices of the 'nervous character' would have been enough to show him the way out of this pettifogging argument. What is meant is simply that civilization is based on the repressions effected by former generations, and that each fresh generation is required to maintain this civilization by effecting the same repressions. I once heard of a child who thought people were laughing at him, and began to cry, because when he asked where eggs come from he was told 'from hens', and when he went on to ask where hens come from he was told 'from eggs'. But they were not playing with words; on the contrary, they were telling him the truth.

[1914d, 2919]

Everything that Adler has to say about dreams, the shibboleth of psycho-analysis, is equally empty and unmeaning. At first he regarded dreams as a turning away from the feminine to the masculine line - which is simply a translation of the wish-fulfilment theory of dreams into the language of the 'masculine protest'. Later he found that the essence of dreams lies in enabling men to accomplish unconsciously what they are denied consciously. Adler must also be credited with priority in confusing dreams with latent dream-thoughts - a confusion on which the discovery of his 'prospective tendency' rests. Maeder followed his lead in this later. Here the fact is readily overlooked that every interpretation of a dream which is incomprehensible in its manifest form is based on the very method of dream-interpretation whose premisses and conclusions are being disputed. In regard to resistance Adler informs us that it serves the purpose of putting into effect the patient's opposition to the physician. This is certainly true; it is as much as to say that it serves the purpose of resistance. Where it comes from, however, or how it happens that its phenomena are at the disposal of the patient is not further enquired into, as being of no interest to the ego. The detailed mechanism of the symptoms and manifestations of diseases, the explanation of the manifold variety of those diseases and their forms of expression, are disregarded in toto; for everything alike is pressed into the service of the masculine protest, self-assertion and the aggrandizement of the personality. the system is complete; to produce it has cost an enormous amount of labour in the recasting of interpretations, while it has not furnished a single new observation. I fancy I have made it clear that it has nothing to do with psycho-analysis.

[1914d, 2920]
I am quite prepared to be told again that I have misunderstood the substance and purpose of the Neo-Zurich theory; but I must protest in advance against any contradictions to my view of it that may be found in the publications of that school being laid at my door instead of theirs. I can find no other way of making the whole range of Jung's innovations intelligible to myself and of grasping all their implications. All the changes that Jung has proposed to make in psychoanalysis flow from his intention to eliminate what is objectionable in the family-complexes, so as not to find it again in religion and ethics. For sexual libido an abstract concept has been substituted, of which one may safely say that it remains mystifying and incomprehensible to wise men and fools alike. The Oedipus complex has a merely 'symbolic' meaning: the mother in it means the unattainable, which must be renounced in the interests of civilization; the father who is killed in the Oedipus myth is the 'inner' father, from whom one must set oneself free in order to become independent. Other parts of the material of sexual ideas will no doubt be subjected to similar re-interpretations in the course of time. In the place of a conflict between ego-dystonic erotic trends and the self-preservative ones a conflict appears between the 'life-task' and 'psychical inertia'; the neurotic's sense of guilt corresponds to his self-reproach for not properly fulfilling his 'life-task'. In this way a new religio-ethical system has been created, which, just like the Adlerian system, was bound to re-interpret, distort or jettison the factual findings of analysis. The truth is that these people have picked out a few cultural overtones from the symphony of life and have once more failed to hear the mighty and primordial melody of the instincts.

The total incompatibility of this new movement with psycho-analysis shows itself too, of course, in Jung's treatment of repression, which is hardly mentioned nowadays in his writings, in his misunderstanding of dreams, which, like Adler, in complete disregard of dream-psychology, he confuses with the latent dream-thoughts, and in his loss of all understanding of the unconscious - in short, in all the points which I should regard as the essence of psycho-analysis. When Jung tells us that the incest-complex is merely 'symbolic', that after all it has no 'real' existence, that after all a savage feels no desire towards an old hag but prefers a young and pretty woman, we are tempted to conclude that 'symbolic' and 'without real existence' simply mean something which, in virtue of its manifestations and pathogenic effects, is described by psycho-analysis as 'existing unconsciously' - a description that disposes of the apparent contradiction.

I cannot tell what you will think of it, but I must assure you that I do not regret having claimed so much of your interest and of the time available to us for the problems of dreams. There is nothing else from which one can so quickly arrive at a conviction of the correctness of the theses by which psycho-analysis stands or falls. Exacting work over many months and even years is called for to show that the symptoms of a case of neurotic illness have a sense, serve a purpose and arise out of the patient's experiences in life. On the other hand, only a few hours' effort may be enough to prove that the same thing is true of a dream which is, to start with, confused to the point of being unintelligible, and thus to confirm all the premisses of psycho-analysis - the unconscious nature of mental processes, the peculiar mechanisms which they obey and the instinctual forces which are expressed in them. And when we bear in mind the sweeping analogy between the structure of dreams and that of neurotic symptoms and at the same time consider the rapidity of the transformation which makes a dreamer into a waking and reasonable man, we arrive at a certainty that neuroses too are based only on an alteration in the play of forces between the powers of mental life.
But in thus emphasizing the unconscious in mental life we have conjured up the most evil spirits of criticism against psycho-analysis. Do not be surprised at this, and do not suppose that the resistance to us rests only on the understandable difficulty of the unconscious or the relative inaccessibility of the experiences which provide evidence of it. Its source, I think, lies deeper. In the course of centuries the naïve self-love of men has had to submit to two major blows at the hands of science. The first was when they learnt that our earth was not the centre of the universe but only a tiny fragment of a cosmic system of scarcely imaginable vastness. This is associated in our mind: with the name of Copernicus, though something similar had already been asserted by Alexandrian science. The second blow fell when biological research destroyed man's supposedly privileged place in creation and proved his descent from the animal kingdom and his ineradicable animal nature. This revaluation has been accomplished in our own days by Darwin, Wallace and their predecessors, though not without the most violent contemporary opposition. But human megalomania will have suffered its third and most wounding blow from the psychological research of the present time which seeks to prove to the ego that it is not even master in its own house, but must content itself with scanty information of what is going on unconsciously in its mind. We psycho-analysts were not the first and not the only ones to utter this call to introspection; but it seems to be our fate to give it its most forcible expression and to support it with empirical material which affects every individual. Hence arises the general revolt against our science, the disregard of all considerations of academic civility and the releasing of the opposition from every restraint of impartial logic. And beyond all this we have yet to disturb the peace of this world in still another way, as you will shortly hear.

[1916-1917, 3361]

_The Corner-Stones of Psycho-Analytic Theory._ - The assumption that there are unconscious mental processes, the recognition of the theory of resistance and repression, the appreciation of the importance of sexuality and of the Oedipus complex - these constitute the principal subject-matter of psycho-analysis and the foundations of its theory. No one who cannot accept them all should count himself a psycho-analyst.

[1923a, 3924]

The division of the psychical into what is conscious and what is unconscious is the fundamental premiss of psycho-analysis; and it alone makes it possible for psycho-analysis to understand the pathological processes in mental life, which are as common as they are important, and to find a place for them in the framework of science. To put it once more, in a different way: psycho-analysis cannot situate the essence of the psychical in consciousness, but is obliged to regard consciousness as a quality of the psychical, which may be present in addition to other qualities or may be absent.

[1923b, 3947]

If I could suppose that everyone interested in psychology would read this book, I should also be prepared to find that at this point some of my readers would already stop short and would go no further; for here we have the first shibboleth of psycho-analysis. To most people who have been educated in philosophy the idea of anything psychical which is not also conscious is so inconceivable that it seems to them absurd and refutable simply by logic. I believe this is only because they have never studied the relevant phenomena of hypnosis and dreams, which - quite apart from pathological manifestations - necessitate this view. Their psychology of consciousness is incapable of solving the problems of dreams and hypnosis.

[1923b, 3947]
It looked as though our work had been made much more difficult and complicated; but the inestimable gain was that an insight was now obtained into an interplay of forces which had been concealed from the observer by the hypnotic state. It became evident that the work of uncovering what had been pathogenically forgotten had to struggle against a constant and very intense resistance. The critical objections which the patient raised in order to avoid communicating the ideas which occurred to him, and against which the fundamental rule of psycho-analysis was directed, had themselves already been manifestations of this resistance. A consideration of the phenomena of resistance led to one of the corner-stones of the psycho-analytic theory of the neuroses - the theory of repression. It was plausible to suppose that the same forces which were now struggling against the pathogenic material being made conscious had at an earlier time made the same efforts with success. A gap in the aetiology of neurotic symptoms was thus filled. The impressions and mental impulses, for which the symptoms were now serving as substitutes, had not been forgotten without reason or on account of a constitutional incapacity for synthesis (as Janet supposed); they had, though the influence of other mental forces, met with a repression the success and evidence of which was precisely their being debarred from consciousness and excluded from memory. It was only in consequence of this repression that they had become pathogenic - that is, had succeeded in manifesting themselves along unusual paths as symptoms.

After hypnosis was replaced by the technique of free association, Breuer's cathartic procedure turned into psycho-analysis, which for more than a decade was developed by the author (Freud) alone. During that time psycho-analysis gradually acquired a theory which appeared to give a satisfactory account of the origin, meaning and purpose of neurotic symptoms and provided a rational basis for medical attempts at curing the complaint. I will once again enumerate the factors that go to make up this theory. They are: emphasis on instinctual life (affectivity), on mental dynamics, on the fact that even the apparently most obscure and arbitrary mental phenomena invariably have a meaning and a causation, the theory of psychical conflict and of the pathogenic nature of repression, the view that symptoms are substitutive satisfactions, the recognition of the aetiological importance of sexual life, and in particular of the beginnings of infantile sexuality. From a philosophical standpoint this theory was bound to adopt the view that the mental does not coincide with the conscious, that mental processes are in themselves unconscious and are only made conscious by the functioning of special organs (agencies or systems). By way of completing this list, I will add that among the affective attitudes of childhood the complicated emotional relation of children to their parents - what is known as the Oedipus complex - came into prominence. It became ever clearer that this was the nucleus of every case of neurosis, and in the patient's behaviour towards his analyst certain phenomena of his emotional transference emerged which came to be of great importance for theory and technique alike.
This state of affairs is enough to account for the reluctant and hesitant reception of analysis in scientific quarters. But it does not explain the outbursts of indignation, derision and scorn which, in disregard of every standard of logic and good taste, have characterized the controversial methods of its opponents. A reaction of such a kind suggests that resistances other than purely intellectual ones were stirred up and that powerful emotional forces were aroused. And there are indeed plenty of things to be found in the theory of psycho-analysis calculated to produce such an effect as this upon the passions of men of every kind and not of scientists alone. Above all there is the very important place in the mental life of human beings which psycho-analysis assigns to what are known as the sexual instincts. Psycho-analytic theory maintained that the symptoms of neuroses are distorted substitutive satisfactions of sexual instinctual forces, the direct satisfaction of which has been frustrated by internal resistances. Later on, when analysis had extended beyond its original field of work and began to be applied to normal mental life, it sought to show that these same sexual components, which could be diverted from their immediate aims and directed to other things, made the most important contributions to the cultural achievements of the individual and of society. These views were not entirely new. The incomparable significance of sexual life had been proclaimed by the philosopher Schopenhauer in an intensely impressive passage. Moreover, what psycho-analysis called sexuality was by no means identical with the impulsion towards a union of the two sexes or towards producing a pleasurable sensation in the genitals; it had far more resemblance to the all-inclusive and all-preserving Eros of Plato's Symposium. [1925e, 4125]

The theory of repression became the corner-stone of our understanding of the neuroses. A different view had now to be taken of the task of therapy. Its aim was no longer to 'abreact' an affect which had got on to the wrong lines but to uncover repressions and replace them by acts of judgement which might result either in the accepting or in the condemning of what had formerly been repudiated. I showed my recognition of the new situation by no longer calling my method of investigation and treatment catharsis but psycho-analysis. [1925d, 4207]

It is possible to take repression as a centre and to bring all the elements of psycho-analytic theory into relation with it. But before doing so I have a further comment of a polemical nature to make. According to Janet's view a hysterical woman was a wretched creature who, on account of a constitutional weakness, was unable to hold her mental acts together, and it was for that reason that she fell a victim to a splitting of her mind and to a restriction of the field of her consciousness. The outcome of psycho-analytic investigations, on the other hand, showed that these phenomena were the result of dynamic factors - of mental conflict and of repression. This distinction seems to me to be far-reaching enough to put an end to the glib repetition of the view that whatever is of value in psycho-analysis is merely borrowed from the ideas of Janet. The reader will have learned from my account that historically psycho-analysis is completely independent of Janet's discoveries, just as in its content it diverges from them and goes far beyond them. Janet's works would never have had the implications which have made psycho-analysis of such importance to the mental sciences and have made it attract such universal interest. I always treated Janet himself with respect, since his discoveries coincided to a considerable extent with those of Breuer, which had been made earlier but were published later than his. But when in the course of time psycho-analysis became a subject of discussion in France, Janet behaved ill, showed ignorance of the facts and used ugly arguments. And finally he revealed himself to my eyes and destroyed the value of his own work by declaring that when he had spoken of 'unconscious' mental acts he had meant nothing by the phrase - it had been no more than a façon de parler. [1925d, 4207]
The theories of resistance and of repression, of the unconscious, of the aetiological significance of sexual life and of the importance of infantile experiences - these form the principal constituents of the theoretical structure of psycho-analysis. In these pages, unfortunately, I have been able to describe only the separate elements and not their interconnections and their bearing upon one another. But I am obliged now to turn to the alterations which gradually took place in the technique of the analytic method.

In Europe during the years 1911-13 two secessionist movements from psycho-analysis took place, led by men who had previously played a considerable part in the young science, Alfred Adler and C. G. Jung. Both movements seemed most threatening and quickly obtained a large following. But their strength lay, not in their own content, but in the temptation which they offered of being freed from what were felt as the repellent findings of psycho-analysis even though its actual material was no longer rejected. Jung attempted to give to the facts of analysis a fresh interpretation of an abstract, impersonal and non-historical character, and thus hoped to escape the need for recognizing the importance of infantile sexuality and of the Oedipus complex as well as the necessity for any analysis of childhood. Adler seemed to depart still further from psycho-analysis; he entirely repudiated the importance of sexuality, traced back the formation both of character and of the neuroses solely to men's desire for power and to their need to compensate for their constitutional inferiorities, and threw all the psychological discoveries of psycho-analysis to the winds. But what he had rejected forced its way back into his closed system under other names; his 'masculine protest' is nothing else than repression unjustifiably sexualized. The criticism with which the two heretics were met was a mild one; I only insisted that both Adler and Jung should cease to describe their theories as 'psycho-analysis'. After a lapse of ten years it can be asserted that both of these attempts against psycho-analysis have blown over without doing any harm.

The first task of psycho-analysis was the elucidation of nervous disorders. The analytic theory of the neuroses is based on three corner-stones: the recognition of (1) 'repression', of (2) the importance of the sexual instinct and of (3) 'transference'.

The reasons for this hostility were to be found, from the medical point of view, in the fact that psycho-analysis lays stress upon psychical factors, and from the philosophical point of view, in its assuming as an underlying postulate the concept of unconscious mental activity; but the strongest reason was undoubtedly the general disinclination of mankind to concede to the factor of sexuality the importance that is assigned to it by psycho-analysis. In spite of this widespread opposition, however, the movement in favour of psycho-analysis was not to be checked. Its adherents formed themselves into an International Association, which passed successfully through the ordeal of the World War, and at the present time (1925) comprises local groups in Vienna, Berlin, Budapest, London, Switzerland, Holland, Moscow and Calcutta, as well as two in the United States. There are three periodicals representing the views of these societies: the Internationale Zeitschrift für Psychoanalyse, Imago (which is concerned with the application of psycho-analysis to non-medical fields of knowledge), and the International Journal of Psycho-Analysis.
Archaeological interests are no doubt most praiseworthy, but no one undertakes an excavation if by doing so he is going to undermine the habitations of the living so that they collapse and bury people under their ruins. The doctrines of religion are not a subject one can quibble about like any other. Our civilization is built up on them, and the maintenance of human society is based on the majority of men's believing in the truth of those doctrines. If men are taught that there is no almighty and all-just God, no divine world-order and no future life, they will feel exempt from all obligation to obey the precepts of civilization. Everyone will, without inhibition or fear, follow his asocial, egoistic instincts and seek to exercise his power; Chaos, which we have banished through many thousands of years of the work of civilization, will come again. Even if we knew, and could prove, that religion was not in possession of the truth, we ought to conceal the fact and behave in the way prescribed by the philosophy of "As if" - and this in the interest of the preservation of us all. And apart from the danger of the undertaking, it would be a purposeless cruelty. Countless people find their one consolation in religious doctrines, and can only bear life with their help. You would rob them of their support, without having anything better to give them in exchange. It is admitted that so far science has not achieved much, but even if it had advanced much further it would not suffice for man. Man has imperative needs of another sort, which can never be satisfied by cold science; and it is very strange - indeed, it is the height of inconsistency - that a psychologist who has always insisted on what a minor part is played in human affairs by the intelligence as compared with the life of the instincts - that such a psychologist should now try to rob mankind of a precious wish-fulfilment and should propose to compensate them for it with intellectual nourishment.'

Behind this magic we recognize the ancient, venerable and incontestably correct pronouncement of Aristotle - that dreaming is the continuation of our mental activity into the state of sleep - combined with the recognition of the unconscious which psycho-analysis first added to it. Only the riddle of dream-distortion finds no solution here.

LADIES AND GENTLEMEN, - If, after an interval of more than fifteen years, I have brought you together again to discuss with you what novelties, and what improvements it may be, the intervening time has introduced into psycho-analysis, it is right and fitting from more than one point of view that we should turn our attention first to the position of the theory of dreams. It occupies a special place in the history of psycho-analysis and marks a turning-point; it was with it that analysis took the step from being a psychotherapeutic procedure to being a depth-psychology. Since then, too, the theory of dreams has remained what is most characteristic and peculiar about the young science, something to which there is no counterpart in the rest of our knowledge, a stretch of new country, which has been reclaimed from popular beliefs and mysticism. The strangeness of the assertions it was obliged to put forward has made it play the part of a shibboleth, the use of which decided who could become a follower of psycho-analysis and to whom it remained forever incomprehensible. I myself found it a sheet-anchor during those difficult times when the unrecognized facts of the neuroses used to confuse my inexperienced judgement. Whenever I began to have doubts of the correctness of my wavering conclusions, the successful transformation of a senseless and muddled dream into a logical and intelligible mental process in the dreamer would renew my confidence of being on the right track.
But that is precisely what psycho-analysis is obliged to assert, and this is its second fundamental hypothesis. It explains the supposedly somatic concomitant phenomena as being what is truly psychical, and thus in the first instance disregards the quality of consciousness. It is not alone in doing this. Some thinkers (such as Theodor Lipps, for instance) have asserted the same thing in the same words; and the general dissatisfaction with the usual view of what is psychical has resulted in an increasingly urgent demand for the inclusion in psychological thought of a concept of the unconscious, though this demand has taken such an indefinite and obscure form that it could have no influence on science.

[1940a [1938], 4968]

Yet more than a century before the emergence of psycho-analysis the French philosopher Diderot bore witness to the importance of the Oedipus complex by expressing the difference between the primitive and civilized worlds in this sentence: 'Si le petit sauvage était abandonné à lui-même, qu'il conservât toute son imbécillité, et qu'il réunît au peu de raison de l'enfant au berceau la violence des passions de l'homme de trente ans, il tordrait le col à son père et coucherait avec sa mère.'² I venture to say that if psycho-analysis could boast of no other achievement than the discovery of the repressed Oedipus complex, that alone would give it a claim to be included among the precious new acquisitions of mankind.

[1940a [1938], 4999]

Here let us pause for a moment to assure the analyst that he has our sincere sympathy in the very exacting demands he has to fulfil in carrying out his activities. It almost looks as if analysis were the third of those 'impossible' professions in which one can be sure beforehand of achieving unsatisfying results. The other two, which have been known much longer, are education and government. Obviously we cannot demand that the prospective analyst should be a perfect being before he takes up analysis, in other words that only persons of such high and rare perfection should enter the profession. But where and how is the poor wretch to acquire the ideal qualifications which he will need in his profession? The answer is, in an analysis of himself, with which his preparation for his future activity begins. For practical reasons this analysis can only be short and incomplete. Its main object is to enable his teacher to make a judgement as to whether the candidate can be accepted for further training. It has accomplished its purpose if it gives the learner a firm conviction of the existence of the unconscious, if it enables him, when repressed material emerges, to perceive in himself things which would otherwise be incredible to him, and if it shows him a first sample of the technique which has proved to be the only effective one in analytic work. This alone would not suffice for his instruction; but we reckon on the stimuli that he has received in his own analysis not ceasing when it ends and on the processes of remodelling the ego continuing spontaneously in the analysed subject and making use of all subsequent experiences in this newly-acquired sense. This does in fact happen, and in so far as it happens it makes the analysed subject qualified to be an analyst himself.

[1937c, 5042]
Nor need it be supposed that this alternative view of the psychical is an innovation due to psycho-analysis. A German philosopher, Theodor Lipps, asserted with the greatest explicitness that the psychical is in itself unconscious and that the unconscious is the truly psychical. The concept of the unconscious has long been knocking at the gates of psychology and asking to be let in. Philosophy and literature have often toyed with it, but science could find no use for it. Psycho-analysis has seized upon the concept, has taken it seriously and has given it a fresh content. By its researches it has led to a knowledge of characteristics of the unconscious psychical which have hitherto been unsuspected, and it has discovered some of the laws which govern it. But none of this implies that the quality of being conscious has lost its importance for us. It remains the one light which illuminates our path and leads us through the darkness of mental life. In consequence of the special character of our discoveries, our scientific work in psychology will consist in translating unconscious processes into conscious ones, and thus filling in the gaps in conscious perception. . . .

[1940b [1938], 5071]
I can do no more in these brief hints than mention the chief factors on which the theory of the psychoneuroses is based: the deferred nature of the effect and the infantile state of the sexual apparatus and of the mental instrument. To reach a true understanding of the mechanism by which the psychoneuroses come about, a more extended exposition would be necessary. Above all, it would be indispensable to put forward as worthy of belief certain hypotheses, which seem to me to be new, about the composition and mode of operation of the psychical apparatus. In a book on the interpretation of dreams on which I am now engaged I shall find occasion to touch upon those fundamental elements of a psychology of the neuroses. For dreams belong to the same set of psychopathological structures as hysterical idées fixes, obsessions, and delusions.

[1897b, 473]

A second observation of Breuer's, again, compels us to attach great importance, among the characteristics of the pathological chain of events, to states of consciousness. Breuer's patient exhibited, alongside of her normal state, a number of mental peculiarities: conditions of 'absence', confusion, and alterations of character. In her normal state she knew nothing of the pathogenic scenes or their connection with her symptoms; she had forgotten the scenes, or at all events had severed the pathogenic link. When she was put under hypnosis, it was possible, at the expense of a considerable amount of labour, to recall the scenes to her memory; and, through this work of recollecting, the symptoms were removed. The explanation of this fact would be a most awkward business, were it not that the way is pointed by experiences and experiments in hypnotism. The study of hypnotic phenomena has accustomed us to what was at first a bewildering realization that in one and the same individual there can be several mental groupings, which can remain more or less independent of one another, which can 'know nothing' of one another and which can alternate with one another in their hold upon consciousness. Cases of this kind, too, occasionally appear spontaneously, and are then described as examples of 'double conscience'.¹ If, where a splitting of the personality such as this has occurred, consciousness remains attached regularly to one of the two states, we call it the conscious mental state and the other, which is detached from it, the unconscious one. In the familiar condition known as 'post-hypnotic suggestion', a command given under hypnosis is slavishly carried out subsequently in the normal state. This phenomenon affords an admirable example of the influences which the unconscious state can exercise over the conscious one; moreover, it provides a pattern upon which we can account for the phenomena of hysteria. Breuer adopted a hypothesis that hysterical symptoms arise in peculiar mental conditions to which he gave the name of 'hypnoid'. On this view, excitations occurring during these hypnoid states can easily become pathogenic because such states do not provide opportunities for the normal discharge of the process of excitation. There consequently arises from the process of excitation an unusual product - the symptom. This finds its way, like a foreign body, into the normal state, which in turn is in ignorance of the hypnoid pathogenic situation. Wherever there is a symptom there is also an amnesia, a gap in the memory, and filling up this gap implies the removal of the conditions which led to the production of the symptom.

[1910a, 2208]

Appropriate experiments have shown that people who are hysterically blind do nevertheless see in some sense, though not in the full sense. Excitations of the blind eye may have certain psychical consequences (for instance, they may produce affects) even though they do not become conscious. Thus hysterically blind people are only blind as far as consciousness is concerned; in their unconscious they see. It is precisely observations such as this that compel us to distinguish between conscious and unconscious mental processes.

[1910i, 2367]
If, Gentlemen, you complain of the obscurity of this exposition I shall not find it easy to defend. I have tried to give you a synthesis of the views of different investigators, and in doing so I have probably coupled them together too closely. I wanted to condense into a single composite whole the concepts that have been brought up to make psychogenic disturbances intelligible - their origin from excessively powerful ideas, the distinction between conscious and unconscious mental processes and the assumption of mental dissociation. And I have been no more successful in this than the French writers, at whose head stands Pierre Janet. I hope, therefore, that you will excuse not only the obscurity but the inaccuracy of my exposition, and will allow me to tell you how psycho-analysis has led us to a view of psychogenic disturbances of vision which is more self-consistent and probably closer to the facts.

The strange behaviour of patients, in being able to combine a conscious knowing with not knowing, remains inexplicable by what is called normal psychology. But to psycho-analysis, which recognizes the existence of the unconscious, it presents no difficulty. The phenomenon we have described, moreover, provides some of the best support for a view which approaches mental processes from the angle of topographical differentiation. The patients now know of the repressed experience in their conscious thought, but this thought lacks any connection with the place where the repressed recollection is in some way or other contained. No change is possible until the conscious thought-process has penetrated to that place and has overcome the resistances of repression there. It is just as though a decree were promulgated by the Ministry of Justice to the effect that juvenile delinquencies should be dealt with in a certain lenient manner. As long as this decree has not come to the knowledge of the local magistrates, or in the event of their not intending to obey it but preferring to administer justice by their own lights, no change can occur in the treatment of particular youthful delinquents. For the sake of complete accuracy, however, it should be added that the communication of repressed material to the patient's consciousness is nevertheless not without effect. It does not produce the hoped-for result of putting an end to the symptoms; but it has other consequences. At first it arouses resistances, but then, when these have been overcome, it sets up a process of thought in the course of which the expected influencing of the unconscious recollection eventually takes place.

In the psychology which is founded on psycho-analysis we have become accustomed to taking as our starting-point the unconscious mental processes, with the peculiarities of which we have become acquainted through analysis. We consider these to be the older, primary processes, the residues of a phase of development in which they were the only kind of mental process. The governing purpose obeyed by these primary processes is easy to recognize; it is described as the pleasure-unpleasure [Lust-Unlust] principle, or more shortly the pleasure principle. These processes strive towards gaining pleasure; psychical activity draws back from any event which might arouse unpleasure. (Here we have repression.) Our dreams at night and our waking tendency to tear ourselves away from distressing impressions are remnants of the dominance of this principle and proofs of its power.
It is not, of course, to be expected that either the primitive or the present-day concept of a 'soul' will be separated from that of the other portion of the personality by the same line of demarcation which our modern science draws between conscious and unconscious mental activity. The animistic soul unites properties from both sides. Its volatile and mobile quality, its power of leaving the body and of taking possession, temporarily or permanently, of another body - these are characteristics which remind us unmistakably of the nature of consciousness. But the way in which it remains concealed behind the manifest personality is reminiscent of the unconscious; immutability and indestructibility are qualities which we no longer attribute to conscious but rather to unconscious processes, and we regard the latter as the true vehicle of mental activity.

[1912-1913, 2736]

A study of the dream-work forces on us irresistibly a view of mental life which appears to decide the most controversial problems of psychology. The dream-work compels us to assume the existence of an unconscious psychical activity which is more comprehensive and more important than the familiar activity that is linked with consciousness. (I shall have some more to say on this point when I come to discuss the philosophical interest of psycho-analysis.) It enables us to dissect the psychical apparatus into a number of different agencies or systems, and shows us that in the system of unconscious mental activity processes operate which are of quite another kind from those perceived in consciousness.

[1913j, 2808]

As a psycho-analyst I am bound to be concerned more with emotional than intellectual processes, with unconscious than with conscious mental life. My emotion at meeting my old schoolmaster warns me to make a first admission: it is hard to decide whether what affected us more and was of greater importance to us was our concern with the sciences that we were taught or with the personalities of our teachers. It is true, at least, that this second concern was a perpetual undercurrent in all of us, and that in many of us the path to the sciences led only through our teachers. Some of us stopped half-way along that path, and for a few - why not admit as much? - it was on that account blocked for good and all.

[1914f, 2872]

It seems to us now that, in view of the very great extent to which repression and what is unconscious are correlated, we must defer probing more deeply into the nature of repression until we have learnt more about the structure of the succession of psychical agencies and about the differentiation between what is unconscious and conscious. Till then, all we can do is to put together in a purely descriptive fashion a few characteristics of repression that have been observed clinically, even though we run the risk of having to repeat unchanged much that has been said elsewhere.

[1915d, 2979]

In a patient of about twenty-one years of age the products of unconscious mental activity became conscious not only in obsessive thoughts but also in obsessive images. The two could accompany each other or appear independently. At one particular time, whenever he saw his father entering the room, there came into his mind in close connection an obsessive word and an obsessive image. The word was 'Vaterarsch' ['father-arse']; the accompanying image represented his father as the naked lower part of a body, provided with arms and legs, but without the head or upper part. The genitals were not indicated, and the facial features were painted on the abdomen.

[1916b, 3120]
But in thus emphasizing the unconscious in mental life we have conjured up the most evil spirits of criticism against psycho-analysis. Do not be surprised at this, and do not suppose that the resistance to us rests only on the understandable difficulty of the unconscious or the relative inaccessibility of the experiences which provide evidence of it. Its source, I think, lies deeper. In the course of centuries the naïve self-love of men has had to submit to two major blows at the hands of science. The first was when they learnt that our earth was not the centre of the universe but only a tiny fragment of a cosmic system of scarcely imaginable vastness. This is associated in our mind: with the name of Copernicus, though something similar had already been asserted by Alexandrian science. The second blow fell when biological research destroyed man's supposedly privileged place in creation and proved his descent from the animal kingdom and his ineradicable animal nature. This revaluation has been accomplished in our own days by Darwin, Wallace and their predecessors, though not without the most violent contemporary opposition. But human megalomania will have suffered its third and most wounding blow from the psychological research of the present time which seeks to prove to the ego that it is not even master in its own house, but must content itself with scanty information of what is going on unconsciously in its mind. We psycho-analysts were not the first and not the only ones to utter this call to introspection; but it seems to be our fate to give it its most forcible expression and to support it with empirical material which affects every individual. Hence arises the general revolt against our science, the disregard of all considerations of academic civility and the releasing of the opposition from every restraint of impartial logic. And beyond all this we have yet to disturb the peace of this world in still another way, as you will shortly hear.

I have credited you with a wish that I might have started my description of the neuroses from the behaviour of neurotic people, from an account of the manner in which they suffer under their neurosis, of how they defend themselves against it and how they come to terms with it. No doubt that is an interesting topic, worth investigating; nor would it be very difficult to handle. But it would be of debatable wisdom to start with it. There would be a risk of not discovering the unconscious and at the same time of overlooking the great importance of the libido and of judging everything as it appears to the ego of the neurotic subject. It is obvious that this ego is not a trustworthy or impartial agency. The ego is indeed the power which disavows the unconscious and has degraded it into being repressed; so how can we trust it to be fair to the unconscious? The most prominent elements in what is thus repressed are the repudiated demands of sexuality, and it is quite self-evident that we should never be able to guess their extent and importance from the ego's conceptions. From the moment the notion of repression dawns on us, we are warned against making one of the two contesting parties (and the victorious one, at that) into being judge in the dispute. We are prepared to find that the ego's assertions will lead us astray. If we are to believe the ego, it was active at every point and itself willed and created its symptoms. But we know that it puts up with a good amount of passivity, which it afterwards tries to disguise and gloss over. It is true that it does not always venture on such an attempt; in the symptoms of obsessional neurosis it is obliged to admit that there is something alien which is confronting it and against which it can only defend itself with difficulty.
The case itself was not a particularly favourable one. The advantage of having a wealth of information about the patient's childhood (an advantage which was made possible by the fact that the child could be studied through the medium of the adult) had to be purchased at the expense of the analysis being all terribly disjointed and of the exposition showing corresponding gaps. Personal peculiarities in the patient and a national character that was foreign to ours made the task of feeling one's way into his mind a laborious one. The contrast between the patient's agreeable and affable personality, his acute intelligence and his nicemindedness on the one hand, and his completely unbridled instinctual life on the other, necessitated an excessively long process of preparatory education, and this made a general perspective more difficult. But the patient himself has no responsibility for that feature of the case which put the severest obstacles in the way of any description of it. In the psychology of adults we have fortunately reached the point of being able to divide mental processes into conscious and unconscious and of being able to give a clearly-worded description of both. With children this distinction leaves us almost completely in the lurch. It is often embarrassing to decide what one would choose to call conscious and what unconscious. Processes which have become the dominant ones, and which from their subsequent behaviour must be equated with conscious ones, have nevertheless not been conscious in the child. It is easy to understand why. In children the conscious has not yet acquired all its characteristics; it is still in process of development, and it does not as yet fully possess the capacity for transposing itself into verbal images. We are constantly guilty of making a confusion between the phenomenon of emergence as a perception in consciousness and the fact of belonging to a hypothetical psychical system to which we ought to assign some conventional name, but which we in fact also call 'consciousness' (the system Cs.). This confusion does no harm when we are giving a psychological description of an adult, but it is misleading when we are dealing with that of a young child. Nor should we be much assisted here if we introduced the 'preconscious'; for a child's preconscious may, in just the same way, fail to coincide with an adult's. We must be content, therefore, with having clearly recognized the obscurity.

[1918b, 3582]

Probably very few people can have realized the momentous significance for science and life of the recognition of unconscious mental processes. It was not psycho-analysis, however, let us hasten to add, which first took this step. There are famous philosophers who may be cited as forerunners - above all the great thinker Schopenhauer, whose unconscious 'Will' is equivalent to the mental instincts of psycho-analysis. It was this same thinker, moreover, who in words of unforgettable impressiveness admonished mankind of the importance, still so greatly underestimated by it, of its sexual craving. Psycho-analysis has this advantage only, that it has not affirmed these two propositions which are so distressing to narcissism - the psychical importance of sexuality and the unconsciousness of mental life - on an abstract basis, but has demonstrated them in matters that touch every individual personally and force him to take up some attitude towards these problems. It is just for this reason, however, that it brings on itself the aversion and resistances which still hold back in awe before the great name of the philosopher.

[1917a, 3615]
For a time psycho-analysis seemed fated to merge into psychology without being able to show why the psychology of the sick differed from that of the normal. In the course of its advance, however, it came up against the problem of dreams, which are abnormal products of the mind created by normal men under regularly recurrent physiological conditions. When psycho-analysis had solved the problem of dreams, it had discovered in unconscious psychical processes the common ground in which the highest and the lowest of mental impulses have their roots and from which spring the most normal as well as the most morbid and erratic of mental productions. The new picture of the workings of the mind began to grow ever clearer and more complete. It was a picture of obscure instinctual forces organic in origin, striving towards inborn aims, and, above them, of an agency comprising more highly organized mental structures - acquisitions of human evolution made under the impact of human history - an agency which has taken over portions of the instinctual impulses, has developed them further or has even directed them towards higher aims, but which in any case binds them firmly and manipulates their energy to suit its own purposes. This higher organization, however, which is known to us as the ego, has rejected another portion of these same elementary instinctual impulses as being unserviceable because they cannot be fitted into the organic unity of the individual or because they rebel against the individual's cultural aims. The ego is not in a position to exterminate these unsubdued mental powers, but it turns its back on them, lets them remain at the lowest psychological level, defends itself from their demands by the energetic erection of protective and antithetical barriers or seeks to come to terms with them by means of substitutive satisfactions. These instincts which have fallen victim to repression - untamed and indestructible, yet inhibited from any kind of activity - together with their primitive mental representatives, constitute the mental underworld, the nucleus of the true unconscious, and are at every moment ready to assert their demands and, by hook or by crook, to force their way forward to satisfaction. To this is due the instability of the proud superstructure of the mind, the emergence at night of the proscribed and repressed material in the form of dreams, and the tendency to fall ill with neuroses and psychoses as soon as the balance of power between the ego and the repressed shifts to the disadvantage of the ego.

We have made use of Le Bon's description by way of introduction, because it fits in so well with our own psychology in the emphasis which it lays upon unconscious mental life. But we must now add that as a matter of fact none of that author's statements bring forward anything new. Everything that he says to the detriment and depreciation of the manifestations of the group mind had already been said by others before him with equal distinctness and equal hostility, and has been repeated in unison by thinkers, statesmen and writers since the earliest periods of literature.¹ The two theses which comprise the most important of Le Bon's opinions, those touching upon the collective inhibition of intellectual functioning and the heightening of affectivity in groups, had been formulated shortly before by Sighele.² At bottom, all that is left over as being peculiar to Le Bon are the two notions of the unconscious and of the comparison with the mental life of primitive people, and even these had naturally often been alluded to before him.

[1919g, 3703]

[1921c, 3777]
The Interpretation of Parapraxes and Haphazard Acts. - It was a triumph for the interpretative art of psycho-analysis when it succeeded in demonstrating that certain common mental acts of normal people, for which no one had hitherto attempted to put forward a psychological explanation, were to be regarded in the same light as the symptoms of neurotics: that is to say, they had a meaning, which was unknown to the subject but which could easily be discovered by analytic means. The phenomena in question were such events as the temporary forgetting of familiar words and names, forgetting to carry out prescribed tasks, everyday slips of the tongue and of the pen, misreadings, losses and mislayings of objects, certain errors, instances of apparently accidental self-injury, and finally habitual movements carried out seemingly without intention or in play, tunes hummed 'thoughtlessly', and so on. All of these were shorn of their physiological explanation, if any such had ever been attempted, were shown to be strictly determined and were revealed as an expression of the subject's suppressed intentions or as a result of a clash between two intentions one of which was permanently or temporarily unconscious. The importance of this contribution to psychology was of many kinds. The range of mental determinism was extended by it in an unforeseen manner; the supposed gulf between normal and pathological mental events was narrowed; in many cases a useful insight was afforded into the play of mental forces that must be suspected to lie behind the phenomena. Finally, a class of material was brought to light which is calculated better than any other to stimulate a belief in the existence of unconscious mental acts even in people to whom the hypothesis of something at once mental and unconscious seems strange and even absurd. The study of one's own parapraxes and haphazard acts, for which most people have ample opportunities, is even to-day the best preparation for an approach to psycho-analysis. In analytic treatment, the interpretation of parapraxes retains a place as a means of uncovering the unconscious, alongside the immeasurably more important interpretation of associations.

[1923a, 3917]

The division of the psychical into what is conscious and what is unconscious is the fundamental premiss of psycho-analysis; and it alone makes it possible for psycho-analysis to understand the pathological processes in mental life, which are as common as they are important, and to find a place for them in the framework of science. To put it once more, in a different way: psycho-analysis cannot situate the essence of the psychical in consciousness, but is obliged to regard consciousness as a quality of the psychical, which may be present in addition to other qualities or may be absent.

[1923b, 3947]

But we have arrived at the term or concept of the unconscious along another path, by considering certain experiences in which mental dynamics play a part. We have found - that is, we have been obliged to assume - that very powerful mental processes or ideas exist (and here a quantitative or economic factor comes into question for the first time) which can produce all the effects in mental life that ordinary ideas do (including effects that can in their turn become conscious as ideas), though they themselves do not become conscious. It is unnecessary to repeat in detail here what has been explained so often before. It is enough to say that at this point psycho-analytic theory steps in and asserts that the reason why such ideas cannot become conscious is that a certain force opposes them, that otherwise they could become conscious, and that it would then be apparent how little they differ from other elements which are admittedly psychical. The fact that in the technique of psycho-analysis a means has been found by which the opposing force can be removed and the ideas in question made conscious renders this theory irrefutable. The state in which the ideas existed before being made conscious is called by us repression, and we assert that the force which instituted the repression and maintains it is perceived as resistance during the work of analysis.

[1923b, 3948]
After hypnosis was replaced by the technique of free association, Breuer's cathartic procedure turned into psycho-analysis, which for more than a decade was developed by the author (Freud) alone. During that time psycho-analysis gradually acquired a theory which appeared to give a satisfactory account of the origin, meaning and purpose of neurotic symptoms and provided a rational basis for medical attempts at curing the complaint. I will once again enumerate the factors that go to make up this theory. They are: emphasis on instinctual life (affectivity), on mental dynamics, on the fact that even the apparently most obscure and arbitrary mental phenomena invariably have a meaning and a causation, the theory of psychical conflict and of the pathogenic nature of repression, the view that symptoms are substitutive satisfactions, the recognition of the aetiological importance of sexual life, and in particular of the beginnings of infantile sexuality. From a philosophical standpoint this theory was bound to adopt the view that the mental does not coincide with the conscious, that mental processes are in themselves unconscious and are only made conscious by the functioning of special organs (agencies or systems). By way of completing this list, I will add that among the affective attitudes of childhood the complicated emotional relation of children to their parents - what is known as the Oedipus complex - came into prominence. It became ever clearer that this was the nucleus of every case of neurosis, and in the patient's behaviour towards his analyst certain phenomena of his emotional transference emerged which came to be of great importance for theory and technique alike.

Evidence of its being of use for throwing light on other than pathological mental activity was early forthcoming in connection with two kinds of phenomena: with the very frequent parapraxes that occur in everyday life - such as forgetting things, slips of the tongue, and mislaying objects - and with the dreams dreamt by healthy and psychically normal people. Small failures of functioning, like the temporary forgetting of normally familiar proper names, slips of the tongue and of the pen, and so on, had hitherto not been considered worthy of any explanation at all or were supposed to be accounted for by conditions of fatigue, by distraction of the attention, etc. The present writer then showed from many examples, in his book The Psychopathology of Everyday Life (1901b), that events of this kind have a meaning, and arise owing to a conscious intention being interfered with by another, suppressed or actually unconscious one. As a rule, quick reflection or a short analysis is enough to reveal the interfering influence. Owing to the frequency of such parapraxes as slips of the tongue, it became easy for anyone to convince himself from his own experience of the existence of mental processes which are not conscious, but which are nevertheless operative and which at least find expression as inhibitions and modifications of other, intended acts.

Thus we may express our expectation that psycho-analysis, whose development and achievements hitherto have been briefly and inadequately related in these pages, will enter into the cultural development of the next decades as a significant ferment, and will help to deepen our understanding of the world and to fight against some things in life which are recognized as injurious. It must not be forgotten, however, that psycho-analysis alone cannot offer a complete picture of the world. If we accept the distinction which I have recently proposed of dividing the mental apparatus into an ego, turned towards the external world and equipped with consciousness, and an unconscious id, dominated by its instinctual needs, then psycho-analysis is to be described as a psychology of the id (and of its effects upon the ego). In each field of knowledge, therefore, it can make only contributions, which require to be completed from the psychology of the ego. If these contributions often contain the essence of the facts, this only corresponds to the important part which, it may be claimed, is played in our lives by the mental unconscious that has so long remained unknown.
What, then, can a philosopher say to a theory which, like psycho-analysis, asserts that on the contrary what is mental is in itself unconscious and that being conscious is only a quality, which may or may not accrue to a particular mental act and the withholding of which may perhaps alter that act in no other respect? He will naturally say that anything both unconscious and mental would be an impossibility, a *contradictio in adjecto*, and he will fail to observe that in making this judgement he is merely repeating his own definition of what is mental, a definition which may perhaps be too narrow. It is easy for philosophers to feel this certainty, since they have no acquaintance with the material whose investigation has compelled analysts to believe in unconscious mental acts. Philosophers have never taken account of hypnosis, they have not concerned themselves with the interpreting of dreams - on the contrary, like doctors, they regard dreams as the meaningless products of reduced mental activity during sleep - they are scarcely aware that there are such things as obsessions and delusions and they would find themselves in a most embarrassing situation if they were asked to explain them on the basis of their own psychological premisses. Analysts, too, refuse to say what the unconscious is, but they can indicate the domain of phenomena whose observation has obliged them to assume its existence. Philosophers, who know no kind of observation other than self-observation, cannot follow them into that domain.

[1925e, 4124]

This implied, of course, that I abandoned the treatment of organic nervous diseases; but that was of little importance. For on the one hand the prospects in the treatment of such disorders were in any case never promising, while, on the other hand, in the private practice of a physician working in a large town, the quantity of such patients was nothing compared to the crowds of neurotics, whose number seemed further multiplied by the way in which they hurried, with their troubles unsolved, from one physician to another. And, apart from this, there was something positively seductive in working with hypnotism. For the first time there was a sense of having overcome one's helplessness; and it was highly flattering to enjoy the reputation of being a miracle-worker. It was not until later that I was to discover the drawbacks of the procedure. At the moment there were only two points to complain of: first, that I could not succeed in hypnotizing every patient, and secondly, that I was unable to put individual patients into as deep a state of hypnosis as I should have wished. With the idea of perfecting my hypnotic technique, I made a journey to Nancy in the summer of 1889 and spent several weeks there. I witnessed the moving spectacle of old Liébeault working among the poor women and children of the labouring classes. I was a spectator of Bernheim's astonishing experiments upon his hospital patients, and I received the profoundest impression of the possibility that there could be powerful mental processes which nevertheless remained hidden from the consciousness of men. Thinking it would be instructive, I had persuaded one of my patients to follow me to Nancy. This patient was a very highly gifted hysterical, a woman of good birth, who had been handed over to me because no one knew what to do with her. By hypnotic influence I had made it possible for her to lead a tolerable existence and I was always able to take her out of the misery of her condition. But she always relapsed again after a short time, and in my ignorance I attributed this to the fact that her hypnosis had never reached the stage of somnambulism with amnesia. Bernheim now attempted several times to bring this about, but he too failed. He frankly admitted to me that his great therapeutic successes by means of suggestion were only achieved in his hospital practice and not with his private patients. I had many stimulating conversations with him, and undertook to translate into German his two works upon suggestion and its therapeutic effects.

[1925d, 4195]
But the study of pathogenic repressions and of other phenomena which have still to be mentioned compelled psycho-analysis to take the concept of the 'unconscious' seriously. Psycho-analysis regarded everything mental as being in the first instance unconscious; the further quality of 'consciousness' might also be present, or again it might be absent. This of course provoked a denial from the philosophers, for whom 'conscious' and 'mental' were identical, and who protested that they could not conceive of such an absurdity as the 'unconscious mental'. There was no help for it, however, and this idiosyncrasy of the philosophers could only be disregarded with a shrug. Experience (gained from pathological material, of which the philosophers were ignorant) of the frequency and power of impulses of which one knew nothing directly, and whose existence had to be inferred like some fact in the external world, left no alternative open. It could be pointed out, incidentally, that this was only treating one's own mental life as one had always treated other people's. One did not hesitate to ascribe mental processes to other people, although one had no immediate consciousness of them and could only infer them from their words and actions. But what held good for other people must be applicable to oneself. Anyone who tried to push the argument further and to conclude from it that one's own hidden processes belonged actually to a second consciousness would be faced with the concept of a consciousness of which one knew nothing, of an 'unconscious consciousness' - and this would scarcely be preferable to the assumption of an 'unconscious mental'. If on the other hand one declared, like some other philosophers, that one was prepared to take pathological phenomena into account, but that the processes underlying them ought not to be described as mental but as 'psychoid', the difference of opinion would degenerate into an unfruitful dispute about words, though even so expediency would decide in favour of keeping the expression 'unconscious mental'. The further question as to the ultimate nature of this unconscious is no more sensible or profitable than the older one as to the nature of the conscious.

[1925d, 4208]

The theories of resistance and of repression, of the unconscious, of the aetiological significance of sexual life and of the importance of infantile experiences - these form the principal constituents of the theoretical structure of psycho-analysis. In these pages, unfortunately, I have been able to describe only the separate elements and not their interconnections and their bearing upon one another. But I am obliged now to turn to the alterations which gradually took place in the technique of the analytic method.

[1925d, 4215]
For, whether a man is a homosexual or a necrophilic, a hysteric suffering from anxiety, an obsessionnal neurotic cut off from society, or a raving lunatic, the 'Individual Psychologist' of the Adlerian school will declare that the impelling motive of his condition is that he wishes to assert himself, to overcompensate for his inferiority, to remain 'on top', to pass from the feminine to the masculine line. In my young student days we used to hear something very much the same in the out-patients' department when a case of hysteria was introduced: hysterical patients, we were told, produce their symptoms to make themselves interesting, to draw attention to themselves. It is a remarkable thing how these ancient pieces of wisdom keep on cropping up. But even at that time this fragment of psychology did not seem to cover the riddle of hysteria. It left unexplained, for instance, why the patients used no other methods for attaining their purpose. There must, of course, be something correct in this theory of the 'Individual Psychologists': a small particle is taken for the whole. The self-preservative instinct will try to profit by every situation; the ego will seek to turn even illness to its advantage. In psycho-analysis this is known as the 'secondary gain from illness'. Though, indeed, when we think of the facts of masochism, of the unconscious need for punishment and of neurotic self-injury, which make plausible the hypothesis of there being instinctual impulses that run contrary to self-preservation, we even feel shaken in our belief in the general validity of the commonplace truth on which the theoretical structure of Individual Psychology is erected. But a theory such as this is bound to be very welcome to the great mass of the people, a theory which recognizes no complications, which introduces no new concepts that are hard to grasp, which knows nothing of the unconscious, which gets rid at a single blow of the universally oppressive problem of sexuality and which restricts itself to the discovery of the artifices by which people seek to make life easy. For the mass of the people themselves take things easily: they call for no more than a single reason by way of explanation, they do not thank science for its diffuseness, they want to have simple solutions and to know that problems are solved. When we consider how very far Individual Psychology goes in meeting these demands, we cannot suppress the recollection of a sentence in Wallenstein:

[1933a, 4743]

The difference between whether a psychical process is conscious or unconscious has served us as a criterion and a means of finding our bearings. The repressed is unconscious. Now it would simplify things agreeably if this sentence admitted of reversal - if, that is, the difference between the qualities of conscious (Cs.) and unconscious (Ucs.) coincided with the distinction between 'belonging to the ego' and 'repressed'. The fact of there being isolated and unconscious things like this in our mental life would be sufficiently novel and important. But in reality the position is more complicated. It is true that everything repressed is unconscious, but it is not true that everything belonging to the ego is conscious. We notice that consciousness is a transient quality which attaches to a psychical process only in passing. For our purposes therefore we must replace 'conscious' by 'capable of being conscious' and we call this quality 'preconscious' (Pcs.). We then say, more correctly, that the ego is mainly preconscious (virtually conscious) but that portions of the ego are unconscious.

[1939a, 4918]

But that is precisely what psycho-analysis is obliged to assert, and this is its second fundamental hypothesis. It explains the supposedly somatic concomitant phenomena as being what is truly psychical, and thus in the first instance disregards the quality of consciousness. It is not alone in doing this. Some thinkers (such as Theodor Lipps, for instance) have asserted the same thing in the same words; and the general dissatisfaction with the usual view of what is psychical has resulted in an increasingly urgent demand for the inclusion in psychological thought of a concept of the unconscious, though this demand has taken such an indefinite and obscure form that it could have no influence on science.

[1940a [1938], 4968]
Every science is based on observations and experiences arrived at through the medium of our psychical apparatus. But since our science has as its subject that apparatus itself, the analogy ends here. We make our observations through the medium of the same perceptual apparatus, precisely with the help of the breaks in the sequence of 'psychical' events: we fill in what is omitted by making plausible inferences and translating it into conscious material. In this way we construct, as it were, a sequence of conscious events complementary to the unconscious psychical processes. The relative certainty of our psychical science is based on the binding force of these inferences. Anyone who enters deeply into our work will find that our technique holds its ground against any criticism.

In the course of this work the distinctions which we describe as psychical qualities force themselves on our notice. There is no need to characterize what we call 'conscious': it is the same as the consciousness of philosophers and of everyday opinion. Everything else psychical is in our view 'the unconscious'. We are soon led to make an important division in this unconscious. Some processes become conscious easily; they may then cease to be conscious, but can become conscious once more without any trouble: as people say, they can be reproduced or remembered. This reminds us that consciousness is in general a highly fugitive state. What is conscious is conscious only for a moment. If our perceptions do not confirm this, the contradiction is only an apparent one; it is explained by the fact that the stimuli which lead to perception may persist for considerable periods, so that meanwhile the perception of them may be repeated. The whole position is made clear in connection with the conscious perception of our thought-processes: these too may persist for some time, but they may just as well pass in a flash. Everything unconscious that behaves in this way, that can thus easily exchange the unconscious state for the conscious one, is therefore preferably described as 'capable of becoming conscious' or as preconscious. Experience has taught us that there is hardly a psychical process, however complicated it may be, which cannot on occasion remain preconscious, even though as a rule it will, as we say, push its way forward into consciousness. There are other psychical processes and psychical material which have no such easy access to becoming conscious but must be inferred, recognized and translated into conscious form in the manner described. For such material we reserve the name of the unconscious proper.

Here let us pause for a moment to assure the analyst that he has our sincere sympathy in the very exacting demands he has to fulfil in carrying out his activities. It almost looks as if analysis were the third of those 'impossible' professions in which one can be sure beforehand of achieving unsatisfying results. The other two, which have been known much longer, are education and government. Obviously we cannot demand that the prospective analyst should be a perfect being before he takes up analysis, in other words that only persons of such high and rare perfection should enter the profession. But where and how is the poor wretch to acquire the ideal qualifications which he will need in his profession? The answer is, in an analysis of himself, with which his preparation for his future activity begins. For practical reasons this analysis can only be short and incomplete. Its main object is to enable his teacher to make a judgement as to whether the candidate can be accepted for further training. It has accomplished its purpose if it gives the learner a firm conviction of the existence of the unconscious, if it enables him, when repressed material emerges, to perceive in himself things which would otherwise be incredible to him, and if it shows him a first sample of the technique which has proved to be the only effective one in analytic work. This alone would not suffice for his instruction; but we reckon on the stimuli that he has received in his own analysis not ceasing when it ends and on the processes of remodelling the ego continuing spontaneously in the analysed subject and making use of all subsequent experiences in this newly-acquired sense. This does in fact happen, and in so far as it happens it makes the analysed subject qualified to be an analyst himself.
Psycho-analysis escaped such difficulties as these by energetically denying the equation between what is psychical and what is conscious. No; being conscious cannot be the essence of what is psychical. It is only a quality of what is psychical, and an inconstant quality at that - one that is far oftener absent than present. The psychical, whatever its nature may be, is in itself unconscious and probably similar in kind to all the other natural processes of which we have obtained knowledge.

[1940b [1938], 5068]

In the second place, I shall pick a single instance to represent an immensely large class of phenomena.¹ The President of a public body (the Lower House of the Austrian Parliament) on one occasion opened a sitting with the following words: 'I take notice that a full quorum of members is present and herewith declare the sitting closed.' It was a slip of the tongue - for there can be no doubt that what the President intended to say was 'opened'. Why, then, did he say the opposite? We shall expect to be told it was an accidental mistake, a failure in carrying out an intention such as may easily happen for various reasons: it had no meaning - and in any case contraries are particularly easily substituted for each other. If, however, we bear in mind the situation in which the slip of the tongue occurred, we shall be inclined to prefer another explanation. Many of the previous sittings of the House had been disagreeably stormy and had accomplished nothing, so that it would be only too natural for the President to think at the moment of making his opening statement: 'If only the sitting that's just beginning were finished! I would much rather be closing then opening it!' When he began to speak he was probably not aware of this wish - it was not conscious to him - but it was certainly present and it succeeded in making itself effective, against the speaker's will, in his apparent mistake. A single instance can scarcely enable us to decide between two such different explanations. But what if every other instance of a slip of the tongue could be explained in the same way, and similarly every slip of the pen, every case of mis-reading or mis-hearing, and every faulty action? What if in all those instances (one might actually say, without a single exception) it was possible to demonstrate the presence of a psychical act - a thought, a wish or an intention - which would account for the apparent mistake and which was unconscious at the moment at which it became effective, even though it may have been conscious previously? If that were so, it would really no longer be possible to dispute the fact that psychical acts which are unconscious do exist and that they are even sometimes active while they are unconscious and that in that case they can even sometimes get the better of conscious intentions. The person concerned in a mistake of this kind can react to it in various ways. He may overlook it completely or he may notice it himself and become embarrassed and ashamed. He cannot as a rule find the explanation of it himself without outside help; and he often refuses to accept the solution when it is put before him - for a time, at all events.

[1940b [1938], 5069]

The question of the relation of the conscious to the psychical may now be regarded as settled: consciousness is only a quality or attribute of what is psychical, and moreover an inconstant one. But there is one further objection with which we have to deal. We are told that, in spite of the facts that have been mentioned, there is no necessity to abandon the identity between what is conscious and what is psychical: the so-called unconscious psychical processes are the organic processes which have long been recognized as running parallel to the mental ones. This, of course, would reduce our problem to an apparently indifferent matter of definition. Our reply is that it would be unjustifiable and inexpedient to make a breach in the unity of mental life for the sake of propping up a definition, since it is clear in any case that consciousness can only offer us an incomplete and broken chain of phenomena. And it can scarcely be a matter of chance that it was not until the change had been made in the definition of the psychical that it became possible to construct a comprehensive and coherent theory of mental life.

[1940b [1938], 5071]
A study of the dream-work forces on us irresistibly a view of mental life which appears to
decide the most controversial problems of psychology. The dream-work compels us to assume
the existence of an unconscious psychical activity which is more comprehensive and more
important than the familiar activity that is linked with consciousness. (I shall have some more to
say on this point when I come to discuss the philosophical interest of psycho-analysis.) It
enables us to dissect the psychical apparatus into a number of different agencies or systems,
and shows us that in the system of unconscious mental activity processes operate which are of
quite another kind from those perceived in consciousness.
[1913j, 2808]

By accepting the existence of these two (or three) psychical systems, psycho-analysis has
departed a step further from the descriptive 'psychology of consciousness' and has raised new
problems and acquired a new content. Up till now, it has differed from that psychology mainly by
reason of its dynamic view of mental processes; now in addition it seems to take account of
psychical topography as well, and to indicate in respect of any given mental act within what
system or between what systems it takes place. On account of this attempt, too, it has been
given the name of 'depth-psychology'. We shall hear that it can be further enriched by taking yet
another point of view into account.
[1915e, 2997]

These lectures were delivered in 1916 and 1917; they gave a fairly accurate account of the
position of the young science at that period and they contained more than their title indicated.
They provided not only an introduction to psycho-analysis but covered the greater part of its
subject-matter. This is naturally no longer true. Advances have in the meantime taken place in
its theory and important additions have been made to it, such as the division of the personality
into an ego, a super-ego and an id, a radical alteration in the theory of the instincts, and
discoveries concerning the origin of conscience and the sense of guilt. These lectures have thus
become to a large extent incomplete; it is in fact only now that they have become truly
'introductory'. But in another sense, even to-day they have not been superseded or become
obsolete. What they contain is still believed and taught, apart from a few modifications, in
psycho-analytic training schools.
[1916-1917, 3127]

Although thus humbled in his external relations, man feels himself to be supreme within his
own mind. Somewhere in the core of his ego he has developed an organ of observation to keep
a watch on his impulses and actions and see whether they harmonize with its demands. If they
do not, they are ruthlessly inhibited and withdrawn. His internal perception, consciousness,
gives the ego news of all the important occurrences in the mind's working, and the will, directed
by these reports, carries out what the ego orders and modifies anything that seeks to
accomplish itself spontaneously. For this mind is not a simple thing; on the contrary, it is a
hierarchy of superordinated and subordinated agencies, a labyrinth of impulses striving
independently of one another towards action, corresponding with the multiplicity of instincts and
of relations with the external world, many of which are antagonistic to one another and
incompatible. For proper functioning it is necessary that the highest of these agencies should
have knowledge of all that is going forward and that its will should penetrate everywhere, so as
to exert its influence. And in fact the ego feels secure both as to the completeness and
trustworthiness of the reports it receives and as to the openness of the channels through which
it enforces its commands.
[1917a, 3612]
We have already said that, if the differentiation we have made of the mind into an id, an ego, and a super-ego represents any advance in our knowledge, it ought to enable us to understand more thoroughly the dynamic relations within the mind and to describe them more clearly. We have also already concluded that the ego is especially under the influence of perception, and that, speaking broadly, perceptions may be said to have the same significance for the ego as instincts have for the id. At the same time the ego is subject to the influence of the instincts, too, like the id, of which it is, as we know, only a specially modified part.

[1923b, 3974]

It is natural that we should turn with interest to enquire whether there may not be instructive connections to be traced between the structures we have assumed to exist - the ego, the super-ego and the id - on the one hand and the two classes of instincts on the other; and, further, whether the pleasure principle which dominates mental processes can be shown to have any constant relation both to the two classes of instincts and to these differentiations which we have drawn in the mind. But before we discuss this, we must clear away a doubt which arises concerning the terms in which the problem itself is stated. There is, it is true, no doubt about the pleasure principle, and the differentiation within the ego has good clinical justification; but the distinction between the two classes of instincts does not seem sufficiently assured and it is possible that facts of clinical analysis may be found which will do away with its pretension.

[1923b, 3976]

The aetiology common to the onset of a psychoneurosis and of a psychosis always remains the same. It consists in a frustration, a non-fulfilment of one of those childhood wishes which are for ever undefeated and which are so deeply rooted in our phylogenetically determined organization. This frustration is in the last resort always an external one; but in the individual case it may proceed from the internal agency (in the super-ego) which has taken over the representation of the demands of reality. The pathogenic effect depends on whether, in a conflictual tension of this kind, the ego remains true to its dependence on the external world and attempts to silence the id, or whether it lets itself be overcome by the id and thus torn away from reality. A complication is introduced into this apparently simple situation, however, by the existence of the super-ego, which, though a link that is not yet clear to us, unites in itself influences coming from the id as well as from the external world, and is to some extent an ideal model of what the whole endeavour of the ego is aiming at - a reconciliation between its various dependent relationships. The attitude of the super-ego should be taken into account - which has not hitherto been done - in every form of psychical illness. We may provisionally assume that there must also be illnesses which are based on a conflict between the ego and the super-ego. Analysis gives us a right to suppose that melancholia is a typical example of this group; and we would set aside the name of 'narcissistic psychoneuroses' for disorders of that kind. Nor will it clash with our impressions if we find reasons for separating states like melancholia from the other psychoses. We now see that we have been able to make our simple genetic formula more complete, without dropping it. Transference neuroses correspond to a conflict between the ego and the id; narcissistic neuroses, to a conflict between the ego and the super-ego; and psychoses, to one between the ego and the external world. It is true that we cannot tell at once whether we have really gained any new knowledge by this, or have only enriched our store of formulas; but I think that this possible application of the proposed differentiation of the mental apparatus into an ego, a super-ego and an id cannot fail to give us courage to keep that hypothesis steadily in view.

[1924b, 4067]
Thus we may express our expectation that psycho-analysis, whose development and achievements hitherto have been briefly and inadequately related in these pages, will enter into the cultural development of the next decades as a significant ferment, and will help to deepen our understanding of the world and to fight against some things in life which are recognized as injurious. It must not be forgotten, however, that psycho-analysis alone cannot offer a complete picture of the world. If we accept the distinction which I have recently proposed of dividing the mental apparatus into an ego, turned towards the external world and equipped with consciousness, and an unconscious id, dominated by its instinctual needs, then psycho-analysis is to be described as a psychology of the id (and of its effects upon the ego). In each field of knowledge, therefore, it can make only contributions, which require to be completed from the psychology of the ego. If these contributions often contain the essence of the facts, this only corresponds to the important part which, it may be claimed, is played in our lives by the mental unconscious that has so long remained unknown.

[1924f, 4118]

It would be more difficult to explain concisely how it came about that psycho-analysis made a further distinction in the unconscious, and separated it into a preconscious and an unconscious proper. It will be sufficient to say that it appeared a legitimate course to supplement the theories that were a direct expression of experience with hypotheses that were designed to facilitate the handling of the material and related to matters which could not be a subject of immediate observation. The very same procedure is adopted by the older sciences. The subdivision of the unconscious is part of an attempt to picture the apparatus of the mind as being built up of a number of agencies or systems whose relations to one another are expressed in spatial terms, without, however, implying any connection with the actual anatomy of the brain. (I have described this as the topographical method of approach.) Such ideas as these are part of a speculative superstructure of psycho-analysis, any portion of which can be abandoned or changed without loss or regret the moment its inadequacy has been proved. But there is still plenty to be described that lies closer to actual experience.

[1925d, 4208]

I had already made attempts at earlier stages of my work to arrive at some more general points of view on the basis of psycho-analytic observation. In a short essay, 'Formulations on the Two Principles of Mental Functioning', I drew attention (and there was, of course, nothing original in this) to the domination of the pleasure-unpleasure principle in mental life and to its displacement by what is called the reality principle. Later on I made an attempt to produce a 'Metapsychology'. By this I meant a method of approach according to which every mental process is considered in relation to three co-ordinates, which I described as dynamic, topographical, and economic respectively; and this seemed to me to represent the furthest goal that psychology could attain. The attempt remained no more than a torso; after writing two or three papers - 'Instincts and their Vicissitudes', 'Repression', 'The Unconscious', 'Mourning and Melancholia', etc. - I broke off, wisely perhaps, since the time for theoretical predications of this kind had not yet come. In my latest speculative works I have set about the task of dissecting our mental apparatus on the basis of the analytic view of pathological facts and have divided it into an ego, an id, and a super-ego.¹ The super-ego is the heir of the Oedipus complex and represents the ethical standards of mankind.

[1925d, 4234]
Shortly before I wrote this study it seemed as though my life would soon be brought to an end by the recurrence of a malignant disease; but surgical skill saved me in 1923 and I was able to continue my life and my work, though no longer in freedom from pain. In the period of more than ten years that has passed since then, I have never ceased my analytic work nor my writing - as is proved by the completion of the twelfth volume of the German edition of my collected works. But I myself find that a significant change has come about. Threads which in the course of my development had become intertangled have now begun to separate; interests which I had acquired in the later part of my life have receded, while the older and original ones become prominent once more. It is true that in this last decade I have carried out some important pieces of analytic work, such as the revision of the problem of anxiety in my book *Inhibitions, Symptoms and Anxiety* (1926d) or the simple explanation of sexual ‘fetishism’ which I was able to make a year later (1927e). Nevertheless it would be true to say that, since I put forward my hypothesis of the existence of two classes of instinct (Eros and the death instinct) and since I proposed a division of the mental personality into an ego, a super-ego, and an id (1923b), I have made no further decisive contributions to psycho-analysis: what I have written on the subject since then has been either unessential or would soon have been supplied by someone else. This circumstance is connected with an alteration in myself, with what might be described as a phase of regressive development. My interest, after making a lifelong détour through the natural sciences, medicine and psychotherapy, returned to the cultural problems which had fascinated me long before, when I was a youth scarcely old enough for thinking. At the very climax of my psycho-analytic work, in 1912, I had already attempted in *Totem and Taboo* to make use of the newly discovered findings of analysis in order to investigate the origins of religion and morality. I now carried this work a stage further in two later essays, *The Future of an Illusion* (1927c) and *Civilization and its Discontents* (1930a). I perceived ever more clearly that the events of human history, the interactions between human nature, cultural development and the precipitates of primateval experiences (the most prominent example of which is religion) are no more than a reflection of the dynamic conflicts between the ego, the id and the super-ego, which psycho-analysis studies in the individual - are the very same processes repeated upon a wider stage. In *The Future of an Illusion* I expressed an essentially negative valuation of religion. Later, I found a formula which did better justice to it: while granting that its power lies in the truth which it contains, I showed that that truth was not a material but a historical truth.

¹ Since the differentiation of the ego and the id, our interest in the problems of repression, too, was bound to receive a fresh impetus. Up till then we had been content to confine our interest to those aspects of repression which concerned the ego - the keeping away from consciousness and from motility, and the formation of substitutes (symptoms). With regard to the repressed instincual impulses themselves, we assumed that they remained unaltered in the unconscious for an indefinite length of time. But now our interest is turned to the vicissitudes of the repressed and we begin to suspect that it is not self-evident, perhaps not even usual, that those impulses should remain unaltered and unalterable in this way. There is no doubt that the original impulses have been inhibited and deflected from their aim through repression. But has the portion of them in the unconscious maintained itself and been proof against the influences of life that tend to alter and depreciate them? In other words, do the old wishes, about whose former existence analysis tells us, still exist? The answer seems ready to hand and certain. It is that the old, repressed wishes must still be present in the unconscious since we still find their derivatives, the symptoms, in operation. But this answer is not sufficient. It does not enable us to decide between two possibilities: either that the old wish is now operating only through its derivatives, having transferred the whole of its cathetic energy to them, or that it is itself still in existence too. If its fate has been to exhaust itself in cathecting its derivatives, there is yet a third possibility. In the course of the neurosis it may have become re-animated by regression, anachronistic though it may now be. These are no idle speculations. There are many things about mental life, both normal and pathological, which seem to call for the raising of such questions. In my paper, ‘The Dissolution of the Oedipus Complex’ (1924d), I had occasion to notice the difference between the mere repression and the real removal of an old wishful impulse.

[1925d, 4244]

[1926d, 4297]
It will soon be clear what the mental apparatus is; but I must beg you not to ask what material it is constructed of. That is not a subject of psychological interest. Psychology can be as indifferent to it as, for instance, optics can be to the question of whether the walls of a telescope are made of metal or cardboard. We shall leave entirely on one side the material line of approach, but not so the spatial one. For we picture the unknown apparatus which serves the activities of the mind as being really like an instrument constructed of several parts (which we speak of as 'agencies'), each of which performs a particular function and which have a fixed spatial relation to one another; it being understood that by spatial relation - 'in front of' and 'behind', 'superficial' and 'deep' - we merely mean in the first instance a representation of the regular succession of the functions. Have I made myself clear?

Topographically, psycho-analysis regards the mental apparatus as a compound instrument, and endeavours to determine at what points in it the various mental processes take place. According to the most recent psycho-analytic views, the mental apparatus is composed of an 'id', which is the repository of the instinctual impulses, of an 'ego', which is the most superficial portion of the id and one which has been modified by the influence of the external world, and of a 'super-ego', which develops out of the id, dominates the ego and represents the inhibitions of instinct that are characteristic of man. The quality of consciousness, too, has a topographical reference; for processes in the id are entirely unconscious, while consciousness is the function of the ego's outermost layer, which is concerned with the perception of the external world.

You will admit, I hope, that so far that is not too bad and allows of convenient handling. Yes, but unluckily the work of psycho-analysis has found itself compelled to use the word 'unconscious' in yet another, third, sense, and this may, to be sure, have led to confusion. Under the new and powerful impression of there being an extensive and important field of mental life which is normally withdrawn from the ego's knowledge so that the processes occurring in it have to be regarded as unconscious in the truly dynamic sense, we have come to understand the term 'unconscious' in a topographical or systematic sense as well; we have come to speak of a 'system' of the preconscious and a 'system' of the unconscious, of a conflict between the ego and the system Ucs, and have used the word more and more to denote a mental province rather than a quality of what is mental. The discovery, actually an inconvenient one, that portions of the ego and super-ego as well are unconscious in the dynamic sense, operates at this point as a relief - it makes possible the removal of a complication. We perceive that we have no right to name the mental region that is foreign to the ego 'the system Ucs', since the characteristic of being unconscious is not restricted to it. Very well; we will no longer use the term 'unconscious' in the systematic sense and we will give what we have hitherto so described a better name and one no longer open to misunderstanding. Following a verbal usage of Nietzsche's and taking up a suggestion by Georg Groddeck, we will in future call it the 'id'. This impersonal pronoun seems particularly well suited for expressing the main characteristic of this province of the mind - the fact of its being alien to the ego. The super-ego, the ego and the id - these, then, are the three realms, regions, provinces, into which we divide an individual's mental apparatus, and with the mutual relations of which we shall be concerned in what follows.
We can best arrive at the characteristics of the actual ego, in so far as it can be distinguished from the id and from the super-ego, by examining its relation to the outermost superficial portion of the mental apparatus, which we describe as the system \( \text{Pcpt.-Cs.} \). This system is turned towards the external world, it is the medium for the perceptions arising thence, and during its functioning the phenomenon of consciousness arises in it. It is the sense-organ of the entire apparatus; moreover it is receptive not only to excitations from outside but also to those arising from the interior of the mind. We need scarcely look for a justification of the view that the ego is that portion of the id which was modified by the proximity and influence of the external world, which is adapted for the reception of stimuli and as a protective shield against stimuli, comparable to the cortical layer by which a small piece of living substance is surrounded. The relation to the external world has become the decisive factor for the ego; it has taken on the task of representing the external world to the id - fortunately for the id, which could not escape destruction if, in its blind efforts for the satisfaction of its instincts, it disregarded that supreme external power. In accomplishing this function, the ego must observe the external world, must lay down an accurate picture of it in the memory-traces of its perceptions, and by its exercise of the function of 'reality-testing' must put aside whatever in this picture of the external world is an addition derived from internal sources of excitation. The ego controls the approaches to motility under the id's orders; but between a need and an action it has interposed a postponement in the form of the activity of thought, during which it makes use of the mnemic residues of experience. In that way it has dethroned the pleasure principle which dominates the course of events in the id without any restriction and has replaced it by the reality principle, which promises more certainty and greater success.

[1933a, 4684]

And here is another warning, to conclude these remarks, which have certainly been exacting and not, perhaps, very illuminating. In thinking of this division of the personality into an ego, a super-ego and an id, you will not, of course, have pictured sharp frontiers like the artificial ones drawn in political geography. We cannot do justice to the characteristics of the mind by linear outlines like those in a drawing or in primitive painting, but rather by areas of colour melting into one another as they are presented by modern artists. After making the separation we must allow what we have separated to merge together once more. You must not judge too harshly a first attempt at giving a pictorial representations of something so intangible as psychical processes. It is highly probable that the development of these divisions is subject to great variations in different individuals; it is possible that in the course of actual functioning they may change and go through a temporary phase of involution. Particularly in the case of what is phylogenetically the last and most delicate of these divisions - the differentiation between the ego and the super-ego - something of the sort seems to be true. There is no question but that the same thing results from psychical illness. It is easy to imagine, too, that certain mystical practices may succeed in upsetting the normal relations between the different regions of the mind, so that, for instance, perception may be able to grasp happenings in the depths of the ego and in the id which were otherwise inaccessible to it. It may safely be doubted, however, whether this road will lead us to the ultimate truths from which salvation is to be expected. Nevertheless it may be admitted that the therapeutic efforts of psycho-analysis have chosen a similar line of approach. Its intention is, indeed, to strengthen the ego, to make it more independent of the super-ego, to widen its field of perception and enlarge its organization, so that it can appropriate fresh portions of the id. Where id was, there ego shall be. It is a work of culture - not unlike the draining of the Zuider Zee.

[1933a, 4687]
Ladies and Gentlemen, the dissection of the mental personality into a super-ego, an ego and an id, which I put before you in my last lecture, has obliged us to take our bearings afresh in the problem of anxiety as well. With the thesis that the ego is the sole seat of anxiety - that the ego alone can produce and feel anxiety - we have established a new and stable position from which a number of things take on a new aspect. And indeed it is difficult to see what sense there would be in speaking of an 'anxiety of the id' or in attributing a capacity for apprehensiveness to the super-ego. On the other hand, we have welcomed a desirable element of correspondence in the fact that the three main species of anxiety, realistic, neurotic and moral, can be so easily connected with the ego's three dependent relations - to the external world, to the id and to the super-ego. Along with this new view, moreover, the function of anxiety as a signal announcing a situation of danger (a notion, incidentally, not unfamiliar to us) comes into prominence, the question of what the material is out of which anxiety is made loses interest, and the relations between realistic and neurotic anxiety have become surprisingly clarified and simplified. It is also to be remarked that we now understand the apparently complicated cases of the generation of anxiety better than those which were considered simple.

[1933a, 4692]

The establishment of this latter fact shows us that the qualities on which we have hitherto relied are insufficient to give us our bearings in the obscurity of mental life. We must introduce another distinction which is no longer qualitative but topographical and - what gives it special value - at the same time genetic. We now distinguish in our mental life (which we regard as an apparatus compounded of several agencies, districts or provinces) one region which we call the ego proper and another which we name the id. The id is the older of the two; the ego has developed out of it, like a cortical layer, through the influence of the external world. It is in the id that all our primary instincts are at work, all the processes in the id take place unconsciously. The ego, as we have already said, coincides with the region of the preconscious; it includes portions which normally remain unconscious. The course of events in the id, and their mutual interaction, are governed by quite other laws than those prevailing in the ego. It is in fact the discovery of these differences that has led to our new view and justifies it.

[1939a, 4919]

Having now decided upon the topographical dissection of the psychical apparatus into an ego and an id, with which the difference in quality between preconscious and unconscious runs parallel, and having agreed that this quality is to be regarded only as an indication of the difference and not as its essence, a further question faces us. What, if this is so, is the true nature of the state which is revealed in the id by the quality of being unconscious and in the ego by that of being preconscious and in what does the difference between them consist?

[1940a [1938], 4973]
In yet another group of cases the distinguishing characteristics of the ego, which are to be held responsible as sources of resistance against analytic treatment and as impediments to therapeutic success, may spring from different and deeper roots. Here we are dealing with the ultimate things which psychological research can learn about: the behaviour of the two primal instincts, their distribution, mingling and defusion - things which we cannot think of as being confined to a single province of the mental apparatus, the id, the ego or the super-ego. No stronger impression arises from the resistances during the work of analysis than of there being a force which is defending itself by every possible means against recovery and which is absolutely resolved to hold on to illness and suffering. One portion of this force has been recognized by us, undoubtedly with justice, as the sense of guilt and need for punishment, and has been localized by us in the ego's relation to the super-ego. But this is only the portion of it which is, as it were, psychically bound by the super-ego and thus becomes recognizable; other quotas of the same force, whether bound or free, may be at work in other, unspecified places. If we take into consideration the total picture made up of the phenomena of masochism immanent in so many people, the negative therapeutic reaction and the sense of guilt found in so many neurotics, we shall no longer be able to adhere to the belief that mental events are exclusively governed by the desire for pleasure. These phenomena are unmistakable indications of the presence of a power in mental life which we call the instinct of aggression or of destruction according to its aims, and which we trace back to the original death instinct of living matter. It is not a question of an antithesis between an optimistic and a pessimistic theory of life. Only by the concurrent or mutually opposing action of the two primal instincts - Eros and the death instinct -, never by one or the other alone, can we explain the rich multiplicity of the phenomena of life. [1937c, 5037]
This extension of the libido theory - in my opinion, a legitimate one - receives reinforcement from a third quarter, namely, from our observations and views on the mental life of children and primitive peoples. In the latter we find characteristics which, if they occurred singly, might be put down to megalomania: an over-estimation of the power of their wishes and mental acts, the 'omnipotence of thoughts', a belief in the thaumaturgic force of words, and a technique for dealing with the external world - 'magic' - which appears to be a logical application of these grandiose premisses.¹ In the children of to-day, whose development is much more obscure to us, we expect to find an exactly analogous attitude towards the external world.² Thus we form the idea of there being an original libidinal cathexis of the ego, from which some is later given off to objects, but which fundamentally persists and is related to the object-cathexes much as the body of an amoeba is related to the pseudopodia which it puts out. In our researches, taking, as they did, neurotic symptoms for their starting-point, this part of the allocation of libido necessarily remained hidden from us at the outset. All that we noticed were the emanations of this libido - the object-cathexes, which can be sent out and drawn back again. We see also, broadly speaking, an antithesis between ego-libido and object-libido. The more of the one is employed, the more the other becomes depleted. The highest phase of development of which object-libido is capable is seen in the state of being in love, when the subject seems to give up his own personality in favour of an object-cathexis; while we have the opposite condition in the paranoid's phantasy (or self-perception) of the 'end of the world'.³ Finally, as regards the differentiation of psychical energies, we are led to the conclusion that to begin with, during the state of narcissism, they exist together and that our analysis is too coarse to distinguish between them; not until there is object-cathexis is it possible to discriminate a sexual energy - the libido - from an energy of the ego-instincts.

[1914c, 2933]

Before going any further I must touch on two questions which lead us to the heart of the difficulties of our subject. In the first place, what is the relation of the narcissism of which we are now speaking to auto-erotism, which we have described as an early state of the libido? Secondly, if we grant the ego a primary cathexis of libido, why is there any necessity for further distinguishing a sexual libido from a non-sexual energy of the ego-instincts? Would not the postulation of a single kind of psychical energy save us all the difficulties of differentiating an energy of the ego-instincts from ego-libido, and ego-libido from object-libido?

[1914c, 2934]
I try in general to keep psychology clear from everything that is different in nature from it, even biological lines of thought. For that very reason I should like at this point expressly to admit that the hypothesis of separate ego-instincts and sexual instincts (that is to say, the libido theory) rests scarcely at all upon a psychological basis, but derives its principal support from biology. But I shall be consistent enough to drop this hypothesis if psycho-analytic work should itself produce some other, more serviceable hypothesis about the instincts. So far, this has not happened. It may turn out that, most basically and on the longest view, sexual energy - libido - is only the product of a differentiation in the energy at work generally in the mind. But such an assertion has no relevance. It relates to matters which are so remote from the problems of our observation, and of which we have so little cognizance, that it is as idle to dispute it as to affirm it; this primal identity may well have as little to do with our analytic interests as the primal kinship of all the races of mankind has to do with the proof of kinship required in order to establish a legal right of inheritance. All these speculations take us nowhere. Since we cannot wait for another science to present us with the final conclusions on the theory of the instincts, it is far more to the purpose that we should try to see what light may be thrown upon this basic problem of biology by a synthesis of the psychological phenomena. Let us face the possibility of error; but do not let us be deterred from pursuing the logical implications of the hypothesis we first adopted of an antithesis between ego-instincts and sexual instincts (a hypothesis to which we were forcibly led by analysis of the transference neuroses), and from seeing whether it turns out to be without contradictions and fruitful, and whether it can be applied to other disorders as well, such as schizophrenia.

Recognition of Two Classes of Instincts in Mental Life. - Though psycho-analysis endeavours as a rule to develop its theories as independently as possible from those of other sciences, it is nevertheless obliged to seek a basis for the theory of the instincts in biology. On the ground of a far-reaching consideration of the processes which go to make up life and which lead to death, it becomes probable that we should recognize the existence of two classes of instincts, corresponding to the contrary processes of construction and dissolution in the organism. On this view, the one set of instincts, which work essentially in silence, would be those which follow the aim of leading the living creature to death and therefore deserve to be called the 'death instincts'; these would be directed outwards as the result of the combination of numbers of unicellular elementary organisms, and would manifest themselves as destructiveness or aggressive impulses. The other set of instincts would be those which are better known to us in analysis - the libidinal, sexual or life instincts, which are best comprised under the name of Eros; their purpose would be to form living substance into ever greater unities, so that life may be prolonged and brought to higher development. The erotic instincts and the death instincts would be present in living beings in regular mixtures or fusions; but 'defusions' would also be liable to occur. Life would consist in the manifestations of the conflict or interaction between the two classes of instincts; death would mean for the individual the victory of the destructive instincts, but reproduction would mean for him the victory of Eros.

The Nature of the Instincts. - This view would enable us to characterize instincts as tendencies inherent in living substance towards restoring an earlier state of things: that is to say, they would be historically determined and of a conservative nature and, as it were, the expression of an inertia or elasticity present in what is organic. Both classes of instincts, Eros as well as the death instinct, would, on this view, have been in operation and working against each other from the first origin of life.
I have lately developed a view of the instincts¹ which I shall here hold to and take as the basis of my further discussions. According to this view we have to distinguish two classes of instincts, one of which, the sexual instincts or Eros, is by far the more conspicuous and accessible to study. It comprises not merely the uninhibited sexual instinct proper and the instinctual impulses of an aim-inhibited or sublimated nature derived from it, but also the self-preservative instinct, which must be assigned to the ego and which at the beginning of our analytic work we had good reason for contrasting with the sexual object-instincts. The second class of instincts was not so easy to point to; in the end we came to recognize sadism as its representative. On the basis of theoretical considerations, supported by biology, we put forward the hypothesis of a death instinct, the task of which is to lead organic life back into the inanimate state; on the other hand, we supposed that Eros, by bringing about a more and more far-reaching combination of the particles into which living substance is dispersed, aims at complicating life and at the same time, of course, at preserving it. Acting in this way, both the instincts would be conservative in the strictest sense of the word, since both would be endeavouring to re-establish a state of things that was disturbed by the emergence of life. The emergence of life would thus be the cause of the continuance of life and also at the same time of the striving towards death; and life itself would be a conflict and compromise between these two trends. The problem of the origin of life would remain a cosmological one; and the problem of the goal and purpose of life would be answered dualistically.

[1923b, 3974]

It is natural that we should turn with interest to enquire whether there may not be instructive connections to be traced between the structures we have assumed to exist - the ego, the super-ego and the id - on the one hand and the two classes of instincts on the other; and, further, whether the pleasure principle which dominates mental processes can be shown to have any constant relation both to the two classes of instincts and to these differentiations which we have drawn in the mind. But before we discuss this, we must clear away a doubt which arises concerning the terms in which the problem itself is stated. There is, it is true, no doubt about the pleasure principle, and the differentiation within the ego has good clinical justification; but the distinction between the two classes of instincts does not seem sufficiently assured and it is possible that facts of clinical analysis may be found which will do away with its pretension.

[1923b, 3976]

Thus masochism appears to us in the light of a great danger, which is in no way true of its counterpart, sadism. We are tempted to call the pleasure principle the watchman over our life rather than merely over our mental life. But in that case we are faced with the task of investigating the relationship of the pleasure principle to the two classes of instincts which we have distinguished - the death instincts and the erotic (libidinal) life instincts; and we cannot proceed further in our consideration of the problem of masochism till we have accomplished that task.

[1924c, 4071]
The inadequacy of this explanation is seen, however, in the fact that it throws no light on the regular and close connections of masochism with its counterpart in instinctual life, sadism. If we go back a little further, to our hypothesis of the two classes of instincts which we regard as operative in the living organism, we arrive at another derivation of masochism, which, however, is not in contradiction with the former one. In (multicellular) organisms the libido meets the instinct of death, or destruction, which is dominant in them and which seeks to disintegrate the cellular organism and to conduct each separate unicellular organism into a state of inorganic stability (relative though this may be). The libido has the task of making the destroying instinct innocuous, and it fulfills the task by diverting that instinct to a great extent outwards - soon with the help of a special organic system, the muscular apparatus - towards objects in the external world. The instinct is then called the destructive instinct, the instinct for mastery, or the will to power. A portion of the instinct is placed directly in the service of the sexual function, where it has an important part to play. This is sadism proper. Another portion does not share in this transposition outwards; it remains inside the organism and, with the help of the accompanying sexual excitation described above, becomes libidinally bound there. It is in this portion that we have to recognize the original, erotogenic masochism.

But the opponents of psycho-analysis forgot its illustrious forerunners; they fell upon it as though it had made an assault upon the dignity of the human race. They accused it of 'pan-sexualism', though the psycho-analytic theory of the instincts had always been strictly dualistic and had at no time failed to recognize, alongside the sexual instincts, others to which it actually ascribed force enough to suppress the sexual instincts. (These mutually opposing forces were described to begin with as the sexual instincts and the ego instincts. A later theoretical development changed them into Eros and the instinct of death or destruction.) The suggestion that art, religion and social order originated in part in a contribution from the sexual instincts was represented by the opponents of analysis as a degradation of the highest cultural values. They emphatically declared that men have other interests besides this eternal one of sex, overlooking in their zeal the fact that animals too have other interests - indeed they are subject to sexuality, not permanently like men, but only in bouts occurring at specific periods - overlooking, too, the fact that the existence of these other interests in men had never been disputed and that nothing can be altered in the value of a cultural achievement by its being shown to have been derived from elementary animal instinctual sources.

The study of judgement affords us, perhaps for the first time, an insight into the origin of an intellectual function from the interplay of the primary instinctual impulses. Judging is a continuation, along lines of expediency, of the original process by which the ego took things into itself or expelled them from itself, according to the pleasure principle. The polarity of judgement appears to correspond to the opposition of the two groups of instincts which we have supposed to exist. Affirmation - as a substitute for uniting - belongs to Eros; negation - the successor to expulsion - belongs to the instinct of destruction. The general wish to negate, the negativism which is displayed by some psychotics, is probably to be regarded as a sign of a defusion of instincts that has taken place through a withdrawal of the libidinal components. But the performance of the function of judgement is not made possible until the creation of the symbol of negation has endowed thinking with a first measure of freedom from the consequences of repression and, with it, from the compulsion of the pleasure principle.
In the works of my later years (Beyond the Pleasure Principle, Group Psychology and the Analysis of the Ego, and The Ego and the Id), I have given free rein to the inclination, which I kept down for so long, to speculation, and I have also contemplated a new solution of the problem of the instincts. I have combined the instincts for self-preservation and for the preservation of the species under the concept of Eros and have contrasted with it an instinct of death or destruction which works in silence. Instinct in general is regarded as a kind of elasticity of living things, an impulsion towards the restoration of a situation which once existed but was brought to an end by some external disturbance. This essentially conservative character of instincts is exemplified by the phenomena of the compulsion to repeat. The picture which life presents to us is the result of the concurrent and mutually opposing action of Eros and the death instinct.

Shortly before I wrote this study it seemed as though my life would soon be brought to an end by the recurrence of a malignant disease; but surgical skill saved me in 1923 and I was able to continue my life and my work, though no longer in freedom from pain. In the period of more than ten years that has passed since then, I have never ceased my analytic work nor my writing - as is proved by the completion of the twelfth volume of the German edition of my collected works. But I myself find that a significant change has come about. Threads which in the course of my development had become intertangled have now begun to separate; interests which I had acquired in the later part of my life have receded, while the older and original ones become prominent once more. It is true that in this last decade I have carried out some important pieces of analytic work, such as the revision of the problem of anxiety in my book Inhibitions, Symptoms and Anxiety (1926d) or the simple explanation of sexual ‘fetishism’ which I was able to make a year later (1927e). Nevertheless it would be true to say that, since I put forward my hypothesis of the existence of two classes of instinct (Eros and the death instinct) and since I proposed a division of the mental personality into an ego, a super-ego, and an id (1923b), I have made no further decisive contributions to psycho-analysis: what I have written on the subject since then has been either unessential or would soon have been supplied by someone else. This circumstance is connected with an alteration in myself, with what might be described as a phase of regressive development. My interest, after making a lifelong détour through the natural sciences, medicine and psychotherapy, returned to the cultural problems which had fascinated me long before, when I was a youth scarcely old enough for thinking. At the very climax of my psycho-analytic work, in 1912, I had already attempted in Totem and Taboo to make use of the newly discovered findings of analysis in order to investigate the origins of religion and morality. I now carried this work a stage further in two later essays, The Future of an Illusion (1927c) and Civilization and its Discontents (1930a). I perceived ever more clearly that the events of human history, the interactions between human nature, cultural development and the precipitates of primeval experiences (the most prominent example of which is religion) are no more than a reflection of the dynamic conflicts between the ego, the id and the super-ego, which psycho-analysis studies in the individual - are the very same processes repeated upon a wider stage. In The Future of an Illusion I expressed an essentially negative valuation of religion. Later, I found a formula which did better justice to it: while granting that its power lies in the truth which it contains, I showed that that truth was not a material but a historical truth.

[1925d, 4232]
It is almost humiliating that, after working so long, we should still be having difficulty in understanding the most fundamental facts. But we have made up our minds to simplify nothing and to hide nothing. If we cannot see things clearly we will at least see clearly what the obscurities are. What is hampering us here is evidently some hitch in the development of our theory of the instincts. We began by tracing the organization of the libido through its successive stages - from the oral through the sadistic-anal to the genital - and in doing so placed all the components of the sexual instinct on the same footing. Later it appeared that sadism was the representative of another instinct, which was opposed to Eros. This new view, that the instincts fall into two groups, seems to explode the earlier construction of the successive stages of libidinal organization. But we do not have to break fresh ground in order to find a way out of the difficulty. The solution has been at hand for a long time and lies in the fact that what we are concerned with are scarcely ever pure instinctual impulses but mixtures in various proportions of the two groups of instincts. If this is so, there is no need to revise our view of the organizations of the libido. A sadistic cathexis of an object may also legitimately claim to be treated as a libidinal one; and an aggressive impulse against the father can just as well be subjected to repression as a tender impulse towards the mother. Nevertheless we shall bear in mind for future consideration the possibility that repression is a process which has a special relation to the genital organization of the libido and that the ego resorts to other methods of defence when it has to secure itself against the libido on other levels of organization. To continue: a case like 'Little Hans's' does not enable us to come to any clear conclusion. It is true that in him an aggressive impulse was disposed of by repression, but this happened after the genital organization had been reached.

From the first of these standpoints, the dynamic one, psycho-analysis derives all mental processes (apart from the reception of external stimuli) from the interplay of forces, which assist or inhibit one another, combine with one another, enter into compromises with one another, etc. All of these forces are originally in the nature of instincts; thus they have an organic origin. They are characterized by possessing an immense (somatic) store of power ('the compulsion to repeat'); and they are represented mentally as images or ideas with an affective charge. In psycho-analysis, no less than in other sciences, the theory of the instincts is an obscure subject. An empirical analysis leads to the formulation of two groups of instincts: the so-called 'ego-instincts', which are directed towards self-preservation, and the 'object-instincts', which are concerned with relations to an external object. The social instincts are not regarded as elementary or irreducible. Theoretical speculation leads to the suspicion that there are two fundamental instincts which lie concealed behind the manifest ego-instincts and object-instincts: namely (a) Eros, the instinct which strives for ever closer union, and (b) the instinct of destruction, which leads towards the dissolution of what is living. In psycho-analysis the manifestation of the force of Eros is given the name 'libido'.

[1926d, 4282]

[1926f, 4403]
Every analyst will admit that even to-day this view has not the sound of a long-discarded error. Nevertheless, alterations in it became essential, as our enquiries advanced from the repressed to the repressing forces, from the object-instincts to the ego. The decisive step forward was the introduction of the concept of narcissism - that is to say, the discovery that the ego itself is cathedgcd with libido, that the ego, indeed, is the libido's original home, and remains to some extent its headquarters. This narcissistic libido turns towards objects, and thus becomes object-libido; and it can change back into narcissistic libido once more. The concept of narcissism made it possible to obtain an analytic understanding of the traumatic neuroses and of many of the affections bordering on the psychoses, as well as of the latter themselves. It was not necessary to give up our interpretation of the transference neuroses as attempts made by the ego to defend itself against sexuality; but the concept of libido was endangered. Since the ego-instincts, too, were libidinal, it seemed for a time inevitable that we should make libido coincide with instinctual energy in general, as C. G. Jung had already advocated earlier. Nevertheless, there still remained in me a kind of conviction, for which I was not as yet able to find reasons, that the instincts could not all be of the same kind. My next step was taken in _Beyond the Pleasure Principle_ (1920g), when the compulsion to repeat and the conservative character of instinctual life first attracted my attention. Starting from speculations on the beginning of life and from biological parallels, I drew the conclusion that, besides the instinct to preserve living substance and to join it into ever larger units,¹ there must exist another, contrary instinct seeking to dissolve those units and to bring them back to their primaeval, inorganic state. That is to say, as well as Eros there was an instinct of death. The phenomena of life could be explained from the concurrent or mutually opposing action of these two instincts. It was not easy, however, to demonstrate the activities of this supposed death instinct. The manifestations of Eros were conspicuous and noisy enough. It might be assumed that the death instinct operated silently within the organism towards its dissolution, but that, of course, was no proof. A more fruitful idea was that a portion of the instinct is diverted towards the external world and comes to light as an instinct of aggressiveness and destructiveness. In this way the instinct itself could be pressed into the service of Eros, in that the organism was destroying some other thing, whether animate or inanimate, instead of destroying its own self. Conversely, any restriction of this aggressiveness directed outwards would be bound to increase the self-destruction, which is in any case proceeding. At the same time one can suspect from this example that the two kinds of instinct seldom - perhaps never - appear in isolation from each other, but are alloyed with each other in varying and very different proportions and so become unrecognizable to our judgement. In sadism, long since known to us as a component instinct of sexuality, we should have before us a particularly strong alloy of this kind between trends of love and the destructive instinct; while its counterpart, masochism, would be a union between destructiveness directed inwards and sexuality - a union which makes what is otherwise an imperceptible trend into a conspicuous and tangible one.

[1930a, 4509]
We did not maintain this position for long. Our feeling of their being a contrariety in instinctual life soon found another and sharper expression. It is not my wish, however, to put before you the origin of this novelty in the theory of the instincts; it too is based essentially on biological considerations. I shall offer it to you as a ready-made product. Our hypothesis is that there are two essentially different classes of instincts: the sexual instincts, understood in the widest sense - Eros, if you prefer that name - and the aggressive instincts, whose aim is destruction. When it is put to you like this, you will scarcely regard it as a novelty. It looks like an attempt at a theoretical transfiguration of the commonplace opposition between loving and hating, which coincides, perhaps, with the other polarity, of attraction and repulsion, which physics assumes in the inorganic world. But it is a remarkable thing that this hypothesis is nevertheless felt by many people as an innovation and, indeed, as a most undesirable one which should be got rid of as quickly as possible. I presume that a strong affective factor is coming into effect in this rejection. Why have we ourselves needed such a long time before we decided to recognize an aggressive instinct? Why did we hesitate to make use, on behalf of our theory, of facts which were obvious and familiar to everyone? We should probably have met with little resistance if we had wanted to ascribe an instinct with such an aim to animals. But to include it in the human constitution appears sacrilegious; it contradicts too many religious presumptions and social conventions. No, man must be naturally good or at least good-natured. If he occasionally shows himself brutal, violent or cruel, these are only passing disturbances of his emotional life, for the most part provoked, or perhaps only consequences of the inexpedient social regulations which he has hitherto imposed on himself.

[1933a, 4707]

It is our opinion, then, that in sadism and in masochism we have before us two excellent examples of a mixture of the two classes of instinct, of Eros and aggressiveness; and we proceed to the hypothesis that this relation is a model one - that every instinctual impulse that we can examine consists of similar fusions or alloys of the two classes of instinct. These fusions, of course, would be in the most varied ratios. Thus the erotic instincts would introduce the multiplicity of their sexual aims into the fusion, while the others would only admit of mitigations or gradations in their monotonous trend. This hypothesis opens a prospect to us of investigations which may some day be of great importance for the understanding of pathological processes. For fusions may also come apart, and we may expect that functioning will be most gravely affected by defusions of such a kind. But these conceptions are still too new; no one has yet tried to apply them in our work.

[1933a, 4708]

But how can this conservative characteristic of instincts help us to understand our self-destructiveness? What earlier state of things does an instinct such as this want to restore? Well, the answer is not far to seek and opens wide perspectives. If it is true that - at some immeasurably remote time and in a manner we cannot conceive - life once proceeded out of inorganic matter, then, according to our presumption, an instinct must have arisen which sought to do away with life once more and to re-establish the inorganic state. If we recognize in this instinct the self-destructiveness of our hypothesis, we may regard the self-destructiveness as an expression of a 'death instinct' which cannot fail to be present in every vital process. And now the instincts that we believe in divide themselves into two groups - the erotic instincts, which seek to combine more and more living substance into ever greater unities, and the death instincts, which oppose this effort and lead what is living back into an inorganic state. From the concurrent and opposing action of these two proceed the phenomena of life which are brought to an end by death.

[1933a, 4711]
You may perhaps shrug your shoulders and say: 'That isn't natural science, it's Schopenhauer's philosophy!' But, Ladies and Gentlemen, why should not a bold thinker have guessed something that is afterwards confirmed by sober and painstaking detailed research? Moreover, there is nothing that has not been said already, and similar things had been said by many people before Schopenhauer. Furthermore, what we are saying is not even genuine Schopenhauer. We are not asserting that death is the only aim of life; we are not overlooking the fact that there is life as well as death. We recognize two basic instincts and give each of them its own aim. How the two of them are mingled in the process of living, how the death instinct is made to serve the purposes of Eros, especially by being turned outwards as aggressiveness - these are tasks which are left to future investigation. We have not gone beyond the point at which this prospect lies open before us. The question, too, of whether the conservative character may not belong to all instincts without exception, whether the erotic instincts as well may not be seeking to bring back an earlier state of things when they strive to bring about a synthesis of living things into greater unities - this question, too, we must leave unanswered.

[1933a, 4711]

According to our hypothesis human instincts are of only two kinds: those which seek to preserve and unite - which we call 'erotic', exactly in the sense in which Plato uses the word 'Eros' in his Symposium, or 'sexual', with a deliberate extension of the popular conception of 'sexuality' - and those which seek to destroy and kill and which we group together as the aggressive or destructive instinct. As you see, this is in fact no more than a theoretical clarification of the universally familiar opposition between Love and Hate which may perhaps have some fundamental relation to the polarity of attraction and repulsion that plays a part in your own field of knowledge. But we must not be too hasty in introducing ethical judgements of good and evil. Neither of these instincts is any less essential than the other; the phenomena of life arise from the concurrent or mutually opposing action of both. Now it seems as though an instinct of the one sort can scarcely ever operate in isolation; it is always accompanied - or, as we say, alloyed - with a certain quota from the other side, which modifies its aim or is, in some cases, what enables it to achieve that aim. Thus, for instance, the instinct of self-preservation is certainly of an erotic kind, but it must nevertheless have aggressiveness at its disposal if it is to fulfil its purpose. So, too, the instinct of love, when it is directed towards an object, stands in need of some contribution from the instinct for mastery if it is in any way to obtain possession of that object. The difficulty of isolating the two classes of instinct in their actual manifestations is indeed what has so long prevented us from recognizing them.

[1933b, 4798]
The forces which we assume to exist behind the tensions caused by the needs of the id are called **instincts**. They represent the somatic demands upon the mind. Though they are the ultimate cause of all activity, they are of a conservative nature; the state, whatever it may be, which an organism has reached gives rise to a tendency to re-establish that state so soon as it has been abandoned. It is thus possible to distinguish an indeterminate number of instincts, and in common practice this is in fact done. For us, however, the important question arises whether it may not be possible to trace all these numerous instincts back to a few basic ones. We have found that instincts can change their aim (by displacement) and also that they can replace one another - the energy of one instinct passing over to another. This latter process is still insufficiently understood. After long hesitancies and vacillations we have decided to assume the existence of only two basic instincts, **Eros** and the **destructive instinct**. (The contrast between the instincts of self-preservation and the preservation of the species, as well as the contrast between ego-love and object-love, fall within Eros.) The aim of the first of these basic instincts is to establish ever greater unities and to preserve them thus - in short, to bind together; the aim of the second is, on the contrary, to undo connections and so to destroy things. In the case of the destructive instinct we may suppose that its final aim is to lead what is living into an inorganic state. For this reason we also call it the **death instinct**. If we assume that living things came later than inanimate ones and arose from them, then the death instinct fits in with the formula we have proposed to the effect that instincts tend towards a return to an earlier state. In the case of Eros (or the love instinct) we cannot apply this formula. To do so would presuppose that living substance was once a unity which had later been torn apart and was now striving towards reunion.¹

[1940a [1938], 4959]

In yet another group of cases the distinguishing characteristics of the ego, which are to be held responsible as sources of resistance against analytic treatment and as impediments to therapeutic success, may spring from different and deeper roots. Here we are dealing with the ultimate things which psychological research can learn about: the behaviour of the two primal instincts, their distribution, mingling and defusion - things which we cannot think of as being confined to a single province of the mental apparatus, the id, the ego or the super-ego. No stronger impression arises from the resistances during the work of analysis than of there being a force which is defending itself by every possible means against recovery and which is absolutely resolved to hold on to illness and suffering. One portion of this force has been recognized by us, undoubtedly with justice, as the sense of guilt and need for punishment, and has been localized by us in the ego's relation to the super-ego. But this is only the portion of it which is, as it were, psychically bound by the super-ego and thus becomes recognizable; other quotas of the same force, whether bound or free, may be at work in other, unspecified places. If we take into consideration the total picture made up of the phenomena of masochism immanent in so many people, the negative therapeutic reaction and the sense of guilt found in so many neurotics, we shall no longer be able to adhere to the belief that mental events are exclusively governed by the desire for pleasure. These phenomena are unmistakable indications of the presence of a power in mental life which we call the instinct of aggression or of destruction according to its aims, and which we trace back to the original death instinct of living matter. It is not a question of an antithesis between an optimistic and a pessimistic theory of life. Only by the concurrent or mutually opposing action of the two primal instincts - Eros and the death instinct -, never by one or the other alone, can we explain the rich multiplicity of the phenomena of life.

[1937c, 5037]
How parts of these two classes of instincts combine to fulfil the various vital functions, under what conditions such combinations grow looser or break up, to what disturbances these changes correspond and with what feelings the perceptual scale of the pleasure principle replies to them - these are problems whose elucidation would be the most rewarding achievement of psychological research. For the moment we must bow to the superiority of the forces against which we see our efforts come to nothing. Even to exert a psychical influence on simple masochism is a severe tax upon our powers.

[1937c, 5038]

If we recognize the case we are discussing as an expression of the destructive or aggressive instinct, the question at once arises whether this view should not be extended to other instances of conflict, and, indeed, whether all that we know about psychical conflict should not be revised from this new angle. After all, we assume that in the course of man's development from a primitive state to a civilized one his aggressiveness undergoes a very considerable degree of internalization or turning inwards; if so, his internal conflicts would certainly be the proper equivalent for the external struggles which have then ceased. I am well aware that the dualistic theory according to which an instinct of death or of destruction or aggression claims equal rights as a partner with Eros as manifested in the libido, has found little sympathy and has not really been accepted even among psycho-analysts. This made me all the more pleased when not long ago I came upon this theory of mine in the writings of one of the great thinkers of ancient Greece. I am very ready to give up the prestige of originality for the sake of such a confirmation, especially as I can never be certain, in view of the wide extent of my reading in early years, whether what I took for a new creation might not be an effect of cryptomnesia.

[1937c, 5038]

The two fundamental principles of Empedocles - φιλία and υεῖκος - are, both in name and function, the same as our two primal instincts, Eros and destructiveness, the first of which endeavours to combine what exists into ever greater unities, while the second endeavours to dissolve those combinations and to destroy the structures to which they have given rise. We shall not be surprised, however, to find that, on its re-emergence after two and a half millennia, this theory has been altered in some of its features. Apart from the restriction to the biophysical field which is imposed on us, we no longer have as our basic substances the four elements of Empedocles; what is living has been sharply differentiated from what is inanimate, and we no longer think of the mingling and separation of particles of substance, but of the soldering together and defusion of instinctual components. Moreover, we have provided some sort of biological basis for the principle of 'strife' by tracing back our instinct of destruction to the death instinct, to the urge of what is living to return to an inanimate state. This is not to deny that an analogous instinct already existed earlier, nor, of course, to assert that an instinct of this sort only came into existence with the emergence of life. And no one can foresee in what guise the nucleus of truth contained in the theory of Empedocles will present itself to later understanding.

[1937c, 5040]
Some notable discoveries have been made in the course of this investigation of the infantile mind. Thus it has been possible to confirm, what has often already been suspected, the extraordinarily important influence exerted by the impressions of childhood (and particularly by its earliest years) on the whole course of later development. This brings us up against a psychological paradox - which for psycho-analysts alone is no paradox - that it is precisely these most important of all impressions that are not remembered in later years. Psycho-analysis has been able to establish the decisive and indestructible character of these earliest experiences in the clearest possible way in the case of sexual life. ‘On revient toujours à ses premiers amours’ is sober truth. The many riddles in the sexual life of adults can only be solved if stress is laid on the infantile factors in love. Theoretical light is thrown on their influence by the consideration that an individual's first experiences in childhood do not occur only by chance but also correspond to the first activities of his innate or constitutional instinctual dispositions.

There is no need to feel surprised, therefore, if, in a large number of people, dreams disclose their wish to get rid of their parents and especially of the parent of their own sex. We may assume that this wish is also present in waking life and is even conscious sometimes, if it can be masked by some other motive, as was the case with our dreamer in Example 3, where it was replaced by pity for his father's useless sufferings. It is rarely that the hostility alone dominates the relationship; far oftener it is in the background of more affectionate impulses by which it is suppressed, and it must wait until a dream isolates it, as it were. What seems to us of enormous size in a dream, on account of this isolation, shrinks up once more when our interpretation has given it its place in the context of real life (Hanns Sachs). But we come upon this dream-wish, too, where it has no relevance in real life, and where the adult need never confess to it in his waking life. The reason for this is that the deepest and most invariable motive for estrangement, especially between two people of the same sex, has already made itself felt in early childhood.

A disturbance of memory of this kind is enough for obsessional neurosis; but the case is different with hysteria. As a rule the latter neurosis is marked by amnesias on a really large scale. In analysing each separate hysterical symptom one is usually led to a whole chain of impressions of events, which, when they recur, are expressly described by the patient as having been till then forgotten. On the one hand, this chain reaches back to the earliest years of life, so that the hysterical amnesia can be recognized as an immediate continuation of the infantile amnesia which, for us normal people, conceals the beginnings of our mental life. On the other hand, we learn with astonishment that even the patient's most recent experiences can be subject to forgetting, and that the occasions which precipitated the outbreak of the illness or led to its intensification are in particular encroached upon, if not completely swallowed up, by amnesia. It regularly happens that important details have disappeared from the total picture of a recent recollection of this sort or that they have been replaced by falsifications of memory. Indeed it happens with almost equal regularity that certain memories of recent experiences only emerge shortly before the end of an analysis - memories which had been held back till that late moment and had left perceptible gaps in the continuity of the case.

[1913], 2819

[1916-1917, 3295]

[1916-1917, 3360]
Now it is a very noteworthy fact that the sexual instincts and the self-preservative instincts do not behave in the same way towards real necessity. The self-preservative instincts, and everything to do with them, are much easier to educate: they learn early to comply with necessity and to arrange their developments in accordance with the instructions of reality. This is intelligible, since they could not obtain the objects they need in any other way; and without those objects the individual would inevitably perish. The sexual instincts are harder to educate, for at first they have no need of an object. Since they are attached like parasites, as it were, to the other bodily functions, and find their satisfaction auto-erotically on the subject's own body, they are to begin with withdrawn from the educative influence of real necessity, and they retain this characteristic of being self-willed and inaccessible to influence (what we describe as being 'unreasonable') in most people in some respect all through their lives. Moreover, as a rule the educability of a youthful individual is at an end when his sexual needs arise in their full strength. Educators are aware of this and act accordingly; but the findings of psycho-analysis may perhaps also induce them to shift the main impact of education on to the earliest years of childhood, from infancy onwards. The little creature is often completed by the fourth or fifth year of life, and after that merely brings gradually to light what is already within him.

The two other doubts are based on a low estimate of the importance of early infantile impressions and an unwillingness to ascribe such enduring effects to them. The supporters of this view look for the causes of neuroses almost exclusively in the grave conflicts of later life; they assume that the importance of childhood is only held up before our eyes in analysis on account of the inclination of neurotics for expressing their present interests in reminiscences and symbols from the remote past. Such an estimate of the importance of the infantile factor would involve the disappearance of much that has formed part of the most intimate characteristics of analysis, though also, no doubt, of much that raises resistance to it and alienates the confidence of the outsider.

The view, then, that we are putting up for discussion is as follows. It maintains that scenes from early infancy, such as are brought up by an exhaustive analysis of neuroses (as, for instance, in the present case), are not reproductions of real occurrences, to which it is possible to ascribe an influence over the course of the patient's later life and over the formation of his symptoms. It considers them rather as products of the imagination, which find their instigation in mature life, which are intended to serve as some kind of symbolic representation of real wishes and interests, and which owe their origin to a regressive tendency, to a turning-away from the tasks of the present. If that is so, we can of course spare ourselves the necessity of attributing such a surprising amount to the mental life and intellectual capacity of children of the tenderest age.

Strictly considered - and why should this question not be considered with all possible strictness? - analytic work deserves to be recognized as genuine psycho-analysis only when it has succeeded in removing the amnesia which conceals from the adult his knowledge of his childhood from its beginning (that is, from about the second to the fifth year). This cannot be said among analysts too emphatically or repeated too often. The motives for disregarding this reminder are, indeed, intelligible. It would be desirable to obtain practical results in a shorter period and with less trouble. But at the present time theoretical knowledge is still far more important to all of us than therapeutic success, and anyone who neglects childhood analysis is bound to fall into the most disastrous errors. The emphasis which is laid here upon the importance of the earliest experiences does not imply any underestimation of the influence of later ones. But the later impressions of life speak loudly enough through the mouth of the patient, while it is the physician who has to raise his voice on behalf of the claims of childhood.
After hypnosis was replaced by the technique of free association, Breuer's cathartic procedure turned into psycho-analysis, which for more than a decade was developed by the author (Freud) alone. During that time psycho-analysis gradually acquired a theory which appeared to give a satisfactory account of the origin, meaning and purpose of neurotic symptoms and provided a rational basis for medical attempts at curing the complaint. I will once again enumerate the factors that go to make up this theory. They are: emphasis on instinctual life (affectivity), on mental dynamics, on the fact that even the apparently most obscure and arbitrary mental phenomena invariably have a meaning and a causation, the theory of psychical conflict and of the pathogenic nature of repression, the view that symptoms are substitutive satisfactions, the recognition of the aetiologica importance of sexual life, and in particular of the beginnings of infantile sexuality. From a philosophical standpoint this theory was bound to adopt the view that the mental does not coincide with the conscious, that mental processes are in themselves unconscious and are only made conscious by the functioning of special organs (agencies or systems). By way of completing this list, I will add that among the affective attitudes of childhood the complicated emotional relation of children to their parents - what is known as the Oedipus complex - came into prominence. It became ever clearer that this was the nucleus of every case of neurosis, and in the patient's behaviour towards his analyst certain phenomena of his emotional transference emerged which came to be of great importance for theory and technique alike.

[1924f, 4107]

The theories of resistance and of repression, of the unconscious, of the aetiologica significance of sexual life and of the importance of infantile experiences - these form the principal constituents of the theoretical structure of psycho-analysis. In these pages, unfortunately, I have been able to describe only the separate elements and not their interconnections and their bearing upon one another. But I am obliged now to turn to the alterations which gradually took place in the technique of the analytic method.

[1925d, 4215]

Let me return to your question about certainty. We have become quite generally convinced from the direct analytic examination of children that we were right in our interpretation of what adults told us about their childhood. In a number of cases, however, another sort of confirmation has become possible. The material of the analysis of some patients has enabled us to reconstruct certain external happenings, certain impressive events of their childhood years, of which they have preserved no conscious memory. Lucky accidents, information from parents or nurses, have afterwards provided irrefutable evidence that these occurrences which we had inferred really did take place. This, of course, has not happened often, but when it has it has made an overwhelming impression. The correct reconstruction, you must know, of such forgotten experiences of childhood always has a great therapeutic effect, whether they permit of objective confirmation or not. These events owe their importance, of course, to their having occurred at such an early age, at a time when they could still produce a traumatic effect on the feeble ego.

[1926e, 4358]

Various sorts. In the first place, impressions capable of permanently influencing the child's budding sexual life - such as observations of sexual activities between adults, or sexual experiences of his own with an adult or another child (no rare events); or, again, overhearing conversations, understood either at the time or retrospectively, from which the child thought it could draw conclusions about mysterious or uncanny matters; or again, remarks or actions by the child himself which give evidence of significant attitudes of affection or enmity towards other people. It is of special importance in an analysis to induce a memory of the patient's own forgotten sexual activity as a child and also of the intervention by the adults which brought it to an end.

[1926e, 4358]
In his childhood: as a rule in his relation with one of his parents. You will remember what importance we had to attribute to these earliest emotional ties. So here the circle closes. [1926e, 4369]

A feebleness of the ego of this sort is to be found in all of us in childhood; and that is why the experiences of the earliest years of childhood are of such great importance for later life. Under the extraordinary burden of this period of childhood we have in a few years to cover the enormous developmental distance between stone-age primitive men and the participants in contemporary civilization, and, at the same time and in particular, we have to fend off the instinctual impulses of the early sexual period - under this burden, then, our ego takes refuge in repression and lays itself open to a childhood neurosis, the precipitate of which it carries with it into maturity as a disposition to a later nervous illness. Everything now depends on how the growing organism is treated by fate. If life becomes too hard, if the gulf between instinctual claims and the demands of reality becomes too great, the ego may fail in its efforts to reconcile the two, and the more readily, the more it is inhibited by the disposition carried over by it from infancy. The process of repression is then repeated, the instincts tear themselves away from the ego's domination, find their substitutive satisfactions along the paths of regression, and the poor ego has become helplessly neurotic. [1926e, 4382]

I think that Goethe would not have rejected psycho-analysis in an unfriendly spirit, as so many of our contemporaries have done. He himself approached it at a number of points, recognized much through his own insight that we have since been able to confirm, and some views, which have brought criticism and mockery down upon us, were expounded by him as self-evident. Thus he was familiar with the incomparable strength of the first affective ties of human creatures. He celebrated them in the Dedication to his Faust poem, in words which we could repeat for each of our analyses: [1930, 4579]

Thus he does not deny that these perennial first inclinations take figures from one's own family circle as their object. [1930, 4579]

Some writers are inclined to reduce the importance of the child's first and most original libidinal impulses in favour of later developmental processes, so that - to put this view in its most extreme form - the only role left to the former is merely to indicate certain paths, while the intensities which flow along those paths are supplied by later regressions and reaction-formations. Thus, for instance, Karin Horney (1926) is of the opinion that we greatly over-estimate the girl's primary penis-envy and that the strength of the masculine trend which she develops later is to be attributed to a secondary penis-envy which is used to fend off her feminine impulses and, in particular, her feminine attachment to her father. This does not tally with my impressions. Certain as is the occurrence of later reinforcements through regression and reaction-formation, and difficult as it is to estimate the relative strength of the confluent libidinal components, I nevertheless think that we should not overlook the fact that the first libidinal impulses have an intensity of their own which is superior to any that come later and which may indeed be termed incommensurable. It is undoubtedly true that there is an antithesis between the attachment to the father and the masculinity complex; it is the general antithesis that exists between activity and passivity, masculinity and femininity. But this gives us no right to assume that only one of them is primary and that the other owes its strength merely to the force of defence. And if the defence against femininity is so energetic, from what other source can it draw its strength than from the masculine trend which found its first expression in the child's penis-envy and therefore deserves to be named after it? [1931b, 4607]
But in this connection two points must be stressed. Firstly, the genesis of a neurosis invariably goes back to very early impressions in childhood.¹ Secondly, it is true that there are cases which are distinguished as being 'traumatic' because their effects go back unmistakably to one or more powerful impressions in these early times - impressions which have escaped being dealt with normally, so that one is inclined to judge that if they had not occurred the neurosis would not have come about either. It would be enough for our purposes if we were obliged to restrict the analogy we are in search of to these traumatic cases. But the gap between the two groups appears not to be unbridgeable. It is quite possible to unite the two aetiological determinants under a single conception; it is merely a question of how one defines 'traumatic'. If we may assume that the experience acquires its traumatic character only as a result of a quantitative factor - that is to say, that in every case it is an excess in demand that is responsible for an experience evoking unusual pathological reactions - then we can easily arrive at the expedient of saying that something acts as a trauma in the case of one constitution but in the case of another would have no such effect. In this way we reach the concept of a sliding 'complemental series' as it is called, in which two factors converge in fulfilling an aetiological requirement. A less of one factor is balanced by a more of the other; as a rule both factors operate together and it is only at the two ends of the series that there can be any question of a simple motive being at work. After mentioning this, we can disregard the distinction between traumatic and non-traumatic aetiologies as irrelevant to the analogy we are in search of.

It has long since become common knowledge that the experiences of a person's first five years exercise a determining effect on his life, which nothing later can withstand. Much that deserves knowing might be said about the way in which these early impressions maintain themselves against any influences in more mature periods of life - but it would not be relevant here. It may, however, be less well known that the strongest compulsive influence arises from impressions which impinge upon a child at a time when we would have to regard his psychical apparatus as not yet completely receptive. The fact itself cannot be doubted; but it is so puzzling that we may make it more comprehensible by comparing it with a photographic exposure which can be developed after any interval of time and transformed into a picture. I am nevertheless glad to point out that this uncomfortable discovery of ours has been anticipated by an imaginative writer, with the boldness that is permitted to poets. E. T. A. Hoffmann used to trace back the wealth of figures that put themselves at his disposal for his creative writings to the changing images and impressions which he had experienced during a journey of some weeks in a post-chaise while he was still an infant at his mother's breast. What children have experienced at the age of two and have not understood, need never be remembered by them except in dreams; they may only come to know of it through psycho-analytic treatment. But at some later time it will break into their life with obsessional impulses, it will govern their actions, it will decide their sympathies and antipathies and will quite often determine their choice of a love-object, for which it is so frequently impossible to find a rational basis. The two points at which these facts touch upon our problem cannot be mistaken.

During the study of the sexual functions we have been able to gain a first, preliminary conviction, or rather a suspicion, of two discoveries which will later be found to be important over the whole of our field. Firstly, the normal and abnormal manifestations observed by us (that is, the phenomenology of the subject) need to be described from the point of view of their dynamics and economics (in our case, from the point of view of the quantitative distribution of the libido). And secondly, the aetiology of the disorders which we study is to be looked for in the individual's developmental history - that is to say, in his early life.
The supposition we have just made finds confirmation. Analytic experiences teach us that there is in fact one instinctual demand attempts to deal with which most easily fail or succeed imperfectly and that there is one period of life which comes in question exclusively or predominantly in connection with the generation of a neurosis. These two factors - the nature of the instinct and the period of life concerned - call for separate consideration, although they are closely enough connected.

We can speak with a fair degree of certainty about the part played by the period of life. It seems that neuroses are acquired only in early childhood (up to the age of six), even though their symptoms may not make their appearance till much later. The childhood neurosis may become manifest for a short time or may even be overlooked. In every case the later neurotic illness links up with the prelude in childhood. It is possible that what are known as traumatic neuroses (due to excessive fright or severe somatic shocks, such as railway collisions, burial under falls of earth, and so on) are an exception to this: their relations to determinants in childhood have hitherto eluded investigation. There is no difficulty in accounting for this aetiological preference for the first period of childhood. The neuroses are, as we know, disorders of the ego; and it is not to be wondered at if the ego, so long as it is feeble, immature and incapable of resistance, fails to deal with tasks which it could cope with later on with the utmost ease. In these circumstances instinctual demands from within, no less than excitations from the external world, operate as 'traumas', particularly if they are met half way by certain innate dispositions. The helpless ego fends them off by means of attempts at flight (repression), which later turn out to be inefficient and which involve permanent restrictions on further development. The damage inflicted on the ego by its first experiences gives us the appearance of being disproportionately great; but we have only to take as an analogy the differences in the results produced by the prick of a needle into a mass of cells in the act of cell-division (as in Roux's experiments) and into the fully grown animal which eventually develops out of them. No human individual is spared such traumatic experiences; none escapes the repressions to which they give rise. These questionable reactions on the part of the ego may perhaps be indispensable for the attainment of another aim which is set for the same period of life: in the space of a few years the little primitive creature must turn into a civilized human being; he must pass through an immensely long stretch of human cultural development in an almost uncannily abbreviated form. This is made possible by hereditary disposition; but it can almost never be achieved without the additional help of upbringing, of parental influence, which, as a precursor of the super-ego, restricts the ego's activity by prohibitions and punishments, and encourages or compels the setting-up of repressions. We must therefore not forget to include the influence of civilization among the determinants of neurosis. It is easy, as we can see, for a barbarian to be healthy; for a civilized man the task is hard. The desire for a powerful, uninhibited ego may seem to us intelligible; but, as we are taught by the times we live in, it is in the profoundest sense hostile to civilization. And since the demands of civilization are represented by family upbringing, we must bear in mind the part played by this biological characteristic of the human species - the prolonged period of its childhood dependence - in the aetiology of the neuroses.

[1940a [1938], 4993]
As regards the other point - the specific instinctual factor - we come upon an interesting discrepancy between theory and experience. Theoretically there is no objection to supposing that any sort of instinctual demand might occasion the same repressions and their consequences; but our observation shows us invariably, so far as we can judge, that the excitations that play this pathogenic part arise from the component instincts of sexual life. The symptoms of neuroses are, it might be said, without exception either a substitutive satisfaction of some sexual urge or measures to prevent such a satisfaction; and as a rule they are compromises between the two, of the kind that come about in accordance with the laws operating between contraries in the unconscious. The gap in our theory cannot at present be filled; our decision is made more difficult by the fact that most of the urges of sexual life are not of a purely erotic nature but have arisen from alloys of the erotic instinct with portions of the destructive instinct. But it cannot be doubted that the instincts which manifest themselves physiologically as sexuality play a prominent, unexpectedly large part in the causation of the neuroses - whether it is an exclusive one remains to be decided. It must also be borne in mind that in the course of cultural development no other function has been so energetically and extensively repudiated as precisely the sexual one. Theory must rest satisfied with a few hints that betray a deeper connection: the fact that the first period of childhood, during which the ego begins to be differentiated from the id, is also the period of the early sexual efflorescence which is brought to an end by the period of latency; that it can hardly be a matter of chance that this momentous early period subsequently falls a victim to infantile amnesia; and lastly, that biological changes in sexual life (such as the function's diphasic onset which we have already mentioned, the disappearance of the periodic character of sexual excitation and the transformation in the relation between female menstruation and male excitation) - that these innovations in sexuality must have been of high importance in the evolution of animals into man. It is left for the science of the future to bring these still isolated data together into a new understanding. It is not in psychology but in biology that there is a gap here. We shall not be wrong, perhaps, in saying that the weak point in the ego's organization seems to lie in its attitude to the sexual function, as though the biological antithesis between self-preservation and the preservation of the species had found a psychological expression at that point.

[1940a [1938], 4994]

Analytic experience has convinced us of the complete truth of the assertion so often to be heard that the child is psychologically father to the adult and that the events of his first years are of paramount importance for his whole later life. It will thus be of special interest to us if there is something that may be described as the central experience of this period of childhood. Our attention is first attracted by the effects of certain influences which do not apply to all children, though they are common enough - such as the sexual abuse of children by adults, their seduction by other children (brothers or sisters) slightly their seniors, and, what we should not expect, their being deeply stirred by seeing or hearing at first hand sexual behaviour between adults (their parents) mostly at a time at which one would not have thought they could either be interested in or understand any such impressions, or be capable of remembering them later. It is easy to confirm the extent to which such experiences arouse a child's susceptibility and force his own sexual urges into certain channels from which they cannot afterwards depart. Since these impressions are subjected to repression either at once or as soon as they seek to return as memories, they constitute the determinant for the neurotic compulsion which will subsequently make it impossible for the ego to control the sexual function and will probably cause it to turn away from that function permanently. If this latter reaction occurs, the result will be a neurosis; if it is absent, a variety of perversions will develop, or the function, which is of immense importance not only for reproduction but also for the entire shaping of life, will become totally unmanageable.

[1940a [1938], 4995]
Psycho-analysis has done justice to the sexual function in man by making a detailed examination of its importance in mental and practical life - an importance which has been emphasized by many creative writers and by some philosophers, but which has never been recognized by science. But in the first place it was necessary to enlarge the unduly restricted concept of sexuality, an enlargement that was justified by reference to the extensions of sexuality occurring in the so-called perversions and to the behaviour of children. It turned out to be impossible to maintain any longer that childhood was asexual and was invaded for the first time by a sudden inrush of sexual impulses at the age of puberty. On the contrary, when once the blinkers of partiality and prejudice had been removed, observation had no difficulty in revealing that sexual interests and activities are present in the human child at almost every age and from the very first. The importance of this infantile sexuality is not impaired by the fact that we cannot everywhere draw a clear line between it and a child's asexual activity. It differs, however, from what is described as the 'normal' sexuality of adults. It includes the germs of all those sexual activities which in later life are sharply contrasted with normal sexual life as being perversions, and as such bound to seem incomprehensible and vicious. The normal sexuality of adults emerges from infantile sexuality by a series of developments, combinations, divisions and suppressions, which are scarcely ever achieved with ideal perfection and consequently leave behind predispositions to a retrogression of the function in the form of illness.

[1913j, 2816]

In my experience antipathy to this outcome of psycho-analytic research is the most important source of resistance which it has met with. Would you like to hear how we explain that fact? We believe that civilization has been created under the pressure of the exigencies of life at the cost of satisfaction of the instincts; and we believe that civilization is to a large extent being constantly created anew, since each individual who makes a fresh entry into human society repeats this sacrifice of instinctual satisfaction for the benefit of the whole community. Among the instinctual forces which are put to this use the sexual impulses play an important part; in this process they are sublimated - that is to say, they are diverted from their sexual aims and directed to others that are socially higher and no longer sexual. But this arrangement is unstable; the sexual instincts are imperfectly tamed, and, in the case of every individual who is supposed to join in the work of civilization, there is a risk that his sexual instincts may refuse to be put to that use. Society believes that no greater threat to its civilization could arise than if the sexual instincts were to be liberated and returned to their original aims. For this reason society does not wish to be reminded of this precarious portion of its foundations. It has no interest in the recognition of the strength of the sexual instincts or in the demonstration of the importance of sexual life to the individual. On the contrary, with an educational aim in view, it has set about diverting attention from that whole field of ideas. That is why it will not tolerate this outcome of psycho-analytic research and far prefers to stamp it as something aesthetically repulsive and morally reprehensible, or as something dangerous. But objections of this sort are ineffective against what claims to be an objective outcome of a piece of scientific work; if the contradiction is to come into the open it must be restated in intellectual terms. Now it is inherent in human nature to have an inclination to consider a thing untrue if one does not like it, and after that it is easy to find arguments against it. Thus society makes what is disagreeable into what is untrue. It disputes the truths of psycho-analysis with logical and factual arguments; but these arise from emotional sources and it maintains these objections as prejudices, against every attempt to counter them.

[1916-1917, 3135]
I have credited you with a wish that I might have started my description of the neuroses from
the behaviour of neurotic people, from an account of the manner in which they suffer under their
neurosis, of how they defend themselves against it and how they come to terms with it. No doubt
that is an interesting topic, worth investigating; nor would it be very difficult to handle. But it would
be of debatable wisdom to start with it. There would be a risk of not discovering the unconscious
and at the same time of overlooking the great importance of the libido and of judging everything
as it appears to the ego of the neurotic subject. It is obvious that this ego is not a trustworthy or
impartial agency. The ego is indeed the power which disavows the unconscious and has
degraded it into being repressed; so how can we trust it to be fair to the unconscious? The most
prominent elements in what is thus repressed are the repudiated demands of sexuality, and it is
quite self-evident that we should never be able to guess their extent and importance from the
ego's conceptions. From the moment the notion of repression dawns on us, we are warned
against making one of the two contesting parties (and the victorious one, at that) into being judge
in the dispute. We are prepared to find that the ego's assertions will lead us astray. If we are to
believe the ego, it was active at every point and itself willed and created its symptoms. But we
know that it puts up with a good amount of passivity, which it afterwards tries to disguise and
gloss over. It is true that it does not always venture on such an attempt; in the symptoms of
obsessional neurosis it is obliged to admit that there is something alien which is confronting it and
against which it can only defend itself with difficulty.

Probably very few people can have realized the momentous significance for science and life of
the recognition of unconscious mental processes. It was not psycho-analysis, however, let us
hasten to add, which first took this step. There are famous philosophers who may be cited as
forerunners - above all the great thinker Schopenhauer, whose unconscious 'Will' is equivalent to
the mental instincts of psycho-analysis. It was this same thinker, moreover, who in words of
unforgettable impressiveness admonished mankind of the importance, still so greatly under-
estimated by it, of its sexual craving. Psycho-analysis has this advantage only, that it has not
affirmed these two propositions which are so distressing to narcissism - the psychical importance
of sexuality and the unconsciousness of mental life - on an abstract basis, but has demonstrated
them in matters that touch every individual personally and force him to take up some attitude
wards these problems. It is just for this reason, however, that it brings on itself the aversion and
resistances which still hold back in awe before the great name of the philosopher.

Its further course led it away from the study of the somatic determinants of nervous disease to
an extent that was bewildering to physicians. Instead, it was brought into contact with the mental
substance of human lives - the lives not only of the sick, but of the healthy, the normal and the
supernormal. It had to deal with emotions and passions, and most of all with those which the
poets never tire of depicting and celebrating - the emotions of love. It learnt to recognize the
power of memories, the unsuspected importance of the years of childhood in shaping the adult,
and the strength of wishes, which falsify human judgements and lay down fixed lines for human
endeavour.
Advance in knowledge made ever clearer the enormous part played in mental life by sexual wishful impulses, and led to a detailed study of the nature and development of the sexual instinct.¹ But we also came upon another purely empirical finding, in the discovery that the experiences and conflicts of the first years of childhood play an unsuspectedly important part in the individual's development and leave behind them ineffaceable dispositions bearing upon the period of maturity. This led to the revelation of something that had hitherto been fundamentally overlooked by science - infantile sexuality, which, from the tenderest age onwards, is manifested both in physical reactions and in mental attitudes. In order to bring together this sexuality of children with what is described as the normal sexuality of adults and the abnormal sexual life of perverts, the concept of what was sexual had itself to be corrected and widened in a manner which could be justified by the evolution of the sexual instinct.

[1924f, 4107]

In the form which it thus assumed, the psycho-analytic theory of the neuroses already contained a number of things which ran counter to accepted opinions and inclinations and which were calculated to provoke astonishment, repugnance and scepticism in outsiders: for instance, the attitude of psycho-analysis to the problem of the unconscious, its recognition of an infantile sexuality and the stress it laid on the sexual factor in mental life generally. But more was to follow.

[1924f, 4108]

This state of affairs is enough to account for the reluctant and hesitant reception of analysis in scientific quarters. But it does not explain the outbursts of indignation, derision and scorn which, in disregard of every standard of logic and good taste, have characterized the controversial methods of its opponents. A reaction of such a kind suggests that resistances other than purely intellectual ones were stirred up and that powerful emotional forces were aroused. And there are indeed plenty of things to be found in the theory of psycho-analysis calculated to produce such an effect as this upon the passions of men of every kind and not of scientists alone. Above all there is the very important place in the mental life of human beings which psycho-analysis assigns to what are known as the sexual instincts. Psycho-analytic theory maintained that the symptoms of neuroses are distorted substitutive satisfactions of sexual instinctual forces, the direct satisfaction of which has been frustrated by internal resistances. Later on, when analysis had extended beyond its original field of work and began to be applied to normal mental life, it sought to show that these same sexual components, which could be diverted from their immediate aims and directed to other things, made the most important contributions to the cultural achievements of the individual and of society. These views were not entirely new. The incomparable significance of sexual life had been proclaimed by the philosopher Schopenhauer in an intensely impressive passage. Moreover, what psycho-analysis called sexuality was by no means identical with the impulsion towards a union of the two sexes or towards producing a pleasurable sensation in the genitals; it had far more resemblance to the all-inclusive and all-preserving Eros of Plato's Symposium.

[1925e, 4125]

The theories of resistance and of repression, of the unconscious, of the aetiological significance of sexual life and of the importance of infantile experiences - these form the principal constituents of the theoretical structure of psycho-analysis. In these pages, unfortunately, I have been able to describe only the separate elements and not their interconnections and their bearing upon one another. But I am obliged now to turn to the alterations which gradually took place in the technique of the analytic method.

[1925d, 4215]
It remains to be seen whether this construction will turn out to be serviceable. Although it arose from a desire to fix some of the most important theoretical ideas of psycho-analysis, it goes far beyond psycho-analysis. I have repeatedly heard it said contemptuously that it is impossible to take a science seriously whose most general concepts are as lacking in precision as those of libido and of instinct in psycho-analysis. But this reproach rests on a complete misconception of the facts. Clear basic concepts and sharply drawn definitions are only possible in the mental sciences in so far as the latter seek to fit a region of facts into the frame of a logical system. In the natural sciences, of which psychology is one, such clear-cut general concepts are superfluous and indeed impossible. Zoology and Botany did not start from correct and adequate definitions of an animal and a plant; to this very day biology has been unable to give any certain meaning to the concept of life. Physics itself, indeed, would never have made any advance if it had had to wait until its concepts of matter, force, gravitation, and so on, had reached the desirable degree of clarity and precision. The basic ideas or most general concepts in any of the disciplines of science are always left indeterminate at first and are only explained to begin with by reference to the realm of phenomena from which they were derived; it is only by means of a progressive analysis of the material of observation that they can be made clear and can find a significant and consistent meaning. I have always felt it as a gross injustice that people have refused to treat psycho-analysis like any other science. This refusal found an expression in the raising of the most obstinate objections. Psycho-analysis was constantly reproached for its incompleteness and insufficiencies; though it is plain that a science based upon observation has no alternative but to work out its findings piecemeal and to solve its problems step by step. Again, when I endeavoured to obtain for the sexual function the recognition which had so long been withheld from it, psycho-analytic theory was branded as 'pan-sexualism'. And when I laid stress on the hitherto neglected importance of the part played by the accidental impressions of early youth, I was told that psycho-analysis was denying constitutional and hereditary factors - a thing which I had never dreamt of doing. It was a case of contradiction at any price and by any methods.

[1925d, 4233]

I should not like to create an impression that during this last period of my work I have turned my back upon patient observation and have abandoned myself entirely to speculation. I have on the contrary always remained in the closest touch with the analytic material and have never ceased working at detailed points of clinical or technical importance. Even when I have moved away from observation, I have carefully avoided any contact with philosophy proper. This avoidance has been greatly facilitated by constitutional incapacity. I was always open to the ideas of G. T. Fechner and have followed that thinker upon many important points. The large extent to which psycho-analysis coincides with the philosophy of Schopenhauer - not only did he assert the dominance of the emotions and the supreme importance of sexuality but he was even aware of the mechanism of repression - is not to be traced to my acquaintance with his teaching. I read Schopenhauer very late in my life. Nietzsche, another philosopher whose guesses and intuitions often agree in the most astonishing way with the laborious findings of psycho-analysis, was for a long time avoided by me on that very account; I was less concerned with the question of priority than with keeping my mind unembarrassed.

[1925d, 4234]
Because that someone else would not have thought any differently from you. But if he had been prepared from the first to recognize the importance of sexual life, everyone would have exclaimed: 'Why, that is no Impartial Person, he is one of your supporters!' No, I am far from abandoning the expectation of being able to influence your opinions. I must admit, however, that from my point of view this situation is different from the one we dealt with earlier. As regards our psychological discussions it is a matter of indifference to me whether you believe me or not, provided only that you get an impression that what we are concerned with are purely psychological problems. But here, as regards the question of sexuality, I should nevertheless be glad if you were accessible to the realization that your strongest motive for contradiction is precisely the ingrained hostility which you share with so many other people.

The reasons for this hostility were to be found, from the medical point of view, in the fact that psycho-analysis lays stress upon psychical factors, and from the philosophical point of view, in its assuming as an underlying postulate the concept of unconscious mental activity; but the strongest reason was undoubtedly the general disinclination of mankind to concede to the factor of sexuality the importance that is assigned to it by psycho-analysis. In spite of this widespread opposition, however, the movement in favour of psycho-analysis was not to be checked. Its adherents formed themselves into an International Association, which passed successfully through the ordeal of the World War, and at the present time (1925) comprises local groups in Vienna, Berlin, Budapest, London, Switzerland, Holland, Moscow and Calcutta, as well as two in the United States. There are three periodicals representing the views of these societies: the *Internationale Zeitschrift für Psychoanalyse*, *Imago* (which is concerned with the application of psycho-analysis to non-medical fields of knowledge), and the *International Journal of Psycho-Analysis*.

² The view expressed above is supported by the following considerations. Man is an animal organism with (like others) an unmistakably bisexual disposition. The individual corresponds to a fusion of two symmetrical halves, of which, according to some investigators, one is purely male and the other female. It is equally possible that each half was originally hermaphrodite. Sex is a biological fact which, although it is of extraordinary importance in mental life, is hard to grasp psychologically. We are accustomed to say that every human being displays both male and female instinctual impulses, needs and attributes; but though anatomy, it is true, can point out the characteristic of maleness and femaleness, psychology cannot. For psychology the contrast between the sexes fades away into one between activity and passivity, in which we far too readily identify activity with maleness and passivity with femaleness, a view which is by no means universally confirmed in the animal kingdom. The theory of bisexuality is still surrounded by many obscurities and we cannot but feel it as a serious impediment in psycho-analysis that it has not yet found any link with the theory of the instincts. However this may be, if we assume it as a fact that each individual seeks to satisfy both male and female wishes in his sexual life, we are prepared for the possibility that those demands are not fulfilled by the same object, and that they interfere with each other unless they can be kept apart and each impulse guided into a particular channel that is suited to it. Another difficulty arises from the circumstance that there is so often associated with the erotic relationship, over and above its own sadistic components, a quota of plain inclination to aggression. The love-object will not always view these complications with the degree of understanding and tolerance shown by the peasant woman who complained that her husband did not love her any more, since he had not beaten her for a week.
For, whether a man is a homosexual or a necrophilic, a hysteric suffering from anxiety, an obsessionnal neurotic cut off from society, or a raving lunatic, the 'Individual Psychologist' of the Adlerian school will declare that the impelling motive of his condition is that he wishes to assert himself, to overcompensate for his inferiority, to remain 'on top', to pass from the feminine to the masculine line. In my young student days we used to hear something very much the same in the out-patients' department when a case of hysteria was introduced: hysterical patients, we were told, produce their symptoms to make themselves interesting, to draw attention to themselves. It is a remarkable thing how these ancient pieces of wisdom keep on cropping up. But even at that time this fragment of psychology did not seem to cover the riddle of hysteria. It left unexplained, for instance, why the patients used no other methods for attaining their purpose. There must, of course, be something correct in this theory of the 'Individual Psychologists': a small particle is taken for the whole. The self-preservative instinct will try to profit by every situation; the ego will seek to turn even illness to its advantage. In psycho-analysis this is known as the 'secondary gain from illness'. Though, indeed, when we think of the facts of masochism, of the unconscious need for punishment and of neurotic self-injury, which make plausible the hypothesis of there being instinctual impulses that run contrary to self-preservation, we even feel shaken in our belief in the general validity of the commonplace truth on which the theoretical structure of Individual Psychology is erected. But a theory such as this is bound to be very welcome to the great mass of the people, a theory which recognizes no complications, which introduces no new concepts that are hard to grasp, which knows nothing of the unconscious, which gets rid at a single blow of the universally oppressive problem of sexuality and which restricts itself to the discovery of the artifices by which people seek to make life easy. For the mass of the people themselves take things easily: they call for no more than a single reason by way of explanation, they do not thank science for its diffuseness, they want to have simple solutions and to know that problems are solved. When we consider how very far Individual Psychology goes in meeting these demands, we cannot suppress the recollection of a sentence in Wallenstein:
[1933a, 4743]
As regards the other point - the specific instinctual factor - we come upon an interesting discrepancy between theory and experience. Theoretically there is no objection to supposing that any sort of instinctual demand might occasion the same repressions and their consequences; but our observation shows us invariably, so far as we can judge, that the excitations that play this pathogenic part arise from the component instincts of sexual life. The symptoms of neuroses are, it might be said, without exception either a substitutive satisfaction of some sexual urge or measures to prevent such a satisfaction; and as a rule they are compromises between the two, of the kind that come about in accordance with the laws operating between contraries in the unconscious. The gap in our theory cannot at present be filled; our decision is made more difficult by the fact that most of the urges of sexual life are not of a purely erotic nature but have arisen from alloys of the erotic instinct with portions of the destructive instinct. But it cannot be doubted that the instincts which manifest themselves physiologically as sexuality play a prominent, unexpectedly large part in the causation of the neuroses - whether it is an exclusive one remains to be decided. It must also be borne in mind that in the course of cultural development no other function has been so energetically and extensively repudiated as precisely the sexual one. Theory must rest satisfied with a few hints that betray a deeper connection: the fact that the first period of childhood, during which the ego begins to be differentiated from the id, is also the period of the early sexual efflorescence which is brought to an end by the period of latency; that it can hardly be a matter of chance that this momentous early period subsequently falls a victim to infantile amnesia; and lastly, that biological changes in sexual life (such as the function's diphasic onset which we have already mentioned, the disappearance of the periodic character of sexual excitation and the transformation in the relation between female menstruation and male excitation) - that these innovations in sexuality must have been of high importance in the evolution of animals into man. It is left for the science of the future to bring these still isolated data together into a new understanding. It is not in psychology but in biology that there is a gap here. We shall not be wrong, perhaps, in saying that the weak point in the ego's organization seems to lie in its attitude to the sexual function, as though the biological antithesis between self-preservation and the preservation of the species had found a psychological expression at that point.

[1940a [1938], 4994]

Analytic experience has convinced us of the complete truth of the assertion so often to be heard that the child is psychologically father to the adult and that the events of his first years are of paramount importance for his whole later life. It will thus be of special interest to us if there is something that may be described as the central experience of this period of childhood. Our attention is first attracted by the effects of certain influences which do not apply to all children, though they are common enough - such as the sexual abuse of children by adults, their seduction by other children (brothers or sisters) slightly their seniors, and, what we should not expect, their being deeply stirred by seeing or hearing at first hand sexual behaviour between adults (their parents) mostly at a time at which one would not have thought they could either be interested in or understand any such impressions, or be capable of remembering them later. It is easy to confirm the extent to which such experiences arouse a child's susceptibility and force his own sexual urges into certain channels from which they cannot afterwards depart. Since these impressions are subjected to repression either at once or as soon as they seek to return as memories, they constitute the determinant for the neurotic compulsion which will subsequently make it impossible for the ego to control the sexual function and will probably cause it to turn away from that function permanently. If this latter reaction occurs, the result will be a neurosis; if it is absent, a variety of perversions will develop, or the function, which is of immense importance not only for reproduction but also for the entire shaping of life, will become totally unmanageable.

[1940a [1938], 4995]
It has justly been said that the Oedipus complex is the nuclear complex of the neuroses, and constitutes the essential part of their content. It represents the peak of infantile sexuality, which, through its after-effects, exercises a decisive influence on the sexuality of adults. Every new arrival on this planet is faced by the task of mastering the Oedipus complex; anyone who fails to do so falls a victim to neurosis. With the progress of psycho-analytic studies the importance of the Oedipus complex has become more and more clearly evident; its recognition has become the shibboleth that distinguishes the adherents of psycho-analysis from its opponents.

If, however, the derivation of perversions from the Oedipus complex can be generally established, our estimate of its importance will have gained added strength. For in our opinion the Oedipus complex is the actual nucleus of neuroses, and the infantile sexuality which culminates in this complex is the true determinant of neuroses. What remains of the complex in the unconscious represents the disposition to the later development of neuroses in the adult. In this way the beating-phantasy and other analogous perverse fixations would also only be precipitates of the Oedipus complex, scars, so to say, left behind after the process has ended, just as the notorious 'sense of inferiority' corresponds to a narcissistic scar of the same sort. In taking this view of the matter I must express my unreserved agreement with Marcinowski (1918), who has recently put it forward most happily. As is well known, this neurotic delusion of inferiority is only a partial one, and is completely compatible with the existence of a self-overvaluation derived from other sources. The origin of the Oedipus complex itself, and the destiny which compels man, probably alone among all animals, to begin his sexual life twice over, first like all other creatures in his early childhood, and then after a long interruption once more at the age of puberty - all the problems that are connected with man's 'archaic heritage' - have been discussed by me elsewhere, and I have no intention of going into them in this place.

The theory of psycho-analysis (a theory based on observation) holds firmly to the view that the motive forces of repression must not be sexualized. Man's archaic heritage forms the nucleus of the unconscious mind; and whatever part of that heritage has to be left behind in the advance to later phases of development, because it is unserviceable or incompatible with what is new and harmful to it, falls a victim to the process of repression. This selection is made more successfully with one group of instincts than with the other. In virtue of special circumstances which have often been pointed out already, the latter group, that of the sexual instincts, are able to defeat the intentions of repression, and to enforce their representation by substitutive formations of a disturbing kind. For this reason infantile sexuality, which is held under repression, acts as the chief motive force in the formation of symptoms; and the essential part of its content, the Oedipus complex, is the nuclear complex of neuroses. I hope that in this paper I have raised an expectation that the sexual aberrations of childhood, as well as those of mature life, are ramifications of the same complex.

In the very earliest years of childhood (approximately between the ages of two and five) a convergence of the sexual impulses occurs of which, in the case of boys, the object is the mother. This choice of an object, in conjunction with a corresponding attitude of rivalry and hostility towards the father, provides the content of what is known as the Oedipus complex, which in every human being is of the greatest importance in determining the final shape of his erotic life. It has been found to be characteristic of a normal individual that he learns to master his Oedipus complex, whereas the neurotic subject remains involved in it.
After hypnosis was replaced by the technique of free association, Breuer's cathartic procedure turned into psycho-analysis, which for more than a decade was developed by the author (Freud) alone. During that time psycho-analysis gradually acquired a theory which appeared to give a satisfactory account of the origin, meaning and purpose of neurotic symptoms and provided a rational basis for medical attempts at curing the complaint. I will once again enumerate the factors that go to make up this theory. They are: emphasis on instinctual life (affectivity), on mental dynamics, on the fact that even the apparently most obscure and arbitrary mental phenomena invariably have a meaning and a causation, the theory of psychical conflict and of the pathogenic nature of repression, the view that symptoms are substitutive satisfactions, the recognition of the aetiological importance of sexual life, and in particular of the beginnings of infantile sexuality. From a philosophical standpoint this theory was bound to adopt the view that the mental does not coincide with the conscious, that mental processes are in themselves unconscious and are only made conscious by the functioning of special organs (agencies or systems). By way of completing this list, I will add that among the affective attitudes of childhood the complicated emotional relation of children to their parents - what is known as the Oedipus complex - came into prominence. It became ever clearer that this was the nucleus of every case of neurosis, and in the patient's behaviour towards his analyst certain phenomena of his emotional transference emerged which came to be of great importance for theory and technique alike.

[1924f, 4107]

In the form which it thus assumed, the psycho-analytic theory of the neuroses already contained a number of things which ran counter to accepted opinions and inclinations and which were calculated to provoke astonishment, repugnance and scepticism in outsiders: for instance, the attitude of psycho-analysis to the problem of the unconscious, its recognition of an infantile sexuality and the stress it laid on the sexual factor in mental life generally. But more was to follow.

[1924f, 4108]

And now, as a third point, psycho-analysis has shown us, to our growing astonishment, the enormously important part played by what is known as the 'Oedipus complex' - that is, the emotional relation of a child to its two parents - in the mental life of human beings. Our astonishment diminishes when we realize that the Oedipus complex is the psychical correlate of two fundamental biological facts: the long period of the human child's dependence, and the remarkable way in which its sexual life reaches a first climax in the third to fifth years of life, and then, after a period of inhibition, sets in again at puberty. And here, the discovery was made that a third and extremely serious part of human intellectual activity, the part which has created the great institutions of religion, law, ethics, and all forms of civic life, has as its fundamental aim the enabling of the individual to master his Oedipus complex and to divert his libido from its infantile attachments into the social ones that are ultimately desired. The applications of psycho-analysis to the science of religion and sociology (e. g. by the present writer, Theodor Reik and Oskar Pfister), which have led to these findings, are still young and insufficiently appreciated; but it cannot be doubted that further studies will only confirm the certainty of these important conclusions.

[1924f, 4117]
By its theory of the instincts psycho-analysis offended the feelings of individuals in so far as they regarded themselves as members of the social community; another branch of its theory was calculated to hurt every single person at the tenderest point of his own psychical development. Psycho-analysis disposed once and for all of the fairy tale of an asexual childhood. It demonstrated the fact that sexual interests and activities occur in small children from the beginning of their lives. It showed what transformations those activities pass through, how at about the age of five they succumb to inhibition and how from puberty onwards they enter the service of the reproductive function. It recognized that early infantile sexual life reaches its peak in what is known as the Oedipus complex (an emotional attachment of the child to the parent of the opposite sex accompanied by an attitude of rivalry to the parent of the same sex) and that at that period of life this impulsion extends uninhibited into a straightforward sexual desire. This can be confirmed so easily that only the greatest efforts could make it possible to overlook it. Every individual has in fact gone through this phase but has afterwards energetically repressed its purport and succeeded in forgetting it. A horror of incest and an enormous sense of guilt are left over from this prehistoric epoch of the individual's existence. It may be that something quite similar occurred in the prehistoric epoch of the human species as a whole and that the beginnings of morality, religion and social order were intimately connected with the surmounting of that primeval era. To adults their prehistory seems so inglorious that they refuse to allow themselves to be reminded of it: they were infuriated when psycho-analysis tried to lift the veil of amnesia from their years of childhood. There was only one way out: what psycho-analysis asserted must be false and what posed as a new science must be a tissue of fancies and distortions.

Every analyst has come across certain women who cling with especial intensity and tenacity to the bond with their father and to the wish in which it culminates of having a child by him. We have good reason to suppose that the same wishful phantasy was also the motive force of their infantile masturbation, and it is easy to form an impression that at this point we have been brought up against an elementary and unanalyzable fact of infantile sexual life. But a thorough analysis of these very cases brings something different to light - namely, that here the Oedipus complex has a long prehistory and is in some respects a secondary formation.
Before going further into the question of infantile sexuality I must mention an error into which I fell for a while and which might well have had fatal consequences for the whole of my work. Under the influence of the technical procedure which I used at that time, the majority of my patients reproduced from their childhood scenes in which they were sexually seduced by some grown-up person. With female patients the part of seducer was almost always assigned to their father. I believed these stories, and consequently supposed that I had discovered the roots of the subsequent neurosis in these experiences of sexual seduction in childhood. My confidence was strengthened by a few cases in which relations of this kind with a father, uncle, or elder brother had continued up to an age at which memory was to be trusted. If the reader feels inclined to shake his head at my credulity, I cannot altogether blame him; though I may plead that this was at a time when I was intentionally keeping my critical faculty in abeyance so as to preserve an unprejudiced and receptive attitude towards the many novelties which were coming to my notice every day. When, however, I was at last obliged to recognize that these scenes of seduction had never taken place, and that they were only phantasies which my patients had made up or which I myself had perhaps forced on them, I was for some time completely at a loss. My confidence alike in my technique and in its results suffered a severe blow; it could not be disputed that I had arrived at these scenes by a technical method which I considered correct, and their subject-matter was unquestionably related to the symptoms from which my investigation had started. When I had pulled myself together, I was able to draw the right conclusions from my discovery: namely, that the neurotic symptoms were not related directly to actual events but to wishful phantasies, and that as far as the neurosis was concerned psychical reality was of more importance than material reality. I do not believe even now that I forced the seduction-phantasies on my patients, that I 'suggested' them. I had in fact stumbled for the first time upon the Oedipus complex, which was later to assume such an overwhelming importance, but which I did not recognize as yet in its disguise of phantasy. Moreover, seduction during childhood retained a certain share, though a humbler one, in the aetiology of neuroses. But the seducers turned out as a rule to have been older children.

In Europe during the years 1911-13 two secessionist movements from psycho-analysis took place, led by men who had previously played a considerable part in the young science, Alfred Adler and C. G. Jung. Both movements seemed most threatening and quickly obtained a large following. But their strength lay, not in their own content, but in the temptation which they offered of being freed from what were felt as the repellent findings of psycho-analysis even though its actual material was no longer rejected. Jung attempted to give to the facts of analysis a fresh interpretation of an abstract, impersonal and non-historical character, and thus hoped to escape the need for recognizing the importance of infantile sexuality and of the Oedipus complex as well as the necessity for any analysis of childhood. Adler seemed to depart still further from psycho-analysis; he entirely repudiated the importance of sexuality, traced back the formation both of character and of the neuroses solely to men's desire for power and to their need to compensate for their constitutional inferiorities, and threw all the psychological discoveries of psycho-analysis to the winds. But what he had rejected forced its way back into his closed system under other names; his 'masculine protest' is nothing else than repression unjustifiably sexualized. The criticism with which the two heretics were met was a mild one; I only insisted that both Adler and Jung should cease to describe their theories as 'psycho-analysis'. After a lapse of ten years it can be asserted that both of these attempts against psycho-analysis have blown over without doing any harm.
Very well. I can now proceed with my exposition. Sexual life is not simply something spicy; it is also a serious scientific problem. There was much that was novel to be learnt about it, many strange things to be explained. I told you just now that analysis has to go back into the early years of the patient's childhood, because the decisive repressions have taken place then, while his ego was feeble. But surely in childhood there is no sexual life? surely it only starts at puberty? On the contrary. We have to learn that sexual instinctual impulses accompany life from birth onwards, and that it is precisely in order to fend off those instincts that the infantile ego institutes repressions. A remarkable coincidence, is it not? that small children should already be struggling against the power of sexuality, just as the speaker in the learned society was to do later, and later still my followers who have set up their own theories. How does that come about? The most general explanation would be that our civilization is built up entirely at the expense of sexuality; but there is much more to be said on the subject.

[1926e, 4352]

The discovery of infantile sexuality is one of those of which we have reason to feel ashamed. A few paediatricians have, it seems, always known about it, and a few children's nurses. Clever men, who call themselves child psychologists, have thereupon spoken in tones of reproach of a 'desecration of the innocence of childhood'. Once again, sentiment instead of argument! Events of that kind are of daily occurrence in political bodies. A member of the Opposition rises and denounces some piece of maladministration in the Civil Service, in the Army, in the Judiciary and so on. Upon this another member, preferably one of the Government, declares that such statements are an affront to the sense of honour of the body politic, of the army, of the dynasty, or even of the nation. So they are as good as untrue. Feelings such as these can tolerate no affronts.

[1926e, 4352]

The most important conflict with which a small child is faced is his relation to his parents, the 'Oedipus complex'; it is in attempting to grapple with this problem that those destined to suffer from a neurosis habitually come to grief. The reactions against the instinctual demands of the Oedipus complex are the source of the most precious and socially important achievements of the human mind; and this holds true not only in the life of individuals but probably also in the history of the human species as a whole. The super-ego, too, the moral agency which dominates the ego, has its origin in the process of overcoming the Oedipus complex.

[1926f, 4406]

I think that Goethe would not have rejected psycho-analysis in an unfriendly spirit, as so many of our contemporaries have done. He himself approached it at a number of points, recognized much through his own insight that we have since been able to confirm, and some views, which have brought criticism and mockery down upon us, were expounded by him as self-evident. Thus he was familiar with the incomparable strength of the first affective ties of human creatures. He celebrated them in the Dedication to his Faust poem, in words which we could repeat for each of our analyses:

[1930, 4579]

Thus he does not deny that these perennial first inclinations take figures from one's own family circle as their object.

[1930, 4579]
I need not say much about other schools which have branched off from our psycho-analysis. The fact that they have done so cannot be used either for or against the validity of psycho-analytic theories. You have only to think of the strong emotional factors that make it hard for many people to fit themselves in with others or to subordinate themselves, and of the still greater difficulty justly insisted on by the dictum 'Quot capita tot sensus'. When the differences of opinion had gone beyond a certain point, the most sensible thing was to part and thereafter to proceed along our different ways - especially when the theoretical divergence involved a change in practical procedure. Suppose, for instance, that an analyst attaches little value to the influence of the patient's personal past and looks for the causation of neuroses exclusively in present-day motives and in expectations of the future. In that case he will also neglect the analysis of childhood; he will have to adopt an entirely different technique and will have to make up for the omission of the events from the analysis of childhood by increasing his didactic influence and by directly indicating certain particular aims in life. We for our part will then say: 'This may be a school of wisdom; but it is no longer analysis.' Or someone else may arrive at the view that the experience of anxiety at birth sows the seed of all later neurotic disturbances. It may thereupon seem to him legitimate to restrict analysis to the consequences of this single impression and to promise therapeutic success from a treatment lasting from three to four months. As you will observe, I have chosen two examples which start from diametrically opposite premisses. It is an almost universal characteristic of these 'secessionist movements' that each of them takes hold of one fragment out of the wealth of themes in psycho-analysis and makes itself independent on the basis of this seizure - selecting the instinct for mastery, for instance, or ethical conflict, or the mother, or genitality, and so on. If it appears to you that secessions of this sort are already more numerous to-day in the history of psycho-analysis than in other intellectual movements, I am not sure that I should agree with you. If it is the case, the responsibility must be laid on the intimate relations which exist in psycho-analysis between theoretical views and therapeutic treatment. Mere differences of opinion would be tolerable for far longer. People like accusing us psycho-analysts of intolerance. The only manifestation of this ugly characteristic has been precisely our parting from those who think differently from us. No other harm has been done to them. On the contrary, they have fallen on their feet, and are better off than they were before. For by their separation they have usually freed themselves of one of the burdens which weigh us down - the odium of infantile sexuality, perhaps, or the absurdity of symbolism - and are regarded by their environment as passably respectable, which is still not true of those of us who are left behind. Moreover, apart from one notable exception, it was they who excluded themselves.

[1933a, 4744]
More could be made, too, of the analysis of this ceremonial if it could be properly linked up with the patient's other symptoms. But our path does not lead in that direction. You must be content with a hint that the girl was in the grip of an erotic attachment to her father whose beginnings went back to her childhood. Perhaps that was why she behaved in such an unfriendly way to her mother. Nor can we overlook the fact that the analysis of this symptom has once again taken us back to a patient's sexual life. We shall perhaps be less surprised at this the more often we gain an insight into the sense and intention of neurotic symptoms.

You will no doubt have heard, Gentlemen, that in psycho-analysis the concept of what is sexual has been unduly extended in order to support the theses of the sexual causation of the neuroses and the sexual meaning of symptoms. You are now in a position to judge for yourselves whether this extension is unjustified. We have only extended the concept of sexuality far enough to be able to comprise the sexual life of perverts and of children. We have, that is to say, given it back its true compass. What is called sexuality outside psycho-analysis relates only to a restricted sexual life, which serves the purpose of reproduction and is described as normal.

But I still owe you further enlightenment, Gentlemen, on my reasons for not starting my account of the theory of the neuroses with the common neurotic state. You may perhaps suppose that it was because in that case I should have had greater difficulty in proving the sexual causation of the neuroses. But you would be wrong there. In the case of the transference neuroses one must work one's way through the interpretation of symptoms before one can arrive at that discovery. In the common forms of what are known as the 'actual neuroses' the aetiological significance of sexual life is a crude fact that springs to the observer's eyes. I came upon it more than twenty years ago when one day I asked myself the question of why in the examination of neurotics their sexual activities were so regularly excluded from consideration. At that time I sacrificed my popularity with my patients for the sake of these enquiries; but after only a brief effort I was able to declare that 'if the vita sexualis is normal, there can be no neurosis' - and by this I meant no 'actual neurosis'. No doubt this statement passes too lightly over people's individual differences; it suffers, too, from the indefiniteness inseparable from the judgement of what is 'normal'. But as a rough guide it retains its value to this day. I had by then reached the point of establishing specific relations between particular forms of neurosis and particular sexual noxae; and I have no doubt that I could repeat the same observations to-day if similar pathological material were still at my disposal. I found often enough that a man who indulged in a certain kind of incomplete sexual satisfaction (for instance, manual masturbation) had fallen ill of a particular form of 'actual neurosis', and that this neurosis promptly gave place to another if he replaced this sexual régime by another equally far from being irreproachable. I was then in a position to infer the change in a patient's sexual mode of life from an alteration in his condition. I also learnt then to stand obstinately by my suspicions till I had overcome the patients' disingenuousness and compelled them to confirm my views. It is true that thereafter they preferred to go to other doctors who did not make such keen enquiries about their sexual life.
Even at that time I could not fail to notice that the causation of the illness did not always point to sexual life. One person, it was true, fell ill directly from a sexual noxa; but another did so because he had lost his fortune or had been through an exhausting organic illness. The explanation of these varieties came later, when we gained an insight into the suspected interrelations between the ego and the libido, and the explanation became the more satisfactory the deeper that insight extended. A person only falls ill of a neurosis if his ego has lost the capacity to allocate his libido in some way. The stronger is his ego, the easier will it be for it to carry out that task. Any weakening of his ego from whatever cause must have the same effect as an excessive increase in the claims of the libido and will thus make it possible for him to fall ill of a neurosis. There are other and more intimate relations between the ego and the libido; but these have not yet come within our scope, so I will not bring them up as part of my present explanation. What remains essential and makes things clear to us is that, in every case and no matter how the illness is set going, the symptoms of the neurosis are sustained by the libido and are consequently evidence that it is being employed abnormally.

[1916-1917, 3438]

Now, however, I must draw your attention to the decisive difference between the symptoms of the 'actual' neuroses and those of the psychoneuroses, the first group of which, the transference neuroses, have occupied us so much hitherto. In both cases the symptoms originate from the libido, and are thus abnormal employments of it, substitutive satisfactions. But the symptoms of the 'actual' neuroses - intracranial pressure, sensations of pain, a state of irritation in an organ, weakening or inhibition of a function - have no 'sense', no psychical meaning. They are not only manifested predominantly in the body (as are hysterical symptoms, for instance, as well), but they are also themselves entirely somatic processes, in the generating of which all the complicated mental mechanisms we have come to know are absent. Thus they really are what psychoneurotic symptoms were so long believed to be. But if so, how can they correspond to employments of the libido, which we have recognized as a force operating in the mind? Well, Gentlemen, that is a very simple matter. Let me remind you of one of the very first objections that were brought up against psycho-analysis. It was said then that it was occupied in finding a purely psychological theory of neurotic phenomena and this was quite hopeless, since psychological theories could never explain an illness. People had chosen to forget that the sexual function is not a purely psychical thing any more than it is a purely somatic one. It influences bodily and mental life alike. If in the symptoms of the psychoneuroses we have become acquainted with manifestations of disturbances in the psychical operation of the sexual function, we shall not be surprised to find in the 'actual' neuroses the direct somatic consequences of sexual disturbances.

[1916-1917, 3439]
Clinical medicine has given us a valuable pointer towards an interpretation of these disturbances, and one that has been taken into account by various enquirers. The 'actual' neuroses, in the details of their symptoms and also in their characteristic of influencing every organic system and every function, exhibit an unmistakable resemblance to the pathological states which arise from the chronic influence of external toxic substances and from a sudden withdrawal of them - to intoxications and conditions of abstinence. The two groups of disorders are brought together still more closely by intermediate conditions such as Grave's disease which we have learnt to recognize as equally due to the operation of toxic substances, but of toxins which are not introduced into the body from outside but originate in the subject's own metabolism. In view of these analogies, we cannot, I think, avoid regarding the neuroses as results of disturbances in the sexual metabolism, whether because more of these sexual toxins is produced than the subject can deal with, or whether because internal and even psychical conditions restrict the proper employment of these substances. The popular mind has from time immemorial paid homage to hypotheses of this kind on the nature of sexual desire, speaking of love as an 'intoxication' and believing that falling in love is brought about by love philtres - though here the operative agent is to some extent externalized. And for us this would be an occasion for recalling the erotogenic zones and our assertion that sexual excitation can be generated in the most various organs. But for the rest the phrase 'sexual metabolism' or 'chemistry of sexuality' is a term without content; we know nothing about it and cannot even decide whether we are to assume two sexual substances, which would then be named 'male' and 'female', or whether we could be satisfied with one sexual toxin which we should have to recognize as the vehicle of all the stimulant effects of the libido. The theoretical structure of psycho-analysis that we have created is in truth a superstructure, which will one day have to be set upon its organic foundation. But we are still ignorant of this.

And now perhaps you understand better why I did not choose to arrange my material differently. If I had promised you an 'Introduction to the Theory of the Neuroses' the correct path would certainly have led from the simple forms of the 'actual' neuroses to the more complicated psychical illnesses due to disturbance of the libido. As regards the former I should have had to collect from various sources what we have learnt or believe we know, and in connection with the psychoneuroses psycho-analysis would have come up for discussion as the most important technical aid in throwing light on those conditions. But what I intended to give and what I announced was an 'Introduction to Psycho-Analysis'. It was more important for me that you should gain an idea of psycho-analysis than that you should obtain some pieces of knowledge about the neuroses; and for that reason the 'actual' neuroses, unproductive so far as psycho-analysis is concerned, could no longer have a place in the foreground. I believe, too, that I have made the better choice for you. For, on account of the profundity of its hypotheses and the comprehensiveness of its connections, psycho-analysis deserves a place in the interest of every educated person, while the theory of the neuroses is a chapter in medicine like any other.
In any case it may be maintained that analysis of children's neuroses can claim to possess a specially high theoretical interest. They afford us, roughly speaking, as much help towards a proper understanding of the neuroses of adults as do children's dreams in respect to the dreams of adults. Not, indeed, that they are more perspicuous or poorer in elements; in fact, the difficulty of feeling one's way into the mental life of a child makes them set the physician a particularly difficult task. But nevertheless, so many of the later deposits are wanting in them that the essence of the neurosis springs to the eyes with unmistakable distinctness. In the present phase of the battle which is raging round psycho-analysis the resistance to its findings has, as we know, taken on a new form. People were content formerly to dispute the reality of the facts which are asserted by analysis; and for this purpose the best technique seemed to be to avoid examining them. That procedure appears to be slowly exhausting itself; and people are now adopting another plan of recognizing the facts, but of eliminating, by means of twisted interpretations, the consequences that follow from them, so that the critics can still ward off the objectionable novelties as efficiently as ever. The study of children's neuroses exposes the complete inadequacy of these shallow or high-handed attempts at re-interpretation. It shows the predominant part that is played in the formation of neuroses by those libidinal motive forces which are so eagerly disavowed, and reveals the absence of any aspirations towards remote cultural aims, of which the child still knows nothing, and which cannot therefore be of any significance for him.

[1918b, 3505]

With this as a starting-point we go on to make our first important discovery. We learn that, when we try to understand neurotic disorders, by far the greater significance attaches to the sexual instincts; that in fact neuroses are the specific disorders, so to speak, of the sexual function; that in general whether or not a person develops a neurosis depends on the quantity of his libido, and on the possibility of satisfying it and of discharging it through satisfaction; that the form taken by the disease is determined by the way in which the individual passes through the course of development of his sexual function, or, as we put it, by the fixations his libido has undergone in the course of its development; and, further, that by a special, not very simple technique for influencing the mind we are able to throw light on the nature of some groups of neuroses and at the same time to do away with them. Our therapeutic efforts have their greatest success with a certain class of neuroses which proceed from a conflict between the ego-instincts and the sexual instincts. For in human beings it may happen that the demands of the sexual instincts, whose reach of course extends far beyond the individual, seem to the ego to constitute a danger which threatens its self-preservation or its self-esteem. The ego then assumes the defensive, denies the sexual instincts the satisfaction they desire and forces them into those by-paths of substitutive satisfaction which become manifest as nervous symptoms.

[1917a, 3609]
There is, however, no need to consider that these approaches to psycho-analysis imply any reconciliation or any appeasement of opposition. Suppose someone has hitherto rejected the whole of a complex of interdependent propositions, but now suddenly finds himself in a position to convince himself of the truth of one portion of the whole. It might be thought that he will begin to hesitate about his opposition in general and permit himself some degree of deferent expectation that the other portion, about which he has had no personal experience and can consequently form no judgement of his own, may also turn out to be true. This other portion of psycho-analytic theory, with which the study of the war neuroses did not come into contact, is to the effect that the motive forces which are expressed in the formation of symptoms are sexual and that neuroses arise from a conflict between the ego and the sexual instincts which it repudiates. (‘Sexuality’ in this context is to be understood in the extended sense in which it is used in psycho-analysis and is not to be confused with the narrower concept of ‘genitality’.) Now it is quite true, as Ernest Jones remarks in his contribution to this volume, that this portion of the theory has not yet been proved to apply to the war neuroses. The work that might prove it has not yet been taken in hand. It may be that the war neuroses are altogether unsuitable material for the purpose. But the opponents of psycho-analysis, whose dislike of sexuality is evidently stronger than their logic, have been in a hurry to proclaim that the investigation of the war neuroses has finally disproved this portion of psycho-analytic theory. They have been guilty here of a slight confusion. If the investigation of the war neuroses (and a very superficial one at that) has not shown that the sexual theory of the neuroses is correct, that is something very different from its showing that that theory is incorrect. With the help of an impartial attitude and a little good will, it should not be hard to find the way to a further clarification of the subject.

Apart from this, the war neuroses are only traumatic neuroses, which, as we know, occur in peace-time too after frightening experiences or severe accidents, without any reference to a conflict in the ego.

But let us pause for a moment and reflect. It cannot be so. The sexual instincts, to which the theory of the neuroses gives a quite special place, appear under a very different aspect.

The psycho-analytic investigation of the psychoneuroses has taught us that their symptoms are to be traced back to directly sexual impulsions which are repressed but still remain active. We can complete this formula by adding - ‘or, to aim-inhibited impulsions, whose inhibition has not been entirely successful or has made room for a return to the repressed sexual aim’. It is in accordance with this that a neurosis should make its victim asocial and should remove him from the usual group formations. It may be said that a neurosis has the same disintegrating effect upon a group as being in love. On the other hand it appears that where a powerful impetus has been given to group formation neuroses may diminish and, at all events temporarily, disappear. Justifiable attempts have also been made to turn this antagonism between neuroses and group formation to therapeutic account. Even those who do not regret the disappearance of religious illusions from the civilized world of to-day will admit that so long as they were in force they offered those who were bound by them the most powerful protection against the danger of neurosis. Nor is it hard to discern that all the ties that bind people to mystico-religious or philosophico-religious sects and communities are expressions of crooked cures of all kinds of neuroses. All of this is correlated with the contrast between directly sexual impulsions and those which are inhibited in their aims.
The Aetiological Significance of Sexual Life. - The second novelty which emerged after the hypnotic technique had been replaced by free associations was of a clinical nature. It was discovered in the course of the prolonged search for the traumatic experiences from which hysterical symptoms appeared to be derived. The more carefully the search was pursued the more extensive seemed to be the network of aetiologically significant impressions involved, but the further back, too, did they reach into the patient's puberty or childhood. At the same time they assumed a uniform character and eventually it became inevitable to bow before the evidence and recognize that at the root of the formation of every symptom there were to be found traumatic experiences from early sexual life. Thus a sexual trauma stepped into the place of an ordinary trauma and the latter was seen to owe its aetiological significance to an associative or symbolic connection with the former, which had preceded it. An investigation of cases of common nervousness (falling into the two classes of neurasthenia and anxiety neurosis) which was simultaneously undertaken led to the conclusion that these disorders could be traced to contemporary abuses in the patients' sexual life and could be removed if these were brought to an end. It was thus easy to infer that neuroses in general are an expression of disturbances in sexual life, the so-called actual-neuroses being the consequences (by chemical agency) of contemporary injuries and the psycho-neuroses the consequences (by psychical modification) of bygone injuries to a biological function which had hitherto been gravely neglected by science. None of the theses of psycho-analysis has met with such tenacious scepticism or such embittered resistance as this assertion of the preponderating aetiological significance of sexual life in the neuroses. It should, however, be expressly remarked that, in its development up to the present day, psycho-analysis has found no reason to retreat from this opinion.

[1923a, 3920]

Transference. - If further proof were needed of the truth that the motive forces behind the formation of neurotic symptoms are of a sexual nature, it would be found in the fact that in the course of analytic treatment a special emotional relation is regularly formed between the patient and the physician. This goes far beyond rational limits. It varies between the most affectionate devotion and the most obstinate enmity and derives all of its characteristics from earlier erotic attitudes of the patient's which have become unconscious. This transference alike in its positive and in its negative form is used as a weapon by the resistance; but in the hands of the physician it becomes the most powerful therapeutic instrument and it plays a part scarcely to be over-estimated in the dynamics of the process of cure.

[1923a, 3924]
After hypnosis was replaced by the technique of free association, Breuer's cathartic procedure turned into psycho-analysis, which for more than a decade was developed by the author (Freud) alone. During that time psycho-analysis gradually acquired a theory which appeared to give a satisfactory account of the origin, meaning and purpose of neurotic symptoms and provided a rational basis for medical attempts at curing the complaint. I will once again enumerate the factors that go to make up this theory. They are: emphasis on instinctual life (affectivity), on mental dynamics, on the fact that even the apparently most obscure and arbitrary mental phenomena invariably have a meaning and a causation, the theory of psychical conflict and of the pathogenic nature of repression, the view that symptoms are substitutive satisfactions, the recognition of the aetiological importance of sexual life, and in particular of the beginnings of infantile sexuality. From a philosophical standpoint this theory was bound to adopt the view that the mental does not coincide with the conscious, that mental processes are in themselves unconscious and are only made conscious by the functioning of special organs (agencies or systems). By way of completing this list, I will add that among the affective attitudes of childhood the complicated emotional relation of children to their parents - what is known as the Oedipus complex - came into prominence. It became ever clearer that this was the nucleus of every case of neurosis, and in the patient's behaviour towards his analyst certain phenomena of his emotional transference emerged which came to be of great importance for theory and technique alike.

[1924f, 4107]

This state of affairs is enough to account for the reluctant and hesitant reception of analysis in scientific quarters. But it does not explain the outbursts of indignation, derision and scorn which, in disregard of every standard of logic and good taste, have characterized the controversial methods of its opponents. A reaction of such a kind suggests that resistances other than purely intellectual ones were stirred up and that powerful emotional forces were aroused. And there are indeed plenty of things to be found in the theory of psycho-analysis calculated to produce such an effect as this upon the passions of men of every kind and not of scientists alone. Above all there is the very important place in the mental life of human beings which psycho-analysis assigns to what are known as the sexual instincts. Psycho-analytic theory maintained that the symptoms of neuroses are distorted substitutive satisfactions of sexual instinctual forces, the direct satisfaction of which has been frustrated by internal resistances. Later on, when analysis had extended beyond its original field of work and began to be applied to normal mental life, it sought to show that these same sexual components, which could be diverted from their immediate aims and directed to other things, made the most important contributions to the cultural achievements of the individual and of society. These views were not entirely new. The incomparable significance of sexual life had been proclaimed by the philosopher Schopenhauer in an intensely impressive passage. Moreover, what psycho-analysis called sexuality was by no means identical with the impulse towards a union of the two sexes or towards producing a pleasurable sensation in the genitals; it had far more resemblance to the all-inclusive and all-preserving Eros of Plato's *Symposium.*

[1925e, 4125]
If the account I have so far given has led the reader to expect that the *Studies on Hysteria* must, in all essentials of their material content, be the product of Breuer's mind, that is precisely what I myself have always maintained and what it has been my aim to repeat here. As regards the *theory* put forward in the book, I was partly responsible, but to an extent which it is to-day no longer possible to determine. That theory was in any case unpretentious and hardly went beyond the direct description of the observations. It did not seek to establish the nature of hysteria but merely to throw light upon the origin of its symptoms. Thus it laid stress upon the significance of the life of the emotions and upon the importance of distinguishing between mental acts which are unconscious and those which are conscious (or rather capable of being conscious); it introduced a dynamic factor, by supposing that a symptom arises through the damming-up of an affect, and an economic factor, by regarding that same symptom as the product of the transformation of an amount of energy which would otherwise have been employed in some other way. (This latter process was described as *conversion*.) Breuer spoke of our method as *cathartic*; its therapeutic aim was explained as being to provide that the quota of affect used for maintaining the symptom, which had got on to the wrong lines and had, as it were, become strangulated there, should be directed on to the normal path along which it could obtain discharge (or *abreaction*). The practical results of the cathartic procedure were excellent. Its defects, which became evident later, were those of all forms of hypnotic treatment. There are still a number of psychotherapists who have not gone beyond catharsis as Breuer understood it and who still speak in its favour. Its value as an abridged method of treatment was shown afresh by Simmel in his treatment of war neuroses in the German army during the Great War. The theory of catharsis had not much to say on the subject of sexuality. In the case histories which I contributed to the *Studies* sexual factors played a certain part, but scarcely more attention was paid to them than to other emotional excitations. Breuer wrote of the girl, who has since become famous as his first patient, that her sexual side was extraordinarily undeveloped. It would have been difficult to guess from the *Studies on Hysteria* what an importance sexuality has in the aetiology of the neuroses.

[1925d, 4200]

The theory which we had attempted to construct in the *Studies* remained, as I have said, very incomplete; and in particular we had scarcely touched on the problem of aetiology, on the question of the ground in which the pathogenic process takes root. I now learned from my rapidly increasing experience that it was not *any* kind of emotional excitation that was in action behind the phenomena of neurosis but habitually one of a sexual nature, whether it was a current sexual conflict or the effect of earlier sexual experiences. I was not prepared for this conclusion and my expectations played no part in it, for I had begun my investigation of neurotics quite unsuspectingly. While I was writing my 'History of the Psycho-Analytic Movement' in 1914, there recurred to my mind some remarks that had been made to me by Breuer, Charcot, and Chrobak, which might have led me to this discovery earlier. But at the time I heard them I did not understand what these authorities meant; indeed they had told me more than they knew themselves or were prepared to defend. What I heard from them lay dormant and inactive within me, until the chance of my cathartic experiments brought it out as an apparently original discovery. Nor was I then aware that in deriving hysteria from sexuality I was going back to the very beginnings of medicine and following up a thought of Plato's. It was not until later that I learnt this from an essay by Havelock Ellis.

[1925d, 4202]
Under the influence of my surprising discovery, I now took a momentous step. I went beyond the domain of hysteria and began to investigate the sexual life of the so-called neurasthenics who used to visit me in numbers during my consultation hours. This experiment cost me, it is true, my popularity as a doctor, but it brought me convictions which to-day, almost thirty years later, have lost none of their force. There was a great deal of equivocation and mystery-making to be overcome, but, once that had been done, it turned out that in all of these patients grave abuses of the sexual function were present. Considering how extremely widespread are these abuses on the one hand and neurasthenia on the other, a frequent coincidence between the two would not have proved much; but there was more in it than that one bald fact. Closer observation suggested to me that it was possible to pick out from the confused jumble of clinical pictures covered by the name of neurasthenia two fundamentally different types, which might appear in any degree of mixture but which were nevertheless to be observed in their pure forms. In the one type the central phenomenon was the anxiety attack with its equivalents, rudimentary forms and chronic substitutive symptoms; I consequently gave it the name of anxiety neurosis, and limited the term neurasthenia to the other type. Now it was easy to establish the fact that each of these types had a different abnormality of sexual life as its corresponding aetiological factor: in the former, coitus interruptus, unconsummated excitation and sexual abstinence, and in the latter, excessive masturbation and too numerous nocturnal emissions. In a few specially instructive cases, which had shown a surprising alteration in the clinical picture from one type to the other, it could be proved that there had been a corresponding change in the underlying sexual régime. If it was possible to put an end to the abuse and allow its place to be taken by normal sexual activity, a striking improvement in the condition was the reward.

I was thus led into regarding the neuroses as being without exception disturbances of the sexual function, the so-called 'actual neuroses' being the direct toxic expression of such disturbances and the psychoneuroses their mental expression. My medical conscience felt pleased at my having arrived at this conclusion. I hoped that I had filled up a gap in medical science, which, in dealing with a function of such great biological importance, had failed to take into account any injuries beyond those caused by infection or by gross anatomical lesions. The medical aspect of the matter was, moreover, supported by the fact that sexuality was not something purely mental. It had a somatic side as well, and it was possible to assign special chemical processes to it and to attribute sexual excitation to the presence of some particular, though at present unknown, substances. There must also have been some good reason why the true spontaneous neuroses resembled no group of diseases more closely than the phenomena of intoxication and abstinence, which are produced by the administration or privation of certain toxic substances, or than exophthalmic goitre, which is known to depend upon the product of the thyroid gland.
During the years that followed the publication of the *Studies*, having reached these conclusions upon the part played by sexuality in the aetiology of the neuroses, I read some papers on the subject before various medical societies, but was only met with incredulity and contradiction. Breuer did what he could for some time longer to throw the great weight of his personal influence into the scales in my favour, but he effected nothing and it was easy to see that he too shrank from recognizing the sexual aetiology of the neuroses. He might have crushed me or at least disconcerted me by pointing to his own first patient, in whose case sexual factors had ostensibly played no part whatever. But he never did so, and I could not understand why this was, until I came to interpret the case correctly and to reconstruct, from some remarks which he had made, the conclusion of his treatment of it. After the work of catharsis had seemed to be completed, the girl had suddenly developed a condition of 'transference love'; he had not connected this with her illness, and had therefore retired in dismay. It was obviously painful to him to be reminded of this apparent *contretemps*. His attitude towards me oscillated for some time between appreciation and sharp criticism; then accidental difficulties arose, as they never fail to do in a strained situation, and we parted.

[1925d, 4203]

I have already mentioned that my investigation of the precipitating and underlying causes of the neuroses led me more and more frequently to conflicts between the subject's sexual impulses and his resistances to sexuality. In my search for the pathogenic situations in which the repressions of sexuality had set in and in which the symptoms, as substitutes for what was repressed, had had their origin, I was carried further and further back into the patient's life and ended by reaching the first years of his childhood. What poets and students of human nature had always asserted turned out to be true: the impressions of that early period of life, though they were for the most part buried in amnesia, left ineradicable traces upon the individual's growth and in particular laid down the disposition to any nervous disorder that was to follow. But since these experiences of childhood were always concerned with sexual excitations and the reaction against them, I found myself faced by the fact of *infantile sexuality* - once again a novelty and a contradiction of one of the strongest of human prejudices. Childhood was looked upon as 'innocent' and free from the lusts of sex, and the fight with the demon of 'sensuality' was not thought to begin until the troubled age of puberty. Such occasional sexual activities as it had been impossible to overlook in children were put down as signs of degeneracy or premature depravity or as a curious freak of nature. Few of the findings of psycho-analysis have met with such universal contradiction or have aroused such an outburst of indignation as the assertion that the sexual function starts at the beginning of life and reveals its presence by important signs even in childhood. And yet no other finding of analysis can be demonstrated so easily and so completely.

[1925d, 4209]
The World War, which broke up so many other organizations, could do nothing against our 'International'. The first meeting after the war took place in 1920, at The Hague, on neutral ground. It was moving to see how hospitably the Dutch welcomed the starving and impoverished subjects of the Central European states; and I believe this was the first occasion in a ruined world on which Englishmen and Germans sat at the same table for the friendly discussion of scientific interests. Both in Germany and in the countries of Western Europe the war had actually stimulated interest in psycho-analysis. The observation of war neuroses had at last opened the eyes of the medical profession to the importance of psychogenesis in neurotic disturbances, and some of our psychological conceptions, such as the 'gain from illness' and the 'flight into illness', quickly became popular. The last Congress before the German collapse, which was held at Budapest in 1918, was attended by official representatives of the allied governments of the Central European powers, and they agreed to the establishment of psycho-analytic Centres for the treatment of war neuroses. But this point was never reached. Similarly too the comprehensive plans made by one of our leading members, Dr. Anton von Freund, for establishing in Budapest a centre for analytic study and treatment came to grief as a result of the political upheavals that followed soon afterwards and of the premature death of their irreplaceable author. At a later date some of his ideas were put into execution by Max Eitingon, who in 1920 founded a psycho-analytical clinic in Berlin. During the brief period of Bolshevik rule in Hungary, Ferenczi was still able to carry on a successful course of instruction as the official representative of psycho-analysis at the University of Budapest. After the war our opponents were pleased to announce that events had produced a conclusive argument against the validity of the theses of analysis. The war neuroses, they said, had proved that sexual factors were unnecessary to the aetiology of neurotic disorders. But their triumph was frivolous and premature. For on the one hand no one had been able to carry out a thorough analysis of a case of war neurosis, so that in fact nothing whatever was known for certain as to their motivation and no conclusions could be drawn from this uncertainty; while on the other hand psycho-analysis had long before arrived at the concept of narcissism and of narcissistic neuroses, in which the subject's libido is attached to his own ego instead of to an object. Though on other occasions, therefore, the charge was brought against psycho-analysis of having made an unjustifiable extension of the concept of sexuality, yet, when it became convenient for controversial ends, this crime was forgotten and we were once more held down to the narrowest meaning of the word.

[1925d, 4229]
The neuroses were the first subject of analysis, and for a long time they were the only one. No analyst could doubt that medical practice was wrong in separating those disorders from the psychoses and in attaching them to the organic nervous diseases. The theory of the neuroses belongs to psychiatry and is indispensable as an introduction to it. It would seem, however, that the analytic study of the psychoses is impracticable owing to its lack of therapeutic results. Mental patients are as a rule without the capacity for forming a positive transference, so that the principal instrument of analytic technique is inapplicable to them. There are nevertheless a number of methods of approach to be found. Transference is often not so completely absent but that it can be used to a certain extent; and analysis has achieved undoubted successes with cyclical depressions, light paranoic modifications, and partial schizophrenias. It has at least been a benefit to science that in many cases the diagnosis can oscillate for quite a long time between assuming the presence of a psychoneurosis or of a dementia praecox; for therapeutic attempts initiated in such cases have resulted in valuable discoveries before they have had to be broken off. But the chief consideration in this connection is that so many things that in the neuroses have to be laboriously fetched up from the depths are found in the psychoses on the surface, visible to every eye. For that reason the best subjects for the demonstration of many of the assertions of analysis are provided by the psychiatric clinic. It was thus bound to happen before long that analysis would find its way to the objects of psychiatric observation. I was able very early (1896) to establish in a case of paranoid dementia the presence of the same aetiological factors and the same emotional complexes as in the neuroses. Jung explained some most puzzling stereotypies in dments by bringing them into relation with the patients' life-histories; Bleuler demonstrated the existence in various psychoses of mechanisms like those which analysis had discovered in neurotics. Since then analysts have never relaxed their efforts to come to an understanding of the psychoses. Especially since it has been possible to work with the concept of narcissism, they have managed, now in this place and now in that, to get a glimpse beyond the wall. Most of all, no doubt, was achieved by Abraham in his elucidation of the melancholias. It is true that in this sphere all our knowledge is not yet converted into therapeutic power; but the mere theoretical gain is not to be despised, and we may be content to wait for its practical application. In the long run even the psychiatrists cannot resist the convincing force of their own clinical material. At the present time German psychiatry is undergoing a kind of 'peaceful penetration' by analytic views. While they continually declare that they will never be psycho-analysts, that they do not belong to the 'orthodox' school or agree with its exaggerations, and in particular that they do not believe in the predominance of the sexual factor, nevertheless the majority of the younger workers take over one piece or another of analytic theory and apply it in their own fashion to the material. All the signs point to the proximity of further developments in the same direction.
[1925d, 4235]
If anxiety is a reaction of the ego to danger, we shall be tempted to regard the traumatic neuroses, which so often follow upon a narrow escape from death, as a direct result of a fear of death (or fear for life) and to dismiss from our minds the question of castration and the dependent relationships of the ego. Most of those who observed the traumatic neuroses that occurred during the last war took this line, and triumphantly announced that proof was now forthcoming that a threat to the instinct of self-preservation could by itself produce a neurosis without any admixture of sexual factors and without requiring any of the complicated hypotheses of psycho-analysis. It is in fact greatly to be regretted that not a single analysis of a traumatic neurosis of any value is extant. And it is to be regretted, not because such an analysis would contradict the aetiological importance of sexuality - for any such contradiction has long since been disposed of by the introduction of the concept of narcissism, which brings the libidinal cathexis of the ego into line with the cathexes of objects and emphasizes the libidinal character of the instinct of self-preservation - but because, in the absence of any analyses of this kind, we have lost a most precious opportunity of drawing decisive conclusions about the relations between anxiety and the formation of symptoms. In view of all that we know about the structure of the comparatively simple neuroses of everyday life, it would seem highly improbable that a neurosis could come into being merely because of the objective presence of danger, without any participation of the deeper levels of the mental apparatus. But the unconscious seems to contain nothing that could give any content to our concept of the annihilation of life. Castration can be pictured on the basis of the daily experience of the faeces being separated from the body or on the basis of losing the mother's breast at weaning. But nothing resembling death can ever have been experienced; or if it has, as in fainting, it has left no observable traces behind. I am therefore inclined to adhere to the view that the fear of death should be regarded as analogous to the fear of castration and that the situation to which the ego is reacting is one of being abandoned by the protecting super-ego - the powers of destiny - so that it has no longer any safeguard against all the dangers that surround it. In addition, it must be remembered that in the experiences which lead to a traumatic neurosis the protective shield against external stimuli is broken through and excessive amounts of excitation impinge upon the mental apparatus; so that we have here a second possibility - that anxiety is not only being signalled as an affect but is also being freshly created out of the economic conditions of the situation.

[1926d, 4286]

On the other hand I cannot identify myself with the view that Rank's theory contradicts the aetiological importance of the sexual instincts as hitherto recognized by psycho-analysis. For his theory only has reference to the individual's relation to the danger-situation, so that it leaves it perfectly open to us to assume that if a person has not been able to master his first dangers he is bound to come to grief as well in later situations involving sexual danger and thus be driven into a neurosis.

[1926d, 4306]
And it must be so, firstly, because analysis is entirely founded on complete candour. Financial circumstances, for instance, are discussed with equal detail and openness: things are said that are kept back from every fellow-citizen, even if he is not a competitor or a tax-collector. I will not dispute - indeed, I will myself insist with energy - that this obligation to candour puts a grave moral responsibility on the analyst as well. And it must be so, secondly, because factors from sexual life play an extremely important, a dominating, perhaps even a specific part among the causes and precipitating factors of neurotic illnesses. What else can analysis do but keep close to its subject-matter, to the material brought up by the patient? The analyst never entices his patient on to the ground of sex. He does not say to him in advance: 'We shall be dealing with the intimacies of your sexual life!' He allows him to begin what he has to say whenever he pleases, and quietly waits until the patient himself touches on sexual things. I used always to warn my pupils: 'Our opponents have told us that we shall come upon cases in which the factor of sex plays no part. Let us be careful not to introduce it into our analyses and so spoil our chance of finding such a case.' But so far none of us has had that good fortune.

I am aware, of course, that our recognition of sexuality has become - whether admittedly or not - the strongest motive for other people's hostility to analysis. Can that shake our confidence? It merely shows us how neurotic our whole civilized life is, since ostensibly normal people do not behave very differently from neurotics. At a time when psycho-analysis was solemnly put on its trial before the learned societies of Germany - to-day things have grown altogether quieter - one of the speakers claimed to possess peculiar authority because, so he said, he even allowed his patients to talk: for diagnostic purposes, clearly, and to test the assertions of analysts. 'But', he added, 'if they begin to talk about sexual matters I shut their mouths.' What do you think of that as a method of demonstration? The learned society applauded the speaker to the echo instead of feeling suitably ashamed on his account. Only the triumphant certainty afforded by the consciousness of prejudices held in common can explain this speaker's want of logical thought. Years later a few of those who had at that time been my followers gave in to the need to free human society from the yoke of sexuality which psycho-analysis was seeking to impose on it. One of them explained that what is sexual does not mean sexuality at all, but something else, something abstract and mystical. And another actually declared that sexual life is merely one of the spheres in which human beings seek to put in action their driving need for power and domination. They have met with much applause, for the moment at least.

Our conviction that a portion of erotic life that has been abnormally employed lies at the basis of neuroses must be unshakeably strengthened by this experience. With this discovery we are once more on a firm footing and can venture to make this love itself the object of analysis. And we can make another observation. Analytic love is not manifested in every case as clearly and blatantly as I have tried to depict it. Why not? We can soon see. In proportion as the purely sensual and the hostile sides of his love try to show themselves, the patient's opposition to them is aroused. He struggles against them and tries to repress them before our very eyes. And now we understand what is happening. The patient is repeating in the form of falling in love with the analyst mental experiences which he has already been through once before; he has transferred on to the analyst mental attitudes that were lying ready in him and were intimately connected with his neurosis. He is also repeating before our eyes his old defensive actions; he would like best to repeat in his relation to the analyst all the history of that forgotten period of his life. So what he is showing us is the kernel of his intimate life history: he is reproducing it tangibly, as though it were actually happening, instead of remembering it. In this way the riddle of the transference-love is solved and the analysis can proceed on its way - with the help of the new situation which had seemed such a menace to it.
The first task of psycho-analysis was the elucidation of nervous disorders. The analytic theory of the neuroses is based on three cornerstones: the recognition of (1) 'repression', of (2) the importance of the sexual instinct and of (3) 'transference'.

[1926f, 4405]

(2) For cultural reasons the most intense repression falls upon the sexual instincts; but it is precisely in connection with them that repression most easily miscarries, so that neurotic symptoms are found to be substitutive satisfactions of repressed sexuality. The belief that in man sexual life begins only at puberty is incorrect. On the contrary, signs of it can be detected from the beginning of extra-uterine existence; it reaches a first culminating point at or before the fifth year ('early period'), after which it is inhibited or interrupted ('latency period') until the age of puberty, which is the second climax of its development. This diphasic onset of sexual development seems to be distinctive of the genus Homo. All experiences during the first period of childhood are of the greatest importance to the individual, and in combination with his inherited sexual constitution form the dispositions for the subsequent development of character and disease. It is wrong to make sexuality coincide with 'genitality'. The sexual instincts pass through a complicated course of development, and it is only at the end of it that the 'primacy of the genital zones' is attained. Before this there are a number of 'pregenital' organizations of the libido - points at which it may become 'fixated' and to which, in the event of subsequent repression, it will return ('regression'). The infantile fixations of the libido are what determine the form of any later neurosis. Thus the neuroses are to be regarded as inhibitions in the development of the libido. There are no specific causes of nervous disorders; the question whether a conflict finds a healthy solution or leads to a neurotic inhibition of function depends upon quantitative considerations.

[1926f, 4405]

Psycho-analytic work has shown us that it is precisely these frustrations of sexual life which people known as neurotics cannot tolerate. The neurotic creates substitutive satisfactions for himself in his symptoms, and these either cause him suffering in themselves or become sources of suffering for him by raising difficulties in his relations with his environment and the society he belongs to. The latter fact is easy to understand; the former presents us with a new problem. But civilization demands other sacrifices besides that of sexual satisfaction.

[1930a, 4500]
As regards the other point - the specific instinctual factor - we come upon an interesting discrepancy between theory and experience. Theoretically there is no objection to supposing that any sort of instinctual demand might occasion the same repressions and their consequences; but our observation shows us invariably, so far as we can judge, that the excitations that play this pathogenic part arise from the component instincts of sexual life. The symptoms of neuroses are, it might be said, without exception either a substitutive satisfaction of some sexual urge or measures to prevent such a satisfaction; and as a rule they are compromises between the two, of the kind that come about in accordance with the laws operating between contraries in the unconscious. The gap in our theory cannot at present be filled; our decision is made more difficult by the fact that most of the urges of sexual life are not of a purely erotic nature but have arisen from alloys of the erotic instinct with portions of the destructive instinct. But it cannot be doubted that the instincts which manifest themselves physiologically as sexuality play a prominent, unexpectedly large part in the causation of the neuroses - whether it is an exclusive one remains to be decided. It must also be borne in mind that in the course of cultural development no other function has been so energetically and extensively repudiated as precisely the sexual one. Theory must rest satisfied with a few hints that betray a deeper connection: the fact that the first period of childhood, during which the ego begins to be differentiated from the id, is also the period of the early sexual efflorescence which is brought to an end by the period of latency; that it can hardly be a matter of chance that this momentous early period subsequently falls a victim to infantile amnesia; and lastly, that biological changes in sexual life (such as the function's diphasic onset which we have already mentioned, the disappearance of the periodic character of sexual excitation and the transformation in the relation between female menstruation and male excitation) - that these innovations in sexuality must have been of high importance in the evolution of animals into man. It is left for the science of the future to bring these still isolated data together into a new understanding. It is not in psychology but in biology that there is a gap here. We shall not be wrong, perhaps, in saying that the weak point in the ego's organization seems to lie in its attitude to the sexual function, as though the biological antithesis between self-preservation and the preservation of the species had found a psychological expression at that point.

[1940a [1938], 4994]
Perhaps I may give you a more vivid picture of repression and of its necessary relation to resistance, by a rough analogy derived from our actual situation at the present moment. Let us suppose that in this lecture-room and among this audience, whose exemplary quiet and attentiveness I cannot sufficiently commend, there is nevertheless someone who is causing a disturbance and whose ill-mannered laughter, chattering and shuffling with his feet are distracting my attention from my task. I have to announce that I cannot proceed with my lecture; and thereupon three or four of you who are strong men stand up and, after a short struggle, put the interrupter outside the door. So now he is 'repressed', and I can continue my lecture. But in order that the interruption shall not be repeated, in case the individual who has been expelled should try to enter the room once more, the gentlemen who have put my will into effect place their chairs up against the door and thus establish a 'resistance' after the repression has been accomplished. If you will now translate the two localities concerned into psychical terms as the 'conscious' and the 'unconscious', you will have before you a fairly good picture of the process of repression.

Among the other new factors which were added to the cathartic procedure as a result of my work and which transformed it into psycho-analysis, I may mention in particular the theory of repression and resistance, the recognition of infantile sexuality, and the interpreting and exploiting of dreams as a source of knowledge of the unconscious.

The Theory of Repression. - These theoretical considerations, taken together with the immediate impressions derived from analytic work, lead to a view of the neuroses which may be described in the roughest outline as follows. The neuroses are the expression of conflicts between the ego and such of the sexual impulses as seem to the ego incompatible with its integrity or with its ethical standards. Since these impulses are not ego-syntonic, the ego has repressed them: that is to say, it has withdrawn its interest from them and has shut them off from becoming conscious as well as from obtaining satisfaction by motor discharge. If in the course of analytic work one attempts to make these repressed impulses conscious, one becomes aware of the repressive forces in the form of resistance. But the achievement of repression fails particularly readily in the case of the sexual instincts. Their dammed-up libido finds other ways out from the unconscious: for it regresses to earlier phases of development and earlier attitudes towards objects, and, at weak points in the libidinal development where there are infantile fixations, it breaks through into consciousness and obtains discharge. What results is a symptom and consequently in its essence a substitutive sexual satisfaction. Nevertheless the symptom cannot entirely escape from the repressive forces of the ego and must therefore submit to modifications and displacements exactly as happens with dreams - by means of which its characteristic of being a sexual satisfaction becomes unrecognizable. Consequently symptoms are in the nature of compromises between the repressed sexual instincts and the repressing ego-instincts; they represent a wish-fulfilment for both partners to the conflict simultaneously, but one which is incomplete for each of them. This is quite strictly true of the symptoms of hysteria, while in the symptoms of obsessional neurosis there is often a stronger emphasis upon the side of the repressing function owing to the erection of reaction-formations, which are assurances against sexual satisfaction.
But we have arrived at the term or concept of the unconscious along another path, by considering certain experiences in which mental dynamics play a part. We have found - that is, we have been obliged to assume - that very powerful mental processes or ideas exist (and here a quantitative or economic factor comes into question for the first time) which can produce all the effects in mental life that ordinary ideas do (including effects that can in their turn become conscious as ideas), though they themselves do not become conscious. It is unnecessary to repeat in detail here what has been explained so often before. It is enough to say that at this point psycho-analytic theory steps in and asserts that the reason why such ideas cannot become conscious is that a certain force opposes them, that otherwise they could become conscious, and that it would then be apparent how little they differ from other elements which are admittedly psychical. The fact that in the technique of psycho-analysis a means has been found by which the opposing force can be removed and the ideas in question made conscious renders this theory irrefutable. The state in which the ideas existed before being made conscious is called by us repression, and we assert that the force which instituted the repression and maintains it is perceived as resistance during the work of analysis [1923b, 3948]

It is possible to take repression as a centre and to bring all the elements of psycho-analytic theory into relation with it. But before doing so I have a further comment of a polemical nature to make. According to Janet's view a hysterical woman was a wretched creature who, on account of a constitutional weakness, was unable to hold her mental acts together, and it was for that reason that she fell a victim to a splitting of her mind and to a restriction of the field of her consciousness. The outcome of psycho-analytic investigations, on the other hand, showed that these phenomena were the result of dynamic factors - of mental conflict and of repression. This distinction seems to me to be far-reaching enough to put an end to the glib repetition of the view that whatever is of value in psycho-analysis is merely borrowed from the ideas of Janet. The reader will have learned from my account that historically psycho-analysis is completely independent of Janet's discoveries, just as in its content it diverges from them and goes far beyond them. Janet's works would never have had the implications which have made psycho-analysis of such importance to the mental sciences and have made it attract such universal interest. I always treated Janet himself with respect, since his discoveries coincided to a considerable extent with those of Breuer, which had been made earlier but were published later than his. But when in the course of time psycho-analysis became a subject of discussion in France, Janet behaved ill, showed ignorance of the facts and used ugly arguments. And finally he revealed himself to my eyes and destroyed the value of his own work by declaring that when he had spoken of 'unconscious' mental acts he had meant nothing by the phrase - it had been no more than a façon de parler: [1925d, 4207]

The theories of resistance and of repression, of the unconscious, of the aetiological significance of sexual life and of the importance of infantile experiences - these form the principal constituents of the theoretical structure of psycho-analysis. In these pages, unfortunately, I have been able to describe only the separate elements and not their interconnections and their bearing upon one another. But I am obliged now to turn to the alterations which gradually took place in the technique of the analytic method. [1925d, 4215]
An important element in the theory of repression is the view that repression is not an event that occurs once but that it requires a permanent expenditure. If this expenditure were to cease, the repressed impulse, which is being fed all the time from its sources, would on the next occasion flow along the channels from which it had been forced away, and the repression would either fail in its purpose or would have to be repeated an indefinite number of times. Thus it is because instincts are continuous in their nature that the ego has to make its defensive action secure by a permanent expenditure. This action undertaken to protect repression is observable in analytic treatment as resistance. Resistance presupposes the existence of what I have called anticathexis. An anticathexis of this kind is clearly seen in obsessional neurosis. It appears there in the form of an alteration of the ego, as a reaction-formation in the ego, and is effected by the reinforcement of the attitude which is the opposite of the instinctual trend that has to be repressed - as, for instance, in pity, conscientiousness and cleanliness. These reaction-formations of obsessional neurosis are essentially exaggerations of the normal traits of character which develop during the latency period. The presence of an anticathexis in hysteria is much more difficult to detect, though theoretically it is equally indispensable. In hysteria, too, a certain amount of alteration of the ego through reaction-formation is unmistakable and in some circumstances becomes so marked that it forces itself on our attention as the principal symptom. The conflict due to ambivalence, for instance, is resolved in hysteria by this means. The subject's hatred of a person whom he loves is kept down by an exaggerated amount of tenderness for him and apprehensiveness about him. But the difference between reaction-formations in obsessional neurosis and in hysteria is that in the latter they do not have the universality of a character-trait but are confined to particular relationships. A hysterical woman, for instance, may be specially affectionate with her own children whom at bottom she hates; but she will not on that account be more loving in general than other women or even more affectionate to other children. The reaction-formation of hysteria clings tenaciously to a particular object and never spreads over into a general disposition of the ego, whereas what is characteristic of obsessional neurosis is precisely a spreading-over of this kind - a loosening of relations to the object and a facilitation of displacement in the choice of object.

(1) There is a force in the mind which exercises the functions of a censorship, and which excludes from consciousness and from any influence upon action all tendencies which displease it. Such tendencies are described as 'repressed'. They remain unconscious; and if one attempts to bring them into the patient's consciousness one provokes a 'resistance'. These repressed instinctual impulses, however, have not always become powerless. In many cases they succeed in making their influence felt in the mind by circuitous paths, and the indirect or substitutive satisfactions of repressed impulses thus achieved are what constitute neurotic symptoms.
The fact that the phenomena of censorship and of dream-distortion correspond down to their smallest details justifies us in presuming that they are similarly determined. We may therefore suppose that dreams are given their shape in individual human beings by the operation of two psychical forces (or we may describe them as currents or systems); and that one of these forces constructs the wish which is expressed by the dream, while the other exercises a censorship upon this dream-wish and, by the use of that censorship, forcibly brings about a distortion in the expression of the wish. It remains to enquire as to the nature of the power enjoyed by this second agency which enables it to exercise its censorship. When we bear in mind that the latent dream-thoughts are not conscious before an analysis has been carried out, whereas the manifest content of the dream is consciously remembered, it seems plausible to suppose that the privilege enjoyed by the second agency is that of permitting thoughts to enter consciousness. Nothing, it would seem, can reach consciousness from the first system without passing the second agency; and the second agency allows nothing to pass without exercising its rights and making such modifications as it thinks fit in the thought which is seeking admission to consciousness. Incidentally, this enables us to form a quite definite view of the 'essential nature' of consciousness: we see the process of a thing becoming conscious as a specific psychical act, distinct from and independent of the process of the formation of a presentation or idea; and we regard consciousness as a sense organ which perceives data that arise elsewhere. It can be demonstrated that these basic assumptions are absolutely indispensable to psychopathology. We must, however, postpone our further consideration of them to a later stage.

If this picture of the two psychical agencies and their relation to consciousness is accepted, there is a complete analogy in political life to the extraordinary affection which I felt in my dream for my friend R., who was treated with such contumely during the dream's interpretation. Let us imagine a society in which a struggle is in process between a ruler who is jealous of his power and an alert public opinion. The people are in revolt against an unpopular official and demand his dismissal. But the autocrat, to show that he need take no heed of the popular wish, chooses that moment for bestowing a high distinction upon the official, though there is no other reason for doing so. In just the same way my second agency, which commands the approaches to consciousness, distinguished my friend R. by a display of excessive affection simply because the wishful impulses belonging to the first system, for particular reasons of their own on which they were intent at the moment, chose to condemn him as a simpleton.

These considerations may lead us to feel that the interpretation of dreams may enable us to draw conclusions as to the structure of our mental apparatus which we have hoped for in vain from philosophy. I do not propose, however, to follow this line of thought; but, having cleared up the matter of distortion in dreams, I shall go back to the problem from which we started. The question raised was how dreams with a distressing content can be resolved into wish-fulfilments. We now see that this is possible if dream-distortion has occurred and if the distressing content serves only to disguise something that is wished for. Bearing in mind our assumption of the existence of two psychical agencies, we can further say that distressing dreams do in fact contain something which is distressing to the second agency, but something which at the same time fulfils a wish on the part of the first agency. They are wishful dreams in so far as every dream arises from the first agency; the relation of the second agency towards dreams is of a defensive and not of a creative kind. If we were to restrict ourselves to considering what the second agency contributes to dreams, we could never arrive at an understanding of them: all the conundrums which the authorities have observed in dreams would remain unsolved.
Of the three characteristics of memory in dreams enumerated at the beginning of this chapter, one - the preference for non-essential material in the content of dreams - has been satisfactorily cleared up by being traced back to dream-distortion. We have been able to confirm the existence of the other two - the emphasis upon recent and upon infantile material - but we have not been able to account for them on the basis of the motives that lead to dreaming. These two characteristics - inclusion of both recent and infantile material, whose explanation and appreciation remain to be discovered, must be kept in mind. Their proper place must be looked for elsewhere - either in the psychology of the state of sleep or in the discussion of the structure of the mental apparatus upon which we shall later embark, after we have learnt that the interpretation of dreams is like a window through which we can get a glimpse of the interior of that apparatus.
[1900a, 699]

When external nervous stimuli and internal somatic stimuli are intense enough to force psychical attention to themselves, then - provided that their outcome is dreaming and not waking up - they serve as a fixed point for the formation of a dream, a nucleus in its material; a wish-fulfilment is then looked for that shall correspond to this nucleus, just as (see above) intermediate ideas are looked for between two psychical dream stimuli. To that extent it is true that in a number of dreams the content of the dream is dictated by the somatic element. In this extreme instance it may even happen that a wish which is not actually a currently active one is called up for the sake of constructing a dream. A dream, however, has no alternative but to represent a wish in the situation of having been fulfilled; it is, as it were, faced with the problem of looking for a wish which can be represented as fulfilled by the currently active sensation. If this immediate material is of a painful or distressing kind, that does not necessarily mean that it cannot be used for the construction of a dream. The mind has wishes at its disposal whose fulfilment produces unpleasure. This seems self-contradictory; but it becomes intelligible when we take into account the presence of two psychical agencies and a censorship between them.
[1900a, 714]

But before starting off along this new path, it will be well to pause and look around, to see whether in the course of our journey up to this point we have overlooked anything of importance. For it must be clearly understood that the easy and agreeable portion of our journey lies behind us. Hitherto, unless I am greatly mistaken, all the paths along which we have travelled have led us towards the light - towards elucidation and fuller understanding. But as soon as we endeavour to penetrate more deeply into the mental process involved in dreaming, every path will end in darkness. There is no possibility of explaining dreams as a psychical process, since to explain a thing means to trace it back to something already known, and there is at the present time no established psychological knowledge under which we could subsume what the psychological examination of dreams enables us to infer as a basis for their explanation. On the contrary, we shall be obliged to set up a number of fresh hypotheses which touch tentatively upon the structure of the apparatus of the mind and upon the play of forces operating in it. We must be careful, however, not to pursue these hypotheses too far beyond their first logical links, or their value will be lost in uncertainties. Even if we make no false inferences and take all the logical possibilities into account, the probable incompleteness of our premises threatens to bring our calculation to a complete miscarriage. No conclusions upon the construction and working methods of the mental instrument can be arrived at or at least fully proved from even the most painstaking investigation of dreams or of any other mental function taken in isolation. To achieve this result, it will be necessary to correlate all the established implications derived from a comparative study of a whole series of such functions. Thus the psychological hypotheses to which we are led by an analysis of the processes of dreaming must be left, as it were, in suspense, until they can be related to the findings of other enquiries which seek to approach the kernel of the same problem from another angle.
[1900a, 947]
We have recognized our mental apparatus as being first and foremost a device designed for mastering excitations which would otherwise be felt as distressing or would have pathogenic effects. Working them over in the mind helps remarkably towards an internal draining away of excitations which are incapable of direct discharge outwards, or for which such a discharge is for the moment undesirable. In the first instance, however, it is a matter of indifference whether this internal process of working-over is carried out upon real or imaginary objects. The difference does not appear till later - if the turning of the libido on to unreal objects (introversion) has led to its being dammed up. In paraphrenics, megalomania allows of a similar internal working-over of libido which has returned to the ego; perhaps it is only when the megalomania fails that the damming-up of libido in the ego becomes pathogenic and starts the process of recovery which gives us the impression of being a disease.

For the moment we will dwell a little longer on regression. After what you have learnt of the development of the libidinal function, you will be prepared to hear that there are regressions of two sorts: a return to the objects first cathected by the libido, which, as we know, are of an incestuous nature, and a return of the sexual organization as a whole to earlier stages. Both sorts are found in the transference neuroses and play a great part in their mechanism. In particular, a return to the first incestuous objects of the libido is a feature that is found in neurotics with positively fatiguing regularity. There is much more to be said about regressions of the libido itself when we take into account as well another group of neuroses, the narcissistic ones, which for the time being we do not intend to do. These disorders give us access to other developmental processes of the libidinal function which we have not yet mentioned, and show us correspondingly new sorts of regression as well. But above all I think I ought to warn you now not to confuse regression with repression and help you to form a clear idea of the relations between the two processes. Repression, as you will recall, is the process by which an act which is admissible to consciousness, one, therefore, which belongs to the system Pcs., is made unconscious - is pushed back, therefore, into the system Ucs. And we equally speak of repression if the unconscious mental act is altogether forbidden access to the neighbouring preconscious system and is turned back at the threshold by the censorship. Thus the concept of repression involves no relation to sexuality: I must ask you to take special note of that. It indicates a purely psychological process, which we can characterize still better if we call it a 'topographical' one. By this we intend to say that it is concerned with the psychical regions which we have assumed to exist, or, if we drop this clumsy working hypothesis, with the construction of the mental apparatus out of distinct psychical systems.
There can be no doubt that that apparatus has only reached its present perfection after a long period of development. Let us attempt to carry it back to an earlier stage of its functioning capacity. Hypotheses, whose justification must be looked for in other directions, tell us that at first the apparatus's efforts were directed towards keeping itself so far as possible free from stimuli; consequently its first structure followed the plan of a reflex apparatus, so that any sensory excitation impinging on it could be promptly discharged along a motor path. But the exigencies of life interfere with this simple function, and it is to them, too, that the apparatus owes the impetus to further development. The exigencies of life confront it first in the form of the major somatic needs. The excitations produced by internal needs seek discharge in movement, which may be described as an 'internal change' or an 'expression of emotion.' A hungry baby screams or kicks helplessly. But the situation remains unaltered, for the excitation arising from an internal need is not due to a force producing a momentary impact but to one which is in continuous operation. A change can only come about if in some way or other (in the case of the baby, through outside help) an 'experience of satisfaction' can be achieved which puts an end to the internal stimulus. An essential component of this experience of satisfaction is a particular perception (that of nourishment, in our example) the mnemonic image of which remains associated thenceforward with the memory trace of the excitation produced by the need. As a result of the link that has thus been established, next time this need arises a psychical impulse will at once emerge which will seek to re-cathect the mnemonic image of the perception and to re-evoke the perception itself, that is to say, to re-establish the situation of the original satisfaction. An impulse of this kind is what we call a wish; the reappearance of the perception is the fulfilment of the wish; and the shortest path to the fulfilment of the wish is a path leading direct from the excitation produced by the need to a complete cathexis of the perception. Nothing prevents us from assuming that there was a primitive state of the psychical apparatus in which this path was actually traversed, that is, in which wishing ended in hallucinating. Thus the aim of this first psychical activity was to produce a 'perceptual identity' - a repetition of the perception which was linked with the satisfaction of the need.

[1900a, 995]
The bitter experience of life must have changed this primitive thought-activity into a more expedient secondary one. The establishment of a perceptual identity along the short path of regression within the apparatus does not have the same result elsewhere in the mind as does the cathectic of the same perception from without. Satisfaction does not follow; the need persists. An internal cathectic could only have the same value as an external one if it were maintained unceasingly, as in fact occurs in hallucinatory psychoses and hunger phantasies, which exhaust their whole psychical activity in clinging to the object of their wish. In order to arrive at a more efficient expenditure of psychical force, it is necessary to bring the regression to a halt before it becomes complete, so that it does not proceed beyond the mnemonic image, and is able to seek out other paths which lead eventually to the desired perceptual identity being established from the direction of the external world.¹ This inhibition of the regression and the subsequent diversion of the excitation become the business of a second system, which is in control of voluntary movement - which for the first time, that is, makes use of movement for purposes remembered in advance. But all the complicated thought-activity which is spun out from the mnemonic image to the moment at which the perceptual identity is established by the external world - all this activity of thought merely constitutes a roundabout path to wish-fulfilment which has been made necessary by experience.² Thought is after all nothing but a substitute for a hallucinatory wish; and it is self-evident that dreams must be wish-fulfilments, since nothing but a wish can set our mental apparatus at work. Dreams, which fulfil their wishes along the short path of regression, have merely preserved for us in that respect a sample of the psychical apparatus's primary method of working, a method which was abandoned as being inefficient. What once dominated waking life, while the mind was still young and incompetent, seems now to have been banished into the night - just as the primitive weapons, the bows and arrows, that have been abandoned by adult men, turn up once more in the nursery. Dreaming is a piece of infantile mental life that has been superseded. These methods of working on the part of the psychical apparatus, which are normally suppressed in waking hours, become current once more in psychosis and then reveal their incapacity for satisfying our needs in relation to the external world.³

We have already explored the fiction of a primitive psychical apparatus whose activities are regulated by an effort to avoid an accumulation of excitation and to maintain itself so far as possible without excitation. For that reason it is built upon the plan of a reflex apparatus. The power of movement, which is in the first instance a means of bringing about internal alterations in its body, is at its disposal as the path to discharge. We went on to discuss the psychical consequences of an 'experience of satisfaction'; and in that connection we were already able to add a second hypothesis, to the effect that the accumulation of excitation (brought about in various ways that need not concern us) is felt as unpleasure and that it sets the apparatus in action with a view to repeating the experience of satisfaction, which involved a diminution of excitation and was felt as pleasure. A current of this kind in the apparatus, starting from unpleasure and aiming at pleasure, we have termed a 'wish'; and we have asserted that only a wish is able to set the apparatus in motion and that the course of the excitation in it is automatically regulated by feelings of pleasure and unpleasure. The first wishing seems to have been a hallucinatory cathecting of the memory of satisfaction. Such hallucinations, however, if they were not to be maintained to the point of exhaustion, proved to be inadequate to bring about the cessation of the need or, accordingly, the pleasure attaching to satisfaction.

[1900a, 996]

[1900a, 1025]
A second activity - or, as we put it, the activity of a second system - became necessary, which would not allow the mnemonic cathexis to proceed as far as perception and from there to bind the psychical forces; instead, it diverted the excitation arising from the need along a roundabout path which ultimately, by means of voluntary movement, altered the external world in such a way that it became possible to arrive at a real perception of the object of satisfaction. We have already outlined our schematic picture of the psychical apparatus up to this point; the two systems are the germ of what, in the fully developed apparatus, we have described as the \( Ucs. \) and \( Pcs. \)

[1900a, 1026]

In order to be able to employ the power of movement to make alterations in the external world that shall be effective, it is necessary to accumulate a great number of experiences in the mnemonic systems and a multiplicity of permanent records of the associations called up in this mnemonic material by different purposive ideas. We can now carry our hypotheses a step further. The activity of this second system, constantly feeling its way, and alternately sending out and withdrawing cathexes, needs on the one hand to have the whole of the material of memory freely at its command; but on the other hand it would be an unnecessary expenditure of energy if it sent out large quantities of cathexis along the various paths of thought and thus caused them to drain away to no useful purpose and diminish the quantity available for altering the external world. I therefore postulate that for the sake of efficiency the second system succeeds in retaining the major part of its cathexes of energy in a state of quiescence and in employing only a small part on displacement. The mechanics of these processes are quite unknown to me; anyone who wished to take these ideas seriously would have to look for physical analogies to them and find a means of picturing the movements that accompany excitation of neurones. All that I insist upon is the idea that the activity of the first \( \Psi \)-system is directed towards securing the free discharge of the quantities of excitation, while the second system, by means of the cathexes emanating from it, succeeds in inhibiting this discharge and in transforming the cathexis into a quiescent one, no doubt with a simultaneous raising of its level. I presume, therefore, that under the dominion of the second system the discharge of excitation is governed by quite different mechanical conditions from those in force under the dominion of the first system. When once the second system has concluded its exploratory thought-activity, it releases the inhibition and damming-up of the excitations and allows them to discharge themselves in movement.

[1900a, 1026]
The hypothesis we have adopted of a psychical apparatus extended in space, expediently put together, developed by the exigencies of life, which gives rise to the phenomena of consciousness only at one particular point and under certain conditions - this hypothesis has put us in a position to establish psychology on foundations similar to those of any other science, such, for instance, as physics. In our science as in the others the problem is the same: behind the attributes (qualities) of the object under examination which are presented directly to our perception, we have to discover something else which is more independent of the particular receptive capacity of our sense organs and which approximates more closely to what may be supposed to be the real state of affairs. We have no hope of being able to reach the latter itself, since it is evident that everything new that we have inferred must nevertheless be translated back into the language of our perceptions, from which it is simply impossible for us to free ourselves. But herein lies the very nature and limitation of our science. It is as though we were to say in physics: 'If we could see clearly enough we should find that what appears to be a solid body is made up of particles of such and such a shape and size and occupying such and such relative positions.' In the meantime we try to increase the efficiency of our sense organs to the furthest possible extent by artificial aids; but it may be expected that all such efforts will fail to affect the ultimate outcome. Reality will always remain 'unknowable'. The yield brought to light by scientific work from our primary sense perceptions will consist in an insight into connections and dependent relations which are present in the external world, which can somehow be reliably reproduced or reflected in the internal world of our thought and a knowledge of which enables us to 'understand' something in the external world, to foresee it and possibly to alter it. Our procedure in psycho-analysis is quite similar. We have discovered technical methods of filling up the gaps in the phenomena of our consciousness, and we make use of those methods just as a physicist makes use of experiment. In this manner we infer a number of processes which are in themselves 'unknowable' and interpolate them in those that are conscious to us. And if, for instance, we say: 'At this point an unconscious memory intervened', what that means is: 'At this point something occurred of which we are totally unable to form a conception, but which, if it had entered our consciousness, could only have been described in such and such a way.'

[1940a [1938], 5003]
What is presented to us in these words is the idea of *psychical locality*. I shall entirely disregard the fact that the mental apparatus with which we are here concerned is also known to us in the form of an anatomical preparation, and I shall carefully avoid the temptation to determine psychical locality in any anatomical fashion. I shall remain upon psychological ground, and I propose simply to follow the suggestion that we should picture the instrument which carries out our mental functions as resembling a compound microscope or a photographic apparatus, or something of the kind. On that basis, psychical locality will correspond to a point inside the apparatus at which one of the preliminary stages of an image comes into being. In the microscope and telescope, as we know, these occur in part at ideal points, regions in which no tangible component of the apparatus is situated. I see no necessity to apologize for the imperfections of this or of any similar imagery. Analogies of this kind are only intended to assist us in our attempt to make the complications of mental functioning intelligible by dissecting the function and assigning its different constituents to different component parts of the apparatus. So far as I know, the experiment has not hitherto been made of using this method of dissection in order to investigate the way in which the mental instrument is put together, and I can see no harm in it. We are justified, in my view, in giving free rein to our speculations so long as we retain the coolness of our judgement and do not mistake the scaffolding for the building. And since at our first approach to something unknown all that we need is the assistance of provisional ideas, I shall give preference in the first instance to hypotheses of the crudest and most concrete description.

Accordingly, we will picture the mental apparatus as a compound instrument, to the components of which we will give the name of 'agencies', or (for the sake of greater clarity) 'systems.' It is to be anticipated, in the next place, that these systems may perhaps stand in a regular spatial relation to one another, in the same kind of way in which the various systems of lenses in a telescope are arranged behind one another. Strictly speaking there is no need for the hypothesis that the psychical systems are actually arranged in a *spatial* order. It would be sufficient if a fixed order were established by the fact that in a given psychical process the excitation passes through the systems in a particular *temporal* sequence. In other processes the sequence may perhaps be a different one; that is a possibility that we shall leave open. For the sake of brevity we will in future speak of the components of the apparatus as ''Ψ'-systems.'

The first thing that strikes us is that this apparatus, compounded of Ψ'-systems, has a sense or direction. All our psychical activity starts from stimuli (whether internal or external) and ends in innervations. Accordingly, we shall ascribe a sensory and a motor end to the apparatus. At the sensory end there lies a system which receives perceptions; at the motor end there lies another, which opens the gateway to motor activity. Psychical processes advance in general from the perceptual end to the motor end. Thus the most general schematic picture of the psychical apparatus may be represented thus (Fig. 1):

This, however, does no more than fulfil a requirement with which we have long been familiar, namely that the psychical apparatus must be constructed like a reflex apparatus. Reflex processes remain the model of every psychical function.
Next, we have grounds for introducing a first differentiation at the sensory end. A trace is left in our psychical apparatus of the perceptions which impinge upon it. This we may describe as a 'memory-trace'; and to the function relating to it we give the name of 'memory.' If we are in earnest over our plan of attaching psychical processes to systems, memory-traces can only consist in permanent modifications of the elements of the systems. But, as has already been pointed out elsewhere, there are obvious difficulties involved in supposing that one and the same system can accurately retain modifications of its elements and yet remain perpetually open to the reception of fresh occasions for modification. In accordance, therefore, with the principle which governs our experiment, we shall distribute these two functions on to different systems. We shall suppose that a system in the very front of the apparatus receives the perceptual stimuli but retains no trace of them and thus has no memory, while behind it there lies a second system which transforms the momentary excitations of the first system into permanent traces. The schematic picture of our psychical apparatus would then be as follows (Fig. 2):

[1900a, 971]

The assumptions we have so far put forward as to the construction of the psychical apparatus at its sensory end have been made without reference to dreams or to the psychological information that we have been able to infer from them. Evidence afforded by dreams will, however, help us towards understanding another portion of the apparatus. We have seen that we were only able to explain the formation of dreams by venturing upon the hypothesis of there being two psychical agencies, one of which submitted the activity of the other to a criticism which involved its exclusion from consciousness. The critical agency, we concluded, stands in a closer relation to consciousness than the agency criticized: it stands like a screen between the latter and consciousness. Further we found reasons for identifying the critical agency with the agency which directs our waking life and determines our voluntary, conscious actions. If, in accordance with our assumptions, we replace these agencies by systems, then our last conclusion must lead us to locate the critical system at the motor end of the apparatus. We will now introduce the two system into our schematic picture and give them names to express their relation to consciousness (Fig. 3):

[1900a, 973]

We have already explored the fiction of a primitive psychical apparatus whose activities are regulated by an effort to avoid an accumulation of excitation and to maintain itself so far as possible without excitation. For that reason it is built upon the plan of a reflex apparatus. The power of movement, which is in the first instance a means of bringing about internal alterations in its body, is at its disposal as the path to discharge. We went on to discuss the psychical consequences of an 'experience of satisfaction'; and in that connection we were already able to add a second hypothesis, to the effect that the accumulation of excitation (brought about in various ways that need not concern us) is felt as unpleasure and that it sets the apparatus in action with a view to repeating the experience of satisfaction, which involved a diminution of excitation and was felt as pleasure. A current of this kind in the apparatus, starting from unpleasure and aiming at pleasure, we have termed a 'wish'; and we have asserted that only a wish is able to set the apparatus in motion and that the course of the excitation in it is automatically regulated by feelings of pleasure and unpleasure. The first wishing seems to have been a hallucinatory cathecting of the memory of satisfaction. Such hallucinations, however, if they were not to be maintained to the point of exhaustion, proved to be inadequate to bring about the cessation of the need or, accordingly, the pleasure attaching to satisfaction.

[1900a, 1025]
Nevertheless, I consider it expedient and justifiable to continue to make use of the figurative image of the two systems. We can avoid any possible abuse of this method of representation by recollecting that ideas, thoughts and psychical structures in general must never be regarded as localized in organic elements of the nervous system but rather, as one might say, *between* them, where resistances and facilitations (*Bahnungen*) provide the corresponding correlates. Everything that can be an object of our internal perception is *virtual*, like the image produced in a telescope by the passage of light-rays. But we are justified in assuming the existence of the systems (which are not in any way psychical entities themselves and can never be accessible to our psychical perception) like the lenses of the telescope, which cast the image. And, if we pursue this analogy, we may compare the censorship between two systems to the refraction which takes place when a ray of light passes into a new medium.

[1900a, 1036]

It seems to us now that, in view of the very great extent to which repression and what is unconscious are correlated, we must defer probing more deeply into the nature of repression until we have learnt more about the structure of the succession of psychical agencies and about the differentiation between what is unconscious and conscious. Till then, all we can do is to put together in a purely descriptive fashion a few characteristics of repression that have been observed clinically, even though we run the risk of having to repeat unchanged much that has been said elsewhere.

[1915d, 2979]

For the moment we will dwell a little longer on regression. After what you have learnt of the development of the libidinal function, you will be prepared to hear that there are regressions of two sorts: a return to the objects first cathected by the libido, which, as we know, are of an incestuous nature, and a return of the sexual organization as a whole to earlier stages. Both sorts are found in the transference neuroses and play a great part in their mechanism. In particular, a return to the first incestuous objects of the libido is a feature that is found in neurotics with positively fatiguing regularity. There is much more to be said about regressions of the libido itself when we take into account as well another group of neuroses, the narcissistic ones, which for the time being we do not intend to do. These disorders give us access to other developmental processes of the libidinal function which we have not yet mentioned, and show us correspondingly new sorts of regression as well. But above all I think I ought to warn you now not to confuse *regression* with *repression* and help you to form a clear idea of the relations between the two processes. Repression, as you will recall, is the process by which an act which is admissible to consciousness, one, therefore, which belongs to the system *Pcs.*, is made unconscious - is pushed back, therefore, into the system *Ucs*. And we equally speak of repression if the unconscious mental act is altogether forbidden access to the neighbouring preconscious system and is turned back at the threshold by the censorship. Thus the concept of repression involves no relation to sexuality: I must ask you to take special note of that. It indicates a purely psychological process, which we can characterize still better if we call it a 'topographical' one. By this we intend to say that it is concerned with the psychical regions which we have assumed to exist, or, if we drop this clumsy working hypothesis, with the construction of the mental apparatus out of distinct psychical systems.

[1916-1917, 3405]
Topographically, psycho-analysis regards the mental apparatus as a compound instrument, and endeavours to determine at what points in it the various mental processes take place. According to the most recent psycho-analytic views, the mental apparatus is composed of an 'id', which is the repository of the instinctual impulses, of an 'ego', which is the most superficial portion of the id and one which has been modified by the influence of the external world, and of a 'super-ego', which develops out of the id, dominates the ego and represents the inhibitions of instinct that are characteristic of man. The quality of consciousness, too, has a topographical reference; for processes in the id are entirely unconscious, while consciousness is the function of the ego's outermost layer, which is concerned with the perception of the external world.

Our two hypotheses start out from these ends or beginnings of our knowledge. The first is concerned with localization. We assume that mental life is the function of an apparatus to which we ascribe the characteristics of being extended in space and of being made up of several portions - which we imagine, that is, as resembling a telescope or microscope or something of the kind. Notwithstanding some earlier attempts in the same direction, the consistent working-out of a conception such as this is a scientific novelty.

The hypothesis we have adopted of a psychical apparatus extended in space, expediently put together, developed by the exigencies of life, which gives rise to the phenomena of consciousness only at one particular point and under certain conditions - this hypothesis has put us in a position to establish psychology on foundations similar to those of any other science, such, for instance, as physics. In our science as in the others the problem is the same: behind the attributes (qualities) of the object under examination which are presented directly to our perception, we have to discover something else which is more independent of the particular receptive capacity of our sense organs and which approximates more closely to what may be supposed to be the real state of affairs. We have no hope of being able to reach the latter itself, since it is evident that everything new that we have inferred must nevertheless be translated back into the language of our perceptions, from which it is simply impossible for us to free ourselves. But herein lies the very nature and limitation of our science. It is as though we were to say in physics: 'If we could see clearly enough we should find that what appears to be a solid body is made up of particles of such and such a shape and size and occupying such and such relative positions.' In the meantime we try to increase the efficiency of our sense organs to the furthest possible extent by artificial aids; but it may be expected that all such efforts will fail to affect the ultimate outcome. Reality will always remain 'unknowable'. The yield brought to light by scientific work from our primary sense perceptions will consist in an insight into connections and dependent relations which are present in the external world, which can somehow be reliably reproduced or reflected in the internal world of our thought and a knowledge of which enables us to 'understand' something in the external world, to foresee it and possibly to alter it. Our procedure in psycho-analysis is quite similar. We have discovered technical methods of filling up the gaps in the phenomena of our consciousness, and we make use of those methods just as a physicist makes use of experiment. In this manner we infer a number of processes which are in themselves 'unknowable' and interpolate them in those that are conscious to us. And if, for instance, we say: 'At this point an unconscious memory intervened', what that means is: 'At this point something occurred of which we are totally unable to form a conception, but which, if it had entered our consciousness, could only have been described in such and such a way.'
As the starting-point for our enquiry, I should like to pick out one from among many remarks made upon the theory of dreaming by those who have written on the subject. In the course of a short discussion on the topic of dreams, the great Fechner (1889, 2, 520-1) puts forward the idea that the scene of action of dreams is different from that of waking ideational life. This is the only hypothesis that makes the special peculiarities of dream-life intelligible.

What is presented to us in these words is the idea of psychical locality. I shall entirely disregard the fact that the mental apparatus with which we are here concerned is also known to us in the form of an anatomical preparation, and I shall carefully avoid the temptation to determine psychical locality in any anatomical fashion. I shall remain upon psychological ground, and I propose simply to follow the suggestion that we should picture the instrument which carries out our mental functions as resembling a compound microscope or a photographic apparatus, or something of the kind. On that basis, psychical locality will correspond to a point inside the apparatus at which one of the preliminary stages of an image comes into being. In the microscope and telescope, as we know, these occur in part at ideal points, regions in which no tangible component of the apparatus is situated. I see no necessity to apologize for the imperfections of this or of any similar imagery. Analogies of this kind are only intended to assist us in our attempt to make the complications of mental functioning intelligible by dissecting the function and assigning its different constituents to different component parts of the apparatus. So far as I know, the experiment has not hitherto been made of using this method of dissection in order to investigate the way in which the mental instrument is put together, and I can see no harm in it. We are justified, in my view, in giving free rein to our speculations so long as we retain the coolness of our judgement and do not mistake the scaffolding for the building. And since at our first approach to something unknown all that we need is the assistance of provisional ideas, I shall give preference in the first instance to hypotheses of the crudest and most concrete description.

Accordingly, we will picture the mental apparatus as a compound instrument, to the components of which we will give the name of 'agencies', or (for the sake of greater clarity) 'systems.' It is to be anticipated, in the next place, that these systems may perhaps stand in a regular spatial relation to one another, in the same kind of way in which the various systems of lenses in a telescope are arranged behind one another. Strictly speaking there is no need for the hypothesis that the psychical systems are actually arranged in a spatial order. It would be sufficient if a fixed order were established by the fact that in a given psychical process the excitation passes through the systems in a particular temporal sequence. In other processes the sequence may perhaps be a different one; that is a possibility that we shall leave open. For the sake of brevity we will in future speak of the components of the apparatus as \( \Psi \)-systems.

The first thing that strikes us is that this apparatus, compounded of \( \Psi \)-systems, has a sense or direction. All our psychical activity starts from stimuli (whether internal or external) and ends in innervations. Accordingly, we shall ascribe a sensory and a motor end to the apparatus. At the sensory end there lies a system which receives perceptions; at the motor end there lies another, which opens the gateway to motor activity. Psychical processes advance in general from the perceptual end to the motor end. Thus the most general schematic picture of the psychical apparatus may be represented thus (Fig. 1):
It is not without intention that I speak of ‘our’ unconscious. For what I thus describe is not the same as the unconscious of the philosophers or even the unconscious of Lipps. By them the term is used merely to indicate a contrast with the conscious: the thesis which they dispute with so much heat and defend with so much energy is the thesis that apart from conscious there are also unconscious psychical processes. Lipps carries things further with his assertion that the whole of what is psychical exists unconsciously and that a part of it also exists consciously. But it is not in order to establish this thesis that we have summoned up the phenomena of dreams and of the formation of hysterical symptoms; the observation of normal waking life would by itself suffice to prove it beyond any doubt. The new discovery that we have been taught by the analysis of psychopathological structures and of the first member of that class - the dream - lies in the fact that the unconscious (that is, the psychical) is found as a function of two separate systems and that this is the case in normal as well as in pathological life. Thus there are two kinds of unconscious, which have not yet been distinguished by psychologists. Both of them are unconscious in the sense used by psychology; but in our sense one of them, which we term the \textit{Ucs}, is also \textit{inadmissible to consciousness}, while we term the other the \textit{Pcs} because its excitations - after observing certain rules, it is true, and perhaps only after passing a fresh censorship, though nonetheless without regard to the \textit{Ucs}. - are able to reach consciousness. The fact that excitations in order to reach consciousness must pass through a fixed series or hierarchy of agencies (which is revealed to us by the modifications made in them by censorship) has enabled us to construct a spatial analogy. We have described the relations of the two systems to each other and to consciousness by saying that the system \textit{Pcs}. stands like a screen between the system \textit{Ucs}. and consciousness. The system \textit{Pcs}. not merely bars access to consciousness, it also controls access to the power of voluntary movement and has at its disposal for distribution a mobile cathectic energy, a part of which is familiar to us in the form of attention.²

[1900a, 1039]

Another and far more surprising discovery has been that, in spite of all the later development that occurs in the adult, none of the infantile mental formations perish. All the wishes, instinctual impulses, modes of reaction and attitudes of childhood are still demonstrably present in maturity and in appropriate circumstances can emerge once more. They are not destroyed but merely overlaid - to use the spatial mode of description which psycho-analytic psychology has been obliged to adopt. Thus it is part of the nature of the mental past that, unlike the historic past, it is not absorbed by its derivatives; it persists (whether actually or only potentially) alongside what has proceeded from it. The proof of this assertion lies in the fact that the dreams of normal people revive their childhood characters every night and reduce their whole mental life to an infantile level. This same return to psychical infantilism (‘regression’) appears in the neuroses and psychoses, whose peculiarities may to a great extent be described as psychical archaisms. The strength in which the residues of infancy are still present in the mind shows us the amount of disposition to illness; that disposition may accordingly be regarded as an expression of an inhibition in development. The part of a person's psychical material which has remained infantile and has been repressed as being unserviceable constitutes the core of his unconscious. And we believe we can follow in our patients' life-histories the way in which this unconscious, held back as it is by the forces of repression, lies in wait for a chance to become active and makes use of its opportunities if the later and higher psychical structures fail to master the difficulties of real life.

[1913j, 2820]
Our two hypotheses start out from these ends or beginnings of our knowledge. The first is concerned with localization. We assume that mental life is the function of an apparatus to which we ascribe the characteristics of being extended in space and of being made up of several portions - which we imagine, that is, as resembling a telescope or microscope or something of the kind. Notwithstanding some earlier attempts in the same direction, the consistent working-out of a conception such as this is a scientific novelty.

[1940a [1938], 4957]

The hypothesis we have adopted of a psychical apparatus extended in space, expediently put together, developed by the exigencies of life, which gives rise to the phenomena of consciousness only at one particular point and under certain conditions - this hypothesis has put us in a position to establish psychology on foundations similar to those of any other science, such, for instance, as physics. In our science as in the others the problem is the same: behind the attributes (qualities) of the object under examination which are presented directly to our perception, we have to discover something else which is more independent of the particular receptive capacity of our sense organs and which approximates more closely to what may be supposed to be the real state of affairs. We have no hope of being able to reach the latter itself, since it is evident that everything new that we have inferred must nevertheless be translated back into the language of our perceptions, from which it is simply impossible for us to free ourselves. But herein lies the very nature and limitation of our science. It is as though we were to say in physics: 'If we could see clearly enough we should find that what appears to be a solid body is made up of particles of such and such a shape and size and occupying such and such relative positions.' In the meantime we try to increase the efficiency of our sense organs to the furthest possible extent by artificial aids; but it may be expected that all such efforts will fail to affect the ultimate outcome. Reality will always remain 'unknowable'. The yield brought to light by scientific work from our primary sense perceptions will consist in an insight into connections and dependent relations which are present in the external world, which can somehow be reliably reproduced or reflected in the internal world of our thought and a knowledge of which enables us to 'understand' something in the external world, to foresee it and possibly to alter it. Our procedure in psycho-analysis is quite similar. We have discovered technical methods of filling up the gaps in the phenomena of our consciousness, and we make use of those methods just as a physicist makes use of experiment. In this manner we infer a number of processes which are in themselves 'unknowable' and interpolate them in those that are conscious to us. And if, for instance, we say: 'At this point an unconscious memory intervened', what that means is: 'At this point something occurred of which we are totally unable to form a conception, but which, if it had entered our consciousness, could only have been described in such and such a way.'

[1940a [1938], 5003]
There are thus abundant signs to be found in healthy, non-neurotic people that the recollection of distressing impressions and the occurrence of distressing thoughts are opposed by a resistance.¹ But the full significance of this fact can be estimated only when the psychology of neurotic people is investigated. We are forced to regard as one of the main pillars of the mechanism supporting hysterical symptoms an *elementary endeavour* of this kind to fend off ideas that can arouse feelings of unpleasure - an endeavour which can only be compared with the flight-reflex in the presence of painful stimuli. The assumption that a defensive trend of this kind exists cannot be objected to on the ground that one often enough finds it impossible, on the contrary, to get rid of distressing memories that pursue one, and to banish distressing affective impulses like remorse and the pangs of conscience. For we are not asserting that this defensive trend is able to put itself into effect in every case, that in the interplay of psychical forces it may not come up against factors which, for other purposes, aim at the opposite effect and bring it about in spite of the defensive trend. It may be surmised that *the architectonic principle of the mental apparatus lies in a stratification - a building up of superimposed agencies*; and it is quite possible that this defensive endeavour belongs to a lower psychical agency and is inhibited by higher agencies. At all events, if we can trace back processes such as those found in our examples of forgetting to this defensive trend, that fact speaks in favour of its existence and power.(As we have seen, a number of things are forgotten on their own account; where this is not possible, the defensive trend shifts its target and causes something else related to the target at least to be forgotten, something less important which has come into associative connection with the thing that is really objectionable.

[1901b, 1229]

When, elsewhere, we come to examine more closely the preconditions for becoming conscious, we shall be able to find a solution of some of the difficulties that arise at this juncture. Here it seems a good plan to look at things from the angle of consciousness, in contrast to our previous approach, which was upwards from the *Ucs*. To consciousness the whole sum of psychical processes presents itself as the realm of the preconscious. A very great part of this preconscious originates in the unconscious, has the character of its derivatives and is subjected to a censorship before it can become conscious. Another part of the *Pcs.* is capable of becoming conscious without any censorship. Here we come upon a contradiction of an earlier assumption. In discussing the subject of repression we were obliged to place the censorship which is decisive for becoming conscious between the systems *Ucs.* and *Pcs.*. Now it becomes probable that there is a censorship between the *Pcs.* and the *Cs.* Nevertheless we shall do well not to regard this complication as a difficulty, but to assume that to every transition from one system to that immediately above it (that is, every advance to a higher stage of psychical organization) there corresponds a new censorship. This, it may be remarked, does away with the assumption of a continuous laying down of new registrations.

[1915e, 3014]
Although thus humbled in his external relations, man feels himself to be supreme within his own mind. Somewhere in the core of his ego he has developed an organ of observation to keep a watch on his impulses and actions and see whether they harmonize with its demands. If they do not, they are ruthlessly inhibited and withdrawn. His internal perception, consciousness, gives the ego news of all the important occurrences in the mind's working, and the will, directed by these reports, carries out what the ego orders and modifies anything that seeks to accomplish itself spontaneously. For this mind is not a simple thing; on the contrary, it is a hierarchy of superordinated and subordinated agencies, a labyrinth of impulses striving independently of one another towards action, corresponding with the multiplicity of instincts and of relations with the external world, many of which are antagonistic to one another and incompatible. For proper functioning it is necessary that the highest of these agencies should have knowledge of all that is going forward and that its will should penetrate everywhere, so as to exert its influence. And in fact the ego feels secure both as to the completeness and trustworthiness of the reports it receives and as to the openness of the channels through which it enforces its commands. [1917a, 3612]
It will be seen on closer consideration that what the psychological discussion in the preceding sections invites us to assume is not the existence of two systems near the motor end of the apparatus but the existence of two kinds of processes of excitation or modes of its discharge. It is all one to us, for we must always be prepared to drop our conceptual scaffolding if we feel that we are in a position to replace it by something that approximates more closely to the unknown reality. So let us try to correct some conceptions which might be misleading so long as we looked upon the two systems in the most literal and crudest sense as two localities in the mental apparatus - conceptions which have left their traces in the expressions 'to repress' and 'to force a way through.' Thus, we may speak of an unconscious thought seeking to convey itself into the preconscious so as to be able then to force its way through into consciousness. What we have in mind here is not the forming of a second thought situated in a new place, like a transcription which continues to exist alongside the original; and the notion of forcing a way through into consciousness must be kept carefully free from any idea of a change of locality. Again, we may speak of a preconscious thought being repressed or driven out and then taken over by the unconscious. These images, derived from a set of ideas relating to a struggle for a piece of ground, may tempt us to suppose that it is literally true that a mental grouping in one locality has been brought to an end and replaced by a fresh one in another locality. Let us replace these metaphors by something that seems to correspond better to the real state of affairs, and let us say instead that some particular mental grouping has had a cathexis of energy attached to it or withdrawn from it, so that the structure in question has come under the sway of a particular agency or been withdrawn from it. What we are doing here is once again to replace a topographical way of representing things by a dynamic one. What we regard as mobile is not the psychical structure itself but its innervation.¹

Nevertheless, I consider it expedient and justifiable to continue to make use of the figurative image of the two systems. We can avoid any possible abuse of this method of representation by recollecting that ideas, thoughts and psychical structures in general must never be regarded as localized in organic elements of the nervous system but rather, as one might say, between them, where resistances and facilitations [Bahnungen] provide the corresponding correlates. Everything that can be an object of our internal perception is virtual, like the image produced in a telescope by the passage of light-rays. But we are justified in assuming the existence of the systems (which are not in any way psychical entities themselves and can never be accessible to our psychical perception) like the lenses of the telescope, which cast the image. And, if we pursue this analogy, we may compare the censorship between two systems to the refraction which takes place when a ray of light passes into a new medium.

¹ [Footnote added 1925:] It became necessary to elaborate and modify this view after it was recognized that the essential feature of a preconscious idea was the fact of its being connected with the residues of verbal presentations. Cf. 'The Unconscious' (1915e).

¹ Psycho-analysis does not at present postulate any relation between this psychical topography and anatomical stratification or histological layers.
If we are to take the topography of mental acts seriously we must direct our interest to a doubt which arises at this point. When a psychical act (let us confine ourselves here to one which is in the nature of an idea) is transposed from the system *Ucs.* into the system *Cs.* (or *Pcs.*), are we to suppose that this transposition involves a fresh record - as it were, a second registration - of the idea in question, which may thus be situated as well in a fresh psychical locality, and alongside of which the original unconscious registration continues to exist? Or are we rather to believe that the transposition consists in a change in the state of the idea, a change involving the same material and occurring in the same locality? This question may appear abstruse, but it must be raised if we wish to form a more definite conception of psychical topography, of the dimension of depth in the mind. It is a difficult one because it goes beyond pure psychology and touches on the relations of the mental apparatus to anatomy. We know that in the very roughest sense such relations exist. Research has given irrefutable proof that mental activity is bound up with the function of the brain as it is with no other organ. We are taken a step further - we do not know how much - by the discovery of the unequal importance of the different parts of the brain and their special relations to particular parts of the body and to particular mental activities. But every attempt to go on from there to discover a localization of mental processes, every endeavour to think of ideas as stored up in nerve-cells and of excitations as travelling along nerve-fibres, has miscarried completely. The same fate would await any theory which attempted to recognize, let us say, the anatomical position of the system *Cs.* - conscious mental activity - as being in the cortex, and to localize the unconscious processes in the sub-cortical parts of the brain. There is a hiatus here which at present cannot be filled, nor is it one of the tasks of psychology to fill it. Our psychical topography has for the present nothing to do with anatomy; it has reference not to anatomical localities, but to regions in the mental apparatus, wherever they may be situated in the body.

[1915e, 2998]

In this respect, then, our work is untrammelled and may proceed according to its own requirements. It will, however, be useful to remind ourselves that as things stand our hypotheses set out to be no more than graphic illustrations. The first of the two possibilities which we considered - namely, that the *Cs.* phase of an idea implies a fresh registration of it, which is situated in another place - is doubtless the cruder but also the more convenient. The second hypothesis - that of a merely functional change of state - is a priori more probable, but it is less plastic, less easy to manipulate. With the first, or topographical, hypothesis is bound up that of a topographical separation of the systems *Ucs.* and *Cs.* and also the possibility that an idea may exist simultaneously in two places in the mental apparatus indeed, that if it is not inhibited by the censorship, it regularly advances from the one position to the other, possibly without losing its first location or registration.

[1915e, 2999]
This view may seem odd, but it can be supported by observations from psycho-analytic practice. If we communicate to a patient some idea which he has at one time repressed but which we have discovered in him, our telling him makes at first no change in his mental condition. Above all, it does not remove the repression nor undo its effects, as might perhaps be expected from the fact that the previously unconscious idea has now become conscious. On the contrary, all that we shall achieve at first will be a fresh rejection of the repressed idea. But now the patient has in actual fact the same idea in two forms indifferent places in his mental apparatus: first, he has the conscious memory of the auditory trace of the idea, conveyed in what we told him; and secondly, he also has - as we know for certain - the unconscious memory of his experience as it was in its earlier form. Actually there is no lifting of the repression until the conscious idea, after the resistances have been overcome, has entered into connection with the unconscious memory-trace. It is only through the making conscious of the latter itself that success is achieved. On superficial consideration this would seem to show that conscious and unconscious ideas are distinct registrations, topographically separated, of the same content. But a moment's reflection shows that the identity of the information given to the patient with his repressed memory is only apparent. To have heard something and to have experienced something are in their psychological nature two quite different things, even though the content of both is the same.

[1915e, 2999]

The crudest idea of these systems is the most convenient for us - a spatial one. Let us therefore compare the system of the unconscious to a large entrance hall, in which the mental impulses jostle one another like separate individuals. Adjoining this entrance hall there is a second, narrower, room - a kind of drawing-room - in which consciousness, too, resides. But on the threshold between these two rooms a watchman performs his function: he examines the different mental impulses, acts as a censor, and will not admit them into the drawing-room if they displease him. You will see at once that it does not make much difference if the watchman turns away a particular impulse at the threshold itself or if he pushes it back across the threshold after it has entered the drawing-room. This is merely a question of the degree of his watchfulness and of how early he carries out his act of recognition. If we keep to this picture, we shall be able to extend our nomenclature further. The impulses in the entrance hall of the unconscious are out of sight of the conscious, which is in the other room; to begin with they must remain unconscious. If they have already pushed their way forward to the threshold and have been turned back by the watchman, then they are inadmissible to consciousness; we speak of them as repressed. But even the impulses which the watchman has allowed to cross the threshold are not on that account necessarily conscious as well; they can only become so if they succeed in catching the eye of consciousness. We are therefore justified in calling this second room the system of the preconscious. In that case becoming conscious retains its purely descriptive sense. For any particular impulse, however, the vicissitude of repression consists in its not being allowed by the watchman to pass from the system of the unconscious into that of the preconscious. It is the same watchman whom we get to know as resistance when we try to lift the repression by means of the analytic treatment.

[1916-1917, 3369]
Now I know you will say that these ideas are both crude and fantastic and quite impermissible in a scientific account. I know that they are crude: and, more than that, I know that they are incorrect, and, if I am not very much mistaken, I already have something better to take their place. Whether it will seem to you equally fantastic I cannot tell. They are preliminary working hypotheses, like Ampère's manikin swimming in the electric current, and they are not to be despised in so far as they are of service in making our observations intelligible. I should like to assure you that these crude hypotheses of the two rooms, the watchman at the threshold between them and consciousness as a spectator at the end of the second room, must nevertheless be very far-reaching approximations to the real facts. And I should like to hear you admit that our terms, 'unconscious', 'preconscious' and 'conscious', prejudge things far less and are far easier to justify than others which have been proposed or are in use, such as 'subconscious', 'paraconscious', 'intraconscious' and the like.

[1916-1917, 3369]

It would be more difficult to explain concisely how it came about that psycho-analysis made a further distinction in the unconscious, and separated it into a preconscious and an unconscious proper. It will be sufficient to say that it appeared a legitimate course to supplement the theories that were a direct expression of experience with hypotheses that were designed to facilitate the handling of the material and related to matters which could not be a subject of immediate observation. The very same procedure is adopted by the older sciences. The subdivision of the unconscious is part of an attempt to picture the apparatus of the mind as being built up of a number of agencies or systems whose relations to one another are expressed in spatial terms, without, however, implying any connection with the actual anatomy of the brain. (I have described this as the topographical method of approach.) Such ideas as these are part of a speculative superstructure of psycho-analysis, any portion of which can be abandoned or changed without loss or regret the moment its inadequacy has been proved. But there is still plenty to be described that lies closer to actual experience.

[1925d, 4208]

It will soon be clear what the mental apparatus is; but I must beg you not to ask what material it is constructed of. That is not a subject of psychological interest. Psychology can be as indifferent to it as, for instance, optics can be to the question of whether the walls of a telescope are made of metal or cardboard. We shall leave entirely on one side the material line of approach, but not so the spatial one. For we picture the unknown apparatus which serves the activities of the mind as being really like an instrument constructed of several parts (which we speak of as 'agencies'), each of which performs a particular function and which have a fixed spatial relation to one another: it being understood that by spatial relation - 'in front of' and 'behind', 'superficial' and 'deep' - we merely mean in the first instance a representation of the regular succession of the functions. Have I made myself clear?

[1926e, 4337]

In psychology we can only describe things by the help of analogies. There is nothing peculiar in this; it is the case elsewhere as well. But we have constantly to keep changing these analogies, for none of them lasts us long enough. Accordingly, in trying to make the relation between the ego and the id clear, I must ask you to picture the ego as a kind of façade of the id, as a frontage, like an external, cortical, layer of it. We can hold on to this last analogy. We know that cortical layers owe their peculiar characteristics to the modifying influence of the external medium on which they abut. Thus we suppose that the ego is the layer of the mental apparatus (of the id) which has been modified by the influence of the external world (of reality). This will show you how in psycho-analysis we take spatial ways of looking at things seriously. For us the ego is really something superficial and the id something deeper - looked at from outside, of course. The ego lies between reality and the id, which is what is truly mental.

[1926e, 4338]
And here is another warning, to conclude these remarks, which have certainly been exacting and not, perhaps, very illuminating. In thinking of this division of the personality into an ego, a super-ego and an id, you will not, of course, have pictured sharp frontiers like the artificial ones drawn in political geography. We cannot do justice to the characteristics of the mind by linear outlines like those in a drawing or in primitive painting, but rather by areas of colour melting into one another as they are presented by modern artists. After making the separation we must allow what we have separated to merge together once more. You must not judge too harshly a first attempt at giving a pictorial representations of something so intangible as psychical processes. It is highly probable that the development of these divisions is subject to great variations in different individuals; it is possible that in the course of actual functioning they may change and go through a temporary phase of involution. Particularly in the case of what is phylogenetically the last and most delicate of these divisions - the differentiation between the ego and the super-ego - something of the sort seems to be true. There is no question but that the same thing results from psychical illness. It is easy to imagine, too, that certain mystical practices may succeed in upsetting the normal relations between the different regions of the mind, so that, for instance, perception may be able to grasp happenings in the depths of the ego and in the id which were otherwise inaccessible to it. It may safely be doubted, however, whether this road will lead us to the ultimate truths from which salvation is to be expected. Nevertheless it may be admitted that the therapeutic efforts of psycho-analysis have chosen a similar line of approach. Its intention is, indeed, to strengthen the ego, to make it more independent of the super-ego, to widen its field of perception and enlarge its organization, so that it can appropriate fresh portions of the id. Where id was, there ego shall be. It is a work of culture - not unlike the draining of the Zuider Zee.

[1933a, 4687]

All of this may appear to be far from simple. But when one has grown reconciled to this unusual spatial view of the mental apparatus, it can present no particular difficulties to the imagination. I will add the further comment that the psychical topography that I have developed here has nothing to do with the anatomy of the brain, and actually only touches it at one point. What is unsatisfactory in this picture - and I am aware of it as clearly as anyone - is due to our complete ignorance of the *dynamic* nature of the mental processes. We tell ourselves that what distinguishes a conscious idea from a preconscious one, and the latter from an unconscious one, can only be a modification, or perhaps a different distribution, of psychical energy. We talk of cathexes and hypercathexes, but beyond this we are without any knowledge on the subject or even any starting-point for a serviceable working hypothesis. Of the phenomenon of consciousness we can at least say that it was originally attached to perception. All sensations which originate from the perception of painful, tactile, auditory or visual stimuli are what are most readily conscious. Thought-processes, and whatever may be analogous to them in the id, are in themselves unconscious and obtain access to consciousness by becoming linked to the mnemonic residues of visual and auditory perceptions along the path of the function of speech. In animals, which lack speech, these conditions must be of a simpler kind.

[1939a, 4919]
The theory of bisexuality has been expressed in its crudest form by a spokesman of the male inverts: 'a feminine brain in a masculine body'. But we are ignorant of what characterizes a feminine brain. There is neither need nor justification for replacing the psychological problem by the anatomical one. Krafft-Ebing's attempted explanation seems to be more exactly framed than that of Ulrichs but does not differ from it in essentials. According to Krafft-Ebing (1895, 5), every individual's bisexual disposition endows him with masculine and feminine brain centres as well as with somatic organs of sex: these centres develop only at puberty, for the most part under the influence of the sex-gland, which is independent of them in the original disposition. But what has just been said of masculine and feminine brains applies equally to masculine and feminine 'centres'; and incidentally we have not even any grounds for assuming that certain areas of the brain ('centres') are set aside for the functions of sex, as is the case, for instance with those of speech.¹

If we are to take the topography of mental acts seriously we must direct our interest to a doubt which arises at this point. When a psychical act (let us confine ourselves here to one which is in the nature of an idea) is transposed from the system $Ucs.$ into the system $Cs.$ (or $Pcs.$), are we to suppose that this transposition involves a fresh record - as it were, a second registration - of the idea in question, which may thus be situated as well in a fresh psychical locality, and alongside of which the original unconscious registration continues to exist? Or are we rather to believe that the transposition consists in a change in the state of the idea, a change involving the same material and occurring in the same locality? This question may appear abstruse, but it must be raised if we wish to form a more definite conception of psychical topography, of the dimension of depth in the mind. It is a difficult one because it goes beyond pure psychology and touches on the relations of the mental apparatus to anatomy. We know that in the very roughest sense such relations exist. Research has given irrefutable proof that mental activity is bound up with the function of the brain as it is with no other organ. We are taken a step further - we do not know how much - by the discovery of the unequal importance of the different parts of the brain and their special relations to particular parts of the body and to particular mental activities. But every attempt to go on from there to discover a localization of mental processes, every endeavour to think of ideas as stored up in nerve-cells and of excitations as travelling along nerve-fibres, has miscarried completely. The same fate would await any theory which attempted to recognize, let us say, the anatomical position of the system $Cs.$ - conscious mental activity - as being in the cortex, and to localize the unconscious processes in the sub-cortical parts of the brain. There is a hiatus here which at present cannot be filled, nor is it one of the tasks of psychology to fill it. Our psychical topography has for the present nothing to do with anatomy; it has reference not to anatomical localities, but to regions in the mental apparatus, wherever they may be situated in the body.

[1905d, 1472]

[1915e, 2998]
Psycho-analysis grew up in a narrowly-restricted field. At the outset, it had only a single aim - that of understanding something of the nature of what were known as the 'functional' nervous diseases, with a view to overcoming the impotence which had so far characterized their medical treatment. The neurologists of that period had been brought up to have a high respect for chemico-physical and pathologico-anatomical facts; and they were latterly under the influence of the findings of Hitzig and Fritsch, of Ferrier, Goltz and others, who seemed to have established an intimate and possibly exclusive connection between certain functions and particular parts of the brain. They did not know what to make of the psychical factor and could not understand it. They left it to the philosophers, the mystics and - the quacks; and they considered it unscientific to have anything to do with it. Accordingly they could find no approach to the secrets of the neuroses, and in particular of the enigmatic 'hysteria', which was, indeed, the prototype of the whole species. As late as in 1885, when I was studying at the Salpêtrière, I found that people were content to account for hysterical paralyses by a formula which asserted that they were founded on slight functional disturbances of the same parts of the brain which, when they were severely damaged, led to the corresponding organic paralyses.

[1924f, 4101]
If, in schizophrenia, this flight consists in withdrawal of instinctual cathexis from the points which represent the unconscious presentation of the object, it may seem strange that the part of the presentation of this object which belongs to the system $\text{Pcs.}$ - namely, the word-presentations corresponding to it - should, on the contrary, receive a more intense cathexis. We might rather expect that the word-presentation, being the preconscious part, would have to sustain the first impact of repression and that it would be totally uncathetabale after repression had proceeded as far as the unconscious thing-presentations. This, it is true, is difficult to understand. It turns out that the cathexis of the word-presentation is not part of the act of repression, but represents the first of the attempts at recovery or cure which so conspicuously dominate the clinical picture of schizophrenia. These endeavours are directed towards regaining the lost object, and it may well be that to achieve this purpose they set off on a path that leads to the object via the verbal part of it, but then find themselves obliged to be content with words instead of things. It is a general truth that our mental activity moves in two opposite directions: either it starts from the instincts and passes through the system $\text{Ucs.}$ to conscious thought-activity; or, beginning with an instigation from outside, it passes through the system $\text{Cs.}$ and $\text{Pcs.}$ till it reaches the $\text{Ucs.}$ cathexes of the ego and objects. This second path must, in spite of the repression which has taken place, remain traversable, and it lies open to some extent to the endeavours made by the neurosis to regain its objects. When we think in abstractions there is a danger that we may neglect the relations of words to unconscious thing-presentations, and it must be confessed that the expression and content of our philosophizing then begins to acquire an unwelcome resemblance to the mode of operation of schizophrenics. We may, on the other hand, attempt a characterization of the schizophrenic’s mode of thought by saying that he treats concrete things as though they were abstract.

Let us, furthermore, bear in mind the great practical importance of distinguishing perceptions from ideas, however intensely recalled. Our whole relation to the external world, to reality, depends on our ability to do so. We have put forward the fiction that we did not always possess this ability and that at the beginning of our mental life we did in fact hallucinate the satisfying object when we felt the need for it. But in such a situation satisfaction did not occur, and this failure must very soon have moved us to create some contrivance with the help of which it was possible to distinguish such wishful perceptions from a real fulfilment and to avoid them for the future. In other words, we gave up hallucinatory satisfaction of our wishes at a very early period and set up a kind of ‘reality-testing’. The question now arises in what this reality-testing consisted, and how the hallucinatory wishful psychosis of dreams and amnesia and similar conditions succeeds in abolishing it and in re-establishing the old mode of satisfaction.
I will put before you the only theoretical ideas which have proved of service for giving a more
definite shape to the concept of repression. It is above all essential for this purpose that we
should proceed from the purely descriptive meaning of the word 'unconscious' to the systematic
meaning of the same word. That is, we will decide to say that the fact of a psychical process
being conscious or unconscious is only one of its attributes and not necessarily an
unambiguous one. If a process of this kind has remained unconscious, its being kept away from
consciousness may perhaps only be an indication of some vicissitude it has gone through, and
not that vicissitude itself. In order to form a picture of this vicissitude, let us assume that every
mental process - we must admit one exception, which we shall mention at a later stage - exists
to begin with in an unconscious stage or phase and that it is only from there that the process
passes over into the conscious phase, just as a photographic picture begins as a negative and
only becomes a picture after being turned into a positive. Not every negative, however,
necessarily becomes a positive; nor is it necessary that every unconscious mental process
should turn into a conscious one. This may be advantageously expressed by saying that an
individual process belongs to begin with to the system of the unconscious and can then, in
certain circumstances, pass over into the system of the conscious.
[1916-1917, 3368]

All perceptions which are received from without (sense-perceptions) and from within - what we
call sensations and feelings - are Cs. from the start. But what about those internal processes
which we may - roughly and inexactly - sum up under the name of thought-processes? They
represent displacements of mental energy which are effected somewhere in the interior of the
apparatus as this energy proceeds on its way towards action. Do they advance to the surface,
which causes consciousness to be generated? Or does consciousness make its way to them?
This is clearly one of the difficulties that arise when one begins to take the spatial or
'topographical' idea of mental life seriously. Both these possibilities are equally unimaginable,
there must be a third alternative.
[1923b, 3953]
It is not clear what Fechner had in mind in speaking of this change of location of mental activity; nor, so far as I know, has anyone else pursued the path indicated by his words. We may, I think, dismiss the possibility of giving the phrase an anatomical interpretation and supposing it to refer to physiological cerebral localization or even to the histological layers of the cerebral cortex. It may be, however, that the suggestion will eventually prove to be sagacious and fertile, if it can be applied to a mental apparatus built up of a number of agencies arranged in a series one behind the other.

Accordingly, we will picture the mental apparatus as a compound instrument, to the components of which we will give the name of 'agencies', or (for the sake of greater clarity) 'systems.' It is to be anticipated, in the next place, that these systems may perhaps stand in a regular spatial relation to one another, in the same kind of way in which the various systems of lenses in a telescope are arranged behind one another. Strictly speaking there is no need for the hypothesis that the psychical systems are actually arranged in a spatial order. It would be sufficient if a fixed order were established by the fact that in a given psychical process the excitation passes through the systems in a particular temporal sequence. In other processes the sequence may perhaps be a different one; that is a possibility that we shall leave open. For the sake of brevity we will in future speak of the components of the apparatus as "Ψ-systems."

The first thing that strikes us is that this apparatus, compounded of Ψ-systems, has a sense or direction. All our psychical activity starts from stimuli (whether internal or external) and ends in innervations. Accordingly, we shall ascribe a sensory and a motor end to the apparatus. At the sensory end there lies a system which receives perceptions; at the motor end there lies another, which opens the gateway to motor activity. Psychical processes advance in general from the perceptual end to the motor end. Thus the most general schematic picture of the psychical apparatus may be represented thus (Fig. 1):

The assumptions we have so far put forward as to the construction of the psychical apparatus at its sensory end have been made without reference to dreams or to the psychological information that we have been able to infer from them. Evidence afforded by dreams will, however, help us towards understanding another portion of the apparatus. We have seen that we were only able to explain the formation of dreams by venturing upon the hypothesis of there being two psychical agencies, one of which submitted the activity of the other to a criticism which involved its exclusion from consciousness. The critical agency, we concluded, stands in a closer relation to consciousness than the agency criticized: it stands like a screen between the latter and consciousness. Further we found reasons for identifying the critical agency with the agency which directs our waking life and determines our voluntary, conscious actions. If, in accordance with our assumptions, we replace these agencies by systems, then our last conclusion must lead us to locate the critical system at the motor end of the apparatus. We will now introduce the two system into our schematic picture and give them names to express their relation to consciousness (Fig. 3):
We will describe the last of the systems at the motor end as 'the preconscious', to indicate that the excitatory processes occurring in it can enter consciousness without further impediment provided that certain other conditions are fulfilled: for instance, that they reach a certain degree of intensity, that the function which can only be described as 'attention' is distributed in a particular way, and so on. This is at the same time the system which holds the key to voluntary movement. We will describe the system that lies behind it as 'the unconscious', because it has no access to consciousness except via the preconscious, in passing through which its excitatory process is obliged to submit to modifications.¹

¹ [Footnote added 1919:] If we attempted to proceed further with this schematic picture, in which the systems are set out in linear succession, we should have to reckon with the fact that the system next beyond the Pcs. is the one to which consciousness must be ascribed - in other words, that \( Pcpt = Cs. \)

There is, however, another point to which I attach importance; and I must confess that it is solely on its account that I have embarked here upon all these discussions of the two psychical systems and their modes of activity and of repression. It is not now a question of whether I have formed an approximately correct opinion of the psychological factors with which we are concerned, or whether, which is quite possible in such difficult matters, my picture of them is distorted and incomplete. However many changes may be made in our reading of the psychical censorship and of the rational and abnormal revisions made of the dream-content, it remains true that processes of this sort are at work in the formation of dreams and that they show the closest analogy in their essentials to the processes observable in the formation of hysterical symptoms. A dream, however, is no pathological phenomenon; it presupposes no disturbance of psychical equilibrium; it leaves behind it no loss of efficiency. The suggestion may be made that no conclusions as to the dreams of normal people can be drawn from my dreams or those of my patients; but this, I think, is an objection which can be safely disregarded. If, then, we may argue back from the phenomena to their motive forces, we must recognize that the psychical mechanism employed by neuroses is not created by the impact of a pathological disturbance upon the mind but is present already in the normal structure of the mental apparatus. The two psychical systems, the censorship upon the passage from one of them to the other, the inhibition and overlaying of one activity by the other, the relations of both of them to consciousness - or whatever more correct interpretations of the observed facts may take their place - all of these form part of the normal structure of our mental instrument, and dreams show us one of the paths leading to an understanding of its structure. If we restrict ourselves to the minimum of new knowledge which has been established with certainty, we can still say this of dreams: they have proved that what is suppressed continues to exist in normal people as well as abnormal, and remains capable of psychical functioning. Dreams themselves are among the manifestations of this suppressed material; this is so theoretically in every case, and it can be observed empirically in a great number of cases at least, and precisely in cases which exhibit most clearly the striking peculiarities of dream-life. In waking life the suppressed material in the mind is prevented from finding expression and is cut off from internal perception owing to the fact that the contradictions present in it are eliminated - one side being disposed of in favour of the other; but during the night, under the sway of an impetus towards the construction of compromises, this suppressed material finds methods and means of forcing its way into consciousness.

[1900a, 1034]
By analysing dreams we can take a step forward in our understanding of the composition of that most marvellous and most mysterious of all instruments. Only a small step, no doubt; but a beginning. And this beginning will enable us to proceed further with its analysis, on the basis of other structures which must be termed pathological. For illnesses - those, at least, which are rightly named 'functional' - do not presuppose the disintegration of the apparatus or the production of fresh splits in its interior. They are to be explained on a dynamic basis - by the strengthening and weakening of the various components in the interplay of forces, so many of whose effects are hidden from view while functions are normal. I hope to be able to show elsewhere how the compounding of the apparatus out of two agencies makes it possible for the normal mind too to function with greater delicacy than would be possible with only one of them.²

[1900a, 1035]

It will be seen on closer consideration that what the psychological discussion in the preceding sections invites us to assume is not the existence of two systems near the motor end of the apparatus but the existence of two kinds of processes of excitation or modes of its discharge. It is all one to us, for we must always be prepared to drop our conceptual scaffolding if we feel that we are in a position to replace it by something that approximates more closely to the unknown reality. So let us try to correct some conceptions which might be misleading so long as we looked upon the two systems in the most literal and crudest sense as two localities in the mental apparatus - conceptions which have left their traces in the expressions 'to repress' and 'to force a way through.' Thus, we may speak of an unconscious thought seeking to convey itself into the preconscious so as to be able then to force its way through into consciousness. What we have in mind here is not the forming of a second thought situated in a new place, like a transcription which continues to exist alongside the original; and the notion of forcing a way through into consciousness must be kept carefully free from any idea of a change of locality. Again, we may speak of a preconscious thought being repressed or driven out and then taken over by the unconscious. These images, derived from a set of ideas relating to a struggle for a piece of ground, may tempt us to suppose that it is literally true that a mental grouping in one locality has been brought to an end and replaced by a fresh one in another locality. Let us replace these metaphors by something that seems to correspond better to the real state of affairs, and let us say instead that some particular mental grouping has had a cathexis of energy attached to it or withdrawn from it, so that the structure in question has come under the sway of a particular agency or been withdrawn from it. What we are doing here is once again to replace a topographical way of representing things by a dynamic one. What we regard as mobile is not the psychical structure itself but its innervation.¹

[1900a, 1036]

Nevertheless, I consider it expedient and justifiable to continue to make use of the figurative image of the two systems. We can avoid any possible abuse of this method of representation by recollecting that ideas, thoughts and psychical structures in general must never be regarded as localized in organic elements of the nervous system but rather, as one might say, between them, where resistances and facilitations [Bahnungen] provide the corresponding correlates. Everything that can be an object of our internal perception is virtual, like the image produced in a telescope by the passage of light-rays. But we are justified in assuming the existence of the systems (which are not in any way psychical entities themselves and can never be accessible to our psychical perception) like the lenses of the telescope, which cast the image. And, if we pursue this analogy, we may compare the censorship between two systems to the refraction which takes place when a ray of light passes into a new medium.

[1900a, 1036]
It is not without intention that I speak of 'our' unconscious. For what I thus describe is not the same as the unconscious of the philosophers or even the unconscious of Lipps. By them the term is used merely to indicate a contrast with the conscious: the thesis which they dispute with so much heat and defend with so much energy is the thesis that apart from conscious there are also unconscious psychical processes. Lipps carries things further with his assertion that the whole of what is psychical exists unconsciously and that a part of it also exists consciously. But it is not in order to establish this thesis that we have summoned up the phenomena of dreams and of the formation of hysterical symptoms; the observation of normal waking life would by itself suffice to prove it beyond any doubt. The new discovery that we have been taught by the analysis of psychopathological structures and of the first member of that class - the dream - lies in the fact that the unconscious (that is, the psychical) is found as a function of two separate systems and that this is the case in normal as well as in pathological life. Thus there are two kinds of unconscious, which have not yet been distinguished by psychologists. Both of them are unconscious in the sense used by psychology; but in our sense one of them, which we term the Ucs, is also inadmissible to consciousness, while we term the other the Pcs. because its excitations - after observing certain rules, it is true, and perhaps only after passing a fresh censorship, though nonetheless without regard to the Ucs. - are able to reach consciousness.

The fact that excitations in order to reach consciousness must pass through a fixed series or hierarchy of agencies (which is revealed to us by the modifications made in them by censorship) has enabled us to construct a spatial analogy. We have described the relations of the two systems to each other and to consciousness by saying that the system Pcs. stands like a screen between the system Ucs. and consciousness. The system Pcs. not merely bars access to consciousness, it also controls access to the power of voluntary movement and has at its disposal for distribution a mobile cathetic energy, a part of which is familiar to us in the form of attention.

But what part is there left to be played in our scheme by consciousness, which was once so omnipotent and hid all else from view? Only that of a sense-organ for the perception of psychical qualities. In accordance with the ideas underlying our attempt at a schematic picture, we can only regard conscious perception as the function proper to a particular system; and for this the abbreviation Cs. seems appropriate. In its mechanical properties we regard this system as resembling the perceptual systems Pcpt.: as being susceptible to excitation by qualities but incapable of retaining traces of alterations - that is to say, as having no memory. The psychical apparatus, which is turned towards the external world with its sense-organ of the Pcpt. systems, is itself the external world in relation to the sense-organ of the Cs., whose teleological justification resides in this circumstance. Here we once more meet the principle of the hierarchy of agencies, which seems to govern the structure of the apparatus. Excitatory material flows in to the Cs. sense-organ from two directions: from the Pcpt. system, whose excitation, determined by qualities, is probably submitted to a fresh revision before it becomes a conscious sensation, and from the interior of the apparatus itself, whose quantitative processes are felt qualitatively in the pleasure-unpleasure series when, subject to certain modifications, they make their way to consciousness.
Hitherto philosophers have had no occasion to concern themselves with a psychology of repression. We may therefore be permitted to make a first approach to this hitherto unknown topic by constructing a pictorial image of the course of events in dream-formation. It is true that the schematic picture we have arrived at - not only from the study of dreams - is a fairly complicated one; but we cannot manage with anything simpler. Our hypothesis is that in our mental apparatus there are two thought-constructing agencies, of which the second enjoys the privilege of having free access to consciousness for its products whereas the activity of the first is in itself unconscious and can only reach consciousness by way of the second. On the frontier between the two agencies, where the first passes over to the second, there is a censorship, which only allows what is agreeable to it to pass through and holds back everything else. According to our definition, then, what is rejected by the censorship is in a state of repression. Under certain conditions, of which the state of sleep is one, the relation between the strength of the two agencies is modified in such a way that what is repressed can no longer be held back. In the state of sleep this probably occurs owing to a relaxation of the censorship; when this happens it becomes possible for what has hitherto been repressed to make a path for itself to consciousness. Since, however, the censorship is never completely eliminated but merely reduced, the repressed material must submit to certain alterations which mitigate its offensive features. What becomes conscious in such cases is a compromise between the intentions of one agency and the demands of the other. Repression - relaxation of the censorship - the formation of a compromise, this is the fundamental pattern for the generation not only of dreams but of many other psychopathological structures; and in the latter cases too we may observe that the formation of compromises is accompanied by processes of condensation and displacement and by the employment of superficial associations, which we have become familiar with in the dream-work.

We have no reason to disguise the fact that in the hypothesis which we have set up in order to explain the dream-work a part is played by what might be described as a ‘daemonic’ element. We have gathered an impression that the formation of obscure dreams occurs as though one person who was dependent upon a second person had to make a remark which was bound to be disagreeable in the ears of this second one; and it is on the basis of this simile that we have arrived at the concepts of dream-distortion and censorship, and have endeavoured to translate our impression into a psychological theory which is no doubt crude but is at least lucid. Whatever it may be with which a further investigation of the subject may enable us to identify our first and second agencies, we may safely expect to find a confirmation of some correlate of our hypothesis that the second agency controls access to consciousness and can bar the first agency from such access.
There are thus abundant signs to be found in healthy, non-neurotic people that the recollection of distressing impressions and the occurrence of distressing thoughts are opposed by a resistance.¹ But the full significance of this fact can be estimated only when the psychology of neurotic people is investigated. We are forced to regard as one of the main pillars of the mechanism supporting hysterical symptoms an elementary endeavour of this kind to fend off ideas that can arouse feelings of unpleasure - an endeavour which can only be compared with the flight-reflex in the presence of painful stimuli. The assumption that a defensive trend of this kind exists cannot be objected to on the ground that one often enough finds it impossible, on the contrary, to get rid of distressing memories that pursue one, and to banish distressing affective impulses like remorse and the pangs of conscience. For we are not asserting that this defensive trend is able to put itself into effect in every case, that in the interplay of psychical forces it may not come up against factors which, for other purposes, aim at the opposite effect and bring it about in spite of the defensive trend. It may be surmised that the architectonic principle of the mental apparatus lies in a stratification - a building up of superimposed agencies; and it is quite possible that this defensive endeavour belongs to a lower psychical agency and is inhibited by higher agencies. At all events, if we can trace back processes such as those found in our examples of forgetting to this defensive trend, that fact speaks in favour of its existence and power.(As we have seen, a number of things are forgotten on their own account; where this is not possible, the defensive trend shifts its target and causes something else related to the target at least to be forgotten, something less important which has come into associative connection with the thing that is really objectionable.

[1901b, 1229]

For the moment we will dwell a little longer on regression. After what you have learnt of the development of the libidinal function, you will be prepared to hear that there are regressions of two sorts: a return to the objects first cathexed by the libido, which, as we know, are of an incestuous nature, and a return of the sexual organization as a whole to earlier stages. Both sorts are found in the transference neuroses and play a great part in their mechanism. In particular, a return to the first incestuous objects of the libido is a feature that is found in neurotics with positively fatiguing regularity. There is much more to be said about regressions of the libido itself when we take into account as well another group of neuroses, the narcissistic ones, which for the time being we do not intend to do. These disorders give us access to other developmental processes of the libidinal function which we have not yet mentioned, and show us correspondingly new sorts of regression as well. But above all I think I ought to warn you now not to confuse regression with repression and help you to form a clear idea of the relations between the two processes. Repression, as you will recall, is the process by which an act which is admissible to consciousness, one, therefore, which belongs to the system Pcs., is made unconscious - is pushed back, therefore, into the system Ucs. And we equally speak of repression if the unconscious mental act is altogether forbidden access to the neighbouring preconscious system and is turned back at the threshold by the censorship. Thus the concept of repression involves no relation to sexuality: I must ask you to take special note of that. It indicates a purely psychological process, which we can characterize still better if we call it a 'topographical' one. By this we intend to say that it is concerned with the psychical regions which we have assumed to exist, or, if we drop this clumsy working hypothesis, with the construction of the mental apparatus out of distinct psychical systems.

[1916-1917, 3405]
Although thus humbled in his external relations, man feels himself to be supreme within his own mind. Somewhere in the core of his ego he has developed an organ of observation to keep a watch on his impulses and actions and see whether they harmonize with its demands. If they do not, they are ruthlessly inhibited and withdrawn. His internal perception, consciousness, gives the ego news of all the important occurrences in the mind's working, and the will, directed by these reports, carries out what the ego orders and modifies anything that seeks to accomplish itself spontaneously. For this mind is not a simple thing; on the contrary, it is a hierarchy of superordinated and subordinated agencies, a labyrinth of impulses striving independently of one another towards action, corresponding with the multiplicity of instincts and of relations with the external world, many of which are antagonistic to one another and incompatible. For proper functioning it is necessary that the highest of these agencies should have knowledge of all that is going forward and that its will should penetrate everywhere, so as to exert its influence. And in fact the ego feels secure both as to the completeness and trustworthiness of the reports it receives and as to the openness of the channels through which it enforces its commands.

We have already said that, if the differentiation we have made of the mind into an id, an ego, and a super-ego represents any advance in our knowledge, it ought to enable us to understand more thoroughly the dynamic relations within the mind and to describe them more clearly. We have also already concluded that the ego is especially under the influence of perception, and that, speaking broadly, perceptions may be said to have the same significance for the ego as instincts have for the id. At the same time the ego is subject to the influence of the instincts, too, like the id, of which it is, as we know, only a specially modified part.

It is natural that we should turn with interest to enquire whether there may not be instructive connections to be traced between the structures we have assumed to exist - the ego, the super-ego and the id - on the one hand and the two classes of instincts on the other; and, further, whether the pleasure principle which dominates mental processes can be shown to have any constant relation both to the two classes of instincts and to these differentiations which we have drawn in the mind. But before we discuss this, we must clear away a doubt which arises concerning the terms in which the problem itself is stated. There is, it is true, no doubt about the pleasure principle, and the differentiation within the ego has good clinical justification; but the distinction between the two classes of instincts does not seem sufficiently assured and it is possible that facts of clinical analysis may be found which will do away with its pretension.
The aetiology common to the onset of a psychoneurosis and of a psychosis always remains the same. It consists in a frustration, a non-fulfilment of one of those childhood wishes which are for ever undefeated and which are so deeply rooted in our phylogenetically determined organization. This frustration is in the last resort always an external one; but in the individual case it may proceed from the internal agency (in the super-ego) which has taken over the representation of the demands of reality. The pathogenic effect depends on whether, in a conflictual tension of this kind, the ego remains true to its dependence on the external world and attempts to silence the id, or whether it lets itself be overcome by the id and thus torn away from reality. A complication is introduced into this apparently simple situation, however, by the existence of the super-ego, which, though a link that is not yet clear to us, unites in itself influences coming from the id as well as from the external world, and is to some extent an ideal model of what the whole endeavour of the ego is aiming at - a reconciliation between its various dependent relationships. The attitude of the super-ego should be taken into account - which has not hitherto been done - in every form of psychical illness. We may provisionally assume that there must also be illnesses which are based on a conflict between the ego and the super-ego. Analysis gives us a right to suppose that melancholia is a typical example of this group; and we would set aside the name of ‘narcissistic psychoneuroses’ for disorders of that kind. Nor will it clash with our impressions if we find reasons for separating states like melancholia from the other psychoses. We now see that we have been able to make our simple genetic formula more complete, without dropping it. Transference neuroses correspond to a conflict between the ego and the id; narcissistic neuroses, to a conflict between the ego and the super-ego; and psychoses, to one between the ego and the external world. It is true that we cannot tell at once whether we have really gained any new knowledge by this, or have only enriched our store of formulas; but I think that this possible application of the proposed differentiation of the mental apparatus into an ego, a super-ego and an id cannot fail to give us courage to keep that hypothesis steadily in view.

Thus we may express our expectation that psycho-analysis, whose development and achievements hitherto have been briefly and inadequately related in these pages, will enter into the cultural development of the next decades as a significant ferment, and will help to deepen our understanding of the world and to fight against some things in life which are recognized as injurious. It must not be forgotten, however, that psycho-analysis alone cannot offer a complete picture of the world. If we accept the distinction which I have recently proposed of dividing the mental apparatus into an ego, turned towards the external world and equipped with consciousness, and an unconscious id, dominated by its instinctual needs, then psycho-analysis is to be described as a psychology of the id (and of its effects upon the ego). In each field of knowledge, therefore, it can make only contributions, which require to be completed from the psychology of the ego. If these contributions often contain the essence of the facts, this only corresponds to the important part which, it may be claimed, is played in our lives by the mental unconscious that has so long remained unknown.
It would be more difficult to explain concisely how it came about that psycho-analysis made a further distinction in the unconscious, and separated it into a preconscious and an unconscious proper. It will be sufficient to say that it appeared a legitimate course to supplement the theories that were a direct expression of experience with hypotheses that were designed to facilitate the handling of the material and related to matters which could not be a subject of immediate observation. The very same procedure is adopted by the older sciences. The subdivision of the unconscious is part of an attempt to picture the apparatus of the mind as being built up of a number of agencies or systems whose relations to one another are expressed in spatial terms, without, however, implying any connection with the actual anatomy of the brain. (I have described this as the topographical method of approach.) Such ideas as these are part of a speculative superstructure of psycho-analysis, any portion of which can be abandoned or changed without loss or regret the moment its inadequacy has been proved. But there is still plenty to be described that lies closer to actual experience.

I had already made attempts at earlier stages of my work to arrive at some more general points of view on the basis of psycho-analytic observation. In a short essay, 'Formulations on the Two Principles of Mental Functioning', I drew attention (and there was, of course, nothing original in this) to the domination of the pleasure-unpleasure principle in mental life and to its displacement by what is called the reality principle. Later on I made an attempt to produce a 'Metapsychology'. By this I meant a method of approach according to which every mental process is considered in relation to three co-ordinates, which I described as dynamic, topographical, and economic respectively; and this seemed to me to represent the furthest goal that psychology could attain. The attempt remained no more than a torso; after writing two or three papers - 'Instincts and their Vicissitudes', 'Repression', 'The Unconscious', 'Mourning and Melancholia', etc. - I broke off, wisely perhaps, since the time for theoretical predications of this kind had not yet come. In my latest speculative works I have set about the task of dissecting our mental apparatus on the basis of the analytic view of pathological facts and have divided it into an ego, an id, and a super-ego.¹ The super-ego is the heir of the Oedipus complex and represents the ethical standards of mankind.

[1925d, 4208]

[1925d, 4234]
Shortly before I wrote this study it seemed as though my life would soon be brought to an end by the recurrence of a malignant disease; but surgical skill saved me in 1923 and I was able to continue my life and my work, though no longer in freedom from pain. In the period of more than ten years that has passed since then, I have never ceased my analytic work nor my writing - as is proved by the completion of the twelfth volume of the German edition of my collected works. But I myself find that a significant change has come about. Threads which in the course of my development had become intertangled have now begun to separate; interests which I had acquired in the later part of my life have receded, while the older and original ones become prominent once more. It is true that in this last decade I have carried out some important pieces of analytic work, such as the revision of the problem of anxiety in my book Inhibitions, Symptoms and Anxiety (1926d) or the simple explanation of sexual 'fetishism' which I was able to make a year later (1927e). Nevertheless it would be true to say that, since I put forward my hypothesis of the existence of two classes of instinct (Eros and the death instinct) and since I proposed a division of the mental personality into an ego, a super-ego, and an id (1923b), I have made no further decisive contributions to psycho-analysis: what I have written on the subject since then has been either unessential or would soon have been supplied by someone else. This circumstance is connected with an alteration in myself, with what might be described as a phase of regressive development. My interest, after making a lifelong détour through the natural sciences, medicine and psychotherapy, returned to the cultural problems which had fascinated me long before, when I was a youth scarcely old enough for thinking. At the very climax of my psycho-analytic work, in 1912, I had already attempted in Totem and Taboo to make use of the newly discovered findings of analysis in order to investigate the origins of religion and morality. I now carried this work a stage further in two later essays, The Future of an Illusion (1927c) and Civilization and its Discontents (1930a). I perceived ever more clearly that the events of human history, the interactions between human nature, cultural development and the precipitates of primateval experiences (the most prominent example of which is religion) are no more than a reflection of the dynamic conflicts between the ego, the id and the super-ego, which psycho-analysis studies in the individual - are the very same processes repeated upon a wider stage. In The Future of an Illusion I expressed an essentially negative valuation of religion. Later, I found a formula which did better justice to it: while granting that its power lies in the truth which it contains, I showed that that truth was not a material but a historical truth.

¹ Since the differentiation of the ego and the id, our interest in the problems of repression, too, was bound to receive a fresh impetus. Up till then we had been content to confine our interest to those aspects of repression which concerned the ego - the keeping away from consciousness and from motility, and the formation of substitues (symptoms). With regard to the repressed instincual impulses themselves, we assumed that they remained unaltered in the unconscious for an indefinite length of time. But now our interest is turned to the vicissitudes of the repressed and we begin to suspect that it is not self-evident, perhaps not even usual, that those impulses should remain unaltered and unalterable in this way. There is no doubt that the original impulses have been inhibited and deflected from their aim through repression. But has the portion of them in the unconscious maintained itself and been proof against the influences of life that tend to alter and depreciate them? In other words, do the old wishes, about whose former existence analysis tells us, still exist? The answer seems ready to hand and certain. It is that the old, repressed wishes must still be present in the unconscious since we still find their derivatives, the symptoms, in operation. But this answer is not sufficient. It does not enable us to decide between two possibilities: either that the old wish is now operating only through its derivatives, having transferred the whole of its cathectic energy to them, or that it is itself still in existence too. If its fate has been to exhaust itself in cathecting its derivatives, there is yet a third possibility. In the course of the neurosis it may have become re-animated by regression, anachronistic though it may now be. These are no idle speculations. There are many things about mental life, both normal and pathological, which seem to call for the raising of such questions. In my paper, 'The Dissolution of the Oedipus Complex' (1924d), I had occasion to notice the difference between the mere repression and the real removal of an old wishful impulse. [1926d, 4297]
It will soon be clear what the mental apparatus is; but I must beg you not to ask what material
it is constructed of. That is not a subject of psychological interest. Psychology can be as
indifferent to it as, for instance, optics can be to the question of whether the walls of a telescope
are made of metal or cardboard. We shall leave entirely on one side the material line of
approach, but not so the spatial one. For we picture the unknown apparatus which serves the
activities of the mind as being really like an instrument constructed of several parts (which we
speak of as ‘agencies’), each of which performs a particular function and which have a fixed
spatial relation to one another; it being understood that by spatial relation - ‘in front of’ and
‘behind’, ‘superficial’ and ‘deep’- we merely mean in the first instance a representation of the
regular succession of the functions. Have I made myself clear?
[1926e, 4337]

Topographically, psycho-analysis regards the mental apparatus as a compound instrument,
and endeavours to determine at what points in it the various mental processes take place.
According to the most recent psycho-analytic views, the mental apparatus is composed of an
‘id’, which is the repository of the instinctual impulses, of an ‘ego’, which is the most superficial
portion of the id and one which has been modified by the influence of the external world, and of
a ‘super-ego’, which develops out of the id, dominates the ego and represents the inhibitions of
instinct that are characteristic of man. The quality of consciousness, too, has a topographical
reference; for processes in the id are entirely unconscious, while consciousness is the function
of the ego’s outermost layer, which is concerned with the perception of the external world.
[1926f, 4404]

You will admit, I hope, that so far that is not too bad and allows of convenient handling. Yes,
but unluckily the work of psycho-analysis has found itself compelled to use the word
‘unconscious’ in yet another, third, sense, and this may, to be sure, have led to confusion.
Under the new and powerful impression of there being an extensive and important field of
mental life which is normally withdrawn from the ego’s knowledge so that the processes
occurring in it have to be regarded as unconscious in the truly dynamic sense, we have come to
understand the term ‘unconscious’ in a topographical or systematic sense as well; we have
come to speak of a ‘system’ of the preconscious and a ‘system’ of the unconscious, of a conflict
between the ego and the system Ucs., and have used the word more and more to denote a
mental province rather than a quality of what is mental. The discovery, actually an inconvenient
one, that portions of the ego and super-ego as well are unconscious in the dynamic sense,
operates at this point as a relief - it makes possible the removal of a complication. We perceive
that we have no right to name the mental region that is foreign to the ego ‘the system Ucs’,
since the characteristic of being unconscious is not restricted to it. Very well; we will no longer
use the term ‘unconscious’ in the systematic sense and we will give what we have hitherto so
described a better name and one no longer open to misunderstanding. Following a verbal
usage of Nietzsche’s and taking up a suggestion by Georg Groddeck, we will in future call it the
’id’. This impersonal pronoun seems particularly well suited for expressing the main
characteristic of this province of the mind - the fact of its being alien to the ego. The super-ego,
the ego and the id - these, then, are the three realms, regions, provinces, into which we divide
an individual's mental apparatus, and with the mutual relations of which we shall be concerned
in what follows.
[1933a, 4680]
We can best arrive at the characteristics of the actual ego, in so far as it can be distinguished from the id and from the super-ego, by examining its relation to the outermost superficial portion of the mental apparatus, which we describe as the system Pcpt.-Cs. This system is turned towards the external world, it is the medium for the perceptions arising thence, and during its functioning the phenomenon of consciousness arises in it. It is the sense-organ of the entire apparatus; moreover it is receptive not only to excitations from outside but also to those arising from the interior of the mind. We need scarcely look for a justification of the view that the ego is that portion of the id which was modified by the proximity and influence of the external world, which is adapted for the reception of stimuli and as a protective shield against stimuli, comparable to the cortical layer by which a small piece of living substance is surrounded. The relation to the external world has become the decisive factor for the ego; it has taken on the task of representing the external world to the id - fortunately for the id, which could not escape destruction if, in its blind efforts for the satisfaction of its instincts, it disregarded that supreme external power. In accomplishing this function, the ego must observe the external world, must lay down an accurate picture of it in the memory-traces of its perceptions, and by its exercise of the function of 'reality-testing' must put aside whatever in this picture of the external world is an addition derived from internal sources of excitation. The ego controls the approaches to motility under the id's orders; but between a need and an action it has interposed a postponement in the form of the activity of thought, during which it makes use of the mnemic residues of experience. In that way it has dethroned the pleasure principle which dominates the course of events in the id without any restriction and has replaced it by the reality principle, which promises more certainty and greater success.

[1933a, 4684]

And here is another warning, to conclude these remarks, which have certainly been exacting and not, perhaps, very illuminating. In thinking of this division of the personality into an ego, a super-ego and an id, you will not, of course, have pictured sharp frontiers like the artificial ones drawn in political geography. We cannot do justice to the characteristics of the mind by linear outlines like those in a drawing or in primitive painting, but rather by areas of colour melting into one another as they are presented by modern artists. After making the separation we must allow what we have separated to merge together once more. You must not judge too harshly a first attempt at giving a pictorial representations of something so intangible as psychical processes. It is highly probable that the development of these divisions is subject to great variations in different individuals; it is possible that in the course of actual functioning they may change and go through a temporary phase of involution. Particularly in the case of what is phylogenetically the last and most delicate of these divisions - the differentiation between the ego and the super-ego - something of the sort seems to be true. There is no question but that the same thing results from psychical illness. It is easy to imagine, too, that certain mystical practices may succeed in upsetting the normal relations between the different regions of the mind, so that, for instance, perception may be able to grasp happenings in the depths of the ego and in the id which were otherwise inaccessible to it. It may safely be doubted, however, whether this road will lead us to the ultimate truths from which salvation is to be expected. Nevertheless it may be admitted that the therapeutic efforts of psycho-analysis have chosen a similar line of approach. Its intention is, indeed, to strengthen the ego, to make it more independent of the super-ego, to widen its field of perception and enlarge its organization, so that it can appropriate fresh portions of the id. Where id was, there ego shall be. It is a work of culture - not unlike the draining of the Zuider Zee.

[1933a, 4687]
Ladies and Gentlemen, the dissection of the mental personality into a super-ego, an ego and an id, which I put before you in my last lecture, has obliged us to take our bearings afresh in the problem of anxiety as well. With the thesis that the ego is the sole seat of anxiety - that the ego alone can produce and feel anxiety - we have established a new and stable position from which a number of things take on a new aspect. And indeed it is difficult to see what sense there would be in speaking of an 'anxiety of the id' or in attributing a capacity for apprehensiveness to the super-ego. On the other hand, we have welcomed a desirable element of correspondence in the fact that the three main species of anxiety, realistic, neurotic and moral, can be so easily connected with the ego's three dependent relations - to the external world, to the id and to the super-ego. Along with this new view, moreover, the function of anxiety as a signal announcing a situation of danger (a notion, incidentally, not unfamiliar to us) comes into prominence, the question of what the material is out of which anxiety is made loses interest, and the relations between realistic and neurotic anxiety have become surprisingly clarified and simplified. It is also to be remarked that we now understand the apparently complicated cases of the generation of anxiety better than those which were considered simple.

[1933a, 4692]

The establishment of this latter fact shows us that the qualities on which we have hitherto relied are insufficient to give us our bearings in the obscurity of mental life. We must introduce another distinction which is no longer qualitative but topographical and - what gives it special value - at the same time genetic. We now distinguish in our mental life (which we regard as an apparatus compounded of several agencies, districts or provinces) one region which we call the ego proper and another which we name the id. The id is the older of the two; the ego has developed out of it, like a cortical layer, through the influence of the external world. It is in the id that all our primary instincts are at work, all the processes in the id take place unconsciously. The ego, as we have already said, coincides with the region of the preconscious; it includes portions which normally remain unconscious. The course of events in the id, and their mutual interaction, are governed by quite other laws than those prevailing in the ego. It is in fact the discovery of these differences that has led to our new view and justifies it.

[1939a, 4919]

Having now decided upon the topographical dissection of the psychical apparatus into an ego and an id, with which the difference in quality between preconscious and unconscious runs parallel, and having agreed that this quality is to be regarded only as an indication of the difference and not as its essence, a further question faces us. What, if this is so, is the true nature of the state which is revealed in the id by the quality of being unconscious and in the ego by that of being preconscious and in what does the difference between them consist?

[1940a [1938], 4973]
In yet another group of cases the distinguishing characteristics of the ego, which are to be held responsible as sources of resistance against analytic treatment and as impediments to therapeutic success, may spring from different and deeper roots. Here we are dealing with the ultimate things which psychological research can learn about: the behaviour of the two primal instincts, their distribution, mingling and defusion - things which we cannot think of as being confined to a single province of the mental apparatus, the id, the ego or the super-ego. No stronger impression arises from the resistances during the work of analysis than of there being a force which is defending itself by every possible means against recovery and which is absolutely resolved to hold on to illness and suffering. One portion of this force has been recognized by us, undoubtedly with justice, as the sense of guilt and need for punishment, and has been localized by us in the ego's relation to the super-ego. But this is only the portion of it which is, as it were, psychically bound by the super-ego and thus becomes recognizable; other quotas of the same force, whether bound or free, may be at work in other, unspecified places. If we take into consideration the total picture made up of the phenomena of masochism immanent in so many people, the negative therapeutic reaction and the sense of guilt found in so many neurotics, we shall no longer be able to adhere to the belief that mental events are exclusively governed by the desire for pleasure. These phenomena are unmistakable indications of the presence of a power in mental life which we call the instinct of aggression or of destruction according to its aims, and which we trace back to the original death instinct of living matter. It is not a question of an antithesis between an optimistic and a pessimistic theory of life. Only by the concurrent or mutually opposing action of the two primal instincts - Eros and the death instinct -, never by one or the other alone, can we explain the rich multiplicity of the phenomena of life. [1937c, 5037]
There are thus abundant signs to be found in healthy, non-neurotic people that the recollection of distressing impressions and the occurrence of distressing thoughts are opposed by a resistance.¹ But the full significance of this fact can be estimated only when the psychology of neurotic people is investigated. We are forced to regard as one of the main pillars of the mechanism supporting hysterical symptoms an elementary endeavour of this kind to fend off ideas that can arouse feelings of unpleasure - an endeavour which can only be compared with the flight-reflex in the presence of painful stimuli. The assumption that a defensive trend of this kind exists cannot be objected to on the ground that one often enough finds it impossible, on the contrary, to get rid of distressing memories that pursue one, and to banish distressing affective impulses like remorse and the pangs of conscience. For we are not asserting that this defensive trend is able to put itself into effect in every case, that in the interplay of psychical forces it may not come up against factors which, for other purposes, aim at the opposite effect and bring it about in spite of the defensive trend. It may be surmised that the architectonic principle of the mental apparatus lies in a stratification - a building up of superimposed agencies; and it is quite possible that this defensive endeavour belongs to a lower psychical agency and is inhibited by higher agencies. At all events, if we can trace back processes such as those found in our examples of forgetting to this defensive trend, that fact speaks in favour of its existence and power.(As we have seen, a number of things are forgotten on their own account; where this is not possible, the defensive trend shifts its target and causes something else related to the target at least to be forgotten, something less important which has come into associative connection with the thing that is really objectionable.

¹[1901b, 1229]

You will now see in what it is that the difference lies between our view and Janet's. We do not derive the psychical splitting from an innate incapacity for synthesis on the part of the mental apparatus; we explain it dynamically, from the conflict of opposing mental forces and recognize it as the outcome of an active struggling on the part of the two psychical groupings against each other. But our view gives rise to a large number of fresh problems. Situations of mental conflict are, of course, exceedingly common; efforts by the ego to ward off painful memories are quite regularly to be observed without their producing the result of a mental split. The reflection cannot be escaped that further determinants must be present if the conflict is to lead to dissociation. I will also readily grant you that the hypothesis of repression leaves us not at the end but at the beginning of a psychological theory. We can only go forward step by step however, and complete knowledge must await the results of further and deeper researches.

²[1910a, 2214]

Psycho-analysis, too, accepts the assumptions of dissociation and the unconscious, but relates them differently to each other. Its view is a dynamic one, which traces mental life back to an interplay between forces that favour or inhibit one another. If in any instance one group of ideas remains in the unconscious, psycho-analysis does not infer that there is a constitutional incapacity for synthesis which is showing itself in this particular dissociation, but maintains that the isolation and state of unconsciousness of this group of ideas have been caused by an active opposition on the part of other groups. The process owing to which it has met with this fate is known as 'repression' and we regard it as something analogous to a condemnatory judgement in the field of logic. Psycho-analysis points out that repressions of this kind play an extraordinarily important part in our mental life, but that they may also frequently fail and that such failures of repression are the precondition of the formation of symptoms.

³[1910i, 2368]
Psycho-analysis started with researches into hysteria, but in the course of years it has extended far beyond that field of work. The Studies on Hysteria by Breuer and myself, published in 1895, were the beginnings of psycho-analysis. They followed in the track of Charcot's work on 'traumatic' hysteria, Liébeault's and Bernheim's investigations of the phenomena of hypnosis, and Janet's studies of unconscious mental processes. Psycho-analysis soon found itself in sharp opposition to Janet's views, because (a) it declined to trace back hysteria directly to congenital hereditary degeneracy, (b) it offered, instead of a mere description, a dynamic explanation based on the interplay of psychical forces and (c) it ascribed the origin of psychical dissociation (whose importance had been recognized by Janet as well) not to a failure of mental synthesis resulting from a congenital disability, but to a special psychical process known as 'repression' ('Verdrängung').

It was conclusively proved that hysterical symptoms are residues (reminiscences) of profoundly moving experiences, which have been withdrawn from everyday consciousness, and that their form is determined (in a manner that excludes deliberate action) by details of the traumatic effects of the experiences. On this view, the therapeutic prospects lie in the possibility of getting rid of this 'repression', so as to allow part of the unconscious psychical material to become conscious and thus to deprive it of its pathogenic power. This view is a dynamic one, in so far as it regards psychical processes as displacements of psychical energy which can be gauged by the amount of their effect on the affective elements. This is most significant in hysteria, where the process of 'conversion' creates the symptoms by transforming a quantity of mental impulses into somatic innervations.

By accepting the existence of these two (or three) psychical systems, psycho-analysis has departed a step further from the descriptive 'psychology of consciousness' and has raised new problems and acquired a new content. Up till now, it has differed from that psychology mainly by reason of its dynamic view of mental processes; now in addition it seems to take account of psychical topography as well, and to indicate in respect of any given mental act within what system or between what systems it takes place. On account of this attempt, too, it has been given the name of 'depth-psychology'. We shall hear that it can be further enriched by taking yet another point of view into account.

At this point, therefore, we will leave the analysis of parapraxes. But there is one point more to which I would draw your attention. I would ask you to bear in mind as a model the manner in which we have treated these phenomena. From this example you can learn the aims of our psychology. We seek not merely to describe and to classify phenomena, but to understand them as signs of an interplay of forces in the mind, as a manifestation of purposeful intentions working concurrently or in mutual opposition. We are concerned with a dynamic view of mental phenomena. On our view the phenomena that are perceived must yield in importance to trends which are only hypothetical.
In the theory of psycho-analysis we have no hesitation in assuming that the course taken by mental events is automatically regulated by the pleasure principle. We believe, that is to say, that the course of those events is invariably set in motion by an unpleasurable tension, and that it takes a direction such that its final outcome coincides with a lowering of that tension - that is, with an avoidance of unpleasure or a production of pleasure. In taking that course into account in our consideration of the mental processes which are the subject of our study, we are introducing an 'economic' point of view into our work; and if, in describing those processes, we try to estimate this 'economic' factor in addition to the 'topographical' and 'dynamic' ones, we shall, I think, be giving the most complete description of them of which we can at present conceive, and one which deserves to be distinguished by the term 'metapsychological'.

[1920g, 3715]

But we have arrived at the term or concept of the unconscious along another path, by considering certain experiences in which mental dynamics play a part. We have found - that is, we have been obliged to assume - that very powerful mental processes or ideas exist (and here a quantitative or economic factor comes into question for the first time) which can produce all the effects in mental life that ordinary ideas do (including effects that can in their turn become conscious as ideas), though they themselves do not become conscious. It is unnecessary to repeat in detail here what has been explained so often before. It is enough to say that at this point psycho-analytic theory steps in and asserts that the reason why such ideas cannot become conscious is that a certain force opposes them, that otherwise they could become conscious, and that it would then be apparent how little they differ from other elements which are admittedly psychical. The fact that in the technique of psycho-analysis a means has been found by which the opposing force can be removed and the ideas in question made conscious renders this theory irrefutable. The state in which the ideas existed before being made conscious is called by us repression, and we assert that the force which instituted the repression and maintains it is perceived as resistance during the work of analysis.

[1923b, 3948]

We have already said that, if the differentiation we have made of the mind into an id, an ego, and a super-ego represents any advance in our knowledge, it ought to enable us to understand more thoroughly the dynamic relations within the mind and to describe them more clearly. We have also already concluded that the ego is especially under the influence of perception, and that, speaking broadly, perceptions may be said to have the same significance for the ego as instincts have for the id. At the same time the ego is subject to the influence of the instincts, too, like the id, of which it is, as we know, only a specially modified part.

[1923b, 3974]
After hypnosis was replaced by the technique of free association, Breuer's cathartic procedure turned into psycho-analysis, which for more than a decade was developed by the author (Freud) alone. During that time psycho-analysis gradually acquired a theory which appeared to give a satisfactory account of the origin, meaning and purpose of neurotic symptoms and provided a rational basis for medical attempts at curing the complaint. I will once again enumerate the factors that go to make up this theory. They are: emphasis on instinctual life (affectivity), on mental dynamics, on the fact that even the apparently most obscure and arbitrary mental phenomena invariably have a meaning and a causation, the theory of psychical conflict and of the pathogenic nature of repression, the view that symptoms are substitutive satisfactions, the recognition of the aetiological importance of sexual life, and in particular of the beginnings of infantile sexuality. From a philosophical standpoint this theory was bound to adopt the view that the mental does not coincide with the conscious, that mental processes are in themselves unconscious and are only made conscious by the functioning of special organs (agencies or systems). By way of completing this list, I will add that among the affective attitudes of childhood the complicated emotional relation of children to their parents - what is known as the Oedipus complex - came into prominence. It became ever clearer that this was the nucleus of every case of neurosis, and in the patient's behaviour towards his analyst certain phenomena of his emotional transference emerged which came to be of great importance for theory and technique alike.

[1924f, 4107]

It was now easy to reconstruct the pathogenic process. Let us keep to a simple example, in which a particular impulsion had arisen in the subject's mind but was opposed by other powerful impulsions. We should have expected the mental conflict which now arose to take the following course. The two dynamic quantities - for our present purposes let us call them 'the instinct' and 'the resistance' - would struggle with each other for some time in the fullest light of consciousness, until the instinct was repudiated and the cathexis of energy withdrawn from its impulsion. This would have been the normal solution. In a neurosis, however (for reasons which were still unknown), the conflict found a different outcome. The ego drew back, as it were, on its first collision with the objectionable instinctual impulse; it debarrd the impulse from access to consciousness and to direct motor discharge, but at the same time the impulse retained its full cathexis of energy. I named this process repression; it was a novelty, and nothing like it had ever before been recognized in mental life. It was obviously a primary mechanism of defence, comparable to an attempt at flight, and was only a forerunner of the later-developed normal condemning judgement. The first act of repression involved further consequences. In the first place the ego was obliged to protect itself against the constant threat of a renewed advance on the part of the repressed impulse by making a permanent expenditure of energy, an anticathexis, and it thus impoverished itself. On the other hand, the repressed impulse, which was now unconscious, was able to find means of discharge and of substitutive satisfaction by circuitous routes and thus to bring the whole purpose of the repression to nothing. In the case of conversion hysteria the circuitous route led to the somatic innervation; the repressed impulse broke its way through at some point or other and produced symptoms. The symptoms were thus results of a compromise, for although they were substitutive satisfactions they were nevertheless distorted and deflected from their aim owing to the resistance of the ego.

[1925d, 4206]
It is possible to take repression as a centre and to bring all the elements of psycho-analytic theory into relation with it. But before doing so I have a further comment of a polemical nature to make. According to Janet's view a hysterical woman was a wretched creature who, on account of a constitutional weakness, was unable to hold her mental acts together, and it was for that reason that she fell a victim to a splitting of her mind and to a restriction of the field of her consciousness. The outcome of psycho-analytic investigations, on the other hand, showed that these phenomena were the result of dynamic factors - of mental conflict and of repression. This distinction seems to me to be far-reaching enough to put an end to the glib repetition of the view that whatever is of value in psycho-analysis is merely borrowed from the ideas of Janet. The reader will have learned from my account that historically psycho-analysis is completely independent of Janet's discoveries, just as in its content it diverges from them and goes far beyond them. Janet's works would never have had the implications which have made psycho-analysis of such importance to the mental sciences and have made it attract such universal interest. I always treated Janet himself with respect, since his discoveries coincided to a considerable extent with those of Breuer, which had been made earlier but were published later than his. But when in the course of time psycho-analysis became a subject of discussion in France, Janet behaved ill, showed ignorance of the facts and used ugly arguments. And finally he revealed himself to my eyes and destroyed the value of his own work by declaring that when he had spoken of 'unconscious' mental acts he had meant nothing by the phrase - it had been no more than a façon de parler. [1925d, 4207]

I had already made attempts at earlier stages of my work to arrive at some more general points of view on the basis of psycho-analytic observation. In a short essay, 'Formulations on the Two Principles of Mental Functioning', I drew attention (and there was, of course, nothing original in this) to the domination of the pleasure-unpleasure principle in mental life and to its displacement by what is called the reality principle. Later on I made an attempt to produce a 'Metapsychology'. By this I meant a method of approach according to which every mental process is considered in relation to three co-ordinates, which I described as dynamic, topographical, and economic respectively; and this seemed to me to represent the furthest goal that psychology could attain. The attempt remained no more than a torso; after writing two or three papers - 'Instincts and their Vicissitudes', 'Repression', 'The Unconscious', 'Mourning and Melancholia', etc. - I broke off, wisely perhaps, since the time for theoretical predications of this kind had not yet come. In my latest speculative works I have set about the task of dissecting our mental apparatus on the basis of the analytic view of pathological facts and have divided it into an ego, an id, and a super-ego.¹ The super-ego is the heir of the Oedipus complex and represents the ethical standards of mankind. [1925d, 4234]

I will try to. But for that purpose we must study our ego and our id from a fresh angle, from the dynamic one - that is to say, having regard to the forces at work in them and between them. Hitherto we have been content with a description of the mental apparatus. [1926e, 4343]
From the first of these standpoints, the dynamic one, psycho-analysis derives all mental processes (apart from the reception of external stimuli) from the interplay of forces, which assist or inhibit one another, combine with one another, enter into compromises with one another, etc. All of these forces are originally in the nature of instincts; thus they have an organic origin. They are characterized by possessing an immense (somatic) store of power ("the compulsion to repeat"); and they are represented mentally as images or ideas with an affective charge. In psycho-analysis, no less than in other sciences, the theory of the instincts is an obscure subject. An empirical analysis leads to the formulation of two groups of instincts: the so-called 'ego-instincts', which are directed towards self-preservation, and the 'object-instincts', which are concerned with relations to an external object. The social instincts are not regarded as elementary or irreducible. Theoretical speculation leads to the suspicion that there are two fundamental instincts which lie concealed behind the manifest ego-instincts and object-instincts: namely (a) Eros, the instinct which strives for ever closer union, and (b) the instinct of destruction, which leads towards the dissolution of what is living. In psycho-analysis the manifestation of the force of Eros is given the name 'libido'.
[1926f, 4403]
Dream-distortion was the profoundest and most difficult problem of dream life. And light was thrown on it by the following consideration, which placed dreams in a class along with other psychopathological formations and revealed them, as it were, as the normal psychoses of human beings. For our mind, that precious instrument by whose means we maintain ourselves in life, is no peacefully self-contained unity. It is rather to be compared with a modern State in which a mob, eager for enjoyment and destruction, has to be held down forcibly by a prudent superior class. The whole flux of our mental life and everything that finds expression in our thoughts are derivations and representatives of the multifarious instincts that are innate in our physical constitution. But these instincts are not all equally susceptible to direction and education, or equally ready to fall in with the demands of the external world and of human society. A number of them have retained their primitive, ungovernable nature; if we let them have their way, they would infallibly bring us to ruin. Consequently, learning by experience, we have developed organizations in our mind which, in the form of inhibitions, set themselves up against the direct manifestations of the instincts. Every impulse in the nature of a wish that arises from the sources of instinctual energy must submit itself to examination by the highest agencies of our mind, and, if it is not approved, is rejected and restrained from exercising any influence upon our movements - that is, from coming into execution. Often enough, indeed, such wishes are even forbidden to enter consciousness, which is habitually unaware even of the existence of these dangerous instinctual sources. We describe such impulses as being repressed from the point of view of consciousness, and as surviving only in the unconscious. If what is repressed contrives somehow to force its way into consciousness or into movement or into both, we are no longer normal: at that point the whole range of neurotic and psychotic symptoms arise. The maintenance of the necessary inhibitions and repressions imposes upon our mind a great expenditure of energy, from which it is glad to be relieved. A good opportunity for this seems to be offered at night by the state of sleep, since sleep involves a cessation of our motor functions. The situation seems safe, and the severity of our internal police-force may therefore be relaxed. It is not entirely withdrawn, since one cannot be certain: it may be that the unconscious never sleeps at all. And now the reduction of pressure upon the repressed unconscious produces its effect. Wishes arise from it which during sleep might find the entrance to consciousness open. If we were to know them we should be appalled, alike by their subject-matter, their unrestraint and indeed the mere possibility of their existence. This, however, occurs only seldom, and when it does we awake as speedily as possible, in a state of fear. But as a rule our consciousness does not experience the dream as it really was. It is true that the inhibitory forces (the dream censorship, as we may call them) are not completely awake, but neither are they wholly asleep. They have had an influence on the dream while it was struggling to find an expression in words and pictures, they have got rid of what was most objectionable, they have altered other parts of it till they are unrecognizable, they have severed real connections while introducing false ones, until the honest but brutal wishful phantasy which lay behind the dream has turned into the manifest dream as we remember it - more or less confused and almost always strange and incomprehensible. Thus the dream (or the distortion which characterizes it) is the expression of a compromise, the evidence of a conflict between the mutually incompatible impulses and strivings of our mental life. And do not let us forget that the same process, the same interplay of forces, which explains the dreams of a normal sleeper, gives us the key to understanding all the phenomena of neurosis and psychosis.

[1932c, 4809]

During the study of the sexual functions we have been able to gain a first, preliminary conviction, or rather a suspicion, of two discoveries which will later be found to be important over the whole of our field. Firstly, the normal and abnormal manifestations observed by us (that is, the phenomenology of the subject) need to be described from the point of view of their dynamics and economics (in our case, from the point of view of the quantitative distribution of the libido). And secondly, the aetiology of the disorders which we study is to be looked for in the individual's developmental history - that is to say, in his early life.

[1940a [1938], 4966]
I should like, finally, to dwell for a moment on the working hypothesis which I have made use of in this exposition of the neuroses of defence. I refer to the concept that in mental functions something is to be distinguished - a quota of affection or sum of excitation - which possesses all the characteristics of a quantity (though we have no means of measuring it), which is capable of increase, diminution, displacement and discharge, and which is spread over the memory-traces of ideas somewhat as an electric charge is spread over the surface of a body.

Accordingly, we will picture the mental apparatus as a compound instrument, to the components of which we will give the name of 'agencies', or (for the sake of greater clarity) 'systems.' It is to be anticipated, in the next place, that these systems may perhaps stand in a regular spatial relation to one another, in the same kind of way in which the various systems of lenses in a telescope are arranged behind one another. Strictly speaking there is no need for the hypothesis that the psychological systems are actually arranged in a spatial order. It would be sufficient if a fixed order were established by the fact that in a given psychical process the excitation passes through the systems in a particular temporal sequence. In other processes the sequence may perhaps be a different one; that is a possibility that we shall leave open. For the sake of brevity we will in future speak of the components of the apparatus as 'Ψ-systems.'

Those philosophers who have become aware that rational and highly complex thought-structures are possible without consciousness playing any part in them have found difficulty in assigning any function to consciousness; it has seemed to them that it can be no more than a superfluous reflected picture of the completed psychical process. We, on the other hand, are rescued from this embarrassment by the analogy between our Cs-system and the perceptual systems. We know that perception by our sense-organs has the result of directing a cathexis of attention to the paths along which the in-coming sensory excitation is spreading: the qualitative excitation of the Pcpt. system acts as a regulator of the discharge of the mobile quantity in the psychical apparatus. We can attribute the same function to the overlying sense-organ of the Cs-system. By perceiving new qualities, it makes a new contribution to directing the mobile quantities of cathexis and distributing them in an expedient fashion. By the help of its perception of pleasure and unpleasure it influences the discharge of the cathexes within what is otherwise an unconscious apparatus operating by means of the displacement of quantities. It seems probable that in the first instance the unpleasure principle regulates the displacement of cathexes automatically. But it is quite possible that consciousness of these qualities may introduce in addition a second and more discriminating regulation, which is even able to oppose the former one, and which perfects the efficiency of the apparatus by enabling it, in contradiction to its original plan, to cathect and work over even what is associated with the release of unpleasure. We learn from the psychology of the neuroses that these processes of regulation carried out by the qualitative excitation of the sense organs play a great part in the functional activity of the apparatus. The automatic domination of the primary unpleasure principle and the consequent restriction imposed upon efficiency are interrupted by the processes of sensory regulation, which are themselves in turn automatic in action. We find that repression (which, though it served a useful purpose to begin with, leads ultimately to a damaging loss of inhibition and mental control) affects memories so much more easily than perceptions because the former can receive no extra cathexis from the excitation of the psychical sense-organs. It is true on the one hand that a thought which has to be warded off cannot become conscious, because it has undergone repression; but on the other hand it sometimes happens that a thought of this kind is only repressed because for other reasons it has been withdrawn from conscious perception. Here are some hints of which we take advantage in our therapeutic procedure in order to undo repressions which have already been effected.
But I shall resist the temptation of going further here or of discussing other situations which can be understood or pictured if we adopt the hypothesis that the object-libido may withdraw into the ego - for I am obliged to meet two objections which, as I know, are now attracting your attention. In the first place you want to call me to account because in talking of sleep, illness and similar situations I invariably try to separate libido from interest, sexual from ego instincts, where observations can be fully satisfied by the hypothesis of a single and uniform energy which, being freely mobile, cathects now the object and now the ego, in obedience to one or the other instinct. And in the second place you want to know how I can venture to treat the detaching of the libido from the object as the source of a pathological state, when a transposition of this kind of object-libido into ego-libido (or, more generally, into ego-energy) is among the normal processes of mental dynamics which are repeated daily and every night.

[1916-1917, 3465]

The opposition which he at first offered to religion had three different points of origin. To begin with, there was, in general, his characteristic (which we have seen exemplified already) of fending off all novelties. Any position of the libido which he had once taken up was obstinately defended by him from fear of what he would lose by giving it up and from distrust of the probability of a complete substitute being afforded by the new position that was in view. This is an important and fundamental psychological peculiarity, which I described in my Three Essays on the Theory of Sexuality (1905) as a susceptibility to 'fixation'. Under the name of psychical 'inertia' Jung has attempted to erect it into the principal cause of all the failures of neurotics. I think he is wrong in this; for this factor has a far more general application and plays an important part in the lives of the non-neurotic as well. Great mobility or sluggishness of libidinal cathexes (as well as of other kinds of energetic cathexes) are special characteristics which attach to many normal people and by no means to all neurotics, and which have hitherto not been brought into relation with other qualities. They are, as it were, like prime numbers, not further divisible. We only know one thing about them, and that is that mobility of the mental cathexes is a quality which shows striking diminution with the advance of age. This has given us one of the indications of the limits within which psycho-analytic treatment is effective. There are some people, however, who retain this mental plasticity far beyond the usual age-limit, and others who lose it very prematurely. If the latter are neurotics, we make the unwelcome discovery that it is impossible to undo developments in them which, in apparently similar circumstances, have been easily dealt with in other people. So that in considering the conversion of psychical energy no less than of physical, we must make use of the concept of an entropy, which opposes the undoing of what has already occurred.

[1918b, 3591]

It will be noticed, however, that by introducing this other mechanism of changing love into hate, we have tacitly made another assumption which deserves to be stated explicitly. We have reckoned as though there existed in the mind - whether in the ego or in the id - a displaceable energy, which, neutral in itself, can be added to a qualitatively differentiated erotic or destructive impulse, and augment its total cathexis. Without assuming the existence of a displaceable energy of this kind we can make no headway. The only question is where it comes from, what it belongs to, and what it signifies.

[1923b, 3978]
But of that we know nothing. And the profound obscurity of the background of our ignorance is scarcely illuminated by a few glimmers of insight. Here we have approached the still shrouded secret of the nature of the psychical. We assume, as other natural sciences have led us to expect, that in mental life some kind of energy is at work; but we have nothing to go upon which will enable us to come nearer to a knowledge of it by analogies with other forms of energy. We seem to recognize that nervous or psychical energy occurs in two forms, one freely mobile and another, by comparison, bound; we speak of cathexes and hypercathexes of psychical material, and even venture to suppose that a hypercathexis brings about a kind of synthesis of different processes - a synthesis in the course of which free energy is transformed into bound energy. Further than this we have not advanced. At any rate, we hold firmly to the view that the distinction between the unconscious and the preconscious state lies in dynamic relations of this kind, which would explain how it is that, whether spontaneously or with our assistance, the one can be changed into the other.

[1940a [1938], 4973]
For a time psycho-analysis seemed fated to merge into psychology without being able to show why the psychology of the sick differed from that of the normal. In the course of its advance, however, it came up against the problem of dreams, which are abnormal products of the mind created by normal men under regularly recurrent physiological conditions. When psycho-analysis had solved the problem of dreams, it had discovered in unconscious psychical processes the common ground in which the highest and the lowest of mental impulses have their roots and from which spring the most normal as well as the most morbid and erratic of mental productions. The new picture of the workings of the mind began to grow ever clearer and more complete. It was a picture of obscure instinctual forces organic in origin, striving towards inborn aims, and, above them, of an agency comprising more highly organized mental structures - acquisitions of human evolution made under the impact of human history -, an agency which has taken over portions of the instinctual impulses, has developed them further or has even directed them towards higher aims, but which in any case binds them firmly and manipulates their energy to suit its own purposes. This higher organization, however, which is known to us as the ego, has rejected another portion of these same elementary instinctual impulses as being unserviceable because they cannot be fitted into the organic unity of the individual or because they rebel against the individual's cultural aims. The ego is not in a position to exterminate these unsubdued mental powers, but it turns its back on them, lets them remain at the lowest psychological level, defends itself from their demands by the energetic erection of protective and antithetical barriers or seeks to come to terms with them by means of substitutive satisfactions. These instincts which have fallen victim to repression - untamed and indestructible, yet inhibited from any kind of activity - together with their primitive mental representatives, constitute the mental underworld, the nucleus of the true unconscious, and are at every moment ready to assert their demands and, by hook or by crook, to force their way forward to satisfaction. To this is due the instability of the proud superstructure of the mind, the emergence at night of the proscribed and repressed material in the form of dreams, and the tendency to fall ill with neuroses and psychoses as soon as the balance of power between the ego and the repressed shifts to the disadvantage of the ego.

[1919g, 3703]

There can be no doubt, however, that the replacement of the pleasure principle by the reality principle can only be made responsible for a small number, and by no means the most intense, of unpleasurable experiences. Another occasion of the release of unpleasure, which occurs with no less regularity, is to be found in the conflicts and dissensions that take place in the mental apparatus while the ego is passing through its development into more highly composite organizations. Almost all the energy with which the apparatus is filled arises from its innate instinctual impulses. But these are not all allowed to reach the same phases of development. In the course of things it happens again and again that individual instincts or parts of instincts turn out to be incompatible in their aims or demands with the remaining ones, which are able to combine into the inclusive unity of the ego. The former are then split off from this unity by the process of repression, held back at lower levels of psychical development and cut off, to begin with, from the possibility of satisfaction. If they succeed subsequently, as can so easily happen with repressed sexual instincts, in struggling through, by roundabout paths, to a direct or to a substitutive satisfaction, that event, which would in other cases have been an opportunity for pleasure, is felt by the ego as unpleasure. As a consequence of the old conflict which ended in repression, a new breach has occurred in the pleasure principle at the very time when certain instincts were endeavouring, in accordance with the principle, to obtain fresh pleasure. The details of the process by which repression turns a possibility of pleasure into a source of unpleasure are not yet clearly understood or cannot be clearly represented; but there is no doubt that all neurotic unpleasure is of that kind - pleasure that cannot be felt as such.¹

[1920g, 3717]
From the first of these standpoints, the dynamic one, psycho-analysis derives all mental processes (apart from the reception of external stimuli) from the interplay of forces, which assist or inhibit one another, combine with one another, enter into compromises with one another, etc. All of these forces are originally in the nature of instincts; thus they have an organic origin. They are characterized by possessing an immense (somatic) store of power ("the compulsion to repeat"); and they are represented mentally as images or ideas with an affective charge. In psycho-analysis, no less than in other sciences, the theory of the instincts is an obscure subject. An empirical analysis leads to the formulation of two groups of instincts: the so-called 'ego-instincts', which are directed towards self-preservation, and the 'object-instincts', which are concerned with relations to an external object. The social instincts are not regarded as elementary or irreducible. Theoretical speculation leads to the suspicion that there are two fundamental instincts which lie concealed behind the manifest ego-instincts and object-instincts: namely (a) Eros, the instinct which strives for ever closer union, and (b) the instinct of destruction, which leads towards the dissolution of what is living. In psycho-analysis the manifestation of the force of Eros is given the name 'libido'.

The theory of the instincts is so to say our mythology. Instincts are mythical entities, magnificent in their indefiniteness. In our work we cannot for a moment disregard them, yet we are never sure that we are seeing them clearly. You know how popular thinking deals with the instincts. People assume as many and as various instincts as they happen to need at the moment - a self-assertive instinct, an imitative instinct, an instinct of play, a gregarious instinct and many others like them. People take them up, as it were, make each of them do its particular job, and then drop them again. We have always been moved by a suspicion that behind all these little ad hoc instincts there lay concealed something serious and powerful which we should like to approach cautiously. Our first step was modest enough. We told ourselves we should probably not be going astray if we began by separating two main instincts or classes of instincts or groups of instincts in accordance with the two great needs - hunger and love. However jealously we usually defend the independence of psychology from every other science, here we stood in the shadow of the unshakable biological fact that the living individual organism is at the command of two intentions, self-preservation and the preservation of the species, which seem to be independent of each other, which, so far as we know at present, have no common origin and whose interests are often in conflict in animal life. Actually what we are talking now is biological psychology, we are studying the psychical accompaniments of biological processes. It was as representing this aspect of the subject that the 'ego-instincts' and the 'sexual instincts' were introduced into psycho-analysis. We included in the former everything that had to do with the preservation, assertion and magnification of the individual. To the latter we had to attribute the copiousness called for by infantile and perverse sexual life. In the course of investigating the neuroses we came to know the ego as the restricting and repressing power and the sexual trends as the restricted and repressed one; we therefore believed that we had clear evidence not only of the difference between the two groups of instincts but also of the conflict between them. The first object of our study was only the sexual instincts, whose energy we named 'libido'. It was in relation to them that we sought to clarify our ideas of what an instinct is and what is to be attributed to it. Here we have the libido theory.

[1926f, 4403]

[1933a, 4701]
An instinct, then, is distinguished from a stimulus by the fact that it arises from sources of stimulation within the body, that it operates as a constant force and that the subject cannot avoid it by flight, as is possible with an external stimulus. We can distinguish an instinct's source, object and aim. Its source is a state of excitation in the body, its aim is the removal of that excitation; on its path from its source to its aim the instinct becomes operative psychically. We picture it as a certain quota of energy which presses in a particular direction. It is from this pressing that it derives its name of 'Trieb'. People speak of 'active' and 'passive' instincts, but it would be more correct to speak of instincts with active and passive aims: for an expenditure of activity is needed to achieve a passive aim as well. The aim can be achieved in the subject's own body; as a rule an external object is brought in, in regard to which the instinct achieves its external aim; its internal aim invariably remains the bodily change which is felt as satisfaction. It has not become clear to us whether the relation of the instinct to its somatic source gives it a specific quality and if so what. The evidence of analytic experience shows that it is an undoubted fact that instinctual impulses from one source attach themselves to those from other sources and share their further vicissitudes and that in general one instinctual satisfaction can be replaced by another. But it must be admitted that we do not understand this very well. The relations of an instinct to its aim and object are also open to alterations; both can be exchanged for other ones, though its relation to its object is nevertheless the more easily loosened. A certain kind of modification of the aim and change of the object, in which our social valuation is taken into account, is described by us as 'sublimation'. Besides this, we have grounds for distinguishing instincts which are 'inhibited in their aim' - instinctual impulses from sources well known to us with an unambiguous aim, but which come to a stop on their way to satisfaction, so that a lasting object-cathexis comes about and a permanent trend. Such, for instance, is the relation of tenderness, which undoubtedly originates from the sources of sexual need and invariably renounces its satisfaction.

[1933a, 4702]
In order to appreciate the full significance of the difference which I have pointed out between the two groups of instincts, we shall have to go back a long way and introduce one of those considerations which deserve to be described as economic. This leads us to one of the most important, but unluckily also one of the most obscure, regions of psycho-analysis. We may ask whether in the operation of our mental apparatus a main purpose can be detected, and we may reply as a first approximation that that purpose is directed to obtaining pleasure. It seems as though our total mental activity is directed towards achieving pleasure and avoiding unpleasure - that it is automatically regulated by the pleasure principle. We should of all things like to know, then, what determines the generation of pleasure and unpleasure; but that is just what we are ignorant of. We can only venture to say this much: that pleasure is in some way connected with the diminution, reduction or extinction of the amounts of stimulus prevailing in the mental apparatus, and that similarly unpleasure is connected with their increase. An examination of the most intense pleasure which is accessible to human beings, the pleasure of accomplishing the sexual act, leaves little doubt on this point. Since in such processes related to pleasure it is a question of what happens to quantities of mental excitation or energy, we call considerations of this kind economic. It will be noticed that we can describe the tasks and achievements of the mental apparatus in another and more general way than by stressing the acquisition of pleasure. We can say that the mental apparatus serves the purpose of mastering and disposing of the amounts of stimulus and sums of excitation that impinge on it from outside and inside. It is immediately obvious that the sexual instincts, from beginning to end of their development, work towards obtaining pleasure; they retain their original function unaltered. The other instincts, the ego-instincts, have the same aim to start with. But under the influence of the instructress Necessity, they soon learn to replace the pleasure principle by a modification of it. For them the task of avoiding unpleasure turns out to be almost as important as that of obtaining pleasure. The ego discovers that it is inevitable for it to renounce immediate satisfaction, to postpone the obtaining of pleasure, to put up with a little unpleasure and to abandon certain sources of pleasure altogether. An ego thus educated has become 'reasonable'; it no longer lets itself be governed by the pleasure principle, but obeys the reality principle, which also at bottom seeks to obtain pleasure, but pleasure which is assured through taking account of reality, even though it is pleasure postponed and diminished.

[1916-1917, 3415]
For a time psycho-analysis seemed fated to merge into psychology without being able to show why the psychology of the sick differed from that of the normal. In the course of its advance, however, it came up against the problem of dreams, which are abnormal products of the mind created by normal men under regularly recurrent physiological conditions. When psycho-analysis had solved the problem of dreams, it had discovered in unconscious psychical processes the common ground in which the highest and the lowest of mental impulses have their roots and from which spring the most normal as well as the most morbid and erratic of mental productions. The new picture of the workings of the mind began to grow ever clearer and more complete. It was a picture of obscure instinctual forces organic in origin, striving towards inborn aims, and, above them, of an agency comprising more highly organized mental structures - acquisitions of human evolution made under the impact of human history -, an agency which has taken over portions of the instinctual impulses, has developed them further or has even directed them towards higher aims, but which in any case binds them firmly and manipulates their energy to suit its own purposes. This higher organization, however, which is known to us as the ego, has rejected another portion of these same elementary instinctual impulses as being unserviceable because they cannot be fitted into the organic unity of the individual or because they rebel against the individual's cultural aims. The ego is not in a position to exterminate these unsubdued mental powers, but it turns its back on them, lets them remain at the lowest psychological level, defends itself from their demands by the energetic erection of protective and antithetical barriers or seeks to come to terms with them by means of substitutive satisfactions. These instincts which have fallen victim to repression - untamed and indestructible, yet inhibited from any kind of activity - together with their primitive mental representatives, constitute the mental underworld, the nucleus of the true unconscious, and are at every moment ready to assert their demands and, by hook or by crook, to force their way forward to satisfaction. To this is due the instability of the proud superstructure of the mind, the emergence at night of the proscribed and repressed material in the form of dreams, and the tendency to fall ill with neuroses and psychoses as soon as the balance of power between the ego and the repressed shifts to the disadvantage of the ego.

[1919g, 3703]

In the theory of psycho-analysis we have no hesitation in assuming that the course taken by mental events is automatically regulated by the pleasure principle. We believe, that is to say, that the course of those events is invariably set in motion by an unpleasurable tension, and that it takes a direction such that its final outcome coincides with a lowering of that tension - that is, with an avoidance of unpleasure or a production of pleasure. In taking that course into account in our consideration of the mental processes which are the subject of our study, we are introducing an 'economic' point of view into our work; and if, in describing those processes, we try to estimate this 'economic' factor in addition to the 'topographical' and 'dynamic' ones, we shall, I think, be giving the most complete description of them of which we can at present conceive, and one which deserves to be distinguished by the term 'metapsychological'.

[1920g, 3715]
I had already made attempts at earlier stages of my work to arrive at some more general points of view on the basis of psycho-analytic observation. In a short essay, 'Formulations on the Two Principles of Mental Functioning', I drew attention (and there was, of course, nothing original in this) to the domination of the pleasure-unpleasure principle in mental life and to its displacement by what is called the reality principle. Later on I made an attempt to produce a 'Metapsychology'. By this I meant a method of approach according to which every mental process is considered in relation to three co-ordinates, which I described as dynamic, topographical, and economic respectively; and this seemed to me to represent the furthest goal that psychology could attain. The attempt remained no more than a torso; after writing two or three papers - 'Instincts and their Vicissitudes', 'Repression', 'The Unconscious', 'Mourning and Melancholia', etc. - I broke off, wisely perhaps, since the time for theoretical predications of this kind had not yet come. In my latest speculative works I have set about the task of dissecting our mental apparatus on the basis of the analytic view of pathological facts and have divided it into an ego, an id, and a super-ego.¹ The super-ego is the heir of the Oedipus complex and represents the ethical standards of mankind.  
[1925d, 4234]

From the economic standpoint psycho-analysis supposes that the mental representatives of the instincts have a charge (cathexis) of definite quantities of energy, and that it is the purpose of the mental apparatus to hinder any damming-up of these energies and to keep as low as possible the total amount of the excitations with which it is loaded. The course of mental processes is automatically regulated by the 'pleasure-unpleasure principle'; and unpleasure is thus in some way related to an increase of excitation and pleasure to a decrease. In the course of development the original pleasure principle undergoes a modification with reference to the external world, giving place to the 'reality principle', in accordance with which the mental apparatus learns to postpone the pleasure of satisfaction and to tolerate temporarily feelings of unpleasure.  
[1926f, 4404]

During the study of the sexual functions we have been able to gain a first, preliminary conviction, or rather a suspicion, of two discoveries which will later be found to be important over the whole of our field. Firstly, the normal and abnormal manifestations observed by us (that is, the phenomenology of the subject) need to be described from the point of view of their dynamics and economics (in our case, from the point of view of the quantitative distribution of the libido). And secondly, the aetiology of the disorders which we study is to be looked for in the individual's developmental history - that is to say, in his early life.  
[1940a [1938], 4966]
A second observation of Breuer's, again, compels us to attach great importance, among the characteristics of the pathological chain of events, to states of consciousness. Breuer's patient exhibited, alongside of her normal state, a number of mental peculiarities: conditions of 'absence', confusion, and alterations of character. In her normal state she knew nothing of the pathogenic scenes or their connection with her symptoms; she had forgotten the scenes, or at all events had severed the pathogenic link. When she was put under hypnosis, it was possible, at the expense of a considerable amount of labour, to recall the scenes to her memory; and, through this work of recollecting, the symptoms were removed. The explanation of this fact would be a most awkward business, were it not that the way is pointed by experiences and experiments in hypnotism. The study of hypnotic phenomena has accustomed us to what was at first a bewildering realization that in one and the same individual there can be several mental groupings, which can remain more or less independent of one another, which can 'know nothing' of one another and which can alternate with one another in their hold upon consciousness. Cases of this kind, too, occasionally appear spontaneously, and are then described as examples of 'double conscience'.¹ If, where a splitting of the personality such as this has occurred, consciousness remains attached regularly to one of the two states, we call it the conscious mental state and the other, which is detached from it, the unconscious one. In the familiar condition known as 'post-hypnotic suggestion', a command given under hypnosis is slavishly carried out subsequently in the normal state. This phenomenon affords an admirable example of the influences which the unconscious state can exercise over the conscious one; moreover, it provides a pattern upon which we can account for the phenomena of hysteria. Breuer adopted a hypothesis that hysterical symptoms arise in peculiar mental conditions to which he gave the name of 'hypnoid'. On this view, excitations occurring during these hypnoid states can easily become pathogenic because such states do not provide opportunities for the normal discharge of the process of excitation. There consequently arises from the process of excitation an unusual product - the symptom. This finds its way, like a foreign body, into the normal state, which in turn is in ignorance of the hypnoid pathogenic situation. Wherever there is a symptom there is also an amnesia, a gap in the memory, and filling up this gap implies the removal of the conditions which led to the production of the symptom.

[1910a, 2208]

Appropriate experiments have shown that people who are hysterically blind do nevertheless see in some sense, though not in the full sense. Excitations of the blind eye may have certain psychical consequences (for instance, they may produce affects) even though they do not become conscious. Thus hysterically blind people are only blind as far as consciousness is concerned; in their unconscious they see. It is precisely observations such as this that compel us to distinguish between conscious and unconscious mental processes.

[1910i, 2367]

If, Gentlemen, you complain of the obscurity of this exposition I shall not find it easy to defend. I have tried to give you a synthesis of the views of different investigators, and in doing so I have probably coupled them together too closely. I wanted to condense into a single composite whole the concepts that have been brought up to make psychogenic disturbances intelligible - their origin from excessively powerful ideas, the distinction between conscious and unconscious mental processes and the assumption of mental dissociation. And I have been no more successful in this than the French writers, at whose head stands Pierre Janet. I hope, therefore, that you will excuse not only the obscurity but the inaccuracy of my exposition, and will allow me to tell you how psycho-analysis has led us to a view of psychogenic disturbances of vision which is more self-consistent and probably closer to the facts.

[1910i, 2367]
The case itself was not a particularly favourable one. The advantage of having a wealth of information about the patient's childhood (an advantage which was made possible by the fact that the child could be studied through the medium of the adult) had to be purchased at the expense of the analysis being most terribly disjointed and of the exposition showing corresponding gaps. Personal peculiarities in the patient and a national character that was foreign to ours made the task of feeling one's way into his mind a laborious one. The contrast between the patient's agreeable and affable personality, his acute intelligence and his nicemindedness on the one hand, and his completely unbridled instinctual life on the other, necessitated an excessively long process of preparatory education, and this made a general perspective more difficult. But the patient himself has no responsibility for that feature of the case which put the severest obstacles in the way of any description of it. In the psychology of adults we have fortunately reached the point of being able to divide mental processes into conscious and unconscious and of being able to give a clearly-worded description of both. With children this distinction leaves us almost completely in the lurch. It is often embarrassing to decide what one would choose to call conscious and what unconscious. Processes which have become the dominant ones, and which from their subsequent behaviour must be equated with conscious ones, have nevertheless not been conscious in the child. It is easy to understand why. In children the conscious has not yet acquired all its characteristics; it is still in process of development, and it does not as yet fully possess the capacity for transposing itself into verbal images. We are constantly guilty of making a confusion between the phenomenon of emergence as a perception in consciousness and the fact of belonging to a hypothetical psychical system to which we ought to assign some conventional name, but which we in fact also call 'consciousness' (the system Cs.). This confusion does no harm when we are giving a psychological description of an adult, but it is misleading when we are dealing with that of a young child. Nor should we be much assisted here if we introduced the 'preconscious'; for a child's preconscious may, in just the same way, fail to coincide with an adult's. We must be content, therefore, with having clearly recognized the obscurity.

[1918b, 3582]

But we have arrived at the term or concept of the unconscious along another path, by considering certain experiences in which mental dynamics play a part. We have found - that is, we have been obliged to assume - that very powerful mental processes or ideas exist (and here a quantitative or economic factor comes into question for the first time) which can produce all the effects in mental life that ordinary ideas do (including effects that can in their turn become conscious as ideas), though they themselves do not become conscious. It is unnecessary to repeat in detail here what has been explained so often before. It is enough to say that at this point psycho-analytic theory steps in and asserts that the reason why such ideas cannot become conscious is that a certain force opposes them, that otherwise they could become conscious, and that it would then be apparent how little they differ from other elements which are admittedly psychical. The fact that in the technique of psycho-analysis a means has been found by which the opposing force can be removed and the ideas in question made conscious renders this theory irrefutable. The state in which the ideas existed before being made conscious is called by us repression, and we assert that the force which instituted the repression and maintains it is perceived as resistance during the work of analysis.

[1923b, 3948]
As regards the second class of major neuroses, hysteria and obsessional neurosis, the solution of the aetiological problem is of surprising simplicity and uniformity. I owe my results to a new method of psycho-analysis, Josef Breuer's exploratory procedure; it is a little intricate, but it is irreplaceable, so fertile has it shown itself to be in throwing light upon the obscure paths of unconscious ideation. By means of that procedure - this is not the place in which to describe it¹ - hysterical symptoms are traced back to their origin, which is always found in some event of the subject's sexual life appropriate for the production of a distressing emotion. Travelling backwards into the patient's past, step by step, and always guided by the organic train of symptoms and of memories and thoughts aroused, I finally reached the starting-point of the pathological process; and I was obliged to see that at bottom the same thing was present in all the cases submitted to analysis - the action of an agent which must be accepted as the specific cause of hysteria.

I have credited you with a wish that I might have started my description of the neuroses from the behaviour of neurotic people, from an account of the manner in which they suffer under their neurosis, of how they defend themselves against it and how they come to terms with it. No doubt that is an interesting topic, worth investigating; nor would it be very difficult to handle. But it would be of debatable wisdom to start with it. There would be a risk of not discovering the unconscious and at the same time of overlooking the great importance of the libido and of judging everything as it appears to the ego of the neurotic subject. It is obvious that this ego is not a trustworthy or impartial agency. The ego is indeed the power which disavows the unconscious and has degraded it into being repressed; so how can we trust it to be fair to the unconscious? The most prominent elements in what is thus repressed are the repudiated demands of sexuality, and it is quite self-evident that we should never be able to guess their extent and importance from the ego's conceptions. From the moment the notion of repression dawns on us, we are warned against making one of the two contesting parties (and the victorious one, at that) into being judge in the dispute. We are prepared to find that the ego's assertions will lead us astray. If we are to believe the ego, it was active at every point and itself willed and created its symptoms. But we know that it puts up with a good amount of passivity, which it afterwards tries to disguise and gloss over. It is true that it does not always venture on such an attempt; in the symptoms of obsessional neurosis it is obliged to admit that there is something alien which is confronting it and against which it can only defend itself with difficulty.

Probably very few people can have realized the momentous significance for science and life of the recognition of unconscious mental processes. It was not psycho-analysis, however, let us hasten to add, which first took this step. There are famous philosophers who may be cited as forerunners - above all the great thinker Schopenhauer, whose unconscious 'Will' is equivalent to the mental instincts of psycho-analysis. It was this same thinker, moreover, who in words of unforgettable impressiveness admonished mankind of the importance, still so greatly underestimated by it, of its sexual craving. Psycho-analysis has this advantage only, that it has not affirmed these two propositions which are so distressing to narcissism - the psychical importance of sexuality and the unconsciousness of mental life - on an abstract basis, but has demonstrated them in matters that touch every individual personally and force him to take up some attitude towards these problems. It is just for this reason, however, that it brings on itself the aversion and resistances which still hold back in awe before the great name of the philosopher.
For a time psycho-analysis seemed fated to merge into psychology without being able to show why the psychology of the sick differed from that of the normal. In the course of its advance, however, it came up against the problem of dreams, which are abnormal products of the mind created by normal men under regularly recurrent physiological conditions. When psycho-analysis had solved the problem of dreams, it had discovered in unconscious psychical processes the common ground in which the highest and the lowest of mental impulses have their roots and from which spring the most normal as well as the most morbid and erratic of mental productions. The new picture of the workings of the mind began to grow ever clearer and more complete. It was a picture of obscure instinctual forces organic in origin, striving towards inborn aims, and, above them, of an agency comprising more highly organized mental structures - acquisitions of human evolution made under the impact of human history - , an agency which has taken over portions of the instinctual impulses, has developed them further or has even directed them towards higher aims, but which in any case binds them firmly and manipulates their energy to suit its own purposes. This higher organization, however, which is known to us as the ego, has rejected another portion of these same elementary instinctual impulses as being unserviceable because they cannot be fitted into the organic unity of the individual or because they rebel against the individual's cultural aims. The ego is not in a position to exterminate these unsubdued mental powers, but it turns its back on them, lets them remain at the lowest psychological level, defends itself from their demands by the energetic erection of protective and antithetical barriers or seeks to come to terms with them by means of substitutive satisfactions. These instincts which have fallen victim to repression - untamed and indestructible, yet inhibited from any kind of activity - together with their primitive mental representatives, constitute the mental underworld, the nucleus of the true unconscious, and are at every moment ready to assert their demands and, by hook or by crook, to force their way forward to satisfaction. To this is due the instability of the proud superstructure of the mind, the emergence at night of the proscribed and repressed material in the form of dreams, and the tendency to fall ill with neuroses and psychoses as soon as the balance of power between the ego and the repressed shifts to the disadvantage of the ego.

We have made use of Le Bon's description by way of introduction, because it fits in so well with our own psychology in the emphasis which it lays upon unconscious mental life. But we must now add that as a matter of fact none of that author's statements bring forward anything new. Everything that he says to the detriment and depreciation of the manifestations of the group mind had already been said by others before him with equal distinctness and equal hostility, and has been repeated in unison by thinkers, statesmen and writers since the earliest periods of literature.¹ The two theses which comprise the most important of Le Bon's opinions, those touching upon the collective inhibition of intellectual functioning and the heightening of affectivity in groups, had been formulated shortly before by Sighele.² At bottom, all that is left over as being peculiar to Le Bon are the two notions of the unconscious and of the comparison with the mental life of primitive people, and even these had naturally often been alluded to before him.

[1919g, 3703]

[1921c, 3777]
This first configuration of the child's love, which in typical cases takes the shape of the Oedipus complex, succumbs, as we know, from the beginning of the period of latency onwards to a wave of repression. Such of it as is left over shows itself as a purely affectionate emotional tie, relating to the same people, but no longer to be described as 'sexual'. Psycho-analysis, which illuminates the depths of mental life, has no difficulty in showing that the sexual ties of the earliest years of childhood also persist, though repressed and unconscious. It gives us courage to assert that wherever we come across an affectionate feeling it is successor to a completely 'sensual' object-tie with the person in question or rather with that person's prototype (or imago). It cannot indeed disclose to us without a special investigation whether in a given case this former complete sexual current still exists under repression or whether it has already been exhausted. To speak still more precisely: it is quite certain that this current is still there as a form and possibility, and can always be cathedrated and put into activity again by means of regression; the only question is (and it cannot always be answered) what degree of cathexis and operative force it still has at the present moment. Equal care must be taken in this connection to avoid two sources of error - the Scylla of underestimating the importance of the repressed unconscious, and the Charybdis of judging the normal entirely by the standards of the pathological.

[1921c, 3829]

A psychology which will not or cannot penetrate the depths of what is repressed regards affectionate emotional ties as being invariably the expression of impulsions which have no sexual aim, even though they are derived from impulsions which have such an aim.¹

[1921c, 3829]

I cannot neglect this opportunity of expressing for once my astonishment that human beings can go through such great and important moments of their erotic life without noticing them much, sometimes even, indeed, without having the faintest suspicion of their existence, or else, having become aware of those moments, deceive themselves so thoroughly in their judgement of them. This happens not only under neurotic conditions, where we are familiar with the phenomenon, but seems also to be common enough in ordinary life. In the present case, for example, a girl develops a sentimental adoration for women, which her parents at first find merely vexatious and hardly take seriously; she herself knows quite well that she is very much occupied with these relationships, but still she experiences few of the sensations of intense love until a particular frustration is followed by a quite excessive reaction, which shows everyone concerned that they have to do with a consuming passion of elemental strength. Nor had the girl ever perceived anything of the state of affairs which was a necessary preliminary to the outbreak of this mental storm. In other cases, too, we come across girls or women in a state of severe depression, who on being asked for a possible cause of their condition tell us that they have, it is true, had a slight feeling for a certain person, but that it was nothing deep and that they soon got over it when they had to give it up. And yet it was this renunciation, apparently so easily borne, that became the cause of serious mental disturbance. Again, we come across men who have passed through casual love-affairs and realize only from the subsequent effects that they had been passionately in love with the person whom they had apparently regarded lightly. One is also amazed at the unexpected results that may follow an artificial abortion, the killing of an unborn child, which had been decided upon without remorse and without hesitation. It must be admitted that poets are right in liking to portray people who are in love without knowing it, or uncertain whether they do love, or who think that they hate when in reality they love. It would seem that the information received by our consciousness about our erotic life is especially liable to be incomplete, full of gaps, or falsified. Needless to say, in this discussion I have not omitted to allow for the part played by subsequent forgetting.

[1920a, 3855]
The Interpretation of Parapraxes and Haphazard Acts. - It was a triumph for the interpretative art of psycho-analysis when it succeeded in demonstrating that certain common mental acts of normal people, for which no one had hitherto attempted to put forward a psychological explanation, were to be regarded in the same light as the symptoms of neurotics: that is to say, they had a meaning, which was unknown to the subject but which could easily be discovered by analytic means. The phenomena in question were such events as the temporary forgetting of familiar words and names, forgetting to carry out prescribed tasks, everyday slips of the tongue and of the pen, misreadings, losses and mislayings of objects, certain errors, instances of apparently accidental self-injury, and finally habitual movements carried out seemingly without intention or in play, tunes hummed 'thoughtlessly', and so on. All of these were shorn of their physiological explanation, if any such had ever been attempted, were shown to be strictly determined and were revealed as an expression of the subject's suppressed intentions or as a result of a clash between two intentions one of which was permanently or temporarily unconscious. The importance of this contribution to psychology was of many kinds. The range of mental determinism was extended by it in an unforeseen manner; the supposed gulf between normal and pathological mental events was narrowed; in many cases a useful insight was afforded into the play of mental forces that must be suspected to lie behind the phenomena. Finally, a class of material was brought to light which is calculated better than any other to stimulate a belief in the existence of unconscious mental acts even in people to whom the hypothesis of something at once mental and unconscious seems strange and even absurd. The study of one's own parapraxes and haphazard acts, for which most people have ample opportunities, is even to-day the best preparation for an approach to psycho-analysis. In analytic treatment, the interpretation of parapraxes retains a place as a means of uncovering the unconscious, alongside the immeasurably more important interpretation of associations. [1923a, 3917]

But we have arrived at the term or concept of the unconscious along another path, by considering certain experiences in which mental dynamics play a part. We have found - that is, we have been obliged to assume - that very powerful mental processes or ideas exist (and here a quantitative or economic factor comes into question for the first time) which can produce all the effects in mental life that ordinary ideas do (including effects that can in their turn become conscious as ideas), though they themselves do not become conscious. It is unnecessary to repeat in detail here what has been explained so often before. It is enough to say that at this point psycho-analytic theory steps in and asserts that the reason why such ideas cannot become conscious is that a certain force opposes them, that otherwise they could become conscious, and that it would then be apparent how little they differ from other elements which are admittedly psychical. The fact that in the technique of psycho-analysis a means has been found by which the opposing force can be removed and the ideas in question made conscious renders this theory irrefutable. The state in which the ideas existed before being made conscious is called by us repression, and we assert that the force which instituted the repression and maintains it is perceived as resistance during the work of analysis [1923b, 3948]
Evidence of its being of use for throwing light on other than pathological mental activity was early forthcoming in connection with two kinds of phenomena: with the very frequent parapraxes that occur in everyday life - such as forgetting things, slips of the tongue, and mislaying objects - and with the dreams dreamt by healthy and psychically normal people. Small failures of functioning, like the temporary forgetting of normally familiar proper names, slips of the tongue and of the pen, and so on, had hitherto not been considered worthy of any explanation at all or were supposed to be accounted for by conditions of fatigue, by distraction of the attention, etc. The present writer then showed from many examples, in his book *The Psychopathology of Everyday Life* (1901b), that events of this kind have a meaning, and arise owing to a conscious intention being interfered with by another, suppressed or actually unconscious one. As a rule, quick reflection or a short analysis is enough to reveal the interfering influence. Owing to the frequency of such parapraxes as slips of the tongue, it became easy for anyone to convince himself from his own experience of the existence of mental processes which are not conscious, but which are nevertheless operative and which at least find expression as inhibitions and modifications of other, intended acts.

Thus we may express our expectation that psycho-analysis, whose development and achievements hitherto have been briefly and inadequately related in these pages, will enter into the cultural development of the next decades as a significant ferment, and will help to deepen our understanding of the world and to fight against some things in life which are recognized as injurious. It must not be forgotten, however, that psycho-analysis alone cannot offer a complete picture of the world. If we accept the distinction which I have recently proposed of dividing the mental apparatus into an ego, turned towards the external world and equipped with consciousness, and an unconscious id, dominated by its instinctual needs, then psycho-analysis is to be described as a psychology of the id (and of its effects upon the ego). In each field of knowledge, therefore, it can make only contributions, which require to be completed from the psychology of the ego. If these contributions often contain the essence of the facts, this only corresponds to the important part which, it may be claimed, is played in our lives by the mental unconscious that has so long remained unknown.

What, then, can a philosopher say to a theory which, like psycho-analysis, asserts that on the contrary what is mental is in itself unconscious and that being conscious is only a quality, which may or may not accrue to a particular mental act and the withholding of which may perhaps alter that act in no other respect? He will naturally say that anything both unconscious and mental would be an impossibility, a *contradictio in adjecto*, and he will fail to observe that in making this judgement he is merely repeating his own definition of what is mental, a definition which may perhaps be too narrow. It is easy for philosophers to feel this certainty, since they have no acquaintance with the material whose investigation has compelled analysts to believe in unconscious mental acts. Philosophers have never taken account of hypnosis, they have not concerned themselves with the interpreting of dreams - on the contrary, like doctors, they regard dreams as the meaningless products of reduced mental activity during sleep - they are scarcely aware that there are such things as obsessions and delusions and they would find themselves in a most embarrassing situation if they were asked to explain them on the basis of their own psychological premisses. Analysts, too, refuse to say what the unconscious is, but they can indicate the domain of phenomena whose observation has obliged them to assume its existence. Philosophers, who know no kind of observation other than self-observation, cannot follow them into that domain.

[1924f, 4109]

[1924f, 4118]

[1925e, 4124]
This implied, of course, that I abandoned the treatment of organic nervous diseases; but that was of little importance. For on the one hand the prospects in the treatment of such disorders were in any case never promising, while, on the other hand, in the private practice of a physician working in a large town, the quantity of such patients was nothing compared to the crowds of neurotics, whose number seemed further multiplied by the way in which they hurried, with their troubles unsolved, from one physician to another. And, apart from this, there was something positively seductive in working with hypnotism. For the first time there was a sense of having overcome one's helplessness; and it was highly flattering to enjoy the reputation of being a miracle-worker. It was not until later that I was to discover the drawbacks of the procedure. At the moment there were only two points to complain of: first, that I could not succeed in hypnotizing every patient, and secondly, that I was unable to put individual patients into as deep a state of hypnosis as I should have wished. With the idea of perfecting my hypnotic technique, I made a journey to Nancy in the summer of 1889 and spent several weeks there. I witnessed the moving spectacle of old Liébeault working among the poor women and children of the labouring classes. I was a spectator of Bernheim's astonishing experiments upon his hospital patients, and I received the profoundest impression of the possibility that there could be powerful mental processes which nevertheless remained hidden from the consciousness of men. Thinking it would be instructive, I had persuaded one of my patients to follow me to Nancy. This patient was a very highly gifted hysterical, a woman of good birth, who had been handed over to me because no one knew what to do with her. By hypnotic influence I had made it possible for her to lead a tolerable existence and I was always able to take her out of the misery of her condition. But she always relapsed again after a short time, and in my ignorance I attributed this to the fact that her hypnosis had never reached the stage of somnambulism with amnesia. Bernheim now attempted several times to bring this about, but he too failed. He frankly admitted to me that his great therapeutic successes by means of suggestion were only achieved in his hospital practice and not with his private patients. I had many stimulating conversations with him, and undertook to translate into German his two works upon suggestion and its therapeutic effects.

[1925d, 4195]
But the study of pathogenic repressions and of other phenomena which have still to be mentioned compelled psycho-analysis to take the concept of the 'unconscious' seriously. Psycho-analysis regarded everything mental as being in the first instance unconscious; the further quality of 'consciousness' might also be present, or again it might be absent. This of course provoked a denial from the philosophers, for whom 'conscious' and 'mental' were identical, and who protested that they could not conceive of such an absurdity as the 'unconscious mental'. There was no help for it, however, and this idiosyncrasy of the philosophers could only be disregarded with a shrug. Experience (gained from pathological material, of which the philosophers were ignorant) of the frequency and power of impulses of which one knew nothing directly, and whose existence had to be inferred like some fact in the external world, left no alternative open. It could be pointed out, incidentally, that this was only treating one's own mental life as one had always treated other people's. One did not hesitate to ascribe mental processes to other people, although one had no immediate consciousness of them and could only infer them from their words and actions. But what held good for other people must be applicable to oneself. Anyone who tried to push the argument further and to conclude from it that one's own hidden processes belonged actually to a second consciousness would be faced with the concept of a consciousness of which one knew nothing, of an 'unconscious consciousness' - and this would scarcely be preferable to the assumption of an 'unconscious mental'. If on the other hand one declared, like some other philosophers, that one was prepared to take pathological phenomena into account, but that the processes underlying them ought not to be described as mental but as 'psychoid', the difference of opinion would degenerate into an unfruitful dispute about words, though even so expediency would decide in favour of keeping the expression 'unconscious mental'. The further question as to the ultimate nature of this unconscious is no more sensible or profitable than the older one as to the nature of the conscious.

"Behind this magic we recognize the ancient, venerable and incontestably correct pronouncement of Aristotle - that dreaming is the continuation of our mental activity into the state of sleep - combined with the recognition of the unconscious which psycho-analysis first added to it. Only the riddle of dream-distortion finds no solution here."

"But that is precisely what psycho-analysis is obliged to assert, and this is its second fundamental hypothesis. It explains the supposedly somatic concomitant phenomena as being what is truly psychical, and thus in the first instance disregards the quality of consciousness. It is not alone in doing this. Some thinkers (such as Theodor Lipps, for instance) have asserted the same thing in the same words; and the general dissatisfaction with the usual view of what is psychical has resulted in an increasingly urgent demand for the inclusion in psychological thought of a concept of the unconscious, though this demand has taken such an indefinite and obscure form that it could have no influence on science."

"Every science is based on observations and experiences arrived at through the medium of our psychical apparatus. But since our science has as its subject that apparatus itself, the analogy ends here. We make our observations through the medium of the same perceptual apparatus, precisely with the help of the breaks in the sequence of 'psychical' events: we fill in what is omitted by making plausible inferences and translating it into conscious material. In this way we construct, as it were, a sequence of conscious events complementary to the unconscious psychical processes. The relative certainty of our psychical science is based on the binding force of these inferences. Anyone who enters deeply into our work will find that our technique holds its ground against any criticism."
In the course of this work the distinctions which we describe as psychical qualities force themselves on our notice. There is no need to characterize what we call 'conscious': it is the same as the consciousness of philosophers and of everyday opinion. Everything else psychical is in our view 'the unconscious'. We are soon led to make an important division in this unconscious. Some processes become conscious easily; they may then cease to be conscious, but can become conscious once more without any trouble: as people say, they can be reproduced or remembered. This reminds us that consciousness is in general a highly fugitive state. What is conscious is conscious only for a moment. If our perceptions do not confirm this, the contradiction is only an apparent one; it is explained by the fact that the stimuli which lead to perception may persist for considerable periods, so that meanwhile the perception of them may be repeated. The whole position is made clear in connection with the conscious perception of our thought-processes: these too may persist for some time, but they may just as well pass in a flash. Everything unconscious that behaves in this way, that can thus easily exchange the unconscious state for the conscious one, is therefore preferably described as 'capable of becoming conscious' or as preconscious. Experience has taught us that there is hardly a psychical process, however complicated it may be, which cannot on occasion remain preconscious, even though as a rule it will, as we say, push its way forward into consciousness. There are other psychical processes and psychical material which have no such easy access to becoming conscious but must be inferred, recognized and translated into conscious form in the manner described. For such material we reserve the name of the unconscious proper.

[1940a [1938], 4969]

Here let us pause for a moment to assure the analyst that he has our sincere sympathy in the very exacting demands he has to fulfil in carrying out his activities. It almost looks as if analysis were the third of those 'impossible' professions in which one can be sure beforehand of achieving unsatisfying results. The other two, which have been known much longer, are education and government. Obviously we cannot demand that the prospective analyst should be a perfect being before he takes up analysis, in other words that only persons of such high and rare perfection should enter the profession. But where and how is the poor wretch to acquire the ideal qualifications which he will need in his profession? The answer is, in an analysis of himself, with which his preparation for his future activity begins. For practical reasons this analysis can only be short and incomplete. Its main object is to enable his teacher to make a judgement as to whether the candidate can be accepted for further training. It has accomplished its purpose if it gives the learner a firm conviction of the existence of the unconscious, if it enables him, when repressed material emerges, to perceive in himself things which would otherwise be incredible to him, and if it shows him a first sample of the technique which has proved to be the only effective one in analytic work. This alone would not suffice for his instruction; but we reckon on the stimuli that he has received in his own analysis not ceasing when it ends and on the processes of remodelling the ego continuing spontaneously in the analysed subject and making use of all subsequent experiences in this newly-acquired sense. This does in fact happen, and in so far as it happens it makes the analysed subject qualified to be an analyst himself.

[1937c, 5042]

Psycho-analysis escaped such difficulties as these by energetically denying the equation between what is psychical and what is conscious. No; being conscious cannot be the essence of what is psychical. It is only a quality of what is psychical, and an inconstant quality at that - one that is far oftener absent than present. The psychical, whatever its nature may be, is in itself unconscious and probably similar in kind to all the other natural processes of which we have obtained knowledge.

[1940b [1938], 5068]
In the second place, I shall pick a single instance to represent an immensely large class of phenomena.¹ The President of a public body (the Lower House of the Austrian Parliament) on one occasion opened a sitting with the following words: 'I take notice that a full quorum of members is present and herewith declare the sitting closed.' It was a slip of the tongue - for there can be no doubt that what the President intended to say was 'opened'. Why, then, did he say the opposite? We shall expect to be told it was an accidental mistake, a failure in carrying out an intention such as may easily happen for various reasons: it had no meaning - and in any case contraries are particularly easily substituted for each other. If, however, we bear in mind the situation in which the slip of the tongue occurred, we shall be inclined to prefer another explanation. Many of the previous sittings of the House had been disagreeably stormy and had accomplished nothing, so that it would be only too natural for the President to think at the moment of making his opening statement: 'If only the sitting that's just beginning were finished! I would much rather be closing then opening it!' When he began to speak he was probably not aware of this wish - it was not conscious to him - but it was certainly present and it succeeded in making itself effective, against the speaker's will, in his apparent mistake. A single instance can scarcely enable us to decide between two such different explanations. But what if every other instance of a slip of the tongue could be explained in the same way, and similarly every slip of the pen, every case of mis-reading or mis-hearing, and every faulty action? What if in all those instances (one might actually say, without a single exception) it was possible to demonstrate the presence of a psychical act - a thought, a wish or an intention - which would account for the apparent mistake and which was unconscious at the moment at which it became effective, even though it may have been conscious previously? If that were so, it would really no longer be possible to dispute the fact that psychical acts which are unconscious do exist and that they are even sometimes active while they are unconscious and that in that case they can even sometimes get the better of conscious intentions. The person concerned in a mistake of this kind can react to it in various ways. He may overlook it completely or he may notice it himself and become embarrassed and ashamed. He cannot as a rule find the explanation of it himself without outside help; and he often refuses to accept the solution when it is put before him - for a time, at all events.

[1940b [1938], 5069]

The question of the relation of the conscious to the psychical may now be regarded as settled: consciousness is only a quality or attribute of what is psychical, and moreover an inconstant one. But there is one further objection with which we have to deal. We are told that, in spite of the facts that have been mentioned, there is no necessity to abandon the identity between what is conscious and what is psychical: the so-called unconscious psychical processes are the organic processes which have long been recognized as running parallel to the mental ones. This, of course, would reduce our problem to an apparently indifferent matter of definition. Our reply is that it would be unjustifiable and inexpedient to make a breach in the unity of mental life for the sake of propping up a definition, since it is clear in any case that consciousness can only offer us an incomplete and broken chain of phenomena. And it can scarcely be a matter of chance that it was not until the change had been made in the definition of the psychical that it became possible to construct a comprehensive and coherent theory of mental life.

[1940b [1938], 5071]
We will describe the last of the systems at the motor end as 'the preconscious', to indicate that the excitatory processes occurring in it can enter consciousness without further impediment provided that certain other conditions are fulfilled: for instance, that they reach a certain degree of intensity, that the function which can only be described as 'attention' is distributed in a particular way, and so on. This is at the same time the system which holds the key to voluntary movement. We will describe the system that lies behind it as 'the unconscious', because it has no access to consciousness except via the preconscious, in passing through which its excitatory process is obliged to submit to modifications.¹

² [Footnote added 1923:] I am here using the word 'consciousness' in a sense which I later avoided, namely, to describe our normal processes of thought - such, that is, as are capable of consciousness. We know that thought processes of this kind may also take place preconsciously; and it is wiser to regard their actual 'consciousness' from a purely phenomenological standpoint. By this I do not, of course, mean to contradict the expectation that consciousness in this more limited sense of the word must also fulfil some biological function.

But we have arrived at the term or concept of the unconscious along another path, by considering certain experiences in which mental dynamics play a part. We have found - that is, we have been obliged to assume - that very powerful mental processes or ideas exist (and here a quantitative or economic factor comes into question for the first time) which can produce all the effects in mental life that ordinary ideas do (including effects that can in their turn become conscious as ideas), though they themselves do not become conscious. It is unnecessary to repeat in detail here what has been explained so often before. It is enough to say that at this point psycho-analytic theory steps in and asserts that the reason why such ideas cannot become conscious is that a certain force opposes them, that otherwise they could become conscious, and that it would then be apparent how little they differ from other elements which are admittedly psychical. The fact that in the technique of psycho-analysis a means has been found by which the opposing force can be removed and the ideas in question made conscious renders this theory irrefutable. The state in which the ideas existed before being made conscious is called by us repression, and we assert that the force which instituted the repression and maintains it is perceived as resistance during the work of analysis.
Thus we obtain our concept of the unconscious from the theory of repression. The repressed is the prototype of the unconscious for us. We see, however, that we have two kinds of unconscious - the one which is latent but capable of becoming conscious, and the one which is repressed and which is not, in itself and without more ado, capable of becoming conscious. This piece of insight into psychical dynamics cannot fail to affect terminology and description. The latent, which is unconscious only descriptively, not in the dynamic sense, we call preconscious; we restrict the term unconscious to the dynamically unconscious repressed; so that now we have three terms, conscious (Cs.), preconscious (Pcs.), and unconscious (Ucs.), whose sense is no longer purely descriptive. The Pcs. is presumably a great deal closer to the Cs. than is the Ucs., and since we have called the Ucs. psychical we shall with even less hesitation call the latent Pcs. psychical. But why do we not rather, instead of this, remain in agreement with the philosophers and, in a consistent way, distinguish the Pcs. as well as the Ucs. from the conscious psychical? The philosophers would then propose that the Pcs. and the Ucs. should be described as two species or stages of the 'psychoid', and harmony would be established. But endless difficulties in exposition would follow; and the one important fact, that these two kinds of 'psychoid' coincide in almost every other respect with what is admittedly psychical, would be forced into the background in the interests of a prejudice dating from a period in which these psychoids, or the most important part of them, were still unknown.

[1923b, 3949]

For our conception of the unconscious, however, the consequences of our discovery are even more important. Dynamic considerations caused us to make our first correction; our insight into the structure of the mind leads to the second. We recognize that the Ucs. does not coincide with the repressed; it is still true that all that is repressed is Ucs., but not all that is Ucs. is repressed. A part of the ego, too - and Heaven knows how important a part - may be Ucs., undoubtedly is Ucs. And this Ucs. belonging to the ego is not latent like the Pcs.; for if it were, it could not be activated without becoming Cs., and the process of making it conscious would not encounter such great difficulties. When we find ourselves thus confronted by the necessity of postulating a third Ucs., which is not repressed, we must admit that the characteristic of being unconscious begins to lose significance for us. It becomes a quality which can have many meanings, a quality which we are unable to make, as we should have hoped to do, the basis of far-reaching and inevitable conclusions. Nevertheless we must beware of ignoring this characteristic, for the property of being conscious or not is in the last resort our one beacon-light in the darkness of depth-psychology.

[1923b, 3952]

It would be more difficult to explain concisely how it came about that psycho-analysis made a further distinction in the unconscious, and separated it into a preconscious and an unconscious proper. It will be sufficient to say that it appeared a legitimate course to supplement the theories that were a direct expression of experience with hypotheses that were designed to facilitate the handling of the material and related to matters which could not be a subject of immediate observation. The very same procedure is adopted by the older sciences. The subdivision of the unconscious is part of an attempt to picture the apparatus of the mind as being built up of a number of agencies or systems whose relations to one another are expressed in spatial terms, without, however, implying any connection with the actual anatomy of the brain. (I have described this as the topographical method of approach.) Such ideas as these are part of a speculative superstructure of psycho-analysis, any portion of which can be abandoned or changed without loss or regret the moment its inadequacy has been proved. But there is still plenty to be described that lies closer to actual experience.

[1925d, 4208]
There is no need to discuss what is to be called conscious: it is removed from all doubt. The oldest and best meaning of the word 'unconscious' is the descriptive one; we call a psychical process unconscious whose existence we are obliged to assume - for some such reason as that we infer it from its effects -, but of which we know nothing. In that case we have the same relation to it as we have to a psychical process in another person, except that it is in fact one of our own. If we want to be still more correct, we shall modify our assertion by saying that we call a process unconscious if we are obliged to assume that it is being activated at the moment, though at the moment we know nothing about it. This qualification makes us reflect that the majority of conscious processes are conscious only for a short time; very soon they become latent, but can easily become conscious again. We might also say that they had become unconscious, if it were at all certain that in the condition of latency they are still something psychical. So far we should have learnt nothing new; nor should we have acquired the right to introduce the concept of an unconscious into psychology. But then comes the new observation that we were already able to make in parapraxes. In order to explain a slip of the tongue, for instance, we find ourselves obliged to assume that the intention to make a particular remark was present in the subject. We infer it with certainty from the interference with his remark which has occurred; but the intention did not put itself through and was thus unconscious. If, when we subsequently put it before the speaker, he recognizes it as one familiar to him, then it was only temporarily unconscious to him; but if he repudiates it as something foreign to him, then it was permanently unconscious. From this experience we retrospectively obtain the right also to pronounce as something unconscious what had been described as latent. A consideration of these dynamic relations permits us now to distinguish two kinds of unconscious - one which is easily, under frequently occurring circumstances, transformed into something conscious, and another with which this transformation is difficult and takes place only subject to a considerable expenditure of effort or possibly never at all. In order to escape the ambiguity as to whether we mean the one or the other unconscious, whether we are using the word in the descriptive or in the dynamic sense, we make use of a permissible and simple way out. We call the unconscious which is only latent, and thus easily becomes conscious, the 'preconscious' and retain the term 'unconscious' for the other. We now have three terms, 'conscious', 'preconscious' and 'unconscious', with which we can get along in our description of mental phenomena. Once again: the preconscious is also unconscious in the purely descriptive sense, but we do not give it that name, except in talking loosely or when we have to make a defence of the existence in mental life of unconscious processes in general.

[1933a, 4679]
You will admit, I hope, that so far that is not too bad and allows of convenient handling. Yes, but unluckily the work of psycho-analysis has found itself compelled to use the word 'unconscious' in yet another, third, sense, and this may, to be sure, have led to confusion. Under the new and powerful impression of there being an extensive and important field of mental life which is normally withdrawn from the ego's knowledge so that the processes occurring in it have to be regarded as unconscious in the truly dynamic sense, we have come to understand the term 'unconscious' in a topographical or systematic sense as well; we have come to speak of a 'system' of the preconscious and a 'system' of the unconscious, of a conflict between the ego and the system Ucs., and have used the word more and more to denote a mental province rather than a quality of what is mental. The discovery, actually an inconvenient one, that portions of the ego and super-ego as well are unconscious in the dynamic sense, operates at this point as a relief - it makes possible the removal of a complication. We perceive that we have no right to name the mental region that is foreign to the ego 'the system Ucs', since the characteristic of being unconscious is not restricted to it. Very well; we will no longer use the term 'unconscious' in the systematic sense and we will give what we have hitherto so described a better name and one no longer open to misunderstanding. Following a verbal usage of Nietzsche's and taking up a suggestion by Georg Groddeck, we will in future call it the 'id'. This impersonal pronoun seems particularly well suited for expressing the main characteristic of this province of the mind - the fact of its being alien to the ego. The super-ego, the ego and the id - these, then, are the three realms, regions, provinces, into which we divide an individual's mental apparatus, and with the mutual relations of which we shall be concerned in what follows.

[1933a, 4680]
Dream-distortion was the profoundest and most difficult problem of dream life. And light was thrown on it by the following consideration, which placed dreams in a class along with other psychopathological formations and revealed them, as it were, as the normal psychoses of human beings. For our mind, that precious instrument by whose means we maintain ourselves in life, is no peacefully self-contained unity. It is rather to be compared with a modern State in which a mob, eager for enjoyment and destruction, has to be held down forcibly by a prudent superior class. The whole flux of our mental life and everything that finds expression in our thoughts are derivations and representatives of the multifarious instincts that are innate in our physical constitution. But these instincts are not all equally susceptible to direction and education, or equally ready to fall in with the demands of the external world and of human society. A number of them have retained their primitive, ungovernable nature; if we let them have their way, they would infallibly bring us to ruin. Consequently, learning by experience, we have developed organizations in our mind which, in the form of inhibitions, set themselves up against the direct manifestations of the instincts. Every impulse in the nature of a wish that arises from the sources of instinctual energy must submit itself to examination by the highest agencies of our mind, and, if it is not approved, is rejected and restrained from exercising any influence upon our movements - that is, from coming into execution. Often enough, indeed, such wishes are even forbidden to enter consciousness, which is habitually unaware even of the existence of these dangerous instinctual sources. We describe such impulses as being repressed from the point of view of consciousness, and as surviving only in the unconscious. If what is repressed contrives somehow to force its way into consciousness or into movement or into both, we are no longer normal: at that point the whole range of neurotic and psychotic symptoms arise. The maintenance of the necessary inhibitions and repressions imposes upon our mind a great expenditure of energy, from which it is glad to be relieved. A good opportunity for this seems to be offered at night by the state of sleep, since sleep involves a cessation of our motor functions. The situation seems safe, and the severity of our internal police-force may therefore be relaxed. It is not entirely withdrawn, since one cannot be certain: it may be that the unconscious never sleeps at all. And now the reduction of pressure upon the repressed unconscious produces its effect. Wishes arise from it which during sleep might find the entrance to consciousness open. If we were to know them we should be appalled, alike by their subject-matter, their unrestraint and indeed the mere possibility of their existence. This, however, occurs only seldom, and when it does we awake as speedily as possible, in a state of fear. But as a rule our consciousness does not experience the dream as it really was. It is true that the inhibitory forces (the dream censorship, as we may call them) are not completely awake, but neither are they wholly asleep. They have had an influence on the dream while it was struggling to find an expression in words and pictures, they have got rid of what was most objectionable, they have altered other parts of it till they are unrecognizable, they have severed real connections while introducing false ones, until the honest but brutal wishful phantasy which lay behind the dream has turned into the manifest dream as we remember it - more or less confused and almost always strange and incomprehensible. Thus the dream (or the distortion which characterizes it) is the expression of a compromise, the evidence of a conflict between the mutually incompatible impulses and strivings of our mental life. And do not let us forget that the same process, the same interplay of forces, which explains the dreams of a normal sleeper, gives us the key to understanding all the phenomena of neurosis and psychosis.

[1932c, 4809]
The difference between whether a psychical process is conscious or unconscious has served us as a criterion and a means of finding our bearings. The repressed is unconscious. Now it would simplify things agreeably if this sentence admitted of reversal - if, that is, the difference between the qualities of conscious (Cs.) and unconscious (Ucs.) coincided with the distinction between 'belonging to the ego' and 'repressed'. The fact of there being isolated and unconscious things like this in our mental life would be sufficiently novel and important. But in reality the position is more complicated. It is true that everything repressed is unconscious, but it is not true that everything belonging to the ego is conscious. We notice that consciousness is a transient quality which attaches to a psychical process only in passing. For our purposes therefore we must replace 'conscious' by 'capable of being conscious' and we call this quality 'preconscious' (Pcs.). We then say, more correctly, that the ego is mainly preconscious (virtually conscious) but that portions of the ego are unconscious.

The repressed is to be counted as belonging to the id and is subject to the same mechanisms; it is distinguished from it only in respect to its genesis. The differentiation is accomplished in the earliest period of life, while the ego is developing out of the id. At that time a portion of the contents of the id is taken into the ego and raised to the preconscious state; another portion is not affected by this translation and remains behind in the id as the unconscious proper. In the further course of the formation of the ego, however, certain psychical impressions and processes in the ego are excluded from it by a defensive process; the characteristic of being preconscious is withdrawn from them, so that they are once more reduced to being component portions of the id. Here then is the 'repressed' in the id. So far as intercourse between the two mental provinces is concerned, we therefore assume that, on the one hand, unconscious processes in the id are raised to the level of the preconscious and incorporated into the ego, and that, on the other hand, preconscious material in the ego can follow the opposite path and be put back into the id. The fact that later on a special region - that of the 'super-ego' - is separated off in the ego lies outside our present interest.

All of this may appear to be far from simple. But when one has grown reconciled to this unusual spatial view of the mental apparatus, it can present no particular difficulties to the imagination. I will add the further comment that the psychical topography that I have developed here has nothing to do with the anatomy of the brain, and actually only touches it at one point. What is unsatisfactory in this picture - and I am aware of it as clearly as anyone - is due to our complete ignorance of the dynamic nature of the mental processes. We tell ourselves that what distinguishes a conscious idea from a preconscious one, and the latter from an unconscious one, can only be a modification, or perhaps a different distribution, of psychical energy. We talk of cathexes and hypercathexes, but beyond this we are without any knowledge on the subject or even any starting-point for a serviceable working hypothesis. Of the phenomenon of consciousness we can at least say that it was originally attached to perception. All sensations which originate from the perception of painful, tactile, auditory or visual stimuli are what are most readily conscious. Thought-processes, and whatever may be analogous to them in the id, are in themselves unconscious and obtain access to consciousness by becoming linked to the mnemonic residues of visual and auditory perceptions along the path of the function of speech. In animals, which lack speech, these conditions must be of a simpler kind.
In the course of this work the distinctions which we describe as psychical qualities force themselves on our notice. There is no need to characterize what we call 'conscious': it is the same as the consciousness of philosophers and of everyday opinion. Everything else psychical is in our view 'the unconscious'. We are soon led to make an important division in this unconscious. Some processes become conscious easily; they may then cease to be conscious, but can become conscious once more without any trouble: as people say, they can be reproduced or remembered. This reminds us that consciousness is in general a highly fugitive state. What is conscious is conscious only for a moment. If our perceptions do not confirm this, the contradiction is only an apparent one; it is explained by the fact that the stimuli which lead to perception may persist for considerable periods, so that meanwhile the perception of them may be repeated. The whole position is made clear in connection with the conscious perception of our thought-processes: these too may persist for some time, but they may just as well pass in a flash. Everything unconscious that behaves in this way, that can thus easily exchange the unconscious state for the conscious one, is therefore preferably described as 'capable of becoming conscious' or as preconscious. Experience has taught us that there is hardly a psychical process, however complicated it may be, which cannot on occasion remain preconscious, even though as a rule it will, as we say, push its way forward into consciousness. There are other psychical processes and psychical material which have no such easy access to becoming conscious but must be inferred, recognized and translated into conscious form in the manner described. For such material we reserve the name of the unconscious proper.

[1940a [1938], 4969]

Thus we have attributed three qualities to psychical processes: they are either conscious, preconscious or unconscious. The division between the three classes of material which possess these qualities is neither absolute nor permanent. What is preconscious becomes conscious, as we have seen, without any assistance from us; what is unconscious can, through our efforts, be made conscious, and in the process we may have a feeling that we are often overcoming very strong resistances. When we attempt to do this with someone else, we should not forget that the conscious filling-in of the gaps in his perceptions - the construction we are presenting him with - does not mean as yet that we have made the unconscious material in question conscious to him. All that is true so far is that the material is present in him in two records, once in the conscious reconstruction he has been given, and besides this in its original unconscious state. Our continued efforts usually succeed eventually in making this unconscious material conscious to him himself, as a result of which the two records are brought to coincide. The amount of effort we have to use, by which we estimate the resistance against the material becoming conscious, varies in magnitude in individual cases. For instance, what comes about in an analytic treatment as a result of our efforts can also occur spontaneously: material which is ordinarily unconscious can transform itself into preconscious material and then becomes conscious - a thing that happens to a large extent in psychotic states. From this we infer that the maintenance of certain internal resistances is a sine qua non of normality. A relaxation of resistances such as this, with a consequent pushing forward of unconscious material, takes place regularly in the state of sleep, and thus brings about a necessary precondition for the construction of dreams. Conversely, preconscious material can become temporarily inaccessible and cut off by resistances, as happens when something is temporarily forgotten or escapes the memory; or a preconscious thought can even be temporarily put back into the unconscious state, as seems to be a precondition in the case of jokes. We shall see that a similar transformation back of preconscious material or processes into the unconscious state plays a great part in the causation of neurotic disorders.

[1940a [1938], 4970]
The sole prevailing quality in the id is that of being unconscious. Id and unconscious are as intimately linked as ego and preconscious: indeed, in the former case the connection is even more exclusive. If we look back at the developmental history of an individual and of his psychical apparatus, we shall be able to perceive an important distinction in the id. Originally, to be sure, everything was id; the ego was developed out of the id by the continual influence of the external world. In the course of this slow development certain of the contents of the id were transformed into the preconscious state and so taken into the ego; others of its contents remained in the id unchanged, as its scarcely accessible nucleus. During this development, however, the young and feeble ego put back into the unconscious state some of the material it had already taken in, dropped it, and behaved in the same way to some fresh impressions which it might have taken in, so that these, having been rejected, could leave a trace only in the id. In consideration of its origin we speak of this latter portion of the id as the repressed. It is of little importance that we are not always able to draw a sharp line between these two categories of contents in the id. They coincide approximately with the distinction between what was innately present originally and what was acquired in the course of the ego's development.

[1940a [1938], 4973]

Having now decided upon the topographical dissection of the psychical apparatus into an ego and an id, with which the difference in quality between preconscious and unconscious runs parallel, and having agreed that this quality is to be regarded only as an indication of the difference and not as its essence, a further question faces us. What, if this is so, is the true nature of the state which is revealed in the id by the quality of being unconscious and in the ego by that of being preconscious and in what does the difference between them consist?

[1940a [1938], 4973]
But what part is there left to be played in our scheme by consciousness, which was once so omnipotent and hid all else from view? Only that of a sense-organ for the perception of psychical qualities. In accordance with the ideas underlying our attempt at a schematic picture, we can only regard conscious perception as the function proper to a particular system; and for this the abbreviation Cs. seems appropriate. In its mechanical properties we regard this system as resembling the perceptual systems \( P_{cpt} \): as being susceptible to excitation by qualities but incapable of retaining traces of alterations - that is to say, as having no memory. The psychical apparatus, which is turned towards the external world with its sense-organ of the \( P_{cpt} \) systems, is itself the external world in relation to the sense-organ of the Cs., whose teleological justification resides in this circumstance. Here we once more meet the principle of the hierarchy of agencies, which seems to govern the structure of the apparatus. Excitatory material flows in to the Cs. sense-organ from two directions: from the \( P_{cpt} \) system, whose excitation, determined by qualities, is probably submitted to a fresh revision before it becomes a conscious sensation, and from the interior of the apparatus itself, whose quantitative processes are felt qualitatively in the pleasure-unpleasure series when, subject to certain modifications, they make their way to consciousness.

\[1900a, 1040\]

On the contrary, the only results of the analysis were that Hans recovered, that he ceased to be afraid of horses, and that he got on to rather familiar terms with his father, as the latter reported with some amusement. But whatever his father may have lost in the boy's respect he won back in his confidence: 'I thought', said Hans, 'you knew everything, as you knew that about the horse.' For analysis does not undo the effects of repression. The instincts which were formerly suppressed remain suppressed; but the same effect is produced in a different way. Analysis replaces the process of repression, which is an automatic and excessive one, by a temperate and purposeful control on the part of the highest agencies of the mind. In a word, analysis replaces repression by condemnation. This seems to bring us the long-looked-for evidence that consciousness has a biological function, and that with its entrance upon the scene an important advantage is secured.²

\[1900b, 2121\]

² \[Footnote added 1923:] I am here using the word 'consciousness' in a sense which I later avoided, namely, to describe our normal processes of thought - such, that is, as are capable of consciousness. We know that thought processes of this kind may also take place preconsciously; and it is wiser to regard their actual 'consciousness' from a purely phenomenological standpoint. By this I do not, of course, mean to contradict the expectation that consciousness in this more limited sense of the word must also fulfil some biological function.

\[1909b, 2121\]

It is not, of course, to be expected that either the primitive or the present-day concept of a 'soul' will be separated from that of the other portion of the personality by the same line of demarcation which our modern science draws between conscious and unconscious mental activity. The animistic soul unites properties from both sides. Its volatile and mobile quality, its power of leaving the body and of taking possession, temporarily or permanently, of another body - these are characteristics which remind us unmistakably of the nature of consciousness. But the way in which it remains concealed behind the manifest personality is reminiscent of the unconscious; immutability and indestructibility are qualities which we no longer attribute to conscious but rather to unconscious processes, and we regard the latter as the true vehicle of mental activity.

\[1912-1913, 2736\]
The reason for all these difficulties is to be found in the circumstance that the attribute of being conscious, which is the only characteristic of psychical processes that is directly presented to us, is in no way suited to serve as a criterion for the differentiation of systems. Apart from the fact that the conscious is not always conscious but also at times latent, observation has shown that much that shares the characteristics of the system $Pcs.$ does not become conscious; and we learn in addition that the act of becoming conscious is dependent on the attention of the $Pcs.$ being turned in certain directions. Hence consciousness stands in no simple relation either to the different systems or to repression. The truth is that it is not only the psychically repressed that remains alien to consciousness, but also some of the impulses which dominate our ego - something, therefore, that forms the strongest functional antithesis to the repressed. The more we seek to win our way to a metapsychological view of mental life, the more we must learn to emancipate ourselves from the importance of the symptom of 'being conscious'.

[1915e, 3014]

I will put before you the only theoretical ideas which have proved of service for giving a more definite shape to the concept of repression. It is above all essential for this purpose that we should proceed from the purely descriptive meaning of the word 'unconscious' to the systematic meaning of the same word. That is, we will decide to say that the fact of a psychical process being conscious or unconscious is only one of its attributes and not necessarily an unambiguous one. If a process of this kind has remained unconscious, its being kept away from consciousness may perhaps only be an indication of some vicissitude it has gone through, and not that vicissitude itself. In order to form a picture of this vicissitude, let us assume that every mental process - we must admit one exception, which we shall mention at a later stage - exists to begin with in an unconscious stage or phase and that it is only from there that the process passes over into the conscious phase, just as a photographic picture begins as a negative and only becomes a picture after being turned into a positive. Not every negative, however, necessarily becomes a positive; nor is it necessary that every unconscious mental process should turn into a conscious one. This may be advantageously expressed by saying that an individual process belongs to begin with to the system of the unconscious and can then, in certain circumstances, pass over into the system of the conscious.

[1916-1917, 3368]
The crudest idea of these systems is the most convenient for us - a spatial one. Let us therefore compare the system of the unconscious to a large entrance hall, in which the mental impulses jostle one another like separate individuals. Adjoining this entrance hall there is a second, narrower, room - a kind of drawing-room - in which consciousness, too, resides. But on the threshold between these two rooms a watchman performs his function: he examines the different mental impulses, acts as a censor, and will not admit them into the drawing-room if they displease him. You will see at once that it does not make much difference if the watchman turns away a particular impulse at the threshold itself or if he pushes it back across the threshold after it has entered the drawing-room. This is merely a question of the degree of his watchfulness and of how early he carries out his act of recognition. If we keep to this picture, we shall be able to extend our nomenclature further. The impulses in the entrance hall of the unconscious are out of sight of the conscious, which is in the other room; to begin with they must remain unconscious. If they have already pushed their way forward to the threshold and have been turned back by the watchman, then they are inadmissible to consciousness; we speak of them as repressed. But even the impulses which the watchman has allowed to cross the threshold are not on that account necessarily conscious as well; they can only become so if they succeed in catching the eye of consciousness. We are therefore justified in calling this second room the system of the preconscious. In that case becoming conscious retains its purely descriptive sense. For any particular impulse, however, the vicissitude of repression consists in its not being allowed by the watchman to pass from the system of the unconscious into that of the preconscious. It is the same watchman whom we get to know as resistance when we try to lift the repression by means of the analytic treatment.

[1916-1917, 3369]

'The whole process, however, only becomes possible through the single circumstance that you are mistaken in another important point as well. You feel sure that you are informed of all that goes on in your mind if it is of any importance at all, because in that case, you believe, your consciousness gives you news of it. And if you have had no information of something in your mind you confidently assume that it does not exist there. Indeed, you go so far as to regard what is "mental" as identical with what is "conscious" - that is, with what is known to you in spite of the most obvious evidence that a great deal more must constantly be going on in your mind than can be known to your consciousness. Come, let yourself be taught something on this one point! What is in your mind does not coincide with what you are conscious of; whether something is going on in your mind and whether you hear of it, are two different things. In the ordinary way, I will admit, the intelligence which reaches your consciousness is enough for your needs; and you may cherish the illusion that you learn of all the more important things. But in some cases, as in that of an instinctual conflict such as I have described, your intelligence service breaks down and your will then extends no further than your knowledge. In every case, however, the news that reaches your consciousness is incomplete and often not to be relied on. Often enough, too, it happens that you get news of events only when they are over and when you can no longer do anything to change them. Even if you are not ill, who can tell all that is stirring in your mind of which you know nothing or are falsely informed? You behave like an absolute ruler who is content with the information supplied him by his highest officials and never goes among the people to hear their voice. Turn your eyes inward, look into your own depths, learn first to know yourself! Then you will understand why you were bound to fall ill; and perhaps, you will avoid falling ill in future.'

[1917a, 3614]
It is thus that psycho-analysis has sought to educate the ego. But these two discoveries - that the life of our sexual instincts cannot be wholly tamed, and that mental processes are in themselves unconscious and only reach the ego and come under its control through incomplete and untrustworthy perceptions - these two discoveries amount to a statement that the ego is not master in its own house. Together they represent the third blow to man's self-love, what I may call the psychological one. No wonder, then, that the ego does not look favourably upon psycho-analysis and obstinately refuses to believe in it.

[1917a, 3614]

Probably very few people can have realized the momentous significance for science and life of the recognition of unconscious mental processes. It was not psycho-analysis, however, let us hasten to add, which first took this step. There are famous philosophers who may be cited as forerunners - above all the great thinker Schopenhauer, whose unconscious 'Will' is equivalent to the mental instincts of psycho-analysis. It was this same thinker, moreover, who in words of unforgettable impressiveness admonished mankind of the importance, still so greatly underestimated by it, of its sexual craving. Psycho-analysis has this advantage only, that it has not affirmed these two propositions which are so distressing to narcissism - the psychical importance of sexuality and the unconsciousness of mental life - on an abstract basis, but has demonstrated them in matters that touch every individual personally and force him to take up some attitude towards these problems. It is just for this reason, however, that it brings on itself the aversion and resistances which still hold back in awe before the great name of the philosopher.

[1917a, 3615]

Psycho-analytic speculation takes as its point of departure the impression, derived from examining unconscious processes, that consciousness may be, not the most universal attribute of mental processes, but only a particular function of them. Speaking in metapsychological terms, it asserts that consciousness is a function of a particular system which it describes as Cs. What consciousness yields consists essentially of perceptions of excitations coming from the external world and of feelings of pleasure and unpleasure which can only arise from within the mental apparatus; it is therefore possible to assign to the system Pcpt.-Cs. a position in space. It must lie on the borderline between outside and inside; it must be turned towards the external world and must envelop the other psychical systems. It will be seen that there is nothing daringly new in these assumptions; we have merely adopted the views on localization held by cerebral anatomy, which locates the 'seat' of consciousness in the cerebral cortex - the outermost, enveloping layer of the central organ. Cerebral anatomy has no need to consider why, speaking anatomically, consciousness should be lodged on the surface of the brain instead of being safely housed somewhere in its inmost interior. Perhaps we shall be more successful in accounting for this situation in the case of our system Pcpt.-Cs.

[1920g, 3728]
Consciousness is not the only distinctive character which we ascribe to the processes in that system. On the basis of impressions derived from our psycho-analytic experience, we assume that all excitatory processes that occur in the other systems leave permanent traces behind in them which form the foundation of memory. Such memory-traces, then, have nothing to do with the fact of becoming conscious; indeed they are often most powerful and most enduring when the process which left them behind was one which never entered consciousness. We find it hard to believe, however, that permanent traces of excitation such as these are also left in the system \( \text{Pcpt.-Cs} \). If they remained constantly conscious, they would very soon set limits to the system's aptitude for receiving fresh excitations.¹ If, on the other hand, they were unconscious, we should be faced with the problem of explaining the existence of unconscious processes in a system whose functioning was otherwise accompanied by the phenomenon of consciousness. We should, so to say, have altered nothing and gained nothing by our hypothesis relegating the process of becoming conscious to a special system. Though this consideration is not absolutely conclusive, it nevertheless leads us to suspect that becoming conscious and leaving behind a memory-trace are processes incompatible with each other within one and the same system. Thus we should be able to say that the excitatory process becomes conscious in the system \( \text{Cs} \) but leaves no permanent trace behind there; but that the excitation is transmitted to the systems lying next within and that it is in \( \text{them} \) that its traces are left. I followed these same lines in the schematic picture which I included in the speculative section of my *Interpretation of Dreams*. It must be borne in mind that little enough is known from other sources of the origin of consciousness; when, therefore, we lay down the proposition that *consciousness arises instead of a memory-trace*, the assertion deserves consideration, at all events on the ground of its being framed in fairly precise terms.

[1920g, 3729]

I cannot neglect this opportunity of expressing for once my astonishment that human beings can go through such great and important moments of their erotic life without noticing them much, sometimes even, indeed, without having the faintest suspicion of their existence, or else, having become aware of those moments, deceive themselves so thoroughly in their judgement of them. This happens not only under neurotic conditions, where we are familiar with the phenomenon, but seems also to be common enough in ordinary life. In the present case, for example, a girl develops a sentimental adoration for women, which her parents at first find merely vexatious and hardly take seriously; she herself knows quite well that she is very much occupied with these relationships, but still she experiences few of the sensations of intense love until a particular frustration is followed by a quite excessive reaction, which shows everyone concerned that they have to do with a consuming passion of elemental strength. Nor had the girl ever perceived anything of the state of affairs which was a necessary preliminary to the outbreak of this mental storm. In other cases, too, we come across girls or women in a state of severe depression, who on being asked for a possible cause of their condition tell us that they have, it is true, had a slight feeling for a certain person, but that it was nothing deep and that they soon got over it when they had to give it up. And yet it was this renunciation, apparently so easily borne, that became the cause of serious mental disturbance. Again, we come across men who have passed through casual love-affairs and realize only from the subsequent effects that they had been passionately in love with the person whom they had apparently regarded lightly. One is also amazed at the unexpected results that may follow an artificial abortion, the killing of an unborn child, which had been decided upon without remorse and without hesitation. It must be admitted that poets are right in liking to portray people who are in love without knowing it, or uncertain whether they do love, or who think that they hate when in reality they love. It would seem that the information received by our consciousness about our erotic life is especially liable to be incomplete, full of gaps, or falsified. Needless to say, in this discussion I have not omitted to allow for the part played by subsequent forgetting.

[1920a, 3855]
The division of the psychical into what is conscious and what is unconscious is the fundamental premiss of psycho-analysis; and it alone makes it possible for psycho-analysis to understand the pathological processes in mental life, which are as common as they are important, and to find a place for them in the framework of science. To put it once more, in a different way: psycho-analysis cannot situate the essence of the psychical in consciousness, but is obliged to regard consciousness as a quality of the psychical, which may be present in addition to other qualities or may be absent.

[1923b, 3947]

If I could suppose that everyone interested in psychology would read this book, I should also be prepared to find that at this point some of my readers would already stop short and would go no further; for here we have the first shibboleth of psycho-analysis. To most people who have been educated in philosophy the idea of anything psychical which is not also conscious is so inconceivable that it seems to them absurd and refutable simply by logic. I believe this is only because they have never studied the relevant phenomena of hypnosis and dreams, which - quite apart from pathological manifestations - necessitate this view. Their psychology of consciousness is incapable of solving the problems of dreams and hypnosis.

[1923b, 3947]

'Being conscious' is in the first place a purely descriptive term, resting on perception of the most immediate and certain character. Experience goes on to show that a psychical element (for instance, an idea) is not as a rule conscious for a protracted length of time. On the contrary, a state of consciousness is characteristically very transitory; an idea that is conscious now is no longer so a moment later, although it can become so again under certain conditions that are easily brought about. In the interval the idea was - we do not know what. We can say that it was latent, and by this we mean that it was capable of becoming conscious at any time. Or, if we say that it was unconscious, we shall also be giving a correct description of it. Here 'unconscious' coincides with 'latent and capable of becoming conscious'. The philosophers would no doubt object: 'No, the term "unconscious" is not applicable here; so long as the idea was in a state of latency it was not anything psychical at all.' To contradict them at this point would lead to nothing more profitable than a verbal dispute.

[1923b, 3948]

But we have arrived at the term or concept of the unconscious along another path, by considering certain experiences in which mental dynamics play a part. We have found - that is, we have been obliged to assume - that very powerful mental processes or ideas exist (and here a quantitative or economic factor comes into question for the first time) which can produce all the effects in mental life that ordinary ideas do (including effects that can in their turn become conscious as ideas), though they themselves do not become conscious. It is unnecessary to repeat in detail here what has been explained so often before. It is enough to say that at this point psycho-analytic theory steps in and asserts that the reason why such ideas cannot become conscious is that a certain force opposes them, that otherwise they could become conscious, and that it would then be apparent how little they differ from other elements which are admittedly psychical. The fact that in the technique of psycho-analysis a means has been found by which the opposing force can be removed and the ideas in question made conscious renders this theory irrefutable. The state in which the ideas existed before being made conscious is called by us repression, and we assert that the force which instituted the repression and maintains it is perceived as resistance during the work of analysis.

[1923b, 3948]
For our conception of the unconscious, however, the consequences of our discovery are even more important. Dynamic considerations caused us to make our first correction; our insight into the structure of the mind leads to the second. We recognize that the Ucs. does not coincide with the repressed; it is still true that all that is repressed is Ucs., but not all that is Ucs. is repressed. A part of the ego, too - and Heaven knows how important a part - may be Ucs., undoubtedly is Ucs. And this Ucs. belonging to the ego is not latent like the Pcs.; for if it were, it could not be activated without becoming Cs., and the process of making it conscious would not encounter such great difficulties. When we find ourselves thus confronted by the necessity of postulating a third Ucs., which is not repressed, we must admit that the characteristic of being unconscious begins to lose significance for us. It becomes a quality which can have many meanings, a quality which we are unable to make, as we should have hoped to do, the basis of far-reaching and inevitable conclusions. Nevertheless we must beware of ignoring this characteristic, for the property of being conscious or not is in the last resort our one beacon-light in the darkness of depth-psychology.

[1923b, 3952]

Now all our knowledge is invariably bound up with consciousness. We can come to know even the Ucs., only by making it conscious. But stop, how is that possible? What does it mean when we say 'making something conscious'? How can that come about?

[1923b, 3953]

We already know the point from which we have to start in this connection. We have said that consciousness is the surface of the mental apparatus; that is, we have ascribed it as a function to a system which is spatially the first one reached from the external world - and spatially not only in the functional sense but, on this occasion, also in the sense of anatomical dissection.¹ Our investigations too must take this perceiving surface as a starting-point.

[1923b, 3953]

All perceptions which are received from without (sense-perceptions) and from within - what we call sensations and feelings - are Cs. from the start. But what about those internal processes which we may - roughly and inexactely - sum up under the name of thought-processes? They represent displacements of mental energy which are effected somewhere in the interior of the apparatus as this energy proceeds on its way towards action. Do they advance to the surface, which causes consciousness to be generated? Or does consciousness make its way to them? This is clearly one of the difficulties that arise when one begins to take the spatial or 'topographical' idea of mental life seriously. Both these possibilities are equally unimaginable, there must be a third alternative.

[1923b, 3953]

These word-presentations are residues of memories; they were at one time perceptions, and like all mnemic residues they can become conscious again. Before we concern ourselves further with their nature, it dawns upon us like a new discovery that only something which has once been a Cs. perception can become conscious, and that anything arising from within (apart from feelings) that seeks to become conscious must try to transform itself into external perceptions: this becomes possible by means of memory-traces.

[1923b, 3954]
We must not be led, in the interests of simplification perhaps, to forget the importance of optical mnemonic residues, when they are of things, or to deny that it is possible for thought-processes to become conscious through a reversion to visual residues, and that in many people this seems to be the favoured method. The study of dreams and of preconscious phantasies as shown in Varendonck's observations can give us an idea of the special character of this visual thinking. We learn that what becomes conscious in it is as a rule only the concrete subject-matter of the thought, and that the relations between the various elements of this subject-matter, which is what specially characterizes thoughts, cannot be given visual expression. Thinking in pictures is, therefore, only a very incomplete form of becoming conscious. In some way, too, it stands nearer to unconscious processes than does thinking in words, and it is unquestionably older than the latter both ontogenetically and phylogenetically.

To return to our argument: if, therefore, this is the way in which something that is in itself unconscious becomes preconscious, the question how we make something that is repressed (pre)conscious would be answered as follows. It is done by supplying \textit{Pcs. intermediate links through the work of analysis. Consciousness remains where it is, therefore; but, on the other hand, the \textit{Ucs. does not rise into the \textit{Cs.}}
The relation of the ego to consciousness has been entered into repeatedly; yet there are some important facts in this connection which remain to be described here. Accustomed as we are to taking our social or ethical scale of values along with us wherever we go, we feel no surprise at hearing that the scene of the activities of the lower passions is in the unconscious; we expect, moreover, that the higher any mental function ranks in our scale of values the more easily it will find access to consciousness assured to it. Here, however, psycho-analytic experience disappoints us. On the one hand, we have evidence that even subtle and difficult intellectual operations which ordinarily require strenuous reflection can equally be carried out preconsciously and without coming into consciousness. Instances of this are quite incontestable; they may occur, for example, during the state of sleep, as is shown when someone finds, immediately after waking, that he knows the solution to a difficult mathematical or other problem with which he had been wrestling in vain the day before.

[1923b, 3960]

After hypnosis was replaced by the technique of free association, Breuer's cathartic procedure turned into psycho-analysis, which for more than a decade was developed by the author (Freud) alone. During that time psycho-analysis gradually acquired a theory which appeared to give a satisfactory account of the origin, meaning and purpose of neurotic symptoms and provided a rational basis for medical attempts at curing the complaint. I will once again enumerate the factors that go to make up this theory. They are: emphasis on instinctual life (affectivity), on mental dynamics, on the fact that even the apparently most obscure and arbitrary mental phenomena invariably have a meaning and a causation, the theory of psychical conflict and of the pathogenic nature of repression, the view that symptoms are substitutive satisfactions, the recognition of the aetiological importance of sexual life, and in particular of the beginnings of infantile sexuality. From a philosophical standpoint this theory was bound to adopt the view that the mental does not coincide with the conscious, that mental processes are in themselves unconscious and are only made conscious by the functioning of special organs (agencies or systems). By way of completing this list, I will add that among the affective attitudes of childhood the complicated emotional relation of children to their parents - what is known as the Oedipus complex - came into prominence. It became ever clearer that this was the nucleus of every case of neurosis, and in the patient's behaviour towards his analyst certain phenomena of his emotional transference emerged which came to be of great importance for theory and technique alike.

[1924f, 4107]

It is easy to understand why doctors, with an attitude of this kind towards the mind, should have had no liking for psycho-analysis and should have demurred to its demand for learning many things afresh and for seeing many things in a different light. But as a compensation it might be supposed that the new theory would be all the more likely to meet with applause from philosophers. For philosophers were accustomed to putting abstract concepts (or, as unkind tongues would say, hazy words) in the forefront of their explanations of the universe, and it would be impossible that they should object to the extension of the sphere of psychology for which psycho-analysis had paved the way. But here another obstacle arose. The philosophers' idea of what is mental was not that of psycho-analysis. The overwhelming majority of philosophers regard as mental only the phenomena of consciousness. For them the world of consciousness coincides with the sphere of what is mental. Everything else that may take place in the 'mind' - an entity so hard to grasp - is relegated by them to the organic determinants of mental processes or to processes parallel to mental ones. Or, more strictly speaking, the mind has no contents other than the phenomena of consciousness, and consequently psychology, the science of the mind, has no other subject-matter. And on this point the layman's view is the same.

[1925e, 4124]
What, then, can a philosopher say to a theory which, like psycho-analysis, asserts that on
the contrary what is mental is in itself unconscious and that being conscious is only a quality, which
may or may not accrue to a particular mental act and the withholding of which may perhaps
alter that act in no other respect? He will naturally say that anything both unconscious and
mental would be an impossibility, a contradictio in adjecto, and he will fail to observe that in
making this judgement he is merely repeating his own definition of what is mental, a definition
which may perhaps be too narrow. It is easy for philosophers to feel this certainty, since they
have no acquaintance with the material whose investigation has compelled analysts to believe
in unconscious mental acts. Philosophers have never taken account of hypnosis, they have not
concerned themselves with the interpreting of dreams - on the contrary, like doctors, they
regard dreams as the meaningless products of reduced mental activity during sleep - they are
scarcely aware that there are such things as obsessions and delusions and they would find
themselves in a most embarrassing situation if they were asked to explain them on the basis of
their own psychological premisses. Analysts, too, refuse to say what the unconscious is, but
they can indicate the domain of phenomena whose observation has obliged them to assume its
existence. Philosophers, who know no kind of observation other than self-observation, cannot
follow them into that domain.

All the forms of auxiliary apparatus which we have invented for the improvement or
intensification of our sensory functions are built on the same model as the sense organs
themselves or portions of them: for instance, spectacles, photographic cameras, ear-trumpets.
Measured by this standard, devices to aid our memory seem particularly imperfect, since our
mental apparatus accomplishes precisely what they cannot: it has an unlimited receptive
capacity for new perceptions and nevertheless lays down permanent - even though not
unalterable - memory-traces of them. As long ago as in 1900 I gave expression in *The
Interpretation of Dreams* to a suspicion that this unusual capacity was to be divided between
two different systems (or organs of the mental apparatus). According to this view, we possess a
system *Pcpt.-Cs.*, which receives perceptions but retains no permanent trace of them, so that it
can react like a clean sheet to every new perception; while the permanent traces of the
excitations which have been received are preserved in 'mnemic systems' lying behind the
perceptual system. Later, in *Beyond the Pleasure Principle* (1920a), I added a remark to the
effect that the inexplicable phenomenon of consciousness arises in the perceptual system
instead of the permanent traces.

If, while the Mystic Pad has writing on it, we cautiously raise the celluloid from the waxed
paper, we can see the writing just as clearly on the surface of the latter, and the question may
arise why there should be any necessity for the celluloid portion of the cover. Experiment will
then show that the thin paper would be very easily crumpled or torn if one were to write directly
upon it with the stilus. The layer of celluloid thus acts as a protective sheath for the waxed
paper, to keep off injurious effects from without. The celluloid is a 'protective shield against
stimuli'; the layer which actually receives the stimuli is the paper. I may at this point recall that in
*Beyond the Pleasure Principle* I showed that the perceptual apparatus of our mind consists of
two layers, of an external protective shield against stimuli whose task it is to diminish the
strength of excitations coming in, and of a surface behind it which receives the stimuli, namely
the system *Pcpt.-Cs.*
We need not be disturbed by the fact that in the Mystic Pad no use is made of the permanent traces of the notes that have been received; it is enough that they are present. There must come a point at which the analogy between an auxiliary apparatus of this kind and the organ which is its prototype will cease to apply. It is true, too, that once the writing has been erased, the Mystic Pad cannot ‘reproduce’ it from within; it would be a mystic pad indeed if, like our memory, it could accomplish that. None the less, I do not think it is too far-fetched to compare the celluloid and waxed paper cover with the system \textit{Pcpt.-Cs}. and its protective shield, the wax slab with the unconscious behind them, and the appearance and disappearance of the writing with the flickering-up and passing-away of consciousness in the process of perception.

[1925a, 4136]

But I must admit that I am inclined to press the comparison still further. On the Mystic Pad the writing vanishes every time the close contact is broken between the paper which receives the stimulus and the wax slab which preserves the impression. This agrees with a notion which I have long had about the method by which the perceptual apparatus of our mind functions, but which I have hitherto kept to myself. My theory was that cathetic innervations are sent out and withdrawn in rapid periodic impulses from within into the completely pervious system \textit{Pcpt.-Cs}. So long as that system is cathected in this manner, it receives perceptions (which are accompanied by consciousness) and passes the excitation on to the unconscious mnemic systems: but as soon as the cathexis is withdrawn, consciousness is extinguished and the functioning of the system comes to a standstill. It is as though the unconscious stretches out feelers, through the medium of the system \textit{Pcpt.-Cs}. towards the external world and hastily withdraws them as soon as they have sampled the excitations coming from it. Thus the interruptions, which in the case of the Mystic Pad have an external origin, were attributed by my hypothesis to the discontinuity in the current of innervation; and the actual breaking of contact which occurs in the Mystic Pad was replaced in my theory by the periodic non-excitability of the perceptual system. I further had a suspicion that this discontinuous method of functioning of the system \textit{Pcpt.-Cs}. lies at the bottom of the origin of the concept of time.

[1925a, 4137]

If we imagine one hand writing upon the surface of the Mystic Writing-Pad while another periodically raises its covering-sheet from the wax slab, we shall have a concrete representation of the way in which I tried to picture the functioning of the perceptual apparatus of our mind.

[1925a, 4137]

Judging is the intellectual action which decides the choice of motor action, which puts an end to the postponement due to thought and which leads over from thinking to acting. This postponement due to thought has also been discussed by me elsewhere. It is to be regarded as an experimental action, a motor palpating, with small expenditure of discharge. Let us consider where the ego has used a similar kind of palpating before, at what place it learnt the technique which it now applies in its processes of thought. It happened at the sensory end of the mental apparatus, in connection with sense perceptions. For, on our hypothesis, perception is not a purely passive process. The ego periodically sends out small amounts of cathexis into the perceptual system, by means of which it samples the external stimuli, and then after every such tentative advance it draws back again.

[1925h, 4143]
But the study of pathogenic repressions and of other phenomena which have still to be mentioned compelled psycho-analysis to take the concept of the 'unconscious' seriously. Psycho-analysis regarded everything mental as being in the first instance unconscious; the further quality of 'consciousness' might also be present, or again it might be absent. This of course provoked a denial from the philosophers, for whom 'conscious' and 'mental' were identical, and who protested that they could not conceive of such an absurdity as the 'unconscious mental'. There was no help for it, however, and this idiosyncrasy of the philosophers could only be disregarded with a shrug. Experience (gained from pathological material, of which the philosophers were ignorant) of the frequency and power of impulses of which one knew nothing directly, and whose existence had to be inferred like some fact in the external world, left no alternative open. It could be pointed out, incidentally, that this was only treating one's own mental life as one had always treated other people's. One did not hesitate to ascribe mental processes to other people, although one had no immediate consciousness of them and could only infer them from their words and actions. But what held good for other people must be applicable to oneself. Anyone who tried to push the argument further and to conclude from it that one's own hidden processes belonged actually to a second consciousness would be faced with the concept of a consciousness of which one knew nothing, of an 'unconscious consciousness' - and this would scarcely be preferable to the assumption of an 'unconscious mental'. If on the other hand one declared, like some other philosophers, that one was prepared to take pathological phenomena into account, but that the processes underlying them ought not to be described as mental but as 'psychoid', the difference of opinion would degenerate into an unfruitful dispute about words, though even so expediency would decide in favour of keeping the expression 'unconscious mental'. The further question as to the ultimate nature of this unconscious is no more sensible or profitable than the older one as to the nature of the conscious.

Then I will pursue the subject further; in any case it is not easy for me to get away from it. I will tell you, then, that the most remarkable thing about the sexual life of children seems to me that it passes through the whole of its very far-reaching development in the first five years of life. From then onwards until puberty there stretches what is known as the period of latency. During it sexuality normally advances no further; on the contrary, the sexual urges diminish in strength and many things are given up and forgotten which the child did and knew. During that period of life, after the early efflorescence of sexuality has withered, such attitudes of the ego as shame, disgust and morality arise, which are destined to stand up against the later tempest of puberty and to lay down the path of the freshly awakening sexual desires. This 'diphasic onset', as it is named, of sexual life has a great deal to do with the genesis of neurotic illnesses. It seems to occur only in human beings, and it is perhaps one of the determinants of the human privilege of becoming neurotic. The prehistory of sexual life was just as much overlooked before psycho-analysis as, in another department, the background to conscious mental life. You will rightly suspect that the two are intimately connected.

Topographically, psycho-analysis regards the mental apparatus as a compound instrument, and endeavours to determine at what points in it the various mental processes take place. According to the most recent psycho-analytic views, the mental apparatus is composed of an 'id', which is the repository of the instinctual impulses, of an 'ego', which is the most superficial portion of the id and one which has been modified by the influence of the external world, and of a 'super-ego', which develops out of the id, dominates the ego and represents the inhibitions of instinct that are characteristic of man. The quality of consciousness, too, has a topographical reference; for processes in the id are entirely unconscious, while consciousness is the function of the ego's outermost layer, which is concerned with the perception of the external world.
The reasons for this hostility were to be found, from the medical point of view, in the fact that psycho-analysis lays stress upon psychical factors, and from the philosophical point of view, in its assuming as an underlying postulate the concept of unconscious mental activity; but the strongest reason was undoubtedly the general disinclination of mankind to concede to the factor of sexuality the importance that is assigned to it by psycho-analysis. In spite of this widespread opposition, however, the movement in favour of psycho-analysis was not to be checked. Its adherents formed themselves into an International Association, which passed successfully through the ordeal of the World War, and at the present time (1925) comprises local groups in Vienna, Berlin, Budapest, London, Switzerland, Holland, Moscow and Calcutta, as well as two in the United States. There are three periodicals representing the views of these societies: the *Internationale Zeitschrift für Psychoanalyse*, *Imago* (which is concerned with the application of psycho-analysis to non-medical fields of knowledge), and the *International Journal of Psycho-Analysis*.

I return now to our topic. In face of the doubt whether the ego and super-ego are themselves unconscious or merely produce unconscious effects, we have, for good reasons, decided in favour of the former possibility. And it is indeed the case that large portions of the ego and super-ego can remain unconscious and are normally unconscious. That is to say, the individual knows nothing of their contents and it requires an expenditure of effort to make them conscious. It is a fact that ego and conscious, repressed and unconscious do not coincide. We feel a need to make a fundamental revision of our attitude to the problem of conscious-unconscious. At first we are inclined greatly to reduce the value of the criterion of being conscious since it has shown itself so untrustworthy. But we should be doing it an injustice. As may be said of our life, it is not worth much, but it is all we have. Without the illumination thrown by the quality of consciousness, we should be lost in the obscurity of depth-psychology; but we must attempt to find our bearings afresh.
There is no need to discuss what is to be called conscious: it is removed from all doubt. The oldest and best meaning of the word 'unconscious' is the descriptive one; we call a psychical process unconscious whose existence we are obliged to assume - for some such reason as that we infer it from its effects - , but of which we know nothing. In that case we have the same relation to it as we have to a psychical process in another person, except that it is in fact one of our own. If we want to be still more correct, we shall modify our assertion by saying that we call a process unconscious if we are obliged to assume that it is being activated at the moment, though at the moment we know nothing about it. This qualification makes us reflect that the majority of conscious processes are conscious only for a short time; very soon they become latent, but can easily become conscious again. We might also say that they had become unconscious, if it were at all certain that in the condition of latency they are still something psychical. So far we should have learnt nothing new; nor should we have acquired the right to introduce the concept of an unconscious into psychology. But then comes the new observation that we were already able to make in parapraxes. In order to explain a slip of the tongue, for instance, we find ourselves obliged to assume that the intention to make a particular remark was present in the subject. We infer it with certainty from the interference with his remark which has occurred; but the intention did not put itself through and was thus unconscious. If, when we subsequently put it before the speaker, he recognizes it as one familiar to him, then it was only temporarily unconscious to him; but if he repudiates it as something foreign to him, then it was permanently unconscious. From this experience we retrospectively obtain the right also to pronounce as something unconscious what had been described as latent. A consideration of these dynamic relations permits us now to distinguish two kinds of unconscious - one which is easily, under frequently occurring circumstances, transformed into something conscious, and another with which this transformation is difficult and takes place only subject to a considerable expenditure of effort or possibly never at all. In order to escape the ambiguity as to whether we mean the one or the other unconscious, whether we are using the word in the descriptive or in the dynamic sense, we make use of a permissible and simple way out. We call the unconscious which is only latent, and thus easily becomes conscious, the 'preconscious' and retain the term 'unconscious' for the other. We now have three terms, 'conscious', 'preconscious' and 'unconscious', with which we can get along in our description of mental phenomena. Once again: the preconscious is also unconscious in the purely descriptive sense, but we do not give it that name, except in talking loosely or when we have to make a defence of the existence in mental life of unconscious processes in general.

[1933a, 4679]
You will admit, I hope, that so far that is not too bad and allows of convenient handling. Yes, but unluckily the work of psycho-analysis has found itself compelled to use the word 'unconscious' in yet another, third, sense, and this may, to be sure, have led to confusion. Under the new and powerful impression of there being an extensive and important field of mental life which is normally withdrawn from the ego's knowledge so that the processes occurring in it have to be regarded as unconscious in the truly dynamic sense, we have come to understand the term 'unconscious' in a topographical or systematic sense as well; we have come to speak of a 'system' of the preconscious and a 'system' of the unconscious, of a conflict between the ego and the system Ucs, and have used the word more and more to denote a mental province rather than a quality of what is mental. The discovery, actually an inconvenient one, that portions of the ego and super-ego as well are unconscious in the dynamic sense, operates at this point as a relief - it makes possible the removal of a complication. We perceive that we have no right to name the mental region that is foreign to the ego 'the system Ucs', since the characteristic of being unconscious is not restricted to it. Very well; we will no longer use the term 'unconscious' in the systematic sense and we will give what we have hitherto so described a better name and one no longer open to misunderstanding. Following a verbal usage of Nietzsche's and taking up a suggestion by Georg Groddeck, we will in future call it the 'id'. This impersonal pronoun seems particularly well suited for expressing the main characteristic of this province of the mind - the fact of its being alien to the ego. The super-ego, the ego and the id - these, then, are the three realms, regions, provinces, into which we divide an individual's mental apparatus, and with the mutual relations of which we shall be concerned in what follows.
[1933a, 4680]
Dream-distortion was the profoundest and most difficult problem of dream life. And light was thrown on it by the following consideration, which placed dreams in a class along with other psychopathological formations and revealed them, as it were, as the normal psychoses of human beings. For our mind, that precious instrument by whose means we maintain ourselves in life, is no peacefully self-contained unity. It is rather to be compared with a modern State in which a mob, eager for enjoyment and destruction, has to be held down forcibly by a prudent superior class. The whole flux of our mental life and everything that finds expression in our thoughts are derivations and representatives of the multifarious instincts that are innate in our physical constitution. But these instincts are not all equally susceptible to direction and education, or equally ready to fall in with the demands of the external world and of human society. A number of them have retained their primitive, ungovernable nature; if we let them have their way, they would infallibly bring us to ruin. Consequently, learning by experience, we have developed organizations in our mind which, in the form of inhibitions, set themselves up against the direct manifestations of the instincts. Every impulse in the nature of a wish that arises from the sources of instinctual energy must submit itself to examination by the highest agencies of our mind, and, if it is not approved, is rejected and restrained from exercising any influence upon our movements - that is, from coming into execution. Often enough, indeed, such wishes are even forbidden to enter consciousness, which is habitually unaware even of the existence of these dangerous instinctual sources. We describe such impulses as being repressed from the point of view of consciousness, and as surviving only in the unconscious. If what is repressed contrives somehow to force its way into consciousness or into movement or into both, we are no longer normal: at that point the whole range of neurotic and psychotic symptoms arise. The maintenance of the necessary inhibitions and repressions imposes upon our mind a great expenditure of energy, from which it is glad to be relieved. A good opportunity for this seems to be offered at night by the state of sleep, since sleep involves a cessation of our motor functions. The situation seems safe, and the severity of our internal police-force may therefore be relaxed. It is not entirely withdrawn, since one cannot be certain: it may be that the unconscious never sleeps at all. And now the reduction of pressure upon the repressed unconscious produces its effect. Wishes arise from it which during sleep might find the entrance to consciousness open. If we were to know them we should be appalled, alike by their subject-matter, their unrestraint and indeed the mere possibility of their existence. This, however, occurs only seldom, and when it does we awake as speedily as possible, in a state of fear. But as a rule our consciousness does not experience the dream as it really was. It is true that the inhibitory forces (the dream censorship, as we may call them) are not completely awake, but neither are they wholly asleep. They have had an influence on the dream while it was struggling to find an expression in words and pictures, they have got rid of what was most objectionable, they have altered other parts of it till they are unrecognizable, they have severed real connections while introducing false ones, until the honest but brutal wishful phantasy which lay behind the dream has turned into the manifest dream as we remember it - more or less confused and almost always strange and incomprehensible. Thus the dream (or the distortion which characterizes it) is the expression of a compromise, the evidence of a conflict between the mutually incompatible impulses and strivings of our mental life. And do not let us forget that the same process, the same interplay of forces, which explains the dreams of a normal sleeper, gives us the key to understanding all the phenomena of neurosis and psychosis.

[1932c, 4809]
I have described the structure of the psychical apparatus and the energies or forces which are active in it, and I have traced in a prominent example the way in which those energies (in the main, the libido) organize themselves into a physiological function which serves the purpose of the preservation of the species. There was nothing in all this to demonstrate the quite peculiar characteristic of what is psychical, apart, of course, from the empirical fact that this apparatus and these energies are the basis of the functions which we describe as our mental life. I will now turn to something which is uniquely characteristic of what is psychical, and which, indeed, according to a very widely held opinion, coincides with it to the exclusion of all else.

[1940a [1938], 4967]

The starting-point for this investigation is provided by a fact without parallel, which defies all explanation or description - the fact of consciousness. Nevertheless, if anyone speaks of consciousness we know immediately and from our most personal experience what is meant by it.¹ Many people, both inside and outside science, are satisfied with the assumption that consciousness alone is psychical; in that case nothing remains for psychology but to discriminate among psychical phenomena between perceptions, feelings, thought-processes and volitions. It is generally agreed, however, that these conscious processes do not form unbroken sequences which are complete in themselves; there would thus be no alternative left to assuming that there are physical or somatic processes which are concomitant with the psychical ones and which we should necessarily have to recognize as more complete than the psychical sequences, since some of them would have conscious processes parallel to them but others would not. If so, it of course becomes plausible to lay the stress in psychology on these somatic processes, to see in them the true essence of what is psychical and to look for some other assessment of the conscious processes. The majority of philosophers, however, as well as many other people, dispute this and declare that the idea of something psychical being unconscious is self-contradictory.

[1940a [1938], 4967]

But that is precisely what psycho-analysis is obliged to assert, and this is its second fundamental hypothesis. It explains the supposedly somatic concomitant phenomena as being what is truly psychical, and thus in the first instance disregards the quality of consciousness. It is not alone in doing this. Some thinkers (such as Theodor Lipps, for instance) have asserted the same thing in the same words; and the general dissatisfaction with the usual view of what is psychical has resulted in an increasingly urgent demand for the inclusion in psychological thought of a concept of the unconscious, though this demand has taken such an indefinite and obscure form that it could have no influence on science.

[1940a [1938], 4968]
Now it would look as though this dispute between psycho-analysis and philosophy is concerned only with a trifling matter of definition - the question whether the name 'psychical' should be applied to one or another sequence of phenomena. In fact, however, this step has become of the highest significance. Whereas the psychology of consciousness never went beyond the broken sequences which were obviously dependent on something else, the other view, which held that the psychical is unconscious in itself, enabled psychology to take its place as a natural science like any other. The processes with which it is concerned are in themselves just as unknowable as those dealt with by other sciences, by chemistry or physics, for example; but it is possible to establish the laws which they obey and to follow their mutual relations and interdependences unbroken over long stretches - in short, to arrive at what is described as an 'understanding' of the field of natural phenomena in question. This cannot be effected without framing fresh hypotheses and creating fresh concepts; but these are not to be despised as evidence of embarrassment on our part but deserve on the contrary to be appreciated as an enrichment of science. They can lay claim to the same value as approximations that belongs to the corresponding intellectual scaffolding found in other natural sciences, and we look forward to their being modified, corrected and more precisely determined as further experience is accumulated and sifted. So too it will be entirely in accordance with our expectations if the basic concepts and principles of the new science (instinct, nervous energy, etc.) remain for a considerable time no less indeterminate than those of the older sciences (force, mass, attraction, etc.),

[1940a [1938], 4968]

In the course of this work the distinctions which we describe as psychical qualities force themselves on our notice. There is no need to characterize what we call 'conscious': it is the same as the consciousness of philosophers and of everyday opinion. Everything else psychical is in our view 'the unconscious'. We are soon led to make an important division in this unconscious. Some processes become conscious easily; they may then cease to be conscious, but can become conscious once more without any trouble: as people say, they can be reproduced or remembered. This reminds us that consciousness is in general a highly fugitive state. What is conscious is conscious only for a moment. If our perceptions do not confirm this, the contradiction is only an apparent one; it is explained by the fact that the stimuli which lead to perception may persist for considerable periods, so that meanwhile the perception of them may be repeated. The whole position is made clear in connection with the conscious perception of our thought-processes: these too may persist for some time, but they may just as well pass in a flash. Everything unconscious that behaves in this way, that can thus easily exchange the unconscious state for the conscious one, is therefore preferably described as 'capable of becoming conscious' or as preconscious. Experience has taught us that there is hardly a psychical process, however complicated it may be, which cannot on occasion remain preconscious, even though as a rule it will, as we say, push its way forward into consciousness. There are other psychical processes and psychical material which have no such easy access to becoming conscious but must be inferred, recognized and translated into conscious form in the manner described. For such material we reserve the name of the unconscious proper.

[1940a [1938], 4969]
The hypothesis we have adopted of a psychical apparatus extended in space, expediently put together, developed by the exigencies of life, which gives rise to the phenomena of consciousness only at one particular point and under certain conditions - this hypothesis has put us in a position to establish psychology on foundations similar to those of any other science, such, for instance, as physics. In our science as in the others the problem is the same: behind the attributes (qualities) of the object under examination which are presented directly to our perception, we have to discover something else which is more independent of the particular receptive capacity of our sense organs and which approximates more closely to what may be supposed to be the real state of affairs. We have no hope of being able to reach the latter itself, since it is evident that everything new that we have inferred must nevertheless be translated back into the language of our perceptions, from which it is simply impossible for us to free ourselves. But herein lies the very nature and limitation of our science. It is as though we were to say in physics: 'If we could see clearly enough we should find that what appears to be a solid body is made up of particles of such and such a shape and size and occupying such and such relative positions.' In the meantime we try to increase the efficiency of our sense organs to the furthest possible extent by artificial aids; but it may be expected that all such efforts will fail to affect the ultimate outcome. Reality will always remain 'unknowable'. The yield brought to light by scientific work from our primary sense perceptions will consist in an insight into connections and dependent relations which are present in the external world, which can somehow be reliably reproduced or reflected in the internal world of our thought and a knowledge of which enables us to 'understand' something in the external world, to foresee it and possibly to alter it. Our procedure in psycho-analysis is quite similar. We have discovered technical methods of filling up the gaps in the phenomena of our consciousness, and we make use of those methods just as a physicist makes use of experiment. In this manner we infer a number of processes which are in themselves 'unknowable' and interpolate them in those that are conscious to us. And if, for instance, we say: 'At this point an unconscious memory intervened', what that means is: 'At this point something occurred of which we are totally unable to form a conception, but which, if it had entered our consciousness, could only have been described in such and such a way.'

[1940a [1938], 5003]

Psychology, too, is a natural science. What else can it be? But its case is different. Not everyone is bold enough to make judgements about physical matters; but everyone - the philosopher and the man in the street alike - has his opinion on psychological questions and behaves as if he were at least an amateur psychologist. And now comes the remarkable thing. Everyone - or almost everyone - was agreed that what is psychical really has a common quality in which its essence is expressed: namely the quality of being conscious - unique, indescribable, but needing no description. All that is conscious, they said, is psychical, and conversely all that is psychical is conscious: that is self-evident and to contradict it is nonsense. It cannot be said that this decision threw much light upon the nature of the psychical, for consciousness is one of the fundamental facts of our life and our researches come up against it like a blank wall and can find no path beyond it. Moreover the equation of what is mental with what is conscious had the unwelcome result of divorcing psychical processes from the general context of events in the universe and of setting them in complete contrast to all others. But this would not do, since the fact could not long be overlooked that psychical phenomena are to a high degree dependent upon somatic influences and on their side have the most powerful effects upon somatic processes. If ever human thought found itself in an impasse it was here. To find a way out, the philosophers at least were obliged to assume that there were organic processes parallel to the conscious psychical ones, related to them in a manner that was hard to explain, which acted as intermediaries in the reciprocal relations between 'body and mind', and which served to re-insert the psychical into the texture of life. But this solution remained unsatisfactory.

[1940b [1938], 5068]
Psycho-analysis escaped such difficulties as these by energetically denying the equation between what is psychical and what is conscious. No; being conscious cannot be the essence of what is psychical. It is only a quality of what is psychical, and an inconstant quality at that - one that is far oftener absent than present. The psychical, whatever its nature may be, is in itself unconscious and probably similar in kind to all the other natural processes of which we have obtained knowledge.

[1940b [1938], 5068]

The question of the relation of the conscious to the psychical may now be regarded as settled: consciousness is only a quality or attribute of what is psychical, and moreover an inconstant one. But there is one further objection with which we have to deal. We are told that, in spite of the facts that have been mentioned, there is no necessity to abandon the identity between what is conscious and what is psychical: the so-called unconscious psychical processes are the organic processes which have long been recognized as running parallel to the mental ones. This, of course, would reduce our problem to an apparently indifferent matter of definition. Our reply is that it would be unjustifiable and inexpedient to make a breach in the unity of mental life for the sake of propping up a definition, since it is clear in any case that consciousness can only offer us an incomplete and broken chain of phenomena. And it can scarcely be a matter of chance that it was not until the change had been made in the definition of the psychical that it became possible to construct a comprehensive and coherent theory of mental life.

[1940b [1938], 5071]

Nor need it be supposed that this alternative view of the psychical is an innovation due to psycho-analysis. A German philosopher, Theodor Lipps, asserted with the greatest explicitness that the psychical is in itself unconscious and that the unconscious is the truly psychical. The concept of the unconscious has long been knocking at the gates of psychology and asking to be let in. Philosophy and literature have often toyed with it, but science could find no use for it. Psycho-analysis has seized upon the concept, has taken it seriously and has given it a fresh content. By its researches it has led to a knowledge of characteristics of the unconscious psychical which have hitherto been unsuspected, and it has discovered some of the laws which govern it. But none of this implies that the quality of being conscious has lost its importance for us. It remains the one light which illuminates our path and leads us through the darkness of mental life. In consequence of the special character of our discoveries, our scientific work in psychology will consist in translating unconscious processes into conscious ones, and thus filling in the gaps in conscious perception. . . .

[1940b [1938], 5071]
The fact that the phenomena of censorship and of dream-distortion correspond down to their smallest details justifies us in presuming that they are similarly determined. We may therefore suppose that dreams are given their shape in individual human beings by the operation of two psychical forces (or we may describe them as currents or systems); and that one of these forces constructs the wish which is expressed by the dream, while the other exercises a censorship upon this dream-wish and, by the use of that censorship, forcibly brings about a distortion in the expression of the wish. It remains to enquire as to the nature of the power enjoyed by this second agency which enables it to exercise its censorship. When we bear in mind that the latent dream-thoughts are not conscious before an analysis has been carried out, whereas the manifest content of the dream is consciously remembered, it seems plausible to suppose that the privilege enjoyed by the second agency is that of permitting thoughts to enter consciousness. Nothing, it would seem, can reach consciousness from the first system without passing the second agency; and the second agency allows nothing to pass without exercising its rights and making such modifications as it thinks fit in the thought which is seeking admission to consciousness. Incidentally, this enables us to form a quite definite view of the ‘essential nature’ of consciousness: we see the process of a thing becoming conscious as a specific psychical act, distinct from and independent of the process of the formation of a presentation or idea; and we regard consciousness as a sense organ which perceives data that arise elsewhere. It can be demonstrated that these basic assumptions are absolutely indispensable to psychopathology. We must, however, postpone our further consideration of them to a later stage.

[1900a, 639]

For consciousness, which we look upon in the light of a sense organ for the apprehension of psychical qualities, is capable in waking life of receiving excitations from two directions. In the first place, it can receive excitations from the periphery of the whole apparatus, the perceptual system; and in addition to this, it can receive excitations of pleasure and unpleasure, which prove to be almost the only psychical quality attaching to transpositions of energy in the inside of the apparatus. All other processes in the $\psi$-systems, including the $Pcs.$, are lacking in any psychical quality and so cannot be objects of consciousness, except in so far as they bring pleasure or unpleasure to perception. We are thus driven to conclude that these releases of pleasure and unpleasure automatically regulate the course of cathetic processes. But, in order to make more delicately adjusted performances possible, it later became necessary to make the course of ideas less dependent upon the presence or absence of unpleasure. For this purpose the $Pcs.$ system needed to have qualities of its own which could attract consciousness; and it seems highly probable that it obtained them by linking the preconscious processes with the mnemonic system of indications of speech, a system which was not without quality. By means of the qualities of that system, consciousness, which had hitherto been a sense organ for perceptions alone. Now, therefore, there are, as it were, two sensory surfaces, one directed towards perception and the other towards the preconscious thought-processes.

[1900a, 1003]
I must assume that the state of sleep makes the sensory surface of consciousness which is directed towards the Pcs. far more insusceptible to excitation than the surface directed towards the Pcpt. systems. Moreover, this abandonment of interest in thought-processes during the night has a purpose: thinking is to come to a standstill, for the Pcs. requires sleep. Once, however, a dream has become a perception, it is in a position to excite consciousness, by means of the qualities it has now acquired. This sensory excitation proceeds to perform what is its essential function: it directs a part of the available cathectic energy in the Pcs. into attention to what is causing the excitation. It must therefore be admitted that every dream has an arousing effect, that it sets a part of the quiescent force of the Pcs. in action. The dream is then submitted by this force to the influence which we have described as secondary revision with an eye to consecutiveness and intelligibility. That is to say, the dream is treated by it just like any other perceptual content; it is met by the same anticipatory ideas, in so far as its subject-matter allows. So far as this third portion of the dream-process has any direction it is once again a progressive one.

[1900a, 1004]

A dream, as we have discovered, takes the place of a number of thoughts which are derived from our daily life and which form a completely logical sequence. We cannot doubt, then, that these thoughts originate from our normal mental life. All the attributes which we value highly in our trains of thought, and which characterize them as complex achievements of a high order, are to be found once more in dream-thoughts. There is no need to assume, however, that this activity of thought is performed during sleep - a possibility which would gravely confuse what has hitherto been our settled picture of the psychical state of sleep. On the contrary, these thoughts may very well have originated from the previous day, they may have proceeded unobserved by our consciousness from their start, and may already have been completed at the onset of sleep. The most that we can conclude from this is that it proves that the most complicated achievements of thought are possible without the assistance of consciousness - a fact which we could not fail to learn in any case from every psycho-analysis of a patient suffering from hysteria or from obsessional ideas. These dream-thoughts are certainly not in themselves inadmissible to consciousness; there may have been a number of reasons for their not having become conscious to us during the day. Becoming conscious is connected with the application of a particular psychical function, that of attention - a function which, as it seems, is only available in a specific quantity, and this may have been diverted from the train of thought in question on to some other purpose. There is another way, too, in which trains of thought of this kind may be withheld from consciousness. The course of our conscious reflections shows us that we follow a particular path in our application of attention. If, as we follow this path, we come upon an idea which will not bear criticism, we break off: we drop the cathexis of attention. Now it seems that the train of thought which has thus been initiated and dropped can continue to spin itself out without attention being turned to it again, unless at some point or other it reaches a specially high degree of intensity which forces attention to it. Thus, if a train of thought is initially rejected (consciously, perhaps) by a judgement that it is wrong or that it is useless for the immediate intellectual purposes in view, the result may be that this train of thought will proceed, unobserved by consciousness, until the onset of sleep.

[1900a, 1020]
In the most favourable cases the generation of unpleasure ceases along with the withdrawal of cathexis from the transference thoughts in the $Pcs$; and this outcome signifies that the intervention of the unpleasure principle has served a useful purpose. But it is another matter when the repressed unconscious wish receives an organic reinforcement, which it passes on to its transference thoughts; in that way it may place them in a position to make an attempt at forcing their way through with their excitation, even if they have lost their cathexis from the $Pcs$.

There then follows a defensive struggle - for the $Pcs$ in turn reinforces its opposition to the repressed thoughts (i.e. produces an 'anticathexis') - and thereafter the transference thoughts, which are the vehicles of the unconscious wish, force their way through in some form of compromise which is reached by the production of a symptom. But from the moment at which the repressed thoughts are strongly cathected by the unconscious wishful impulse and, on the other hand, abandoned by the preconscious cathexis, they become subject to the primary psychical process and their one aim is motor discharge or, if the path is open, hallucinatory revival of the desired perceptual identity. We have already found empirically that the irrational processes which we have described are only carried out with thoughts that are under repression. We can now see our way a little further into the whole position. The irrational processes which occur in the psychical apparatus are the primary ones. They appear wherever ideas are abandoned by the preconscious cathexis, are left to themselves and can become charged with the uninhibited energy from the unconscious which is striving to find an outlet. Some other observations lend support to the view that these processes which are described as irrational are not in fact falsifications of normal processes - intellectual errors - but are modes of activity of the psychical apparatus that have been freed from an inhibition. Thus we find that the transition from preconscious excitation to movement is governed by the same processes, and that the linking of preconscious ideas to words may easily exhibit the same displacements and confusions, which are then attributed to inattention. Evidence, finally, of the increase in activity which becomes necessary when these primary modes of functioning are inhibited is to be found in the fact that we produce a *comic* effect, that is, a surplus of energy which has to be discharged in laughter, *if we allow these modes of thinking to force their way through into consciousness*.

[1900a, 1032]

¹ *Footnote added 1925:* It became necessary to elaborate and modify thus view after it was recognized that the essential feature of a preconscious idea was the fact of its being connected with the residues of verbal presentations. Cf. 'The Unconscious' (1915e).

[1900a, 1036]

But what part is there left to be played in our scheme by consciousness, which was once so omnipotent and hid all else from view? *Only that of a sense-organ for the perception of psychical qualities.* In accordance with the ideas underlying our attempt at a schematic picture, we can only regard conscious perception as the function proper to a particular system; and for this the abbreviation Cs. seems appropriate. In its mechanical properties we regard this system as resembling the perceptual systems $Pcpt$. as being susceptible to excitation by qualities but incapable of retaining traces of alterations - that is to say, as having no memory. The psychical apparatus, which is turned towards the external world with its sense-organ of the $Pcpt$. systems, is itself the external world in relation to the sense-organ of the Cs., whose teleological justification resides in this circumstance. Here we once more meet the principle of the hierarchy of agencies, which seems to govern the structure of the apparatus. Excitatory material flows in to the Cs. sense-organ from two directions: from the $Pcpt$. system, whose excitation, determined by qualities, is probably submitted to a fresh revision before it becomes a conscious sensation, and from the interior of the apparatus itself, whose quantitative processes are felt qualitatively in the pleasure-unpleasure series when, subject to certain modifications, they make their way to consciousness.

[1900a, 1040]
Those philosophers who have become aware that rational and highly complex thought-structures are possible without consciousness playing any part in them have found difficulty in assigning any function to consciousness; it has seemed to them that it can be no more than a superfluous reflected picture of the completed psychical process. We, on the other hand, are rescued from this embarrassment by the analogy between our Cs. system and the perceptual systems. We know that perception by our sense-organs has the result of directing a cathexis of attention to the paths along which the in-coming sensory excitation is spreading: the qualitative excitation of the Pcpt. system acts as a regulator of the discharge of the mobile quantity in the psychical apparatus. We can attribute the same function to the overlying sense-organ of the Cs. system. By perceiving new qualities, it makes a new contribution to directing the mobile quantities of cathexis and distributing them in an expedient fashion. By the help of its perception of pleasure and unpleasure it influences the discharge of the cathexes within what is otherwise an unconscious apparatus operating by means of the displacement of quantities. It seems probable that in the first instance the unpleasure principle regulates the displacement of cathexes automatically. But it is quite possible that consciousness of these qualities may introduce in addition a second and more discriminating regulation, which is even able to oppose the former one, and which perfects the efficiency of the apparatus by enabling it, in contradiction to its original plan, to cathect and work over even what is associated with the release of unpleasure. We learn from the psychology of the neuroses that these processes of regulation carried out by the qualitative excitation of the sense organs play a great part in the functional activity of the apparatus. The automatic domination of the primary unpleasure principle and the consequent restriction imposed upon efficiency are interrupted by the processes of sensory regulation, which are themselves in turn automatic in action. We find that repression (which, though it served a useful purpose to begin with, leads ultimately to a damaging loss of inhibition and mental control) affects memories so much more easily than perceptions because the former can receive no extra cathexis from the excitation of the psychical sense-organs. It is true on the one hand that a thought which has to be warded off cannot become conscious, because it has undergone repression; but on the other hand it sometimes happens that a thought of this kind is only repressed because for other reasons it has been withdrawn from conscious perception. Here are some hints of which we take advantage in our therapeutic procedure in order to undo repressions which have already been effected.

[1900a, 1041]

The value of the hypercathexis which is set up in the mobile quantities by the regulating influence of the sense organ of the Cs. cannot be better illustrated in its teleological aspect than by the fact of its creation of a new series of qualities and consequently of a new process of regulation which constitutes the superiority of men over animals. Thought-processes are in themselves without quality, except for the pleasurable and unpleasurable excitations which accompany them, and which, in view of their possible disturbing effect upon thinking, must be kept within bounds. In order that thought-processes may acquire quality, they are associated in human beings with verbal memories, whose residues of quality are sufficient to draw the attention of consciousness to them and to endow the process of thinking with a new mobile cathexis from consciousness.

[1900a, 1042]
The whole multiplicity of the problems of consciousness can only be grasped by an analysis of the thought-processes in hysteria. These give one the impression that the transition from a preconscious to a conscious cathexis is marked by a censorship similar to that between the Ucs. and the Pcs. This censorship, too, only comes into force above a certain quantitative limit, so that thought-structures of low intensity escape it. Examples of every possible variety of how a thought can be withheld from consciousness or can force its way into consciousness under certain limitations are to be found included within the framework of psychoneurotic phenomena; and they all point to the intimate and reciprocal relations between censorship and consciousness. I will bring these psychological reflections to an end with a report of two such examples.

[1900a, 1042]

On the basis of suitable specimens of innocent jokes, in which there was no fear of our judgement being disturbed by their content or purpose, we were driven to conclude that the techniques of jokes are themselves sources of pleasure; and we shall now try to discover whether it may perhaps be possible to trace that pleasure back to economy in psychical expenditure. In one group of these jokes (play upon words) the technique consisted in focusing our psychical attitude upon the sound of the word instead of upon its meaning - in making the (acoustic) word presentation itself take the place of its significance as given by its relations to thing-presentations. It may really be suspected that in doing so we are bringing about a great relief in psychical work and that when we make serious use of words we are obliged to hold ourselves back with a certain effort from this comfortable procedure. We can observe how pathological states of thought-activity, in which the possibility of concentrating psychical expenditure on a particular point is probably restricted, do in fact give this sort of sound-presentation of the word greater prominence than its meaning, and that sufferers in such states proceed in their speech on the lines (as the formula runs) of the 'external' instead of the 'internal' associations of the word-presentation. We notice, too, that children, who, as we know, are in the habit of still treating words as things, tend to expect words that are the same or similar to have the same meaning behind them - which is a source of many mistakes that are laughed at by grown-up people. If, therefore, we derive unmistakable enjoyment in jokes from being transported by the use of the same or a similar word from one circle of ideas to another, remote one (in the 'Home-Roulard', for instance, from the kitchen to politics), this enjoyment is no doubt correctly to be attributed to economy in psychical expenditure. The pleasure in a joke arising from a 'short-circuit' like this seems to be the greater the more alien the two circles of ideas that are brought together by the same word - the further apart they are, and thus the greater the economy which the joke's technical method provides in the train of thought. We may notice, too, that here jokes are making use of a method of linking things up which is rejected and studiously avoided by serious thought.

[1905c, 1712]
The projection of unconscious hostility on to demons in the case of the taboo upon the dead is only a single instance of a number of processes to which the greatest influence must be attributed in the shaping of the primitive mind. In the case we have been dealing with, projection served the purpose of dealing with an emotional conflict; and it is employed in the same way in a large number of psychical situations that lead to neuroses. But projection was not created for the purpose of defence; it also occurs where there is no conflict. The projection outwards of internal perceptions is a primitive mechanism, to which, for instance, our sense perceptions are subject, and which therefore normally plays a very large part in determining the form taken by our external world. Under conditions whose nature has not yet been sufficiently established, internal perceptions of emotional and thought processes can be projected outwards in the same way as sense perceptions; they are thus employed for building up the external world, though they should by rights remain part of the internal world. This may have some genetic connection with the fact that the function of attention was originally directed not towards the internal world but towards the stimuli that stream in from the external world, and that that function's only information upon endopsychic processes was received from feelings of pleasure and unpleasure. It was not until a language of abstract thought had been developed, that is to say, not until the sensory residues of verbal presentations had been linked to the internal processes, that the latter themselves gradually became capable of being perceived. Before that, owing to the projection outwards of internal perceptions, primitive men arrived at a picture of the external world which we, with our intensified conscious perception, have now to translate back into psychology.

[1912-1913, 2708]

The reason for all these difficulties is to be found in the circumstance that the attribute of being conscious, which is the only characteristic of psychical processes that is directly presented to us, is in no way suited to serve as a criterion for the differentiation of systems. Apart from the fact that the conscious is not always conscious but also at times latent, observation has shown that much that shares the characteristics of the system Pcs. does not become conscious; and we learn in addition that the act of becoming conscious is dependent on the attention of the Pcs. being turned in certain directions. Hence consciousness stands in no simple relation either to the different systems or to repression. The truth is that it is not only the psychically repressed that remains alien to consciousness, but also some of the impulses which dominate our ego - something, therefore, that forms the strongest functional antithesis to the repressed. The more we seek to win our way to a metapsychological view of mental life, the more we must learn to emancipate ourselves from the importance of the symptom of 'being conscious'.

[1915e, 3014]

In psycho-analytic treatment the existence of the second censorship, located between the systems Pcs. and Cs., is proved beyond question. We require the patient to form numerous derivatives of the Ucs., we make him pledge himself to overcome the objections of the censorship to these preconscious formations becoming conscious, and by overthrowing this censorship, we open up the way to abrogating the repression accomplished by the earlier one. To this let us add that the existence of the censorship between the Pcs. and the Cs. teaches us that becoming conscious is no mere act of perception, but is probably also a hypercathexis, a further advance in the psychical organization.

[1915e, 3015]
If now we put this finding alongside the hypothesis that in schizophrenia object-cathexes are
given up, we shall be obliged to modify the hypothesis by adding that the cathexis of the word-
presentations of objects is retained. What we have permissibly called the conscious
presentation of the object can now be split up into the presentation of the word and the
presentation of the thing; the latter consists in the cathexis, if not of the direct memory-images
of the thing, at least of remoter memory-traces derived from these. We now seem to know all at
once what the difference is between a conscious and an unconscious presentation. The two are
not, as we supposed, different registrations of the same content in different psychical localities,
nor yet different functional states of cathexis in the same locality; but the conscious presentation
comprises the presentation of the thing plus the presentation of the word belonging to it, while
the unconscious presentation is the presentation of the thing alone. The system \( Ucs. \) contains
the thing-cathexes of the objects, the first and true object-cathexes; the system \( Pcs. \) comes
about by this thing-presentation being hypercathected through being linked with the word-
presentations corresponding to it. It is these hypercathexes, we may suppose, that bring about
a higher psychical organization and make it possible for the primary process to be succeeded
by the secondary process which is dominant in the \( Pcs. \). Now, too, we are in a position to state
precisely what it is that repression denies to the rejected presentation in the transference
neuroses: what it denies to the presentation is translation into words which shall remain
attached to the object. A presentation which is not put into words, or a psychical act which is not
hypercathected, remains thereafter in the \( Ucs. \) in a state of repression.
[1915e, 3022]

I should like to point out at what an early date we already possessed the insight which to-day
enables us to understand one of the most striking characteristics of schizophrenia. In the last
few pages of \( The Interpretation of Dreams \), which was published in 1900, the view was
developed that thought-processes, i.e. those acts of cathexis which are comparatively remote
from perception, are in themselves without quality and unconscious, and that they attain their
capacity to become conscious only through being linked with the residues of perceptions of
words. But word-presentations, for their part too, are derived from sense-perceptions, in the
same way as thing-presentations are; the question might therefore be raised why presentations
of objects cannot become conscious through the medium of their own perceptual residues.
Probably, however, thought proceeds in systems so far remote from the original perceptual
residues that they have no longer retained anything of the qualities of those residues, and, in
order to become conscious, need to be reinforced by new qualities. Moreover, by being linked
with words, cathexes can be provided with quality even when they represent only relations
between presentations of objects and are thus unable to derive any quality from perceptions.
Such relations, which become comprehensible only through words, form a major part of our
thought-processes. As we can see, being linked with word-presentations is not yet the same
thing as becoming conscious, but only makes it possible to become so; it is therefore
characteristic of the system \( Pcs. \) and of that system alone. With these discussions, however, we
have evidently departed from our subject proper and find ourselves plunged into problems
concerning the preconscious and the conscious, which for good reasons we are reserving for
separate treatment.
[1915e, 3023]

If we have made a true assessment of the nature of the \( Ucs. \) and have correctly defined the
difference between an unconscious and a preconscious presentation, then our researches will
inevitably bring us back from many other points to this same piece of insight.
[1915e, 3024]
The answer can be given if we now proceed to define more precisely the third of our psychical systems, the system Cs., which hitherto we have not sharply distinguished from the Pcs. In *The Interpretation of Dreams* we were already led to a decision to regard conscious perception as the function of a special system, to which we ascribed certain curious properties, and to which we shall now have good grounds for attributing other characteristics as well. We may regard this system, which is there called the Pcpt., as coinciding with the system Cs., on whose activity becoming conscious usually depends. Nevertheless, even so, the fact of a thing's becoming conscious still does not wholly coincide with its belonging to a system, for we have learnt that it is possible to be aware of sensory mnemonic images to which we cannot possibly allow a psychical location in the systems Cs. or Pcpt.

[1917d, 3036]

We must, however, put off discussing this difficulty till we can focus our interest upon the system Cs. itself. In the present connection we may be allowed to assume that hallucination consists in a cathexis of the system Cs. (Pcpt.), which, however, is not effected - as normally - from without, but from within, and that a necessary condition for the occurrence of hallucination is that regression shall be carried far enough to reach this system itself and in so doing be able to pass over reality-testing.¹

[1917d, 3036]

And now a few more considerations. In the case of the dream-work it is clearly a matter of transforming the latent thoughts which are expressed in words into sensory images, mostly of a visual sort. Now our thoughts originally arose from sensory images of that kind: their first material and their preliminary stages were sense impressions, or, more properly, mnemonic images of such impressions. Only later were words attached to them and the words in turn linked up into thoughts. The dream-work thus submits thoughts to a *regressive* treatment and undoes their development; and in the course of the regression everything has to be dropped that had been added as a new acquisition in the course of the development of the mnemonic images into thoughts.

[1916-1917, 3271]

The clinical picture of dementia praecox (which, incidentally, is very changeable) is not determined exclusively by the symptoms arising from the forcing away of the libido on objects and its accumulation in the ego as narcissistic libido. A large part, rather, is played by other phenomena, which are derived from efforts of the libido to attain objects once more and which thus correspond to an attempt at restitution or recovery. These latter symptoms are indeed the more striking and noisy; they exhibit an undeniable resemblance to those of hysteria or, less frequently, of obsessional neurosis, but nevertheless differ from them in every respect. It seems as though in dementia praecox the libido, in its efforts once more to reach objects (that is, the presentations of objects), does in fact snatch hold something of them, but, as it were, only their shadows - I mean the word-presentations belonging to them. I cannot say more about this now, but I believe that this behaviour of the libido as it strives to find its way back has enabled us to obtain an insight into what really constitutes the difference between a conscious and an unconscious idea.

[1916-1917, 3466]
I have already, in another place,¹ suggested that the real difference between a Ucs. and a Pcs. idea (thought) consists in this: that the former is carried out on some material which remains unknown, whereas the latter (the Pcs.) is in addition brought into connection with word-presentations. This is the first attempt to indicate distinguishing marks for the two systems, the Pcs. and the Ucs., other than their relation to consciousness. The question, 'How does a thing become conscious?' would thus be more advantageously stated: 'How does a thing become preconscious?' And the answer would be: 'Through becoming connected with the word-presentations corresponding to it.'

[1923b, 3954]

These word-presentations are residues of memories; they were at one time perceptions, and like all mnemic residues they can become conscious again. Before we concern ourselves further with their nature, it dawns upon us like a new discovery that only something which has once been a Cs. perception can become conscious, and that anything arising from within (apart from feelings) that seeks to become conscious must try to transform itself into external perceptions: this becomes possible by means of memory-traces.

[1923b, 3954]

We think of the mnemic residues as being contained in systems which are directly adjacent to the system Pcpt.-Cs., so that the cathexes of those residues can readily extend from within on to the elements of the latter system. We immediately think here of hallucinations, and of the fact that the most vivid memory is always distinguishable both from a hallucination and from an external perception; but it will also occur to us at once that when a memory is revived the cathexis remains in the mnemic system, whereas a hallucination, which is not distinguishable from a perception, can arise when the cathexis does not merely spread over from the memory-trace on to the Pcpt. element, but passes over to it entirely.

[1923b, 3954]

Verbal residues are derived primarily from auditory perceptions, so that the system Pcs. has, as it were, a special sensory source. The visual components of word-presentations are secondary, acquired through reading, and may to begin with be left on one side; so may the motor images of words, which, except with deaf-mutes, play the part of auxiliary indications. In essence a word is after all the mnemic residue of a word that has been heard.

[1923b, 3955]

We must not be led, in the interests of simplification perhaps, to forget the importance of optical mnemic residues, when they are of things, or to deny that it is possible for thought-processes to become conscious through a reversion to visual residues, and that in many people this seems to be the favoured method. The study of dreams and of preconscious phantasies as shown in Varendonck's observations can give us an idea of the special character of this visual thinking. We learn that what becomes conscious in it is as a rule only the concrete subject-matter of the thought, and that the relations between the various elements of this subject-matter, which is what specially characterizes thoughts, cannot be given visual expression. Thinking in pictures is, therefore, only a very incomplete form of becoming conscious. In some way, too, it stands nearer to unconscious processes than does thinking in words, and it is unquestionably older than the latter both ontogenetically and phylogenetically.

[1923b, 3955]

The part played by word-presentations now becomes perfectly clear. By their interposition internal thought-processes are made into perceptions. It is like a demonstration of the theorem that all knowledge has its origin in external perception. When a hypercathexis of the process of thinking takes place, thoughts are actually perceived - as if they came from without and are consequently held to be true.

[1923b, 3957]
After this clarifying of the relations between external and internal perception and the superficial system *Pcpt.-Cs.*, we can go on to work out our idea of the ego. It starts out, as we see, from the system *Pcpt.*, which is its nucleus, and begins by embracing the *Pcs.*, which is adjacent to the mnemonic residues. But, as we have learnt, the ego is also unconscious.

[1923b, 3957]

In all these situations the super-ego displays its independence of the conscious ego and its intimate relations with the unconscious id. Having regard, now, to the importance we have ascribed to preconscious verbal residues in the ego, the question arises whether it can be the case that the super-ego, in so far as it is *Ucs.*, consists in such word-presentations and, if it does not, what else it consists in. Our tentative answer will be that it is as impossible for the super-ego as for the ego to disclaim its origin from things heard; for it is a part of the ego and remains accessible to consciousness by way of these word-presentations (concepts, abstractions). But the *cathetic energy* does not reach these contents of the super-ego from auditory perception (instruction or reading) but from sources in the id.

[1923b, 3986]

It seems to me that the ego obtains this influence in virtue of its intimate connections with the perceptual system - connections which, as we know, constitute its essence and provide the basis of its differentiation from the id. The function of this system, which we have called *Pcpt.-Cs.*, is bound up with the phenomenon of consciousness. It receives excitations not only from outside but from within, and endeavours, by means of the sensations of pleasure and unpleasure which reach it from these quarters, to direct the course of mental events in accordance with the pleasure principle. We are very apt to think of the ego as powerless against the id; but when it is opposed to an instinctual process in the id it has only to give a 'signal of unpleasure' in order to attain its object with the aid of that almost omnipotent institution, the pleasure principle. To take this situation by itself for a moment, we can illustrate it by an example from another field. Let us imagine a country in which a certain small faction objects to a proposed measure the passage of which would have the support of the masses. This minority obtains command of the press and by its help manipulates the supreme arbiter, 'public opinion', and so succeeds in preventing the measure from being passed.

[1926d, 4253]

The becoming conscious of a mental process is a complicated affair. I cannot resist telling you - once again, dogmatically - our hypotheses about it. The ego, as you will remember, is the external, peripheral layer of the id. Now, we believe that on the outermost surface of this ego there is a special agency directed immediately to the external world, a system, an organ, through the excitation of which alone the phenomenon that we call consciousness comes about. This organ can be equally well excited from outside - thus receiving (with the help of the sense-organs) the stimuli from the external world - and from inside - thus becoming aware, first, of the sensations in the id, and then also of the processes in the ego.

[1926e, 4341]
All of this may appear to be far from simple. But when one has grown reconciled to this unusual spatial view of the mental apparatus, it can present no particular difficulties to the imagination. I will add the further comment that the psychical topography that I have developed here has nothing to do with the anatomy of the brain, and actually only touches it at one point. What is unsatisfactory in this picture - and I am aware of it as clearly as anyone - is due to our complete ignorance of the dynamic nature of the mental processes. We tell ourselves that what distinguishes a conscious idea from a preconscious one, and the latter from an unconscious one, can only be a modification, or perhaps a different distribution, of psychical energy. We talk of cathexes and hypercathexes, but beyond this we are without any knowledge on the subject or even any starting-point for a serviceable working hypothesis. Of the phenomenon of consciousness we can at least say that it was originally attached to perception. All sensations which originate from the perception of painful, tactile, auditory or visual stimuli are what are most readily conscious. Thought-processes, and whatever may be analogous to them in the id, are in themselves unconscious and obtain access to consciousness by becoming linked to the mnemic residues of visual and auditory perceptions along the path of the function of speech. In animals, which lack speech, these conditions must be of a simpler kind.

[1939a, 4919]

The process of something becoming conscious is above all linked with the perceptions which our sense organs receive from the external world. From the topographical point of view, therefore, it is a phenomenon which takes place in the outermost cortex of the ego. It is true that we also receive conscious information from the inside of the body - the feelings, which actually exercise a more peremptory influence on our mental life than external perceptions; moreover, in certain circumstances the sense organs themselves transmit feelings, sensations of pain, in addition to the perceptions specific to them. Since, however, these sensations (as we call them in contrast to conscious perceptions) also emanate from the terminal organs and since we regard all these as prolongations or offshoots of the cortical layer, we are still able to maintain the assertion made above. The only distinction would be that, as regards the terminal organs of sensation and feeling, the body itself would take the place of the external world.

[1940a [1938], 4971]

Conscious processes on the periphery of the ego and everything else in the ego unconscious - such would be the simplest state of affairs that we might picture. And such may in fact be the state that prevails in animals. But in men there is an added complication through which internal processes in the ego may also acquire the quality of consciousness. This is the work of the function of speech, which brings material in the ego into a firm connection with mnemic residues of visual, but more particularly of auditory, perceptions. Thenceforward the perceptual periphery of the cortical layer can be excited to a much greater extent from inside as well, internal events such as passages of ideas and thought-processes can become conscious, and a special device is called for in order to distinguish between the two possibilities - a device known as reality-testing. The equation 'perception = reality (external world)' no longer holds. Errors, which can now easily arise and do so regularly in dreams, are called hallucinations.

[1940a [1938], 4972]
The other agency of the mind, which we believe we know best and in which we recognize ourselves most easily - what is known as the ego - has been developed out of the id's cortical layer, which, through being adapted to the reception and exclusion of stimuli, is in direct contact with the external world (reality). Starting from conscious perception it has subjected to its influence ever larger regions and deeper strata of the id, and, in the persistence with which it maintains its dependence on the external world, it bears the indelible stamp of its origin (as it might be 'Made in Germany'). Its psychological function consists in raising the passage in the id to a higher dynamic level (perhaps by transforming freely mobile energy into bound energy, such as corresponds to the preconscious state); its constructive function consists in interpolating, between the demand made by an instinct and the action that satisfies it, the activity of thought which, after taking its bearings in the present and assessing earlier experiences, endeavours by means of experimental actions to calculate the consequences of the course of action proposed. In this way the ego comes to a decision on whether the attempt to obtain satisfaction is to be carried out or postponed or whether it may not be necessary for the demand by the instinct to be suppressed altogether as being dangerous. (Here we have the reality principle.) Just as the id is directed exclusively to obtaining pleasure, so the ego is governed by considerations of safety. The ego has set itself the task of self-preservation, which the id appears to neglect. It makes use of the sensations of anxiety as a signal to give a warning of dangers that threaten its integrity. Since memory traces can become conscious just as perceptions do, especially through their association with residues of speech, the possibility arises of a confusion which would lead to a mistaking of reality. The ego guards itself against this possibility by the institution of reality-testing, which is allowed to fall into abeyance in dreams on account of the conditions prevailing in the state of sleep. The ego, which seeks to maintain itself in an environment of overwhelming mechanical forces, is threatened by dangers which come in the first instance from external reality; but dangers do not threaten it from there alone. Its own id is a source of similar dangers, and that for two different reasons. In the first place, an excessive strength of instinct can damage the ego in a similar way to an excessive 'stimulus' from the external world. It is true that the former cannot destroy it; but it can destroy its characteristic dynamic organization and change the ego back into a portion of the id. In the second place, experience may have taught the ego that the satisfaction of some instinctual demand which is not in itself intolerable would involve dangers in the external world, so that an instinctual demand of that kind itself becomes a danger. Thus the ego is fighting on two fronts: it has to defend its existence against an external world which threatens it with annihilation as well as against an internal world that makes excessive demands. It adopts the same methods of defence against both, but its defence against the internal enemy is particularly inadequate. As a result of having originally been identical with this latter enemy and of having lived with it since on the most intimate terms, it has great difficulty in escaping from the internal dangers. They persist as threats, even if they can be temporarily held down.

[1940a [1938], 5005]
If, then, as we have learnt, psychogenic disturbances of vision depend on certain ideas connected with seeing being cut off from consciousness, we must, on the psycho-analytic view, assume that these ideas have come into opposition to other, more powerful ones, for which we use the collective concept of the 'ego'- a compound which is made up variously at different times - and have for that reason come under repression. But what can be the origin of this opposition, which makes for repression, between the ego and various groups of ideas? You will no doubt notice that it was not possible to frame such a question before the advent of psycho-analysis, for nothing was known earlier of psychical conflict and repression. Our researches, however, have put us in a position to give us the desired answer. Our attention has been drawn to the importance of the instincts in ideational life. We have discovered that every instinct tries to make itself effective by activating ideas that are in keeping with its aims. These instincts are not always compatible with one another; their interests often come into conflict. Opposition between ideas is only an expression of struggles between the various instincts. From the point of view of our attempted explanation, a quite specially important part is played by the undeniable opposition between the instincts which subserve sexuality, the attainment of sexual pleasure, and those other instincts, which have as their aim the self-preservation of the individual - the ego-instincts. As the poet has said, all the organic instincts that operate in our mind may be classified as 'hunger' or 'love'. We have traced the 'sexual instinct' from its first manifestations in children to its final form, which is described as 'normal'. We have found that it is put together from numerous 'component instincts' which are attached to excitations of regions of the body; and we have come to see that these separate instincts have to pass through a complicated development before they can be brought effectively to serve the aims of reproduction. The light thrown by psychology on the evolution of our civilization has shown us that it originates mainly at the cost of the sexual component instincts, and that these must be suppressed, restricted, transformed and directed to higher aims, in order that the mental constructions of civilization may be established. We have been able to recognize as a valuable outcome of these researches something that our colleagues have not yet been willing to believe, namely that the human ailments known as 'neuroses' are derived from the many different ways in which these processes of transformation in the sexual component instincts may miscarry. The 'ego' feels threatened by the claims of the sexual instincts and fends them off by repressions; these, however, do not always have the desired result, but lead to the formation of dangerous substitutes for the repressed and to burdensome reactions on the part of the ego. From these two classes of phenomena taken together there emerge what we call the symptoms of neuroses.

I am in fact of the opinion that the antithesis of conscious and unconscious is not applicable to instincts. An instinct can never become an object of consciousness - only the idea that represents the instinct can. Even in the unconscious, moreover, an instinct cannot be represented otherwise than by an idea. If the instinct did not attach itself to an idea or manifest itself as an affective state, we could know nothing about it. When we nevertheless speak of an unconscious instinctual impulse or of a repressed instinctual impulse, the looseness of phraseology is a harmless one. We can only mean an instinctual impulse the ideational representative of which is unconscious, for nothing else comes into consideration.
From the first of these standpoints, the dynamic one, psycho-analysis derives all mental processes (apart from the reception of external stimuli) from the interplay of forces, which assist or inhibit one another, combine with one another, enter into compromises with one another, etc. All of these forces are originally in the nature of instincts; thus they have an organic origin. They are characterized by possessing an immense (somatic) store of power ("the compulsion to repeat"); and they are represented mentally as images or ideas with an affective charge. In psycho-analysis, no less than in other sciences, the theory of the instincts is an obscure subject. An empirical analysis leads to the formulation of two groups of instincts: the so-called 'ego-instincts', which are directed towards self-preservation, and the 'object-instincts', which are concerned with relations to an external object. The social instincts are not regarded as elementary or irreducible. Theoretical speculation leads to the suspicion that there are two fundamental instincts which lie concealed behind the manifest ego-instincts and object-instincts: namely (a) Eros, the instinct which strives for ever closer union, and (b) the instinct of destruction, which leads towards the dissolution of what is living. In psycho-analysis the manifestation of the force of Eros is given the name 'libido'.
[1926f, 4403]
Dreams, then, think predominantly in visual images - but not exclusively. They make use of auditory images as well, and, to a lesser extent, of impressions belonging to the other senses. Many things, too, occur in dreams (just as they normally do in waking life) simply as thoughts or ideas - probably, that is to say, in the form of residues of verbal presentations. Nevertheless, what are truly characteristic of dreams are only those elements of their content which behave like images, which are more like perceptions, that is, than they are like mnemonic presentations. Leaving on one side all the arguments, so familiar to psychiatrists, on the nature of hallucinations, we shall be in agreement with every authority on the subject in asserting that dreams hallucinate - that they replace thoughts by hallucinations. In this respect there is no distinction between visual and acoustic presentations: it has been observed that if one falls asleep with the memory of a series of musical notes in one's mind, the memory becomes transformed into an hallucination of the same melody; while, if one then wakes up again - and the two states may alternate more than once during the process of dropping asleep - the hallucination gives way in turn to the mnemonic presentation, which is at once fainter and qualitatively different from it.

[1900a, 559]

If now we put this finding alongside the hypothesis that in schizophrenia object-cathexes are given up, we shall be obliged to modify the hypothesis by adding that the cathexis of the word-presentations of objects is retained. What we have permissibly called the conscious presentation of the object can now be split up into the presentation of the word and the presentation of the thing; the latter consists in the cathexis, if not of the direct memory-images of the thing, at least of remoter memory-traces derived from these. We now seem to know all at once what the difference is between a conscious and an unconscious presentation. The two are not, as we supposed, different registrations of the same content in different psychical localities, nor yet different functional states of cathexis in the same locality; but the conscious presentation comprises the presentation of the thing plus the presentation of the word belonging to it, while the unconscious presentation is the presentation of the thing alone. The system Ucs. contains the thing-cathexes of the objects, the first and true object-cathexes; the system Pcs. comes about by this thing-presentation being hypercathected through being linked with the word-presentations corresponding to it. It is these hypercathexes, we may suppose, that bring about a higher psychical organization and make it possible for the primary process to be succeeded by the secondary process which is dominant in the Pcs. Now, too, we are in a position to state precisely what it is that repression denies to the rejected presentation in the transference neuroses: what it denies to the presentation is translation into words which shall remain attached to the object. A presentation which is not put into words, or a psychical act which is not hypercathected, remains thereafter in the Ucs. in a state of repression.

[1915e, 3022]

The clinical picture of dementia praecox (which, incidentally, is very changeable) is not determined exclusively by the symptoms arising from the forcing away of the libido on objects and its accumulation in the ego as narcissistic libido. A large part, rather, is played by other phenomena, which are derived from efforts of the libido to attain objects once more and which thus correspond to an attempt at restitution or recovery. These latter symptoms are indeed the more striking and noisy; they exhibit an undeniable resemblance to those of hysteria or, less frequently, of obsessional neurosis, but nevertheless differ from them in every respect. It seems as though in dementia praecox the libido, in its efforts once more to reach objects (that is, the presentations of objects), does in fact snatch hold something of them, but, as it were, only their shadows - I mean the word-presentations belonging to them. I cannot say more about this now, but I believe that this behaviour of the libido as it strives to find its way back has enabled us to obtain an insight into what really constitutes the difference between a conscious and an unconscious idea.

[1916-1917, 3466]
I have already, in another place,¹ suggested that the real difference between a Ucs. and a Pcs. idea (thought) consists in this: that the former is carried out on some material which remains unknown, whereas the latter (the Pcs.) is in addition brought into connection with word-presentations. This is the first attempt to indicate distinguishing marks for the two systems, the Pcs. and the Ucs., other than their relation to consciousness. The question, 'How does a thing become conscious?' would thus be more advantageously stated: 'How does a thing become preconscious?' And the answer would be: 'Through becoming connected with the word-presentations corresponding to it.'

[1923b, 3954]

These word-presentations are residues of memories; they were at one time perceptions, and like all mnemonic residues they can become conscious again. Before we concern ourselves further with their nature, it dawns upon us like a new discovery that only something which has once been a Cs. perception can become conscious, and that anything arising from within (apart from feelings) that seeks to become conscious must try to transform itself into external perceptions: this becomes possible by means of memory-traces.

[1923b, 3954]

In all these situations the super-ego displays its independence of the conscious ego and its intimate relations with the unconscious id. Having regard, now, to the importance we have ascribed to preconscious verbal residues in the ego, the question arises whether it can be the case that the super-ego, in so far as it is Ucs., consists in such word-presentations and, if it does not, what else it consists in. Our tentative answer will be that it is as impossible for the super-ego as for the ego to disclaim its origin from things heard; for it is a part of the ego and remains accessible to consciousness by way of these word-presentations (concepts, abstractions). But the cathectic energy does not reach these contents of the super-ego from auditory perception (instruction or reading) but from sources in the id.

[1923b, 3986]
There is no need to discuss what is to be called conscious: it is removed from all doubt. The oldest and best meaning of the word 'unconscious' is the descriptive one; we call a psychical process unconscious whose existence we are obliged to assume - for some such reason as that we infer it from its effects -, but of which we know nothing. In that case we have the same relation to it as we have to a psychical process in another person, except that it is in fact one of our own. If we want to be still more correct, we shall modify our assertion by saying that we call a process unconscious if we are obliged to assume that it is being activated at the moment, though at the moment we know nothing about it. This qualification makes us reflect that the majority of conscious processes are conscious only for a short time; very soon they become latent, but can easily become conscious again. We might also say that they had become unconscious, if it were at all certain that in the condition of latency they are still something psychical. So far we should have learnt nothing new; nor should we have acquired the right to introduce the concept of an unconscious into psychology. But then comes the new observation that we were already able to make in parapraxes. In order to explain a slip of the tongue, for instance, we find ourselves obliged to assume that the intention to make a particular remark has occurred; but the intention did not put itself through and was thus unconscious. If, when we subsequently put it before the speaker, he recognizes it as one familiar to him, then it was only temporarily unconscious to him; but if he repudiates it as something foreign to him, then it was permanently unconscious. From this experience we retrospectively obtain the right also to pronounce as something unconscious what had been described as latent. A consideration of these dynamic relations permits us now to distinguish two kinds of unconscious - one which is easily, under frequently occurring circumstances, transformed into something conscious, and another with which this transformation is difficult and takes place only subject to a considerable expenditure of effort or possibly never at all. In order to escape the ambiguity as to whether we mean the one or the other unconscious, whether we are using the word in the descriptive or in the dynamic sense, we make use of a permissible and simple way out. We call the unconscious which is only latent, and thus easily becomes conscious, the 'preconscious' and retain the term 'unconscious' for the other. We now have three terms, 'conscious', 'preconscious' and 'unconscious', with which we can get along in our description of mental phenomena. Once again: the preconscious is also unconscious in the purely descriptive sense, but we do not give it that name, except in talking loosely or when we have to make a defence of the existence in mental life of unconscious processes in general.

[1933a, 4679]

The difference between whether a psychical process is conscious or unconscious has served us as a criterion and a means of finding our bearings. The repressed is unconscious. Now it would simplify things agreeably if this sentence admitted of reversal - if, that is, the difference between the qualities of conscious (Cs.) and unconscious (Ucs.) coincided with the distinction between 'belonging to the ego' and 'repressed'. The fact of there being isolated and unconscious things like this in our mental life would be sufficiently novel and important. But in reality the position is more complicated. It is true that everything repressed is unconscious, but it is not true that everything belonging to the ego is conscious. We notice that consciousness is a transient quality which attaches to a psychical process only in passing. For our purposes therefore we must replace 'conscious' by 'capable of being conscious' and we call this quality 'preconscious' (Pcs.). We then say, more correctly, that the ego is mainly preconscious (virtually conscious) but that portions of the ego are unconscious.

[1939a, 4918]
In the course of this work the distinctions which we describe as psychical qualities force
themselves on our notice. There is no need to characterize what we call 'conscious': it is the
same as the consciousness of philosophers and of everyday opinion. Everything else psychical
is in our view 'the unconscious'. We are soon led to make an important division in this
unconscious. Some processes become conscious easily; they may then cease to be conscious,
but can become conscious once more without any trouble: as people say, they can be
reproduced or remembered. This reminds us that consciousness is in general a highly fugitive
state. What is conscious is conscious only for a moment. If our perceptions do not confirm this,
the contradiction is only an apparent one; it is explained by the fact that the stimuli which lead to
perception may persist for considerable periods, so that meanwhile the perception of them may
be repeated. The whole position is made clear in connection with the conscious perception of
our thought-processes: these too may persist for some time, but they may just as well pass in a
flash. Everything unconscious that behaves in this way, that can thus easily exchange the
unconscious state for the conscious one, is therefore preferably described as 'capable of
becoming conscious' or as preconscious. Experience has taught us that there is hardly a
psychical process, however complicated it may be, which cannot on occasion remain
preconscious, even though as a rule it will, as we say, push its way forward into consciousness.
There are other psychical processes and psychical material which have no such easy access to
becoming conscious but must be inferred, recognized and translated into conscious form in the
manner described. For such material we reserve the name of the unconscious proper.
[1940a [1938], 4969]

The question of the relation of the conscious to the psychical may now be regarded as settled:
consciousness is only a quality or attribute of what is psychical, and moreover an inconstant
one. But there is one further objection with which we have to deal. We are told that, in spite of
the facts that have been mentioned, there is no necessity to abandon the identity between what
is conscious and what is psychical: the so-called unconscious psychical processes are the
organic processes which have long been recognized as running parallel to the mental ones.
This, of course, would reduce our problem to an apparently indifferent matter of definition. Our
reply is that it would be unjustifiable and inexpedient to make a breach in the unity of mental life
for the sake of propping up a definition, since it is clear in any case that consciousness can only
offer us an incomplete and broken chain of phenomena. And it can scarcely be a matter of
chance that it was not until the change had been made in the definition of the psychical that it
became possible to construct a comprehensive and coherent theory of mental life.
[1940b [1938], 5071]
But what part is there left to be played in our scheme by consciousness, which was once so omnipotent and hid all else from view? Only that of a sense-organ for the perception of psychical qualities. In accordance with the ideas underlying our attempt at a schematic picture, we can only regard conscious perception as the function proper to a particular system; and for this the abbreviation Cs. seems appropriate. In its mechanical properties we regard this system as resembling the perceptual systems \( Pcpt. \): as being susceptible to excitation by qualities but incapable of retaining traces of alterations - that is to say, as having no memory. The psychical apparatus, which is turned towards the external world with its sense-organ of the \( Pcpt. \) systems, is itself the external world in relation to the sense-organ of the Cs., whose teleological justification resides in this circumstance. Here we once more meet the principle of the hierarchy of agencies, which seems to govern the structure of the apparatus. Excitatory material flows in to the Cs. sense-organ from two directions: from the \( Pcpt. \) system, whose excitation, determined by qualities, is probably submitted to a fresh revision before it becomes a conscious sensation, and from the interior of the apparatus itself, whose quantitative processes are felt qualitatively in the pleasure-unpleasure series when, subject to certain modifications, they make their way to consciousness.

[1900a, 1040]

We have pointed out how the living vesicle is provided with a shield against stimuli from the external world; and we had previously shown that the cortical layer next to that shield must be differentiated as an organ for receiving stimuli from without. This sensitive cortex, however, which is later to become the system Cs., also receives excitations from within. The situation of the system between the outside and the inside and the difference between the conditions governing the reception of excitations in the two cases have a decisive effect on the functioning of the system and of the whole mental apparatus. Towards the outside it is shielded against stimuli, and the amounts of excitation impinging on it have only a reduced effect. Towards the inside there can be no such shield; the excitations in the deeper layers extend into the system directly and in undiminished amount, in so far as certain of their characteristics give rise to feelings in the pleasure-unpleasure series. The excitations coming from within are, however, in their intensity and in other, qualitative, respects - in their amplitude, perhaps - more commensurate with the system's method of working than the stimuli which stream in from the external world. This state of things produces two definite results. First, the feelings of pleasure and unpleasure (which are an index to what is happening in the interior of the apparatus) predominate over all external stimuli. And secondly, a particular way is adopted of dealing with any internal excitations which produce too great an increase of unpleasure: there is a tendency to treat them as though they were acting, not from the inside, but from the outside, so that it may be possible to bring the shield against stimuli into operation as a means of defence against them. This is the origin of projection, which is destined to play such a large part in the causation of pathological processes.

[1920g, 3732]
Here might be the starting-point for fresh investigations. Our consciousness communicates to us feelings from within not only of pleasure and unpleasure but also of a peculiar tension which in its turn can be either pleasurable or unpleasurable. Should the difference between these feelings enable us to distinguish between bound and unbound processes of energy? or is the feeling of tension to be related to the absolute magnitude, or perhaps to the level, of the cathexis, while the pleasure and unpleasure series indicates a change in magnitude of the cathexis within a given unit of time? Another striking fact is that the life instincts have so much more contact with our internal perception - emerging as breakers of the peace and constantly producing tensions whose release is felt as pleasure - while the death instincts seem to do their work unobtrusively. The pleasure principle seems actually to serve the death instincts. It is true that it keeps watch upon stimuli from without, which are regarded as dangers by both kinds of instincts; but it is more especially on guard against increases of stimulation from within, which would make the task of living more difficult. This in turn raises a host of other questions to which we can at present find no answer. We must be patient and await fresh methods and occasions of research. We must be ready, too, to abandon a path that we have followed for a time, if it seems to be leading to no good end. Only believers, who demand that science shall be a substitute for the catechism they have given up, will blame an investigator for developing or even transforming his views. We may take comfort, too, for the slow advances of our scientific knowledge in the words of the poet:

[1920g, 3762]

All perceptions which are received from without (sense-perceptions) and from within - what we call sensations and feelings - are Cs. from the start. But what about those internal processes which we may - roughly and inexacty - sum up under the name of thought-processes? They represent displacements of mental energy which are effected somewhere in the interior of the apparatus as this energy proceeds on its way towards action. Do they advance to the surface, which causes consciousness to be generated? Or does consciousness make its way to them? This is clearly one of the difficulties that arise when one begins to take the spatial or 'topographical' idea of mental life seriously. Both these possibilities are equally unimaginable, there must be a third alternative.

[1923b, 3953]

Internal perceptions yield sensations of processes arising in the most diverse and certainly also in the deepest strata of the mental apparatus. Very little is known about these sensations and feelings; those belonging to the pleasure-unpleasure series may still be regarded as the best examples of them. They are more primordial, more elementary, than perceptions arising externally and they can come about even when consciousness is clouded. I have elsewhere expressed my views about their greater economic significance and the metapsychological reasons for this. These sensations are multilocular, like external perceptions; they may come from different places simultaneously and may thus have different or even opposite qualities.

[1923b, 3956]

Sensations of a pleasurable nature have not anything inherently impelling about them, whereas unpleasurable ones have it in the highest degree. The latter impel towards change, towards discharge, and that is why we interpret unpleasure as implying a heightening and pleasure a lowering of energetic cathexis. Let us call what becomes conscious as pleasure and unpleasure a quantitative and qualitative 'something' in the course of mental events; the question then is whether this 'something' can become conscious in the place where it is, or whether it must first be transmitted to the system Pcpt.

[1923b, 3956]
Clinical experience decides for the latter. It shows us that this 'something' behaves like a repressed impulse. It can exert driving force without the ego noticing the compulsion. Not until there is resistance to the compulsion, a hold-up in the discharge-reaction, does the 'something' at once become conscious as unpleasure. In the same way that tensions arising from physical needs can remain unconscious, so also can pain - a thing intermediate between external and internal perception, which behaves like an internal perception even when its source is in the external world. It remains true, therefore, that sensations and feelings, too, only become conscious through reaching the system \( P_{cpt} \); if the way forward is barred, they do not come into being as sensations, although the 'something' that corresponds to them in the course of excitation is the same as if they did. We then come to speak, in a condensed and not entirely correct manner, of 'unconscious feelings', keeping up an analogy with unconscious ideas which is not altogether justifiable. Actually the difference is that, whereas with \( Ucs ideas \) connecting links must be created before they can be brought into the \( Cs \), with \( feelings \), which are themselves transmitted directly, this does not occur. In other words: the distinction between \( Cs \) and \( Pcs \), has no meaning where feelings are concerned; the \( Pcs \) here drops out - and feelings are either conscious or unconscious. Even when they are attached to word-presentations, their becoming conscious is not due to that circumstance, but they become so directly.

[1923b, 3956]

This mention of the protective shield sounds a note which recalls to us the fact that repression occurs in two different situations - namely, when an undesirable instinctual impulse is aroused by some external perception, and when it arises internally without any such provocation. We shall return to this difference later. But the protective shield exists only in regard to external stimuli, not in regard to internal instinctual demands.

[1926d, 4255]

The becoming conscious of a mental process is a complicated affair. I cannot resist telling you - once again, dogmatically - our hypotheses about it. The ego, as you will remember, is the external, peripheral layer of the id. Now, we believe that on the outermost surface of this ego there is a special agency directed immediately to the external world, a system, an organ, through the excitation of which alone the phenomenon that we call consciousness comes about. This organ can be equally well excited from outside - thus receiving (with the help of the sense-organs) the stimuli from the external world - and from inside - thus becoming aware, first, of the sensations in the id, and then also of the processes in the ego.

[1926e, 4341]
We can best arrive at the characteristics of the actual ego, in so far as it can be distinguished from the id and from the super-ego, by examining its relation to the outermost superficial portion of the mental apparatus, which we describe as the system Pcpt.-Cs. This system is turned towards the external world, it is the medium for the perceptions arising thence, and during its functioning the phenomenon of consciousness arises in it. It is the sense-organ of the entire apparatus; moreover it is receptive not only to excitations from outside but also to those arising from the interior of the mind. We need scarcely look for a justification of the view that the ego is that portion of the id which was modified by the proximity and influence of the external world, which is adapted for the reception of stimuli and as a protective shield against stimuli, comparable to the cortical layer by which a small piece of living substance is surrounded. The relation to the external world has become the decisive factor for the ego; it has taken on the task of representing the external world to the id - fortunately for the id, which could not escape destruction if, in its blind efforts for the satisfaction of its instincts, it disregarded that supreme external power. In accomplishing this function, the ego must observe the external world, must lay down an accurate picture of it in the memory-traces of its perceptions, and by its exercise of the function of 'reality-testing' must put aside whatever in this picture of the external world is an addition derived from internal sources of excitation. The ego controls the approaches to motility under the id's orders; but between a need and an action it has interposed a postponement in the form of the activity of thought, during which it makes use of the mnemic residues of experience. In that way it has dethroned the pleasure principle which dominates the course of events in the id without any restriction and has replaced it by the reality principle, which promises more certainty and greater success.

The process of something becoming conscious is above all linked with the perceptions which our sense organs receive from the external world. From the topographical point of view, therefore, it is a phenomenon which takes place in the outermost cortex of the ego. It is true that we also receive conscious information from the inside of the body - the feelings, which actually exercise a more peremptory influence on our mental life than external perceptions; moreover, in certain circumstances the sense organs themselves transmit feelings, sensations of pain, in addition to the perceptions specific to them. Since, however, these sensations (as we call them in contrast to conscious perceptions) also emanate from the terminal organs and since we regard all these as prolongations or offshoots of the cortical layer, we are still able to maintain the assertion made above. The only distinction would be that, as regards the terminal organs of sensation and feeling, the body itself would take the place of the external world.

Conscious processes on the periphery of the ego and everything else in the ego unconscious - such would be the simplest state of affairs that we might picture. And such may in fact be the state that prevails in animals. But in men there is an added complication through which internal processes in the ego may also acquire the quality of consciousness. This is the work of the function of speech, which brings material in the ego into a firm connection with mnemic residues of visual, but more particularly of auditory, perceptions. Thenceforward the perceptual periphery of the cortical layer can be excited to a much greater extent from inside as well, internal events such as passages of ideas and thought-processes can become conscious, and a special device is called for in order to distinguish between the two possibilities - a device known as reality-testing. The equation 'perception = reality (external world)' no longer holds. Errors, which can now easily arise and do so regularly in dreams, are called hallucinations.
But what part is there left to be played in our scheme by consciousness, which was once so omnipotent and hid all else from view? Only that of a sense-organ for the perception of psychical qualities. In accordance with the ideas underlying our attempt at a schematic picture, we can only regard conscious perception as the function proper to a particular system; and for this the abbreviation Cs. seems appropriate. In its mechanical properties we regard this system as resembling the perceptual systems Pcpt.: as being susceptible to excitation by qualities but incapable of retaining traces of alterations - that is to say, as having no memory. The psychical apparatus, which is turned towards the external world with its sense-organ of the Pcpt. systems, is itself the external world in relation to the sense-organ of the Cs., whose teleological justification resides in this circumstance. Here we once more meet the principle of the hierarchy of agencies, which seems to govern the structure of the apparatus. Excitatory material flows in to the Cs. sense-organ from two directions: from the Pcpt. system, whose excitation, determined by qualities, is probably submitted to a fresh revision before it becomes a conscious sensation, and from the interior of the apparatus itself, whose quantitative processes are felt qualitatively in the pleasure-unpleasure series when, subject to certain modifications, they make their way to consciousness.

Consciousness is not the only distinctive character which we ascribe to the processes in that system. On the basis of impressions derived from our psycho-analytic experience, we assume that all excitatory processes that occur in the other systems leave permanent traces behind in them which form the foundation of memory. Such memory-traces, then, have nothing to do with the fact of becoming conscious; indeed they are often most powerful and most enduring when the process which left them behind was one which never entered consciousness. We find it hard to believe, however, that permanent traces of excitation such as these are also left in the system Pcpt.-Cs. If they remained constantly conscious, they would very soon set limits to the system's aptitude for receiving fresh excitations. If, on the other hand, they were unconscious, we should be faced with the problem of explaining the existence of unconscious processes in a system whose functioning was otherwise accompanied by the phenomenon of consciousness. We should, so to say, have altered nothing and gained nothing by our hypothesis relegating the process of becoming conscious to a special system. Though this consideration is not absolutely conclusive, it nevertheless leads us to suspect that becoming conscious and leaving behind a memory-trace are processes incompatible with each other within one and the same system. Thus we should be able to say that the excitatory process becomes conscious in the system Cs. but leaves no permanent trace behind there; but that the excitation is transmitted to the systems lying next within and that it is in them that its traces are left. I followed these same lines in the schematic picture which I included in the speculative section of my Interpretation of Dreams. It must be borne in mind that little enough is known from other sources of the origin of consciousness; when, therefore, we lay down the proposition that consciousness arises instead of a memory-trace, the assertion deserves consideration, at all events on the ground of its being framed in fairly precise terms.

If this is so, then, the system Cs. is characterized by the peculiarity that in it (in contrast to what happens in the other psychical systems) excitatory processes do not leave behind any permanent change in its elements but expire, as it were, in the phenomenon of becoming conscious. An exception of this sort to the general rule requires to be explained by some factor that applies exclusively to that one system. Such a factor, which is absent in the other systems, might well be the exposed situation of the system Cs., immediately abutting as it does on the external world.
Let us picture a living organism in its most simplified possible form as an undifferentiated vesicle of a substance that is susceptible to stimulation. Then the surface turned towards the external world will from its very situation be differentiated and will serve as an organ for receiving stimuli. Indeed embryology, in its capacity as a recapitulation of developmental history, actually shows us that the central nervous system originates from the ectoderm; the grey matter of the cortex remains a derivative of the primitive superficial layer of the organism and may have inherited some of its essential properties. It would be easy to suppose, then, that as a result of the ceaseless impact of external stimuli on the surface of the vesicle, its substance to a certain depth may have become permanently modified, so that excitatory processes run a different course in it from what they run in the deeper layers. A crust would thus be formed which would at last have been so thoroughly 'baked through' by stimulation that it would present the most favourable possible conditions for the reception of stimuli and become incapable of any further modification. In terms of the system $C_s$, this would mean that its elements could undergo no further permanent modification from the passage of excitation, because they had already been modified in the respect in question to the greatest possible extent: now, however, they would have become capable of giving rise to consciousness. Various ideas may be formed which cannot at present be verified as to the nature of this modification of the substance and of the excitatory process. It may be supposed that, in passing from one element to another, an excitation has to overcome a resistance, and that the diminution of resistance thus effected is what lays down a permanent trace of the excitation, that is, a facilitation. In the system $C_s$, then, resistance of this kind to passage from one element to another would no longer exist. This picture can be brought into relation with Breuer's distinction between quiescent (or bound) and mobile cathetic energy in the elements of the psychical systems;¹ the elements of the system $C_s$ would carry no bound energy but only energy capable of free discharge. It seems best, however, to express oneself as cautiously as possible on these points. None the less, this speculation will have enabled us to bring the origin of consciousness into some sort of connection with the situation of the system $C_s$ and with the peculiarities that must be ascribed to the excitatory processes taking place in it.

The analogy would not be of much value if it could not be pursued further than this. If we lift the entire covering-sheet - both the celluloid and the waxed paper - off the wax slab, the writing vanishes and, as I have already remarked, does not re-appear again. The surface of the Mystic Pad is clear of writing and once more capable of receiving impressions. But it is easy to discover that the permanent trace of what was written is retained upon the wax slab itself and is legible in suitable lights. Thus the Pad provides not only a receptive surface that can be used over and over again, like a slate, but also permanent traces of what has been written, like an ordinary paper pad: it solves the problem of combining the two functions by dividing them between two separate but interrelated component parts or systems. But this is precisely the way in which, according to the hypothesis which I mentioned just now, our mental apparatus performs its perceptual function. The layer which receives the stimuli - the system $P_{opt.-C_s}$ - forms no permanent traces; the foundations of memory come about in other, adjoining, systems.

¹[1920g, 3730] [1925a, 4136]
But I must admit that I am inclined to press the comparison still further. On the Mystic Pad the writing vanishes every time the close contact is broken between the paper which receives the stimulus and the wax slab which preserves the impression. This agrees with a notion which I have long had about the method by which the perceptual apparatus of our mind functions, but which I have hitherto kept to myself. My theory was that cathectic innervations are sent out and withdrawn in rapid periodic impulses from within into the completely pervious system \textit{Pcpt.-Cs}. So long as that system is cathected in this manner, it receives perceptions (which are accompanied by consciousness) and passes the excitation on to the unconscious mnemic systems; but as soon as the cathexis is withdrawn, consciousness is extinguished and the functioning of the system comes to a standstill. It is as though the unconscious stretches out feelers, through the medium of the system \textit{Pcpt.-Cs}., towards the external world and hastily withdraws them as soon as they have sampled the excitations coming from it. Thus the interruptions, which in the case of the Mystic Pad have an external origin, were attributed by my hypothesis to the discontinuity in the current of innervation; and the actual breaking of contact which occurs in the Mystic Pad was replaced in my theory by the periodic non-excitability of the perceptual system. I further had a suspicion that this discontinuous method of functioning of the system \textit{Pcpt.-Cs}. lies at the bottom of the origin of the concept of time.

[1925a, 4137]

If we imagine one hand writing upon the surface of the Mystic Writing-Pad while another periodically raises its covering-sheet from the wax slab, we shall have a concrete representation of the way in which I tried to picture the functioning of the perceptual apparatus of our mind.

[1925a, 4137]
We will describe the last of the systems at the motor end as 'the preconscious', to indicate that
the excitatory processes occurring in it can enter consciousness without further impediment
provided that certain other conditions are fulfilled: for instance, that they reach a certain degree
of intensity, that the function which can only be described as 'attention' is distributed in a
particular way, and so on. This is at the same time the system which holds the key to voluntary
movement. We will describe the system that lies behind it as 'the unconscious', because it has
no access to consciousness except via the preconscious, in passing through which its excitatory
process is obliged to submit to modifications.

It is not without intention that I speak of 'our' unconscious. For what I thus describe is not the
same as the unconscious of the philosophers or even the unconscious of Lipps. By them the
term is used merely to indicate a contrast with the conscious: the thesis which they dispute with
so much heat and defend with so much energy is the thesis that apart from conscious there are
also unconscious psychical processes. Lipps carries things further with his assertion that the
whole of what is psychical exists unconsciously and that a part of it also exists consciously. But
it is not in order to establish this thesis that we have summoned up the phenomena of dreams
and of the formation of hysterical symptoms; the observation of normal waking life would by
itself suffice to prove it beyond any doubt. The new discovery that we have been taught by the
analysis of psychopathological structures and of the first member of that class - the dream - lies
in the fact that the unconscious (that is, the psychical) is found as a function of two separate
systems and that this is the case in normal as well as in pathological life. Thus there are two
kinds of unconscious, which have not yet been distinguished by psychologists. Both of them are
unconscious in the sense used by psychology; but in our sense one of them, which we term the
Ucs., is also inadmissible to consciousness, while we term the other the Pcs. because its
excitations - after observing certain rules, it is true, and perhaps only after passing a fresh
censorship, though nonetheless without regard to the Ucs. - are able to reach consciousness.
The fact that excitations in order to reach consciousness must pass through a fixed series or
hierarchy of agencies (which is revealed to us by the modifications made in them by censorship)
has enabled us to construct a spatial analogy. We have described the relations of the two
systems to each other and to consciousness by saying that the system Pcs. stands like a
screen between the system Ucs. and consciousness. The system Pcs. not merely bars access
to consciousness, it also controls access to the power of voluntary movement and has at its
disposal for distribution a mobile cathectic energy, a part of which is familiar to us in the form of
attention.

[1900a, 974]

[1900a, 1039]
Those philosophers who have become aware that rational and highly complex thought-structures are possible without consciousness playing any part in them have found difficulty in assigning any function to consciousness; it has seemed to them that it can be no more than a superfluous reflected picture of the completed psychical process. We, on the other hand, are rescued from this embarrassment by the analogy between our Cs. system and the perceptual systems. We know that perception by our sense-organs has the result of directing a cathexis of attention to the paths along which the in-coming sensory excitation is spreading; the qualitative excitation of the $Pcpt.$ system acts as a regulator of the discharge of the mobile quantity in the psychical apparatus. We can attribute the same function to the overlying sense-organ of the Cs. system. By perceiving new qualities, it makes a new contribution to directing the mobile quantities of cathexis and distributing them in an expedient fashion. By the help of its perception of pleasure and unpleasure it influences the discharge of the cathexes within what is otherwise an unconscious apparatus operating by means of the displacement of quantities. It seems probable that in the first instance the unpleasure principle regulates the displacement of cathexes automatically. But it is quite possible that consciousness of these qualities may introduce in addition a second and more discriminating regulation, which is even able to oppose the former one, and which perfects the efficiency of the apparatus by enabling it, in contradiction to its original plan, to cathect and work over even what is associated with the release of unpleasure. We learn from the psychology of the neuroses that these processes of regulation carried out by the qualitative excitation of the sense organs play a great part in the functional activity of the apparatus. The automatic domination of the primary unpleasure principle and the consequent restriction imposed upon efficiency are interrupted by the processes of sensory regulation, which are themselves in turn automatic in action. We find that repression (which, though it served a useful purpose to begin with, leads ultimately to a damaging loss of inhibition and mental control) affects memories so much more easily than perceptions because the former can receive no extra cathexis from the excitation of the psychical sense-organs. It is true on the one hand that a thought which has to be warded off cannot become conscious, because it has undergone repression; but on the other hand it sometimes happens that a thought of this kind is only repressed because for other reasons it has been withdrawn from conscious perception. Here are some hints of which we take advantage in our therapeutic procedure in order to undo repressions which have already been effected. [1900a, 1041]
We must, however, put off discussing this difficulty till we can focus our interest upon the system Cs. itself. In the present connection we may be allowed to assume that hallucination consists in a cathexis of the system Cs. (Pcpt.), which, however, is not effected - as normally - from without, but from within, and that a necessary condition for the occurrence of hallucination is that regression shall be carried far enough to reach this system itself and in so doing be able to pass over reality-testing.¹

[1917d, 3036]

We think of the mnemic residues as being contained in systems which are directly adjacent to the system Pcpt.-Cs., so that the cathexes of those residues can readily extend from within on to the elements of the latter system. We immediately think here of hallucinations, and of the fact that the most vivid memory is always distinguishable both from a hallucination and from an external perception; but it will also occur to us at once that when a memory is revived the cathexis remains in the mnemic system, whereas a hallucination, which is not distinguishable from a perception, can arise when the cathexis does not merely spread over from the memory-trace on to the Pcpt. element, but passes over to it entirely.

[1923b, 3954]

Conscious processes on the periphery of the ego and everything else in the ego unconscious - such would be the simplest state of affairs that we might picture. And such may in fact be the state that prevails in animals. But in men there is an added complication through which internal processes in the ego may also acquire the quality of consciousness. This is the work of the function of speech, which brings material in the ego into a firm connection with mnemic residues of visual, but more particularly of auditory, perceptions. Thenceforward the perceptual periphery of the cortical layer can be excited to a much greater extent from inside as well, internal events such as passages of ideas and thought-processes can become conscious, and a special device is called for in order to distinguish between the two possibilities - a device known as reality-testing. The equation 'perception = reality (external world)' no longer holds. Errors, which can now easily arise and do so regularly in dreams, are called hallucinations.

[1940a [1938], 4972]

These recollections might have been described as hallucinations if a belief in their actual presence had been added to their clearness. The importance of this analogy seemed greater when I noticed that true hallucinations occasionally occurred in the case of other patients who were certainly not psychotic. My line of thought proceeded as follows. Perhaps it may be a general characteristic of hallucinations to which sufficient attention has not hitherto been paid that in them something that has been experienced in infancy and then forgotten returns - something that the child has seen or heard at a time when he could still hardly speak and that now forces its way into consciousness, probably distorted and displaced owing to the operation of forces that are opposed to this return. And, in view of the close relation between hallucinations and particular forms of psychosis, our line of thought may be carried still further. It may be that the delusions into which these hallucinations are so constantly incorporated may themselves be less independent of the upward drive of the unconscious and the return of the repressed than we usually assume. In the mechanism of a delusion we stress as a rule only two factors: the turning away from the real world and its motive forces on the one hand, and the influence exercised by wish-fulfilment on the content of the delusion on the other. But may it not be that the dynamic process is rather that the turning away from reality is exploited by the upward drive of the repressed in order to force its content into consciousness, while the resistances stirred up by this process and the trend to wish-fulfilment share the responsibility for the distortion and displacement of what is recollected? This is after all the familiar mechanism of dreams, which intuition has equated with madness from time immemorial.

[1937d, 5058]
But what part is there left to be played in our scheme by consciousness, which was once so omnipotent and hid all else from view? Only that of a sense-organ for the perception of psychical qualities. In accordance with the ideas underlying our attempt at a schematic picture, we can only regard conscious perception as the function proper to a particular system; and for this the abbreviation Cs. seems appropriate. In its mechanical properties we regard this system as resembling the perceptual systems Pcpt.: as being susceptible to excitation by qualities but incapable of retaining traces of alterations - that is to say, as having no memory. The psychical apparatus, which is turned towards the external world with its sense-organ of the Pcpt. systems, is itself the external world in relation to the sense-organ of the Cs., whose teleological justification resides in this circumstance. Here we once more meet the principle of the hierarchy of agencies, which seems to govern the structure of the apparatus. Excitatory material flows in to the Cs. sense-organ from two directions: from the Pcpt. system, whose excitation, determined by qualities, is probably submitted to a fresh revision before it becomes a conscious sensation, and from the interior of the apparatus itself, whose quantitative processes are felt qualitatively in the pleasure-unpleasure series when, subject to certain modifications, they make their way to consciousness.

Those philosophers who have become aware that rational and highly complex thought-structures are possible without consciousness playing any part in them have found difficulty in assigning any function to consciousness; it has seemed to them that it can be no more than a superfluous reflected picture of the completed psychical process. We, on the other hand, are rescued from this embarrassment by the analogy between our Cs. system and the perceptual systems. We know that perception by our sense-organs has the result of directing a cathexis of attention to the paths along which the incoming sensory excitation is spreading: the qualitative excitation of the Pcpt. system acts as a regulator of the discharge of the mobile quantity in the psychical apparatus. We can attribute the same function to the overlying sense-organ of the Cs. system. By perceiving new qualities, it makes a new contribution to directing the mobile quantities of cathexis and distributing them in an expedient fashion. By the help of its perception of pleasure and unpleasure it influences the discharge of the cathexes within what is otherwise an unconscious apparatus operating by means of the displacement of quantities. It seems probable that in the first instance the unpleasure principle regulates the displacement of cathexes automatically. But it is quite possible that consciousness of these qualities may introduce in addition a second and more discriminating regulation, which is even able to oppose the former one, and which perfects the efficiency of the apparatus by enabling it, in contradiction to its original plan, to cathect and work over even what is associated with the release of unpleasure. We learn from the psychology of the neuroses that these processes of regulation carried out by the qualitative excitation of the sense organs play a great part in the functional activity of the apparatus. The automatic domination of the primary unpleasure principle and the consequent restriction imposed upon efficiency are interrupted by the processes of sensory regulation, which are themselves in turn automatic in action. We find that repression (which, though it served a useful purpose to begin with, leads ultimately to a damaging loss of inhibition and mental control) affects memories so much more easily than perceptions because the former can receive no extra cathexis from the excitation of the psychical sense-organs. It is true on the one hand that a thought which has to be warded off cannot become conscious, because it has undergone repression; but on the other hand it sometimes happens that a thought of this kind is only repressed because for other reasons it has been withdrawn from conscious perception. Here are some hints of which we take advantage in our therapeutic procedure in order to undo repressions which have already been effected.

[1900a, 1041]
The value of the hypercathexis which is set up in the mobile quantities by the regulating influence of the sense organ of the Cs. cannot be better illustrated in its teleological aspect than by the fact of its creation of a new series of qualities and consequently of a new process of regulation which constitutes the superiority of men over animals. Thought-processes are in themselves without quality, except for the pleasurable and unpleasurable excitations which accompany them, and which, in view of their possible disturbing effect upon thinking, must be kept within bounds. In order that thought-processes may acquire quality, they are associated in human beings with verbal memories, whose residues of quality are sufficient to draw the attention of consciousness to them and to endow the process of thinking with a new mobile cathexis from consciousness.

[1900a, 1042]

I cannot neglect this opportunity of expressing for once my astonishment that human beings can go through such great and important moments of their erotic life without noticing them much, sometimes even, indeed, without having the faintest suspicion of their existence, or else, having become aware of those moments, deceive themselves so thoroughly in their judgement of them. This happens not only under neurotic conditions, where we are familiar with the phenomenon, but seems also to be common enough in ordinary life. In the present case, for example, a girl develops a sentimental adoration for women, which her parents at first find merely vexatious and hardly take seriously; she herself knows quite well that she is very much occupied with these relationships, but still she experiences few of the sensations of intense love until a particular frustration is followed by a quite excessive reaction, which shows everyone concerned that they have to do with a consuming passion of elemental strength. Nor had the girl ever perceived anything of the state of affairs which was a necessary preliminary to the outbreak of this mental storm. In other cases, too, we come across girls or women in a state of severe depression, who on being asked for a possible cause of their condition tell us that they have, it is true, had a slight feeling for a certain person, but that it was nothing deep and that they soon got over it when they had to give it up. And yet it was this renunciation, apparently so easily borne, that became the cause of serious mental disturbance. Again, we come across men who have passed through casual love-affairs and realize only from the subsequent effects that they had been passionately in love with the person whom they had apparently regarded lightly. One is also amazed at the unexpected results that may follow an artificial abortion, the killing of an unborn child, which had been decided upon without remorse and without hesitation. It must be admitted that poets are right in liking to portray people who are in love without knowing it, or uncertain whether they do love, or who think that they hate when in reality they love. It would seem that the information received by our consciousness about our erotic life is especially liable to be incomplete, full of gaps, or falsified. Needless to say, in this discussion I have not omitted to allow for the part played by subsequent forgetting.

[1920a, 3855]
On the contrary, the only results of the analysis were that Hans recovered, that he ceased to be afraid of horses, and that he got on to rather familiar terms with his father, as the latter reported with some amusement. But whatever his father may have lost in the boy's respect he won back in his confidence: 'I thought', said Hans, 'you knew everything, as you knew that about the horse.' For analysis does not undo the effects of repression. The instincts which were formerly suppressed remain suppressed; but the same effect is produced in a different way. Analysis replaces the process of repression, which is an automatic and excessive one, by a temperate and purposeful control on the part of the highest agencies of the mind. In a word, analysis replaces repression by condemnation. This seems to bring us the long-looked-for evidence that consciousness has a biological function, and that with its entrance upon the scene an important advantage is secured.

² [Footnote added 1923:] I am here using the word 'consciousness' in a sense which I later avoided, namely, to describe our normal processes of thought - such, that is, as are capable of consciousness. We know that thought processes of this kind may also take place preconsciously; and it is wiser to regard their actual 'consciousness' from a purely phenomenological standpoint. By this I do not, of course, mean to contradict the expectation that consciousness in this more limited sense of the word must also fulfil some biological function.

[1909b, 2121]
I believe I can see that this inverse relation between the psychical effect of the memory and of the event contains the reason for the memory remaining unconscious.

[1896a, 378]

All the events subsequent to puberty to which an influence must be attributed upon the development of the hysterical neurosis and upon the formation of its symptoms are in fact only concurrent causes - 'agents provocateurs' as Charcot used to say, although for him nervous heredity occupied the place which I claim for the precocious sexual experience. These accessory agents are not subject to the strict conditions imposed on the specific causes; analysis demonstrates in an irrefutable fashion that they enjoy a pathogenic influence for hysteria only owing to their faculty for awakening the unconscious psychical trace of the childhood event. It is also thanks to their connection with the primary pathogenic impression, and inspired by it, that their memories will become unconscious in their turn and will be able to assist in the growth of a psychical activity withdrawn from the power of the conscious functions.

[1896a, 379]

The obsessional neurosis (Zwangsneurose) arises from a specific cause very analogous to that of hysteria. Here too we find a precocious sexual event, occurring before puberty, the memory of which becomes active during or after that period; and the same remarks and arguments which I put forward in connection with hysteria will apply to my observations of the other neurosis (six cases, three of which were pure ones). There is only one difference which seems capital. At the basis of the aetiology of hysteria we found an event of passive sexuality, an experience submitted to with indifference or with a small degree of annoyance or fright. In obsessional neurosis it is a question on the other hand, of an event which has given pleasure, of an act of aggression inspired by desire (in the case of a boy) or of a participation in sexual relations accompanied by enjoyment (in the case of a little girl). The obsessional ideas, when their intimate meaning has been recognized by analysis, when they have been reduced, as it were, to their simplest expression, are nothing other than reproaches addressed by the subject himself on account of this anticipated sexual enjoyment, but reproaches distorted by an unconscious psychical work of transformation and substitution.

[1896a, 379]

I have now come to the end of what I have to say to-day. Prepared as I am to meet with contradiction and disbelief, I should like to say one thing more in support of my position. Whatever you may think about the conclusions I have come to, I must ask you not to regard them as the fruit of idle speculation. They are based on a laborious individual examination of patients which has in most cases taken up a hundred or more hours of work. What is even more important to me than the value you put on my results is the attention you give to the procedure I have employed. This procedure is new and difficult to handle, but it is nevertheless irreplaceable for scientific and therapeutic purposes. You will realize, I am sure, that one cannot properly deny the findings which follow from this modification of Breuer's procedure so long as one puts it aside and uses only the customary method of questioning patients. To do so would be like trying to refute the findings of histological technique by relying upon macroscopic examination. The new method of research gives wide access to a new element in the psychical field of events, namely, to processes of thought which have remained unconscious - which, to use Breuer's expression, are 'inadmissible to consciousness'. Thus it inspires us with the hope of a new and better understanding of all functional psychical disturbances. I cannot believe that psychiatry will long hold back from making use of this new pathway to knowledge.

[1896c, 433]
Reports of numerous cases seem to put it beyond dispute that dreams can carry on the intellectual work of daytime and bring it to conclusions which had not been reached during the day, and that they can resolve doubts and problems and be the source of new inspiration for poets and musical composers. But though the fact may be beyond dispute, its implications are open to many doubts, which raise matters of principle.

So far we have been psychologizing on our own account. It is time now to consider the theoretical views which govern present-day psychology and to examine their relation to our hypotheses. The problem of the unconscious in psychology is, in the forcible words of Lipps (1897), less a psychological problem than the problem of psychology. So long as psychology dealt with this problem by a verbal explanation to the effect that ‘psychical’ meant ‘conscious’ and that to speak of ‘unconscious psychical processes’ was palpable nonsense, any psychological evaluation of the observations made by physicians upon abnormal mental states was out of the question. The physician and the philosopher can only come together if they both recognize that the term ‘unconscious psychical processes’ is ‘the appropriate and justified expression of a solidly established fact’. The physician can only shrug his shoulders when he is assured that ‘consciousness is an indispensable characteristic of what is psychical’, and perhaps, if he still feels enough respect for the utterances of philosophers, he may presume that they have not been dealing with the same thing or working at the same science. For even a single understanding observation of a neurotic’s mental life or a single analysis of a dream must leave him with an unshakeable conviction that the most complicated and most rational thought-processes, which can surely not be denied the name of psychical processes, can occur without exciting the subject's consciousness. It is true that the physical cannot learn of these unconscious processes until they have produced some effect upon consciousness which can be communicated or observed. But this conscious effect may exhibit a psychical character quite different from that of the unconscious process, so that internal perception cannot possibly regard the one as a substitute for the other. The physician must feel at liberty to proceed by inference from the conscious effect to the unconscious psychical process. He thus learns that the conscious effect is only a remote psychical result of the unconscious process and that the latter has not become conscious as such; and moreover that the latter was present and operative even without betraying its existence in any way to consciousness.

It is essential to abandon the overvaluation of the property of being conscious before it becomes possible to form any correct view of the origin of what is mental. In Lipps's words, the unconscious must be assumed to be the general basis of psychical life. The unconscious is the larger sphere, which includes within it the smaller sphere of the conscious. Everything conscious has an unconscious preliminary stage; whereas what is unconscious may remain at that stage and nevertheless claim to be regarded as having the full value of a psychical process. The unconscious is the true psychical reality; in its innermost nature it is as much unknown to us as the reality of the external world, and it is as incompletely presented by the data of consciousness as is the external world by the communications of our sense organs.
Now that the old antithesis between conscious life and dream life has been reduced to its proper proportions by the establishment of unconscious psychical reality, a number of dream-problems with which earlier writers were deeply concerned have lost their significance. Thus some of the activities whose successful performance in dreams excited astonishment are now no longer to be attributed to dreams but to unconscious thinking, which is active during the day no less than at night. If, as Scherner has said, dreams appear to engage in making symbolic representations of the body, we now know that those representations are the product of certain unconscious phantasies (deriving, probably, from sexual impulses) which find expression not only in dreams but also in hysterical phobias and other symptoms. If a dream carries on the activities of the day and completes them and even brings valuable fresh ideas to light, all we need do is to strip it of the dream disguise, which is the product of dream-work and the mark of assistance rendered by obscure forces from the depths of the mind (cf. the Devil in Tartini’s sonata dream); the intellectual achievement is due to the same mental forces which produce every similar result during the daytime. We are probably inclined greatly to over-estimate the conscious character of intellectual and artistic production as well. Accounts given us by some of the most highly productive men, such as Goethe and Helmholtz, show rather that what is essential and new in their creations came to them without premeditation and as an almost ready-made whole. There is nothing strange if in other cases, where a concentration of every intellectual faculty was needed, conscious activity also contributed its share. But it is the much-abused privilege of conscious activity, wherever it plays a part, to conceal every other activity from our eyes.

[1900a, 1038]

It is not without intention that I speak of 'our' unconscious. For what I thus describe is not the same as the unconscious of the philosophers or even the unconscious of Lipps. By them the term is used merely to indicate a contrast with the conscious: the thesis which they dispute with so much heat and defend with so much energy is the thesis that apart from conscious there are also unconscious psychical processes. Lipps carries things further with his assertion that the whole of what is psychical exists unconsciously and that a part of it also exists consciously. But it is not in order to establish this thesis that we have summoned up the phenomena of dreams and of the formation of hysterical symptoms; the observation of normal waking life would by itself suffice to prove it beyond any doubt. The new discovery that we have been taught by the analysis of psychopathological structures and of the first member of that class - the dream - lies in the fact that the unconscious (that is, the psychical) is found as a function of two separate systems and that this is the case in normal as well as in pathological life. Thus there are two kinds of unconscious, which have not yet been distinguished by psychologists. Both of them are unconscious in the sense used by psychology; but in our sense one of them, which we term the Ucs., is also inadmissible to consciousness, while we term the other the Pcs. because its excitations - after observing certain rules, it is true, and perhaps only after passing a fresh censorship, though nonetheless without regard to the Ucs. - are able to reach consciousness. The fact that excitations in order to reach consciousness must pass through a fixed series or hierarchy of agencies (which is revealed to us by the modifications made in them by censorship) has enabled us to construct a spatial analogy. We have described the relations of the two systems to each other and to consciousness by saying that the system Pcs. stands like a screen between the system Ucs. and consciousness. The system Pcs. not merely bars access to consciousness, it also controls access to the power of voluntary movement and has at its disposal for distribution a mobile cathetic energy, a part of which is familiar to us in the form of attention.²

[1900a, 1039]
(5) I shall dwell longer on analyses of numerical associations, since I know of no other separate observations that would prove so forcefully the existence of highly composite thought-processes which are yet quite unknown to consciousness. At the same time I know of no better example of analyses in which the part contributed by the physician (suggestion) - so often held responsible - is so definitely ruled out. I shall therefore give a report here (with his consent) of the analysis of a number which occurred to a patient of mine. I need only add that he is the youngest child in a large family and at an early age lost his greatly admired father. While he was in a particularly cheerful mood the number 426718 came to his mind, and he asked himself: 'What ideas occur to me in that connection? First of all, a joke I have heard: "When a doctor treats a cold it lasts for 42 days; when it is not treated, it lasts 6 weeks."' This corresponds to the first figures in the number (42 = 6 x 7). In the stoppage that followed this first solution I drew his attention to the fact that the six-figure number he had chosen contained all the first digits except for 3 and 5. He then immediately found the continuation of the interpretation. 'There are 7 of us brothers and sisters, and I am the youngest. In the order of our age, 3 corresponds to my sister A., and 5 to my brother L.; they were my two enemies. As a child I used to pray to God every night for him to remove these two tormenting spirits from life. It seems to me now that in this choice of numbers I was myself fulfilling this wish; 3 and 5, the wicked brother and the hated sister, are passed over.' - If the number represents the order of your brothers and sisters, what does the 18 at the end mean? There were only 7 of you after all. - 'I have often thought that if my father had lived longer I should not have remained the youngest child. If there had been 1 more we should have been 8 and I should have had a younger child after me to whom I should have played the elder brother.'
[1901b, 1319]

Though we admit that these remarks of ours in no way exhaust the psychology of superstition, we shall at least have to touch on the question of whether we are to deny entirely that superstition has any real roots: whether there are definitely no such things as true presentiments, prophetic dreams, telepathic experiences, manifestations of supernatural forces and the like. I am far from meaning to pass so sweeping a condemnation of these phenomena, of which so many detailed observations have been made even by men of outstanding intellect, and which it would be best to make the subject of further investigations. We may even hope that some portion of these observations will then be explained by our growing recognition of unconscious mental processes, without necessitating radical alterations in the views we hold today. If the existence of still other phenomena - those, for example, claimed by spiritualists - were to be established, we should merely set about modifying our 'laws' in the way demanded by the new discovery, without being shaken in our belief in the coherence of things in the world.
[1901b, 1330]

¹ [Footnote added 1924:] This book is of an entirely popular character; it merely aims, by an accumulation of examples, at paving the way for the necessary assumption of unconscious yet operative mental processes, and it avoids all theoretical considerations on the nature of this unconscious.
[1901b, 1341]
A number of the results of the analysis have been omitted, because at the time when work was broken off they had either not been established with sufficient certainty or they required further study before any general statement could be made about them. At other points, where it seemed to be permissible, I have indicated the direction along which some particular solution would probably have been found to lie. I have in this paper left entirely out of account the technique, which does not at all follow as a matter of course, but by whose means alone the pure metal of valuable unconscious thoughts can be extracted from the raw material of the patient's associations. This brings with it the disadvantage of the reader being given no opportunity of testing the correctness of my procedure in the course of this exposition of the case. I found it quite impracticable, however, to deal simultaneously with the technique of analysis and with the internal structure of a case of hysteria: I could scarcely have accomplished such a task, and if I had, the result would have been almost unreadable. The technique of analysis demands an entirely separate exposition, which would have to be illustrated by numerous examples chosen from a very great variety of cases and which would not have to take the results obtained in each particular case into account. Nor have I attempted in this paper to substantiate the psychological postulates which will be seen to underlie my descriptions of mental phenomena. A cursory attempt to do so would have effected nothing; an exhaustive one would have been a volume in itself. I can only assure the reader that I approached the study of the phenomena revealed by observation of the psychoneuroses without being pledged to any particular psychological system, and that I then proceeded to adjust my views until they seemed adapted for giving an account of the collection of facts which had been observed. I take no pride in having avoided speculation; the material for my hypotheses was collected by the most extensive and laborious series of observations. The decidedness of my attitude on the subject of the unconscious is perhaps specially likely to cause offence, for I handle unconscious ideas, unconscious trains of thought, and unconscious impulses as though they were no less valid and unimpeachable psychological data than conscious ones. But of this I am certain - that any one who sets out to investigate the same region of phenomena and employs the same method will find himself compelled to take up the same position, however much philosophers may expostulate.

[1905e, 1446]

Now that the flood-waters of war have subsided, it is satisfactory to be able to record the fact that interest in psycho-analytic research remains unimpaired in the world at large. But the different parts of the theory have not all had the same history. The purely psychological theses and findings of psycho-analysis on the unconscious, repression, conflict as a cause of illness, the advantage accruing from illness, the mechanisms of the formation of symptoms, etc., have come to enjoy increasing recognition and have won notice even from those who are in general opposed to our views. That part of the theory, however, which lies on the frontiers of biology and the foundations of which are contained in this little work is still faced with undiminished contradiction. It has even led some who for a time took a very active interest in psycho-analysis to abandon it and to adopt fresh views which were intended to restrict once more the part played by the factor of sexuality in normal and pathological mental life.

[1905d, 1462]
Finally, Gentlemen, I must confess that it is hardly fair to take up your attention for so long on the subject of psycho-analytic therapy without telling you in what this treatment consists and on what it is based. Still, as I am forced to be brief, I can only hint at this: This therapy, then, is based on the recognition that unconscious ideas - or better, the unconsciousness of certain mental processes - are the direct cause of the morbid symptoms. We share this opinion with the French school (Janet) who, by the way, owing to excessive schematization, refer the cause of hysterical symptoms to an unconscious *idée fixe*. Now please do not be afraid that this is going to land us in the depths of philosophical obscurities. Our unconscious is not quite the same thing as that of philosophers and, moreover, the majority of philosophers will hear nothing of 'unconscious mental processes'. If, however, you will look at the matter from our point of view, you will understand that the transformation of this unconscious material in the mind of the patient into conscious material must have the result of correcting his deviation from normality and of lifting the compulsion to which his mind has been subjected. For conscious will-power governs only conscious mental processes, and every mental compulsion is rooted in the unconscious. Nor need you ever fear that the patient will be harmed by the shock accompanying the introduction of the unconscious into consciousness, for you can convince yourselves theoretically that the somatic and emotional effect of an impulse that has become conscious can never be so powerful as that of an unconscious one. It is only by the application of our highest mental functions, which are bound up with consciousness, that we can control all our impulses.

A theory which is novel, which lacks simplicity and which runs counter to our habits of thought, can scarcely gain in clarity from a concise presentation. All I can aim at in these remarks, therefore, is to draw attention to the fuller treatment of the unconscious in my *Interpretation of Dreams* and to the writings of Lipps, which seem to me of the highest importance. I am aware that anyone who is under the spell of a good academic philosophical education, or who takes his opinions at long range from some so-called system of philosophy, will be opposed to the assumption of an 'unconscious psychical' in the sense in which Lipps and I use the term, and will prefer to prove its impossibility on the basis of a definition of the psychical. But definitions are a matter of convention and can be altered. I have often found that people who dispute the unconscious as being something absurd and impossible have not formed their impressions from the sources from which I at least was brought to the necessity of recognizing it. These opponents of the unconscious had never witnessed the effect of a post-hypnotic suggestion, and when I have told them examples from my analyses with non-hypnotized neurotics they have been filled with the greatest astonishment. They had never realized the idea that the unconscious is something which we really do not know, but which we are obliged by compelling inferences to supply; they had understood it as being something capable of becoming conscious but which was not being thought of at the moment, which did not occupy 'the focal point of attention'. Nor had they ever tried to convince themselves of the existence in their own minds of unconscious thoughts like these by analysing one of their own dreams; and when I attempted to do so with them they could only greet their own associations with surprise and confusion. I have also formed an impression that fundamental emotional resistances stand in the way of accepting the 'unconscious', and that these are based on the fact that no one wants to get to know his unconscious and that the most convenient plan is to deny its possibility altogether.

[1905a, 1571]

[1905c, 1747]
I should be very glad if it were possible for me on the one hand to give a clearer exposition of this single decisive point in my view of jokes and on the other hand to reinforce it with conclusive arguments. But in fact what I am faced with here is not a two-fold failure but one and the same failure. I cannot give a clearer exposition because I have no further proof of my view. I arrived at it on the basis of a study of the technique and of a comparison with the dream-work, and on no other basis; and I then found that on the whole it fits in excellently with the characteristics of jokes. Thus this view has been arrived at by inference; and if from an inference of this kind one is led, not to a familiar region, but on the contrary, to one that is alien and new to one's thought, one calls the inference a 'hypothesis' and rightly refuses to regard the relation of the hypothesis to the material from which it was inferred as a 'proof' of it. It can only be regarded as 'proved' if it is reached by another path as well and if it can be shown to be the nodal point of still other connections. But proof of this sort is not to be had, in view of the fact that our knowledge of unconscious processes has scarcely begun. In the realization that we are standing upon ground which has never before been trodden, we are thus content, from our point of observation, to take one single, short and uncertain step forward into the unexplored region. [1905c, 1760]

The state of permanently turning away from women produces a personal susceptibility, or, as we are accustomed to say, a 'disposition' to the formation of a delusion. The development of the mental disorder sets in at the moment when a chance impression arouses the childhood experiences which have been forgotten and which have traces, at least, of an erotic colouring. 'Arouses', however, is certainly not the right description, if we take into account what follows. We must repeat the author's accurate account in correct psychological technical terms. When Norbert Hanold saw the relief, he did not remember that he had already seen a similar posture of the foot in his childhood friend; he remembered nothing at all, but all the effects brought about by the relief originated from this link that was made with the impression of his childhood. Thus the childhood impression was stirred up, it became active, so that it began to produce effects, but it did not come into consciousness - it remained 'unconscious', to use a term which has to-day become unavoidable in psychopathology. We are anxious that this unconscious shall not be involved in any of the disputes of philosophers and natural philosophers, which have often no more than an etymological importance. For the time being we possess no better name for psychical processes which behave actively but nevertheless do not reach the consciousness of the person concerned, and that is all we mean by our 'unconsciousness'. When some thinkers try to dispute the existence of an unconscious of this kind, on the ground that it is nonsensical, we can only suppose that they have never had to do with the corresponding mental phenomena, that they are under the spell of the regular experience that everything mental that becomes active and intense becomes at the same time conscious as well, and that they have still to learn (what our author knows very well) that there are most certainly mental processes which, in spite of being intense and producing effects, none the less remain apart from consciousness. [1907a, 1846]
It is quite possible that the author's disavowal does not stop at this. He may perhaps altogether deny any knowledge of the rules which we have shown that he has followed, and he may repudiate all the purposes we have recognized in his work. I do not regard this as improbable; but if it is so, there are only two possible explanations. It may be that we have produced a complete caricature of an interpretation by introducing into an innocent work of art purposes of which its creator had no notion, and by so doing have shown once more how easy it is to find what one is looking for and what is occupying one's own mind - a possibility of which the strangest examples are to be found in the history of literature. Let every reader now make up his mind whether he is able to accept this explanation. We ourselves, of course, hold to the other view, the remaining alternative. Our opinion is that the author need have known nothing of these rules and purposes, so that he could disavow them in good faith, but that nevertheless we have not discovered anything in his work that is not already in it. We probably draw from the same source and work upon the same object, each of us by another method. And the agreement of our results seems to guarantee that we have both worked correctly. Our procedure consists in the conscious observation of abnormal mental processes in other people so as to be able to elicit and announce their laws. The author no doubt proceeds differently. He directs his attention to the unconscious in his own mind, he listens to its possible developments and lends them artistic expression instead of suppressing them by conscious criticism. Thus he experiences from himself what we learn from others - the laws which the activities of this unconscious must obey. But he need not state these laws, nor even be clearly aware of them; as a result of the tolerance of his intelligence, they are incorporated within his creations. We discover these laws by analysing his writings just as we find them from cases of real illness; but the conclusion seems inescapable that either both of us, the writer and the doctor, have misunderstood the unconscious in the same way, or we have both understood it correctly. This conclusion is of great value to us, and it is on its account that it has been worth while to investigate by the methods of medical psycho-analysis the way in which the formation and the cure of the delusions as well as the dreams are represented in Jensen's Gradiva.

[1907a, 1883]

We can go a step further in vindicating little Hans's honour. As a matter of fact, he was behaving no worse than a philosopher of the school of Wundt. In the view of that school, consciousness is the invariable characteristic of what is mental, just as in the view of little Hans a widdler is the indispensable criterion of what is animate. If now the philosopher comes across mental processes whose existence cannot but be inferred, but about which there is not a trace of consciousness to be detected - for the subject, in fact, knows nothing of them, although it is impossible to avoid inferring their existence - then, instead of saying that they are unconscious mental processes, he calls them semi-conscious. The widdler's still very small! And in this comparison the advantage is in favour of little Hans. For, as is so often the case with the sexual researches of children, behind the mistake a piece of genuine knowledge lies concealed. Little girls do possess a small widdler, which we call a clitoris, though it does not grow any larger but remains permanently stunted. Compare my short paper on 'The Sexual Theories of Children' (1908c).

[1909b, 2007]
We find, accordingly: an erotic instinct and a revolt against it; a wish which has not yet become compulsive and, struggling against it, a fear which is already compulsive; a distressing affect and an impulsion towards the performance of defensive acts. The inventory of the neurosis has reached its full muster. Indeed, something more is present, namely, a kind of delusion or delirium with the strange content that his parents knew his thoughts because he spoke them out loud without his hearing himself do it. We shall not go far astray if we suppose that in making this attempt at an explanation the child had some inkling of those remarkable mental processes which we describe as unconscious and which we cannot dispense with if we are to throw any scientific light upon this obscure subject. 'I speak my thoughts out loud, without hearing them' sounds like a projection into the external world of our own hypothesis that he had thoughts without knowing anything about them; it sounds like an endopsychic perception of what has been repressed.

[1909d, 2134]

I shall not in the present paper attempt any discussion of the psychological significance of obsessional thinking. Such a discussion would be of extraordinary value in its results, and would do more to clarify our ideas upon the nature of the conscious and the unconscious than any study of hysteria or the phenomena of hypnosis. It would be a most desirable thing if the philosophers and psychologists who develop brilliant theoretical views on the unconscious upon a basis of hearsay knowledge or from their own conventional definitions would first submit to the convincing impressions which may be gained from a first-hand study of the phenomena of obsessional thinking. We might almost go to the length of requiring it of them, if the task were not so far more laborious than the methods of work to which they are accustomed. I will only add here that in obsessional neuroses the unconscious mental processes occasionally break through into consciousness in their pure and undistorted form, that such incursions may take place at every possible stage of the unconscious process of thought, and that at the moment of the incursion the obsessional ideas can, for the most part, be recognized as formations of very long standing. This accounts for the striking circumstance that, when the analyst tries, with the patient's help, to discover the date of the first occurrence of an obsessional idea, the patient is obliged to place it further and further back as the analysis proceeds, and is constantly finding fresh 'first' occasions for the appearance of the obsession.

[1909d, 2178]
You may have formed an impression that the technique through whose armory I have just conducted you is particularly difficult. In my opinion that technique is entirely in conformity with the material with which it has to deal. But this much at least is clear: it is not a self-evident one and it must be learnt just as the techniques of histology or surgery must be learnt. You will perhaps be surprised to hear that in Europe we have heard a large number of judgements on psycho-analysis from people who know nothing of this technique and do not employ it; and who go on to demand with apparent scorn that we shall prove to them the correctness of our findings. Among these adversaries there are no doubt some to whom a scientific mode of thought is not as a rule alien, who, for instance, would not reject the results of a microscopic examination because it could not be confirmed on the anatomical preparation with the naked eye, but who would first form a judgement on the matter themselves with the help of a microscope. But, where psycho-analysis is concerned, the prospects of recognition are in truth less favourable. Psycho-analysis is seeking to bring to conscious recognition the things in mental life which are repressed; and everyone who forms a judgement on it is himself a human being, who possesses similar repressions and may perhaps be maintaining them with difficulty. They are therefore bound to call up the same resistance in him as in our patients; and that resistance finds it easy to disguise itself is an intellectual rejection and to bring up arguments like those which we ward off in our patients by means of the fundamental rule of psycho-analysis. We often become aware in our opponents, just as we do in our patients, that their power of judgement is very noticeably influenced affectively in the sense of being diminished. The arrogance of consciousness (in rejecting dreams with such contempt, for instance) is one of the most powerful of the devices with which we are provided as a universal protection against the incursion of unconscious complexes. That is why it is so hard to convince people of the reality of the unconscious and to teach them to recognize something new which is in contradiction to their conscious knowledge.

[1910a, 2226]
Ladies and Gentlemen, from the intellectual point of view we must, I think, take into account two special obstacles to recognizing psycho-analytic trains of thought. In the first place, people are unaccustomed to reckoning with a strict and universal application of determinism to mental life; and in the second place, they are ignorant of the peculiarities which distinguish unconscious mental processes from the conscious ones that are familiar to us. One of the most widespread resistances to psycho-analytic work, in the sick and healthy alike, can be traced to the second of these two factors. People are afraid of doing harm by psycho-analysis; they are afraid of bringing the repressed sexual instincts into the patient's consciousness, as though that involved a danger of their overwhelming his higher ethical trends and of their robbing him of his cultural acquisitions. People notice that the patient has sore spots in his mind, but shrink from touching them for fear of increasing his sufferings. We can accept this analogy. It is no doubt kinder not to touch diseased spots if it can do nothing else but cause pain. But, as we know, a surgeon does not refrain from examining and handling a focus of disease, if he is intending to take active measures which he believes will lead to a permanent cure. No one thinks of blaming him for the inevitable suffering caused by the examination or for the reactions to the operation, if only it gains its end and the patient achieves a lasting recovery as a result of the temporary worsening of his state. The case is similar with psycho-analysis. It may make the same claims as surgery: the increase in suffering which it causes the patient during treatment is incomparably less than what a surgeon causes, and is quite negligible in proportion to the severity of the underlying ailment. On the other hand, the final outcome that is so much dreaded - the destruction of the patient's cultural character by the instincts which have been set free from repression - is totally impossible. For alarm on this score takes no account of what our experiences have taught us with certainty - namely that the mental and somatic power of a wishful impulse, when once its repression has failed, is far stronger if it is unconscious than if it is conscious; so that to make it conscious can only be to weaken it. An unconscious wish cannot be influenced and it is independent of any contrary tendencies, whereas a conscious one is inhibited by whatever else is conscious and opposed to it. Thus the work of psycho-analysis puts itself at the orders of precisely the highest and most valuable cultural trends, as a better substitute for the unsuccessful repression.

Appropriate experiments have shown that people who are hysterically blind do nevertheless see in some sense, though not in the full sense. Excitations of the blind eye may have certain psychical consequences (for instance, they may produce affects) even though they do not become conscious. Thus hysterically blind people are only blind as far as consciousness is concerned; in their unconscious they see. It is precisely observations such as this that compel us to distinguish between conscious and unconscious mental processes.

A conception - or any other psychical element - which is now present to my consciousness may become absent the next moment, and may become present again, after an interval, unchanged, and, as we say, from memory, not as a result of a fresh perception by our senses. It is this fact which we are accustomed to account for by the supposition that during the interval the conception has been present in our mind, although latent in consciousness. In what shape it may have existed while present in the mind and latent in consciousness we have no means of guessing.

This might be considered an uninteresting piece of descriptive or classificatory work if no experience appealed to our judgement other than the facts of memory, or the cases of association by unconscious links. The well-known experiment, however, of the 'post-hypnotic suggestion' teaches us to insist upon the importance of the distinction between conscious and unconscious and seems to increase its value.
Now we do not know whether these two modes of psychical activity are identical or essentially divergent from their beginning, but we may ask why they should become different in the course of psychical action. To this last question psycho-analysis gives a clear and unhesitating answer. It is by no means impossible for the product of unconscious activity to pierce into consciousness, but a certain amount of exertion is needed for this task. When we try to do it in ourselves, we become aware of a distinct feeling of repulsion¹ which must be overcome, and when we produce it in a patient we get the most unquestionable signs of what we call his resistance to it. So we learn that the unconscious idea is excluded from consciousness by living forces which oppose themselves to its reception, while they do not object to other ideas, the foreconscious ones. Psycho-analysis leaves no room for doubt that the repulsion from unconscious ideas is only provoked by the tendencies embodied in their contents. The next and most probable theory which can be formulated at this stage of our knowledge is the following.

Unconsciousness is a regular and inevitable phase in the processes constituting our psychical activity; every psychical act begins as an unconscious one, and it may either remain so or go on developing into consciousness, according as it meets with resistance or not. The distinction between foreconscious and unconscious activity is not a primary one, but comes to be established after repulsion has sprung up. Only then the difference between foreconscious ideas, which can appear in consciousness and reappear at any moment, and unconscious ideas which cannot do so gains a theoretical as well as a practical value. A rough but not inadequate analogy to this supposed relation of conscious to unconscious activity might be drawn from the field of ordinary photography. The first stage of the photograph is the 'negative'; every photographic picture has to pass through the 'negative process', and some of these negatives which have held good in examination are admitted to the 'positive process' ending in the picture.

[1912g, 2581]

Unconsciousness seemed to us at first only an enigmatical characteristic of a definite psychical act. Now it means more for us. It is a sign that this act partakes of the nature of a certain psychical category known to us by other and more important characters¹ and that it belongs to a system of psychical activity which is deserving of our fullest attention. The index-value of the unconscious has far outgrown its importance as a property. The system revealed by the sign that the single acts forming parts of it are unconscious we designate by the name 'The Unconscious', for want of a better and less ambiguous term. In German, I propose to denote this system by the letters Ubw, an abbreviation of the German word 'Unbewusst'.² And this is the third and most significant sense which the term 'unconscious' has acquired in psycho-analysis.

[1912g, 2583]

The projection of their own evil impulses into demons is only one portion of a system which constituted the Weltanschauung of primitive peoples, and which we shall come to know as 'animism' in the following essay. There we shall have to investigate that system's psychological characteristics, and we shall do so once again by reference to the similar systems which we find constructed by neurotics. For the moment I will only say that the prototype of all such systems is what we have termed the 'secondary revision' of the content of dreams. And we must not forget that, at and after the stage at which systems are constructed, two sets of reasons can be assigned for every psychical event that is consciously judged - one set belonging to the system and the other set real but unconscious.¹

[1912-1913, 2709]
It is not, of course, to be expected that either the primitive or the present-day concept of a 'soul' will be separated from that of the other portion of the personality by the same line of demarcation which our modern science draws between conscious and unconscious mental activity. The animistic soul unites properties from both sides. Its volatile and mobile quality, its power of leaving the body and of taking possession, temporarily or permanently, of another body - these are characteristics which remind us unmistakably of the nature of consciousness. But the way in which it remains concealed behind the manifest personality is reminiscent of the unconscious; immutability and indestructibility are qualities which we no longer attribute to conscious but rather to unconscious processes, and we regard the latter as the true vehicle of mental activity.

A study of the dream-work forces on us irresistibly a view of mental life which appears to decide the most controversial problems of psychology. The dream-work compels us to assume the existence of an unconscious psychical activity which is more comprehensive and more important than the familiar activity that is linked with consciousness. (I shall have some more to say on this point when I come to discuss the philosophical interest of psycho-analysis.) It enables us to dissect the psychical apparatus into a number of different agencies or systems, and shows us that in the system of unconscious mental activity processes operate which are of quite another kind from those perceived in consciousness.

The psychological novelties inferred from dreams and parapraxes must be applicable as an explanation of other phenomena if we are to believe in the value of these novelties, or, indeed, in their existence. And we do in fact find that psycho-analysis has shown that the hypotheses of unconscious mental activity, of censorship and repression and of distortion and substitution, at which we have arrived from our study of these normal phenomena, also afford us a first understanding of a number of pathological phenomena and, as one might say, put into our hands the key to all the riddles of the psychology of the neuroses. Thus dreams are to be regarded as the normal prototypes of all psychopathological structures. Anyone who understands dreams can also grasp the psychical mechanism of the neuroses and psychoses.

The language of dreams may be looked upon as the method by which unconscious mental activity expresses itself. But the unconscious speaks more than one dialect. According to the differing psychological conditions governing and distinguishing the various forms of neurosis, we find regular modifications in the way in which unconscious mental impulses are expressed. While the gesture-language of hysteria agrees on the whole with the picture-language of dreams and visions, etc., the thought-language of obsessional neurosis and of the paraphrenias (dementia praecox and paranoia) exhibits special idiomatic peculiarities which, in a number of instances, we have been able to understand and interrelate. For instance, what a hysterical expresses by vomiting an obsessional will express by painstaking protective measures against infection, while a paraphrenic will be led to complaints or suspicions that he is being poisoned. These are all of them different representations of the patient's wish to become pregnant which have been repressed into the unconscious, or of his defensive reaction against that wish.
Philosophy, in so far as it is built on psychology, will be unable to avoid taking the psychoanalytic contributions to psychology fully into account and reacting to this new enrichment of our knowledge just as it has to every considerable advance in the specialized sciences. In particular, the setting up of the hypothesis of unconscious mental activities must compel philosophy to decide one way or the other and, if it accepts the idea, to modify its own views on the relation of mind to body so that they may conform to the new knowledge. It is true that philosophy has repeatedly dealt with the problem of the unconscious, but, with few exceptions, philosophers have taken up one or other of the two following positions. Either their unconscious has been something mystical, something intangible and undemonstrable, whose relation to the mind has remained obscure, or they have identified the mental with the conscious and have proceeded to infer from this definition that what is unconscious cannot be mental or a subject for psychology. These opinions must be put down to the fact that philosophers have formed their judgement on the unconscious without being acquainted with the phenomena of unconscious mental activity, and therefore without any suspicion of how far unconscious phenomena resemble conscious ones or of the respects in which they differ from them. If anyone possessing that knowledge nevertheless holds to the conviction which equates the conscious and the psychical and consequently denies the unconscious the attribute of being psychical, no objection can, of course, be made except that such a distinction turns out to be highly unpractical. For it is easy to describe the unconscious and to follow its developments if it is approached from the direction of its relation to the conscious, with which it has so much in common. On the other hand, there still seems no possibility of approaching it from the direction of physical events. So that it is bound to remain a matter for psychological study.

As a psycho-analyst I am bound to be concerned more with emotional than intellectual processes, with unconscious than with conscious mental life. My emotion at meeting my old schoolmaster warns me to make a first admission: it is hard to decide whether what affected us more and was of greater importance to us was our concern with the sciences that we were taught or with the personalities of our teachers. It is true, at least, that this second concern was a perpetual undercurrent in all of us, and that in many of us the path to the sciences led only through our teachers. Some of us stopped half-way along that path, and for a few - why not admit as much? - it was on that account blocked for good and all.

The theory of repression is the corner-stone on which the whole structure of psycho-analysis rests. It is the most essential part of it; and yet it is nothing but a theoretical formulation of a phenomenon which may be observed as often as one pleases if one undertakes an analysis of a neurotic without resorting to hypnosis. In such cases one comes across a resistance which opposes the work of analysis and in order to frustrate it pleads a failure of memory. The use of hypnosis was bound to hide this resistance; the history of psycho-analysis proper, therefore, only begins with the new technique that dispenses with hypnosis. The theoretical consideration of the fact that this resistance coincides with an amnesia leads inevitably to the view of unconscious mental activity which is peculiar to psycho-analysis and which, too, distinguishes it quite clearly from philosophical speculations about the unconscious. It may thus be said that the theory of psycho-analysis is an attempt to account for two striking and unexpected facts of observation which emerge whenever an attempt is made to trace the symptoms of a neurotic back to their sources in his past life: the facts of transference and of resistance. Any line of investigation which recognizes these two facts and takes them as the starting-point of its work has a right to call itself psycho-analysis, even though it arrives at results other than my own. But anyone who takes up other sides of the problem while avoiding these two hypotheses will hardly escape a charge of misappropriation of property by attempted impersonation, if he persists in calling himself a psycho-analyst.
Another path led from the investigation of dreams to the analysis of works of imagination and ultimately to the analysis of their creators - writers and artists themselves. At an early stage it was discovered that dreams invented by writers will often yield to analysis in the same way as genuine ones. (Cf. 'Gradiva'.) The conception of unconscious mental activity made it possible to form a preliminary idea of the nature of imaginative creative writing; and the realization, gained in the study of neurotics, of the part played by the instinctual impulses enabled us to perceive the sources of artistic production and confronted us with two problems: how the artist reacts to this instigation and what means he employs to disguise his reactions.¹ Most analysts with general interests have contributed something to the solution of these problems, which are the most fascinating among the applications of psycho-analysis. Naturally, opposition was not lacking in this direction either on the part of people who knew nothing of analysis; it took the same form as it did in the original field of psycho-analytic research - the same misconceptions and vehement rejections. It was only to be expected from the beginning that, whatever the regions into which psycho-analysis might penetrate, it would inevitably experience the same struggles with those already in possession of the field. These attempted invasions, however, have not yet stirred up the attention in some quarters which awaits them in the future. Among the strictly scientific applications of analysis to literature, Rank's exhaustive work on the theme of incest easily takes the first place. Its subject is bound to arouse the greatest unpopularity. Up to the present, little work based on psycho-analysis has been done in the sciences of language and history. I myself ventured the first approach to the problems of the psychology of religion by drawing a parallel between religious ritual and the ceremonials of neurotics (1907b). Dr. Pfister, a pastor in Zurich, has traced back the origin of religious fanaticism to perverse eroticism in his book on the piety of Count von Zinzendorf, as well as in other contributions. In the latest works of the Zurich school, however, we find analysis permeated with religious ideas rather than the opposite outcome that had been in view.

[1914d, 2902]
The first task confronting psycho-analysis was to explain the neuroses; it used the two facts of resistance and transference as starting-points, and, taking into consideration the third fact of amnesia, accounted for them with its theories of repression, of the sexual motive forces in neurosis and of the unconscious. Psycho-analysis has never claimed to provide a complete theory of human mentality in general, but only expected that what it offered should be applied to supplement and correct the knowledge acquired by other means. Adler's theory, however, goes far beyond this point; it seeks at one stroke to explain the behaviour and character of human beings as well as their neurotic and psychotic illnesses. It is actually more suited to any other field than that of neurosis, although for reasons connected with the history of its development it still places this in the foreground. For many years I had opportunities of studying Dr. Adler and have never refused to recognize his unusual ability, combined with a particularly speculative disposition. As an instance of the 'persecution' to which he asserts he has been subjected by me, I can point to the fact that after the Association was founded I made over to him the leadership of the Vienna group. It was not until urgent demands were put forward by all the members of the society that I let myself be persuaded to take the chair again at its scientific meetings. When I perceived how little gift Adler had precisely for judging unconscious material, my view changed to an expectation that he would succeed in discovering the connections of psycho-analysis with psychology and with the biological foundations of instinctual processes - an expectation which was in some sense justified by the valuable work he had done on 'organ-inferiority'. And he did in fact effect something of the kind; but his work conveys an impression 'as if' - to speak in his own 'jargon' - it was intended to prove that psycho-analysis was wrong in everything and that it had only attributed so much importance to sexual motive forces because of its credulity in accepting the assertions of neurotics. I may even speak publicly of the personal motive for his work, since he himself announced it in the presence of a small circle of members of the Vienna group: - 'Do you think it gives me such great pleasure to stand in your shadow my whole life long?' To be sure, I see nothing reprehensible in a younger man freely admitting his ambition, which one would in any case guess was among the incentives for his work. But even though a man is dominated by a motive of this kind he should know how to avoid being what the English, with their fine social tact, call 'unfair' - which in German can only be expressed by a much cruder word. How little Adler has succeeded in this is shown by the profusion of petty outbursts of malice which disfigure his writings and by the indications they contain of an uncontrolled craving for priority. At the Vienna Psycho-Analytical Society we once actually heard him claim priority for the conception of the 'unity of the neuroses' and for the 'dynamic view' of them. This came as a great surprise to me, for I had always believed that these two principles were stated by me before I ever made Adler's acquaintance. [1914d, 2913]
I will not dwell any longer on the biological aspect of the Adlerian theory nor discuss whether either actual 'organ-inferiority' or the subjective feeling of it - one does not know which - is really capable of serving as the foundation of Adler's system. I will merely remark in passing that if it were so neurosis would appear as a by-product of every kind of physical decrepitude, whereas observation shows that an impressive majority of ugly, misshapen, crippled and miserable people fail to react to their defects by neurosis. Nor will I deal with the interesting assertion according to which inferiority is to be traced back to the feeling of being a child. It shows the disguise under which the factor of infantilism, which is so strongly emphasized by psycho-analysis, re-appears in 'Individual Psychology'. On the other hand, I must point out how all the psychological acquisitions of psycho-analysis have been thrown to the winds by Adler. In his book Über den nervösen Charakter the unconscious is still mentioned as a psychological peculiarity, without, however, any relation to his system. Later, he has consistently declared that it is a matter of indifference to him whether an idea is conscious or unconscious. Adler has never from the first shown any understanding of repression. In an abstract of a paper read by him at the Vienna Society (February, 1911) he wrote that it must be pointed out that the evidence in a particular case showed that the patient had never repressed his libido, but had been continually 'safeguarding' himself against it. Soon afterwards, in a discussion at the Vienna Society, he said: 'If you ask where repression comes from, you are told, "from civilization"; but if you go on to ask where civilization comes from, you are told "from repression". So you see it is all simply playing with words.' A tithe of the acuteness and ingenuity with which Adler has unmasked the defensive devices of the 'nervous character' would have been enough to show him the way out of this pettifogging argument. What is meant is simply that civilization is based on the repressions effected by former generations, and that each fresh generation is required to maintain this civilization by effecting the same repressions. I once heard of a child who thought people were laughing at him, and began to cry, because when he asked where eggs come from he was told 'from hens', and when he went on to ask where hens come from he was told 'from eggs'. But they were not playing with words; on the contrary, they were telling him the truth.

[1914d, 2919]

The total incompatibility of this new movement with psycho-analysis shows itself too, of course, in Jung's treatment of repression, which is hardly mentioned nowadays in his writings, in his misunderstanding of dreams, which, like Adler, in complete disregard of dream-psychology, he confuses with the latent dream-thoughts, and in his loss of all understanding of the unconscious - in short, in all the points which I should regard as the essence of psycho-analysis. When Jung tells us that the incest-complex is merely 'symbolic', that after all it has no 'real' existence, that after all a savage feels no desire towards an old hag but prefers a young and pretty woman, we are tempted to conclude that 'symbolic' and 'without real existence' simply mean something which, in virtue of its manifestations and pathogenic effects, is described by psycho-analysis as 'existing unconsciously' - a description that disposes of the apparent contradiction.

[1914d, 2926]
This process of inference, when applied to oneself in spite of internal opposition, does not, however, lead to the disclosure of an unconscious; it leads logically to the assumption of another, second consciousness which is united in one's self with the consciousness one knows. But at this point, certain criticisms may fairly be made. In the first place, a consciousness of which its own possessor knows nothing is something very different from a consciousness belonging to another person, and it is questionable whether such a consciousness, lacking, as it does, its most important characteristic, deserves any discussion at all. Those who have resisted the assumption of an unconscious *psychical* are not likely to be ready to exchange it for an unconscious *consciousness*. The second place, analysis shows that the different latent mental processes inferred by us enjoy a high degree of mutual independence, as though they had no connection with one another, and knew nothing of one another. We must be prepared, if so, to assume the existence in us not only of a second consciousness, but of a third, fourth, perhaps of an unlimited number of states of consciousness, all unknown to us and to one another. In the third place - and this is the most weighty argument of all - we have to take into account the fact that analytic investigation reveals some of these latent processes as having characteristics and peculiarities which seem alien to us, or even incredible, and which run directly counter to the attributes of consciousness with which we are familiar. Thus we have grounds for modifying our inference about ourselves and saying that what is proved is not the existence of a second consciousness in us, but the existence of psychical acts which lack consciousness. We shall also be right in rejecting the term 'subconsciousness' as incorrect and misleading. The well-known cases of 'double conscience'¹ (splitting of consciousness) prove nothing against our view. We may most aptly describe them as cases of a splitting of the mental activities into two groups, and say that the same consciousness turns to one or the other of these groups alternately.

[1915e, 2994]

In psycho-analysis there is no choice for us but to assert that mental processes are in themselves unconscious, and to liken the perception of them by means of consciousness to the perception of the external world by means of the sense-organs. We can even hope to gain fresh knowledge from the comparison. The psycho-analytic assumption of unconscious mental activity appears to us, on the one hand, as a further expansion of the primitive animism which caused us to see copies of our own consciousness all around us, and, on the other hand, as an extension of the corrections undertaken by Kant of our views on external perception. Just as Kant warned us not to overlook the fact that our perceptions are subjectively conditioned and must not be regarded as identical with what is perceived though unknowable, so psycho-analysis warns us not to equate perceptions by means of consciousness with the unconscious mental processes which are their object. Like the physical, the psychical is not necessarily in reality what it appears to us to be. We shall be glad to learn, however, that the correction of internal perception will turn out not to offer such great difficulties as the correction of external perception - that internal objects are less unknowable than the external world.

[1915e, 2995]
Before going any further, let us state the important, though inconvenient, fact that the attribute of being unconscious is only one feature that is found in the psychical and is by no means sufficient fully to characterize it. There are psychical acts of very varying value which yet agree in possessing the characteristic of being unconscious. The unconscious comprises, on the one hand, acts which are merely latent, temporarily unconscious, but which differ in no other respect from conscious ones and, on the other hand, processes such as repressed ones, which if they were to become conscious would be bound to stand out in the crudest contrast to the rest of the conscious processes. It would put an end to all misunderstandings if, from now on, in describing the various kinds of psychical acts we were to disregard the question of whether they were conscious or unconscious, and were to classify and correlate them only according to their relation to instincts and aims, according to their composition and according to which of the hierarchy of psychical systems they belong to. This, however, is for various reasons impracticable, so that we cannot escape the ambiguity of using the words 'conscious' and 'unconscious' sometimes in a descriptive and sometimes in a systematic sense, in which latter they signify inclusion in particular systems and possession of certain characteristics. We might attempt to avoid confusion by giving the psychical systems which we have distinguished certain arbitrarily chosen names which have no reference to the attribute of being conscious. Only we should first have to specify what the grounds are on which we distinguish the systems, and in doing this we should not be able to evade the attribute of being conscious, seeing that it forms the point of departure for all our investigations. Perhaps we may look for some assistance from the proposal to employ, at any rate in writing, the abbreviation Cs. for consciousness and Ucs. for what is unconscious, when we are using the two words in the systematic sense.

[1915e, 2996]

Let us now leave primaeval man, and turn to the unconscious in our own mental life. Here we depend entirely upon the psycho-analytic method of investigation, the only one which reaches to such depths. What, we ask, is the attitude of our unconscious towards the problem of death? The answer must be: almost exactly the same as that of primaeval man. In this respect, as in many others, the man of prehistoric times survives unchanged in our unconscious. Our unconscious, then, does not believe in its own death; it behaves as if it were immortal. What we call our 'unconscious' - the deepest strata of our minds, made up of instinctual impulses - knows nothing that is negative, and no negation; in it contradictories coincide. For that reason it does not know its own death, for to that we can give only a negative content. Thus there is nothing instinctual in us which responds to a belief in death. This may even be the secret of heroism. The rational grounds for heroism rest on a judgement that the subject's own life cannot be so precious as certain abstract and general goods. But more frequent, in my view, is the instinctive and impulsive heroism which knows no such reasons, and flouts danger in the spirit of Anzengruber's Steinklopfers: 'Nothing can happen to me'. Or else those reasons only serve to clear away the hesitations which might hold back the heroic reaction that corresponds to the unconscious. The fear of death, which dominates us oftener than we know, is on the other hand something secondary, and is usually the outcome of a sense of guilt.

[1915b, 3088]

Any peculiarities of this book which may strike its readers are accounted for by the conditions in which it originated. It was not possible in my presentation to preserve the unruffled calm of a scientific treatise. On the contrary, the lecturer had to make it his business to prevent his audience's attention from lapsing during a session lasting for almost two hours. The necessities of the moment often made it impossible to avoid repetitions in treating some particular subject - it might emerge once, for instance, in connection with dream-interpretation and then again later on in connection with the problems of the neuroses. As a result, too, of the way in which the material was arranged, some important topics (the unconscious, for instance) could not be exhaustively treated at a single point, but had to be taken up repeatedly and then dropped again until a fresh opportunity arose for adding some further information about it.

[1916-1917, 3126]
The first of these unpopular assertions made by psycho-analysis declares that mental processes are in themselves unconscious and that of all mental life it is only certain individual acts and portions that are conscious. You know that on the contrary we are in the habit of identifying what is psychical with what is conscious. We look upon consciousness as nothing more nor less than the defining characteristic of the psychical, and psychology as the study of the contents of consciousness. Indeed it seems to us so much a matter of course to equate them in this way that any contradiction of the idea strikes us as obvious nonsense. Yet psycho-analysis cannot avoid raising this contradiction; it cannot accept the identity of the conscious and the mental. It defines what is mental as processes such as feeling, thinking and willing, and it is obliged to maintain that there is unconscious thinking and unapprehended willing. In saying this it has from the start frivolously forfeited the sympathy of every friend of sober scientific thought, and laid itself open to the suspicion of being a fantastic esoteric doctrine eager to make mysteries and fish in troubled waters. But you, Ladies and Gentlemen, naturally cannot understand as yet what right I have to describe as a prejudice a statement of so abstract a nature as 'what is mental is conscious'. Nor can you guess what development can have led to a denial of the unconscious - should such a thing exist - and what advantage there may have been in that denial. The question whether we are to make the psychical coincide with the conscious or make it extend further sounds like an empty dispute about words; yet I can assure you that the hypothesis of there being unconscious mental processes paves the way to a decisive new orientation in the world and in science.

[1916-1917, 3134]

You will point out to me that I am once more introducing an assumption, the second already in this short argument, and that in doing so I am enormously reducing my procedure's claim to credibility: 'Subject to the premiss that dreams are psychical phenomena, and subject to the further premiss that there are mental things in a man which he knows without knowing that he knows them.' and so on. If so, one has only to consider the internal improbability of each of these two premisses, and one can quietly divert one's interest from any conclusions that may be based on them.

[1916-1917, 3200]

Where, then, in what field, can it be that proof has been found that there is knowledge of which the person concerned nevertheless knows nothing, as we are proposing to assume of dreamers? After all, this would be a strange, surprising fact and one which would alter our view of mental life and which would have no need to hide itself: a fact, incidentally, which cancels itself in its very naming and which nevertheless claims to be something real - a contradiction in terms. Well, it does not hide itself. It is not its fault if people know nothing about it or do not pay enough attention to it. Any more than we are to blame because judgement is passed on all these psychological problems by people who have kept at a distance from all the observations and experiences which are decisive on the matter.

[1916-1917, 3201]
I hope you will be surprised that this fact has been established and will ask me: 'Why did you omit to bring this proof forward earlier, in connection with the parapraxes, when we came to the point of attributing to a man who had made a slip of the tongue an intention to say things of which he knew nothing and which he denied? If a person thinks he knows nothing of experiences the memory of which he nevertheless has within him, it is no longer so improbable that he knows nothing of other mental processes within him. This argument would certainly have impressed us, and helped us to understand parapraxes.' Of course I could have brought it forward then, but I reserved it for another place, where it was more needed. The parapraxes explained themselves in part, and in part left us with a suggestion that, in order to preserve the continuity of the phenomena concerned, it would be wise to assume the existence of mental processes of which the subject knows nothing. In the case of dreams we are compelled to bring in explanations from elsewhere and moreover I expect that in their case you will find it easier to accept my carrying over of the explanations from hypnosis. The state in which a parapraxis occurs is bound to strike you as being the normal one; it has no similarity with the hypnotic state. On the other hand there an obvious kinship between the hypnotic state and the state of sleep, which is a necessary condition of dreaming. Hypnosis, indeed, is described as an artificial sleep. We tell the person we are hypnotizing to sleep, and the suggestions we make are comparable to the dreams of natural sleep. The psychical situations in the two cases are really analogous. In natural sleep we withdraw our interest from the whole external world; and in hypnotic sleep we also withdraw it from the whole world, but with the single exception of the person who has hypnotized us and with whom we remain in rapport. Incidentally, the sleep of a nursing mother, who remains in rapport with her child and can be woken only by him, is a normal counterpart of hypnotic sleep. So it scarcely seems a very bold venture to transpose a situation from hypnosis to natural sleep. The assumption that in a dreamer too a knowledge about his dreams is present, though it is inaccessible to him so that he himself does not believe it, is not something entirely out of the blue. It should be noticed, moreover, that a third line of approach to the study of dreams is opened at this point: from the stimuli which disturb sleep, from day-dreams, and now in addition from the suggested dreams of the hypnotic state.

If then things that occur to one quite freely are determined in this way and form parts of a connected whole, we shall no doubt be justified in concluding that things that occur to one with a single link - namely their link with the idea which serves as their starting-point - cannot be any less determined. Investigation shows, in fact, that, apart from the link we have given them with the initial idea, they are found to be dependent as well on groups of strongly emotional thoughts and interests, 'complexes', whose participation is not known at the moment - that is to say, is unconscious.

LADIES AND GENTLEMEN, - As you see, our study of parapraxes has not been unprofitable. Thanks to our labours over them we have, subject to the premisses I have explained to you, achieved two things: a conception of the nature of dream-elements and a technique for interpreting dreams. The conception of dream-elements tells us that they are unguenuine things, substitutes for something else that is unknown to the dreamer (like the purpose of a parapraxis), substitutes for something the knowledge of which is present in the dreamer but which is inaccessible to him. We are in hopes that it will be possible to carry over the same conception to whole dreams, which are made up of such elements. Our technique lies in employing free association to these elements in order to bring about the emergence of other substitutive structures, which will enable us to arrive at what is concealed from view.
I now propose that we should introduce a change into our nomenclature which will give us more freedom of movement. Instead of speaking of 'concealed', 'inaccessible', or 'ungenuine', let us adopt the correct description and say 'inaccessible to the dreamer's consciousness' or 'unconscious'. I mean nothing else by this than what may be suggested to you when you think of a word that has escaped you or the disturbing purpose in a parapraxis - that is to say, I mean nothing else than 'unconscious at the moment'. In contrast to this, we can of course speak of the dream-elements themselves, and the substitutive ideas that have been newly arrived at from them by association, as 'conscious'. This nomenclature so far involves no theoretical construction. No objection can be made to using the word 'unconscious' as an apt and easily understandable description.

Furthermore, we have not got nearly far enough yet to be able to feel indignant at this result of our work of interpretation. We do not yet, I think, understand it properly; but our first duty is to defend it against certain aspersions. There is no difficulty in finding a weak point in it. Our dream-interpretations are made on the basis of the premisses which we have already accepted - that dreams in general have a sense, that it is legitimate to carry across from hypnotic to normal sleep the fact of the existence of mental processes which are at the time unconscious, and that everything that occurs to the mind is determined. If on the basis of these premisses we had arrived at plausible findings from dream-interpretation, we should have been justified in concluding that the premisses were valid. But how about it if these findings seem to be as I have pictured them? We should then be tempted to say: 'These are impossible, senseless or at the least most improbable findings; so there was something wrong about the premisses. Either dreams are not psychical phenomena, or there is nothing unconscious in the normal state, or our technique has a flaw in it. Is it not simpler and more satisfactory to suppose this rather than accept all the abominations which we are supposed to have discovered on the basis of our premisses?'

No, not even now. Even this stronger argument collapses if we examine it critically. Granted that there are unconscious purposes in mental life, nothing is proved by showing that purposes opposed to these are dominant in conscious life. Perhaps there is room in the mind for contrary purposes, for contradictions, to exist side by side. Possibly, indeed, the dominance of one impulse is precisely a necessary condition of its contrary being unconscious. We are after all left, then, with the first objections that were raised: the findings of dream-interpretation are not simple and they are very disagreeable. We may reply to the first that all your passion for what is simple will not be able to solve a single one of the problems of dreams. You must get accustomed here to assuming a complicated state of affairs. And we may reply to the second that you are plainly wrong to use a liking or disliking that you may feel as the ground for a scientific judgement. What difference does it make if the findings of dream-interpretation seem disagreeable to you or, indeed, embarrassing and repulsive. 'Ça n'empêche pas d'exister!', as I heard my teacher Charcot say in a similar case when I was a young doctor. One must be humble and hold back one's sympathies and antipathies if one wants to discover what is real in this world. If a physicist were able to prove to you that in a short period organic life on this earth would be brought to an end by freezing, would you venture to make the same reply to him: 'That cannot be so, the prospect is too disagreeable'? You would, I think, be silent, until another physicist came and pointed out to the first one an error in his premisses or calculations. When you reject something that is disagreeable to you, what you are doing is repeating the mechanism of constructing dreams rather than understanding it and surmounting it.
But it would be unfair if we neglected at this point to emphasize sufficiently another outcome of our investigations. The dream-wishes which seek to disturb us in our sleep are unknown to us and indeed we only learnt of them through dream-interpretation. They are thus to be described, in the sense we have discussed, as unconscious for the time being. But we must reflect that they are unconscious too for more than the time being. The dreamer also disavows them, as we have seen in so many instances, after he has come to know them through the interpretation of his dream. We are then faced once again with the position we first came across in the 'hiccoughing' slip of the tongue, where the proposer of the toast protested indignantly that neither then nor at any earlier time had he become conscious of any disrespectful impulse towards his Chief. Already at the time we felt some doubts about the weight of an assurance of this kind, and suggested instead the hypothesis that the speaker was permanently unaware of the presence of this impulse in him. This situation is repeated now with every interpretation of a strongly distorted dream and consequently gains an increased importance in its bearing on the view we have taken. We are now prepared to assume that there are in the mind processes and purposes of which one knows nothing at all has known nothing for a long time, and has even perhaps never known anything. With this the unconscious acquires a new sense for us; the characteristic of 'for the time being' or 'temporary' disappears from its essential nature. It can mean permanently unconscious and not merely 'latent at the time'. We shall of course have to hear more about this on some other occasion.

I am also aware that we are not yet able to make a survey of the whole of the new acquisitions which these studies have brought to psychology. I will only point out the fresh proofs they have provided of the existence of unconscious mental acts - for this is what the latent dream-thoughts are - and what an unimaginably broad access to a knowledge of unconscious mental life we are promised by the interpretation of dreams.

As the outcome of our whole enquiry, let us grasp two discoveries, though they only signify the beginning of fresh enigmas and fresh doubts. First, the regression of the dream-work is not only a formal but also a material one. It not only translates our thoughts into a primitive form of expression; but it also revives the characteristics of our primitive mental life - the old dominance of the ego, the initial impulses of our sexual life, and even, indeed, our old intellectual endowment, if symbolic connections may be regarded as such. And secondly, all this, which is old and infantile and was once dominant and alone dominant, must to-day be ascribed to the unconscious, our ideas of which are now becoming altered and extended. 'Unconscious' is no longer the name of what is latent at the moment; the unconscious is a particular realm of the mind with its own wishful impulses, its own mode of expression and its peculiar mental mechanisms which are not in force elsewhere. But the latent dream-thoughts which we have discovered by interpreting dreams do not belong to this realm; they are on the contrary thoughts just as we might have thought them in waking life. Nevertheless, they are unconscious. How, then, is this contradiction to be solved? We begin to suspect that a distinction is to be drawn here. Something which is derived from our conscious life and shares its characteristics - we call it 'the day's residues' - combines with something else coming from the realm of the unconscious in order to construct a dream. The dream-work is accomplished between these two components. The influence exercised upon the day's residues by the addition of the unconscious is no doubt among the determinants of regression. This is the deepest insight that we can reach here into the essential nature of dreams - until we have investigated further regions of the mind. But the time will soon have come to provide another name for the unconscious character of the latent dream-thoughts in order to distinguish it from the unconscious which comes from the realm of the infantile.
I cannot tell what you will think of it, but I must assure you that I do not regret having claimed so much of your interest and of the time available to us for the problems of dreams. There is nothing else from which one can so quickly arrive at a conviction of the correctness of the theses by which psycho-analysis stands or falls. Exacting work over many months and even years is called for to show that the symptoms of a case of neurotic illness have a sense, serve a purpose and arise out of the patient's experiences in life. On the other hand, only a few hours' effort may be enough to prove that the same thing is true of a dream which is, to start with, confused to the point of being unintelligible, and thus to confirm all the premisses of psycho-analysis - the unconscious nature of mental processes, the peculiar mechanisms which they obey and the instinctual forces which are expressed in them. And when we bear in mind the sweeping analogy between the structure of dreams and that of neurotic symptoms and at the same time consider the rapidity of the transformation which makes a dreamer into a waking and reasonable man, we arrive at a certainty that neuroses too are based only on an alteration in the play of forces between the powers of mental life.

[1916-1917, 3324]

I notice now, Gentlemen, that I have been talking to you about a number of things which you are not yet prepared to understand. I did so in order to carry out the comparison between psychiatry and psycho-analysis. But there is one thing that I can ask you now. Have you observed any sign of a contradiction between them? Psychiatry does not employ the technical methods of psycho-analysis; it omits to make any inferences from the content of the delusion, and, in pointing to heredity, it gives us a very general and remote aetiology instead of indicating first the more special and proximate causes. But is there a contradiction, an opposition in this? Is it not rather a case of one supplementing the other? Does the hereditary factor contradict the importance of experience? Do not the two things rather combine in the most effective manner? You will grant that there is nothing in the nature of psychiatric work which could be opposed to psycho-analytic research. What is opposed to psycho-analysis is not psychiatry but psychiatrists. Psycho-analysis is related to psychiatry approximately as histology is to anatomy: the one studies the external forms of the organs, the other studies their construction out of tissues and cells. It is not easy to imagine a contradiction between these two species of study, of which one is a continuation of the other. To-day, as you know, anatomy is regarded by us as the foundation of scientific medicine. But there was a time when it was as much forbidden to dissect the human cadaver in order to discover the internal structure of the body as it now seems to be to practise psycho-analysis in order to learn about the internal mechanism of the mind. It is to be expected that in the not too distant future it will be realized that a scientifically based psychiatry is not possible without a sound knowledge of the deeper-lying unconscious processes in mental life.

[1916-1917, 3336]
The link with the scene after her unhappy wedding-night and the patient's affectionate motive constituted, taken together, what we have called the 'sense' of the obsessional action. But while she was carrying out the obsessional action this sense had been unknown to her in both directions - both its 'whence' and its 'whither'. Mental processes had therefore been at work in her and the obsessional action was the effect of them; she had been aware of this effect in a normal mental fashion, but none of the mental predeterminants of this effect came to the knowledge of her consciousness. She behaved in precisely the same way as a hypnotized subject whom Bernheim had ordered to open an umbrella in the hospital ward five minutes after he woke up. The man carried out this instruction when he was awake, but he could produce no motive for his action. It is a state of affairs of this sort that we have before our eyes when we speak of the existence of unconscious mental processes. We can challenge anyone in the world to give a more correct scientific account of this state of affairs, and if he does we will gladly renounce our hypothesis of unconscious mental processes. Till that happens, however, we will hold fast to the hypothesis; and if someone objects that here the unconscious is nothing real in a scientific sense, is a makeshift, une façon de parler, we can only shrug our shoulders resignedly and dismiss what he says as unintelligible. Something not real, which produces effects of such tangible reality as an obsessional action!
[1916-1917, 3354]

And we meet with what is in essence the same thing in our second patient. She had made a rule that the pillow must not touch the back of the bedstead, and she had to obey this rule though she did not know where it came from, what it meant or to what motives it owed its power. Whether she herself regarded the rule as a matter of indifference, or whether she struggled against it or raged against it or decided to transgress it - none of this made any difference to her carrying it out. It had to be obeyed, and she asked herself vainly why. We must recognize, however, that these symptoms of obsessional neurosis, these ideas and impulses which emerge one knows not whence, which prove so resistant to every influence from an otherwise normal mind, which give the patient himself the impression of being all-powerful guests from an alien world, immortal beings intruding into the turmoil of mortal life - these symptoms offer the plainest indication of there being a special region of the mind, shut off from the rest. They lead, by a path that cannot be missed, to a conviction of the existence of the unconscious in the mind; and that is precisely why clinical psychiatry, which is acquainted only with a psychology of consciousness, can deal with these symptoms in no other way than by declaring them to be signs of a special sort of degeneracy. Obsessional ideas and obsessional impulses are not, of course, themselves unconscious, any more than the performance of obsessional actions escapes conscious perception. They would not have become symptoms if they had not forced their way into consciousness. But their psychical predeterminants which we infer by means of analysis, the connections into which we insert them by interpretation, are unconscious, at least until we have made them conscious to the patient by the work of analysis.
[1916-1917, 3355]
If, now, you consider further that the state of affairs which we have established in our two cases is confirmed for every symptom of every neurotic illness - that always and everywhere the sense of the symptoms is unknown to the patient and that analysis regularly shows that these symptoms are derivatives of unconscious processes but can, subject to a variety of favourable circumstances, be made conscious - if you consider this, you will understand that in psychoanalysis we cannot do without what is at the same time unconscious and mental, and are accustomed to operate with it as though it were something palpable to the senses. But you will understand as well, perhaps, how incapable of forming a judgement on this question are all those other people, who are only acquainted with the unconscious as a concept, who have never carried out an analysis and have never interpreted dreams or found a sense and intention in neurotic symptoms. To say it for our ends once again: the possibility of giving a sense to neurotic symptoms by analytic interpretation is an unshakeable proof of the existence - or, if you prefer it, of the necessity for the hypothesis - of unconscious mental processes.

I find a parallel here which is not uninteresting. Whereas for most people 'conscious' and 'psychical' are the same, we have been obliged to extend the concept of 'psychical' and to recognize something 'psychical' that is not 'conscious'. And in just the same way, whereas other people declare that 'sexual' and 'connected with reproduction' (or, if you prefer to put it more shortly, 'genital') are identical, we cannot avoid postulating something 'sexual' that is not 'genital' - has nothing to do with reproduction. The similarity here is only a formal one, but it is not without a deeper foundation.

I have credited you with a wish that I might have started my description of the neuroses from the behaviour of neurotic people, from an account of the manner in which they suffer under their neurosis, of how they defend themselves against it and how they come to terms with it. No doubt that is an interesting topic, worth investigating; nor would it be very difficult to handle. But it would be of debatable wisdom to start with it. There would be a risk of not discovering the unconscious and at the same time of overlooking the great importance of the libido and of judging everything as it appears to the ego of the neurotic subject. It is obvious that this ego is not a trustworthy or impartial agency. The ego is indeed the power which disavows the unconscious and has degraded it into being repressed; so how can we trust it to be fair to the unconscious? The most prominent elements in what is thus repressed are the repudiated demands of sexuality, and it is quite self-evident that we should never be able to guess their extent and importance from the ego's conceptions. From the moment the notion of repression dawns on us, we are warned against making one of the two contesting parties (and the victorious one, at that) into being judge in the dispute. We are prepared to find that the ego's assertions will lead us astray. If we are to believe the ego, it was active at every point and itself willed and created its symptoms. But we know that it puts up with a good amount of passivity, which it afterwards tries to disguise and gloss over. It is true that it does not always venture on such an attempt; in the symptoms of obsessional neurosis it is obliged to admit that there is something alien which is confronting it and against which it can only defend itself with difficulty.
Probably very few people can have realized the momentous significance for science and life of the recognition of unconscious mental processes. It was not psycho-analysis, however, let us hasten to add, which first took this step. There are famous philosophers who may be cited as forerunners - above all the great thinker Schopenhauer, whose unconscious 'Will' is equivalent to the mental instincts of psycho-analysis. It was this same thinker, moreover, who in words of unforgettable impressiveness admonished mankind of the importance, still so greatly underestimated by it, of its sexual craving. Psycho-analysis has this advantage only, that it has not affirmed these two propositions which are so distressing to narcissism - the psychical importance of sexuality and the unconsciousness of mental life - on an abstract basis, but has demonstrated them in matters that touch every individual personally and force him to take up some attitude towards these problems. It is just for this reason, however, that it brings on itself the aversion and resistances which still hold back in awe before the great name of the philosopher.
[1917a, 3615]

For a time psycho-analysis seemed fated to merge into psychology without being able to show why the psychology of the sick differed from that of the normal. In the course of its advance, however, it came up against the problem of dreams, which are abnormal products of the mind created by normal men under regularly recurrent physiological conditions. When psycho-analysis had solved the problem of dreams, it had discovered in unconscious psychical processes the common ground in which the highest and the lowest of mental impulses have their roots and from which spring the most normal as well as the most morbid and erratic of mental productions. The new picture of the workings of the mind began to grow ever clearer and more complete. It was a picture of obscure instinctual forces organic in origin, striving towards inborn aims, and, above them, of an agency comprising more highly organized mental structures - acquisitions of human evolution made under the impact of human history - , an agency which has taken over portions of the instinctual impulses, has developed them further or has even directed them towards higher aims, but which in any case binds them firmly and manipulates their energy to suit its own purposes. This higher organization, however, which is known to us as the ego, has rejected another portion of these same elementary instinctual impulses as being unserviceable because they cannot be fitted into the organic unity of the individual or because they rebel against the individual's cultural aims. The ego is not in a position to exterminate these unsubdued mental powers, but it turns its back on them, lets them remain at the lowest psychological level, defends itself from their demands by the energetic erection of protective and antithetical barriers or seeks to come to terms with them by means of substitutive satisfactions. These instincts which have fallen victim to repression - untamed and indestructible, yet inhibited from any kind of activity - together with their primitive mental representatives, constitute the mental underworld, the nucleus of the true unconscious, and are at every moment ready to assert their demands and, by hook or by crook, to force their way forward to satisfaction. To this is due the instability of the proud superstructure of the mind, the emergence at night of the proscribed and repressed material in the form of dreams, and the tendency to fall ill with neuroses and psychoses as soon as the balance of power between the ego and the repressed shifts to the disadvantage of the ego.
[1919g, 3703]
Psycho-analytic speculation takes as its point of departure the impression, derived from examining unconscious processes, that consciousness may be, not the most universal attribute of mental processes, but only a particular function of them. Speaking in metapsychological terms, it asserts that consciousness is a function of a particular system which it describes as C.s. What consciousness yields consists essentially of perceptions of excitations coming from the external world and of feelings of pleasure and unpleasure which can only arise from within the mental apparatus; it is therefore possible to assign to the system Pcpt.-Cs a position in space. It must lie on the borderline between outside and inside; it must be turned towards the external world and must envelop the other psychical systems. It will be seen that there is nothing daringly new in these assumptions; we have merely adopted the views on localization held by cerebral anatomy, which locates the 'seat' of consciousness in the cerebral cortex - the outermost, enveloping layer of the central organ. Cerebral anatomy has no need to consider why, speaking anatomically, consciousness should be lodged on the surface of the brain instead of being safely housed somewhere in its inmost interior. Perhaps we shall be more successful in accounting for this situation in the case of our system Pcpt.-Cs.

Consciousness is not the only distinctive character which we ascribe to the processes in that system. On the basis of impressions derived from our psycho-analytic experience, we assume that all excitatory processes that occur in the other systems leave permanent traces behind in them which form the foundation of memory. Such memory-traces, then, have nothing to do with the fact of becoming conscious; indeed they are often most powerful and most enduring when the process which left them behind was one which never entered consciousness. We find it hard to believe, however, that permanent traces of excitation such as these are also left in the system Pcpt.-Cs. If they remained constantly conscious, they would very soon set limits to the system's aptitude for receiving fresh excitations. If, on the other hand, they were unconscious, we should be faced with the problem of explaining the existence of unconscious processes in a system whose functioning was otherwise accompanied by the phenomenon of consciousness. We should, so to say, have altered nothing and gained nothing by our hypothesis relegating the process of becoming conscious to a special system. Though this consideration is not absolutely conclusive, it nevertheless leads us to suspect that becoming conscious and leaving behind a memory-trace are processes incompatible with each other within one and the same system. Thus we should be able to say that the excitatory process becomes conscious in the system Cs. but leaves no permanent trace behind there; but that the excitation is transmitted to the systems lying next within and that it is in them that its traces are left. I followed these same lines in the schematic picture which I included in the speculative section of my Interpretation of Dreams. It must be borne in mind that little enough is known from other sources of the origin of consciousness; when, therefore, we lay down the proposition that consciousness arises instead of a memory-trace, the assertion deserves consideration, at all events on the ground of its being framed in fairly precise terms.

[1920g, 3729]
I cannot neglect this opportunity of expressing for once my astonishment that human beings can go through such great and important moments of their erotic life without noticing them much, sometimes even, indeed, without having the faintest suspicion of their existence, or else, having become aware of those moments, deceive themselves so thoroughly in their judgement of them. This happens not only under neurotic conditions, where we are familiar with the phenomenon, but seems also to be common enough in ordinary life. In the present case, for example, a girl develops a sentimental adoration for women, which her parents at first find merely vexatious and hardly take seriously; she herself knows quite well that she is very much occupied with these relationships, but still she experiences few of the sensations of intense love until a particular frustration is followed by a quite excessive reaction, which shows everyone concerned that they have to do with a consuming passion of elemental strength. Nor had the girl ever perceived anything of the state of affairs which was a necessary preliminary to the outbreak of this mental storm. In other cases, too, we come across girls or women in a state of severe depression, who on being asked for a possible cause of their condition tell us that they have, it is true, had a slight feeling for a certain person, but that it was nothing deep and that they soon got over it when they had to give it up. And yet it was this renunciation, apparently so easily borne, that became the cause of serious mental disturbance. Again, we come across men who have passed through casual love-affairs and realize only from the subsequent effects that they had been passionately in love with the person whom they had apparently regarded lightly. One is also amazed at the unexpected results that may follow an artificial abortion, the killing of an unborn child, which had been decided upon without remorse and without hesitation. It must be admitted that poets are right in liking to portray people who are in love without knowing it, or uncertain whether they do love, or who think that they hate when in reality they love. It would seem that the information received by our consciousness about our erotic life is especially liable to be incomplete, full of gaps, or falsified. Needless to say, in this discussion I have not omitted to allow for the part played by subsequent forgetting.

The Interpretation of Parapraxes and Haphazard Acts. - It was a triumph for the interpretative art of psycho-analysis when it succeeded in demonstrating that certain common mental acts of normal people, for which no one had hitherto attempted to put forward a psychological explanation, were to be regarded in the same light as the symptoms of neurotics: that is to say, they had a meaning, which was unknown to the subject but which could easily be discovered by analytic means. The phenomena in question were such events as the temporary forgetting of familiar words and names, forgetting to carry out prescribed tasks, everyday slips of the tongue and of the pen, misreadings, losses and mislayings of objects, certain errors, instances of apparently accidental self-injury, and finally habitual movements carried out seemingly without intention or in play, tunes hummed 'thoughtlessly', and so on. All of these were shorn of their physiological explanation, if any such had ever been attempted, were shown to be strictly determined and were revealed as an expression of the subject's suppressed intentions or as a result of a clash between two intentions one of which was permanently or temporarily unconscious. The importance of this contribution to psychology was of many kinds. The range of mental determinism was extended by it in an unforeseen manner; the supposed gulf between normal and pathological mental events was narrowed; in many cases a useful insight was afforded into the play of mental forces that must be suspected to lie behind the phenomena. Finally, a class of material was brought to light which is calculated better than any other to stimulate a belief in the existence of unconscious mental acts even in people to whom the hypothesis of something at once mental and unconscious seems strange and even absurd. The study of one's own parapraxes and haphazard acts, for which most people have ample opportunities, is even to-day the best preparation for an approach to psycho-analysis. In analytic treatment, the interpretation of parapraxes retains a place as a means of uncovering the unconscious, alongside the immeasurably more important interpretation of associations.

[1920a, 3855]

[1923a, 3917]
The division of the psychical into what is conscious and what is unconscious is the fundamental premiss of psycho-analysis; and it alone makes it possible for psycho-analysis to understand the pathological processes in mental life, which are as common as they are important, and to find a place for them in the framework of science. To put it once more, in a different way: psycho-analysis cannot situate the essence of the psychical in consciousness, but is obliged to regard consciousness as a quality of the psychical, which may be present in addition to other qualities or may be absent.

[1923b, 3947]

If I could suppose that everyone interested in psychology would read this book, I should also be prepared to find that at this point some of my readers would already stop short and would go no further; for here we have the first shibboleth of psycho-analysis. To most people who have been educated in philosophy the idea of anything psychical which is not also conscious is so inconceivable that it seems to them absurd and refutable simply by logic. I believe this is only because they have never studied the relevant phenomena of hypnosis and dreams, which - quite apart from pathological manifestations - necessitate this view. Their psychology of consciousness is incapable of solving the problems of dreams and hypnosis.

[1923b, 3947]

'Being conscious' is in the first place a purely descriptive term, resting on perception of the most immediate and certain character. Experience goes on to show that a psychical element (for instance, an idea) is not as a rule conscious for a protracted length of time. On the contrary, a state of consciousness is characteristically very transitory; an idea that is conscious now is no longer so a moment later, although it can become so again under certain conditions that are easily brought about. In the interval the idea was - we do not know what. We can say that it was latent, and by this we mean that it was capable of becoming conscious at any time. Or, if we say that it was unconscious, we shall also be giving a correct description of it. Here 'unconscious' coincides with 'latent and capable of becoming conscious'. The philosophers would no doubt object: 'No, the term "unconscious" is not applicable here; so long as the idea was in a state of latency it was not anything psychical at all.' To contradict them at this point would lead to nothing more profitable than a verbal dispute.

[1923b, 3948]

But we have arrived at the term or concept of the unconscious along another path, by considering certain experiences in which mental dynamics play a part. We have found - that is, we have been obliged to assume - that very powerful mental processes or ideas exist (and here a quantitative or economic factor comes into question for the first time) which can produce all the effects in mental life that ordinary ideas do (including effects that can in their turn become conscious as ideas), though they themselves do not become conscious. It is unnecessary to repeat in detail here what has been explained so often before. It is enough to say that at this point psycho-analytic theory steps in and asserts that the reason why such ideas cannot become conscious is that a certain force opposes them, that otherwise they could become conscious, and that it would then be apparent how little they differ from other elements which are admittedly psychical. The fact that in the technique of psycho-analysis a means has been found by which the opposing force can be removed and the ideas in question made conscious renders this theory irrefutable. The state in which the ideas existed before being made conscious is called by us repression, and we assert that the force which instituted the repression and maintains it is perceived as resistance during the work of analysis.

[1923b, 3948]
After hypnosis was replaced by the technique of free association, Breuer's cathartic procedure turned into psycho-analysis, which for more than a decade was developed by the author (Freud) alone. During that time psycho-analysis gradually acquired a theory which appeared to give a satisfactory account of the origin, meaning and purpose of neurotic symptoms and provided a rational basis for medical attempts at curing the complaint. I will once again enumerate the factors that go to make up this theory. They are: emphasis on instinctual life (affectivity), on mental dynamics, on the fact that even the apparently most obscure and arbitrary mental phenomena invariably have a meaning and a causation, the theory of psychical conflict and of the pathogenic nature of repression, the view that symptoms are substitutive satisfactions, the recognition of the aetiological importance of sexual life, and in particular of the beginnings of infantile sexuality. From a philosophical standpoint this theory was bound to adopt the view that the mental does not coincide with the conscious, that mental processes are in themselves unconscious and are only made conscious by the functioning of special organs (agencies or systems). By way of completing this list, I will add that among the affective attitudes of childhood the complicated emotional relation of children to their parents - what is known as the Oedipus complex - came into prominence. It became ever clearer that this was the nucleus of every case of neurosis, and in the patient's behaviour towards his analyst certain phenomena of his emotional transference emerged which came to be of great importance for theory and technique alike.

Evidence of its being of use for throwing light on other than pathological mental activity was early forthcoming in connection with two kinds of phenomena: with the very frequent parapraxes that occur in everyday life - such as forgetting things, slips of the tongue, and mislaying objects - and with the dreams dreamt by healthy and psychically normal people. Small failures of functioning, like the temporary forgetting of normally familiar proper names, slips of the tongue and of the pen, and so on, had hitherto not been considered worthy of any explanation at all or were supposed to be accounted for by conditions of fatigue, by distraction of the attention, etc. The present writer then showed from many examples, in his book *The Psychopathology of Everyday Life* (1901b), that events of this kind have a meaning, and arise owing to a conscious intention being interfered with by another, suppressed or actually unconscious one. As a rule, quick reflection or a short analysis is enough to reveal the interfering influence. Owing to the frequency of such parapraxes as slips of the tongue, it became easy for anyone to convince himself from his own experience of the existence of mental processes which are not conscious, but which are nevertheless operative and which at least find expression as inhibitions and modifications of other, intended acts.

If we may assume that the most general features of unconscious mental life (conflicts between instinctual impulses, repressions and substitutive satisfactions) are present everywhere, and if there is a depth-psychology which leads to a knowledge of those features, then we may reasonably expect that the application of psycho-analysis to the most varied spheres of human mental activity will everywhere bring to light important and hitherto unattainable results. In an exceedingly valuable study, Otto Rank and Hanns Sachs (1913) have tried to bring together what the work of psycho-analysts had been able to achieve up to that time towards fulfilling these expectations. Lack of space prevents me from attempting to complete their enumeration here. I can only select for mention the most important findings with the addition of a few details.
What, then, can a philosopher say to a theory which, like psycho-analysis, asserts that on the contrary what is mental is in itself unconscious and that being conscious is only a quality, which may or may not accrue to a particular mental act and the withholding of which may perhaps alter that act in no other respect? He will naturally say that anything both unconscious and mental would be an impossibility, a contradictio in adjecto, and he will fail to observe that in making this judgement he is merely repeating his own definition of what is mental, a definition which may perhaps be too narrow. It is easy for philosophers to feel this certainty, since they have no acquaintance with the material whose investigation has compelled analysts to believe in unconscious mental acts. Philosophers have never taken account of hypnosis, they have not concerned themselves with the interpreting of dreams - on the contrary, like doctors, they regard dreams as the meaningless products of reduced mental activity during sleep - they are scarcely aware that there are such things as obsessions and delusions and they would find themselves in a most embarrassing situation if they were asked to explain them on the basis of their own psychological premisses. Analysts, too, refuse to say what the unconscious is, but they can indicate the domain of phenomena whose observation has obliged them to assume its existence. Philosophers, who know no kind of observation other than self-observation, cannot follow them into that domain.

[1925e, 4124]

This implied, of course, that I abandoned the treatment of organic nervous diseases; but that was of little importance. For on the one hand the prospects in the treatment of such disorders were in any case never promising, while, on the other hand, in the private practice of a physician working in a large town, the quantity of such patients was nothing compared to the crowds of neurotics, whose number seemed further multiplied by the way in which they hurried, with their troubles unsolved, from one physician to another. And, apart from this, there was something positively seductive in working with hypnotism. For the first time there was a sense of having overcome one's helplessness; and it was highly flattering to enjoy the reputation of being a miracle-worker. It was not until later that I was to discover the drawbacks of the procedure. At the moment there were only two points to complain of: first, that I could not succeed in hypnotizing every patient, and secondly, that I was unable to put individual patients into as deep a state of hypnosis as I should have wished. With the idea of perfecting my hypnotic technique, I made a journey to Nancy in the summer of 1889 and spent several weeks there. I witnessed the moving spectacle of old Liébeault working among the poor women and children of the labouring classes. I was a spectator of Bernheim's astonishing experiments upon his hospital patients, and I received the profoundest impression of the possibility that there could be powerful mental processes which nevertheless remained hidden from the consciousness of men. Thinking it would be instructive, I had persuaded one of my patients to follow me to Nancy. This patient was a very highly gifted hysteric, a woman of good birth, who had been handed over to me because no one knew what to do with her. By hypnotic influence I had made it possible for her to lead a tolerable existence and I was always able to take her out of the misery of her condition. But she always relapsed again after a short time, and in my ignorance I attributed this to the fact that her hypnosis had never reached the stage of somnambulism with amnesia. Bernheim now attempted several times to bring this about, but he too failed. He frankly admitted to me that his great therapeutic successes by means of suggestion were only achieved in his hospital practice and not with his private patients. I had many stimulating conversations with him, and undertook to translate into German his two works upon suggestion and its therapeutic effects.

[1925d, 4195]
But the study of pathogenic repressions and of other phenomena which have still to be mentioned compelled psycho-analysis to take the concept of the 'unconscious' seriously. Psycho-analysis regarded everything mental as being in the first instance unconscious; the further quality of 'consciousness' might also be present, or again it might be absent. This of course provoked a denial from the philosophers, for whom 'conscious' and 'mental' were identical, and who protested that they could not conceive of such an absurdity as the 'unconscious mental'. There was no help for it, however, and this idiosyncrasy of the philosophers could only be disregarded with a shrug. Experience (gained from pathological material, of which the philosophers were ignorant) of the frequency and power of impulses of which one knew nothing directly, and whose existence had to be inferred like some fact in the external world, left no alternative open. It could be pointed out, incidentally, that this was only treating one's own mental life as one had always treated other people's. One did not hesitate to ascribe mental processes to other people, although one had no immediate consciousness of them and could only infer them from their words and actions. But what held good for other people must be applicable to oneself. Anyone who tried to push the argument further and to conclude from it that one's own hidden processes belonged actually to a second consciousness would be faced with the concept of a consciousness of which one knew nothing, of an 'unconscious consciousness' - and this would scarcely be preferable to the assumption of an 'unconscious mental'. If on the other hand one declared, like some other philosophers, that one was prepared to take pathological phenomena into account, but that the processes underlying them ought not to be described as mental but as 'psychoid', the difference of opinion would degenerate into an unfruitful dispute about words, though even so expediency would decide in favour of keeping the expression 'unconscious mental'. The further question as to the ultimate nature of this unconscious is no more sensible or profitable than the older one as to the nature of the conscious.

The theories of resistance and of repression, of the unconscious, of the aetiologcal significance of sexual life and of the importance of infantile experiences - these form the principal constituents of the theoretical structure of psycho-analysis. In these pages, unfortunately, I have been able to describe only the separate elements and not their interconnections and their bearing upon one another. But I am obliged now to turn to the alterations which gradually took place in the technique of the analytic method.

Then I will pursue the subject further; in any case it is not easy for me to get away from it. I will tell you, then, that the most remarkable thing about the sexual life of children seems to me that it passes through the whole of its very far-reaching development in the first five years of life. From then onwards until puberty there stretches what is known as the period of latency. During it sexuality normally advances no further; on the contrary, the sexual urges diminish in strength and many things are given up and forgotten which the child did and knew. During that period of life, after the early efflorescence of sexuality has withered, such attitudes of the ego as shame, disgust and morality arise, which are destined to stand up against the later tempest of puberty and to lay down the path of the freshly awakening sexual desires. This 'diphasic onset', as it is named, of sexual life has a great deal to do with the genesis of neurotic illnesses. It seems to occur only in human beings, and it is perhaps one of the determinants of the human privilege of becoming neurotic. The prehistory of sexual life was just as much overlooked before psycho-analysis as, in another department, the background to conscious mental life. You will rightly suspect that the two are intimately connected.
The reasons for this hostility were to be found, from the medical point of view, in the fact that psycho-analysis lays stress upon psychical factors, and from the philosophical point of view, in its assuming as an underlying postulate the concept of unconscious mental activity; but the strongest reason was undoubtedly the general disinclination of mankind to concede to the factor of sexuality the importance that is assigned to it by psycho-analysis. In spite of this widespread opposition, however, the movement in favour of psycho-analysis was not to be checked. Its adherents formed themselves into an International Association, which passed successfully through the ordeal of the World War, and at the present time (1925) comprises local groups in Vienna, Berlin, Budapest, London, Switzerland, Holland, Moscow and Calcutta, as well as two in the United States. There are three periodicals representing the views of these societies: the *Internationale Zeitschrift für Psychoanalyse*, *Imago* (which is concerned with the application of psycho-analysis to non-medical fields of knowledge), and the *International Journal of Psycho-Analysis*.

[1926f, 4407]

Behind this magic we recognize the ancient, venerable and incontestably correct pronouncement of Aristotle - that dreaming is the continuation of our mental activity into the state of sleep - combined with the recognition of the unconscious which psycho-analysis first added to it. Only the riddle of dream-distortion finds no solution here.

[1930, 4579]
There is no need to discuss what is to be called conscious: it is removed from all doubt. The oldest and best meaning of the word 'unconscious' is the descriptive one; we call a psychical process unconscious whose existence we are obliged to assume - for some such reason as that we infer it from its effects -, but of which we know nothing. In that case we have the same relation to it as we have to a psychical process in another person, except that it is in fact one of our own. If we want to be still more correct, we shall modify our assertion by saying that we call a process unconscious if we are obliged to assume that it is being activated at the moment, though at the moment we know nothing about it. This qualification makes us reflect that the majority of conscious processes are conscious only for a short time; very soon they become latent, but can easily become conscious again. We might also say that they had become unconscious, if it were at all certain that in the condition of latency they are still something psychical. So far we should have learnt nothing new; nor should we have acquired the right to introduce the concept of an unconscious into psychology. But then comes the new observation that we were already able to make in parapraxes. In order to explain a slip of the tongue, for instance, we find ourselves obliged to assume that the intention to make a particular remark was present in the subject. We infer it with certainty from the interference with his remark which has occurred; but the intention did not put itself through and was thus unconscious. If, when we subsequently put it before the speaker, he recognizes it as one familiar to him, then it was only temporarily unconscious to him; but if he repudiates it as something foreign to him, then it was permanently unconscious. From this experience we retrospectively obtain the right also to pronounce as something unconscious what had been described as latent. A consideration of these dynamic relations permits us now to distinguish two kinds of unconscious - one which is easily, under frequently occurring circumstances, transformed into something conscious, and another with which this transformation is difficult and takes place only subject to a considerable expenditure of effort or possibly never at all. In order to escape the ambiguity as to whether we mean the one or the other unconscious, whether we are using the word in the descriptive or in the dynamic sense, we make use of a permissible and simple way out. We call the unconscious which is only latent, and thus easily becomes conscious, the 'preconscious' and retain the term 'unconscious' for the other. We now have three terms, 'conscious', 'preconscious' and 'unconscious', with which we can get along in our description of mental phenomena. Once again: the preconscious is also unconscious in the purely descriptive sense, but we do not give it that name, except in talking loosely or when we have to make a defence of the existence in mental life of unconscious processes in general.

[1933a, 4679]
You will admit, I hope, that so far that is not too bad and allows of convenient handling. Yes, but unluckily the work of psycho-analysis has found itself compelled to use the word 'unconscious' in yet another, third, sense, and this may, to be sure, have led to confusion. Under the new and powerful impression of there being an extensive and important field of mental life which is normally withdrawn from the ego's knowledge so that the processes occurring in it have to be regarded as unconscious in the truly dynamic sense, we have come to understand the term 'unconscious' in a topographical or systematic sense as well; we have come to speak of a 'system' of the preconscious and a 'system' of the unconscious, of a conflict between the ego and the system Ucs., and have used the word more and more to denote a mental province rather than a quality of what is mental. The discovery, actually an inconvenient one, that portions of the ego and super-ego as well are unconscious in the dynamic sense, operates at this point as a relief - it makes possible the removal of a complication. We perceive that we have no right to name the mental region that is foreign to the ego 'the system Ucs', since the characteristic of being unconscious is not restricted to it. Very well; we will no longer use the term 'unconscious' in the systematic sense and we will give what we have hitherto so described a better name and one no longer open to misunderstanding. Following a verbal usage of Nietzsche's and taking up a suggestion by Georg Groddeck, we will in future call it the 'id'. This impersonal pronoun seems particularly well suited for expressing the main characteristic of this province of the mind - the fact of its being alien to the ego. The super-ego, the ego and the id - these, then, are the three realms, regions, provinces, into which we divide an individual's mental apparatus, and with the mutual relations of which we shall be concerned in what follows. [1933a, 4680]

But you must not expect to hear the glad tidings that the struggle about analysis is over and has ended in its recognition as a science and its admission as a subject for instruction at universities. There is no question of that. The struggle continues, though in more polite forms. What is also new is that a sort of buffer-layer has formed in scientific society between analysis and its opponents. This consists of people who allow the validity of some portions of analysis and admit as much, subject to the most entertaining qualifications, but who on the other hand reject other portions of it, a fact which they cannot proclaim too loudly. It is not easy to divine what determines their choice in this. It seems to depend on personal sympathies. One person will take objection to sexuality, another to the unconscious; what seems particularly unpopular is the fact of symbolism. Though the structure of psycho-analysis is unfinished, it nevertheless presents, even to-day, a unity from which elements cannot be broken off at the caprice of whoever comes along; but these eclectics seem to disregard this. I have never had the impression that these half- or quarter-adherents based their rejection on an examination of the facts. Some distinguished men, too, are included in this category. They, to be sure, are excused by the fact that their time and their interest belong to other things - to those things, namely, in mastering which they have achieved so much. But in that case would they not do better to suspend their judgement instead of taking sides so decisively? With one of these great men I once succeeded in effecting a rapid conversion. He was a world-famous critic, who had followed the spiritual currents of the time with benevolent understanding and prophetic penetration. I only came to know him when he was past his eightieth year; but he was still enchanting in his talk. You will easily guess whom I mean. Nor was it I who introduced the subject of psycho-analysis. It was he who did so, by comparing himself with me in the most modest fashion. 'I am only a literary man,' he said, 'but you are a natural scientist and discoverer. However, there is one thing I must say to you: I have never had sexual feelings towards my mother.' 'But there is no need at all for you to have known them,' was my reply; 'to grown-up people those are unconscious feelings.' 'Oh! so that's what you think!' he said with relief, and pressed my hand. We went on talking together on the best of terms for another few hours. I heard later that in the few remaining years of his life he often spoke of analysis in a friendly way and was pleased at being able to use a word that was new to him - 'repression'. [1933a, 4740]
All of this may appear to be far from simple. But when one has grown reconciled to this unusual spatial view of the mental apparatus, it can present no particular difficulties to the imagination. I will add the further comment that the psychical topography that I have developed here has nothing to do with the anatomy of the brain, and actually only touches it at one point. What is unsatisfactory in this picture - and I am aware of it as clearly as anyone - is due to our complete ignorance of the dynamic nature of the mental processes. We tell ourselves that what distinguishes a conscious idea from a preconscious one, and the latter from an unconscious one, can only be a modification, or perhaps a different distribution, of psychical energy. We talk of cathexes and hypercathexes, but beyond this we are without any knowledge on the subject or even any starting-point for a serviceable working hypothesis. Of the phenomenon of consciousness we can at least say that it was originally attached to perception. All sensations which originate from the perception of painful, tactile, auditory or visual stimuli are what are most readily conscious. Thought-processes, and whatever may be analogous to them in the id, are in themselves unconscious and obtain access to consciousness by becoming linked to the mnemonic residues of visual and auditory perceptions along the path of the function of speech. In animals, which lack speech, these conditions must be of a simpler kind.
[1939a, 4919]

The starting-point for this investigation is provided by a fact without parallel, which defies all explanation or description - the fact of consciousness. Nevertheless, if anyone speaks of consciousness we know immediately and from our most personal experience what is meant by it.¹ Many people, both inside and outside science, are satisfied with the assumption that consciousness alone is psychical; in that case nothing remains for psychology but to discriminate among psychical phenomena between perceptions, feelings, thought-processes and volitions. It is generally agreed, however, that these conscious processes do not form unbroken sequences which are complete in themselves; there would thus be no alternative left to assuming that there are physical or somatic processes which are concomitant with the psychical ones and which we should necessarily have to recognize as more complete than the psychical sequences, since some of them would have conscious processes parallel to them but others would not. If so, it of course becomes plausible to lay the stress in psychology on these somatic processes, to see in them the true essence of what is psychical and to look for some other assessment of the conscious processes. The majority of philosophers, however, as well as many other people, dispute this and declare that the idea of something psychical being unconscious is self-contradictory.
[1940a [1938], 4967]

But that is precisely what psycho-analysis is obliged to assert, and this is its second fundamental hypothesis. It explains the supposedly somatic concomitant phenomena as being what is truly psychical, and thus in the first instance disregards the quality of consciousness. It is not alone in doing this. Some thinkers (such as Theodor Lipps, for instance) have asserted the same thing in the same words; and the general dissatisfaction with the usual view of what is psychical has resulted in an increasingly urgent demand for the inclusion in psychological thought of a concept of the unconscious, though this demand has taken such an indefinite and obscure form that it could have no influence on science.
[1940a [1938], 4968]
Every science is based on observations and experiences arrived at through the medium of our psychical apparatus. But since our science has as its subject that apparatus itself, the analogy ends here. We make our observations through the medium of the same perceptual apparatus, precisely with the help of the breaks in the sequence of 'psychical' events: we fill in what is omitted by making plausible inferences and translating it into conscious material. In this way we construct, as it were, a sequence of conscious events complementary to the unconscious psychical processes. The relative certainty of our psychical science is based on the binding force of these inferences. Anyone who enters deeply into our work will find that our technique holds its ground against any criticism.

In the course of this work the distinctions which we describe as psychical qualities force themselves on our notice. There is no need to characterize what we call 'conscious': it is the same as the consciousness of philosophers and of everyday opinion. Everything else psychical is in our view 'the unconscious'. We are soon led to make an important division in this unconscious. Some processes become conscious easily; they may then cease to be conscious, but can become conscious once more without any trouble: as people say, they can be reproduced or remembered. This reminds us that consciousness is in general a highly fugitive state. What is conscious is conscious only for a moment. If our perceptions do not confirm this, the contradiction is only an apparent one; it is explained by the fact that the stimuli which lead to perception may persist for considerable periods, so that meanwhile the perception of them may be repeated. The whole position is made clear in connection with the conscious perception of our thought-processes: these too may persist for some time, but they may just as well pass in a flash. Everything unconscious that behaves in this way, that can thus easily exchange the unconscious state for the conscious one, is therefore preferably described as 'capable of becoming conscious' or as preconscious. Experience has taught us that there is hardly a psychical process, however complicated it may be, which cannot on occasion remain preconscious, even though as a rule it will, as we say, push its way forward into consciousness. There are other psychical processes and psychical material which have no such easy access to becoming conscious but must be inferred, recognized and translated into conscious form in the manner described. For such material we reserve the name of the unconscious proper.

Here let us pause for a moment to assure the analyst that he has our sincere sympathy in the very exacting demands he has to fulfil in carrying out his activities. It almost looks as if analysis were the third of those 'impossible' professions in which one can be sure beforehand of achieving unsatisfying results. The other two, which have been known much longer, are education and government. Obviously we cannot demand that the prospective analyst should be a perfect being before he takes up analysis, in other words that only persons of such high and rare perfection should enter the profession. But where and how is the poor wretch to acquire the ideal qualifications which he will need in his profession? The answer is, in an analysis of himself, with which his preparation for his future activity begins. For practical reasons this analysis can only be short and incomplete. Its main object is to enable his teacher to make a judgement as to whether the candidate can be accepted for further training. It has accomplished its purpose if it gives the learner a firm conviction of the existence of the unconscious, if it enables him, when repressed material emerges, to perceive in himself things which would otherwise be incredible to him, and if it shows him a first sample of the technique which has proved to be the only effective one in analytic work. This alone would not suffice for his instruction; but we reckon on the stimuli that he has received in his own analysis not ceasing when it ends and on the processes of remodelling the ego continuing spontaneously in the analysed subject and making use of all subsequent experiences in this newly-acquired sense. This does in fact happen, and in so far as it happens it makes the analysed subject qualified to be an analyst himself.

[1940a [1938], 4969]
Psycho-analysis escaped such difficulties as these by energetically denying the equation between what is psychical and what is conscious. No; being conscious cannot be the essence of what is psychical. It is only a quality of what is psychical, and an inconstant quality at that - one that is far oftener absent than present. The psychical, whatever its nature may be, is in itself unconscious and probably similar in kind to all the other natural processes of which we have obtained knowledge.

In the second place, I shall pick a single instance to represent an immensely large class of phenomena.¹ The President of a public body (the Lower House of the Austrian Parliament) on one occasion opened a sitting with the following words: 'I take notice that a full quorum of members is present and herewith declare the sitting closed.' It was a slip of the tongue - for there can be no doubt that what the President intended to say was 'opened'. Why, then, did he say the opposite? We shall expect to be told it was an accidental mistake, a failure in carrying out an intention such as may easily happen for various reasons: it had no meaning - and in any case contraries are particularly easily substituted for each other. If, however, we bear in mind the situation in which the slip of the tongue occurred, we shall be inclined to prefer another explanation. Many of the previous sittings of the House had been disagreeably stormy and had accomplished nothing, so that it would be only too natural for the President to think at the moment of making his opening statement: 'If only the sitting that's just beginning were finished! I would much rather be closing then opening it!' When he began to speak he was probably not aware of this wish - it was not conscious to him - but it was certainly present and it succeeded in making itself effective, against the speaker's will, in his apparent mistake. A single instance can scarcely enable us to decide between two such different explanations. But what if every other instance of a slip of the tongue could be explained in the same way, and similarly every slip of the pen, every case of mis-reading or mis-hearing, and every faulty action? What if in all those instances (one might actually say, without a single exception) it was possible to demonstrate the presence of a psychical act - a thought, a wish or an intention - which would account for the apparent mistake and which was unconscious at the moment at which it became effective, even though it may have been conscious previously? If that were so, it would really no longer be possible to dispute the fact that psychical acts which are unconscious do exist and that they are even sometimes active while they are unconscious and that in that case they can even sometimes get the better of conscious intentions. The person concerned in a mistake of this kind can react to it in various ways. He may overlook it completely or he may notice it himself and become embarrassed and ashamed. He cannot as a rule find the explanation of it himself without outside help; and he often refuses to accept the solution when it is put before him - for a time, at all events.

¹[1940b [1938], 5068]
In the third place, finally, it is possible in the case of persons in a state of hypnosis to prove experimentally that there are such things as unconscious psychical acts and that consciousness is not an indispensable condition of activity. Anyone who has witnessed such an experiment will receive an unforgettable impression and a conviction that can never be shaken. Here is more or less what happens. The doctor enters the hospital ward, puts his umbrella in the corner, hypnotizes one of the patients and says to him: ‘I'm going out now. When I come in again, you will come to meet me with my umbrella open and hold it over my head.’ The doctor and his assistants then leave the ward. As soon as they come back, the patient, who is no longer under hypnosis, carries out exactly the instructions that were given him while he was hypnotized. The doctor questions him: ‘What's this you're doing? What's the meaning of all this?’ The patient is clearly embarrassed. He makes some lame remark such as ‘I only thought, doctor, as it's raining outside you'd open your umbrella in the room before you went out.’ The explanation is obviously quite inadequate and made up on the spur of the moment to offer some sort of motive for his senseless behaviour. It is clear to us spectators that he is in ignorance of his real motive. We, however, know what it is, for we were present when the suggestion was made to him which he is now carrying out, while he himself knows nothing of the fact that it is at work in him.

The question of the relation of the conscious to the psychical may now be regarded as settled: consciousness is only a quality or attribute of what is psychical, and moreover an inconstant one. But there is one further objection with which we have to deal. We are told that, in spite of the facts that have been mentioned, there is no necessity to abandon the identity between what is conscious and what is psychical: the so-called unconscious psychical processes are the organic processes which have long been recognized as running parallel to the mental ones. This, of course, would reduce our problem to an apparently indifferent matter of definition. Our reply is that it would be unjustifiable and inexpedient to make a breach in the unity of mental life for the sake of propping up a definition, since it is clear in any case that consciousness can only offer us an incomplete and broken chain of phenomena. And it can scarcely be a matter of chance that it was not until the change had been made in the definition of the psychical that it became possible to construct a comprehensive and coherent theory of mental life.
A dream, as we have discovered, takes the place of a number of thoughts which are derived from our daily life and which form a completely logical sequence. We cannot doubt, then, that these thoughts originate from our normal mental life. All the attributes which we value highly in our trains of thought, and which characterize them as complex achievements of a high order, are to be found once more in dream-thoughts. There is no need to assume, however, that this activity of thought is performed during sleep - a possibility which would gravely confuse what has hitherto been our settled picture of the psychical state of sleep. On the contrary, these thoughts may very well have originated from the previous day, they may have proceeded unobserved by our consciousness from their start, and may already have been completed at the onset of sleep. The most that we can conclude from this is that it proves that the most complicated achievements of thought are possible without the assistance of consciousness - a fact which we could not fail to learn in any case from every psycho-analysis of a patient suffering from hysteria or from obsessional ideas. These dream-thoughts are certainly not in themselves inadmissible to consciousness; there may have been a number of reasons for their not having become conscious to us during the day. Becoming conscious is connected with the application of a particular psychical function, that of attention - a function which, as it seems, is only available in a specific quantity, and this may have been diverted from the train of thought in question on to some other purpose. There is another way, too, in which trains of thought of this kind may be withheld from consciousness. The course of our conscious reflections shows us that we follow a particular path in our application of attention. If, as we follow this path, we come upon an idea which will not bear criticism, we break off: we drop the cathexis of attention. Now it seems that the train of thought which has thus been initiated and dropped can continue to spin itself out without attention being turned to it again, unless at some point or other it reaches a specially high degree of intensity which forces attention to it. Thus, if a train of thought is initially rejected (consciously, perhaps) by a judgement that it is wrong or that it is useless for the immediate intellectual purposes in view, the result may be that this train of thought will proceed, unobserved by consciousness, until the onset of sleep.

[1900a, 1020]

It is essential to abandon the overvaluation of the property of being conscious before it becomes possible to form any correct view of the origin of what is mental. In Lipps's words, the unconscious must be assumed to be the general basis of psychical life. The unconscious is the larger sphere, which includes within it the smaller sphere of the conscious. Everything conscious has an unconscious preliminary stage; whereas what is unconscious may remain at that stage and nevertheless claim to be regarded as having the full value of a psychical process. The unconscious is the true psychical reality; in its innermost nature it is as much unknown to us as the reality of the external world, and it is as incompletely presented by the data of consciousness as is the external world by the communications of our sense organs.

[1900a, 1038]
Those philosophers who have become aware that rational and highly complex thought-structures are possible without consciousness playing any part in them have found difficulty in assigning any function to consciousness; it has seemed to them that it can be no more than a superfluous reflected picture of the completed psychical process. We, on the other hand, are rescued from this embarrassment by the analogy between our Cs. system and the perceptual systems. We know that perception by our sense-organs has the result of directing a cathexis of attention to the paths along which the in-coming sensory excitation is spreading: the qualitative excitation of the Pcpt. system acts as a regulator of the discharge of the mobile quantity in the psychical apparatus. We can attribute the same function to the overlying sense-organ of the Cs. system. By perceiving new qualities, it makes a new contribution to directing the mobile quantities of cathexis and distributing them in an expedient fashion. By the help of its perception of pleasure and unpleasure it influences the discharge of the cathexes within what is otherwise an unconscious apparatus operating by means of the displacement of quantities. It seems probable that in the first instance the unpleasure principle regulates the displacement of cathexes automatically. But it is quite possible that consciousness of these qualities may introduce in addition a second and more discriminating regulation, which is even able to oppose the former one, and which perfects the efficiency of the apparatus by enabling it, in contradiction to its original plan, to cathect and work over even what is associated with the release of unpleasure. We learn from the psychology of the neuroses that these processes of regulation carried out by the qualitative excitation of the sense organs play a great part in the functional activity of the apparatus. The automatic domination of the primary unpleasure principle and the consequent restriction imposed upon efficiency are interrupted by the processes of sensory regulation, which are themselves in turn automatic in action. We find that repression (which, though it served a useful purpose to begin with, leads ultimately to a damaging loss of inhibition and mental control) affects memories so much more easily than perceptions because the former can receive no extra cathexis from the excitation of the psychical sense-organs. It is true on the one hand that a thought which has to be warded off cannot become conscious, because it has undergone repression; but on the other hand it sometimes happens that a thought of this kind is only repressed because for other reasons it has been withdrawn from conscious perception. Here are some hints of which we take advantage in our therapeutic procedure in order to undo repressions which have already been effected.

[1900a, 1041]

The value of the hypercathexis which is set up in the mobile quantities by the regulating influence of the sense organ of the Cs. cannot be better illustrated in its teleological aspect than by the fact of its creation of a new series of qualities and consequently of a new process of regulation which constitutes the superiority of men over animals. Thought-processes are in themselves without quality, except for the pleasurable and unpleasurable excitations which accompany them, and which, in view of their possible disturbing effect upon thinking, must be kept within bounds. In order that thought-processes may acquire quality, they are associated in human beings with verbal memories, whose residues of quality are sufficient to draw the attention of consciousness to them and to endow the process of thinking with a new mobile cathexis from consciousness.

[1900a, 1042]
Nevertheless, we feel a need to modify Spencer's notion, in part to give a more definite form to the ideas contained in it and in part to change them. We should say that laughter arises if a quota of psychical energy which has earlier been used for the cathexis of particular psychical paths has become unusable, so that it can find free discharge. We are well aware what 'evil looks' we are inviting with such a hypothesis; but we will venture to quote in our defence an apposite sentence from Lipps's book *Komik und Humor* (1898, 71), from which illumination is to be derived on more subjects than that of the comic and humour: 'Finally, specific psychological problems always lead fairly deep into psychology, so that at bottom no psychological problem can be treated in isolation.' The concepts of 'psychical energy' and 'discharge' and the treatment of psychical energy as a quantity have become habitual in my thoughts since I began to arrange the facts of psychopathology philosophically; and already in my *Interpretation of Dreams* (1900a) I tried (in the same sense as Lipps) to establish the fact that what are 'really psychically effective' are psychical processes which are unconscious in themselves, not the contents of consciousness.¹ It is only when I speak of the 'cathexis of psychical paths' that I seem to depart from the analogies commonly used by Lipps. My experiences of the displaceability of psychical energy along certain paths of association, and of the almost indestructible persistence of the traces of psychical processes, have in fact suggested to me an attempt at picturing the unknown in some such way. To avoid misunderstanding, I must add that I am making no attempt to proclaim that the cells and nerve fibres, or the systems of neurones which are taking their place to-day, are these psychical paths, even though it would have to be possible in some manner which cannot yet be indicated to represent such paths by organic elements of the nervous system.

[1905c, 1735]

The reason for all these difficulties is to be found in the circumstance that the attribute of being conscious, which is the only characteristic of psychical processes that is directly presented to us, is in no way suited to serve as a criterion for the differentiation of systems. Apart from the fact that the conscious is not always conscious but also at times latent, observation has shown that much that shares the characteristics of the system *Pcs.* does not become conscious; and we learn in addition that the act of becoming conscious is dependent on the attention of the *Pcs.* being turned in certain directions. Hence consciousness stands in no simple relation either to the different systems or to repression. The truth is that it is not only the psychically repressed that remains alien to consciousness, but also some of the impulses which dominate our ego - something, therefore, that forms the strongest functional antithesis to the repressed. The more we seek to win our way to a metapsychological view of mental life, the more we must learn to emancipate ourselves from the importance of the symptom of 'being conscious'.

[1915e, 3014]
The first of these unpopular assertions made by psycho-analysis declares that mental processes are in themselves unconscious and that of all mental life it is only certain individual acts and portions that are conscious. You know that on the contrary we are in the habit of identifying what is psychical with what is conscious. We look upon consciousness as nothing more nor less than the defining characteristic of the psychical, and psychology as the study of the contents of consciousness. Indeed it seems to us so much a matter of course to equate them in this way that any contradiction of the idea strikes us as obvious nonsense. Yet psycho-analysis cannot avoid raising this contradiction; it cannot accept the identity of the conscious and the mental. It defines what is mental as processes such as feeling, thinking and willing, and it is obliged to maintain that there is unconscious thinking and unapprehended willing. In saying this it has from the start frivolously forfeited the sympathy of every friend of sober scientific thought, and laid itself open to the suspicion of being a fantastic esoteric doctrine eager to make mysteries and fish in troubled waters. But you, Ladies and Gentlemen, naturally cannot understand as yet what right I have to describe as a prejudice a statement of so abstract a nature as "what is mental is conscious". Nor can you guess what development can have led to a denial of the unconscious - should such a thing exist - and what advantage there may have been in that denial. The question whether we are to make the psychical coincide with the conscious or make it extend further sounds like an empty dispute about words; yet I can assure you that the hypothesis of there being unconscious mental processes paves the way to a decisive new orientation in the world and in science.

[1916-1917, 3134]

'The whole process, however, only becomes possible through the single circumstance that you are mistaken in another important point as well. You feel sure that you are informed of all that goes on in your mind if it is of any importance at all, because in that case, you believe, your consciousness gives you news of it. And if you have had no information of something in your mind you confidently assume that it does not exist there. Indeed, you go so far as to regard what is "mental" as identical with what is "conscious" - that is, with what is known to you in spite of the most obvious evidence that a great deal more must constantly be going on in your mind than can be known to your consciousness. Come, let yourself be taught something on this one point! What is in your mind does not coincide with what you are conscious of; whether something is going on in your mind and whether you hear of it, are two different things. In the ordinary way, I will admit, the intelligence which reaches your consciousness is enough for your needs; and you may cherish the illusion that you learn of all the more important things. But in some cases, as in that of an instinctual conflict such as I have described, your intelligence service breaks down and your will then extends no further than your knowledge. In every case, however, the news that reaches your consciousness is incomplete and often not to be relied on. Often enough, too, it happens that you get news of events only when they are over and when you can no longer do anything to change them. Even if you are not ill, who can tell all that is stirring in your mind of which you know nothing or are falsely informed? You behave like an absolute ruler who is content with the information supplied him by his highest officials and never goes among the people to hear their voice. Turn your eyes inward, look into your own depths, learn first to know yourself! Then you will understand why you were bound to fall ill; and perhaps, you will avoid falling ill in future.'

[1917a, 3614]

It is thus that psycho-analysis has sought to educate the ego. But these two discoveries - that the life of our sexual instincts cannot be wholly tamed, and that mental processes are in themselves unconscious and only reach the ego and come under its control through incomplete and untrustworthy perceptions - these two discoveries amount to a statement that the ego is not master in its own house. Together they represent the third blow to man's self-love, what I may call the psychological one. No wonder, then, that the ego does not look favourably upon psycho-analysis and obstinately refuses to believe in it.

[1917a, 3614]
Probably very few people can have realized the momentous significance for science and life of the recognition of unconscious mental processes. It was not psycho-analysis, however, let us hasten to add, which first took this step. There are famous philosophers who may be cited as forerunners - above all the great thinker Schopenhauer, whose unconscious 'Will' is equivalent to the mental instincts of psycho-analysis. It was this same thinker, moreover, who in words of unforgettable impressiveness admonished mankind of the importance, still so greatly underestimated by it, of its sexual craving. Psycho-analysis has this advantage only, that it has not affirmed these two propositions which are so distressing to narcissism - the psychical importance of sexuality and the unconsciousness of mental life - on an abstract basis, but has demonstrated them in matters that touch every individual personally and force him to take up some attitude towards these problems. It is just for this reason, however, that it brings on itself the aversion and resistances which still hold back in awe before the great name of the philosopher.

[1917a, 3615]

Psycho-analytic speculation takes as its point of departure the impression, derived from examining unconscious processes, that consciousness may be, not the most universal attribute of mental processes, but only a particular function of them. Speaking in metapsychological terms, it asserts that consciousness is a function of a particular system which it describes as Cs. What consciousness yields consists essentially of perceptions of excitations coming from the external world and of feelings of pleasure and unpleasure which can only arise from within the mental apparatus; it is therefore possible to assign to the system Pcpt.-Cs. a position in space. It must lie on the borderline between outside and inside; it must be turned towards the external world and must envelop the other psychical systems. It will be seen that there is nothing daringly new in these assumptions; we have merely adopted the views on localization held by cerebral anatomy, which locates the 'seat' of consciousness in the cerebral cortex - the outermost, enveloping layer of the central organ. Cerebral anatomy has no need to consider why, speaking anatomically, consciousness should be lodged on the surface of the brain instead of being safely housed somewhere in its inmost interior. Perhaps we shall be more successful in accounting for this situation in the case of our system Pcpt.-Cs.

[1920g, 3728]
Consciousness is not the only distinctive character which we ascribe to the processes in that system. On the basis of impressions derived from our psycho-analytic experience, we assume that all excitatory processes that occur in the other systems leave permanent traces behind in them which form the foundation of memory. Such memory-traces, then, have nothing to do with the fact of becoming conscious; indeed they are often most powerful and most enduring when the process which left them behind was one which never entered consciousness. We find it hard to believe, however, that permanent traces of excitation such as these are also left in the system _Pt.-Cs_. If they remained constantly conscious, they would very soon set limits to the system's aptitude for receiving fresh excitations.¹ If, on the other hand, they were unconscious, we should be faced with the problem of explaining the existence of unconscious processes in a system whose functioning was otherwise accompanied by the phenomenon of consciousness. We should, so to say, have altered nothing and gained nothing by our hypothesis relegating the process of becoming conscious to a special system. Though this consideration is not absolutely conclusive, it nevertheless leads us to suspect that becoming conscious and leaving behind a memory-trace are processes incompatible with each other within one and the same system. Thus we should be able to say that the excitatory process becomes conscious in the system _Cs_ but leaves no permanent trace behind there; but that the excitation is transmitted to the systems lying next within and that it is in them that its traces are left. I followed these same lines in the schematic picture which I included in the speculative section of my _Interpretation of Dreams_. It must be borne in mind that little enough is known from other sources of the origin of consciousness; when, therefore, we lay down the proposition that consciousness arises instead of a memory-trace, the assertion deserves consideration, at all events on the ground of its being framed in fairly precise terms.

[1920g, 3729]

The division of the psychical into what is conscious and what is unconscious is the fundamental premiss of psycho-analysis; and it alone makes it possible for psycho-analysis to understand the pathological processes in mental life, which are as common as they are important, and to find a place for them in the framework of science. To put it once more, in a different way: psycho-analysis cannot situate the essence of the psychical in consciousness, but is obliged to regard consciousness as a quality of the psychical, which may be present in addition to other qualities or may be absent.

[1923b, 3947]

After hypnosis was replaced by the technique of free association, Breuer's cathartic procedure turned into psycho-analysis, which for more than a decade was developed by the author (Freud) alone. During that time psycho-analysis gradually acquired a theory which appeared to give a satisfactory account of the origin, meaning and purpose of neurotic symptoms and provided a rational basis for medical attempts at curing the complaint. I will once again enumerate the factors that go to make up this theory. They are: emphasis on instinctual life (affectivity), on mental dynamics, on the fact that even the apparently most obscure and arbitrary mental phenomena invariably have a meaning and a causation, the theory of psychical conflict and of the pathogenic nature of repression, the view that symptoms are substitutive satisfactions, the recognition of the aetiological importance of sexual life, and in particular of the beginnings of infantile sexuality. From a philosophical standpoint this theory was bound to adopt the view that the mental does not coincide with the conscious, that mental processes are in themselves unconscious and are only made conscious by the functioning of special organs (agencies or systems). By way of completing this list, I will add that among the affective attitudes of childhood the complicated emotional relation of children to their parents - what is known as the Oedipus complex - came into prominence. It became ever clearer that this was the nucleus of every case of neurosis, and in the patient's behaviour towards his analyst certain phenomena of his emotional transference emerged which came to be of great importance for theory and technique alike.

[1924f, 4107]
What, then, can a philosopher say to a theory which, like psycho-analysis, asserts that on the contrary what is mental is in itself unconscious and that being conscious is only a quality, which may or may not accrue to a particular mental act and the withholding of which may perhaps alter that act in no other respect? He will naturally say that anything both unconscious and mental would be an impossibility, a contradictio in adjecto, and he will fail to observe that in making this judgement he is merely repeating his own definition of what is mental, a definition which may perhaps be too narrow. It is easy for philosophers to feel this certainty, since they have no acquaintance with the material whose investigation has compelled analysts to believe in unconscious mental acts. Philosophers have never taken account of hypnosis, they have not concerned themselves with the interpreting of dreams - on the contrary, like doctors, they regard dreams as the meaningless products of reduced mental activity during sleep - they are scarcely aware that there are such things as obsessions and delusions and they would find themselves in a most embarrassing situation if they were asked to explain them on the basis of their own psychological premisses. Analysts, too, refuse to say what the unconscious is, but they can indicate the domain of phenomena whose observation has obliged them to assume its existence. Philosophers, who know no kind of observation other than self-observation, cannot follow them into that domain.

But the study of pathogenic repressions and of other phenomena which have still to be mentioned compelled psycho-analysis to take the concept of the 'unconscious' seriously. Psycho-analysis regarded everything mental as being in the first instance unconscious; the further quality of 'consciousness' might also be present, or again it might be absent. This of course provoked a denial from the philosophers, for whom 'conscious' and 'mental' were identical, and who protested that they could not conceive of such an absurdity as the 'unconscious mental'. There was no help for it, however, and this idiosyncrasy of the philosophers could only be disregarded with a shrug. Experience (gained from pathological material, of which the philosophers were ignorant) of the frequency and power of impulses of which one knew nothing directly, and whose existence had to be inferred like some fact in the external world, left no alternative open. It could be pointed out, incidentally, that this was only treating one's own mental life as one had always treated other people's. One did not hesitate to ascribe mental processes to other people, although one had no immediate consciousness of them and could only infer them from their words and actions. But what held good for other people must be applicable to oneself. Anyone who tried to push the argument further and to conclude from it that one's own hidden processes belonged actually to a second consciousness would be faced with the concept of a consciousness of which one knew nothing, of an 'unconscious consciousness' - and this would scarcely be preferable to the assumption of an 'unconscious mental'. If on the other hand one declared, like some other philosophers, that one was prepared to take pathological phenomena into account, but that the processes underlying them ought not to be described as mental but as 'psychoid', the difference of opinion would degenerate into an unfruitful dispute about words, though even so expediency would decide in favour of keeping the expression 'unconscious mental'. The further question as to the ultimate nature of this unconscious is no more sensible or profitable than the older one as to the nature of the conscious.
You will admit, I hope, that so far that is not too bad and allows of convenient handling. Yes, but unluckily the work of psycho-analysis has found itself compelled to use the word 'unconscious' in yet another, third, sense, and this may, to be sure, have led to confusion. Under the new and powerful impression of there being an extensive and important field of mental life which is normally withdrawn from the ego's knowledge so that the processes occurring in it have to be regarded as unconscious in the truly dynamic sense, we have come to understand the term 'unconscious' in a topographical or systematic sense as well; we have come to speak of a 'system' of the preconscious and a 'system' of the unconscious, of a conflict between the ego and the system Ucs., and have used the word more and more to denote a mental province rather than a quality of what is mental. The discovery, actually an inconvenient one, that portions of the ego and super-ego as well are unconscious in the dynamic sense, operates at this point as a relief - it makes possible the removal of a complication. We perceive that we have no right to name the mental region that is foreign to the ego 'the system Ucs', since the characteristic of being unconscious is not restricted to it. Very well; we will no longer use the term 'unconscious' in the systematic sense and we will give what we have hitherto so described a better name and one no longer open to misunderstanding. Following a verbal usage of Nietzsche's and taking up a suggestion by Georg Groddeck, we will in future call it the 'id'. This impersonal pronoun seems particularly well suited for expressing the main characteristic of this province of the mind - the fact of its being alien to the ego. The super-ego, the ego and the id - these, then, are the three realms, regions, provinces, into which we divide an individual's mental apparatus, and with the mutual relations of which we shall be concerned in what follows.

All of this may appear to be far from simple. But when one has grown reconciled to this unusual spatial view of the mental apparatus, it can present no particular difficulties to the imagination. I will add the further comment that the psychical topography that I have developed here has nothing to do with the anatomy of the brain, and actually only touches it at one point. What is unsatisfactory in this picture - and I am aware of it as clearly as anyone - is due to our complete ignorance of the dynamic nature of the mental processes. We tell ourselves that what distinguishes a conscious idea from a preconscious one, and the latter from an unconscious one, can only be a modification, or perhaps a different distribution, of psychical energy. We talk of cathexes and hypercathexes, but beyond this we are without any knowledge on the subject or even any starting-point for a serviceable working hypothesis. Of the phenomenon of consciousness we can at least say that it was originally attached to perception. All sensations which originate from the perception of painful, tactile, auditory or visual stimuli are what are most readily conscious. Thought-processes, and whatever may be analogous to them in the id, are in themselves unconscious and obtain access to consciousness by becoming linked to the mnemonic residues of visual and auditory perceptions along the path of the function of speech. In animals, which lack speech, these conditions must be of a simpler kind.

But that is precisely what psycho-analysis is obliged to assert, and this is its second fundamental hypothesis. It explains the supposedly somatic concomitant phenomena as being what is truly psychical, and thus in the first instance disregards the quality of consciousness. It is not alone in doing this. Some thinkers (such as Theodor Lipps, for instance) have asserted the same thing in the same words; and the general dissatisfaction with the usual view of what is psychical has resulted in an increasingly urgent demand for the inclusion in psychological thought of a concept of the unconscious, though this demand has taken such an indefinite and obscure form that it could have no influence on science.
In the course of this work the distinctions which we describe as psychical qualities force themselves on our notice. There is no need to characterize what we call ‘conscious’: it is the same as the consciousness of philosophers and of everyday opinion. Everything else psychical is in our view ‘the unconscious’. We are soon led to make an important division in this unconscious. Some processes become conscious easily; they may then cease to be conscious, but can become conscious once more without any trouble: as people say, they can be reproduced or remembered. This reminds us that consciousness is in general a highly fugitive state. What is conscious is conscious only for a moment. If our perceptions do not confirm this, the contradiction is only an apparent one; it is explained by the fact that the stimuli which lead to perception may persist for considerable periods, so that meanwhile the perception of them may be repeated. The whole position is made clear in connection with the conscious perception of our thought-processes: these too may persist for some time, but they may just as well pass in a flash. Everything unconscious that behaves in this way, that can thus easily exchange the unconscious state for the conscious one, is therefore preferably described as ‘capable of becoming conscious’ or as preconscious. Experience has taught us that there is hardly a psychical process, however complicated it may be, which cannot on occasion remain preconscious, even though as a rule it will, as we say, push its way forward into consciousness. There are other psychical processes and psychical material which have no such easy access to becoming conscious but must be inferred, recognized and translated into conscious form in the manner described. For such material we reserve the name of the unconscious proper.

Psycho-analysis escaped such difficulties as these by energetically denying the equation between what is psychical and what is conscious. No; being conscious cannot be the essence of what is psychical. It is only a quality of what is psychical, and an inconstant quality at that - one that is far oftener absent than present. The psychical, whatever its nature may be, is in itself unconscious and probably similar in kind to all the other natural processes of which we have obtained knowledge.
Nevertheless, we feel a need to modify Spencer's notion, in part to give a more definite form to the ideas contained in it and in part to change them. We should say that laughter arises if a quota of psychical energy which has earlier been used for the cathexis of particular psychical paths has become unusable, so that it can find free discharge. We are well aware what 'evil looks' we are inviting with such a hypothesis; but we will venture to quote in our defence an apposite sentence from Lipps's book *Komik und Humor* (1898, 71), from which illumination is to be derived on more subjects than that of the comic and humour: 'Finally, specific psychological problems always lead fairly deep into psychology, so that at bottom no psychological problem can be treated in isolation.' The concepts of 'psychical energy' and 'discharge' and the treatment of psychical energy as a quantity have become habitual in my thoughts since I began to arrange the facts of psychopathology philosophically; and already in my *Interpretation of Dreams* (1900a) I tried (in the same sense as Lipps) to establish the fact that what are 'really psychically effective' are psychical processes which are unconscious in themselves, not the contents of consciousness.¹ It is only when I speak of the 'cathexis of psychical paths' that I seem to depart from the analogies commonly used by Lipps. My experiences of the displaceability of psychical energy along certain paths of association, and of the almost indestructible persistence of the traces of psychical processes, have in fact suggested to me an attempt at picturing the unknown in some such way. To avoid misunderstanding, I must add that I am making no attempt to proclaim that the cells and nerve fibres, or the systems of neurones which are taking their place to-day, are these psychical paths, even though it would have to be possible in some manner which cannot yet be indicated to represent such paths by organic elements of the nervous system.

[1905c, 1735]

The state of permanently turning away from women produces a personal susceptibility, or, as we are accustomed to say, a 'disposition' to the formation of a delusion. The development of the mental disorder sets in at the moment when a chance impression arouses the childhood experiences which have been forgotten and which have traces, at least, of an erotic colouring. 'Arouses', however, is certainly not the right description, if we take into account what follows. We must repeat the author's accurate account in correct psychological technical terms. When Norbert Hanold saw the relief, he did not remember that he had already seen a similar posture of the foot in his childhood friend; he remembered nothing at all, but all the effects brought about by the relief originated from this link that was made with the impression of his childhood. Thus the childhood impression was stirred up, it became active, so that it began to produce effects, but it did not come into consciousness - it remained 'unconscious', to use a term which has to-day become unavoidable in psychopathology. We are anxious that this unconscious shall not be involved in any of the disputes of philosophers and natural philosophers, which have often no more than an etymological importance. For the time being we possess no better name for psychical processes which behave actively but nevertheless do not reach the consciousness of the person concerned, and that is all we mean by our 'unconsciousness'. When some thinkers try to dispute the existence of an unconscious of this kind, on the ground that it is nonsensical, we can only suppose that they have never had to do with the corresponding mental phenomena, that they are under the spell of the regular experience that everything mental that becomes active and intense becomes at the same time conscious as well, and that they have still to learn (what our author knows very well) that there are most certainly mental processes which, in spite of being intense and producing effects, none the less remain apart from consciousness.

[1907a, 1846]
You will admit, I hope, that so far that is not too bad and allows of convenient handling. Yes, but unluckily the work of psycho-analysis has found itself compelled to use the word 'unconscious' in yet another, third, sense, and this may, to be sure, have led to confusion. Under the new and powerful impression of there being an extensive and important field of mental life which is normally withdrawn from the ego's knowledge so that the processes occurring in it have to be regarded as unconscious in the truly dynamic sense, we have come to understand the term 'unconscious' in a topographical or systematic sense as well; we have come to speak of a 'system' of the preconscious and a 'system' of the unconscious, of a conflict between the ego and the system $Ucs$, and have used the word more and more to denote a mental province rather than a quality of what is mental. The discovery, actually an inconvenient one, that portions of the ego and super-ego as well are unconscious in the dynamic sense, operates at this point as a relief - it makes possible the removal of a complication. We perceive that we have no right to name the mental region that is foreign to the ego 'the system $Ucs$', since the characteristic of being unconscious is not restricted to it. Very well; we will no longer use the term 'unconscious' in the systematic sense and we will give what we have hitherto so described a better name and one no longer open to misunderstanding. Following a verbal usage of Nietzsche's and taking up a suggestion by Georg Groddeck, we will in future call it the 'id'. This impersonal pronoun seems particularly well suited for expressing the main characteristic of this province of the mind - the fact of its being alien to the ego. The super-ego, the ego and the id - these, then, are the three realms, regions, provinces, into which we divide an individual's mental apparatus, and with the mutual relations of which we shall be concerned in what follows.

[1933a, 4680]
Nevertheless, we feel a need to modify Spencer's notion, in part to give a more definite form to the ideas contained in it and in part to change them. We should say that laughter arises if a quota of psychical energy which has earlier been used for the cathexis of particular psychical paths has become unusable, so that it can find free discharge. We are well aware what 'evil looks' we are inviting with such a hypothesis; but we will venture to quote in our defence an apposite sentence from Lipps's book *Komik und Humor* (1898, 71), from which illumination is to be derived on more subjects than that of the comic and humour: 'Finally, specific psychological problems always lead fairly deep into psychology, so that at bottom no psychological problem can be treated in isolation.' The concepts of 'psychical energy' and 'discharge' and the treatment of psychical energy as a quantity have become habitual in my thoughts since I began to arrange the facts of psychopathology philosophically; and already in my *Interpretation of Dreams* (1900a) I tried (in the same sense as Lipps) to establish the fact that what are 'really psychically effective' are psychical processes which are unconscious in themselves, not the contents of consciousness.¹ It is only when I speak of the 'cathexis of psychical paths' that I seem to depart from the analogies commonly used by Lipps. To avoid misunderstanding, I must add that I am making no attempt to proclaim that the cells and nerve fibres, or the systems of neurones which are taking their place to-day, are these psychical paths, even though it would have to be possible in some manner which cannot yet be indicated to represent such paths by organic elements of the nervous system.

[1905c, 1735]

It is not, of course, to be expected that either the primitive or the present-day concept of a 'soul' will be separated from that of the other portion of the personality by the same line of demarcation which our modern science draws between conscious and unconscious mental activity. The animistic soul unites properties from both sides. Its volatile and mobile quality, its power of leaving the body and of taking possession, temporarily or permanently, of another body - these are characteristics which remind us unmistakably of the nature of consciousness. But the way in which it remains concealed behind the manifest personality is reminiscent of the unconscious; immutability and indestructibility are qualities which we no longer attribute to conscious but rather to unconscious processes, and we regard the latter as the true vehicle of mental activity.

[1912-1913, 2736]
'The whole process, however, only becomes possible through the single circumstance that you are mistaken in another important point as well. You feel sure that you are informed of all that goes on in your mind if it is of any importance at all, because in that case, you believe, your consciousness gives you news of it. And if you have had no information of something in your mind you confidently assume that it does not exist there. Indeed, you go so far as to regard what is "mental" as identical with what is "conscious" - that is, with what is known to you in spite of the most obvious evidence that a great deal more must constantly be going on in your mind than can be known to your consciousness. Come, let yourself be taught something on this one point! What is in your mind does not coincide with what you are conscious of; whether something is going on in your mind and whether you hear of it, are two different things. In the ordinary way, I will admit, the intelligence which reaches your consciousness is enough for your needs; and you may cherish the illusion that you learn of all the more important things. But in some cases, as in that of an instinctual conflict such as I have described, your intelligence service breaks down and your will then extends no further than your knowledge. In every case, however, the news that reaches your consciousness is incomplete and often not to be relied on. Often enough, too, it happens that you get news of events only when they are over and when you can no longer do anything to change them. Even if you are not ill, who can tell all that is stirring in your mind of which you know nothing or are falsely informed? You behave like an absolute ruler who is content with the information supplied him by his highest officials and never goes among the people to hear their voice. Turn your eyes inward, look into your own depths, learn first to know yourself! Then you will understand why you were bound to fall ill; and perhaps, you will avoid falling ill in future.'

[1917a, 3614]

After hypnosis was replaced by the technique of free association, Breuer's cathartic procedure turned into psycho-analysis, which for more than a decade was developed by the author (Freud) alone. During that time psycho-analysis gradually acquired a theory which appeared to give a satisfactory account of the origin, meaning and purpose of neurotic symptoms and provided a rational basis for medical attempts at curing the complaint. I will once again enumerate the factors that go to make up this theory. They are: emphasis on instinctual life (affectivity), on mental dynamics, on the fact that even the apparently most obscure and arbitrary mental phenomena invariably have a meaning and a causation, the theory of psychical conflict and of the pathogenic nature of repression, the view that symptoms are substitutive satisfactions, the recognition of the aetiological importance of sexual life, and in particular of the beginnings of infantile sexuality. From a philosophical standpoint this theory was bound to adopt the view that the mental does not coincide with the conscious, that mental processes are in themselves unconscious and are only made conscious by the functioning of special organs (agencies or systems). By way of completing this list, I will add that among the affective attitudes of childhood the complicated emotional relation of children to their parents - what is known as the Oedipus complex - came into prominence. It became ever clearer that this was the nucleus of every case of neurosis, and in the patient's behaviour towards his analyst certain phenomena of his emotional transference emerged which came to be of great importance for theory and technique alike.

[1924f, 4107]
What, then, can a philosopher say to a theory which, like psycho-analysis, asserts that on the contrary what is mental is in itself unconscious and that being conscious is only a quality, which may or may not accrue to a particular mental act and the withholding of which may perhaps alter that act in no other respect? He will naturally say that anything both unconscious and mental would be an impossibility, a contradictio in adjecto, and he will fail to observe that in making this judgement he is merely repeating his own definition of what is mental, a definition which may perhaps be too narrow. It is easy for philosophers to feel this certainty, since they have no acquaintance with the material whose investigation has compelled analysts to believe in unconscious mental acts. Philosophers have never taken account of hypnosis, they have not concerned themselves with the interpreting of dreams - on the contrary, like doctors, they regard dreams as the meaningless products of reduced mental activity during sleep - they are scarcely aware that there are such things as obsessions and delusions and they would find themselves in a most embarrassing situation if they were asked to explain them on the basis of their own psychological premisses. Analysts, too, refuse to say what the unconscious is, but they can indicate the domain of phenomena whose observation has obliged them to assume its existence. Philosophers, who know no kind of observation other than self-observation, cannot follow them into that domain.

But the study of pathogenic repressions and of other phenomena which have still to be mentioned compelled psycho-analysis to take the concept of the 'unconscious' seriously. Psycho-analysis regarded everything mental as being in the first instance unconscious; the further quality of 'consciousness' might also be present, or again it might be absent. This of course provoked a denial from the philosophers, for whom 'conscious' and 'mental' were identical, and who protested that they could not conceive of such an absurdity as the 'unconscious mental'. There was no help for it, however, and this idiosyncrasy of the philosophers could only be disregarded with a shrug. Experience (gained from pathological material, of which the philosophers were ignorant) of the frequency and power of impulses of which one knew nothing directly, and whose existence had to be inferred like some fact in the external world, left no alternative open. It could be pointed out, incidentally, that this was only treating one's own mental life as one had always treated other people's. One did not hesitate to ascribe mental processes to other people, although one had no immediate consciousness of them and could only infer them from their words and actions. But what held good for other people must be applicable to oneself. Anyone who tried to push the argument further and to conclude from it that one's own hidden processes belonged actually to a second consciousness would be faced with the concept of a consciousness of which one knew nothing, of an 'unconscious consciousness' - and this would scarcely be preferable to the assumption of an 'unconscious mental'. If on the other hand one declared, like some other philosophers, that one was prepared to take pathological phenomena into account, but that the processes underlying them ought not to be described as mental but as 'psychoid', the difference of opinion would degenerate into an unfruitful dispute about words, though even so expediency would decide in favour of keeping the expression 'unconscious mental'. The further question as to the ultimate nature of this unconscious is no more sensible or profitable than the older one as to the nature of the conscious.

[1925d, 4208]
But that is precisely what psycho-analysis is obliged to assert, and this is its second fundamental hypothesis. It explains the supposedly somatic concomitant phenomena as being what is truly psychical, and thus in the first instance disregards the quality of consciousness. It is not alone in doing this. Some thinkers (such as Theodor Lipps, for instance) have asserted the same thing in the same words; and the general dissatisfaction with the usual view of what is psychical has resulted in an increasingly urgent demand for the inclusion in psychological thought of a concept of the unconscious, though this demand has taken such an indefinite and obscure form that it could have no influence on science.

[1940a [1938], 4968]

Now it would look as though this dispute between psycho-analysis and philosophy is concerned only with a trifling matter of definition - the question whether the name 'psychical' should be applied to one or another sequence of phenomena. In fact, however, this step has become of the highest significance. Whereas the psychology of consciousness never went beyond the broken sequences which were obviously dependent on something else, the other view, which held that the psychical is unconscious in itself, enabled psychology to take its place as a natural science like any other. The processes with which it is concerned are in themselves just as unknowable as those dealt with by other sciences, by chemistry or physics, for example; but it is possible to establish the laws which they obey and to follow their mutual relations and interdependences unbroken over long stretches - in short, to arrive at what is described as an 'understanding' of the field of natural phenomena in question. This cannot be effected without framing fresh hypotheses and creating fresh concepts; but these are not to be despised as evidence of embarrassment on our part but deserve on the contrary to be appreciated as an enrichment of science. They can lay claim to the same value as approximations that belongs to the corresponding intellectual scaffolding found in other natural sciences, and we look forward to their being modified, corrected and more precisely determined as further experience is accumulated and sifted. So too it will be entirely in accordance with our expectations if the basic concepts and principles of the new science (instinct, nervous energy, etc.) remain for a considerable time no less indeterminate than those of the older sciences (force, mass, attraction, etc.).

[1940a [1938], 4968]

Psycho-analysis escaped such difficulties as these by energetically denying the equation between what is psychical and what is conscious. No; being conscious cannot be the essence of what is psychical. It is only a quality of what is psychical, and an inconstant quality at that - one that is far oftener absent than present. The psychical, whatever its nature may be, is in itself unconscious and probably similar in kind to all the other natural processes of which we have obtained knowledge.

[1940b [1938], 5068]
Footnote added 1924:] This book is of an entirely popular character; it merely aims, by an accumulation of examples, at paving the way for the necessary assumption of unconscious yet operative mental processes, and it avoids all theoretical considerations on the nature of this unconscious.

[1901b, 1341]

A number of the results of the analysis have been omitted, because at the time when work was broken off they had either not been established with sufficient certainty or they required further study before any general statement could be made about them. At other points, where it seemed to be permissible, I have indicated the direction along which some particular solution would probably have been found to lie. I have in this paper left entirely out of account the technique, which does not at all follow as a matter of course, but by whose means alone the pure metal of valuable unconscious thoughts can be extracted from the raw material of the patient's associations. This brings with it the disadvantage of the reader being given no opportunity of testing the correctness of my procedure in the course of this exposition of the case. I found it quite impracticable, however, to deal simultaneously with the technique of analysis and with the internal structure of a case of hysteria: I could scarcely have accomplished such a task, and if I had, the result would have been almost unreadable. The technique of analysis demands an entirely separate exposition, which would have to be illustrated by numerous examples chosen from a very great variety of cases and which would not have to take the results obtained in each particular case into account. Nor have I attempted in this paper to substantiate the psychological postulates which will be seen to underlie my descriptions of mental phenomena. A cursory attempt to do so would have effected nothing; an exhaustive one would have been a volume in itself. I can only assure the reader that I approached the study of the phenomena revealed by observation of the psychoneuroses without being pledged to any particular psychological system, and that I then proceeded to adjust my views until they seemed adapted for giving an account of the collection of facts which had been observed. I take no pride in having avoided speculation; the material for my hypotheses was collected by the most extensive and laborious series of observations. The decidedness of my attitude on the subject of the unconscious is perhaps specially likely to cause offence, for I handle unconscious ideas, unconscious trains of thought, and unconscious impulses as though they were no less valid and unimpeachable psychological data than conscious ones. But of this I am certain - that any one who sets out to investigate the same region of phenomena and employs the same method will find himself compelled to take up the same position, however much philosophers may expostulate.

[1905e, 1446]
A theory which is novel, which lacks simplicity and which runs counter to our habits of thought, can scarcely gain in clarity from a concise presentation. All I can aim at in these remarks, therefore, is to draw attention to the fuller treatment of the unconscious in my Interpretation of Dreams and to the writings of Lipps, which seem to me of the highest importance. I am aware that anyone who is under the spell of a good academic philosophical education, or who takes his opinions at long range from some so-called system of philosophy, will be opposed to the assumption of an 'unconscious psychical' in the sense in which Lipps and I use the term, and will prefer to prove its impossibility on the basis of a definition of the psychical. But definitions are a matter of convention and can be altered. I have often found that people who dispute the unconscious as being something absurd and impossible have not formed their impressions from the sources from which I at least was brought to the necessity of recognizing it. These opponents of the unconscious had never witnessed the effect of a post-hypnotic suggestion, and when I have told them examples from my analyses with non-hypnotized neurotics they have been filled with the greatest astonishment. They had never realized the idea that the unconscious is something which we really do not know, but which we are obliged by compelling inferences to supply; they had understood it as being something capable of becoming conscious but which was not being thought of at the moment, which did not occupy 'the focal point of attention'. Nor had they ever tried to convince themselves of the existence in their own minds of unconscious thoughts like these by analysing one of their own dreams; and when I attempted to do so with them they could only greet their own associations with surprise and confusion. I have also formed an impression that fundamental emotional resistances stand in the way of accepting the 'unconscious', and that these are based on the fact that no one wants to get to know his unconscious and that the most convenient plan is to deny its possibility altogether.

[1905c, 1747]

And here we must give what will perhaps be an unexpected answer. In fact the situation is quite the reverse: it is science that cannot hold its own before the achievement of the author. Science allows a gulf to yawn between the hereditary and constitutional preconditions of a delusion and its creations, which seem to emerge ready-made - a gulf which we find that our author has filled. Science does not as yet suspect the importance of repression, it does not recognize that in order to explain the world of psychopathological phenomena the unconscious is absolutely essential, it does not look for the basis of delusions in a psychical conflict, and it does not regard their symptoms as compromises. Does our author stand alone, then, in the face of united science? No, that is not the case (if, that is, I may count my own works as part of science), since for a number of years - and, until recently, more or less alone¹ - I myself have supported all the views that I have here extracted from Jensen's Gradiva and stated in technical terms. I indicated, in most detail in connection with the states known as hysteria and obsessions, that the individual determinant of these psychical disorders is the suppression of a part of instinctual life and the repression of the ideas by which the suppressed instinct is represented, and soon afterwards I repeated the same views in relation to some forms of delusion.² The question whether the instincts concerned in this causation are always components of the sexual instinct or may be of another kind as well is a problem which may be regarded as a matter of indifference in the particular case of the analysis of Gradiva; for in the instance chosen by our author what was at issue was quite certainly nothing other than the suppression of erotic feelings. The validity of the hypotheses of psychical conflict and of the formation of symptoms by means of compromises between the two mental currents struggling against each other has been demonstrated by me in the case of patients observed and medically treated in real life, just as I have been able to in the imaginary case of Norbert Hanold.³ Even before me, Pierre Janet, a pupil of the great Charcot, and Josef Breuer, in collaboration with me, had traced back the products of neurotic, and especially of hysterical, illness to the power of unconscious thoughts.⁴

[1907a, 1851]
We find, accordingly: an erotic instinct and a revolt against it; a wish which has not yet become compulsive and, struggling against it, a fear which is already compulsive; a distressing affect and an impulsion towards the performance of defensive acts. The inventory of the neurosis has reached its full muster. Indeed, something more is present, namely, a kind of delusion or delirium with the strange content that his parents knew his thoughts because he spoke them out loud without his hearing himself do it. We shall not go far astray if we suppose that in making this attempt at an explanation the child had some inkling of those remarkable mental processes which we describe as unconscious and which we cannot dispense with if we are to throw any scientific light upon this obscure subject. 'I speak my thoughts out loud, without hearing them' sounds like a projection into the external world of our own hypothesis that he had thoughts without knowing anything about them; it sounds like an endopsychic perception of what has been repressed.

I shall not in the present paper attempt any discussion of the psychological significance of obsessional thinking. Such a discussion would be of extraordinary value in its results, and would do more to clarify our ideas upon the nature of the conscious and the unconscious than any study of hysteria or the phenomena of hypnosis. It would be a most desirable thing if the philosophers and psychologists who develop brilliant theoretical views on the unconscious upon a basis of hearsay knowledge or from their own conventional definitions would first submit to the convincing impressions which may be gained from a first-hand study of the phenomena of obsessional thinking. We might almost go to the length of requiring it of them, if the task were not so far more laborious than the methods of work to which they are accustomed. I will only add here that in obsessional neuroses the unconscious mental processes occasionally break through into consciousness in their pure and undistorted form, that such incursions may take place at every possible stage of the unconscious process of thought, and that at the moment of the incursion the obsessional ideas can, for the most part, be recognized as formations of very long standing. This accounts for the striking circumstance that, when the analyst tries, with the patient's help, to discover the date of the first occurrence of an obsessional idea, the patient is obliged to place it further and further back as the analysis proceeds, and is constantly finding fresh 'first' occasions for the appearance of the obsession.

This seems perfectly sound and will satisfy anyone who can ignore the many enigmas that lie concealed behind the concepts of hypnosis, suggestion and autosuggestion. Autosuggestion in particular raises further questions. When and under what conditions does an idea become so powerful that it is able to behave like a suggestion and turn into reality without more ado? Closer investigation has taught us that we cannot answer this question without calling the concept of the 'unconscious' to our assistance. Many philosophers rebel against the assumption of a mental unconscious of this kind, because they have not concerned themselves with the phenomena which compel us to make that assumption. Psychopathologists have found that they cannot avoid working with such things as unconscious mental processes, unconscious ideas, and so on.

Appropriate experiments have shown that people who are hysterically blind do nevertheless see in some sense, though not in the full sense. Excitations of the blind eye may have certain psychical consequences (for instance, they may produce affects) even though they do not become conscious. Thus hysterically blind people are only blind as far as consciousness is concerned; in their unconscious they see. It is precisely observations such as this that compel us to distinguish between conscious and unconscious mental processes.
This might be considered an uninteresting piece of descriptive or classificatory work if no experience appealed to our judgement other than the facts of memory, or the cases of association by unconscious links. The well-known experiment, however, of the ‘post-hypnotic suggestion’ teaches us to insist upon the importance of the distinction between conscious and unconscious and seems to increase its value. [1912g, 2577]

In this experiment, as performed by Bernheim, a person is put into a hypnotic state and is subsequently aroused. While he was in the hypnotic state, under the influence of the physician, he was ordered to execute a certain action at a certain fixed moment after his awakening, say half an hour later. He awakes, and seems fully conscious and in his ordinary condition; he has no recollection of his hypnotic state, and yet at the prearranged moment there rushes into his mind the impulse to do such and such a thing, and he does it consciously, though not knowing why. It seems impossible to give any other description of the phenomenon than to say that the order had been present in the mind of the person in a condition of latency, or had been present unconsciously, until the given moment came, and then had become conscious. But not the whole of it emerged into consciousness: only the conception of the act to be executed. All the other ideas associated with this conception - the order, the influence of the physician, the recollection of the hypnotic state, remained unconscious even then. [1912g, 2578]

Philosophy, in so far as it is built on psychology, will be unable to avoid taking the psychoanalytic contributions to psychology fully into account and reacting to this new enrichment of our knowledge just as it has to every considerable advance in the specialized sciences. In particular, the setting up of the hypothesis of unconscious mental activities must compel philosophy to decide one way or the other and, if it accepts the idea, to modify its own views on the relation of mind to body so that they may conform to the new knowledge. It is true that philosophy has repeatedly dealt with the problem of the unconscious, but, with few exceptions, philosophers have taken up one or other of the two following positions. Either their unconscious has been something mystical, something intangible and undemonstrable, whose relation to the mind has remained obscure, or they have identified the mental with the conscious and have proceeded to infer from this definition that what is unconscious cannot be mental or a subject for psychology. These opinions must be put down to the fact that philosophers have formed their judgement on the unconscious without being acquainted with the phenomena of unconscious mental activity, and therefore without any suspicion of how far unconscious phenomena resemble conscious ones or of the respects in which they differ from them. If anyone possessing that knowledge nevertheless holds to the conviction which equates the conscious and the psychical and consequently denies the unconscious the attribute of being psychical, no objection can, of course, be made except that such a distinction turns out to be highly unpractical. For it is easy to describe the unconscious and to follow its developments if it is approached from the direction of its relation to the conscious, with which it has so much in common. On the other hand, there still seems no possibility of approaching it from the direction of physical events. So that it is bound to remain a matter for psychological study. [1913j, 2815]

Our right to assume the existence of something mental that is unconscious and to employ that assumption for the purposes of scientific work is disputed in many quarters. To this we can reply that our assumption of the unconscious is necessary and legitimate, and that we possess numerous proofs of its existence. [1915e, 2991]
The link with the scene after her unhappy wedding-night and the patient's affectionate motive constituted, taken together, what we have called the 'sense' of the obsessional action. But while she was carrying out the obsessional action this sense had been unknown to her in both directions - both its 'whence' and its 'whither'. Mental processes had therefore been at work in her and the obsessional action was the effect of them; she had been aware of this effect in a normal mental fashion, but none of the mental predeterminants of this effect came to the knowledge of her consciousness. She behaved in precisely the same way as a hypnotized subject whom Bernheim had ordered to open an umbrella in the hospital ward five minutes after he woke up. The man carried out this instruction when he was awake, but he could produce no motive for his action. It is a state of affairs of this sort that we have before our eyes when we speak of the existence of unconscious mental processes. We can challenge anyone in the world to give a more correct scientific account of this state of affairs, and if he does we will gladly renounce our hypothesis of unconscious mental processes. Till that happens, however, we will hold fast to the hypothesis; and if someone objects that here the unconscious is nothing real in a scientific sense, is a makeshift, *une façon de parler*, we can only shrug our shoulders resignedly and dismiss what he says as unintelligible. Something not real, which produces effects of such tangible reality as an obsessional action!

If, now, you consider further that the state of affairs which we have established in our two cases is confirmed for every symptom of every neurotic illness - that always and everywhere the sense of the symptoms is unknown to the patient and that analysis regularly shows that these symptoms are derivatives of unconscious processes but can, subject to a variety of favourable circumstances, be made conscious - if you consider this, you will understand that in psycho-analysis we cannot do without what is at the same time unconscious and mental, and are accustomed to operate with it as though it were something palpable to the senses. But you will understand as well, perhaps, how incapable of forming a judgement on this question are all those other people, who are only acquainted with the unconscious as a concept, who have never carried out an analysis and have never interpreted dreams or found a sense and intention in neurotic symptoms. To say it for our ends once again: the possibility of giving a sense to neurotic symptoms by analytic interpretation is an unshakeable proof of the existence - or, if you prefer it, of the necessity for the hypothesis - of unconscious mental processes.

The division of the psychical into what is conscious and what is unconscious is the fundamental premiss of psycho-analysis; and it alone makes it possible for psycho-analysis to understand the pathological processes in mental life, which are as common as they are important, and to find a place for them in the framework of science. To put it once more, in a different way: psycho-analysis cannot situate the essence of the psychical in consciousness, but is obliged to regard consciousness as a quality of the psychical, which may be present in addition to other qualities or may be absent.

If I could suppose that everyone interested in psychology would read this book, I should also be prepared to find that at this point some of my readers would already stop short and would go no further; for here we have the first shibboleth of psycho-analysis. To most people who have been educated in philosophy the idea of anything psychical which is not also conscious is so inconceivable that it seems to them absurd and refutable simply by logic. I believe this is only because they have never studied the relevant phenomena of hypnosis and dreams, which - quite apart from pathological manifestations - necessitate this view. Their psychology of consciousness is incapable of solving the problems of dreams and hypnosis.
But we have arrived at the term or concept of the unconscious along another path, by considering certain experiences in which mental dynamics play a part. We have found - that is, we have been obliged to assume - that very powerful mental processes or ideas exist (and here a quantitative or economic factor comes into question for the first time) which can produce all the effects in mental life that ordinary ideas do (including effects that can in their turn become conscious as ideas), though they themselves do not become conscious. It is unnecessary to repeat in detail here what has been explained so often before. It is enough to say that at this point psycho-analytic theory steps in and asserts that the reason why such ideas cannot become conscious is that a certain force opposes them, that otherwise they could become conscious, and that it would then be apparent how little they differ from other elements which are admittedly psychical. The fact that in the technique of psycho-analysis a means has been found by which the opposing force can be removed and the ideas in question made conscious renders this theory irrefutable. The state in which the ideas existed before being made conscious is called by us repression, and we assert that the force which instituted the repression and maintains it is perceived as resistance during the work of analysis.

If we may assume that the most general features of unconscious mental life (conflicts between instinctual impulses, repressions and substitutive satisfactions) are present everywhere, and if there is a depth-psychology which leads to a knowledge of those features, then we may reasonably expect that the application of psycho-analysis to the most varied spheres of human mental activity will everywhere bring to light important and hitherto unattainable results. In an exceedingly valuable study, Otto Rank and Hanns Sachs (1913) have tried to bring together what the work of psycho-analysts had been able to achieve up to that time towards fulfilling these expectations. Lack of space prevents me from attempting to complete their enumeration here. I can only select for mention the most important findings with the addition of a few details.

What, then, can a philosopher say to a theory which, like psycho-analysis, asserts that on the contrary what is mental is in itself unconscious and that being conscious is only a quality, which may or may not accrue to a particular mental act and the withholding of which may perhaps alter that act in no other respect? He will naturally say that anything both unconscious and mental would be an impossibility, a contradictio in adjecto, and he will fail to observe that in making this judgement he is merely repeating his own definition of what is mental, a definition which may perhaps be too narrow. It is easy for philosophers to feel this certainty, since they have no acquaintance with the material whose investigation has compelled analysts to believe in unconscious mental acts. Philosophers have never taken account of hypnosis, they have not concerned themselves with the interpreting of dreams - on the contrary, like doctors, they regard dreams as the meaningless products of reduced mental activity during sleep - they are scarcely aware that there are such things as obsessions and delusions and they would find themselves in a most embarrassing situation if they were asked to explain them on the basis of their own psychological premisses. Analysts, too, refuse to say what the unconscious is, but they can indicate the domain of phenomena whose observation has obliged them to assume its existence. Philosophers, who know no kind of observation other than self-observation, cannot follow them into that domain.

<1055>
The question of the relation of the conscious to the psychical may now be regarded as settled: consciousness is only a quality or attribute of what is psychical, and moreover an inconstant one. But there is one further objection with which we have to deal. We are told that, in spite of the facts that have been mentioned, there is no necessity to abandon the identity between what is conscious and what is psychical: the so-called unconscious psychical processes are the organic processes which have long been recognized as running parallel to the mental ones. This, of course, would reduce our problem to an apparently indifferent matter of definition. Our reply is that it would be unjustifiable and inexpedient to make a breach in the unity of mental life for the sake of propping up a definition, since it is clear in any case that consciousness can only offer us an incomplete and broken chain of phenomena. And it can scarcely be a matter of chance that it was not until the change had been made in the definition of the psychical that it became possible to construct a comprehensive and coherent theory of mental life. [1940b [1938], 5071]
A dream, as we have discovered, takes the place of a number of thoughts which are derived from our daily life and which form a completely logical sequence. We cannot doubt, then, that these thoughts originate from our normal mental life. All the attributes which we value highly in our trains of thought, and which characterize them as complex achievements of a high order, are to be found once more in dream-thoughts. There is no need to assume, however, that this activity of thought is performed during sleep - a possibility which would gravely confuse what has hitherto been our settled picture of the psychical state of sleep. On the contrary, these thoughts may very well have originated from the previous day, they may have proceeded unobserved by our consciousness from their start, and may already have been completed at the onset of sleep. The most that we can conclude from this is that it proves that the most complicated achievements of thought are possible without the assistance of consciousness - a fact which we could not fail to learn in any case from every psycho-analysis of a patient suffering from hysteria or from obsessional ideas. These dream-thoughts are certainly not in themselves inadmissible to consciousness; there may have been a number of reasons for their not having become conscious to us during the day. Becoming conscious is connected with the application of a particular psychical function, that of attention - a function which, as it seems, is only available in a specific quantity, and this may have been diverted from the train of thought in question on to some other purpose. There is another way, too, in which trains of thought of this kind may be withheld from consciousness. The course of our conscious reflections shows us that we follow a particular path in our application of attention. If, as we follow this path, we come upon an idea which will not bear criticism, we break off: we drop the cathexis of attention. Now it seems that the train of thought which has thus been initiated and dropped can continue to spin itself out without attention being turned to it again, unless at some point or other it reaches a specially high degree of intensity which forces attention to it. Thus, if a train of thought is initially rejected (consciously, perhaps) by a judgement that it is wrong or that it is useless for the immediate intellectual purposes in view, the result may be that this train of thought will proceed, unobserved by consciousness, until the onset of sleep.
So far we have been psychologizing on our own account. It is time now to consider the theoretical views which govern present-day psychology and to examine their relation to our hypotheses. The problem of the unconscious in psychology is, in the forcible words of Lipps (1897), less a psychological problem than the problem of psychology. So long as psychology dealt with this problem by a verbal explanation to the effect that 'psychical' meant 'conscious' and that to speak of 'unconscious psychical processes' was palpable nonsense, any psychological evaluation of the observations made by physicians upon abnormal mental states was out of the question. The physician and the philosopher can only come together if they both recognize that the term 'unconscious psychical processes' is 'the appropriate and justified expression of a solidly established fact'. The physician can only shrug his shoulders when he is assured that 'consciousness is an indispensable characteristic of what is psychical', and perhaps, if he still feels enough respect for the utterances of philosophers, he may presume that they have not been dealing with the same thing or working at the same science. For even a single understanding observation of a neurotic's mental life or a single analysis of a dream must leave him with an unshakeable conviction that the most complicated and most rational thought-processes, which can surely not be denied the name of psychical processes, can occur without exciting the subject's consciousness.¹ It is true that the physical cannot learn of these unconscious processes until they have produced some effect upon consciousness which can be communicated or observed. But this conscious effect may exhibit a psychical character quite different from that of the unconscious process, so that internal perception cannot possibly regard the one as a substitute for the other. The physician must feel at liberty to proceed by inference from the conscious effect to the unconscious psychical process. He thus learns that the conscious effect is only a remote psychical result of the unconscious process and that the latter has not become conscious as such; and moreover that the latter was present and operative even without betraying its existence in any way to consciousness.

¹ [Footnote added 1914:] I am happy to be able to point to an author who has drawn from the study of dreams the same conclusions as I have on the relation between conscious and unconscious activity. Du Prel (1885, 47) writes: 'The problem of the nature of the mind evidently calls for a preliminary investigation as to whether consciousness and mind are identical. This preliminary question is answered in the negative by dreams, which show that the concept of the mind is a wider one than that of consciousness, in the same kind of way in which the gravitational force of a heavenly body extends beyond its range of luminosity.' And again (ibid., 306): 'It is a truth which cannot be too distinctly borne in mind that consciousness is not co-extensive with mind.'
Now that the old antithesis between conscious life and dream life has been reduced to its proper proportions by the establishment of unconscious psychical reality, a number of dream-problems with which earlier writers were deeply concerned have lost their significance. Thus some of the activities whose successful performance in dreams excited astonishment are now no longer to be attributed to dreams but to unconscious thinking, which is active during the day no less than at night. If, as Scherner has said, dreams appear to engage in making symbolic representations of the body, we now know that those representations are the product of certain unconscious phantasies (deriving, probably, from sexual impulses) which find expression not only in dreams but also in hysterical phobias and other symptoms. If a dream carries on the activities of the day and completes them and even brings valuable fresh ideas to light, all we need do is to strip it of the dream disguise, which is the product of dream-work and the mark of assistance rendered by obscure forces from the depths of the mind (cf. the Devil in Tartini's sonata dream); the intellectual achievement is due to the same mental forces which produce every similar result during the daytime. We are probably inclined greatly to over-estimate the conscious character of intellectual and artistic production as well. Accounts given us by some of the most highly productive men, such as Goethe and Helmholtz, show rather that what is essential and new in their creations came to them without premeditation and as an almost ready-made whole. There is nothing strange if in other cases, where a concentration of every intellectual faculty was needed, conscious activity also contributed its share. But it is the much-abused privilege of conscious activity, wherever it plays a part, to conceal every other activity from our eyes.

It is not without intention that I speak of 'our' unconscious. For what I thus describe is not the same as the unconscious of the philosophers or even the unconscious of Lipps. By them the term is used merely to indicate a contrast with the conscious: the thesis which they dispute with so much heat and defend with so much energy is the thesis that apart from conscious there are also unconscious psychical processes. Lipps carries things further with his assertion that the whole of what is psychical exists unconsciously and that a part of it also exists consciously. But it is not in order to establish this thesis that we have summoned up the phenomena of dreams and of the formation of hysterical symptoms; the observation of normal waking life would by itself suffice to prove it beyond any doubt. The new discovery that we have been taught by the analysis of psychopathological structures and of the first member of that class - the dream - lies in the fact that the unconscious (that is, the psychical) is found as a function of two separate systems and that this is the case in normal as well as in pathological life. Thus there are two kinds of unconscious, which have not yet been distinguished by psychologists. Both of them are unconscious in the sense used by psychology; but in our sense one of them, which we term the Ucs., is also inadmissible to consciousness, while we term the other the Pcs. because its excitations - after observing certain rules, it is true, and perhaps only after passing a fresh censorship, though nonetheless without regard to the Ucs. - are able to reach consciousness. The fact that excitations in order to reach consciousness must pass through a fixed series or hierarchy of agencies (which is revealed to us by the modifications made in them by censorship) has enabled us to construct a spatial analogy. We have described the relations of the two systems to each other and to consciousness by saying that the system Pcs. stands like a screen between the system Ucs. and consciousness. The system Pcs. not merely bars access to consciousness, it also controls access to the power of voluntary movement and has at its disposal for distribution a mobile cathectic energy, a part of which is familiar to us in the form of attention.²
But what part is there left to be played in our scheme by consciousness, which was once so omnipotent and hid all else from view? Only that of a sense-organ for the perception of psychical qualities. In accordance with the ideas underlying our attempt at a schematic picture, we can only regard conscious perception as the function proper to a particular system; and for this the abbreviation Cs. seems appropriate. In its mechanical properties we regard this system as resembling the perceptual systems Pcpt.: as being susceptible to excitation by qualities but incapable of retaining traces of alterations - that is to say, as having no memory. The psychical apparatus, which is turned towards the external world with its sense-organ of the Pcpt. systems, is itself the external world in relation to the sense-organ of the Cs., whose teleological justification resides in this circumstance. Here we once more meet the principle of the hierarchy of agencies, which seems to govern the structure of the apparatus. Excitatory material flows in to the Cs. sense-organ from two directions: from the Pcpt. system, whose excitation, determined by qualities, is probably submitted to a fresh revision before it becomes a conscious sensation, and from the interior of the apparatus itself, whose quantitative processes are felt qualitatively in the pleasure-unpleasure series when, subject to certain modifications, they make their way to consciousness.

Those philosophers who have become aware that rational and highly complex thought-structures are possible without consciousness playing any part in them have found difficulty in assigning any function to consciousness; it has seemed to them that it can be no more than a superfluous reflected picture of the completed psychical process. We, on the other hand, are rescued from this embarrassment by the analogy between our Cs. system and the perceptual systems. We know that perception by our sense-organs has the result of directing a cathexis of attention to the paths along which the in-coming sensory excitation is spreading: the qualitative excitation of the Pcpt. system acts as a regulator of the discharge of the mobile quantity in the psychical apparatus. We can attribute the same function to the overlying sense-organ of the Cs. system. By perceiving new qualities, it makes a new contribution to directing the mobile quantities of cathexis and distributing them in an expedient fashion. By the help of its perception of pleasure and unpleasure it influences the discharge of the cathexes within what is otherwise an unconscious apparatus operating by means of the displacement of quantities. It seems probable that in the first instance the unpleasure principle regulates the displacement of cathexes automatically. But it is quite possible that consciousness of these qualities may introduce in addition a second and more discriminating regulation, which is even able to oppose the former one, and which perfects the efficiency of the apparatus by enabling it, in contradiction to its original plan, to cathect and work over even what is associated with the release of unpleasure. We learn from the psychology of the neuroses that these processes of regulation carried out by the qualitative excitation of the sense organs play a great part in the functional activity of the apparatus. The automatic domination of the primary unpleasure principle and the consequent restriction imposed upon efficiency are interrupted by the processes of sensory regulation, which are themselves in turn automatic in action. We find that repression (which, though it served a useful purpose to begin with, leads ultimately to a damaging loss of inhibition and mental control) affects memories so much more easily than perceptions because the former can receive no extra cathexis from the excitation of the psychical sense-organs. It is true on the one hand that a thought which has to be warded off cannot become conscious, because it has undergone repression; but on the other hand it sometimes happens that a thought of this kind is only repressed because for other reasons it has been withdrawn from conscious perception. Here are some hints of which we take advantage in our therapeutic procedure in order to undo repressions which have already been effected.

[1900a, 1040]
Of all parapraxes errors seem to have the least rigid mechanism. That is to say, the occurrence of an error is a quite general indication that the mental activity in question has had to struggle with a disturbing influence of some sort or other; but the particular form that the error takes is not determined by the quality of the concealed disturbing idea. We may add here retrospectively that the same thing can be assumed to be true of many simple cases of slips of the tongue and pen. Every time we make a slip in talking or writing we may infer that there has been a disturbance due to mental processes lying outside our intention; but it must be admitted that slips of the tongue and of the pen often obey the laws of resemblance, of indolence or of the tendency to haste, without the disturbing element succeeding in imposing any part of its own character on the resulting mistake in speech or writing. It is the compliance of the linguistic material which alone makes the determining of the mistakes possible, and at the same time sets the limits up to which the determining can go.

(5) I shall dwell longer on analyses of numerical associations, since I know of no other separate observations that would prove so forcefully the existence of highly composite thought-processes which are yet quite unknown to consciousness. At the same time I know of no better example of analyses in which the part contributed by the physician (suggestion) - so often held responsible - is so definitely ruled out. I shall therefore give a report here (with his consent) of the analysis of a number which occurred to a patient of mine. I need only add that he is the youngest child in a large family and at an early age lost his greatly admired father. While he was in a particularly cheerful mood the number 426718 came to his mind, and he asked himself: 'What ideas occur to me in that connection? First of all, a joke I have heard: “When a doctor treats a cold it lasts for 42 days; when it is not treated, it lasts 6 weeks.”' This corresponds to the first figures in the number (42 = 6 x 7). In the stoppage that followed this first solution I drew his attention to the fact that the six-figure number he had chosen contained all the first digits except for 3 and 5. He then immediately found the continuation of the interpretation. 'There are 7 of us brothers and sisters, and I am the youngest. In the order of our age, 3 corresponds to my sister A., and 5 to my brother L.; they were my two enemies. As a child I used to pray to God every night for him to remove these two tormenting spirits from life. It seems to me now that in this choice of numbers I was myself fulfilling this wish; 3 and 5, the wicked brother and the hated sister, are passed over.' - If the number represents the order of your brothers and sisters, what does the 18 at the end mean? There were only 7 of you after all, - 'I have often thought that if my father had lived longer I should not have remained the youngest child. If there had been 1 more we should have been 8 and I should have had a younger child after me to whom I should have played the elder brother.'

And yet illnesses of this kind are the result of intention for the purposes they serve. They are as a rule levelled at a particular person, and consequently vanish with that person's departure. The crudest and most commonplace views on the character of hysterical disorder - such as are to be heard from uneducated relatives or nurses - are in a certain sense right. It is true that the paralysed and bedridden woman would spring to her feet if a fire were to break out in her room, and that the spoiled wife would forget all her sufferings if her child were to fall dangerously ill or if some catastrophe were to threaten the family circumstances. People who speak of the patients in this way are right except upon a single point: they overlook the psychological distinction between what is conscious and what is unconscious. This may be permissible where children are concerned, but with adults it is no longer possible. That is why all these asseverations that it is 'only a question of willing' and all the encouragements and abuse that are addressed to the patient are of no avail. An attempt must first be made by the roundabout methods of analysis to convince the patient herself of the existence in her of an intention to be ill.
Nevertheless, we feel a need to modify Spencer's notion, in part to give a more definite form to the ideas contained in it and in part to change them. We should say that laughter arises if a quota of psychical energy which has earlier been used for the cathexis of particular psychical paths has become unusable, so that it can find free discharge. We are well aware what 'evil looks' we are inviting with such a hypothesis; but we will venture to quote in our defence an apposite sentence from Lipps's book *Komik und Humor* (1898, 71), from which illumination is to be derived on more subjects than that of the comic and humour: 'Finally, specific psychological problems always lead fairly deep into psychology, so that at bottom no psychological problem can be treated in isolation.' The concepts of 'psychical energy' and 'discharge' and the treatment of psychical energy as a quantity have become habitual in my thoughts since I began to arrange the facts of psychopathology philosophically; and already in my *Interpretation of Dreams* (1900a) I tried (in the same sense as Lipps) to establish the fact that what are 'really psychically effective' are psychical processes which are unconscious in themselves, not the contents of consciousness.¹ It is only when I speak of the 'cathexis of psychical paths' that I seem to depart from the analogies commonly used by Lipps. My experiences of the displaceability of psychical energy along certain paths of association, and of the almost indestructible persistence of the traces of psychical processes, have in fact suggested to me an attempt at picturing the unknown in some such way. To avoid misunderstanding, I must add that I am making no attempt to proclaim that the cells and nerve fibres, or the systems of neurones which are taking their place to-day, are these psychical paths, even though it would have to be possible in some manner which cannot yet be indicated to represent such paths by organic elements of the nervous system.

[1905c, 1735]

A theory which is novel, which lacks simplicity and which runs counter to our habits of thought, can scarcely gain in clarity from a concise presentation. All I can aim at in these remarks, therefore, is to draw attention to the fuller treatment of the unconscious in my *Interpretation of Dreams* and to the writings of Lipps, which seem to me of the highest importance. I am aware that anyone who is under the spell of a good academic philosophical education, or who takes his opinions at long range from some so-called system of philosophy, will be opposed to the assumption of an 'unconscious psychical' in the sense in which Lipps and I use the term, and will prefer to prove its impossibility on the basis of a definition of the psychical. But definitions are a matter of convention and can be altered. I have often found that people who dispute the unconscious as being something absurd and impossible have not formed their impressions from the sources from which I at least was brought to the necessity of recognizing it. These opponents of the unconscious had never witnessed the effect of a post-hypnotic suggestion, and when I have told them examples from my analyses with non-hypnotized neurotics they have been filled with the greatest astonishment. They had never realized the idea that the unconscious is something which we really do not know, but which we are obliged by compelling inferences to supply; they had understood it as being something capable of becoming conscious but which was not being thought of at the moment, which did not occupy 'the focal point of attention'. Nor had they ever tried to convince themselves of the existence in their own minds of unconscious thoughts like these by analysing one of their own dreams; and when I attempted to do so with them they could only greet their own associations with surprise and confusion. I have also formed an impression that fundamental emotional resistances stand in the way of accepting the 'unconscious', and that these are based on the fact that no one wants to get to know his unconscious and that the most convenient plan is to deny its possibility altogether.

[1905c, 1747]
The state of permanently turning away from women produces a personal susceptibility, or, as we are accustomed to say, a 'disposition' to the formation of a delusion. The development of the mental disorder sets in at the moment when a chance impression arouses the childhood experiences which have been forgotten and which have traces, at least, of an erotic colouring. 'Arouses', however, is certainly not the right description, if we take into account what follows. We must repeat the author's accurate account in correct psychological technical terms. When Norbert Hanold saw the relief, he did not remember that he had already seen a similar posture of the foot in his childhood friend; he remembered nothing at all, but all the effects brought about by the relief originated from this link that was made with the impression of his childhood. Thus the childhood impression was stirred up, it became active, so that it began to produce effects, but it did not come into consciousness - it remained 'unconscious', to use a term which has to-day become unavoidable in psychopathology. We are anxious that this unconscious shall not be involved in any of the disputes of philosophers and natural philosophers, which have often no more than an etymological importance. For the time being we possess no better name for psychical processes which behave actively but nevertheless do not reach the consciousness of the person concerned, and that is all we mean by our 'unconsciousness'. When some thinkers try to dispute the existence of an unconscious of this kind, on the ground that it is nonsensical, we can only suppose that they have never had to do with the corresponding mental phenomena, that they are under the spell of the regular experience that everything mental that becomes active and intense becomes at the same time conscious as well, and that they have still to learn (what our author knows very well) that there are most certainly mental processes which, in spite of being intense and producing effects, none the less remain apart from consciousness.

[1907a, 1846]

Anyone who studies hysteria, therefore, soon finds his interest turned away from its symptoms to the phantasies from which they proceed. The technique of psycho-analysis enables us in the first place to infer from the symptoms what those unconscious phantasies are and then to make them conscious to the patient. By this means it has been found that the content of the hysterics' unconscious phantasies corresponds completely to the situations in which satisfaction is consciously obtained by perverts; and if anyone is at a loss for examples of such situations he has only to recall the world-famous performances of the Roman Emperors, the wild excesses of which were, of course, determined only by the enormous and unrestrained power possessed by the authors of the phantasies. The delusions of paranoics are phantasies of the same nature, though they are phantasies which have become directly conscious. They rest on the sadomasochistic components of the sexual instinct, and they, too, may find their complete counterpart in certain unconscious phantasies of hysterical subjects. We also know of cases - cases which have their practical importance as well - in which hysterics do not give expression to their phantasies in the form of symptoms but as conscious realizations, and in that way devise and stage assaults, attacks or acts of sexual aggression.

[1908a, 1935]

We can go a step further in vindicating little Hans's honour. As a matter of fact, he was behaving no worse than a philosopher of the school of Wundt. In the view of that school, consciousness is the invariable characteristic of what is mental, just as in the view of little Hans a widdler is the indispensable criterion of what is animate. If now the philosopher comes across mental processes whose existence cannot but be inferred, but about which there is not a trace of consciousness to be detected - for the subject, in fact, knows nothing of them, although it is impossible to avoid inferring their existence - then, instead of saying that they are unconscious mental processes, he calls them semi-conscious. The widdler's still very small! And in this comparison the advantage is in favour of little Hans. For, as is so often the case with the sexual researches of children, behind the mistake a piece of genuine knowledge lies concealed. Little girls do possess a small widdler, which we call a clitoris, though it does not grow any larger but remains permanently stunted. Compare my short paper on 'The Sexual Theories of Children' (1908c).

[1909b, 2007]
Two other boys were reported to me as having made the same judgement, expressed in identical words and followed by the same anticipation, when they were allowed to satisfy their curiosity and look at their baby sister's body for the first time. One might well feel horrified at such signs of the premature decay of a child's intellect. Why was it that these young enquirers did not report what they really saw - namely, that there was no widdler there? In little Hans's case, at all events, we can account completely for the faulty perception. We are aware that by a process of careful induction he had arrived at the general proposition that every animate object, in contradistinction to inanimate ones, possesses a widdler. His mother had confirmed him in this conviction by giving him corroborative information in regard to persons inaccessible to his own observation. He was now utterly incapable of surrendering what he had achieved merely on the strength of this single observation made upon his little sister. He therefore made a judgement that in that instance also there was a widdler present, only that it was still very small, but that it would grow till it was as big as a horse's.

[1909b, 2007]

At this very point we may be prepared to meet with the philosophical objection that the latent conception did not exist as an object of psychology, but as a physical disposition for the recurrence of the same psychical phenomenon, i.e. of the said conception. But we may reply that this is a theory far overstepping the domain of psychology proper; that it simply begs the question by asserting 'conscious' to be an identical term with 'psychical', and that it is clearly at fault in denying psychology the right to account for its most common facts, such as memory, by its own means.

[1912g, 2577]

We learn therefore by the analysis of neurotic phenomena that a latent or unconscious idea is not necessarily a weak one, and that the presence of such an idea in the mind admits of indirect proofs of the most cogent kind, which are equivalent to the direct proof furnished by consciousness. We feel justified in making our classification agree with this addition to our knowledge by introducing a fundamental distinction between different kinds of latent or unconscious ideas. We were accustomed to think that every latent idea was so because it was weak and that it grew conscious as soon as it became strong. We have not gained the conviction that there are some latent ideas which do not penetrate into consciousness, however strong they may have become. Therefore we may call the latent ideas of the first type foreconscious,¹ while we reserve the term unconscious (proper) for the latter type which we came to study in the neuroses. The term unconscious, which was used in the purely descriptive sense before, now comes to imply something more. It designates not only latent ideas in general, but especially ideas with a certain dynamic character, ideas keeping apart from consciousness in spite of their intensity and activity.

[1912g, 2579]

The other objection that may probably be raised would be that we apply to normal psychology conclusions which are drawn chiefly from the study of pathological conditions. We are enabled to answer it by another fact, the knowledge of which we owe to psycho-analysis. Certain deficiencies of function of most frequent occurrence among healthy people, e.g. lapsus linguae, errors in memory and speech, forgetting of names, etc., may easily be shown to depend on the action of strong unconscious ideas in the same way as neurotic symptoms. We shall meet with another still more convincing argument at a later stage of this discussion.

[1912g, 2580]

How are we to arrive at a knowledge of the unconscious? It is of course only as something conscious that we know it, after it has undergone transformation or translation into something conscious. Psycho-analytic work shows us every day that translation of this kind is possible. In order that this should come about, the person under analysis must overcome certain resistances - the same resistances as those which, earlier, made the material concerned into something repressed by rejecting it from the conscious.

[1915e, 2991]
Our right to assume the existence of something mental that is unconscious and to employ that assumption for the purposes of scientific work is disputed in many quarters. To this we can reply that our assumption of the unconscious is necessary and legitimate, and that we possess numerous proofs of its existence.

It is necessary because the data of consciousness have a very large number of gaps in them; both in healthy and in sick people psychical acts often occur which can be explained only by presupposing other acts, of which, nevertheless, consciousness affords no evidence. These not only include parapraxes and dreams in healthy people, and everything described as a psychical symptom or an obsession in the sick; our most personal daily experience acquaints us with ideas that come into our head we do not know from where, and with intellectual conclusions arrived at we do not know how. All these conscious acts remain disconnected and unintelligible if we insist upon claiming that every mental act that occurs in us must also necessarily be experienced by us through consciousness; on the other hand, they fall into a demonstrable connection if we interpolate between them the unconscious acts which we have inferred. A gain in meaning is a perfectly justifiable ground for going beyond the limits of direct experience. When, in addition, it turns out that the assumption of there being an unconscious enables us to construct a successful procedure by which we can exert an effective influence upon the course of conscious processes, this success will have given us an incontrovertible proof of the existence of what we have assumed. This being so, we must adopt the position that to require that whatever goes on in the mind must also be known to consciousness is to make an untenable claim.

We can go further and argue, in support of there being an unconscious psychical state, that at any given moment consciousness includes only a small content, so that the greater part of what we call conscious knowledge must in any case be for very considerable periods of time in a state of latency, that is to say, of being psychically unconscious. When all our latent memories are taken into consideration it becomes totally incomprehensible how the existence of the unconscious can be denied. But here we encounter the objection that these latent recollections can no longer be described as psychical, but that they correspond to residues of somatic processes from which what is psychical can once more arise. The obvious answer to this is that a latent memory is, on the contrary, an unquestionable residuum of a psychical process. But it is more important to realize clearly that this objection is based on the equation - not, it is true, explicitly stated but taken as axiomatic - of what is conscious with what is mental. This equation is either a petitio principii which begs the question whether everything that in psychical is also necessarily conscious; or else it is a matter of convention, of nomenclature. In the latter case it is, of course, like any other convention, not open to refutation. The question remains, however, whether the convention is so expedient that we are bound to adopt it. To this we may reply that the conventional equation of the psychical with the conscious is totally inexpedient. It disrupts psychical continuities, plunges us into the insoluble difficulties of psycho-physical parallelism, is open to the reproach that for no obvious reason it over-estimates the part played by consciousness, and that it forces us prematurely to abandon the field of psychological research without being able to offer us any compensation from other fields.
It is clear in any case that this question - whether the latent states of mental life, whose existence is undeniable, are to be conceived of as conscious mental states or as physical ones - threatens to resolve itself into a verbal dispute. We shall therefore be better advised to focus our attention on what we know with certainty of the nature of these debatable states. As far as their physical characteristics are concerned, they are totally inaccessible to us: no physiological concept or chemical process can give us any notion of their nature. On the other hand, we know for certain that they have abundant points of contact with conscious mental processes; with the help of a certain amount of work they can be transformed into, or replaced by, conscious mental processes, and all the categories which we employ to describe conscious mental acts, such as ideas, purposes, resolutions and so on, can be applied to them. Indeed, we are obliged to say of some of these latent states that the only respect in which they differ from conscious ones is precisely in the absence of consciousness. Thus we shall not hesitate to treat them as objects of psychological research, and to deal with them in the most intimate connection with conscious mental acts.

[1915e, 2992]

The stubborn denial of a psychical character to latent mental acts is accounted for by the circumstance that most of the phenomena concerned have not been the subject of study outside psycho-analysis. Anyone who is ignorant of pathological facts, who regards the parapraxes of normal people as accidental, and who is content with the old saw that dreams are froth ['Träume sind Schäume'] has only to ignore a few more problems of the psychology of consciousness in order to spare himself any need to assume an unconscious mental activity. Incidentally, even before the time of psycho-analysis, hypnotic experiments, and especially post-hypnotic suggestion, had tangibly demonstrated the existence and mode of operation of the mental unconscious.

[1915e, 2992]

The assumption of an unconscious is, moreover, a perfectly legitimate one, inasmuch as in postulating it we are not departing a single step from our customary and generally accepted mode of thinking. Consciousness makes each of us aware only of his own states of mind; that other people, too, possess a consciousness is an inference which we draw by analogy from their observable utterances and actions, in order to make this behaviour of theirs intelligible to us. (It would no doubt be psychologically more correct to put it in this way: that without any special reflection we attribute to everyone else our own constitution and therefore our consciousness as well, and that this identification is a sine qua non of our understanding.) This inference (or this identification) was formerly extended by the ego to other human beings, to animals, plants, inanimate objects and to the world at large, and proved serviceable so long as their similarity to the individual ego was overwhelmingly great; but it became more untrustworthy in proportion as the difference between the ego and these 'others' widened. To-day, our critical judgement is already in doubt on the question of consciousness in animals; we refuse to admit it in plants and we regard the assumption of its existence in inanimate matter as mysticism. But even where the original inclination to identification has withstood criticism - that is, when the 'others' are our fellow-men - the assumption of a consciousness in them rests upon an inference and cannot share the immediate certainty which we have of our own consciousness.

[1915e, 2993]
Psycho-analysis demands nothing more than that we should apply this process of inference to ourselves also - a proceeding to which, it is true, we are not constitutionally inclined. If we do this, we must say: all the acts and manifestations which I notice in myself and do not know how to link up with the rest of my mental life must be judged as if they belonged to someone else: they are to be explained by a mental life ascribed to this other person. Furthermore, experience shows that we understand very well how to interpret in other people (that is, how to fit into their chain of mental events) the same acts which we refuse to acknowledge as being mental in ourselves. Here some special hindrance evidently deflects our investigations from our own self and prevents our obtaining a true knowledge of it.

This process of inference, when applied to oneself in spite of internal opposition, does not, however, lead to the disclosure of an unconscious; it leads logically to the assumption of another, second consciousness which is united in one's self with the consciousness one knows. But at this point, certain criticisms may fairly be made. In the first place, a consciousness of which its own possessor knows nothing is something very different from a consciousness belonging to another person, and it is questionable whether such a consciousness, lacking, as it does, its most important characteristic, deserves any discussion at all. Those who have resisted the assumption of an unconscious psychical are not likely to be ready to exchange it for an unconscious consciousness. The second place, analysis shows that the different latent mental processes inferred by us enjoy a high degree of mutual independence, as though they had no connection with one another, and knew nothing of one another. We must be prepared, if so, to assume the existence in us not only of a second consciousness, but of a third, fourth, perhaps of an unlimited number of states of consciousness, all unknown to us and to one another. In the third place - and this is the most weighty argument of all - we have to take into account the fact that analytic investigation reveals some of these latent processes as having characteristics and peculiarities which seem alien to us, or even incredible, and which run directly counter to the attributes of consciousness with which we are familiar. Thus we have grounds for modifying our inference about ourselves and saying that what is proved is not the existence of a second consciousness in us, but the existence of psychical acts which lack consciousness. We shall also be right in rejecting the term 'subconsciousness'¹ as incorrect and misleading. The well-known cases of 'double conscience'¹ (splitting of consciousness) prove nothing against our view. We may most aptly describe them as cases of a splitting of the mental activities into two groups, and say that the same consciousness turns to one or the other of these groups alternately.

The reason for all these difficulties is to be found in the circumstance that the attribute of being conscious, which is the only characteristic of psychical processes that is directly presented to us, is in no way suited to serve as a criterion for the differentiation of systems. Apart from the fact that the conscious is not always conscious but also at times latent, observation has shown that much that shares the characteristics of the system Pcs. does not become conscious; and we learn in addition that the act of becoming conscious is dependent on the attention of the Pcs. being turned in certain directions. Hence consciousness stands in no simple relation either to the different systems or to repression. The truth is that it is not only the psychically repressed that remains alien to consciousness, but also some of the impulses which dominate our ego - something, therefore, that forms the strongest functional antithesis to the repressed. The more we seek to win our way to a metapsychological view of mental life, the more we must learn to emancipate ourselves from the importance of the symptom of 'being conscious'.

¹[1915e, 2993, 3014]
So long as we still cling to this belief we see our generalizations regularly broken through by exceptions. On the one hand we find that derivatives of the Ucs. become conscious as substitutive formations and symptoms - generally, it is true, after having undergone great distortion as compared with the unconscious, though often retaining many characteristics which call for repression. On the other hand, we find that many preconscious formations remain unconscious, though we should have expected that, from their nature, they might very well have become conscious. Probably in the latter case the stronger attraction of the Ucs. is asserting itself. We are led to look for the more important distinction as lying, not between the conscious and the preconscious, but between the preconscious and the unconscious. The Ucs. is turned back on the frontier of the Pcs. by the censorship, but derivatives of the Ucs. can circumvent this censorship, achieve a high degree of organization and reach a certain intensity of cathexis in the Pcs. When, however, this intensity is exceeded and they try to force themselves into consciousness, they are recognized as derivatives of the Ucs. and are repressed afresh at the new frontier of censorship, between the Pcs. and the Cs. Thus the first of these censorships is exercised against the Ucs. itself, and the second against its Pcs. derivatives. One might suppose that in the course of individual development the censorship had taken a step forward. [1915e, 3015]

I will put before you the only theoretical ideas which have proved of service for giving a more definite shape to the concept of repression. It is above all essential for this purpose that we should proceed from the purely descriptive meaning of the word 'unconscious' to the systematic meaning of the same word. That is, we will decide to say that the fact of a psychical process being conscious or unconscious is only one of its attributes and not necessarily an unambiguous one. If a process of this kind has remained unconscious, its being kept away from consciousness may perhaps only be an indication of some vicissitude it has gone through, and not that vicissitude itself. In order to form a picture of this vicissitude, let us assume that every mental process - we must admit one exception, which we shall mention at a later stage - exists to begin with in an unconscious stage or phase and that it is only from there that the process passes over into the conscious phase, just as a photographic picture begins as a negative and only becomes a picture after being turned into a positive. Not every negative, however, necessarily becomes a positive; nor is it necessary that every unconscious mental process should turn into a conscious one. This may be advantageously expressed by saying that an individual process belongs to begin with to the system of the unconscious and can then, in certain circumstances, pass over into the system of the conscious. [1916-1917, 3368]
'The whole process, however, only becomes possible through the single circumstance that you are mistaken in another important point as well. You feel sure that you are informed of all that goes on in your mind if it is of any importance at all, because in that case, you believe, your consciousness gives you news of it. And if you have had no information of something in your mind you confidently assume that it does not exist there. Indeed, you go so far as to regard what is "mental" as identical with what is "conscious" - that is, with what is known to you in spite of the most obvious evidence that a great deal more must constantly be going on in your mind than can be known to your consciousness. Come, let yourself be taught something on this one point! What is in your mind does not coincide with what you are conscious of; whether something is going on in your mind and whether you hear of it, are two different things. In the ordinary way, I will admit, the intelligence which reaches your consciousness is enough for your needs; and you may cherish the illusion that you learn of all the more important things. But in some cases, as in that of an instinctual conflict such as I have described, your intelligence service breaks down and your will then extends no further than your knowledge. In every case, however, the news that reaches your consciousness is incomplete and often not to be relied on. Often enough, too, it happens that you get news of events only when they are over and when you can no longer do anything to change them. Even if you are not ill, who can tell all that is stirring in your mind of which you know nothing or are falsely informed? You behave like an absolute ruler who is content with the information supplied him by his highest officials and never goes among the people to hear their voice. Turn your eyes inward, look into your own depths, learn first to know yourself! Then you will understand why you were bound to fall ill; and perhaps, you will avoid falling ill in future.'
[1917a, 3614]

It is thus that psycho-analysis has sought to educate the ego. But these two discoveries - that the life of our sexual instincts cannot be wholly tamed, and that mental processes are in themselves unconscious and only reach the ego and come under its control through incomplete and untrustworthy perceptions - these two discoveries amount to a statement that the ego is not master in its own house. Together they represent the third blow to man's self-love, what I may call the psychological one. No wonder, then, that the ego does not look favourably upon psycho-analysis and obstinately refuses to believe in it.
[1917a, 3614]

Psycho-analytic speculation takes as its point of departure the impression, derived from examining unconscious processes, that consciousness may be, not the most universal attribute of mental processes, but only a particular function of them. Speaking in metapsychological terms, it asserts that consciousness is a function of a particular system which it describes as Cs. What consciousness yields consists essentially of perceptions of excitations coming from the external world and of feelings of pleasure and unpleasure which can only arise from within the mental apparatus; it is therefore possible to assign to the system Pcpt.-Cs. a position in space. It must lie on the borderline between outside and inside; it must be turned towards the external world and must envelop the other psychical systems. It will be seen that there is nothing daringly new in these assumptions; we have merely adopted the views on localization held by cerebral anatomy, which locates the 'seat' of consciousness in the cerebral cortex - the outermost, enveloping layer of the central organ. Cerebral anatomy has no need to consider why, speaking anatomically, consciousness should be lodged on the surface of the brain instead of being safely housed somewhere in its inmost interior. Perhaps we shall be more successful in accounting for this situation in the case of our system Pcpt.-Cs.
[1920g, 3728]
I cannot neglect this opportunity of expressing for once my astonishment that human beings can go through such great and important moments of their erotic life without noticing them much, sometimes even, indeed, without having the faintest suspicion of their existence, or else, having become aware of those moments, deceive themselves so thoroughly in their judgement of them. This happens not only under neurotic conditions, where we are familiar with the phenomenon, but seems also to be common enough in ordinary life. In the present case, for example, a girl develops a sentimental adoration for women, which her parents at first find merely vexatious and hardly take seriously; she herself knows quite well that she is very much occupied with these relationships, but still she experiences few of the sensations of intense love until a particular frustration is followed by a quite excessive reaction, which shows everyone concerned that they have to do with a consuming passion of elemental strength. Nor had the girl ever perceived anything of the state of affairs which was a necessary preliminary to the outbreak of this mental storm. In other cases, too, we come across girls or women in a state of severe depression, who on being asked for a possible cause of their condition tell us that they have, it is true, had a slight feeling for a certain person, but that it was nothing deep and that they soon got over it when they had to give it up. And yet it was this renunciation, apparently so easily borne, that became the cause of serious mental disturbance. Again, we come across men who have passed through casual love-affairs and realize only from the subsequent effects that they had been passionately in love with the person whom they had apparently regarded lightly. One is also amazed at the unexpected results that may follow an artificial abortion, the killing of an unborn child, which had been decided upon without remorse and without hesitation. It must be admitted that poets are right in liking to portray people who are in love without knowing it, or uncertain whether they do love, or who think that they hate when in reality they love. It would seem that the information received by our consciousness about our erotic life is especially liable to be incomplete, full of gaps, or falsified. Needless to say, in this discussion I have not omitted to allow for the part played by subsequent forgetting.

[1920a, 3855]

The Interpretation of Parapraxes and Haphazard Acts. - It was a triumph for the interpretative art of psycho-analysis when it succeeded in demonstrating that certain common mental acts of normal people, for which no one had hitherto attempted to put forward a psychological explanation, were to be regarded in the same light as the symptoms of neurotics: that is to say, they had a meaning, which was unknown to the subject but which could easily be discovered by analytic means. The phenomena in question were such events as the temporary forgetting of familiar words and names, forgetting to carry out prescribed tasks, everyday slips of the tongue and of the pen, misreadings, losses and mislayings of objects, certain errors, instances of apparently accidental self-injury, and finally habitual movements carried out seemingly without intention or in play, tunes hummed 'thoughtlessly', and so on. All of these were shorn of their physiological explanation, if any such had ever been attempted, were shown to be strictly determined and were revealed as an expression of the subject's suppressed intentions or as a result of a clash between two intentions one of which was permanently or temporarily unconscious. The importance of this contribution to psychology was of many kinds. The range of mental determinism was extended by it in an unforeseen manner; the supposed gulf between normal and pathological mental events was narrowed; in many cases a useful insight was afforded into the play of mental forces that must be suspected to lie behind the phenomena. Finally, a class of material was brought to light which is calculated better than any other to stimulate a belief in the existence of unconscious mental acts even in people to whom the hypothesis of something at once mental and unconscious seems strange and even absurd. The study of one's own parapraxes and haphazard acts, for which most people have ample opportunities, is even to-day the best preparation for an approach to psycho-analysis. In analytic treatment, the interpretation of parapraxes retains a place as a means of uncovering the unconscious, alongside the immeasurably more important interpretation of associations. [1923a, 3917]
It is not my intention to give a review of the author's results. I will content myself with pointing to the significance of his work and will permit myself only a remark concerning the terminology which he has adopted. He includes the sort of thought-activity which he has observed in Bleuler's autistic thinking, but calls it, as a rule, fore-conscious thinking, according to the custom prevailing in psycho-analysis. However, the autistic thinking of Bleuler does not by any means correspond with the extension and the contents of the fore-conscious, neither can I admit that the name used by Bleuler has been happily chosen. The designation 'fore-conscious' thinking itself as a characteristic appears to me misleading and unsatisfactory. The point in question is that the sort of thought-activity of which the well-known day-dream is an example - complete by itself, developing a situation or an act that is being brought to a close - constitutes the best and until now the only studied example. This day-dreaming does not owe its peculiarities to the circumstances that it proceeds mostly fore-consciously, nor are the forms changed when it is accomplished consciously. From another point of view we know also that even strictly directed reflection may be achieved without the co-operation of consciousness, that is to say, fore-consciously. For that reason I think it is advisable, when establishing a distinction between the different modes of thought-activity, not to utilize the relation to consciousness in the first instance, and to designate the day-dream, as well as the chains of thought studied by Varendonck, as freely wandering or phantastic thinking, in opposition to intentionally directed reflection. At the same time it should be taken into consideration that even phantastic thinking is not invariably in want of an aim and end-representations.

The division of the psychical into what is conscious and what is unconscious is the fundamental premiss of psycho-analysis; and it alone makes it possible for psycho-analysis to understand the pathological processes in mental life, which are as common as they are important, and to find a place for them in the framework of science. To put it once more, in a different way: psycho-analysis cannot situate the essence of the psychical in consciousness, but is obliged to regard consciousness as a quality of the psychical, which may be present in addition to other qualities or may be absent.

If I could suppose that everyone interested in psychology would read this book, I should also be prepared to find that at this point some of my readers would already stop short and would go no further; for here we have the first shibboleth of psycho-analysis. To most people who have been educated in philosophy the idea of anything psychical which is not also conscious is so inconceivable that it seems to them absurd and refutable simply by logic. I believe this is only because they have never studied the relevant phenomena of hypnosis and dreams, which - quite apart from pathological manifestations - necessitate this view. Their psychology of consciousness is incapable of solving the problems of dreams and hypnosis.

'Being conscious' is in the first place a purely descriptive term, resting on perception of the most immediate and certain character. Experience goes on to show that a psychical element (for instance, an idea) is not as a rule conscious for a protracted length of time. On the contrary, a state of consciousness is characteristically very transitory; an idea that is conscious now is no longer so a moment later, although it can become so again under certain conditions that are easily brought about. In the interval the idea was - we do not know what. We can say that it was latent, and by this we mean that it was capable of becoming conscious at any time. Or, if we say that is was unconscious, we shall also be giving a correct description of it. Here 'unconscious' coincides with 'latent and capable of becoming conscious'. The philosophers would no doubt object: 'No, the term "unconscious" is not applicable here; so long as the idea was in a state of latency it was not anything psychical at all.' To contradict them at this point would lead to nothing more profitable than a verbal dispute.
In so far as it is possible to influence by arguments the decision of a question of this kind which depends either on convention or on emotional factors, we may make the following comments. The reference to gradations of clarity in consciousness is in no way conclusive and has no more evidential value than such analogous statements as: 'There are so very many gradations in illumination - from the most glaring and dazzling light to the dimmest glimmer - therefore there is no such thing as darkness at all'; or, 'There are varying degrees of vitality, therefore there is no such thing as death.' Such statements may in a certain way have a meaning, but for practical purposes they are worthless. This will be seen if one tries to draw particular conclusions from them, such as, 'there is therefore no need to strike a light', or, 'therefore all organisms are immortal'. Further, to include 'what is unnoticeable' under the concept of 'what is conscious' is simply to play havoc with the one and only piece of direct and certain knowledge that we have about the mind. And after all, a consciousness of which one knows nothing seems to me a good deal more absurd than something mental that is unconscious. Finally, this attempt to equate what is unnoticed with what is unconscious is obviously made without taking into account the dynamic conditions involved, which were the decisive factors in forming the psycho-analytic view. For it ignores two facts: first, that it is exceedingly difficult and requires very great effort to concentrate enough attention on something unnoticed of this kind; and secondly, that when this has been achieved the thought which was previously unnoticed is not recognized by consciousness, but often seems entirely alien and opposed to it and is promptly disavowed by it. Thus, seeking refuge from the unconscious in what is scarcely noticed or unnoticed is after all only a derivative of the preconceived belief which regards the identity of the psychical and the conscious as settled once and for all. [1923b, 3950]

After these preliminaries we can return to our consideration of moral masochism. We have said that, by their behaviour during treatment and in life, the individuals in question give an impression of being morally inhibited to an excessive degree, of being under the domination of an especially sensitive conscience, although they are not conscious of any of this ultra-morality. On closer inspection, we can see the difference there is between an unconscious extension of morality of this kind and moral masochism. In the former, the accent falls on the heightened sadism of the super-ego to which the ego submits; in the latter, it falls on the ego's own masochism which seeks punishment, whether from the super-ego or from the parental powers outside. We may be forgiven for having confused the two to begin with; for in both cases it is a question of a relationship between the ego and the super-ego (or powers that are equivalent to it), and in both cases what is involved is a need which is satisfied by punishment and suffering. It can hardly be an insignificant detail, then, that the sadism of the super-ego becomes for the most part glaringly conscious, whereas the masochistic trend of the ego remains as a rule concealed from the subject and has to be inferred from his behaviour. [1924c, 4081]

Evidence of its being of use for throwing light on other than pathological mental activity was early forthcoming in connection with two kinds of phenomena: with the very frequent parapraxes that occur in everyday life - such as forgetting things, slips of the tongue, and mislaying objects - and with the dreams dreamt by healthy and psychically normal people. Small failures of functioning, like the temporary forgetting of normally familiar proper names, slips of the tongue and of the pen, and so on, had hitherto not been considered worthy of any explanation at all or were supposed to be accounted for by conditions of fatigue, by distraction of the attention, etc. The present writer then showed from many examples, in his book The Psychopathology of Everyday Life (1901b), that events of this kind have a meaning, and arise owing to a conscious intention being interfered with by another, suppressed or actually unconscious one. As a rule, quick reflection or a short analysis is enough to reveal the interfering influence. Owing to the frequency of such parapraxes as slips of the tongue, it became easy for anyone to convince himself from his own experience of the existence of mental processes which are not conscious, but which are nevertheless operative and which at least find expression as inhibitions and modifications of other, intended acts. [1924f, 4109]
What, then, can a philosopher say to a theory which, like psycho-analysis, asserts that on the contrary what is mental is in itself unconscious and that being conscious is only a quality, which may or may not accrue to a particular mental act and the withholding of which may perhaps alter that act in no other respect? He will naturally say that anything both unconscious and mental would be an impossibility, a contradictio in adjecto, and he will fail to observe that in making this judgement he is merely repeating his own definition of what is mental, a definition which may perhaps be too narrow. It is easy for philosophers to feel this certainty, since they have no acquaintance with the material whose investigation has compelled analysts to believe in unconscious mental acts. Philosophers have never taken account of hypnosis, they have not concerned themselves with the interpreting of dreams - on the contrary, like doctors, they regard dreams as the meaningless products of reduced mental activity during sleep - they are scarcely aware that there are such things as obsessions and delusions and they would find themselves in a most embarrassing situation if they were asked to explain them on the basis of their own psychological premisses. Analysts, too, refuse to say what the unconscious is, but they can indicate the domain of phenomena whose observation has obliged them to assume its existence. Philosophers, who know no kind of observation other than self-observation, cannot follow them into that domain.

But the study of pathogenic repressions and of other phenomena which have still to be mentioned compelled psycho-analysis to take the concept of the 'unconscious' seriously. Psycho-analysis regarded everything mental as being in the first instance unconscious; the further quality of 'consciousness' might also be present, or again it might be absent. This of course provoked a denial from the philosophers, for whom 'conscious' and 'mental' were identical, and who protested that they could not conceive of such an absurdity as the 'unconscious mental'. There was no help for it, however, and this idiosyncrasy of the philosophers could only be disregarded with a shrug. Experience (gained from pathological material, of which the philosophers were ignorant) of the frequency and power of impulses of which one knew nothing directly, and whose existence had to be inferred like some fact in the external world, left no alternative open. It could be pointed out, incidentally, that this was only treating one's own mental life as one had always treated other people's. One did not hesitate to ascribe mental processes to other people, although one had no immediate consciousness of them and could only infer them from their words and actions. But what held good for other people must be applicable to oneself. Anyone who tried to push the argument further and to conclude from it that one's own hidden processes belonged actually to a second consciousness would be faced with the concept of a consciousness of which one knew nothing, of an 'unconscious consciousness' - and this would scarcely be preferable to the assumption of an 'unconscious mental'. If on the other hand one declared, like some other philosophers, that one was prepared to take pathological phenomena into account, but that the processes underlying them ought not to be described as mental but as 'psychoid', the difference of opinion would degenerate into an unfruitful dispute about words, though even so expediency would decide in favour of keeping the expression 'unconscious mental'. The further question as to the ultimate nature of this unconscious is no more sensible or profitable than the older one as to the nature of the conscious.

That brings us back to one of your earlier questions. Psychology had barred its own access to the region of the id by insisting on a postulate which is plausible enough but untenable: namely, that all mental acts are conscious to us - that being conscious is the criterion of what is mental, and that, if there are processes in our brain which are not conscious, they do not deserve to be called mental acts and are no concern of psychology.
Yes, and that is what psychologists think. Nevertheless it can easily be shown to be false - that is, to be a quite inexpedient distinction. The idolest self-observation shows that ideas may occur to us which cannot have come about without preparation. But you experience nothing of these preliminaries of your thought, though they too must certainly have been of a mental nature; all that enters your consciousness is the ready-made result. Occasionally you can make these preparatory thought-structures conscious in retrospect, as though in a reconstruction.

Evasions! You cannot in that way get around the fact that acts of a mental nature, and often very complicated ones, can take place in you, of which your consciousness learns nothing and of which you know nothing. Or are you prepared to suppose that a greater or smaller amount of your 'attention' is enough to transform a non-mental act into a mental one? But what is the use of disputing? There are hypnotic experiments in which the existence of such non-conscious thoughts are irrefutably demonstrated to anyone who cares to learn.

There is no need to discuss what is to be called conscious: it is removed from all doubt. The oldest and best meaning of the word 'unconscious' is the descriptive one; we call a psychical process unconscious whose existence we are obliged to assume - for some such reason as that we infer it from its effects -, but of which we know nothing. In that case we have the same relation to it as we have to a psychical process in another person, except that it is in fact one of our own. If we want to be still more correct, we shall modify our assertion by saying that we call a process unconscious if we are obliged to assume that it is being activated at the moment, though at the moment we know nothing about it. This qualification makes us reflect that the majority of conscious processes are conscious only for a short time; very soon they become latent, but can easily become conscious again. We might also say that they had become unconscious, if it were at all certain that in the condition of latency they are still something psychical. So far we should have learnt nothing new; nor should we have acquired the right to introduce the concept of an unconscious into psychology. But then comes the new observation that we were already able to make in parapraxes. In order to explain a slip of the tongue, for instance, we find ourselves obliged to assume that the intention to make a particular remark was present in the subject. We infer it with certainty from the interference with his remark which has occurred; but the intention did not put itself through and was thus unconscious. If, when we subsequently put it before the speaker, he recognizes it as one familiar to him, then it was only temporarily unconscious to him; but if he repudiates it as something foreign to him, then it was permanently unconscious. From this experience we retrospectively obtain the right also to pronounce as something unconscious what had been described as latent. A consideration of these dynamic relations permits us now to distinguish two kinds of unconscious - one which is easily, under frequently occurring circumstances, transformed into something conscious, and another with which this transformation is difficult and takes place only subject to a considerable expenditure of effort or possibly never at all. In order to escape the ambiguity as to whether we mean the one or the other unconscious, whether we are using the word in the descriptive or in the dynamic sense, we make use of a permissible and simple way out. We call the unconscious which is only latent, and thus easily becomes conscious, the 'preconscious' and retain the term 'unconscious' for the other. We now have three terms, 'conscious', 'preconscious' and 'unconscious', with which we can get along in our description of mental phenomena. Once again: the preconscious is also unconscious in the purely descriptive sense, but we do not give it that name, except in talking loosely or when we have to make a defence of the existence in mental life of unconscious processes in general.
Dream-distortion was the profoundest and most difficult problem of dream life. And light was thrown on it by the following consideration, which placed dreams in a class along with other psychopathological formations and revealed them, as it were, as the normal psychoses of human beings. For our mind, that precious instrument by whose means we maintain ourselves in life, is no peacefully self-contained unity. It is rather to be compared with a modern State in which a mob, eager for enjoyment and destruction, has to be held down forcibly by a prudent superior class. The whole flux of our mental life and everything that finds expression in our thoughts are derivations and representatives of the multifarious instincts that are innate in our physical constitution. But these instincts are not all equally susceptible to direction and education, or equally ready to fall in with the demands of the external world and of human society. A number of them have retained their primitive, ungovernable nature; if we let them have their way, they would infallibly bring us to ruin. Consequently, learning by experience, we have developed organizations in our mind which, in the form of inhibitions, set themselves up against the direct manifestations of the instincts. Every impulse in the nature of a wish that arises from the sources of instinctual energy must submit itself to examination by the highest agencies of our mind, and, if it is not approved, is rejected and restrained from exercising any influence upon our movements - that is, from coming into execution. Often enough, indeed, such wishes are even forbidden to enter consciousness, which is habitually unaware even of the existence of these dangerous instinctual sources. We describe such impulses as being repressed from the point of view of consciousness, and as surviving only in the unconscious. If what is repressed contrives somehow to force its way into consciousness or into movement or into both, we are no longer normal: at that point the whole range of neurotic and psychotic symptoms arise. The maintenance of the necessary inhibitions and repressions imposes upon our mind a great expenditure of energy, from which it is glad to be relieved. A good opportunity for this seems to be offered at night by the state of sleep, since sleep involves a cessation of our motor functions. The situation seems safe, and the severity of our internal police-force may therefore be relaxed. It is not entirely withdrawn, since one cannot be certain: it may be that the unconscious never sleeps at all. And now the reduction of pressure upon the repressed unconscious produces its effect. Wishes arise from it which during sleep might find the entrance to consciousness open. If we were to know them we should be appalled, alike by their subject-matter, their unrestraint and indeed the mere possibility of their existence. This, however, occurs only seldom, and when it does we awake as speedily as possible, in a state of fear. But as a rule our consciousness does not experience the dream as it really was. It is true that the inhibitory forces (the dream censorship, as we may call them) are not completely awake, but neither are they wholly asleep. They have had an influence on the dream while it was struggling to find an expression in words and pictures, they have got rid of what was most objectionable, they have altered other parts of it till they are unrecognizable, they have severed real connections while introducing false ones, until the honest but brutal wishful phantasy which lay behind the dream has turned into the manifest dream as we remember it - more or less confused and almost always strange and incomprehensible. Thus the dream (or the distortion which characterizes it) is the expression of a compromise, the evidence of a conflict between the mutually incompatible impulses and strivings of our mental life. And do not let us forget that the same process, the same interplay of forces, which explains the dreams of a normal sleeper, gives us the key to understanding all the phenomena of neurosis and psychosis.

[1932c, 4809]
The difference between whether a psychical process is conscious or unconscious has served us as a criterion and a means of finding our bearings. The repressed is unconscious. Now it would simplify things agreeably if this sentence admitted of reversal - if, that is, the difference between the qualities of conscious (Cs.) and unconscious (Ucs.) coincided with the distinction between 'belonging to the ego' and 'repressed'. The fact of there being isolated and unconscious things like this in our mental life would be sufficiently novel and important. But in reality the position is more complicated. It is true that everything repressed is unconscious, but it is not true that everything belonging to the ego is conscious. We notice that consciousness is a transient quality which attaches to a psychical process only in passing. For our purposes therefore we must replace 'conscious' by 'capable of being conscious' and we call this quality 'preconscious' (Pcs.). We then say, more correctly, that the ego is mainly preconscious (virtually conscious) but that portions of the ego are unconscious.

All of this may appear to be far from simple. But when one has grown reconciled to this unusual spatial view of the mental apparatus, it can present no particular difficulties to the imagination. I will add the further comment that the psychical topography that I have developed here has nothing to do with the anatomy of the brain, and actually only touches it at one point. What is unsatisfactory in this picture - and I am aware of it as clearly as anyone - is due to our complete ignorance of the dynamic nature of the mental processes. We tell ourselves that what distinguishes a conscious idea from a preconscious one, and the latter from an unconscious one, can only be a modification, or perhaps a different distribution, of psychical energy. We talk of cathexes and hypercathexes, but beyond this we are without any knowledge on the subject or even any starting-point for a serviceable working hypothesis. Of the phenomenon of consciousness we can at least say that it was originally attached to perception. All sensations which originate from the perception of painful, tactile, auditory or visual stimuli are what are most readily conscious. Thought-processes, and whatever may be analogous to them in the id, are in themselves unconscious and obtain access to consciousness by becoming linked to the mnemonic residues of visual and auditory perceptions along the path of the function of speech. In animals, which lack speech, these conditions must be of a simpler kind.

The starting-point for this investigation is provided by a fact without parallel, which defies all explanation or description - the fact of consciousness. Nevertheless, if anyone speaks of consciousness we know immediately and from our most personal experience what is meant by it.¹ Many people, both inside and outside science, are satisfied with the assumption that consciousness alone is psychical; in that case nothing remains for psychology but to discriminate among psychical phenomena between perceptions, feelings, thought-processes and volitions. It is generally agreed, however, that these conscious processes do not form unbroken sequences which are complete in themselves; there would thus be no alternative left to assuming that there are physical or somatic processes which are concomitant with the psychical ones and which we should necessarily have to recognize as more complete than the psychical sequences, since some of them would have conscious processes parallel to them but others would not. If so, it of course becomes plausible to lay the stress in psychology on these somatic processes, to see in them the true essence of what is psychical and to look for some other assessment of the conscious processes. The majority of philosophers, however, as well as many other people, dispute this and declare that the idea of something psychical being unconscious is self-contradictory.

[1939a, 4918]

[1939a, 4919]

[1940a [1938], 4967]
But that is precisely what psycho-analysis is obliged to assert, and this is its second fundamental hypothesis. It explains the supposedly somatic concomitant phenomena as being what is truly psychical, and thus in the first instance disregards the quality of consciousness. It is not alone in doing this. Some thinkers (such as Theodor Lipps, for instance) have asserted the same thing in the same words; and the general dissatisfaction with the usual view of what is psychical has resulted in an increasingly urgent demand for the inclusion in psychological thought of a concept of the unconscious, though this demand has taken such an indefinite and obscure form that it could have no influence on science.

[1940a [1938], 4968]

Every science is based on observations and experiences arrived at through the medium of our psychical apparatus. But since our science has as its subject that apparatus itself, the analogy ends here. We make our observations through the medium of the same perceptual apparatus, precisely with the help of the breaks in the sequence of 'psychical' events: we fill in what is omitted by making plausible inferences and translating it into conscious material. In this way we construct, as it were, a sequence of conscious events complementary to the unconscious psychical processes. The relative certainty of our psychical science is based on the binding force of these inferences. Anyone who enters deeply into our work will find that our technique holds its ground against any criticism.

[1940a [1938], 4969]

In the course of this work the distinctions which we describe as psychical qualities force themselves on our notice. There is no need to characterize what we call 'conscious': it is the same as the consciousness of philosophers and of everyday opinion. Everything else psychical is in our view 'the unconscious'. We are soon led to make an important division in this unconscious. Some processes become conscious easily; they may then cease to be conscious, but can become conscious once more without any trouble: as people say, they can be reproduced or remembered. This reminds us that consciousness is in general a highly fugitive state. What is conscious is conscious only for a moment. If our perceptions do not confirm this, the contradiction is only an apparent one; it is explained by the fact that the stimuli which lead to perception may persist for considerable periods, so that meanwhile the perception of them may be repeated. The whole position is made clear in connection with the conscious perception of our thought-processes: these too may persist for some time, but they may just as well pass in a flash. Everything unconscious that behaves in this way, that can thus easily exchange the unconscious state for the conscious one, is therefore preferably described as 'capable of becoming conscious' or as preconscious. Experience has taught us that there is hardly a psychical process, however complicated it may be, which cannot on occasion remain preconscious, even though as a rule it will, as we say, push its way forward into consciousness. There are other psychical processes and psychical material which have no such easy access to becoming conscious but must be inferred, recognized and translated into conscious form in the manner described. For such material we reserve the name of the unconscious proper.

[1940a [1938], 4969]
Psychology, too, is a natural science. What else can it be? But its case is different. Not everyone is bold enough to make judgements about physical matters; but everyone - the philosopher and the man in the street alike - has his opinion on psychological questions and behaves as if he were at least an amateur psychologist. And now comes the remarkable thing. Everyone - or almost everyone - was agreed that what is psychical really has a common quality in which its essence is expressed: namely the quality of being conscious - unique, indescribable, but needing no description. All that is conscious, they said, is psychical, and conversely all that is psychical is conscious: that is self-evident and to contradict it is nonsense. It cannot be said that this decision threw much light upon the nature of the psychical, for consciousness is one of the fundamental facts of our life and our researches come up against it like a blank wall and can find no path beyond it. Moreover the equation of what is mental with what is conscious had the unwelcome result of divorcing psychical processes from the general context of events in the universe and of setting them in complete contrast to all others. But this would not do, since the fact could not long be overlooked that psychical phenomena are to a high degree dependent upon somatic influences and on their side have the most powerful effects upon somatic processes. If ever human thought found itself in an impasse it was here. To find a way out, the philosophers at least were obliged to assume that there were organic processes parallel to the conscious psychical ones, related to them in a manner that was hard to explain, which acted as intermediaries in the reciprocal relations between 'body and mind', and which served to re-insert the psychical into the texture of life. But this solution remained unsatisfactory.

[1940b [1938], 5068]

Psycho-analysis escaped such difficulties as these by energetically denying the equation between what is psychical and what is conscious. No; being conscious cannot be the essence of what is psychical. It is only a quality of what is psychical, and an inconstant quality at that - one that is far oftener absent than present. The psychical, whatever its nature may be, is in itself unconscious and probably similar in kind to all the other natural processes of which we have obtained knowledge.

[1940b [1938], 5068]

We know what is meant by ideas 'occurring' to one - thoughts that suddenly come into consciousness without one's being aware of the steps that led up to them, though they, too, must have been psychical acts. It can even happen that one arrives in this way at the solution of some difficult intellectual problem which has previously for a time baffled one's efforts. All the complicated processes of selection, rejection and decision which occupied the interval were withdrawn from consciousness. We shall not be putting forward any new theory in saying that they were unconscious and perhaps, too, remained so.

[1940b [1938], 5068]
In the second place, I shall pick a single instance to represent an immensely large class of phenomena.¹ The President of a public body (the Lower House of the Austrian Parliament) on one occasion opened a sitting with the following words: 'I take notice that a full quorum of members is present and herewith declare the sitting closed.' It was a slip of the tongue - for there can be no doubt that what the President intended to say was 'opened'. Why, then, did he say the opposite? We shall expect to be told it was an accidental mistake, a failure in carrying out an intention such as may easily happen for various reasons: it had no meaning - and in any case contraries are particularly easily substituted for each other. If, however, we bear in mind the situation in which the slip of the tongue occurred, we shall be inclined to prefer another explanation. Many of the previous sittings of the House had been disagreeably stormy and had accomplished nothing, so that it would be only too natural for the President to think at the moment of making his opening statement: 'If only the sitting that's just beginning were finished! I would much rather be closing then opening it!' When he began to speak he was probably not aware of this wish - it was not conscious to him - but it was certainly present and it succeeded in making itself effective, against the speaker's will, in his apparent mistake. A single instance can scarcely enable us to decide between two such different explanations. But what if every other instance of a slip of the tongue could be explained in the same way, and similarly every slip of the pen, every case of mis-reading or mis-hearing, and every faulty action? What if in all those instances (one might actually say, without a single exception) it was possible to demonstrate the presence of a psychical act - a thought, a wish or an intention - which would account for the apparent mistake and which was unconscious at the moment at which it became effective, even though it may have been conscious previously? If that were so, it would really no longer be possible to dispute the fact that psychical acts which are unconscious do exist and that they are even sometimes active while they are unconscious and that in that case they can even sometimes get the better of conscious intentions. The person concerned in a mistake of this kind can react to it in various ways. He may overlook it completely or he may notice it himself and become embarrassed and ashamed. He cannot as a rule find the explanation of it himself without outside help; and he often refuses to accept the solution when it is put before him - for a time, at all events.

[1940b [1938], 5069]

In the third place, finally, it is possible in the case of persons in a state of hypnosis to prove experimentally that there are such things as unconscious psychical acts and that consciousness is not an indispensable condition of activity. Anyone who has witnessed such an experiment will receive an unforgettable impression and a conviction that can never be shaken. Here is more or less what happens. The doctor enters the hospital ward, puts his umbrella in the corner, hypnotizes one of the patients and says to him: 'I'm going out now. When I come in again, you will come to meet me with my umbrella open and hold it over my head.' The doctor and his assistants then leave the ward. As soon as they come back, the patient, who is no longer under hypnosis, carries out exactly the instructions that were given him while he was hypnotized. The doctor questions him: 'What's this you're doing? What's the meaning of all this?' The patient is clearly embarrassed. He makes some lame remark such as 'I only thought, doctor, as it's raining outside you'd open your umbrella in the room before you went out.' The explanation is obviously quite inadequate and made up on the spur of the moment to offer some sort of motive for his senseless behaviour. It is clear to us spectators that he is in ignorance of his real motive. We, however, know what it is, for we were present when the suggestion was made to him which he is now carrying out, while he himself knows nothing of the fact that it is at work in him.¹

[1940b [1938], 5070]
The question of the relation of the conscious to the psychical may now be regarded as settled: consciousness is only a *quality* or attribute of what is psychical, and moreover an inconstant one. But there is one further objection with which we have to deal. We are told that, in spite of the facts that have been mentioned, there is no necessity to abandon the identity between what is conscious and what is psychical: the so-called unconscious psychical processes are the organic processes which have long been recognized as running parallel to the mental ones. This, of course, would reduce our problem to an apparently indifferent matter of definition. Our reply is that it would be unjustifiable and inexpedient to make a breach in the unity of mental life for the sake of propping up a definition, since it is clear in any case that consciousness can only offer us an incomplete and broken chain of phenomena. And it can scarcely be a matter of chance that it was not until the change had been made in the definition of the psychical that it became possible to construct a comprehensive and coherent theory of mental life.

[1940b [1938], 5071]
In complete opposition to Janet's views, I believe that in a great many cases what underlies dissociation is an excess of efficiency, the habitual co-existence of two heterogeneous trains of ideas. It has frequently been pointed out that we are often not merely 'mechanically' active while our conscious thought is occupied by trains of ideas which have nothing in common with our activity, but that we are also capable of what is undoubtedly psychical functioning while our thoughts are 'busy elsewhere' - as, for instance, when we read aloud correctly and with the appropriate intonation, but afterwards have not the slightest idea of what we have been reading.

[1895d [Breuer], 210]

¹ I purposely leave out of this discussion the question of what the category is to which the association between the two memories belong, (whether it is an association by simultaneity, or by causal connections or by similarity of content), and of what psychological character is to be attributed to the various 'memories' (conscious or unconscious).

[1896c, 411]

The best procedure for getting hold of the missing name is, as is generally known, 'not to think of it' - that is, to divert from the task that part of the attention over which one has voluntary control. After a while, the missing name 'shoots' into one's mind; one cannot prevent oneself from calling it out aloud - to the great astonishment of one's companion, who has already forgotten the episode and who has in any case only taken very little interest in the speaker's efforts. 'Really,' he is apt to say, 'it makes no difference what the man is called; only go on with your story.' The whole of the time until the matter is cleared up, and even after the intentional diversion, one feels preoccupied to a degree which cannot in fact be explained by the amount of interest possessed by the whole affair.¹

[1898b, 479]

¹ Reports of numerous cases seem to put it beyond dispute that dreams can carry on the intellectual work of daytime and bring it to conclusions which had not been reached during the day, and that they can resolve doubts and problems and be the source of new inspiration for poets and musical composers. But though the fact may be beyond dispute, its implications are open to many doubts, which raise matters of principle.²

[1900a, 572]

² How, then, are we to picture psychical conditions during the period of sleep which precedes dreams? Are all the dream-thoughts present alongside one another? or do they occur in sequence? or do a number of trains of thought start out simultaneously from different centres and afterwards unite? There is no need for the present, in my opinion, to form any plastic idea of psychical conditions during the formation of dreams. It must not be forgotten, however, that we are dealing with an unconscious process of thought, which may easily be different from what we perceive during purposive reflection accompanied by consciousness.

[1900a, 754]
I do not wish to deny categorically that this fourth power in dream-construction - which we shall soon recognize as all old acquaintance, since in fact it is the only one of the four with which we are familiar in other connections - I do not wish to deny that this fourth factor has the capacity to create new contributions to dreams. It is certain, however, that, like the others, it exerts its influence principally by its preferences and selections from psychical material in the dream-thoughts that has already been formed. Now there is one case in which it is to a great extent spared the labour of, as it were, building up a façade for the dream - the case, namely, in which a formation of that kind already exists, available for use in the material of the dream-thoughts. I am in the habit of describing the element in the dream-thoughts which I have in mind as a 'phantasy.' I shall perhaps avoid misunderstanding if I mention the 'day-dream' as something analogous to it in waking life.¹ The part played in our mental life by these structures has not yet been fully recognized and elucidated by psychiatrists, though M. Benedikt has made what seems to me a very promising start in that direction. The importance of day-dreams has not escaped the unerring vision of imaginative writers; there is, for instance, a well-known account by Alphonse Daudet in *Le Nabab* of the day-dreams of one of the minor characters in that story. The study of the psychoneuroses leads to the surprising discovery that these phantasies or day-dreams are the immediate forerunners of hysterical symptoms, or at least of a whole number of them. Hysterical symptoms are not attached to actual memories, but to phantasies erected on the basis of memories. The frequent occurrence of conscious daytime phantasies brings these structures to our knowledge; but just as there are phantasies of this kind which are conscious, so, too, there are unconscious ones in great numbers, which have to remain unconscious on account of their content and of their origin from repressed material. Closer investigation of the characteristics of these day-time phantasies shows us how right it is that these formations should bear the same name as we give to the products of our thought during the night - the name, that is, of 'dreams.' They share a large number of their properties with night-dreams, and their investigation might, in fact, have served as the shortest and best approach to an understanding of night-dreams.

[1900a, 931]
The function of 'secondary revision', which we have attributed to the fourth of the factors concerned in shaping the content of dreams, shows us in operation once more the activity which is able to find free vent in the creation of day-dreams without being inhibited by any other influences. We might put it simply by saying that this fourth factor of ours seeks to mould the material offered to it into something like a day-dream. If, however, a day-dream of this kind has already been formed within the nexus of the dream-thoughts, this fourth factor in the dream-work will prefer to take possession of the ready-made day-dream and seek to introduce it into the content of the dream. There are some dreams which consist merely in the repetition of a day-time phantasy which may perhaps have remained unconscious: such, for instance, as the boy’s dream of driving in a war-chariot with the heroes of the Trojan War. In my 'Autodidasker' dream the second part at all events was a faithful reproduction of a daytime phantasy, innocent in itself, of a conversation with Professor N. In view of the complicated conditions which a dream has to satisfy when it comes into existence, it happens more frequently that the ready-made phantasy forms only a portion of the dream, or that only a portion of the phantasy forces its way into the dream. Thereafter, the phantasy is treated in general like any other portion of the latent material, though it often remains recognizable as an entity in the dream. There are often parts of my dreams which stand out as producing a different impression from the rest. They strike me as being, as it were, more fluent, more connected and at the same time more fleeting than other parts of the same dream. These, I know, are unconscious phantasies which have found their way into the fabric of the dream, but I have never succeeded in pinning down a phantasy of this kind. Apart from this, these phantasies, like any other component of the dream-thoughts, are compressed, condensed, superimposed on one another, and so on. There are, however, transitional cases, between the case in which they constitute the content (or at least the façade) of the dream unaltered and the extreme opposite in which they are represented in the content of the dream only by one of their elements or by a distant allusion. What happens to phantasies present in the dream-thoughts is evidently also determined by any advantages they may have to offer the requirements of the censorship and of the urge towards condensation.

In selecting examples of dream-interpretation I have so far as possible avoided dreams in which unconscious phantasies play any considerable part, because the introduction of this particular psychical element would have necessitated lengthy discussions on the psychology of unconscious thinking. Nevertheless, I cannot completely escape a consideration of phantasies in this connection, since they often make their way complete into dreams and since still more often clear glimpses of them can be seen behind the dream. I will therefore quote one more dream, which seems to be composed of two different and opposing phantasies which coincide with each other at a few points and of which one is superficial while the second is, as it were, an interpretation of the first.

[1900a, 932]
Nor is it necessary that this long-prepared phantasy should have been gone through during sleep; it would have been sufficient for it to be merely touched on. What I mean is this. If a few bars of music are played and someone comments that it is from Mozart's *Figaro* (as happens in *Don Giovanni*) a number of recollections are roused in me all at once, none of which can enter my consciousness singly at the first moment. The key-phrase serves as a port of entry through which the whole network is simultaneously put in a state of excitation. It may well be the same in the case of unconscious thinking. The rousing stimulus excites the psychical port of entry which allows access to the whole guillotine phantasy. But the phantasy is not gone through during sleep but only in the recollection of the sleeper after his awakening. After waking he remembers in all its details the phantasy which was stirred up as a whole in his dream. One has no means of assuring oneself in such a case that one is really remembering something one has dreamt. This same explanation - that it is a question of ready-made phantasies which are brought into excitation as a whole by the rousing stimulus - can be applied to other dreams which are focused upon a rousing stimulus, such, for instance, as Napoleon's battle dream before the explosion of the infernal machine.

[1900a, 936]

¹ [Footnote added 1914:] It was not until later that my attention was drawn to the fact that Eduard von Hartmann takes the same view on thus important matter of psychology: 'In discussing the part played by the unconscious in artistic creation, Eduard von Hartmann (1890, I, Section B, Chapter V) made a clear statement of the law in accordance with which the association of ideas is governed by unconscious purposive ideas, though he was unaware of the scope of the law. He set out to prove that "every combination of sensuous presentations, when it is not left purely to chance, but is led to a definite end, requires the help of the unconscious", and that the part played by conscious interest is to stimulate the unconscious to select the most appropriate idea among the countless possible ones. It is the unconscious which makes the appropriate selection of a purpose for the interest and this "holds good of the association of ideas in abstract thinking as well as in sensuous imagining and artistic combination" and in the production of jokes. For this reason a limitation of the association of ideas to an exciting idea and an excited idea (in the sense of a pure association psychology) can not be upheld. Such a limitation could be justified "only if there are conditions in human life in which man is free not only from every conscious purpose, but also from the sway or co-operation of every unconscious interest, every passing mood. This is, however, a condition hardly ever occurring, for even if one in appearance completely abandons his train of thought to accident, or if one abandons oneself entirely to the involuntary dreams of fancy, yet always other leading interests, dominant feelings and moods prevail at one time rather than at another, and these will always exert an influence on the association of ideas."

"In semi-conscious dreams always only such ideas as correspond to the main interest of the moment occur." The emphasis thus laid upon the influence of feelings and moods on the free sequence of thoughts make it possible to justify the methodological procedure of psycho-analysis completely from the standpoint of Hartmann's psychology. (Pohorlies, 1913.) - Du Prei (1885, 107) refers to the fact that after we have vainly tried to recall a name, it often comes into our heads again suddenly and without any warning. He concludes from this that unconscious but none the less purposeful thinking has taken place and that its result has suddenly entered consciousness.

[1900a, 962]
At this point I will interpolate a remark of a general nature which may perhaps have important implications. It is the *Pcpt.* system, which is without the capacity to retain modifications and is thus without memory, that provides our consciousness with the whole multiplicity of sensory qualities. On the other hand, our memories - not excepting those which are most deeply stamped on our minds - are in themselves unconscious. They can be made conscious; but there can be no doubt that they can produce all their effects while in an unconscious condition. What we describe as our ‘character’ is based on the memory-traces of our impressions; and, moreover, the impressions which have had the greatest effect on us - those of our earliest youth - are precisely the ones which scarcely ever become conscious. But if memories become conscious once more they exhibit no sensory quality or a very slight one in comparison with perceptions. A most promising light would be thrown on the conditions governing the excitation of neurone if it could be confirmed that the \( \Psi \)-systems of memory and the quality that characterizes consciousness are mutually exclusive.¹

We have so far been studying dream-wishes: we have traced them from their origin in the region of the *Ucs.* and have analysed their relations to the day’s residues, which in their turn may either be wishes or psychical impulses of some other kind or simply recent impressions. In this way we have allowed room for every claim that may be raised by any of the multifarious waking thought-activities on behalf of the importance of the part played by them in the process of constructing dreams. It is not impossible, even, that our account may have provided an explanation of the extreme cases in which a dream, pursuing the activities of daytime, arrives at a happy solution of some unsolved problem of waking life. All we need is an example of this kind, so that we might analyse it and trace the source of the infantile or repressed wishes whose help has been enlisted and has reinforced the efforts of preconscious activity with such success. But all this has not brought us a step nearer to solving the riddle of why it is that the unconscious has nothing else to offer during sleep but the motive force for the fulfilment of a wish. The answer to this question must throw light upon the psychical nature of wishes, and I propose to give the answer by reference to our schematic picture of the psychical apparatus. [1900a, 972]

[1900a, 994]
A dream, as we have discovered, takes the place of a number of thoughts which are derived from our daily life and which form a completely logical sequence. We cannot doubt, then, that these thoughts originate from our normal mental life. All the attributes which we value highly in our trains of thought, and which characterize them as complex achievements of a high order, are to be found once more in dream-thoughts. There is no need to assume, however, that this activity of thought is performed during sleep - a possibility which would gravely confuse what has hitherto been our settled picture of the psychical state of sleep. On the contrary, these thoughts may very well have originated from the previous day, they may have proceeded unobserved by our consciousness from their start, and may already have been completed at the onset of sleep. The most that we can conclude from this is that it proves that the most complicated achievements of thought are possible without the assistance of consciousness - a fact which we could not fail to learn in any case from every psycho-analysis of a patient suffering from hysteria or from obsessional ideas. These dream-thoughts are certainly not in themselves inadmissible to consciousness; there may have been a number of reasons for their not having become conscious to us during the day. Becoming conscious is connected with the application of a particular psychical function, that of attention - a function which, as it seems, is only available in a specific quantity, and this may have been diverted from the train of thought in question on to some other purpose. There is another way, too, in which trains of thought of this kind may be withheld from consciousness. The course of our conscious reflections shows us that we follow a particular path in our application of attention. If, as we follow this path, we come upon an idea which will not bear criticism, we break off: we drop the cathexis of attention. Now it seems that the train of thought which has thus been initiated and dropped can continue to spin itself out without attention being turned to it again, unless at some point or other it reaches a specially high degree of intensity which forces attention to it. Thus, if a train of thought is initially rejected (consciously, perhaps) by a judgement that it is wrong or that it is useless for the immediate intellectual purposes in view, the result may be that this train of thought will proceed, unobserved by consciousness, until the onset of sleep.

[1900a, 1020]

To sum up - we describe a train of thought such as this as 'preconscious'; we regard it as completely rational and believe that it may either have been simply neglected or broken off and suppressed. Let us add a frank account of how we picture the occurrence of a train of ideas. We believe that, starting from a purposive idea, a given amount of excitation, which we term 'cathectic energy', is displaced along the associative paths selected by that purposive idea. A train of thought which is 'neglected' is one which has not received this cathexis; a train of thought which is 'suppressed' or 'repudiated' is one from which this cathexis has been withdrawn. In both cases they are left to their own excitations. Under certain conditions a train of thought with a purposive cathexis is capable of attracting the attention of consciousness to itself and in that event, through the agency of consciousness, receives a 'hypercathexis.' We shall be obliged presently to explain our view of the nature and function of consciousness.

[1900a, 1021]
A train of thought that has been set going like this in the preconscious may either cease spontaneously or persist. We picture the first of these outcomes as implying that the energy attaching to the train of thought is diffused along all the associative paths that radiate from it; this energy sets the whole network of thoughts in a state of excitation which lasts for a certain time and then dies away as the excitation in search of discharge becomes transformed into a quiescent cathexis. If this first outcome supervenes, the process is of no further significance so far as dream-formation is concerned. Lurking in our preconscious, however, there are other purposive ideas, which are derived from sources in our unconscious and from wishes which are always on the alert. These may take control of the excitation attaching to the group of thoughts which has been left to its own devices, they may establish a connection between it and an unconscious wish, and they may 'transfer' to it the energy belonging to the unconscious wish. Thenceforward the neglected or suppressed train of thought is in a position to persist, though the reinforcement it has received gives it no right of entry into consciousness. We may express this by saying that what has hitherto been a preconscious train of thought has now been 'drawn into the unconscious.'

It will be seen on closer consideration that what the psychological discussion in the preceding sections invites us to assume is not the existence of two systems near the motor end of the apparatus but the existence of two kinds of processes of excitation or modes of its discharge. It is all one to us, for we must always be prepared to drop our conceptual scaffolding if we feel that we are in a position to replace it by something that approximates more closely to the unknown reality. So let us try to correct some conceptions which might be misleading so long as we looked upon the two systems in the most literal and crudest sense as two localities in the mental apparatus - conceptions which have left their traces in the expressions 'to repress' and 'to force a way through.' Thus, we may speak of an unconscious thought seeking to convey itself into the preconscious so as to be able then to force its way through into consciousness. What we have in mind here is not the forming of a second thought situated in a new place, like a transcription which continues to exist alongside the original; and the notion of forcing a way through into consciousness must be kept carefully free from any idea of a change of locality. Again, we may speak of a preconscious thought being repressed or driven out and then taken over by the unconscious. These images, derived from a set of ideas relating to a struggle for a piece of ground, may tempt us to suppose that it is literally true that a mental grouping in one locality has been brought to an end and replaced by a fresh one in another locality. Let us replace these metaphors by something that seems to correspond better to the real state of affairs, and let us say instead that some particular mental grouping has had a cathexis of energy attached to it or withdrawn from it, so that the structure in question has come under the sway of a particular agency or been withdrawn from it. What we are doing here is once again to replace a topographical way of representing things by a dynamic one. What we regard as mobile is not the psychical structure itself but its innervation.
So far we have been psychologizing on our own account. It is time now to consider the theoretical views which govern present-day psychology and to examine their relation to our hypotheses. The problem of the unconscious in psychology is, in the forcible words of Lipps (1897), less a psychological problem than the problem of psychology. So long as psychology dealt with this problem by a verbal explanation to the effect that 'psychical' meant 'conscious' and that to speak of 'unconscious psychical processes' was palpable nonsense, any psychological evaluation of the observations made by physicians upon abnormal mental states was out of the question. The physician and the philosopher can only come together if they both recognize that the term 'unconscious psychical processes' is 'the appropriate and justified expression of a solidly established fact'. The physician can only shrug his shoulders when he is assured that 'consciousness is an indispensable characteristic of what is psychical', and perhaps, if he still feels enough respect for the utterances of philosophers, he may presume that they have not been dealing with the same thing or working at the same science. For even a single understanding observation of a neurotic's mental life or a single analysis of a dream must leave him with an unshakeable conviction that the most complicated and most rational thought-processes, which can surely not be denied the name of psychical processes, can occur without exciting the subject's consciousness.¹ It is true that the physical cannot learn of these unconscious processes until they have produced some effect upon consciousness which can be communicated or observed. But this conscious effect may exhibit a psychical character quite different from that of the unconscious process, so that internal perception cannot possibly regard the one as a substitute for the other. The physician must feel at liberty to proceed by inference from the conscious effect to the unconscious psychical process. He thus learns that the conscious effect is only a remote psychical result of the unconscious process and that the latter has not become conscious as such; and moreover that the latter was present and operative even without betraying its existence in any way to consciousness.

[1900a, 1037]

Now that the old antithesis between conscious life and dream life has been reduced to its proper proportions by the establishment of unconscious psychical reality, a number of dream-problems with which earlier writers were deeply concerned have lost their significance. Thus some of the activities whose successful performance in dreams excited astonishment are now no longer to be attributed to dreams but to unconscious thinking, which is active during the day no less than at night. If, as Scherner has said, dreams appear to engage in making symbolic representations of the body, we now know that those representations are the product of certain unconscious phantasies (deriving, probably, from sexual impulses) which find expression not only in dreams but also in hysterical phobias and other symptoms. If a dream carries on the activities of the day and completes them and even brings valuable fresh ideas to light, all we need do is to strip it of the dream disguise, which is the product of dream-work and the mark of assistance rendered by obscure forces from the depths of the mind (cf. the Devil in Tartini's sonata dream); the intellectual achievement is due to the same mental forces which produce every similar result during the daytime. We are probably inclined greatly to over-estimate the conscious character of intellectual and artistic production as well. Accounts given us by some of the most highly productive men, such as Goethe and Helmholtz, show rather that what is essential and new in their creations came to them without premeditation and as an almost ready-made whole. There is nothing strange if in other cases, where a concentration of every intellectual faculty was needed, conscious activity also contributed its share. But it is the much-abused privilege of conscious activity, wherever it plays a part, to conceal every other activity from our eyes.

[1900a, 1038]
(5) I shall dwell longer on analyses of numerical associations, since I know of no other separate observations that would prove so forcefully the existence of highly composite thought-processes which are yet quite unknown to consciousness. At the same time I know of no better example of analyses in which the part contributed by the physician (suggestion) - so often held responsible - is so definitely ruled out. I shall therefore give a report here (with his consent) of the analysis of a number which occurred to a patient of mine. I need only add that he is the youngest child in a large family and at an early age lost his greatly admired father. While he was in a particularly cheerful mood the number 426718 came to his mind, and he asked himself: 'What ideas occur to me in that connection? First of all, a joke I have heard: "When a doctor treats a cold it lasts for 42 days; when it is not treated, it lasts 6 weeks."' This corresponds to the first figures in the number (42 = 6 x 7). In the stoppage that followed this first solution I drew his attention to the fact that the six-figure number he had chosen contained all the first digits except for 3 and 5. He then immediately found the continuation of the interpretation. 'There are 7 of us brothers and sisters, and I am the youngest. In the order of our age, 3 corresponds to my sister A., and 5 to my brother L.; they were my two enemies. As a child I used to pray to God every night for him to remove these two tormenting spirits from life. It seems to me now that in this choice of numbers I was myself fulfilling this wish; 3 and 5, the wicked brother and the hated sister, are passed over.' - If the number represents the order of your brothers and sisters, what does the 18 at the end mean? There were only 7 of you after all, - 'I have often thought that if my father had lived longer I should not have remained the youngest child. If there had been 1 more we should have been 8 and I should have had a younger child after me to whom I should have played the elder brother.'

[1901b, 1319]

We must also include in the category of the miraculous and the 'uncanny' the peculiar feeling we have, in certain moments and situations, of having had exactly the same experience once before or of having once before been in the same place, though our efforts never succeed in clearly remembering the previous occasion that announces itself in this way. I am aware that I am merely following loose linguistic usage when I call what arises in a person at such moments a 'feeling'. What is no doubt in question is a judgement, and, more precisely, a perceptual judgement; but these cases have nevertheless a character quite of their own, and we must not leave out of account the fact that what is looked for is never remembered. I do not know whether this phenomenon of 'déjà vu' has ever been seriously offered in proof of an individual's previous psychical existence; but psychologists have certainly turned their attention to it and have endeavoured to solve the problem in a whole variety of speculative ways. None of the attempted explanations which they have brought forward seems to me to be correct, because none of them takes into consideration anything other than the concomitant manifestations and the conditions which favour the phenomenon. Those psychical processes which according to my observations are alone responsible for the explanation of 'déjà vu' - namely, unconscious phantasies - are still generally neglected by psychologists even to-day.

[1901b, 1335]

It is in my view wrong to call the feeling of having experienced something before an illusion. It is rather that at such moments something is really touched on which we have already experienced once before, only we cannot consciously remember it because it has never been conscious. To put it briefly, the feeling of 'déjà vu' corresponds to the recollection of an unconscious phantasy. There exist unconscious phantasies (or day-dreams) just as there exist conscious creations of the same kind which everybody knows from his own experience.

[1901b, 1335]
I know that the subject would merit the most exhaustive treatment; but I shall here do no more
than give the analysis of a single case of 'déjà vu' where the feeling was characterized by
especial intensity and persistence. A lady who is now thirty-seven claimed to have a most
distinct memory of having at the age of twelve and a half paid her first visit to some school
friends in the country. When she entered the garden, she had an immediate feeling of having
been there before. This feeling was repeated when she went into the reception rooms, so that
she felt she knew in advance what room would be the next one, what view there would be from
it, and so on. But the possibility that this feeling of familiarity could have owed its origin to an
earlier visit to the house and garden, perhaps one in her earliest childhood, was absolutely ruled
out and was disproved as a result of her questioning her parents. The lady who reported this
was not in search of any psychological explanation, but saw the occurrence of this feeling as a
prophetic indication of the significance for her emotional life which these same school friends
later acquired. However, a consideration of the circumstances in which the phenomenon
occurred in her shows us the way to another view of the matter. At the time when she paid the
visit she knew that these girls had an only brother, who was seriously ill. During the visit she
actually set eyes on him, though he looked very ill and she said to herself that he would die
soon. Now, her own only brother had been dangerously ill with diphtheria a few months earlier;
during his illness she had spent several weeks away from her parents' house, staying with a
relative. She believed that her brother had been with her on this visit to the country; she even
thought it had been his first considerable journey after his illness; but her memory was
remarkably uncertain on these points while of all the other details, and in particular of the dress
she was wearing that day, she had an ultra-clear picture. Anyone who is well-informed will find
no difficulty in concluding from these hints that the expectation that her brother would die had at
that time played an important part in the girl's thoughts and either had never become conscious
or, after the favourable termination of the illness, had succumbed to energetic repression. If
things had turned out otherwise, she would have had to wear a different dress - mourning. She
found an analogous situation in the home of her friends, whose only brother was in danger of
dying soon, as in fact he did shortly after. She ought to have remembered consciously that she
herself had lived through this situation a few months before: instead of remembering it - which
was prevented by repression - she transferred her feeling of remembering something to her
surroundings, the garden and the house, and fell a victim to the 'fausse reconnaissance' of
having seen all this exactly the same once before. From the fact that repression occurred we
may conclude that her former expectation of her brother's death had not been far removed from
a wishful phantasy. She would then have been the only child. In her later neurosis she suffered
most severely from a fear of losing her parents, behind which, as usual, analysis was able to
reveal the unconscious wish with the same content.
[1901b, 1336]

On the other hand we must not overlook the fact that repressed thoughts and impulses
certainly do not achieve expression in symptomatic acts and parapraxes by their own unaided
efforts. The technical possibility for such side-sliping on the part of the innervations must be
presented independently; this will then be readily exploited by the intention of the repressed to
make itself felt consciously. In the case of verbal parapraxes, detailed investigations by
philosophers and philologists have endeavoured to determine what are the structural and
functional relations that put themselves at the service of such an intention. If we distinguish,
among the determinants of parapraxes and symptomatic acts, between the unconscious motive
on the one hand and the physiological and psycho-physical relations that come to meet it on the
other, it remains an open question whether there are, within the range of normality, yet other
factors that can - like the unconscious motive, and in place of it - create parapraxes and
symptomatic acts along the lines of these relations. It is not my task to answer this question.
[1901b, 1340]
¹ [Footnote added 1924:] This book is of an entirely popular character; it merely aims, by an accumulation of examples, at paving the way for the necessary assumption of unconscious yet operative mental processes, and it avoids all theoretical considerations on the nature of this unconscious.
[1901b, 1341]

I suspect that we are here concerned with unconscious processes of thought which are twined around a pre-existing structure of organic connections, much as festoons of flowers are twined around a wire; so that on another occasion one might find other lines of thought inserted between the same points of departure and termination. Yet a knowledge of the thought connections which have been effective in the individual case is of a value which cannot be exaggerated for clearing up the symptoms. It is only because the analysis was prematurely broken off that we have been obliged in Dora’s case to resort to framing conjectures and filling in deficiencies. Whatever I have brought forward for filling up the gaps is based upon other cases which have been more thoroughly analysed.
[1905e, 1420]

¹ I will add a few remarks on the structure of this dream, though it is not possible to understand it thoroughly enough to allow of a synthesis being attempted. A prominent piece of the dream is to be seen in the phantasy of revenge against her father, which stands out like a façade in front of the rest. (She had gone away from home by her own choice; her father was ill, and then dead. . . . Then she went home; all the others were already at the cemetery. She went to her room, not the least sadly, and calmly began reading the encyclopaedia.) This part of the material also contained two allusions to her other act of revenge, which she had actually carried out, when she let her parents discover a farewell letter from her. (The letter - from her mother, in the dream and the mention of the funeral of the aunt who had always been her model.) Behind this phantasy lie concealed her thoughts of revenge against Herr K., for which she found an outlet in her behaviour to me. (The maid servant, the invitation, the wood, the two and a half hours - all these came from material connected with the events at L--.) Her recollection of the governess, and of the latter’s exchange of letters with her parents, is related, no less than her farewell letter, to the letter in the dream allowing her to come home. Her refusal to let herself be accompanied and her decision to go alone may perhaps be translated into these words: ’Since you have treated me like a servant, I shall take no more notice of you, I shall go my own way by myself, and not marry.’ - Screened by these thoughts of revenge, glimpses can be caught in other places of material derived from tender phantasies based upon the love for Herr K. which still persisted unconsciously in Dora. (’I would have waited for you till I could be your wife’ - defloration - childbirth.) - Finally, we can see the action of the fourth and most deeply buried group of thoughts – those relating to her love for Frau K. - in the fact that the phantasy of defloration is represented from the man’s point of view (her identification of herself with her admirer who lived abroad) and in the fact that in two places there are the clearest allusions to ambiguous speeches (’Does Herr -- live here?’) and to that source of her sexual knowledge which had not been oral (the encyclopaedia). - Cruel and sadistic tendencies find satisfaction in this dream.
[1905e, 1445]
A number of the results of the analysis have been omitted, because at the time when work was broken off they had either not been established with sufficient certainty or they required further study before any general statement could be made about them. At other points, where it seemed to be permissible, I have indicated the direction along which some particular solution would probably have been found to lie. I have in this paper left entirely out of account the technique, which does not at all follow as a matter of course, but by whose means alone the pure metal of valuable unconscious thoughts can be extracted from the raw material of the patient's associations. This brings with it the disadvantage of the reader being given no opportunity of testing the correctness of my procedure in the course of this exposition of the case. I found it quite impracticable, however, to deal simultaneously with the technique of analysis and with the internal structure of a case of hysteria: I could scarcely have accomplished such a task, and if I had, the result would have been almost unreadable. The technique of analysis demands an entirely separate exposition, which would have to be illustrated by numerous examples chosen from a very great variety of cases and which would not have to take the results obtained in each particular case into account. Nor have I attempted in this paper to substantiate the psychological postulates which will be seen to underlie my descriptions of mental phenomena. A cursory attempt to do so would have effected nothing; an exhaustive one would have been a volume in itself. I can only assure the reader that I approached the study of the phenomena revealed by observation of the psychoneuroses without being pledged to any particular psychological system, and that I then proceeded to adjust my views until they seemed adapted for giving an account of the collection of facts which had been observed. I take no pride in having avoided speculation; the material for my hypotheses was collected by the most extensive and laborious series of observations. The decidedness of my attitude on the subject of the unconscious is perhaps specially likely to cause offence, for I handle unconscious ideas, unconscious trains of thought, and unconscious impulses as though they were no less valid and unimpeachable psychological data than conscious ones. But of this I am certain - that any one who sets out to investigate the same region of phenomena and employs the same method will find himself compelled to take up the same position, however much philosophers may expostulate.

¹ The contents of the clearly conscious phantasies of perverts (which in favourable circumstances can be transformed into manifest behaviour), of the delusional fears of paranoics (which are projected in a hostile sense on to other people) and of the unconscious phantasies of hysterics (which psycho-analysis reveals behind their symptoms) - all of these coincide with one another even down to their details.
Norbert Hanold’s memories of his childhood relations with the girl with the graceful gait were repressed; but this is not yet the correct view of the psychological situation. We remain on the surface so long as we are dealing only with memories and ideas. What is alone of value in mental life is rather the feelings. No mental forces are significant unless they possess the characteristic of arousing feelings. Ideas are only repressed because they are associated with the release of feelings which ought not to occur. It would be more correct to say that repression acts upon feelings, but we can only be aware of these in their association with ideas. So that it was Norbert Hanold’s erotic feelings that were repressed; and since his erotism knew and had known no other object than Zoe Bertgang in his childhood, his memories of her were forgotten. The ancient relief aroused the slumbering erotism in him, and made his childhood memories active. On account of a resistance to erotism that was present in him, these memories could only become operative as unconscious ones. What now took place in him was a struggle between the power of erotism and that of the forces that were repressing it; the manifestation of this struggle was a delusion.

And here we must give what will perhaps be an unexpected answer. In fact the situation is quite the reverse: it is science that cannot hold its own before the achievement of the author. Science allows a gulf to yawn between the hereditary and constitutional preconditions of a delusion and its creations, which seem to emerge ready-made - a gulf which we find that our author has filled. Science does not as yet suspect the importance of repression, it does not recognize that in order to explain the world of psychopathological phenomena the unconscious is absolutely essential, it does not look for the basis of delusions in a psychical conflict, and it does not regard their symptoms as compromises. Does our author stand alone, then, in the face of united science? No, that is not the case (if, that is, I may count my own works as part of science), since for a number of years - and, until recently, more or less alone⁴ - I myself have supported all the views that I have here extracted from Jensen’s Gradiva and stated in technical terms. I indicated, in most detail in connection with the states known as hysteria and obsessions, that the individual determinant of these psychical disorders is the suppression of a part of instinctual life and the repression of the ideas by which the suppressed instinct is represented, and soon afterwards I repeated the same views in relation to some forms of delusion.² The question whether the instincts concerned in this causation are always components of the sexual instinct or may be of another kind as well is a problem which may be regarded as a matter of indifference in the particular case of the analysis of Gradiva; for in the instance chosen by our author what was at issue was quite certainly nothing other than the suppression of erotic feelings. The validity of the hypotheses of psychical conflict and of the formation of symptoms by means of compromises between the two mental currents struggling against each other has been demonstrated by me in the case of patients observed and medically treated in real life, just as I have been able to in the imaginary case of Norbert Hanold.⁵ Even before me, Pierre Janet, a pupil of the great Charcot, and Josef Breuer, in collaboration with me, had traced back the products of neurotic, and especially of hysterical, illness to the power of unconscious thoughts.⁴

[1907a, 1848]
Since the author has taken so much trouble over describing the journey, it must be worth while too to discuss its relation to Hanold's delusion and its position in the chain of events. The journey was undertaken for reasons which its subject did not recognize at first and only admitted to himself later on, reasons which the author describes in so many words as 'unconscious'. This is certainly taken from the life. One does not need to be suffering from a delusion in order to behave like this. On the contrary, it is an event of daily occurrence for a person - even a healthy person - to deceive himself over the motives for an action and to become conscious of them only after the event, provided only that a conflict between several currents of feeling furnishes the necessary condition for such a confusion. Accordingly, Hanold's journey was from the first calculated to serve the delusion, and was intended to take him to Pompeii, where he could proceed further with his search for Gradiva. It will be recalled that his mind was occupied with that search both before and immediately after the dream, and that the dream itself was simply an answer to the question of Gradiva's whereabouts, though an answer which was stifled by his consciousness. Some power which we do not recognize was, however, also inhibiting him to begin with from becoming aware of his delusional intention; so that, for the conscious reasons for his journey, he was left only with insufficient pretexts which had to be renewed from place to place. The author presents us with a further puzzle by making the dream, the discovery of the supposed Gradiva in the street, and the decision to undertake the journey as a result of the singing canary succeed one another as a series of chance events without any internal connection with one another.

This obscure region of the story is made intelligible to us by some explanations which we derive from the later remarks of Zoe Bertgang. It was in fact the original of Gradiva, Fräulein Zoe herself, whom Hanold saw out of his window walking past in the street (89.) and whom he nearly overtook. If this had happened, the information given him by the dream - that she was in fact living at the same time and in the same town as he was - would by a lucky chance have received an irresistible confirmation, which would have brought about the collapse of his internal struggle. But the canary, whose singing sent Hanold off on his distant journey, belonged to Zoe, and its cage stood in her window diagonally across the street from Hanold's house. (135.) Hanold, who, according to the girl's accusation, had the gift of 'negative hallucination', who possessed the art of not seeing and not recognizing people who were actually present, must from the first have had an unconscious knowledge of what we only learned later. The indications of Zoe's proximity (her appearance in the street and her bird's singing so near his window) intensified the effect of the dream, and in this position, so perilous for his resistance to his erotic feelings, he took to flight. His journey was a result of his resistance gathering new strength after the surge forward of his erotic desires in the dream; it was an attempt at flight from the physical presence of the girl he loved. In a practical sense it meant a victory for repression, just as his earlier activity, his 'pedestrian researches' upon women and girls, had meant a victory for erotism. But everywhere in these oscillations in the struggle the compromise character of the outcome was preserved: the journey to Pompeii, which was supposed to lead him away from the living Zoe, led him at least to her surrogate, to Gradiva. The journey which was undertaken in defiance of the latent dream-thoughts, was nevertheless following the path to Pompeii that was pointed out by the manifest content of the dream. Thus at every fresh struggle between erotism and resistance we find the delusion triumphant.

[1907a, 1861]
The chief difference has already been named. In the neurotic the secret is hidden from his own consciousness; in the criminal it is hidden only from you. In the former there is a genuine ignorance, though not an ignorance in every sense, while in the latter there is nothing but a pretence of ignorance. Connected with this is another difference, which is in practice of importance. In psycho-analysis the patient assists with his conscious efforts to combat his resistance, because he expects to gain something from the investigation, namely, his recovery. The criminal, on the other hand, does not work with you; if he did, he would be working against his whole ego. As though to make up for this, however, all you are endeavouring to arrive at in your investigation is an objective certainty on your part, whereas our therapy demands that the patient himself should also arrive at the same certainty. But it remains to be seen how far your procedure will be rendered more difficult or be altered by the lack of co-operation on the part of the subject of your examination. This is a situation which you can never create in your experiments in seminars, since the colleague who is playing the part of the accused man remains a fellow-worker after all, and assists you in spite of his conscious determination not to betray himself.

If you look more deeply into the comparison between the two situations it will become clear to you in general that psycho-analysis is concerned with a simpler, special, form of the task of uncovering what is hidden in the mind; whereas in your work the task is a more comprehensive one. That the case of the psychoneurotic is invariably concerned with a repressed sexual complex (in the widest sense) is a difference which you need not take into account. But there is something else that you must. The aim of psycho-analysis is absolutely uniform in every case: complexes have to be uncovered which have been repressed because of feelings of unpleasure and which produce signs of resistance if an attempt is made to bring them into consciousness. This resistance is as it were localized; it arises at the frontier between unconscious and conscious. In your cases what is concerned is a resistance which comes entirely from consciousness. You cannot dismiss this difference out of hand. You will first have to determine experimentally whether conscious resistance is betrayed by exactly the same indications as unconscious resistance. Further, you cannot yet be certain, in my opinion, whether you may interpret your objective indications of a complex as a 'resistance', as we psycho-therapists do. It may happen with your experimental subjects - even though not very frequently with criminals - that the complex you touch on is pleasurably toned; and the question then arises whether such a complex will produce the same reaction as a complex that is unpleasurably toned.

[1906c, 1895]
These day-dreams are cathected with a large amount of interest; they are carefully cherished by the subject and usually concealed with a great deal of sensitivity, as though they were among the most intimate possessions of his personality. It is easy to recognize a person who is absorbed in day-dreaming in the street, however, by his sudden, as it were absent-minded, smile, his way of talking to himself, or by the hastening of his steps which marks the climax of the imagined situation. Every hysterical attack which I have been able to investigate up to the present has proved to be an involuntary irruption of day-dreams of this kind. For our observations no longer leave any room for doubt that such phantasies may be unconscious just as well as conscious; and as soon as the latter have become unconscious they may also become pathogenic - that is, they may express themselves in symptoms and attacks. In favourable circumstances, the subject can still capture an unconscious phantasy of this sort in consciousness. After I had drawn the attention of one of my patients to her phantasies, she told me that on one occasion she had suddenly found herself in tears in the street and that, rapidly considering what it was she was actually crying about, she had got hold of a phantasy to the following effect. In her imagination she had formed a tender attachment to a pianist who was well known in the town (though she was not personally acquainted with him); she had had a child by him (she was in fact childless); and he had then deserted her and her child and left them in poverty. It was at this point in her romance that she had burst into tears.

[1908a, 1933]

Unconscious phantasies have either been unconscious all along and have been formed in the unconscious; or - as is more often the case - they were once conscious phantasies, day-dreams, and have since been purposely forgotten and have become unconscious through 'repression'. Their content may afterwards either have remained the same or have undergone alterations, so that the present unconscious phantasies are derivatives of the once conscious ones. Now an unconscious phantasy has a very important connection with the subject's sexual life; for it is identical with the phantasy which served to give him sexual satisfaction during a period of masturbation. At that time the masturbatory act (in the widest sense of the term) was compounded of two parts. One was the evocation of a phantasy and the other some active behaviour for obtaining self-gratification at the height of the phantasy. This compound, as we know, was itself merely soldered together.¹ Originally the action was a purely auto-erotic procedure for the purpose of obtaining pleasure from some particular part of the body, which could be described as erotogenic. Later, this action became merged with a wishful idea from the sphere of object-love and served as a partial realization of the situation in which the phantasy culminated. When, subsequently, the subject renounces this type of satisfaction, composed of masturbation and phantasy, the action is given up, while the phantasy, from being conscious, becomes unconscious. If no other mode of sexual satisfaction supervenes, the subject remains abstinent; and if he does not succeed in sublimating his libido - that is, in deflecting his sexual excitation to higher aims -, the condition is now fulfilled for his unconscious phantasy to be revived and to proliferate, and, at least as regards some part of its content, to put itself into effect, with the whole force of his need for love, in the form of a pathological symptom.

[1908a, 1934]

The material on which the following synthesis is based is derived from several sources. Firstly, from the direct observation of what children say and do; secondly, from what adult neurotics consciously remember from their childhood and relate during psycho-analytic treatment; and thirdly, from the inferences and constructions, and from the unconscious memories translated into conscious material, which result from the psycho-analysis of neurotics.

[1908c, 1966]
Solving the mystery of sleep might well have been reserved to science; the pious author, however, operates with biblical arguments and teleological causes. For example: it would be an idea unworthy of divine providence to suppose that it would allow human beings to spend a full third of their life in spiritual inactivity. Sleep is rather that state in which divine influence penetrates most freely and most effectively into human mental life. But in spite of all objections to the author's way of thinking we will not omit to emphasize the kernel of truth in his assertion. Scientific studies of the state of mental life during sleep, too, oblige us to relinquish as inadequate our previous assumption that sleep reduces the play of mental activity to a minimum. The important processes of unconscious mental and even intellectual activity continue - as the elucidation of dreams given by your reviewer demonstrates - even during profound sleep. This unconscious mental activity deserves to be called 'daemonic' but scarcely divine.

[1903-1904, 1997]

¹ I cannot interrupt the discussion so far as to demonstrate the typical character of the unconscious train of thought which I think there is here reason for attributing to little Hans. The castration complex is the deepest unconscious root of anti-Semitism; for even in the nursery little boys hear that a Jew has something cut off his penis - a piece of his penis, they think - and this gives them a right to despise Jews. And there is no stronger unconscious root for the sense of superiority over women. Weininger (the young philosopher who, highly gifted but sexually deranged, committed suicide after producing his remarkable book, Geschlecht und Charakter), in a chapter that attracted much attention, treated Jews and women with equal hostility and overwhelmed them with the same insults. Being a neurotic, Weininger was completely under the sway of his infantile complexes; and from that standpoint what is common to Jews and women is their relation to the castration complex.

[1909b, 2026]

If I went more deeply into the details of the analysis I could produce plenty more evidence of Hans's independence of 'suggestion'; but I shall break off the discussion of this preliminary objection at this point. I am aware that even with this analysis I shall not succeed in convincing any one who will not let himself be convinced, and I shall proceed with my discussion of the case for the benefit of those readers who are already convinced of the objective reality of unconscious pathogenic material. And I do this with the agreeable assurance that the number of such readers is steadily increasing.

[1909b, 2090]

We find, accordingly: an erotic instinct and a revolt against it; a wish which has not yet become compulsive and, struggling against it, a fear which is already compulsive; a distressing affect and an impulse towards the performance of defensive acts. The inventory of the neurosis has reached its full muster. Indeed, something more is present, namely, a kind of delusion or delirium with the strange content that his parents knew his thoughts because he spoke them out loud without his hearing himself do it. We shall not go far astray if we suppose that in making this attempt at an explanation the child had some inkling of those remarkable mental processes which we describe as unconscious and which we cannot dispense with if we are to throw any scientific light upon this obscure subject. 'I speak my thoughts out loud, without hearing them' sounds like a projection into the external world of our own hypothesis that he had thoughts without knowing anything about them; it sounds like an endopsychic perception of what has been repressed.

[1909d, 2134]
At all the more important moments while he was telling his story his face took on a very strange, composite expression. I could only interpret it as one of horror at pleasure of his own of which he himself was unaware. He proceeded with the greatest difficulty: "At that moment the idea flashed through my mind that this was happening to a person who was very dear to me."¹ In answer to a direct question he said that it was not he himself who was carrying out the punishment, but that it was being carried out as it were impersonally. After a little prompting I learnt that the person to whom this 'idea' of his related was the lady whom he admired.

¹ In psycho-analyses we frequently come across occurrences of this kind, dating back to the earliest years of the patient's childhood, in which his infantile sexual activity appears to reach its climax and often comes to a catastrophic end owing to some misfortune or punishment. Such occurrences are apt to appear in a shadowy way in dreams. Often they will become so clear that the analyst thinks he has a firm hold of them, and will nevertheless evade any final elucidation; and unless he proceeds with the greatest skill and caution he may be compelled to leave it undecided whether the scene in question actually took place or not. It will help to put us upon the right track in interpreting it, if we recognize that more than one version of the scene (each often differing greatly from the other) may be detected in the patient's unconscious phantasies. If we do not wish to go astray in our judgement of their historical reality, we must above all bear in mind that people's 'childhood memories' are only consolidated at a later period, usually at the age of puberty; and that this involves a complicated process of remodelling, analogous in every way to the process by which a nation constructs legends about its early history. It at once becomes evident that in his phantasies about his infancy the individual as he grows up endeavours to efface the recollection of his auto-erotic activities; and this he does by exalting their memory-traces to the level of object-love, just as a real historian will view the past in the light of the present. This explains why these phantasies abound in seductions and assaults, where the facts will have been confined to auto-erotic activities and the caresses or punishments that stimulated them. Furthermore, it becomes clear that in constructing phantasies about his childhood the individual sexualizes his memories; that is, he brings commonplace experiences into relation with his sexual activity, and extends his sexual interest to them - though in doing this he is probably following upon the traces of a really existing connection. No one who remembers my 'Analysis of a Phobia in a Five-Year-Old Boy' will need to be told that it is not my intention in these remarks to detract from the importance which I have hitherto attached to infantile sexuality by reducing it to nothing more than sexual interest at the age of puberty. I merely wish to give some technical advice that may help to clear up a class of phantasy which is calculated to falsify the picture of infantile sexual activity.
In my description I shall, as I have already said, content myself with the briefest possible summary of the circumstances. Obviously the first problem to be solved was why the two speeches of the Czech captain - his rat story, and his request to the patient that he should pay back the money to Lieutenant A. - should have had such an agitating effect on him and should have provoked such violently pathological reactions. The presumption was that it was a question of 'complexive sensitiveness', and that the speeches had jarred upon certain hyperaesthetic spots in his unconscious. And so it proved to be. As always happened with the patient in connection with military matters, he had been in a state of unconscious identification with his father, who had seen many years' service and had been full of stories of his soldiering days. Now it happened by chance - for chance may play a part in the formation of a symptom, just as the wording may help in the making of a joke - that one of his father's little adventures had an important element in common with the captain's request. His father, in his capacity as non-commissioned officer, had control over a small sum of money and had on one occasion lost it at cards. (Thus he had been a 'Spielratte'.¹) He would have found himself in a serious position if one of his comrades had not advanced him the amount. After he had left the army and become well-off, he had tried to find this friend in need so as to pay him back the money, but had not managed to trace him. The patient was uncertain whether he had ever succeeded in returning the money. The recollection of this sin of his father's youth was painful to him, for, in spite of appearances, his unconscious was filled with hostile strictures upon his father's character. The captain's words, 'You must pay back the 3.80 kronen to Lieutenant A.', had sounded to his ears like an allusion to this unpaid debt of his father's.

The technique of distortion by ellipsis seems to be typical of obsessional neuroses; I have come across it in the obsessional thoughts of other patients as well. One example, a particularly transparent one, is of especial interest on account of a certain structural similarity with the rat idea. It was a case of doubting, and occurred in a lady who suffers principally from obsessional acts. This lady was going for a walk with her husband in Nuremberg, and made him take her into a shop, where she purchased various objects for her child and amongst them a comb. Her husband, finding that the shopping was too long a business for his taste, said that he had noticed some coins in an antique shop on the way which he was anxious to secure, adding that after he had made his purchase he would come and fetch her in the shop in which they at present were. But he stayed away, as she thought, far too long. When he came back she accordingly asked him where he had been. 'Why,' he replied, 'at the antique shop I told you about.' At the same instant she was seized by a tormenting doubt whether she had not as a matter of fact always possessed the comb which she had just bought for her child. She was naturally quite unable to discover the simple mental link that was involved. There is nothing for it but to regard the doubt as having become displaced, and to reconstruct the complete chain of unconscious thoughts as follows: 'If it is true that you were only at the antique shop, if I am really to believe that, then I may just as well believe that this comb that I bought a moment ago has been in my possession for years.' Here, therefore, the lady was drawing a derisive and ironical parallel, just as when our patient thought: 'Oh yes, as sure as those two' (his father and the lady) 'will have children, I shall pay back the money to A.' In the lady's case the doubt was dependent upon her unconscious jealousy, which led her to suppose that her husband had spent the interval of his absence in paying a visit of gallantry.

¹[1909d, 2164]
I shall not in the present paper attempt any discussion of the psychological significance of obsessional thinking. Such a discussion would be of extraordinary value in its results, and would do more to clarify our ideas upon the nature of the conscious and the unconscious than any study of hysteria or the phenomena of hypnosis. It would be a most desirable thing if the philosophers and psychologists who develop brilliant theoretical views on the unconscious upon a basis of hearsay knowledge or from their own conventional definitions would first submit to the convincing impressions which may be gained from a first-hand study of the phenomena of obsessional thinking. We might almost go to the length of requiring it of them, if the task were not so far more laborious than the methods of work to which they are accustomed. I will only add here that in obsessional neuroses the unconscious mental processes occasionally break through into consciousness in their pure and undistorted form, that such incursions may take place at every possible stage of the unconscious process of thought, and that at the moment of the incursion the obsessional ideas can, for the most part, be recognized as formations of very long standing. This accounts for the striking circumstance that, when the analyst tries, with the patient's help, to discover the date of the first occurrence of an obsessional idea, the patient is obliged to place it further and further back as the analysis proceeds, and is constantly finding fresh 'first' occasions for the appearance of the obsession. [1909d, 2178]

If we consider a number of analyses of obsessional neurotics we shall find it impossible to escape the impression that a relation between love and hatred such as we have found in our present patient is among the most frequent, the most marked, and probably, therefore, the most important characteristics of obsessional neurosis. But however tempting it may be to bring the problem of the 'choice of neurosis' into connection with instinctual life, there are reasons enough for avoiding such a course. For we must remember that in every neurosis we come upon the same suppressed instincts behind the symptoms. After all, hatred, kept suppressed in the unconscious by love, plays a great part in the pathogenesis of hysteria and paranoia. We know too little of the nature of love to be able to arrive at any definite conclusion here; and, in particular, the relation between the negative factor in love and the sadistic components of the libido remains completely obscure. What follows is therefore to be regarded as no more than a provisional explanation. We may suppose, then, that in the cases of unconscious hatred with which we are concerned the sadistic components of love have, from constitutional causes, been exceptionally strongly developed, and have consequently undergone a premature and all too thorough suppression, and that the neurotic phenomena we have observed arise on the one hand from conscious feelings of affection which have become exaggerated as a reaction, and on the other hand from sadism persisting in the unconscious in the form of hatred. [1909d, 2187]
It is this same doubt that leads the patient to uncertainty about his protective measures, and to his continual repetition of them in order to banish that uncertainty; and it is this doubt, too, that eventually brings it about that the patient's protective acts themselves become as impossible to carry out as his original inhibited decision in connection with his love. At the beginning of my investigations I was led to assume another and more general origin for the uncertainty of obsessional neurotics and one which seemed to be nearer the normal. If, for instance, while I am writing a letter some one interrupts me with questions, I afterwards feel a quite justifiable uncertainty as to what I may not have written under the influence of the disturbance, and, to make sure, I am obliged to read the letter over after I have finished it. In the same way I might suppose that the uncertainty of obsessional neurotics, when they are praying, for instance, is due to unconscious phantasies constantly mingling with their prayers and disturbing them. This hypothesis is correct, but it may be easily reconciled with what I have just said. It is true that the patient's uncertainty whether he has carried through a protective measure is due to the disturbing effect of unconscious phantasies; but the content of these phantasies is precisely the contrary impulse - which it was the very aim of the prayer to ward off. This became clearly evident in our patient on one occasion, for the disturbing element did not remain unconscious but made its appearance openly. The words he wanted to use in his prayer were, 'May God protect her', but a hostile 'not' suddenly darted out of his unconscious and inserted itself into the sentence; and he understood that this was an attempt at a curse (p. 2152). If the 'not' had remained mute, he would have found himself in a state of uncertainty and would have kept on prolonging his prayers indefinitely. But since it became articulate he eventually gave up praying. Before doing so, however, he, like other obsessional patients, tried every kind of method for preventing the opposite feeling from insinuating itself. He shortened his prayers, for instance, or said them more rapidly. And similarly other patients will endeavour to 'isolate' all such protective acts from other things. But none of these technical procedures are of any avail in the long run. If the impulse of love achieves any success by displacing itself on to some trivial act, the impulse of hostility will very soon follow it on to its new ground and once more proceed to undo all that it has done.

To take the place of a number of instances, I will relate a single one of my cases, in which the determinants and advantages of repression are sufficiently evident. For my present purpose I shall have once again to abridge the case history and omit some important underlying material. The patient was a girl, who had lost her beloved father after she had taken a share in nursing him - a situation analogous to that of Breuer's patient. Soon afterwards her elder sister married, and her new brother-in-law aroused in her a peculiar feeling of sympathy which was easily masked under a disguise of family affection. Not long afterwards her sister fell ill and died, in the absence of the patient and her mother. They were summoned in all haste without being given any definite information of the tragic event. When the girl reached the bedside of her dead sister, there came to her for a brief moment an idea that might be expressed in these words: 'Now he is free and can marry me.' We may assume with certainty that this idea, which betrayed to her consciousness the intense love for her brother-in-law of which she had not herself been conscious, was surrendered to repression a moment later, owing to the revolt of her feelings. The girl fell ill with severe hysterical symptoms; and while she was under my treatment it turned out that she had completely forgotten the scene by her sister's bedside and the odious egoistic impulse that had emerged in her. She remembered it during the treatment and reproduced the pathogenic moment with signs of the most violent emotion, and, as a result of the treatment, she became healthy once more.

[1909d, 2189]

[1910a, 2213]
This seems perfectly sound and will satisfy anyone who can ignore the many enigmas that lie concealed behind the concepts of hypnosis, suggestion and autosuggestion. Autosuggestion in particular raises further questions. When and under what conditions does an idea become so powerful that it is able to behave like a suggestion and turn into reality without more ado? Closer investigation has taught us that we cannot answer this question without calling the concept of the 'unconscious' to our assistance. Many philosophers rebel against the assumption of a mental unconscious of this kind, because they have not concerned themselves with the phenomena which compel us to make that assumption. Psychopathologists have found that they cannot avoid working with such things as unconscious mental processes, unconscious ideas, and so on. 
[1910i, 2366]

Appropriate experiments have shown that people who are hysterically blind do nevertheless see in some sense, though not in the full sense. Excitations of the blind eye may have certain psychical consequences (for instance, they may produce affects) even though they do not become conscious. Thus hysterically blind people are only blind as far as consciousness is concerned; in their unconscious they see. It is precisely observations such as this that compel us to distinguish between conscious and unconscious mental processes. 
[1910i, 2367]

At a later stage in this paper I intend to return to a discussion of some further objections; but in the meantime I shall consider myself justified in maintaining the view that the basis of Schreber's illness was the outburst of a homosexual impulse. This hypothesis harmonizes with a noteworthy detail of the case history, which remains otherwise inexplicable. The patient had a fresh 'nervous collapse', which exercised a decisive effect upon the course of his illness, at a time when his wife was taking a short holiday on account of her own health. Up till then she had spent several hours with him every day and had taken her mid-day meal with him. But when she returned after an absence of four days, she found him most sadly altered: so much so, indeed, that he himself no longer wished to see her. 'What especially determined my mental breakdown was a particular night, during which I had a quite extraordinary number of emissions - quite half a dozen, all in that one night.' (44.) It is easy to understand that the mere presence of his wife must have acted as a protection against the attractive power of the men about him; and if we are prepared to admit that an emission cannot occur in an adult without some mental concomitant, we shall be able to supplement the patient's emissions that night by assuming that they were accompanied by homosexual phantasies which remained unconscious. 
[1911c, 2418]

This might be considered an uninteresting piece of descriptive or classificatory work if no experience appealed to our judgement other than the facts of memory, or the cases of association by unconscious links. The well-known experiment, however, of the 'post-hypnotic suggestion' teaches us to insist upon the importance of the distinction between conscious and unconscious and seems to increase its value. 
[1912g, 2577]
In this experiment, as performed by Bernheim, a person is put into a hypnotic state and is subsequently aroused. While he was in the hypnotic state, under the influence of the physician, he was ordered to execute a certain action at a certain fixed moment after his awakening, say half an hour later. He awakes, and seems fully conscious and in his ordinary condition; he has no recollection of his hypnotic state, and yet at the prearranged moment there rushes into his mind the impulse to do such and such a thing, and he does it consciously, though not knowing why. It seems impossible to give any other description of the phenomenon than to say that the order had been present in the mind of the person in a condition of latency, or had been present unconsciously, until the given moment came, and then had become conscious. But not the whole of it emerged into consciousness: only the conception of the act to be executed. All the other ideas associated with this conception - the order, the influence of the physician, the recollection of the hypnotic state, remained unconscious even then.

[1912g, 2578]

A post-hypnotic suggestion is a laboratory production, an artificial fact. But if we adopt the theory of hysterical phenomena first put forward by P. Janet and elaborated by Breuer and myself, we shall not be at a loss for plenty of natural facts showing the psychological character of the post-hypnotic suggestion even more clearly and distinctly.

[1912g, 2578]

It cannot be disputed that this process of projection, which turns a dead man into a malignant enemy, is able to find support in any real acts of hostility on his part that may be recollected and felt as a grudge against him: his severity, his love of power, his unfairness, or whatever else may form the background of even the tenderest of human relationships. But it cannot be such a simple matter as that. This factor alone cannot explain the creation of demons by projection. The faults of the dead no doubt provide a part of the explanation of the survivors’ hostility; but they would not operate in this way unless the survivors had first developed hostility on their own account. The moment of death, moreover, would certainly seem to be a most inappropriate occasion for recalling any justifiable grounds of complaint that might exist. It is impossible to escape the fact that the true determining factor is invariably unconscious hostility. A hostile current of feeling such as this against a person’s nearest and dearest relatives may remain latent during their lifetime, that is, its existence may not be betrayed to consciousness either directly or through some substitute. But when they die this is no longer possible and the conflict becomes acute. The mourning which derives from an intensification of the affectionate feelings becomes on the one hand more impatient of the latent hostility and, on the other hand, will not allow it to give rise to any sense of satisfaction. Accordingly, there follow the repression of the unconscious hostility by the method of projection and the construction of the ceremonial which gives expression to the fear of being punished by the demons. When in course of time the mourning runs its course, the conflict grows less acute, so that the taboo upon the dead is able to diminish in severity or sink into oblivion.

[1912-1913, 2707]
It cannot be disputed that this process of projection, which turns a dead man into a malignant enemy, is able to find support in any real acts of hostility on his part that may be recollected and felt as a grudge against him: his severity, his love of power, his unfairness, or whatever else may form the background of even the tenderest of human relationships. But it cannot be such a simple matter as that. This factor alone cannot explain the creation of demons by projection. The faults of the dead no doubt provide a part of the explanation of the survivors’ hostility; but they would not operate in this way unless the survivors had first developed hostility on their own account. The moment of death, moreover, would certainly seem to be a most inappropriate occasion for recalling any justifiable grounds of complaint that might exist. It is impossible to escape the fact that the true determining factor is invariably unconscious hostility. When in course of time the mourning runs its course, the conflict grows less acute, so that the taboo upon the dead is able to diminish in severity or sink into oblivion.

[1912-1913, 2707]

The problem would seem even more difficult if we had to admit that mental impulses could be so completely suppressed as to leave no trace whatever behind them. But that is not the case. Even the most ruthless suppression must leave room for distorted surrogate impulses and for reactions resulting from them. If so, however, we may safely assume that no generation is able to conceal any of its more important mental processes from its successor. For psycho-analysis has shown us that everyone possesses in his unconscious mental activity an apparatus which enables him to interpret other people’s reactions, that is, to undo the distortions which other people have imposed on the expression of their feelings. An unconscious understanding such as this of all the customs, ceremonies and dogmas left behind by the original relation to the father may have made it possible for later generations to take over their heritage of emotion.

[1912-1913, 2797]

In 1904 Grasset put forward an explanation of the \textit{déjà vu} which must be reckoned as one of the group which ‘believes’ in the phenomenon. He was of opinion that the phenomenon indicates that at some earlier time there has been an unconscious perception, which only now makes its way into consciousness under the influence of a new and similar impression. Several other authorities have agreed with this view, and have maintained that the basis of the phenomenon is the recollection of something that has been dreamed and then forgotten. In both cases it would be a question of the activation of an unconscious impression.

[1914a, 2838]

The stubborn denial of a psychical character to latent mental acts is accounted for by the circumstance that most of the phenomena concerned have not been the subject of study outside psycho-analysis. Anyone who is ignorant of pathological facts, who regards the parapraxes of normal people as accidental, and who is content with the old saw that dreams are froth ['\textit{Träume sind Schäume}'] has only to ignore a few more problems of the psychology of consciousness in order to spare himself any need to assume an unconscious mental activity. Incidentally, even before the time of psycho-analysis, hypnotic experiments, and especially post-hypnotic suggestion, had tangibly demonstrated the existence and mode of operation of the mental unconscious.

[1915e, 2992]
We have limited the foregoing discussion to ideas; we may now raise a new question, the
answer to which is bound to contribute to the elucidation of our theoretical views. We have said
that there are conscious and unconscious ideas; but are there also unconscious instinctual
impulses, emotions and feelings, or is it in this instance meaningless to form combinations of
the kind?
[1915e, 3000]

I am in fact of the opinion that the antithesis of conscious and unconscious is not applicable to
instincts. An instinct can never become an object of consciousness - only the idea that
represents the instinct can. Even in the unconscious, moreover, an instinct cannot be
represented otherwise than by an idea. If the instinct did not attach itself to an idea or manifest
itself as an affective state, we could know nothing about it. When we nevertheless speak of an
unconscious instinctual impulse or of a repressed instinctual impulse, the looseness of
phraseology is a harmless one. We can only mean an instinctual impulse the ideational
representative of which is unconscious, for nothing else comes into consideration.
[1915e, 3000]

We should expect the answer to the question about unconscious feelings, emotions and
affects to be just as easily given. It is surely of the essence of an emotion that we should be
aware of it, i.e. that it should become known to consciousness. Thus the possibility of the
attribute of unconsciousness would be completely excluded as far as emotions, feelings and
affects are concerned. But in psycho-analytic practice we are accustomed to speak of
unconscious love, hate, anger, etc., and find it impossible to avoid even the strange conjunction
'unconscious consciousness of guilt', or a paradoxical 'unconscious anxiety'. Is there more
meaning in the use of these terms than there is in speaking of 'unconscious instincts'?
[1915e, 3000]

The two cases are in fact not on all fours. In the first place, it may happen that an affective or
emotional impulse is perceived but misconstrued. Owing to the repression of its proper
representative it has been forced to become connected with another idea, and is now regarded
by consciousness as the manifestation of that idea. If we restore the true connection, we call the
original affective impulse an 'unconscious' one. Yet its affect was never unconscious; all that
had happened was that its idea had undergone repression. In general, the use of the terms
'unconscious affect' and 'unconscious emotion' has reference to the vicissitudes undergone, in
consequence of repression, by the quantitative factor in the instinctual impulse. We know that
three such vicissitudes are possible:¹ either the affect remains, wholly or in part, as it is; or it is
transformed into a qualitatively different quota of affect, above all into anxiety; or it is
suppressed, i.e. it is prevented from developing at all. (These possibilities may perhaps be
studied even more easily in the dream-work than in neuroses.) We know, too, that to suppress
the development of affect is the true aim of repression and that its work is incomplete if this aim
is not achieved. In every instance where repression has succeeded in inhibiting the
development of affects, we term those affects (which we restore when we undo the work of
repression) 'unconscious'. Thus it cannot be denied that the use of the terms in question is
consistent; but in comparison with unconscious ideas there is the important difference that
unconscious ideas continue to exist after repression as actual structures in the system Ucs.,
whereas all that corresponds in that system to unconscious affects is a potential beginning
which is prevented from developing. Strictly speaking, then, and although no fault can be found
with the linguistic usage, there are no unconscious affects as there are unconscious ideas. But
there may very well be in the system Ucs. affective structures which, like others, become
conscious. The whole difference arises from the fact that ideas are cathexes - basically of
memory-traces - whilst affects and feelings correspond to processes of discharge, the final
manifestations of which are perceived as feelings. In the present state of our knowledge of
affects and feelings we cannot express this difference more clearly.
[1915e, 3001]
The first of these unpopular assertions made by psycho-analysis declares that mental processes are in themselves unconscious and that of all mental life it is only certain individual acts and portions that are conscious. You know that on the contrary we are in the habit of identifying what is psychical with what is conscious. We look upon consciousness as nothing more nor less than the defining characteristic of the psychical, and psychology as the study of the contents of consciousness. Indeed it seems to us so much a matter of course to equate them in this way that any contradiction of the idea strikes us as obvious nonsense. Yet psycho-analysis cannot avoid raising this contradiction; it cannot accept the identity of the conscious and the mental. It defines what is mental as processes such as feeling, thinking and willing, and it is obliged to maintain that there is unconscious thinking and unapprehended willing. In saying this it has from the start frivolously forfeited the sympathy of every friend of sober scientific thought, and laid itself open to the suspicion of being a fantastic esoteric doctrine eager to make mysteries and fish in troubled waters. But you, Ladies and Gentlemen, naturally cannot understand as yet what right I have to describe as a prejudice a statement of so abstract a nature as 'what is mental is conscious'. Nor can you guess what development can have led to a denial of the unconscious - should such a thing exist - and what advantage there may have been in that denial. The question whether we are to make the psychical coincide with the conscious or make it extend further sounds like an empty dispute about words; yet I can assure you that the hypothesis of there being unconscious mental processes paves the way to a decisive new orientation in the world and in science.

[1916-1917, 3134]

As regards the meaning of the dream and the dreamer's attitude to it, we might point out much that is similarly surprising. She agreed to the interpretation indeed, but she was astonished at it. She was not aware that she assigned such a low value to her husband; nor did she know why she should set such a low value on him. So there is still much that is unintelligible about it. It really seems to me that we are not yet equipped for interpreting a dream and that we need first to be given some further instruction and preparation.

[1916-1917, 3220]

But it would be unfair if we neglected at this point to emphasize sufficiently another outcome of our investigations. The dream-wishes which seek to disturb us in our sleep are unknown to us and indeed we only learnt of them through dream-interpretation. They are thus to be described, in the sense we have discussed, as unconscious for the time being. But we must reflect that they are unconscious too for more than the time being. The dreamer also disavows them, as we have seen in so many instances, after he has come to know them through the interpretation of his dream. We are then faced once again with the position we first came across in the 'hiccupping' slip of the tongue, where the proposer of the toast protested indignantly that neither then nor at any earlier time had he become conscious of any disrespectful impulse towards his Chief. Already at the time we felt some doubts about the weight of an assurance of this kind, and suggested instead the hypothesis that the speaker was permanently unaware of the presence of this impulse in him. This situation is repeated now with every interpretation of a strongly distorted dream and consequently gains an increased importance in its bearing on the view we have taken. We are now prepared to assume that there are in the mind processes and purposes of which one knows nothing at all has known nothing for a long time, and has even perhaps never known anything. With this the unconscious acquires a new sense for us; the characteristic of 'for the time being' or 'temporary' disappears from its essential nature. It can mean permanently unconscious and not merely 'latent at the time'. We shall of course have to hear more about this on some other occasion.

[1916-1917, 3242]
In the first place we are faced by the fact that the dreamer has a symbolic mode of expression at his disposal which he does not know in waking life and does not recognize. This is as extraordinary as if you were to discover that your housemaid understood Sanskrit, though you know that she was born in a Bohemian village and never learnt it. It is not easy to account for this fact by the help of our psychological views. We can only say that the knowledge of symbolism is unconscious to the dreamer, that it belongs to his unconscious mental life. But even with this assumption we do not meet the point. Hitherto it has only been necessary for us to assume the existence of unconscious endeavours - endeavours, that is, of which, temporarily or permanently, we know nothing. Now, however, it is a question of more than this, of unconscious pieces of knowledge, of connections of thought, of comparisons between different objects which result in its being possible for one of them to be regularly put in place of the other. These comparisons are not freshly made on each occasion; they lie ready to hand and are complete, once and for all. This is implied by the fact of their agreeing in the case of different individuals - possibly, indeed, agreeing in spite of differences of language. What can be the origin of these symbolic relations? Linguistic usage covers only a small part of them. The multiplicity of parallels in other spheres of knowledge are mostly unknown to the dreamer; we ourselves have been obliged to collect them laboriously.

Thus, quite incidentally, we learn from our examination of the latent dream-thoughts that all these highly complicated mental acts that we have named can take place unconsciously - a discovery as imposing as it is perplexing!

The link with the scene after her unhappy wedding-night and the patient's affectionate motive constituted, taken together, what we have called the 'sense' of the obsessional action. But while she was carrying out the obsessional action this sense had been unknown to her in both directions - both its 'whence' and its 'whither'. Mental processes had therefore been at work in her and the obsessional action was the effect of them; she had been aware of this effect in a normal mental fashion, but none of the mental predeterminants of this effect came to the knowledge of her consciousness. She behaved in precisely the same way as a hypnotized subject whom Bernheim had ordered to open an umbrella in the hospital ward five minutes after he woke up. The man carried out this instruction when he was awake, but he could produce no motive for his action. It is a state of affairs of this sort that we have before our eyes when we speak of the existence of unconscious mental processes. We can challenge anyone in the world to give a more correct scientific account of this state of affairs, and if he does we will gladly renounce our hypothesis of unconscious mental processes. Till that happens, however, we will hold fast to the hypothesis; and if someone objects that here the unconscious is nothing real in a scientific sense, is a makeshift, une façon de parler, we can only shrug our shoulders resignedly and dismiss what he says as unintelligible. Something not real, which produces effects of such tangible reality as an obsessional action!
Resistances of this kind should not be one-sidedly condemned. They include so much of the most important material from the patient's past and bring it back in so convincing a fashion that they become some of the best supports of the analysis if a skilful technique knows how to give them the right turn. Nevertheless, it remains a remarkable fact that this material is always in the service of the resistance to begin with and brings to the fore a façade that is hostile to the treatment. It may also be said that what is being mobilized for fighting against the alterations we are striving for are character-traits, attitudes of the ego. In this connection we discover that these character-traits were formed in relation to the determinants of the neurosis and in reaction against its demands, and we come upon traits which cannot normally emerge, or not to the same extent, and which may be described as latent. Nor must you get an impression that we regard the appearance of these resistances as an unforeseen risk to analytic influence. No, we are aware that these resistances are bound to come to light; in fact we are dissatisfied if we cannot provoke them clearly enough and are unable to demonstrate them to the patient. Indeed we come finally to understand that the overcoming of these resistances is the essential function of analysis and is the only part of our work which gives us an assurance that we have achieved something with the patient.

It is a surprising thing that the tragedy of Sophocles does not call up indignant repudiation in his audience - a reaction similar to that of our simple-minded army doctor but far better justified. For fundamentally it is an amoral work: it absolves men from moral responsibility, exhibits the gods as promoters of crime and shows the impotence of the moral impulses of men which struggle against crime. It might easily be supposed that the material of the legend had in view an indictment of the gods and of fate; and in the hands of Euripides, the critic and enemy of the gods, it would probably have become such an indictment. But with the devout Sophocles there is no question of an application of that kind. The difficulty is overcome by the pious sophistry that to bow to the will of the gods is the highest morality even when it promotes crime. I cannot think that this morality is a strong point of the play, but it has no influence on its effect. It is not to it that the auditor reacts but to the secret sense and content of the legend. He reacts as though by self-analysis he had recognized the Oedipus complex in himself and had unveiled the will of the gods and the oracle as exalted disguises of his own unconscious. It is as though he was obliged to remember the two wishes - to do away with his father and in place of him to take his mother to wife - and to be horrified at them. And he understands the dramatist's voice as though it were saying to him: 'You are struggling in vain against your responsibility and are protesting in vain of what you have done in opposition to these criminal intentions. You are guilty, for you have not been able to destroy them; they still persist in you unconsciously.' And there is psychological truth contained in this. Even if a man has repressed his evil impulses into the unconscious and would like to tell himself afterwards that he is not responsible for them, he is nevertheless bound to be aware of this responsibility as a sense of guilt whose basis is unknown to him.

The best-known productions of phantasy are the so-called 'day-dreams', which we have already come across, imagined satisfactions of ambitious, megalomaniac, erotic wishes, which flourish all the more exuberantly the more reality counsels modesty and restraint. The essence of the happiness of phantasy - making the obtaining of pleasure free once more from the assent of reality - is shown in them unmistakably. We know that such day-dreams are the nucleus and prototype of night-dreams. A night-dream is at bottom nothing other than a day-dream that has been made utilizable owing the liberation of the instinctual impulses at night, and that has been distorted by the form assumed by mental activity at night. We have already become familiar with the idea that even a day-dream is not necessarily conscious - that there are unconscious day-dreams, as well. Such unconscious day-dreams are thus the source not only of night-dreams but also of neurotic symptoms.
The importance of the part played by phantasy in the formation of symptoms will be made clear to you by what I have to tell you. I have explained how in the case of frustration the libido cathects regressively the positions which it has given up but to which some quotas of it have remained adhering. I shall not withdraw this or correct it, but I have to insert a connecting link. How does the libido find its way to these points of fixation? All the objects and trends which the libido has given up have not yet been given up in every sense. They or their derivatives are still retained with a certain intensity in phantasies. Thus the libido need only withdraw on to phantasies in order to find the path open to every repressed fixation. These phantasies have enjoyed a certain amount of toleration: they have not come into conflict with the ego, however sharp the contrasts between them may have been, so long as a particular condition is observed. This condition is of a quantitative nature and it is now upset by the backward flow of libido on to the phantasies. As a result of this surplus, the energetic cathexis of the phantasies is so much increased that they begin to raise claims, that they develop a pressure in the direction of becoming realized. But this makes a conflict between them and the ego inevitable. Whether they were previously preconscious or conscious, they are now subjected to repression from the direction of the ego and are at the mercy of attraction from the direction of the unconscious. From what are now unconscious phantasies the libido travels back to their origins in the unconscious - to its own points of fixation.

[1916-1917, 3428]

As you will recall, we have dealt with repression at great length, but in doing so we have always followed the vicissitudes only of the idea that is to be repressed - naturally, since this was easier to recognize and describe. We have always left on one side the question of what happens to the affect that was attached to the repressed idea; and it is only now that we learn that the immediate vicissitude of that affect is to be transformed into anxiety, whatever quality it may have exhibited apart from this in the normal course of events. This transformation of affect is, however, by far the most important part of the process of repression. It is not so easy to speak of this, since we cannot assert the existence of unconscious affects in the same sense as that of unconscious ideas. An idea remains the same, except for the one difference, whether it is conscious or unconscious; we can state what it is that corresponds to an unconscious idea. But an affect is a process of discharge and must be judged quite differently from an idea; what corresponds to it in the unconscious cannot be declared without deeper reflection and a clarification of our hypotheses about psychical processes. And that we cannot undertake here. We will, however, emphasize the impression we have now gained that the generation of anxiety is intimately linked to the system of the unconscious.

[1916-1917, 3455]
When the news of his sister's death arrived, so the patient told me, he felt hardly a trace of grief. He had to force himself to show signs of sorrow, and was able quite coolly to rejoice at having now become the sole heir to the property. He had already been suffering from his recent illness for several years when this occurred. But I must confess that this one piece of information made me for a long time uncertain in my diagnostic judgement of the case. It was to be assumed, no doubt, that his grief over the loss of the most dearly loved member of his family would meet with an inhibition in its expression, as a result of the continued operation of his jealousy of her and of the added presence of his incestuous love for her which had now become unconscious. But I could not do without some substitute for the missing outbursts of grief. And this was at last found in another expression of feeling which had remained inexplicable to the patient. A few months after his sister's death he himself made a journey in the neighbourhood in which she had died. There he sought out the burial-place of a great poet, who was at that time his ideal, and shed bitter tears upon his grave. This reaction seemed strange to him himself, for he knew that more than two generations had passed by since the death of the poet he admired. He only understood it when he remembered that his father had been in the habit of comparing his dead sister's works with the great poet's. He gave me another indication of the correct way of interpreting the homage which he ostensibly paid to the poet, by a mistake in his story which I was able to detect at this point. He had repeatedly specified before that his sister had shot herself; but he was now obliged to make a correction and say that she had taken poison. The poet, however, had been shot in a duel.

[1918b, 3515]

The wolf that he was afraid of was undoubtedly his father; but his fear of the wolf was conditional upon the creature being in an upright posture. His recollection asserted most definitely that he had not been terrified by pictures of wolves going on all fours or, as in the story of 'Little Red Riding-Hood', lying in bed. The posture which, according to our construction of the primal scene, he had seen the woman assume, was of no less significance; though in this case the significance was limited to the sexual sphere. The most striking phenomenon of his erotic life after maturity was his liability to compulsive attacks of falling physically in love which came on and disappeared again in the most puzzling succession. These attacks released a tremendous energy in him even at times when he was otherwise inhibited, and they were quite beyond his control. I must, for a specially important reason, postpone a full consideration of this compulsive love; but I may mention here that it was subject to a definite condition, which was concealed from his consciousness and was discovered only during the treatment. It was necessary that the woman should have assumed the posture which we have ascribed to his mother in the primal scene. From his puberty he had felt large and conspicuous buttocks as the most powerful attraction in a woman; to copulate except from behind gave him scarcely any enjoyment. At this point a criticism may justly be raised: it may be objected that a sexual preference of this kind for the hind parts of the body is a general characteristic of people who are inclined to an obsessional neurosis, and that its presence does not justify us in referring it back to a special impression in childhood. It is part of the fabric of the anal-erotic disposition and is one of the archaic traits which distinguish that constitution. Indeed, copulation from behind - *more feraurum* [in the fashion of animals] - may, after all, be regarded as phylogenetically the older form. We shall return to this point too in a later discussion, when we have brought forward the supplementary material which showed the basis of the unconscious condition upon which his falling in love depended.

[1918b, 3531]
In certain diseases - including the very neuroses of which we have made special study - things are different. The ego feels uneasy; it comes up against limits to its power in its own house, the mind. Thoughts emerge suddenly without one's knowing where they come from, nor can one do anything to drive them away. These alien guests even seem to be more powerful than those which are at the ego's command. They resist all the well-proved measures of enforcement used by the will, remain unmoved by logical refutation, and are unaffected by the contradictory assertions of reality. Or else impulses appear which seem like those of a stranger, so that the ego disowns them; yet it has to fear them and take precautions against them. The ego says to itself: 'This is an illness, a foreign invasion.' It increases its vigilance, but cannot understand why it feels so strangely paralysed.

"The whole process, however, only becomes possible through the single circumstance that you are mistaken in another important point as well. You feel sure that you are informed of all that goes on in your mind if it is of any importance at all, because in that case, you believe, your consciousness gives you news of it. And if you have had no information of something in your mind you confidently assume that it does not exist there. Indeed, you go so far as to regard what is "mental" as identical with what is "conscious" - that is, with what is known to you in spite of the most obvious evidence that a great deal more must constantly be going on in your mind than can be known to your consciousness. Come, let yourself be taught something on this one point! What is in your mind does not coincide with what you are conscious of; whether something is going on in your mind and whether you hear of it, are two different things. In the ordinary way, I will admit, the intelligence which reaches your consciousness is enough for your needs; and you may cherish the illusion that you learn of all the more important things. But in some cases, as in that of an instinctual conflict such as I have described, your intelligence service breaks down and your will then extends no further than your knowledge. In every case, however, the news that reaches your consciousness is incomplete and often not to be relied on. Often enough, too, it happens that you get news of events only when they are over and when you can no longer do anything to change them. Even if you are not ill, who can tell all that is stirring in your mind of which you know nothing or are falsely informed? You behave like an absolute ruler who is content with the information supplied him by his highest officials and never goes among the people to hear their voice. Turn your eyes inward, look into your own depths, learn first to know yourself! Then you will understand why you were bound to fall ill; and perhaps, you will avoid falling ill in future."

Probably very few people can have realized the momentous significance for science and life of the recognition of unconscious mental processes. It was not psycho-analysis, however, let us hasten to add, which first took this step. There are famous philosophers who may be cited as forerunners - above all the great thinker Schopenhauer, whose unconscious 'Will' is equivalent to the mental instincts of psycho-analysis. It was this same thinker, moreover, who in words of unforgettable impressiveness admonished mankind of the importance, still so greatly underestimated by it, of its sexual craving. Psycho-analysis has this advantage only, that it has not affirmed these two propositions which are so distressing to narcissism - the psychical importance of sexuality and the unconsciousness of mental life - on an abstract basis, but has demonstrated them in matters that touch every individual personally and force him to take up some attitude towards these problems. It is just for this reason, however, that it brings on itself the aversion and resistances which still hold back in awe before the great name of the philosopher.

[1917a, 3612]

[1917a, 3614]
The work by which we bring the repressed mental material into the patient's consciousness has been called by us psycho-analysis. Why 'analysis' - which means breaking up or separating out, and suggests an analogy with the work carried out by chemists on substances which they find in nature and bring into their laboratories? Because in an important respect there really is an analogy between the two. The patient's symptoms and pathological manifestations, like all his mental activities, are of a highly composite kind; the elements of this compound are at bottom motives, instinctual impulses. But the patient knows nothing of these elementary motives or not nearly enough. We teach him to understand the way in which these highly complicated mental formations are compounded; we trace the symptoms back to the instinctual impulses which motivate them; we point out to the patient these instinctual motives, which are present in his symptoms and of which he has hitherto been unaware, - just as a chemist isolates the fundamental substance, the chemical 'element', out of the salt in which it had been combined with other elements and in which it was unrecognizable. In the same way, as regards those of the patient's mental manifestations that were not considered pathological, we show him that he was only to a certain extent conscious of their motivation - that other instinctual impulses of which he had remained in ignorance had co-operated in producing them.

[1919a, 3629]

I repeat, however, that as a rule the phantasy remains unconscious, and can only be reconstructed in the course of the analysis. This fact perhaps vindicates patients who say they remember that with them masturbation made its appearance before the third phase of the beating-phantasy (shortly to be discussed), and that this phase was only a later addition, made perhaps under the impression of scenes at school. Every time I have given credit to these statements I have felt inclined to assume that the masturbation was at first under the dominance of unconscious phantasies and that conscious ones were substituted for them later.

[1919e, 3652]

I cannot neglect this opportunity of expressing for once my astonishment that human beings can go through such great and important moments of their erotic life without noticing them much, sometimes even, indeed, without having the faintest suspicion of their existence, or else, having become aware of those moments, deceive themselves so thoroughly in their judgement of them. This happens not only under neurotic conditions, where we are familiar with the phenomenon, but seems also to be common enough in ordinary life. In the present case, for example, a girl develops a sentimental adoration for women, which her parents at first find merely vexatious and hardly take seriously; she herself knows quite well that she is very much occupied with these relationships, but still she experiences few of the sensations of intense love until a particular frustration is followed by a quite excessive reaction, which shows everyone concerned that they have to do with a consuming passion of elemental strength. Nor had the girl ever perceived anything of the state of affairs which was a necessary preliminary to the outbreak of this mental storm. In other cases, too, we come across girls or women in a state of severe depression, who on being asked for a possible cause of their condition tell us that they have, it is true, had a slight feeling for a certain person, but that it was nothing deep and that they soon got over it when they had to give it up. And yet it was this renunciation, apparently so easily borne, that became the cause of serious mental disturbance. Again, we come across men who have passed through casual love-affairs and realize only from the subsequent effects that they had been passionately in love with the person whom they had apparently regarded lightly. One is also amazed at the unexpected results that may follow an artificial abortion, the killing of an unborn child, which had been decided upon without remorse and without hesitation. It must be admitted that poets are right in liking to portray people who are in love without knowing it, or uncertain whether they do love, or who think that they hate when in reality they love. It would seem that the information received by our consciousness about our erotic life is especially liable to be incomplete, full of gaps, or falsified. Needless to say, in this discussion I have not omitted to allow for the part played by subsequent forgetting.

[1920a, 3855]
I am afraid that you may behave like the writer of these two letters. You, too, will be primarily interested in the question whether this dream can really be regarded as a telepathic notification of the unexpected birth of the twin children, and you will not be disposed to submit this dream to analysis like any other. I foresee that it will always be so when psycho-analysis and occultism encounter each other. The former has, so to speak, all our mental instincts against it; the latter is met half-way by powerful and mysterious sympathies. I am not, however, going to take up the position that I am nothing but a psycho-analyst, that the problems of occultism do not concern me: you would rightly judge that to be only an evasion of a problem. On the contrary, I may say that it would be a great satisfaction to me if I could convince myself and others on unimpeachable evidence of the existence of telepathic processes, but I also consider that the information provided about this dream is altogether inadequate to justify any such pronouncement. You will observe that it does not once occur to this intelligent man, deeply interested as he is in the problem of his dream, to tell us when he had last seen his daughter or what news he had lately had from her. He writes in the first letter that the birth was a month too soon; in the second, however, the month has become three weeks only, and in neither are we told whether the birth was really premature, or whether, as so often happens, those concerned were out in their reckoning. But we should have to consider these and other details of the occurrence if we are to weigh the probability of the dreamer having made unconscious estimates and guesses. I felt too that it would be of no use even if I succeeded in getting answers to such questions. In the course of arriving at the information new doubts would constantly arise, which could only be set at rest if one had the man in front of one and could revive all the relevant memories which he had perhaps dismissed as unessential. He is certainly right in what he says at the beginning of his second letter that more would have come out in talking.

Consider another and similar case, in which the disturbing interest of occultism has no part. You must often have been in a position to compare the anamnesis and the information about the illness given during the first session by any neurotic with what you have gained from him after some months of psycho-analysis. Apart from inevitable abbreviations, how many essentials were left out or suppressed, how many connections were displaced - in fact, how much that was incorrect or untrue was told you on that first occasion! You will not call me hyper-critical if I refuse in the circumstances to make any pronouncement whether the dream in question is a telepathic event or a particularly subtle achievement on the part of the dreamer's unconscious or whether it is simply to be taken as a striking coincidence. Our curiosity must be satisfied with the hope of some later occasion on which it may be possible to make a detailed oral examination of the dreamer. But you cannot say that this outcome of our investigation has disappointed you, for I prepared you for it; I said you would hear nothing which would throw any light on the problem of telepathy.
The Interpretation of Parapraxes and Haphazard Acts. - It was a triumph for the interpretative art of psycho-analysis when it succeeded in demonstrating that certain common mental acts of normal people, for which no one had hitherto attempted to put forward a psychological explanation, were to be regarded in the same light as the symptoms of neurotics: that is to say, they had a meaning, which was unknown to the subject but which could easily be discovered by analytic means. The phenomena in question were such events as the temporary forgetting of familiar words and names, forgetting to carry out prescribed tasks, everyday slips of the tongue and of the pen, misreadings, losses and mislayings of objects, certain errors, instances of apparently accidental self-injury, and finally habitual movements carried out seemingly without intention or in play, tunes hummed 'thoughtlessly', and so on. All of these were shorn of their physiological explanation, if any such had ever been attempted, were shown to be strictly determined and were revealed as an expression of the subject's suppressed intentions or as a result of a clash between two intentions one of which was permanently or temporarily unconscious. The importance of this contribution to psychology was of many kinds. The range of mental determinism was extended by it in an unforeseen manner; the supposed gulf between normal and pathological mental events was narrowed; in many cases a useful insight was afforded into the play of mental forces that must be suspected to lie behind the phenomena. Finally, a class of material was brought to light which is calculated better than any other to stimulate a belief in the existence of unconscious mental acts even in people to whom the hypothesis of something at once mental and unconscious seems strange and even absurd. The study of one's own parapraxes and haphazard acts, for which most people have ample opportunities, is even to-day the best preparation for an approach to psycho-analysis. In analytic treatment, the interpretation of parapraxes retains a place as a means of uncovering the unconscious, alongside the immeasurably more important interpretation of associations. [1923a, 3917]

It is not my intention to give a review of the author's results. I will content myself with pointing to the significance of his work and will permit myself only a remark concerning the terminology which he has adopted. He includes the sort of thought-activity which he has observed in Bleuler's autistic thinking, but calls it, as a rule, fore-conscious thinking, according to the custom prevailing in psycho-analysis. However, the autistic thinking of Bleuler does not by any means correspond with the extension and the contents of the fore-conscious, neither can I admit that the name used by Bleuler has been happily chosen. The designation 'fore-conscious' thinking itself as a characteristic appears to me misleading and unsatisfactory. The point in question is that the sort of thought-activity of which the well-known day-dream is an example - complete by itself, developing a situation or an act that is being brought to a close - constitutes the best and until now the only studied example. This day-dreaming does not owe its peculiarities to the circumstances that it proceeds mostly fore-consciously, nor are the forms changed when it is accomplished consciously. From another point of view we know also that even strictly directed reflection may be achieved without the co-operation of consciousness, that is to say, fore-consciously. For that reason I think it is advisable, when establishing a distinction between the different modes of thought-activity, not to utilize the relation to consciousness in the first instance, and to designate the day-dream, as well as the chains of thought studied by Varendonck, as freely wandering or phantastic thinking, in opposition to intentionally directed reflection. At the same time it should be taken into consideration that even phantastic thinking is not invariably in want of an aim and end-representations. [1921b, 3942]
But we have arrived at the term or concept of the unconscious along another path, by considering certain experiences in which mental dynamics play a part. We have found - that is, we have been obliged to assume - that very powerful mental processes or ideas exist (and here a quantitative or economic factor comes into question for the first time) which can produce all the effects in mental life that ordinary ideas do (including effects that can in their turn become conscious as ideas), though they themselves do not become conscious. It is unnecessary to repeat in detail here what has been explained so often before. It is enough to say that at this point psycho-analytic theory steps in and asserts that the reason why such ideas cannot become conscious is that a certain force opposes them, that otherwise they could become conscious, and that it would then be apparent how little they differ from other elements which are admittedly psychical. The fact that in the technique of psycho-analysis a means has been found by which the opposing force can be removed and the ideas in question made conscious renders this theory irrefutable. The state in which the ideas existed before being made conscious is called by us repression, and we assert that the force which instituted the repression and maintains it is perceived as resistance during the work of analysis.

Clinical experience decides for the latter. It shows us that this 'something' behaves like a repressed impulse. It can exert driving force without the ego noticing the compulsion. Not until there is resistance to the compulsion, a hold-up in the discharge-reaction, does the 'something' at once become conscious as unpleasure. In the same way that tensions arising from physical needs can remain unconscious, so also can pain - a thing intermediate between external and internal perception, which behaves like an internal perception even when its source is in the external world. It remains true, therefore, that sensations and feelings, too, only become conscious through reaching the system Pcpt.; if the way forward is barred, they do not come into being as sensations, although the 'something' that corresponds to them in the course of excitation is the same as if they did. We then come to speak, in a condensed and not entirely correct manner, of 'unconscious feelings', keeping up an analogy with unconscious ideas which is not altogether justifiable. Actually the difference is that, whereas with Ucs ideas connecting links must be created before they can be brought into the Cs., with feelings, which are themselves transmitted directly, this does not occur. In other words: the distinction between Cs. and Pcs, has no meaning where feelings are concerned; the Pcs. here drops out - and feelings are either conscious or unconscious. Even when they are attached to word-presentations, their becoming conscious is not due to that circumstance, but they become so directly.

The relation of the ego to consciousness has been entered into repeatedly; yet there are some important facts in this connection which remain to be described here. Accustomed as we are to taking our social or ethical scale of values along with us wherever we go, we feel no surprise at hearing that the scene of the activities of the lower passions is in the unconscious; we expect, moreover, that the higher any mental function ranks in our scale of values the more easily it will find access to consciousness assured to it. Here, however, psycho-analytic experience disappoints us. On the one hand, we have evidence that even subtle and difficult intellectual operations which ordinarily require strenuous reflection can equally be carried out preconsciously and without coming into consciousness. Instances of this are quite incontestable; they may occur, for example, during the state of sleep, as is shown when someone finds, immediately after waking, that he knows the solution to a difficult mathematical or other problem with which he had been wrestling in vain the day before.
There is another phenomenon, however, which is far stranger. In our analyses we discover that there are people in whom the faculties of self-criticism and conscience - mental activities, that is, that rank as extremely high ones - are unconscious and unconsciously produce effects of the greatest importance; the example of resistance remaining unconscious during analysis is therefore by no means unique. But this new discovery, which compels us, in spite of our better critical judgement, to speak of an 'unconscious sense of guilt', bewilders us far more than the other and sets us fresh problems, especially when we gradually come to see that in a great number of neuroses an unconscious sense of guilt of this kind plays a decisive economic part and puts the most powerful obstacles in the way of recovery. If we come back once more to our scale of values, we shall have to say that not only what is lowest but also what is highest in the ego can be unconscious. It is as if we were thus supplied with a proof of what we have just asserted of the conscious ego: that it is first and foremost a body-ego.

[1923b, 3961]

The situation takes a favourable turn if the analysis of a corroborative dream of this sort, which 'tags along behind', is immediately followed by feelings of remembering what has hitherto been forgotten. But even then the sceptic can fall back upon an assertion that the recollections are illusory. Moreover, such feelings are for the most part absent. The repressed material is only allowed through bit by bit; and every lack of completeness inhibits or delays the forming of a sense of conviction. Furthermore, what we are dealing with may not be the reproduction of a real and forgotten event but the bringing forward of an unconscious phantasy, about which no feeling of memory is ever to be expected, though the possibility may sometimes remain of a sense of subjective conviction.

[1923c, 4036]

The fact that moral masochism is unconscious leads us to an obvious clue. We were able to translate the expression 'unconscious sense of guilt' as meaning a need for punishment at the hands of a parental power. We now know that the wish, which so frequently appears in phantasies, to be beaten by the father stands very close to the other wish, to have a passive (feminine) sexual relation to him and is only a regressive distortion of it. If we insert this explanation into the content of moral masochism, its hidden meaning becomes clear to us. Conscience and morality have arisen through the overcoming, the desexualization, of the Oedipus complex; but through moral masochism morality becomes sexualized once more, the Oedipus complex is revived and the way is opened for a regression from morality to the Oedipus complex. This is to the advantage neither of morality nor of the person concerned. An individual may, it is true, have preserved the whole or some measure of ethical sense alongside of his masochism; but, alternatively, a large part of his conscience may have vanished into his masochism. Again, masochism creates a temptation to perform 'sinful' actions, which must then be expiated by the reproaches of the sadistic conscience (as is exemplified in so many Russian character-types) or by chastisement from the great parental power of Destiny. In order to provoke punishment from this last representative of the parents, the masochist must do what is inexpedient, must act against his own interests, must ruin the prospects which open out to him in the real world and must, perhaps, destroy his own real existence.

[1924c, 4081]
Of course this lack of understanding affected the treatment of these pathological conditions badly as well. In general this consisted in measures designed to 'harden' the patient - in the prescription of medicines and in attempts, mostly very ill-contrived and executed in an unfriendly manner, at bringing mental influences to bear on him by threats, jeers and warnings and by exhorting him to make up his mind to 'pull himself together'. Electrical treatment was given out as being a specific cure for nervous conditions; but anyone who has endeavoured to carry out Erb's detailed instructions must marvel at the space that phantasy can occupy even in what professes to be an exact science. The decisive turn was taken in the eighties, when the phenomena of hypnotism made one more attempt to find admission to medical science - this time with more success than so often before, thanks to the work of Liébeault, Bernheim, Heidenhain and Forel. The essential thing was that the genuineness of these phenomena was recognized. Once this had been admitted, two fundamental and unforgettable lessons could not fail to be drawn from hypnotism. First, one was given convincing proof that striking somatic changes could after all be brought about solely by mental influences, which in this case one had oneself set in motion. Secondly, one received the clearest impression - especially from the behaviour of subjects after hypnosis - of the existence of mental processes that one could only describe as 'unconscious'. The 'unconscious' had, it is true, long been under discussion among philosophers as a theoretical concept; but now for the first time, in the phenomena of hypnotism, it became something actual, tangible and subject to experiment. Apart from all this, hypnotic phenomena showed an unmistakable similarity to the manifestations of some neuroses.

[1924f, 4102]

The precipitating causes of the symptoms were compared by Breuer to Charcot's traumas. Now it was a remarkable fact that all these traumatic precipitating causes, and all the mental impulses starting from them, were lost to the patient's memory, as though they had never happened; while their products - the symptoms - persisted unaltered, as though, so far as they were concerned, there was no such thing as the effacing effect of time. Here, therefore, we had a fresh proof of the existence of mental processes which were unconscious but for that very reason especially powerful - processes which we had first come to know in post-hypnotic suggestion. The therapeutic procedure adopted by Breuer was to induce the patient, under hypnosis, to remember the forgotten traumas and to react to them with powerful expressions of affect. When this had been done, the symptom, which had till then taken the place of these expressions of emotion, disappeared. Thus one and the same procedure served simultaneously the purposes of investigating and of getting rid of the ailment; and this unusual conjunction was later retained in psycho-analysis.

[1924f, 4104]

Evidence of its being of use for throwing light on other than pathological mental activity was early forthcoming in connection with two kinds of phenomena: with the very frequent parapraxes that occur in everyday life - such as forgetting things, slips of the tongue, and mislaying objects - and with the dreams dreamt by healthy and psychically normal people. Small failures of functioning, like the temporary forgetting of normally familiar proper names, slips of the tongue and of the pen, and so on, had hitherto not been considered worthy of any explanation at all or were supposed to be accounted for by conditions of fatigue, by distraction of the attention, etc. The present writer then showed from many examples, in his book The Psychopathology of Everyday Life (1901b), that events of this kind have a meaning, and arise owing to a conscious intention being interfered with by another, suppressed or actually unconscious one. As a rule, quick reflection or a short analysis is enough to reveal the interfering influence. Owing to the frequency of such parapraxes as slips of the tongue, it became easy for anyone to convince himself from his own experience of the existence of mental processes which are not conscious, but which are nevertheless operative and which at least find expression as inhibitions and modifications of other, intended acts.

[1924f, 4109]
Some preparation must of course be given to him; and there is a simple way of doing it. We call on him to be completely straightforward with his analyst, to keep nothing back intentionally that comes into his head, and then to put aside every reservation that might prevent his reporting certain thoughts or memories. Everyone is aware that there are some things in himself that he would be very unwilling to tell other people or that he considers it altogether out of the question to tell. These are his 'intimacies'. He has a notion too - and this represents a great advance in psychological self-knowledge - that there are other things that one would not care to admit to oneself: things that one likes to conceal from oneself and which for that reason one breaks off short and drives out of one's thoughts if, in spite of everything, they turn up. Perhaps he may himself notice that a very remarkable psychological problem begins to appear in this situation - of a thought of his own being kept secret from his own self. It looks as though his own self were no longer the unity which he had always considered it to be, as though there were something else as well in him that could confront that self. He may become obscurely aware of a contrast between a self and a mental life in the wider sense. If now he accepts the demand made by analysis that he shall say everything, he will easily become accessible to an expectation that to have relations and exchanges of thought with someone under such unusual conditions might also lead to peculiar results.

Yes, and that is what psychologists think. Nevertheless it can easily be shown to be false - that is, to be a quite inexpedient distinction. The idiest self-observation shows that ideas may occur to us which cannot have come about without preparation. But you experience nothing of these preliminaries of your thought, though they too must certainly have been of a mental nature; all that enters your consciousness is the ready-made result. Occasionally you can make these preparatory thought-structures conscious in retrospect, as though in a reconstruction.

Evasions! You cannot in that way get around the fact that acts of a mental nature, and often very complicated ones, can take place in you, of which your consciousness learns nothing and of which you know nothing. Or are you prepared to suppose that a greater or smaller amount of your 'attention' is enough to transform a non-mental act into a mental one? But what is the use of disputing? There are hypnotic experiments in which the existence of such non-conscious thoughts are irrefutably demonstrated to anyone who cares to learn.

'That really sounds most mysterious. The strangest thing about it is that apparently even this mighty force of the patient's conscience does not reach his consciousness.'
In the first place, I suspect that the reader has the impression that our discussions on the sense of guilt disrupt the framework of this essay: that they take up too much space, so that the rest of its subject-matter, with which they are not always closely connected, is pushed to one side. This may have spoiled the structure of my paper; but it corresponds faithfully to my intention to represent the sense of guilt as the most important problem in the development of civilization and to show that the price we pay for our advance in civilization is a loss of happiness through the heightening of the sense of guilt.¹ Anything that still sounds strange about this statement, which is the final conclusion of our investigation, can probably be traced to the quite peculiar relationship - as yet completely unexplained - which the sense of guilt has to our consciousness. In the common case of remorse, which we regard as normal, this feeling makes itself clearly enough perceptible to consciousness. Indeed, we are accustomed to speak of a 'consciousness of guilt' instead of a 'sense of guilt'. Our study of the neuroses, to which, after all we owe the most valuable pointers to an understanding of normal conditions, brings us up against some contradictions. In one of those affections, obsessional neurosis, the sense of guilt makes itself noisily heard in consciousness; it dominates the clinical picture and the patient's life as well, and it hardly allows anything else to appear alongside of it. But in most other cases and forms of neurosis it remains completely unconscious, without on that account producing any less important effects. Our patients do not believe us when we attribute an 'unconscious sense of guilt' to them. In order to make ourselves at all intelligible to them, we tell them of an unconscious need for punishment, in which the sense of guilt finds expression. But its connection with a particular form of neurosis must not be over-estimated. Even in obsessional neurosis there are types of patients who are not aware of their sense of guilt, or who only feel it as a tormented uneasiness, a kind of anxiety, if they are prevented from carrying out certain actions. It ought to be possible eventually to understand these things; but as yet we cannot. Here perhaps we may be glad to have it pointed out that the sense of guilt is at bottom nothing else but a topographical variety of anxiety; in its later phases it coincides completely with fear of the super-ego. And the relations of anxiety to consciousness exhibit the same extraordinary variations. Anxiety is always present somewhere or other behind every symptom; but at one time it takes noisy possession of the whole of consciousness, while at another it conceals itself so completely that we are obliged to speak of unconscious anxiety or, if we want to have a clearer psychological conscience, since anxiety is in the first instance simply a feeling, of possibilities of anxiety. Consequently it is very conceivable that the sense of guilt produced by civilization is not perceived as such either, and remains to a large extent unconscious, or appears as a sort of malaise, a dissatisfaction, for which people seek other motivations. Religions, at any rate, have never overlooked the part played in civilization by a sense of guilt. Furthermore - a point which I failed to appreciate elsewhere² - they claim to redeem mankind from this sense of guilt, which they call sin. From the manner in which, in Christianity, this redemption is achieved - by the sacrificial death of a single person, who in this manner takes upon himself a guilt that is common to everyone - we have been able to infer what the first occasion may have been on which this primal guilt, which was also the beginning of civilization, was acquired.³ [1930a, 4523]
Nor will it do any harm if we once more review the contradictions which have for a while perplexed us during our enquiry. Thus, at one point the sense of guilt was the consequence of acts of aggression that had been abstained from; but at another point - and precisely at its historical beginning, the killing of the father - it was the consequence of an act of aggression that had been carried out. But a way out of this difficulty was found. For the institution of the internal authority, the super-ego, altered the situation radically. Before this, the sense of guilt coincided with remorse. (We may remark, incidentally, that the term ‘remorse’ should be reserved for the reaction after an act of aggression has actually been carried out.) After this, owing to the omniscience of the super-ego, the difference between an aggression intended and an aggression carried out lost its force. Henceforward a sense of guilt could be produced not only by an act of violence that is actually carried out (as all the world knows), but also by one that is merely intended (as psycho-analysis has discovered). Irrespective of this alteration in the psychological situation, the conflict arising from ambivalence - the conflict between the two primal instincts - leaves the same result behind. We are tempted to look here for the solution of the problem of the varying relation in which the sense of guilt stands to consciousness. It might be thought that a sense of guilt arising from remorse for an evil deed must always be conscious, whereas a sense of guilt arising from the perception of an evil impulse may remain unconscious. But the answer is not so simple as that. Obsessional neurosis speaks energetically against it.

[1930a, 4525]

The analogy between the process of civilization and the path of individual development may be extended in an important respect. It can be asserted that the community, too, evolves a super-ego under whose influence cultural development proceeds. It would be a tempting task for anyone who has a knowledge of human civilizations to follow out this analogy in detail. I will confine myself to bringing forward a few striking points. The super-ego of an epoch of civilization has an origin similar to that of an individual. It is based on the impression left behind by the personalities of great leaders - men of overwhelming force of mind or men in whom one of the human impulsions has found its strongest and purest, and therefore often its most one-sided, expression. In many instances the analogy goes still further, in that during their lifetime these figures were - often enough, even if not always - mocked and maltreated by others and even dispatched in a cruel fashion. In the same way, indeed, the primal father did not attain divinity until long after he had met his death by violence. The most arresting example of this fateful conjunction is to be seen in the figure of Jesus Christ - if, indeed, that figure is not a part of mythology, which called it into being from an obscure memory of that primal event. Another point of agreement between the cultural and the individual super-ego is that the former, just like the latter, sets up strict ideal demands, disobedience to which is visited with ‘fear of conscience’. Here, indeed, we come across the remarkable circumstance that the mental processes concerned are actually more familiar to us and more accessible to consciousness as they are seen in the group than they can be in the individual man. In him, when tension arises, it is only the aggressiveness of the super-ego which, in the form of reproaches, makes itself noisily heard; its actual demands often remain unconscious in the background. If we bring them to conscious knowledge, we find that they coincide with the precepts of the prevailing cultural super-ego. At this point the two processes, that of the cultural development of the group and that of the cultural development of the individual, are, as it were, always interlocked. For that reason some of the manifestations and properties of the super-ego can be more easily detected in its behaviour in the cultural community than in the separate individual.

[1930a, 4529]
I am sorry, though I cannot alter the facts, if this exposition of the attitudes of hatred and love towards the father and their transformations under the influence of the threat of castration seems to readers unfamiliar with psycho-analysis unsavoury and incredible. I should myself expect that it is precisely the castration complex that would be bound to arouse the most general repudiation. But I can only insist that psycho-analytic experience has put these matters in particular beyond the reach of doubt and has taught us to recognize in them the key to every neurosis. This key, then, we must apply to our author's so-called epilepsy. So alien to our consciousness are the things by which our unconscious mental life is governed!

[1928b, 4560]

Now, however, another problem awaits us - at the opposite end of the ego, as we might put it. It is presented to us by an observation during the work of analysis, an observation which is actually a very old one. As not infrequently happens, it has taken a long time to come to the point of appreciating its importance. The whole theory of psycho-analysis is, as you know, in fact built up on the perception of the resistance offered to us by the patient when we attempt to make his unconscious conscious to him. The objective sign of this resistance is that his associations fail or depart widely from the topic that is being dealt with. He may also recognize the resistance subjectively by the fact that he has distressing feelings when he approaches the topic. But this last sign may also be absent. We then say to the patient that we infer from his behaviour that he is now in a state of resistance; and he replies that he knows nothing of that, and is only aware that his associations have become more difficult. It turns out that we were right; but in that case his resistance was unconscious too, just as unconscious as the repressed, at the lifting of which we were working. We should long ago have asked the question: from what part of his mind does an unconscious resistance like this arise? The beginner in psycho-analysis will be ready at once with the answer: it is, of course, the resistance of the unconscious. An ambiguous and unserviceable answer! If it means that the resistance arises from the repressed, we must rejoin: certainly not! We must rather attribute to the repressed a strong upward drive, an impulsion to break through into consciousness. The resistance can only be a manifestation of the ego, which originally put the repression into force and now wishes to maintain it. That, moreover, is the view we always took. Since we have come to assume a special agency in the ego, the super-ego, which represents demands of a restrictive and rejecting character, we may say that repression is the work of this super-ego and that it is carried out either by itself or by the ego in obedience to its orders. If then we are met by the case of the resistance in analysis not being conscious to the patient, this means either that in quite important situations the super-ego and the ego can operate unconsciously, or - and this would be still more important - that portions of both of them, the ego and the super-ego themselves, are unconscious. In both cases we have to reckon with the disagreeable discovery that on the one hand (super-) ego and conscious and on the other hand repressed and unconscious are far from coinciding.

[1933a, 4677]
But you must not expect to hear the glad tidings that the struggle about analysis is over and has ended in its recognition as a science and its admission as a subject for instruction at universities. There is no question of that. The struggle continues, though in more polite forms. What is also new is that a sort of buffer-layer has formed in scientific society between analysis and its opponents. This consists of people who allow the validity of some portions of analysis and admit as much, subject to the most entertaining qualifications, but who on the other hand reject other portions of it, a fact which they cannot proclaim too loudly. It is not easy to divine what determines their choice in this. It seems to depend on personal sympathies. One person will take objection to sexuality, another to the unconscious; what seems particularly unpopular is the fact of symbolism. Though the structure of psycho-analysis is unfinished, it nevertheless presents, even to-day, a unity from which elements cannot be broken off at the caprice of whoever comes along; but these eclectics seem to disregard this. I have never had the impression that these half- or quarter-adherents based their rejection on an examination of the facts. Some distinguished men, too, are included in this category. They, to be sure, are excused by the fact that their time and their interest belong to other things - to those things, namely, in mastering which they have achieved so much. But in that case would they not do better to suspend their judgement instead of taking sides so decisively? With one of these great men I once succeeded in effecting a rapid conversion. He was a world-famous critic, who had followed the spiritual currents of the time with benevolent understanding and prophetic penetration. I only came to know him when he was past his eightieth year; but he was still enchanting in his talk. You will easily guess whom I mean. Nor was it I who introduced the subject of psycho-analysis. It was he who did so, by comparing himself with me in the most modest fashion. 'I am only a literary man,' he said, 'but you are a natural scientist and discoverer. However, there is one thing I must say to you: I have never had sexual feelings towards my mother.' 'But there is no need at all for you to have known them,' was my reply; 'to grown-up people those are unconscious feelings.' 'Oh! so that's what you think!' he said with relief, and pressed my hand. We went on talking together on the best of terms for another few hours. I heard later that in the few remaining years of his life he often spoke of analysis in a friendly way and was pleased at being able to use a word that was new to him - 'repression'.

[1933a, 4740]
Dream-distortion was the profoundest and most difficult problem of dream life. And light was thrown on it by the following consideration, which placed dreams in a class along with other psychopathological formations and revealed them, as it were, as the normal psychoses of human beings. For our mind, that precious instrument by whose means we maintain ourselves in life, is no peacefully self-contained unity. It is rather to be compared with a modern State in which a mob, eager for enjoyment and destruction, has to be held down forcibly by a prudent superior class. The whole flux of our mental life and everything that finds expression in our thoughts are derivations and representatives of the multifarious instincts that are innate in our physical constitution. But these instincts are not all equally susceptible to direction and education, or equally ready to fall in with the demands of the external world and of human society. A number of them have retained their primitive, ungovernable nature; if we let them have their way, they would infallibly bring us to ruin. Consequently, learning by experience, we have developed organizations in our mind which, in the form of inhibitions, set themselves up against the direct manifestations of the instincts. Every impulse in the nature of a wish that arises from the sources of instinctual energy must submit itself to examination by the highest agencies of our mind, and, if it is not approved, is rejected and restrained from exercising any influence upon our movements - that is, from coming into execution. Often enough, indeed, such wishes are even forbidden to enter consciousness, which is habitually unaware even of the existence of these dangerous instinctual sources. We describe such impulses as being repressed from the point of view of consciousness, and as surviving only in the unconscious. If what is repressed contrives somehow to force its way into consciousness or into movement or into both, we are no longer normal: at that point the whole range of neurotic and psychotic symptoms arise. The maintenance of the necessary inhibitions and repressions imposes upon our mind a great expenditure of energy, from which it is glad to be relieved. A good opportunity for this seems to be offered at night by the state of sleep, since sleep involves a cessation of our motor functions. The situation seems safe, and the severity of our internal police-force may therefore be relaxed. It is not entirely withdrawn, since one cannot be certain: it may be that the unconscious never sleeps at all. And now the reduction of pressure upon the repressed unconscious produces its effect. Wishes arise from it which during sleep might find the entrance to consciousness open. If we were to know them we should be appalled, alike by their subject-matter, their unrestraint and indeed the mere possibility of their existence. This, however, occurs only seldom, and when it does we awake as speedily as possible, in a state of fear. But as a rule our consciousness does not experience the dream as it really was. It is true that the inhibitory forces (the dream censorship, as we may call them) are not completely awake, but neither are they wholly asleep. They have had an influence on the dream while it was struggling to find an expression in words and pictures, they have got rid of what was most objectionable, they have altered other parts of it till they are unrecognizable, they have severed real connections while introducing false ones, until the honest but brutal wishful phantasy which lay behind the dream has turned into the manifest dream as we remember it - more or less confused and almost always strange and incomprehensible. Thus the dream (or the distortion which characterizes it) is the expression of a compromise, the evidence of a conflict between the mutually incompatible impulses and strivings of our mental life. And do not let us forget that the same process, the same interplay of forces, which explains the dreams of a normal sleeper, gives us the key to understanding all the phenomena of neurosis and psychosis.

[1932c, 4809]
In the case of the individual we believe we can see clearly. The memory-trace of his early experience has been preserved in him, but in a special psychological condition. The individual may be said to have known it always, just as one knows about the repressed. Here we have formed ideas, which can be confirmed without difficulty through analysis, of how something can be forgotten and how it can then reappear after a while. What is forgotten is not extinguished but only 'repressed'; its memory-traces are present in all their freshness, but isolated by 'anticathexes'. They cannot enter into communication with other intellectual processes; they are unconscious - inaccessible to consciousness. It may also be that certain portions of the repressed, having evaded the process, remain accessible to memory and occasionally emerge into consciousness; but even so they are isolated, like foreign bodies out of connection with the rest. It may be so, but it need not be so; repression may also be complete, and it is with that alternative that we shall deal in what follows.

[1939a, 4917]

The difference between whether a psychical process is conscious or unconscious has served us as a criterion and a means of finding our bearings. The repressed is unconscious. Now it would simplify things agreeably if this sentence admitted of reversal - if, that is, the difference between the qualities of conscious (Cs.) and unconscious (Ucs.) coincided with the distinction between 'belonging to the ego' and 'repressed'. The fact of there being isolated and unconscious things like this in our mental life would be sufficiently novel and important. But in reality the position is more complicated. It is true that everything repressed is unconscious, but it is not true that everything belonging to the ego is conscious. We notice that consciousness is a transient quality which attaches to a psychical process only in passing. For our purposes therefore we must replace 'conscious' by 'capable of being conscious' and we call this quality 'preconscious' (Pcs.). We then say, more correctly, that the ego is mainly preconscious (virtually conscious) but that portions of the ego are unconscious.

[1939a, 4918]

All of this may appear to be far from simple. But when one has grown reconciled to this unusual spatial view of the mental apparatus, it can present no particular difficulties to the imagination. I will add the further comment that the psychical topography that I have developed here has nothing to do with the anatomy of the brain, and actually only touches it at one point. What is unsatisfactory in this picture - and I am aware of it as clearly as anyone - is due to our complete ignorance of the dynamic nature of the mental processes. We tell ourselves that what distinguishes a conscious idea from a preconscious one, and the latter from an unconscious one, can only be a modification, or perhaps a different distribution, of psychical energy. We talk of cathexes and hypercathexes, but beyond this we are without any knowledge on the subject or even any starting-point for a serviceable working hypothesis. Of the phenomenon of consciousness we can at least say that it was originally attached to perception. All sensations which originate from the perception of painful, tactile, auditory or visual stimuli are what are most readily conscious. Thought-processes, and whatever may be analogous to them in the id, are in themselves unconscious and obtain access to consciousness by becoming linked to the mnemonic residues of visual and auditory perceptions along the path of the function of speech. In animals, which lack speech, these conditions must be of a simpler kind.

[1939a, 4919]
I might, however, console myself with the reflection that the things I am treating are in any case so new and so important, apart from how far my account of them is correct, that it can be no misfortune if the public is obliged to read the same thing about them twice over. There are things which should be said more than once and which cannot be said often enough. But the reader must decide of his own free will whether to linger over the subject or to come back to it. He must not be surreptitiously led into having the same thing put before him twice in one book. It is a piece of clumsiness for which the author must take the blame. Unluckily an author's creative power does not always obey his will: the work proceeds as it can, and often presents itself to the author as something independent or even alien.

[1939a, 4925]

It has long since become common knowledge that the experiences of a person's first five years exercise a determining effect on his life, which nothing later can withstand. Much that deserves knowing might be said about the way in which these early impressions maintain themselves against any influences in more mature periods of life - but it would not be relevant here. It may, however, be less well known that the strongest compulsive influence arises from impressions which impinge upon a child at a time when we would have to regard his psychical apparatus as not yet completely receptive. The fact itself cannot be doubted; but it is so puzzling that we may make it more comprehensible by comparing it with a photographic exposure which can be developed after any interval of time and transformed into a picture. I am nevertheless glad to point out that this uncomfortable discovery of ours has been anticipated by an imaginative writer, with the boldness that is permitted to poets. E. T. A. Hoffmann used to trace back the wealth of figures that put themselves at his disposal for his creative writings to the changing images and impressions which he had experienced during a journey of some weeks in a post-chaise while he was still an infant at his mother's breast. What children have experienced at the age of two and have not understood, need never be remembered by them except in dreams; they may only come to know of it through psycho-analytic treatment. But at some later time it will break into their life with obsessional impulses, it will govern their actions, it will decide their sympathies and antipathies and will quite often determine their choice of a love-object, for which it is so frequently impossible to find a rational basis. The two points at which these facts touch upon our problem cannot be mistaken.

[1939a, 4944]

First, there is the remoteness of the period concerned,¹ which is recognized here as the truly determining factor - in the special state of the memory, for instance, which in the case of these childhood experiences we classify as 'unconscious'. We expect to find an analogy in this with the state which we are seeking to attribute to tradition in the mental life of the people. It was not easy, to be sure, to introduce the idea of the unconscious into group psychology.

[1939a, 4944]

We have learnt from the psycho-analyses of individuals that their earliest impressions, received at a time when the child was scarcely yet capable of speaking, produce at some time or another effects of a compulsive character without themselves being consciously remembered. We believe we have a right to make the same assumption about the earliest experiences of the whole of humanity. One of these effects would be the emergence of the idea of a single great god - an idea which must be recognized as a completely justified memory, though, it is true, one that has been distorted. An idea such as this has a compulsive character: it must be believed. To the extent to which it is distorted, it may be described as a delusion; in so far as it brings a return of the past, it must be called the truth. Psychiatric delusions, too, contain a small fragment of truth and the patient's conviction extends over from this truth on to its delusional wrappings.

[1939a, 4947]
The facts of this splitting of the ego, which we have just described, are neither so new nor so strange as they may at first appear. It is indeed a universal characteristic of neuroses that there are present in the subject's mental life, as regards some particular behaviour, two different attitudes, contrary to each other and independent of each other. In the case of neuroses, however, one of these attitudes belongs to the ego and the contrary one, which is repressed, belongs to the id. The difference between this case and the other is essentially a topographical or structural one, and it is not always easy to decide in an individual instance with which of the two possibilities one is dealing. They have, however, the following important characteristic in common. Whatever the ego does in its efforts of defence, whether it seeks to disavow a portion of the real external world or whether it seeks to reject an instinctual demand from the internal world, its success is never complete and unqualified. The outcome always lies in two contrary attitudes, of which the defeated, weaker one, no less than the other, leads to psychical complications. In conclusion, it is only necessary to point out how little of all these processes becomes known to us through our conscious perception.

[1940a [1938], 5009]

The therapeutic effect depends on making conscious what is repressed, in the widest sense of the word, in the id. We prepare the way for this making conscious by interpretations and constructions, but we have interpreted only for ourselves not for the patient so long as the ego holds on to its earlier defences and does not give up its resistances. Now these resistances, although they belong to the ego, are nevertheless unconscious and in some sense separated off within the ego. The analyst recognizes them more easily than he does the hidden material in the id. One might suppose that it would be sufficient to treat them like portions of the id and, by making them conscious, bring them into connection with the rest of the ego. In this way, we should suppose, one half of the task of analysis would be accomplished; we should not reckon on meeting with a resistance against the uncovering of resistances. But what happens is this. During the work on the resistances the ego withdraws - with a greater or less degree of seriousness - from the agreement on which the analytic situation is founded. The ego ceases to support our efforts at uncovering the id; it opposes them, disobeys the fundamental rule of analysis, and allows no further derivatives of the repressed to emerge. We cannot expect the patient to have a strong conviction of the curative power of analysis. He may have brought along with him a certain amount of confidence in his analyst, which will be strengthened to an effective point by the factors of the positive transference which will be aroused in him. Under the influence of the unpleasurable impulses which he feels as a result of the fresh activation of his defensive conflicts, negative transferences may now gain the upper hand and completely annul the analytic situation. The patient now regards the analyst as no more than a stranger who is making disagreeable demands on him, and he behaves towards him exactly like a child who does not like the stranger and does not believe anything he says. If the analyst tries to explain to the patient one of the distortions made by him for the purposes of defence, and to correct it, he finds him uncomprehending and inaccessible to sound arguments. Thus we see that there is a resistance against the uncovering of resistances, and the defensive mechanisms really do deserve the name which we gave them originally, before they had been more closely examined. They are resistances not only to the making conscious of contents of the id, but also to the analysis as a whole, and thus to recovery.

[1937c, 5034]

We know what is meant by ideas 'occurring' to one - thoughts that suddenly come into consciousness without one's being aware of the steps that led up to them, though they, too, must have been psychical acts. It can even happen that one arrives in this way at the solution of some difficult intellectual problem which has previously for a time baffled one's efforts. All the complicated processes of selection, rejection and decision which occupied the interval were withdrawn from consciousness. We shall not be putting forward any new theory in saying that they were unconscious and perhaps, too, remained so.

[1940b [1938], 5068]
In the second place, I shall pick a single instance to represent an immensely large class of phenomena.¹ The President of a public body (the Lower House of the Austrian Parliament) on one occasion opened a sitting with the following words: 'I take notice that a full quorum of members is present and herewith declare the sitting closed.' It was a slip of the tongue - for there can be no doubt that what the President intended to say was 'opened'. Why, then, did he say the opposite? We shall expect to be told it was an accidental mistake, a failure in carrying out an intention such as may easily happen for various reasons: it had no meaning - and in any case contraries are particularly easily substituted for each other. If, however, we bear in mind the situation in which the slip of the tongue occurred, we shall be inclined to prefer another explanation. Many of the previous sittings of the House had been disagreeably stormy and had accomplished nothing, so that it would be only too natural for the President to think at the moment of making his opening statement: 'If only the sitting that's just beginning were finished! I would much rather be closing then opening it!' When he began to speak he was probably not aware of this wish - it was not conscious to him - but it was certainly present and it succeeded in making itself effective, against the speaker's will, in his apparent mistake. A single instance can scarcely enable us to decide between two such different explanations. But what if every other instance of a slip of the tongue could be explained in the same way, and similarly every slip of the pen, every case of mis-reading or mis-hearing, and every faulty action? What if in all those instances (one might actually say, without a single exception) it was possible to demonstrate the presence of a psychical act - a thought, a wish or an intention - which would account for the apparent mistake and which was unconscious at the moment at which it became effective, even though it may have been conscious previously? If that were so, it would really no longer be possible to dispute the fact that psychical acts which are unconscious do exist and that they are even sometimes active while they are unconscious and that in that case they can even sometimes get the better of conscious intentions. The person concerned in a mistake of this kind can react to it in various ways. He may overlook it completely or he may notice it himself and become embarrassed and ashamed. He cannot as a rule find the explanation of it himself without outside help; and he often refuses to accept the solution when it is put before him - for a time, at all events.

[1940b [1938], 5069]

In the third place, finally, it is possible in the case of persons in a state of hypnosis to prove experimentally that there are such things as unconscious psychical acts and that consciousness is not an indispensable condition of activity. Anyone who has witnessed such an experiment will receive an unforgettable impression and a conviction that can never be shaken. Here is more or less what happens. The doctor enters the hospital ward, puts his umbrella in the corner, hypnotizes one of the patients and says to him: 'I'm going out now. When I come in again, you will come to meet me with my umbrella open and hold it over my head.' The doctor and his assistants then leave the ward. As soon as they come back, the patient, who is no longer under hypnosis, carries out exactly the instructions that were given him while he was hypnotized. The doctor questions him: 'What's this you're doing? What's the meaning of all this?' The patient is clearly embarrassed. He makes some lame remark such as 'I only thought, doctor, as it's raining outside you'd open your umbrella in the room before you went out.' The explanation is obviously quite inadequate and made up on the spur of the moment to offer some sort of motive for his senseless behaviour. It is clear to us spectators that he is in ignorance of his real motive. We, however, know what it is, for we were present when the suggestion was made to him which he is now carrying out, while he himself knows nothing of the fact that it is at work in him.¹

[1940b [1938], 5070]
When, here and later on, we speak of ideas that are currently present and operative but yet unconscious, we are seldom concerned with single ideas (such as the big snake hallucinated by Anna O. which started her contracture). It is almost always a question of complexes of ideas, of recollections of external events and trains of thought of the subject's own. It may sometimes happen that every one of the individual ideas comprised in such a complex of ideas is thought of consciously, and that what is exiled from consciousness is only the particular combination of them.

[1895d [Breuer], 191]

I will begin by bringing together some material for answering the last question. In discussing the examples of slips of the tongue we found it necessary to go beyond the content of what was intended to be said, and were obliged to look for the cause of the speech-disturbance in something outside the intention. What this was was obvious in a number of cases, and was known to the speaker's consciousness. In the examples that seemed simplest and most transparent it was another version of the same thought - one which sounded as if it had an equal right, and which disturbed the expression of the thought without its being possible to explain why the one version had succumbed and the other had won the day. (These are Meringer and Mayer's 'contaminations'.) In a second group of cases the motive for the defeat of one version was a consideration which, however, did not prove strong enough to withhold it completely ('zum Vorschwein gekommen'). The version which was withheld was perfectly conscious too. Only of the third group can it be asserted unreservedly that the disturbing thought differed from the one intended, and only in their case can a distinction which is apparently essential be established. The disturbing thought is either connected with the disturbed thought by thought associations (disturbance as a result of internal contradiction), or it is unrelated to it in its nature and the disturbed word happens to be connected with the disturbing thought - which is often unconscious - by an unexpected external association. In the examples I have given from my psycho-analyses the entire speech is under the influence of thoughts which have become active but have at the same time remained entirely unconscious; either these are betrayed by the disturbance itself ('Klapperschlange' - 'Kleopatra') or they exercise an indirect influence by making it possible for the different parts of the consciously intended speech to disturb each other ('Ase natmen', where 'Hasenauer Street' and reminiscences of a Frenchwoman are in the background). The withheld or unconscious thoughts from which the disturbance in speech derives are of the most varied origin. This survey therefore does not enable us to generalize in any direction.

[1901b, 1341]

¹ [Footnote added 1924:] This book is of an entirely popular character; it merely aims, by an accumulation of examples, at paving the way for the necessary assumption of unconscious yet operative mental processes, and it avoids all theoretical considerations on the nature of this unconscious.

[1901b, 1341]

But we have more to learn from such an experiment. We are led from the purely descriptive to a dynamic view of the phenomenon. The idea of the action ordered in hypnosis not only became an object of consciousness at a certain moment, but the more striking aspect of the fact is that this idea grew active: it was translated into action as soon as consciousness became aware of its presence. The real stimulus to the action being the order of the physician, it is hard not to concede that the idea of the physician's order became active too. Yet this last idea did not reveal itself to consciousness, as did its outcome, the idea of the action; it remained unconscious, and so it was active and unconscious at the same time.

[1912g, 2578]
The mind of the hysterical patient is full of active yet unconscious ideas; all her symptoms proceed from such ideas. It is in fact the most striking character of the hysterical mind to be ruled by them. If the hysterical woman vomits, she may do so from the idea of being pregnant. She has, however, no knowledge of this idea, although it can easily be detected in her mind, and made conscious to her, by one of the technical procedures of psycho-analysis. If she is executing the jerks and movements constituting her 'fit', she does not even consciously represent to herself the intended actions, and she may perceive those actions with the detached feelings of an onlooker. Nevertheless analysis will show that she was acting her part in the dramatic reproduction of some incident in her life, the memory of which was unconsciously active during the attack. The same preponderance of active unconscious ideas is revealed by analysis as the essential fact in the psychology of all other forms of neurosis.

We learn therefore by the analysis of neurotic phenomena that a latent or unconscious idea is not necessarily a weak one, and that the presence of such an idea in the mind admits of indirect proofs of the most cogent kind, which are equivalent to the direct proof furnished by consciousness. We feel justified in making our classification agree with this addition to our knowledge by introducing a fundamental distinction between different kinds of latent or unconscious ideas. We were accustomed to think that every latent idea was so because it was weak and that it grew conscious as soon as it became strong. We have not gained the conviction that there are some latent ideas which do not penetrate into consciousness, however strong they may have become. Therefore we may call the latent ideas of the first type foreconscious,¹ while we reserve the term unconscious (proper) for the latter type which we came to study in the neuroses. The term unconscious, which was used in the purely descriptive sense before, now comes to imply something more. It designates not only latent ideas in general, but especially ideas with a certain dynamic character, ideas keeping apart from consciousness in spite of their intensity and activity.

We have learnt from psycho-analysis that the essence of the process of repression lies, not in putting an end to, in annihilating, the idea which represents an instinct, but in preventing it from becoming conscious. When this happens we say of the idea that it is in a state of being 'unconscious', and we can produce good evidence to show that even when it is unconscious it can produce effects, even including some which finally reach consciousness. Everything that is repressed must remain unconscious; but let us state at the very outset that the repressed does not cover everything that is unconscious. The unconscious has the wider compass: the repressed is a part of the unconscious.
The second point I have in mind is this. If in a large majority of instances we find confirmation of the fact that the forgetting of an intention goes back to a counter-will, we grow bold enough to extend the solution to another set of instances in which the person under analysis does not confirm but denies the counter-will we have inferred. Take as examples of this such extremely common events as forgetting to return books one has been lent or to pay bills or debts. We shall venture to insist to the person concerned that an intention exists in him to keep the books and not to pay the debts, while he will deny this intention but will not be able to produce any other explanation of his behaviour. Thereupon we shall go on to say that he has this intention but knows nothing about it, but that it is enough for us that it reveals its presence by producing the forgetting in him. He may repeat to us that he has in fact forgotten. You will now recognize the situation as one in which we found ourselves once before. If we want to pursue our interpretations of parapraxes, which have so frequently proved justified, to a consistent conclusion, we are forced to the inescapable hypothesis that there are purposes in people which can become operative without their knowing about them. But this brings us into opposition to all the views that dominate both ordinary life and psychology.

[1916-1917, 3179]

But can psycho-analysis do more here? Yes, it actually can. I hope to be able to show you that, even in a case so hard of access as this, it can discover something which makes a first understanding possible. And to begin with I would draw your attention to the inconspicuous detail that the patient herself positively provoked the anonymous letter, which now gave support to her delusion, by informing the scheming housemaid on the previous day that it would cause her the greatest unhappiness if her husband had a love affair with a young girl. In this way she first put the notion of sending the anonymous letter into the housemaid's head. Thus the delusion acquires a certain independence of the letter; it had been present already in the patient as a fear - or was it as a wish? Let us now add to this the small further indications yielded by only two analytic sessions. The patient, indeed, behaved in a very unco-operative way when, after telling me her story, she was asked for her further thoughts, ideas and memories. She said that nothing occurred to her, that she had told me everything already, and after two sessions the experiment with me had in fact to be broken off because she announced that she already felt well and that she was sure the pathological idea would not come back. She only said this, of course, from resistance and from dread of the continuation of the analysis. Nevertheless, during these two sessions she let fall a few remarks which allowed of, and indeed necessitated, a particular interpretation; and this interpretation threw a clear light on the genesis of her delusion of jealousy. She herself was intensely in love with a young man, with the same son-in-law who had persuaded her to come to me as a patient. She herself knew nothing, or perhaps only a very little, of this love; in the family relationship that existed between them it was easy for this passionate liking to disguise itself as innocent affection. After all our experiences elsewhere, it is not hard for us to feel our way into the mental life of this upright wife and worthy mother, of the age of fifty-three. Being in love like this, a monstrous and impossible thing, could not become conscious; but it remained in existence and, even though it was unconscious, it exercised a severe pressure. Something had to become of it, some relief had to be looked for; and the easiest mitigation was offered, no doubt, by the mechanism of displacement which plays a part so regularly in the generating of delusional jealousy. If not only were she, the old woman, in love with a young man, but if also her old husband were having a love affair with a young girl, then her conscience would be relieved of the weight of her unfaithfulness. The phantasy of her husband's unfaithfulness thus acted as a cooling compress on her burning wound. Her own love had not become conscious to her, but its mirror-reflection, which brought her such an advantage, now became conscious as an obsession and delusion. No arguments against it could, of course, have any effect, for they were only directed against the mirror-image and not against the original which gave the other its strength and which lay hidden, inviolable, in the unconscious.

[1916-1917, 3334]
It is a surprising thing that the tragedy of Sophocles does not call up indignant repudiation in his audience - a reaction similar to that of our simple-minded army doctor but far better justified. For fundamentally it is an amoral work: it absolves men from moral responsibility, exhibits the gods as promoters of crime and shows the impotence of the moral impulses of men which struggle against crime. It might easily be supposed that the material of the legend had in view an indictment of the gods and of fate; and in the hands of Euripides, the critic and enemy of the gods, it would probably have become such an indictment. But with the devout Sophocles there is no question of an application of that kind. The difficulty is overcome by the pious sophistry that to bow to the will of the gods is the highest morality even when it promotes crime. I cannot think that this morality is a strong point of the play, but it has no influence on its effect. It is not to it that the auditor reacts but to the secret sense and content of the legend. He reacts as though by self-analysis he had recognized the Oedipus complex in himself and had unveiled the will of the gods and the oracle as exalted disguises of his own unconscious. It is as though he was obliged to remember the two wishes - to do away with his father and in place of him to take his mother to wife - and to be horrified at them. And he understands the dramatist's voice as though it were saying to him: 'You are struggling in vain against your responsibility and are protesting in vain of what you have done in opposition to these criminal intentions. You are guilty, for you have not been able to destroy them; they still persist in you unconsciously.' And there is psychological truth contained in this. Even if a man has repressed his evil impulses into the unconscious and would like to tell himself afterwards that he is not responsible for them, he is nevertheless bound to be aware of this responsibility as a sense of guilt whose basis is unknown to him.

[1916-1917, 3398]
In order to demonstrate to you the influence which the development of the ego has upon the construction of conflicts and upon the causation of neuroses, I should like to put an example before you - one which, it is true, is a complete invention but which is nowhere divorced from probability. I shall describe it (on the basis of the title of one of Nestroy's farces) as 'In the Basement and on the First Floor'. The caretaker of the house inhabits the basement and its landlord, a wealthy and respectable gentleman, the first floor. Both have children, and we may suppose that the landlord's little daughter is allowed to play, without any supervision, with the proletarian girl. It might very easily happen, then, that the children's games would take on a 'naughty' - that is to say, a sexual - character, that they would play at 'father and mother', that they would watch each other at their most private business and excite each other's genitals. The caretaker's girl, though only five or six years old, would have had an opportunity of observing a good deal of adult sexuality, and she might well play the part of seductress in all this. These experiences, even if they were not continued over a long period, would be enough to set certain sexual impulses to work in the two children; and, after their games together had ceased, these impulses would for several years afterwards find expression in masturbation. So much for their experiences in common; the final outcome in the two children will be very different. The caretaker's daughter will continue her masturbation, perhaps, till her menstrual periods begin and she will then give it up with no difficulty. A few years later she will find a lover and perhaps have a baby. She will take up some occupation or other, possibly become a popular figure on the stage and end up as an aristocrat. Her career is more likely to be less brilliant, but in any case she will go through her life undamaged by the early exercise of her sexuality and free from neurosis. With the landlord's little girl things will be different. At an early stage and while she is still a child she will get an idea that she has done something wrong; after a short time, but perhaps only after a severe struggle, she will give up her masturbatory satisfaction, but she will nevertheless still have some sense of oppression about her. When in her later girlhood she is in a position to learn something of human sexual intercourse, she will turn away from it with unexplained disgust and prefer to remain in ignorance. And now she will probably be subject to a fresh emergence of an irresistible pressure to masturbate of which she will not dare to complain. During the years in which she should exercise a feminine attraction upon some man, a neurosis breaks out in her which cheats her of marriage and her hopes in life. If after this an analysis succeeds in gaining an insight into her neurosis, it will turn out that the well-brought-up, intelligent and high-minded girl has completely repressed her sexual impulses, but that these, unconscious to her, are still attached to her petty experiences with her childhood friend.

[1916-1917, 3413]

We are justified in assuming that no great change is effected by the repression of the original unconscious phantasy. Whatever is repressed from consciousness or replaced in it by something else remains intact and potentially operative in the unconscious. The effect of regression to an earlier stage of the sexual organization is quite another matter. As regards this we are led to believe that the state of things changes in the unconscious as well. Thus in both sexes the masochistic phantasy of being beaten by the father, though not the passive phantasy of being loved by him, lives on in the unconscious after repression has taken place. There are, besides, plenty of indications that the repression has only very incompletely attained its object. The boy, who has tried to escape from a homosexual object-choice, and who has not changed his sex, nevertheless feels like a woman in his conscious phantasies, and endows the women who are beating him with masculine attributes and characteristics. The girl, who has even renounced her sex, and who has on the whole accomplished a more thoroughgoing work of repression, nevertheless does not become freed from her father; she does not venture to do the beating herself; and since she has herself become a boy, it is principally boys whom she causes to be beaten.

[1919e, 3658]
The psycho-analytic investigation of the psychoneuroses has taught us that their symptoms are to be traced back to directly sexual impulsions which are repressed but still remain active. We can complete this formula by adding - 'or, to aim-inhibited impulsions, whose inhibition has not been entirely successful or has made room for a return to the repressed sexual aim'. It is in accordance with this that a neurosis should make its victim asocial and should remove him from the usual group formations. It may be said that a neurosis has the same disintegrating effect upon a group as being in love. On the other hand it appears that where a powerful impetus has been given to group formation neuroses may diminish and, at all events temporarily, disappear. Justifiable attempts have also been made to turn this antagonism between neuroses and group formation to therapeutic account. Even those who do not regret the disappearance of religious illusions from the civilized world of to-day will admit that so long as they were in force they offered those who were bound by them the most powerful protection against the danger of neurosis. Nor is it hard to discern that all the ties that bind people to mystico-religious or philosophico-religious sects and communities are expressions of crooked cures of all kinds of neuroses. All of this is correlated with the contrast between directly sexual impulsions and those which are inhibited in their aims.

I cannot neglect this opportunity of expressing for once my astonishment that human beings can go through such great and important moments of their erotic life without noticing them much, sometimes even, indeed, without having the faintest suspicion of their existence, or else, having become aware of those moments, deceive themselves so thoroughly in their judgement of them. This happens not only under neurotic conditions, where we are familiar with the phenomenon, but seems also to be common enough in ordinary life. In the present case, for example, a girl develops a sentimental adoration for women, which her parents at first find merely vexatious and hardly take seriously; she herself knows quite well that she is very much occupied with these relationships, but still she experiences few of the sensations of intense love until a particular frustration is followed by a quite excessive reaction, which shows everyone concerned that they have to do with a consuming passion of elemental strength. Nor had the girl ever perceived anything of the state of affairs which was a necessary preliminary to the outbreak of this mental storm. In other cases, too, we come across girls or women in a state of severe depression, who on being asked for a possible cause of their condition tell us that they have, it is true, had a slight feeling for a certain person, but that it was nothing deep and that they soon got over it when they had to give it up. And yet it was this renunciation, apparently so easily borne, that became the cause of serious mental disturbance. Again, we come across men who have passed through casual love-affairs and realize only from the subsequent effects that they had been passionately in love with the person whom they had apparently regarded lightly. One is also amazed at the unexpected results that may follow an artificial abortion, the killing of an unborn child, which had been decided upon without remorse and without hesitation. It must be admitted that poets are right in liking to portray people who are in love without knowing it, or uncertain whether they do love, or who think that they hate when in reality they love. It would seem that the information received by our consciousness about our erotic life is especially liable to be incomplete, full of gaps, or falsified. Needless to say, in this discussion I have not omitted to allow for the part played by subsequent forgetting.

[1920a, 3855]
But we have arrived at the term or concept of the unconscious along another path, by considering certain experiences in which mental dynamics play a part. We have found - that is, we have been obliged to assume - that very powerful mental processes or ideas exist (and here a quantitative or economic factor comes into question for the first time) which can produce all the effects in mental life that ordinary ideas do (including effects that can in their turn become conscious as ideas), though they themselves do not become conscious. It is unnecessary to repeat in detail here what has been explained so often before. It is enough to say that at this point psycho-analytic theory steps in and asserts that the reason why such ideas cannot become conscious is that a certain force opposes them, that otherwise they could become conscious, and that it would then be apparent how little they differ from other elements which are admittedly psychical. The fact that in the technique of psycho-analysis a means has been found by which the opposing force can be removed and the ideas in question made conscious renders this theory irrefutable. The state in which the ideas existed before being made conscious is called by us repression, and we assert that the force which instituted the repression and maintains it is perceived as resistance during the work of analysis [1923b, 3948]

In the further course of psycho-analytic work, however, even these distinctions have proved to be inadequate and, for practical purposes, insufficient. This has become clear in more ways than one; but the decisive instance is as follows. We have formed the idea that in each individual there is a coherent organization of mental processes; and we call this his ego. It is to this ego that consciousness is attached; the ego controls the approaches to motility - that is, to the discharge of excitations into the external world; it is the mental agency which supervises all its own constituent processes, and which goes to sleep at night, though even then it exercises the censorship on dreams. From this ego proceed the repressions, too, by means of which it is sought to exclude certain trends in the mind not merely from consciousness but also from other forms of effectiveness and activity. In analysis these trends which have been shut out stand in opposition to the ego, and the analysis is faced with the task of removing the resistances which the ego displays against concerning itself with the repressed. Now we find during analysis that, when we put certain tasks before the patient, he gets into difficulties; his associations fail when they should be coming near the repressed. We then tell him that he is dominated by a resistance; but he is quite unaware of the fact, and, even if he guesses from his unpleasurable feelings that a resistance is now at work in him, he does not know what it is or how to describe it. Since, however, there can be no question but that this resistance emanates from his ego and belongs to it, we find ourselves in an unforeseen situation. We have come upon something in the ego itself which is also unconscious, which behaves exactly like the repressed - that is, which produces powerful effects without itself being conscious and which requires special work before it can be made conscious. From the point of view of analytic practice, the consequence of this discovery is that we land in endless obscurities and difficulties if we keep to our habitual forms of expression and try, for instance, to derive neuroses from a conflict between the conscious and the unconscious. We shall have to substitute for this antithesis another, taken from our insight into the structural conditions of the mind - the antithesis between the coherent ego and the repressed which is split off from it.¹ [1923b, 3951]
There is another phenomenon, however, which is far stranger. In our analyses we discover that there are people in whom the faculties of self-criticism and conscience - mental activities, that is, that rank as extremely high ones - are unconscious and unconsciously produce effects of the greatest importance; the example of resistance remaining unconscious during analysis is therefore by no means unique. But this new discovery, which compels us, in spite of our better critical judgement, to speak of an 'unconscious sense of guilt', bewilders us far more than the other and sets us fresh problems, especially when we gradually come to see that in a great number of neuroses an unconscious sense of guilt of this kind plays a decisive economic part and puts the most powerful obstacles in the way of recovery. If we come back once more to our scale of values, we shall have to say that not only what is lowest but also what is highest in the ego can be unconscious. It is as if we were thus supplied with a proof of what we have just asserted of the conscious ego: that it is first and foremost a body-ego.

[1923b, 3961]

The precipitating causes of the symptoms were compared by Breuer to Charcot's traumas. Now it was a remarkable fact that all these traumatic precipitating causes, and all the mental impulses starting from them, were lost to the patient's memory, as though they had never happened; while their products - the symptoms - persisted unaltered, as though, so far as they were concerned, there was no such thing as the effacing effect of time. Here, therefore, we had a fresh proof of the existence of mental processes which were unconscious but for that very reason especially powerful - processes which we had first come to know in post-hypnotic suggestion. The therapeutic procedure adopted by Breuer was to induce the patient, under hypnosis, to remember the forgotten traumas and to react to them with powerful expressions of affect. When this had been done, the symptom, which had till then taken the place of these expressions of emotion, disappeared. Thus one and the same procedure served simultaneously the purposes of investigating and of getting rid of the ailment; and this unusual conjunction was later retained in psycho-analysis.

[1924f, 4104]

Evidence of its being of use for throwing light on other than pathological mental activity was early forthcoming in connection with two kinds of phenomena: with the very frequent parapraxes that occur in everyday life - such as forgetting things, slips of the tongue, and mislaying objects - and with the dreams dreamt by healthy and psychically normal people. Small failures of functioning, like the temporary forgetting of normally familiar proper names, slips of the tongue and of the pen, and so on, had hitherto not been considered worthy of any explanation at all or were supposed to be accounted for by conditions of fatigue, by distraction of the attention, etc. The present writer then showed from many examples, in his book *The Psychopathology of Everyday Life* (1901b), that events of this kind have a meaning, and arise owing to a conscious intention being interfered with by another, suppressed or actually unconscious one. As a rule, quick reflection or a short analysis is enough to reveal the interfering influence. Owing to the frequency of such parapraxes as slips of the tongue, it became easy for anyone to convince himself from his own experience of the existence of mental processes which are not conscious, but which are nevertheless operative and which at least find expression as inhibitions and modifications of other, intended acts.

[1924f, 4109]
There is no need to discuss what is to be called conscious: it is removed from all doubt. The oldest and best meaning of the word 'unconscious' is the descriptive one; we call a psychical process unconscious whose existence we are obliged to assume - for some such reason as that we infer it from its effects -, but of which we know nothing. In that case we have the same relation to it as we have to a psychical process in another person, except that it is in fact one of our own. If we want to be still more correct, we shall modify our assertion by saying that we call a process unconscious if we are obliged to assume that it is being activated at the moment, though at the moment we know nothing about it. This qualification makes us reflect that the majority of conscious processes are conscious only for a short time; very soon they become latent, but can easily become conscious again. We might also say that they had become unconscious, if it were at all certain that in the condition of latency they are still something psychical. So far we should have learnt nothing new; nor should we have acquired the right to introduce the concept of an unconscious into psychology. But then comes the new observation that we were already able to make in parapraxes. In order to explain a slip of the tongue, for instance, we find ourselves obliged to assume that the intention to make a particular remark was present in the subject. We infer it with certainty from the interference with his remark which has occurred; but the intention did not put itself through and was thus unconscious. If, when we subsequently put it before the speaker, he recognizes it as one familiar to him, then it was only temporarily unconscious to him; but if he repudiates it as something foreign to him, then it was permanently unconscious. From this experience we retrospectively obtain the right also to pronounce as something unconscious what had been described as latent. A consideration of these dynamic relations permits us now to distinguish two kinds of unconscious - one which is easily, under frequently occurring circumstances, transformed into something conscious, and another with which this transformation is difficult and takes place only subject to a considerable expenditure of effort or possibly never at all. In order to escape the ambiguity as to whether we mean the one or the other unconscious, whether we are using the word in the descriptive or in the dynamic sense, we make use of a permissible and simple way out. We call the unconscious which is only latent, and thus easily becomes conscious, the 'preconscious' and retain the term 'unconscious' for the other. We now have three terms, 'conscious', 'preconscious' and 'unconscious', with which we can get along in our description of mental phenomena. Once again: the preconscious is also unconscious in the purely descriptive sense, but we do not give it that name, except in talking loosely or when we have to make a defence of the existence in mental life of unconscious processes in general.

[1933a, 4679]
In the second place, I shall pick a single instance to represent an immensely large class of phenomena.¹ The President of a public body (the Lower House of the Austrian Parliament) on one occasion opened a sitting with the following words: 'I take notice that a full quorum of members is present and herewith declare the sitting closed.' It was a slip of the tongue - for there can be no doubt that what the President intended to say was 'opened'. Why, then, did he say the opposite? We shall expect to be told it was an accidental mistake, a failure in carrying out an intention such as may easily happen for various reasons: it had no meaning - and in any case contraries are particularly easily substituted for each other. If, however, we bear in mind the situation in which the slip of the tongue occurred, we shall be inclined to prefer another explanation. Many of the previous sittings of the House had been disagreeably stormy and had accomplished nothing, so that it would be only too natural for the President to think at the moment of making his opening statement: 'If only the sitting that's just beginning were finished! I would much rather be closing then opening it!' When he began to speak he was probably not aware of this wish - it was not conscious to him - but it was certainly present and it succeeded in making itself effective, against the speaker's will, in his apparent mistake. A single instance can scarcely enable us to decide between two such different explanations. But what if every other instance of a slip of the tongue could be explained in the same way, and similarly every slip of the pen, every case of mis-reading or mis-hearing, and every faulty action? What if in all those instances (one might actually say, without a single exception) it was possible to demonstrate the presence of a psychical act - a thought, a wish or an intention - which would account for the apparent mistake and which was unconscious at the moment at which it became effective, even though it may have been conscious previously? If that were so, it would really no longer be possible to dispute the fact that psychical acts which are unconscious do exist and that they are even sometimes active while they are unconscious and that in that case they can even sometimes get the better of conscious intentions. The person concerned in a mistake of this kind can react to it in various ways. He may overlook it completely or he may notice it himself and become embarrassed and ashamed. He cannot as a rule find the explanation of it himself without outside help; and he often refuses to accept the solution when it is put before him - for a time, at all events.

[1940b [1938], 5069]

In the third place, finally, it is possible in the case of persons in a state of hypnosis to prove experimentally that there are such things as unconscious psychical acts and that consciousness is not an indispensable condition of activity. Anyone who has witnessed such an experiment will receive an unforgettable impression and a conviction that can never be shaken. Here is more or less what happens. The doctor enters the hospital ward, puts his umbrella in the corner, hypnotizes one of the patients and says to him: 'I'm going out now. When I come in again, you will come to meet me with my umbrella open and hold it over my head.' The doctor and his assistants then leave the ward. As soon as they come back, the patient, who is no longer under hypnosis, carries out exactly the instructions that were given him while he was hypnotized. The doctor questions him: 'What's this you're doing? What's the meaning of all this?' The patient is clearly embarrassed. He makes some lame remark such as 'I only thought, doctor, as it's raining outside you'd open your umbrella in the room before you went out.' The explanation is obviously quite inadequate and made up on the spur of the moment to offer some sort of motive for his senseless behaviour. It is clear to us spectators that he is in ignorance of his real motive. We, however, know what it is, for we were present when the suggestion was made to him which he is now carrying out, while he himself knows nothing of the fact that it is at work in him.¹

[1940b [1938], 5070]
Not everyone who suffers from obsessions is as clear as this about their origin. As a rule, when one draws a patient's attention to the original idea of a sexual kind, the answer is: 'It can't come from that. I didn't think at all much about that. For a moment I was frightened, but I turned my mind away from it and I haven't been troubled by it since.' In this frequent objection we have evidence that the obsession represents a substitute or surrogate for the incompatible sexual idea and has taken its place in consciousness.

[1894a, 308]

The state of permanently turning away from women produces a personal susceptibility, or, as we are accustomed to say, a 'disposition' to the formation of a delusion. The development of the mental disorder sets in at the moment when a chance impression arouses the childhood experiences which have been forgotten and which have traces, at least, of an erotic colouring. 'Arouses', however, is certainly not the right description, if we take into account what follows. We must repeat the author's accurate account in correct psychological technical terms. When Norbert Hanold saw the relief, he did not remember that he had already seen a similar posture of the foot in his childhood friend; he remembered nothing at all, but all the effects brought about by the relief originated from this link that was made with the impression of his childhood. Thus the childhood impression was stirred up, it became active, so that it began to produce effects, but it did not come into consciousness - it remained 'unconscious', to use a term which has to-day become unavoidable in psychopathology. We are anxious that this unconscious shall not be involved in any of the disputes of philosophers and natural philosophers, which have often no more than an etymological importance. For the time being we possess no better name for psychical processes which behave actively but nevertheless do not reach the consciousness of the person concerned, and that is all we mean by our 'unconsciousness'. When some thinkers try to dispute the existence of an unconscious of this kind, on the ground that it is nonsensical, we can only suppose that they have never had to do with the corresponding mental phenomena, that they are under the spell of the regular experience that everything mental that becomes active and intense becomes at the same time conscious as well, and that they have still to learn (what our author knows very well) that there are most certainly mental processes which, in spite of being intense and producing effects, none the less remain apart from consciousness.

[1907a, 1846]
The first manifestations of the process that had been set going in Hanold by the relief were phantasies, which played around the figure represented in it. The figure seemed to him to have something 'of to-day' about her, in the best sense of the words, and it was as though the artist had captured her 'from the life' stepping along the street. He gave the girl in the ancient relief the name of 'Gradiva', which he constructed on the model of an epithet of the war-god striding into battle - 'Mars Gradivus'. He endowed her personality with more and more characteristics. She may have been the daughter of a respected personage, of a patrician, perhaps, who was connected with the temple service of a deity. He thought he could trace a Greek origin in her features; and finally he felt compelled to remove her from the busy life of a capital and to transport her to the more peaceful Pompeii, and there he made her step across the lava stepping-stones which made it possible to cross from one side of the street to the other. These products of his phantasy seem arbitrary enough, but at the same time innocently unsuspicious. And, indeed, even when for the first time they gave rise to an incitement to action - when the archaeologist, obsessed by the problem of whether this posture of the feet corresponded to reality, began to make observations from life in order to examine the feet of contemporary women and girls - even this action was screened by conscious scientific motives, as though all his interest in the sculpture of Gradiva had sprung from the soil of his professional concern with archaeology. The women and girls in the street, whom he chose as the subjects of his investigation, must, of course, have taken another, crudely erotic view of his behaviour, and we cannot but think them right. We ourselves can be in no doubt that Hanold was as much in ignorance of the motives of his researches as he was of the origin of his phantasies about Gradiva. These, as we learned later, were echoes of his memories of his youthful love, derivatives of those memories, transformations and distortions of them, after they had failed to make their way into his consciousness in an unmodified form. The ostensibly aesthetic judgement that the sculpture had something 'of to-day' about it took the place of his knowledge that a gait of that kind belonged to a girl whom he knew and who stepped across the street at the present time. Behind the impression of the sculpture being 'from the life' and the phantasy of its subject being Greek lay his memory of the name Zoe, which means 'life' in Greek. 'Gradiva', as we learn from our hero himself at the end of the story, after he has been cured of his delusion, is a good translation of the surname 'Bertgang' which means something like 'someone who steps along brilliantly or splendidly'. The details about Gradiva's father originated from Hanold's knowledge that Zoe Bertgang was the daughter of a respected teacher at the University, which can well be translated into classical terms as 'temple-service'. Finally, his phantasy transported her to Pompeii, not 'because her quiet, calm nature seemed to demand it', but because no other or better analogy could be found in his science for his remarkable state, in which he became aware of his memories of his childhood friendship through obscure channels of information. Once he had made his own childhood coincide with the classical past (which it was so easy for him to do), there was a perfect similarity between the burial of Pompeii - the disappearance of the past combined with its preservation - and repression, of which he possessed a knowledge through what might be described as 'endopsychic' perception. In this he was employing the same symbolism that the author makes the girl use consciously towards the conclusion of the story: 'I told myself I should be able to dig out something interesting here even by myself. Of course I hadn't counted on making the find that I have . . .' (124.) And at the very end she replied to Hanold's plan for their honeymoon with a reference to her childhood friend who had also in a sense been dug out of the ruins again'. (150.)

[1907a, 1849]
And here we must give what will perhaps be an unexpected answer. In fact the situation is quite the reverse: it is science that cannot hold its own before the achievement of the author. Science allows a gulf to yawn between the hereditary and constitutional preconditions of a delusion and its creations, which seem to emerge ready-made - a gulf which we find that our author has filled. Science does not as yet suspect the importance of repression, it does not recognize that in order to explain the world of psychopathological phenomena the unconscious is absolutely essential, it does not look for the basis of delusions in a psychical conflict, and it does not regard their symptoms as compromises. Does our author stand alone, then, in the face of united science? No, that is not the case (if, that is, I may count my own works as part of science), since for a number of years - and, until recently, more or less alone¹ - I myself have supported all the views that I have here extracted from Jensen's *Gradiva* and stated in technical terms. I indicated, in most detail in connection with the states known as hysteria and obsessions, that the individual determinant of these psychical disorders is the suppression of a part of instinctual life and the repression of the ideas by which the suppressed instinct is represented, and soon afterwards I repeated the same views in relation to some forms of delusion.² The question whether the instincts concerned in this causation are always components of the sexual instinct or may be of another kind as well is a problem which may be regarded as a matter of indifference in the particular case of the analysis of *Gradiva*; for in the instance chosen by our author what was at issue was quite certainly nothing other than the suppression of erotic feelings. The validity of the hypotheses of psychical conflict and of the formation of symptoms by means of compromises between the two mental currents struggling against each other has been demonstrated by me in the case of patients observed and medically treated in real life, just as I have been able to in the imaginary case of Norbert Hanold.³ Even before me, Pierre Janet, a pupil of the great Charcot, and Josef Breuer, in collaboration with me, had traced back the products of neurotic, and especially of hysterical, illness to the power of unconscious thoughts.⁴

We find, accordingly: an erotic instinct and a revolt against it; a wish which has not yet become compulsive and, struggling against it, a fear which is already compulsive; a distressing affect and an impulsion towards the performance of defensive acts. The inventory of the neurosis has reached its full muster. Indeed, something more is present, namely, a kind of delusion or delirium with the strange content that his parents knew his thoughts because he spoke them out loud without his hearing himself do it. We shall not go far astray if we suppose that in making this attempt at an explanation the child had some inkling of those remarkable mental processes which we describe as unconscious and which we cannot dispense with if we are to throw any scientific light upon this obscure subject. 'I speak my thoughts out loud, without hearing them' sounds like a projection into the external world of our own hypothesis that he had thoughts without knowing anything about them; it sounds like an endopsychic perception of what has been repressed.

Only vague intelligence of these events reached the patient's consciousness. But his revolt against the captain's order and the sudden transformation of that revolt into its opposite were both represented there. First had come the idea that he was *not* to pay back the money, or it (that is, the rat punishment) would happen; and then had come the transformation of this idea into a vow to the opposite effect, as a punishment for his revolt.
In the second place, we cannot help being struck by the fact that a sense of guilt has about it much of the nature of anxiety: we could describe it without any misgivings as 'dread of conscience'. But the anxiety points to unconscious sources. The psychology of the neuroses has taught us that, if wishful impulses are repressed, their libido is transformed into anxiety. And this reminds us that there is something unknown and unconscious in connection with the sense of guilt, namely the reasons for the act of repudiation. The character of anxiety that is inherent in the sense of guilt corresponds to this unknown factor.

[1912-1913, 2713]

It is in obsessional neuroses that the survival of the omnipotence of thoughts is most clearly visible and that the consequences of this primitive mode of thinking come closest to consciousness. But we must not be misled into supposing that it is a distinguishing feature of this particular neurosis, for analytic investigation reveals the same thing in the other neuroses as well. In all of them what determines the formation of symptoms is the reality not of experience but of thought. Neurotics live in a world apart, where, as I have said elsewhere, only 'neurotic currency' is legal tender; that is to say, they are only affected by what is thought with intensity and pictured with emotion, whereas agreement with external reality is a matter of no importance. What hysterics repeat in their attacks and fix by means of their symptoms are experiences which have occurred in that form only in their imagination though it is true that in the last resort those imagined experiences go back to actual events or are based upon them. To attribute the neurotic sense of guilt to real misdeeds would show an equal misunderstanding. An obsessional neurotic may be weighed down by a sense of guilt that would be appropriate in a mass-murderer, while in fact, from his childhood onwards, he has behaved to his fellow-men as the most considerate and scrupulous member of society. Nevertheless, his sense of guilt has a justification: it is founded on the intense and frequent death wishes against his fellows which are unconsciously at work in him. It has a justification if what we take into account are unconscious thoughts and not intentional deeds. Thus the omnipotence of thoughts, the overvaluation of mental processes as compared with reality, is seen to have unrestricted play in the emotional life of neurotic patients and in everything that derives from it. If one of them undergoes psycho-analytic treatment, which makes what is unconscious in him conscious, he will be unable to believe that thoughts are free and will constantly be afraid of expressing evil wishes, as though their expression would lead inevitably to their fulfilment. This behaviour, as well as the superstitions which he practises in ordinary life, reveals his resemblance to the savages who believe they can alter the external world by mere thinking.

[1912-1913, 2729]
But can psycho-analysis do more here? Yes, it actually can. I hope to be able to show you that, even in a case so hard of access as this, it can discover something which makes a first understanding possible. And to begin with I would draw your attention to the inconspicuous detail that the patient herself positively provoked the anonymous letter, which now gave support to her delusion, by informing the scheming housemaid on the previous day that it would cause her the greatest unhappiness if her husband had a love affair with a young girl. In this way she first put the notion of sending the anonymous Letter into the housemaid’s head. Thus the delusion acquires a certain independence of the letter; it had been present already in the patient as a fear - or was it as a wish? Let us now add to this the small further indications yielded by only two analytic sessions. The patient, indeed, behaved in a very unco-operative way when, after telling me her story, she was asked for her further thoughts, ideas and memories. She said that nothing occurred to her, that she had told me everything already, and after two sessions the experiment with me had in fact to be broken off because she announced that she already felt well and that she was sure the pathological idea would not come back. She only said this, of course, from resistance and from dread of the continuation of the analysis. Nevertheless, during these two sessions she let fall a few remarks which allowed of, and indeed necessitated, a particular interpretation; and this interpretation threw a clear light on the genesis of her delusion of jealousy. She herself was intensely in love with a young man, with the same son-in-law who had persuaded her to come to me as a patient. She herself knew nothing, or perhaps only a very little, of this love; in the family relationship that existed between them it was easy for this passionate liking to disguise itself as innocent affection. After all our experiences elsewhere, it is not hard for us to feel our way into the mental life of this upright wife and worthy mother, of the age of fifty-three. Being in love like this, a monstrous and impossible thing, could not become conscious; but it remained in existence and, even though it was unconscious, it exercised a severe pressure. Something had to become of it, some relief had to be looked for; and the easiest mitigation was offered, no doubt, by the mechanism of displacement which plays a part so regularly in the generating of delusional jealousy. If not only were she, the old woman, in love with a young man, but if also her old husband were having a love affair with a young girl, then her conscience would be relieved of the weight of her unfaithfulness. The phantasy of her husband’s unfaithfulness thus acted as a cooling compress on her burning wound. Her own love had not become conscious to her, but its mirror-reflection, which brought her such an advantage, now became conscious as an obsession and delusion. No arguments against it could, of course, have any effect, for they were only directed against the mirror-image and not against the original which gave the other its strength and which lay hidden, inviolable, in the unconscious.

[1916-1917, 3334]
The link with the scene after her unhappy wedding-night and the patient's affectionate motive constituted, taken together, what we have called the 'sense' of the obsessional action. But while she was carrying out the obsessional action this sense had been unknown to her in both directions - both its 'whence' and its 'whither'. Mental processes had therefore been at work in her and the obsessional action was the effect of them; she had been aware of this effect in a normal mental fashion, but none of the mental predeterminants of this effect came to the knowledge of her consciousness. She behaved in precisely the same way as a hypnotized subject whom Bernheim had ordered to open an umbrella in the hospital ward five minutes after he woke up. The man carried out this instruction when he was awake, but he could produce no motive for his action. It is a state of affairs of this sort that we have before our eyes when we speak of the existence of unconscious mental processes. We can challenge anyone in the world to give a more correct scientific account of this state of affairs, and if he does we will gladly renounce our hypothesis of unconscious mental processes. Till that happens, however, we will hold fast to the hypothesis; and if someone objects that here the unconscious is nothing real in a scientific sense, is a makeshift, une façon de parler, we can only shrug our shoulders resignedly and dismiss what he says as unintelligible. Something not real, which produces effects of such tangible reality as an obsessional action!
[1916-1917, 3354]

And we meet with what is in essence the same thing in our second patient. She had made a rule that the pillow must not touch the back of the bedstead, and she had to obey this rule though she did not know where it came from, what it meant or to what motives it owed its power. Whether she herself regarded the rule as a matter of indifference, or whether she struggled against it or raged against it or decided to transgress it - none of this made any difference to her carrying it out. It had to be obeyed, and she asked herself vainly why. We must recognize, however, that these symptoms of obsessional neurosis, these ideas and impulses which emerge one knows not whence, which prove so resistant to every influence from an otherwise normal mind, which give the patient himself the impression of being all-powerful guests from an alien world, immortal beings intruding into the turmoil of mortal life - these symptoms offer the plainest indication of there being a special region of the mind, shut off from the rest. They lead, by a path that cannot be missed, to a conviction of the existence of the unconscious in the mind; and that is precisely why clinical psychiatry, which is acquainted only with a psychology of consciousness, can deal with these symptoms in no other way than by declaring them to be signs of a special sort of degeneracy. Obsessional ideas and obsessional impulses are not, of course, themselves unconscious, any more than the performance of obsessional actions escapes conscious perception. They would not have become symptoms if they had not forced their way into consciousness. But their psychical predeterminants which we infer by means of analysis, the connections into which we insert them by interpretation, are unconscious, at least until we have made them conscious to the patient by the work of analysis.
[1916-1917, 3355]
If, now, you consider further that the state of affairs which we have established in our two cases is confirmed for every symptom of every neurotic illness - that always and everywhere the sense of the symptoms is unknown to the patient and that analysis regularly shows that these symptoms are derivatives of unconscious processes but can, subject to a variety of favourable circumstances, be made conscious - if you consider this, you will understand that in psychoanalysis we cannot do without what is at the same time unconscious and mental, and are accustomed to operate with it as though it were something palpable to the senses. But you will understand as well, perhaps, how incapable of forming a judgement on this question are all those other people, who are only acquainted with the unconscious as a concept, who have never carried out an analysis and have never interpreted dreams or found a sense and intention in neurotic symptoms. To say it for our ends once again: the possibility of giving a sense to neurotic symptoms by analytic interpretation is an unshakeable proof of the existence - or, if you prefer it, of the necessity for the hypothesis - of unconscious mental processes.

[1916-1917, 3356]

But that is not all. Thanks to a second discovery of Breuer's, which seems to me even more significant than the other and which he shared with no one, we learn still more of the connection between neurotic symptoms and the unconscious. Not only is the sense of the symptoms regularly unconscious, but there is an inseparable relation between this fact of the symptoms being unconscious and the possibility of their existing. You will understand me in a moment. I follow Breuer in asserting that every time we come upon a symptom we can infer that there are certain definite unconscious processes in the patient which contain the sense of the symptom. But it is also necessary for that sense to be unconscious in order that the symptom can come about. Symptoms are never constructed from conscious processes; as soon as the unconscious processes concerned have become conscious, the symptom must disappear. Here you will at once perceive a means of approach to therapy, a way of making symptoms disappear. And in this way Breuer did in fact restore his hysterical patient - that is, freed her from her symptoms; he found a technique for bringing to her consciousness the unconscious processes which contained the sense of the symptoms, and the symptoms disappeared.

[1916-1917, 3356]

'The whole process, however, only becomes possible through the single circumstance that you are mistaken in another important point as well. You feel sure that you are informed of all that goes on in your mind if it is of any importance at all, because in that case, you believe, your consciousness gives you news of it. And if you have had no information of something in your mind you confidently assume that it does not exist there. Indeed, you go so far as to regard what is "mental" as identical with what is "conscious" - that is, with what is known to you in spite of the most obvious evidence that a great deal more must constantly be going on in your mind than can be known to your consciousness. Come, let yourself be taught something on this one point! What is in your mind does not coincide with what you are conscious of; whether something is going on in your mind and whether you hear of it, are two different things. In the ordinary way, I will admit, the intelligence which reaches your consciousness is enough for your needs; and you may cherish the illusion that you learn of all the more important things. But in some cases, as in that of an instinctual conflict such as I have described, your intelligence service breaks down and your will then extends no further than your knowledge. In every case, however, the news that reaches your consciousness is incomplete and often not to be relied on. Often enough, too, it happens that you get news of events only when they are over and when you can no longer do anything to change them. Even if you are not ill, who can tell all that is stirring in your mind of which you know nothing or are falsely informed? You behave like an absolute ruler who is content with the information supplied him by his highest officials and never goes among the people to hear their voice. Turn your eyes inward, look into your own depths, learn first to know yourself! Then you will understand why you were bound to fall ill; and perhaps, you will avoid falling ill in future.'

[1917a, 3614]
But this episode, though it is now closed, was not without an important influence on the spread of psycho-analysis. Medical men who had hitherto held back from any approach to psycho-analytic theories were brought into closer contact with them when, in the course of their duties as army doctors, they were obliged to deal with war neuroses. The reader will be able to gather from Ferenczi's paper with what hesitations and under what disguises these closer contacts were made. Some of the factors which psycho-analysis had recognized and described long before as being at work in peace-time neuroses - the psychogenic origin of the symptoms, the importance of unconscious instinctual impulses, the part played in dealing with mental conflicts by the primary gain from being ill ('the flight into illness') - were observed to be present equally in the war neuroses and were accepted almost universally. Simmel's studies show, too, what successes could be achieved by treating war neurotics by the method of catharsis, which, as we know, was the first step towards the psycho-analytic technique.

[1919d, 3665]

What is known as the psycho-analytic school of psychiatry, which was brought into being by me, had taught for the last twenty-five years that the neuroses of peace could be traced back to disturbances of emotional life. This explanation was now applied quite generally to war neurotics. We had further asserted that neurotic patients suffered from mental conflicts and that the wishes and inclinations which were expressed in the symptoms were unknown to the patients themselves - were, that is to say, unconscious. It was therefore easy to infer that the immediate cause of all war neuroses was an unconscious inclination in the soldier to withdraw from the demands, dangerous or outrageous to his feelings, made upon him by active service. Fear of losing his own life, opposition to the command to kill other people, rebellion against the ruthless suppression of his own personality by his superiors - these were the most important affective sources on which the inclination to escape from war was nourished.

[1919d, 3669]

A soldier in whom these affective motives were very powerful and clearly conscious would, if he was a healthy man, have been obliged to desert or pretend to be ill. Only the smallest proportion of war neurotics, however, were malingerers; the emotional impulses which rebelled in them against active service and drove them into illness were operative in them without becoming conscious to them. They remained unconscious because other motives, such as ambition, self-esteem, patriotism, the habit of obedience and the example of others, were to start with more powerful until, on some appropriate occasion, they were overwhelmed by the other, unconsciously operating motives.

[1919d, 3670]
For a time psycho-analysis seemed fated to merge into psychology without being able to show why the psychology of the sick differed from that of the normal. In the course of its advance, however, it came up against the problem of dreams, which are abnormal products of the mind created by normal men under regularly recurrent physiological conditions. When psycho-analysis had solved the problem of dreams, it had discovered in unconscious psychical processes the common ground in which the highest and the lowest of mental impulses have their roots and from which spring the most normal as well as the most morbid and erratic of mental productions. The new picture of the workings of the mind began to grow ever clearer and more complete. It was a picture of obscure instinctual forces organic in origin, striving towards inborn aims, and, above them, of an agency comprising more highly organized mental structures - acquisitions of human evolution made under the impact of human history -, an agency which has taken over portions of the instinctual impulses, has developed them further or has even directed them towards higher aims, but which in any case binds them firmly and manipulates their energy to suit its own purposes. This higher organization, however, which is known to us as the ego, has rejected another portion of these same elementary instinctual impulses as being unserviceable because they cannot be fitted into the organic unity of the individual or because they rebel against the individual's cultural aims. The ego is not in a position to exterminate these unsubdued mental powers, but it turns its back on them, lets them remain at the lowest psychological level, defends itself from their demands by the energetic erection of protective and antithetical barriers or seeks to come to terms with them by means of substitutive satisfactions. These instincts which have fallen victim to repression - untamed and indestructible, yet inhibited from any kind of activity - together with their primitive mental representatives, constitute the mental underworld, the nucleus of the true unconscious, and are at every moment ready to assert their demands and, by hook or by crook, to force their way forward to satisfaction. To this is due the instability of the proud superstructure of the mind, the emergence at night of the proscribed and repressed material in the form of dreams, and the tendency to fall ill with neuroses and psychoses as soon as the balance of power between the ego and the repressed shifts to the disadvantage of the ego.

[1919g, 3703]
I cannot neglect this opportunity of expressing for once my astonishment that human beings can go through such great and important moments of their erotic life without noticing them much, sometimes even, indeed, without having the faintest suspicion of their existence, or else, having become aware of those moments, deceive themselves so thoroughly in their judgement of them. This happens not only under neurotic conditions, where we are familiar with the phenomenon, but seems also to be common enough in ordinary life. In the present case, for example, a girl develops a sentimental adoration for women, which her parents at first find merely vexatious and hardly take seriously; she herself knows quite well that she is very much occupied with these relationships, but still she experiences few of the sensations of intense love until a particular frustration is followed by a quite excessive reaction, which shows everyone concerned that they have to do with a consuming passion of elemental strength. Nor had the girl ever perceived anything of the state of affairs which was a necessary preliminary to the outbreak of this mental storm. In other cases, too, we come across girls or women in a state of severe depression, who on being asked for a possible cause of their condition tell us that they have, it is true, had a slight feeling for a certain person, but that it was nothing deep and that they soon got over it when they had to give it up. And yet it was this renunciation, apparently so easily borne, that became the cause of serious mental disturbance. Again, we come across men who have passed through casual love-affairs and realize only from the subsequent effects that they had been passionately in love with the person whom they had apparently regarded lightly. One is also amazed at the unexpected results that may follow an artificial abortion, the killing of an unborn child, which had been decided upon without remorse and without hesitation. It must be admitted that poets are right in liking to portray people who are in love without knowing it, or uncertain whether they do love, or who think that they hate when in reality they love. It would seem that the information received by our consciousness about our erotic life is especially liable to be incomplete, full of gaps, or falsified. Needless to say, in this discussion I have not omitted to allow for the part played by subsequent forgetting.

But the study of pathogenic repressions and of other phenomena which have still to be mentioned compelled psycho-analysis to take the concept of the 'unconscious' seriously. Psycho-analysis regarded everything mental as being in the first instance unconscious; the further quality of 'consciousness' might also be present, or again it might be absent. This of course provoked a denial from the philosophers, for whom 'conscious' and 'mental' were identical, and who protested that they could not conceive of such an absurdity as the 'unconscious mental'. There was no help for it, however, and this idiosyncrasy of the philosophers could only be disregarded with a shrug. Experience (gained from pathological material, of which the philosophers were ignorant) of the frequency and power of impulses of which one knew nothing directly, and whose existence had to be inferred like some fact in the external world, left no alternative open. It could be pointed out, incidentally, that this was only treating one's own mental life as one had always treated other people's. One did not hesitate to ascribe mental processes to other people, although one had no immediate consciousness of them and could only infer them from their words and actions. But what held good for other people must be applicable to oneself. Anyone who tried to push the argument further and to conclude from it that one's own hidden processes belonged actually to a second consciousness would be faced with the concept of a consciousness of which one knew nothing, of an 'unconscious consciousness' - and this would scarcely be preferable to the assumption of an 'unconscious mental'. If on the other hand one declared, like some other philosophers, that one was prepared to take pathological phenomena into account, but that the processes underlying them ought not to be described as mental but as 'psychoid', the difference of opinion would degenerate into an unfruitful dispute about words, though even so expediency would decide in favour of keeping the expression 'unconscious mental'. The further question as to the ultimate nature of this unconscious is no more sensible or profitable than the older one as to the nature of the conscious.
Thus we have attributed three qualities to psychical processes: they are either conscious, preconscious or unconscious. The division between the three classes of material which possess these qualities is neither absolute nor permanent. What is preconscious becomes conscious, as we have seen, without any assistance from us; what is unconscious can, through our efforts, be made conscious, and in the process we may have a feeling that we are often overcoming very strong resistances. When we attempt to do this with someone else, we should not forget that the conscious filling-in of the gaps in his perceptions - the construction we are presenting him with - does not mean as yet that we have made the unconscious material in question conscious to him. All that is true so far is that the material is present in him in two records, once in the conscious reconstruction he has been given, and besides this in its original unconscious state. Our continued efforts usually succeed eventually in making this unconscious material conscious to him himself, as a result of which the two records are brought to coincide. The amount of effort we have to use, by which we estimate the resistance against the material becoming conscious, varies in magnitude in individual cases. For instance, what comes about in an analytic treatment as a result of our efforts can also occur spontaneously: material which is ordinarily unconscious can transform itself into preconscious material and then becomes conscious - a thing that happens to a large extent in psychotic states. From this we infer that the maintenance of certain internal resistances is a *sine qua non* of normality. A relaxation of resistances such as this, with a consequent pushing forward of unconscious material, takes place regularly in the state of sleep, and thus brings about a necessary precondition for the construction of dreams. Conversely, preconscious material can become temporarily inaccessible and cut off by resistances, as happens when something is temporarily forgotten or escapes the memory; or a preconscious thought can even be temporarily put back into the unconscious state, as seems to be a precondition in the case of jokes. We shall see that a similar transformation back of preconscious material or processes into the unconscious state plays a great part in the causation of neurotic disorders.

The facts of this splitting of the ego, which we have just described, are neither so new nor so strange as they may at first appear. It is indeed a universal characteristic of neuroses that there are present in the subject's mental life, as regards some particular behaviour, two different attitudes, contrary to each other and independent of each other. In the case of neuroses, however, one of these attitudes belongs to the ego and the contrary one, which is repressed, belongs to the id. The difference between this case and the other is essentially a topographical or structural one, and it is not always easy to decide in an individual instance with which of the two possibilities one is dealing. They have, however, the following important characteristic in common. Whatever the ego does in its efforts of defence, whether it seeks to disavow a portion of the real external world or whether it seeks to reject an instinctual demand from the internal world, its success is never complete and unqualified. The outcome always lies in two contrary attitudes, of which the defeated, weaker one, no less than the other, leads to psychical complications. In conclusion, it is only necessary to point out how little of all these processes becomes known to us through our conscious perception.
It is a surprising thing that the tragedy of Sophocles does not call up indignant repudiation in his audience - a reaction similar to that of our simple-minded army doctor but far better justified. For fundamentally it is an amoral work: it absolves men from moral responsibility, exhibits the gods as promoters of crime and shows the impotence of the moral impulses of men which struggle against crime. It might easily be supposed that the material of the legend had in view an indictment of the gods and of fate; and in the hands of Euripides, the critic and enemy of the gods, it would probably have become such an indictment. But with the devout Sophocles there is no question of an application of that kind. The difficulty is overcome by the pious sophistry that to bow to the will of the gods is the highest morality even when it promotes crime. I cannot think that this morality is a strong point of the play, but it has no influence on its effect. It is not to it that the auditor reacts but to the secret sense and content of the legend. He reacts as though by self-analysis he had recognized the Oedipus complex in himself and had unveiled the will of the gods and the oracle as exalted disguises of his own unconscious. It is as though he was obliged to remember the two wishes - to do away with his father and in place of him to take his mother to wife - and to be horrified at them. And he understands the dramatist's voice as though it were saying to him: 'You are struggling in vain against your responsibility and are protesting in vain of what you have done in opposition to these criminal intentions. You are guilty, for you have not been able to destroy them; they still persist in you unconsciously.' And there is psychological truth contained in this. Even if a man has repressed his evil impulses into the unconscious and would like to tell himself afterwards that he is not responsible for them, he is nevertheless bound to be aware of this responsibility as a sense of guilt whose basis is unknown to him.

[1916-1917, 3398]

Internal perceptions yield sensations of processes arising in the most diverse and certainly also in the deepest strata of the mental apparatus. Very little is known about these sensations and feelings; those belonging to the pleasure-unpleasure series may still be regarded as the best examples of them. They are more primordial, more elementary, than perceptions arising externally and they can come about even when consciousness is clouded. I have elsewhere expressed my views about their greater economic significance and the metapsychological reasons for this. These sensations are multilocular, like external perceptions; they may come from different places simultaneously and may thus have different or even opposite qualities. [1923b, 3956]
In which of these systems, then, are we to locate the impetus to the construction of dreams? For simplicity's sake, in the system Ucs. It is true that in the course of our future discussion we shall learn that this is not entirely accurate, and that the process of forming dreams is obliged to attach itself to dream-thoughts belonging to the preconscious system. But when we consider the dream-wish, we shall find that the motive force for producing dreams is supplied by the Ucs.; and owing to this latter factor we shall take the unconscious system as the starting-point of dream-formation. Like all other thought structures, this dream-instigator will make an effort to advance into the Pcs. and from there to obtain access to consciousness.

[1900a, 974]

Unpleasurable dreams may also be 'punishment-dreams'. It must be admitted that their recognition means in a certain sense a new addition to the theory of dreams. What is fulfilled in them is equally an unconscious wish, namely a wish that the dreamer may be punished for a repressed and forbidden wishful impulse. To that extent dreams of this kind fall in with the condition that has been laid down here that the motive force for constructing a dream must be provided by a wish belonging to the unconscious. A closer psychological analysis, however, shows how they differ from other wishful dreams. In the cases forming Group B the dream-constructing wish is an unconscious one and belongs to the repressed, while in punishment-dreams, though it is equally an unconscious one, it must be reckoned as belonging not to the repressed but to the 'ego.' Thus punishment-dreams indicate the possibility that the ego may have a greater share than was supposed in the construction of dreams. The mechanism of dream-formation would in general be greatly clarified if instead of the opposition between 'conscious' and 'unconscious' we were to speak of that between the 'ego' and the 'repressed.' This cannot be done, however, without taking account of the processes underlying the psychoneuroses, and for that reason it has not been carried out in the present work. I will only add that punishment-dreams are not in general subject to the condition that the day's residues shall be of a distressing kind. On the contrary, they occur most easily where the opposite is the case - where the day's residues are thoughts of a satisfying nature but the satisfaction which they express is a forbidden one. The only trace of these thoughts that appears in the manifest dream is their diametric opposite, just as in the case of dreams belonging to Group A. The essential characteristic of punishment-dreams would thus be that in their case the dream-constructing wish is not an unconscious wish derived from the repressed (from the system Ucs.), but a punitive one reacting against it and belonging to the ego, though at the same time an unconscious (that is to say, preconscious) one.¹

[1900a, 990]
It is not without intention that I speak of 'our' unconscious. For what I thus describe is not the same as the unconscious of the philosophers or even the unconscious of Lipps. By them the term is used merely to indicate a contrast with the conscious: the thesis which they dispute with so much heat and defend with so much energy is the thesis that apart from conscious there are also unconscious psychical processes. Lipps carries things further with his assertion that the whole of what is psychical exists unconsciously and that a part of it also exists consciously. But it is not in order to establish this thesis that we have summoned up the phenomena of dreams and of the formation of hysterical symptoms; the observation of normal waking life would by itself suffice to prove it beyond any doubt. The new discovery that we have been taught by the analysis of psychopathological structures and of the first member of that class - the dream - lies in the fact that the unconscious (that is, the psychical) is found as a function of two separate systems and that this is the case in normal as well as in pathological life. Thus there are two kinds of unconscious, which have not yet been distinguished by psychologists. Both of them are unconscious in the sense used by psychology; but in our sense one of them, which we term the Ucs., is also inadmissible to consciousness, while we term the other the Pcs. because its excitations - after observing certain rules, it is true, and perhaps only after passing a fresh censorship, though nonetheless without regard to the Ucs. - are able to reach consciousness. The fact that excitations in order to reach consciousness must pass through a fixed series or hierarchy of agencies (which is revealed to us by the modifications made in them by censorship) has enabled us to construct a spatial analogy. We have described the relations of the two systems to each other and to consciousness by saying that the system Pcs. stands like a screen between the system Ucs. and consciousness. The system Pcs. not merely bars access to consciousness, it also controls access to the power of voluntary movement and has at its disposal for distribution a mobile cathectic energy, a part of which is familiar to us in the form of attention.²

The achievements of the dream-work can, however, be described as follows. A tissue of thoughts, usually a very complicated one, which has been built up during the day and has not been completely dealt with - 'a day's residue' - continues during the night to retain the quota of energy - the 'interest' claimed by it, and threatens to disturb sleep. This 'day's residue' is transformed by the dream-work into a dream and made innocuous to sleep. In order to provide a fulcrum for the dream-work, the 'day's residue' must be capable of constructing a wish - which is not a very hard condition to fulfil. The wish arising from the dream-thoughts forms the preliminary stage and later the core of the dream. Experience derived from analyses - and not the theory of dreams - informs us that in children any wish left over from waking life is sufficient to call up a dream, which emerges as connected and ingenious but usually short, and which is easily recognized as a 'wish-fulfilment'. In the case of adults it seems to be a generally binding condition that the wish which creates the dream shall be one that is alien to conscious thinking - a repressed wish - or will possibly at least have reinforcements that are unknown to consciousness. Without assuming the existence of the unconscious in the sense explained above, I should not be able to develop the theory of dreams further or to interpret the material met with in dream-analyses. The action of this unconscious wish upon the consciously rational material of the dream-thoughts produces the dream. While this happens, the dream is, as it were, dragged down into the unconscious, or, more precisely, is submitted to a treatment such as is met with at the level of unconscious thought-processes and is characteristic of that level. Hitherto it is only from the results of the 'dream-work' that we are in fact acquainted with the characteristics of unconscious thinking and its differences from thinking that is capable of becoming conscious - 'preconscious' thinking.

[1900a, 1039]

[1905c, 1746]
Apart from the dream-work and the technique of jokes, there is another kind of mental event in which I have been able to show that condensation is a regular and important process: namely the mechanism of normal (non-tendentious) forgetting. Unique impressions offer difficulties to forgetting; those that are analogous in any way are forgotten by being condensed in regard to their points of resemblance. Confusion between analogous impressions is one of the preliminary stages of forgetting.

But we have more to learn from such an experiment. We are led from the purely descriptive to a dynamic view of the phenomenon. The idea of the action ordered in hypnosis not only became an object of consciousness at a certain moment, but the more striking aspect of the fact is that this idea grew active: it was translated into action as soon as consciousness became aware of its presence. The real stimulus to the action being the order of the physician, it is hard not to concede that the idea of the physician's order became active too. Yet this last idea did not reveal itself to consciousness, as did its outcome, the idea of the action; it remained unconscious, and so it was active and unconscious at the same time.

We learn therefore by the analysis of neurotic phenomena that a latent or unconscious idea is not necessarily a weak one, and that the presence of such an idea in the mind admits of indirect proofs of the most cogent kind, which are equivalent to the direct proof furnished by consciousness. We feel justified in making our classification agree with this addition to our knowledge by introducing a fundamental distinction between different kinds of latent or unconscious ideas. We were accustomed to think that every latent idea was so because it was weak and that it grew conscious as soon as it became strong. We have not gained the conviction that there are some latent ideas which do not penetrate into consciousness, however strong they may have become. Therefore we may call the latent ideas of the first type foreconscious,¹ while we reserve the term unconscious (proper) for the latter type which we came to study in the neuroses. The term unconscious, which was used in the purely descriptive sense before, now comes to imply something more. It designates not only latent ideas in general, but especially ideas with a certain dynamic character, ideas keeping apart from consciousness in spite of their intensity and activity.

By the differentiation of foreconscious and unconscious ideas, we are led on to leave the field of classification and to form an opinion about functional and dynamical relations in psychical action. We have found a foreconscious activity passing into consciousness with no difficulty, and an unconscious activity which remains so and seems to be cut off from consciousness.
Now we do not know whether these two modes of psychical activity are identical or essentially divergent from their beginning, but we may ask why they should become different in the course of psychical action. To this last question psycho-analysis gives a clear and unhesitating answer. It is by no means impossible for the product of unconscious activity to pierce into consciousness, but a certain amount of exertion is needed for this task. When we try to do it in ourselves, we become aware of a distinct feeling of repulsion which must be overcome, and when we produce it in a patient we get the most unquestionable signs of what we call his resistance to it. So we learn that the unconscious idea is excluded from consciousness by living forces which oppose themselves to its reception, while they do not object to other ideas, the foreconscious ones. Psycho-analysis leaves no room for doubt that the repulsion from unconscious ideas is only provoked by the tendencies embodied in their contents. The next and most probable theory which can be formulated at this stage of our knowledge is the following. Unconsciousness is a regular and inevitable phase in the processes constituting our psychical activity; every psychical act begins as an unconscious one, and it may either remain so or go on developing into consciousness, according as it meets with resistance or not. The distinction between foreconscious and unconscious activity is not a primary one, but comes to be established after repulsion has sprung up. Only then the difference between foreconscious ideas, which can appear in consciousness and reappear at any moment, and unconscious ideas which cannot do so gains a theoretical as well as a practical value. A rough but not inadequate analogy to this supposed relation of conscious to unconscious activity might be drawn from the field of ordinary photography. The first stage of the photograph is the 'negative'; every photographic picture has to pass through the 'negative process', and some of these negatives which have held good in examination are admitted to the 'positive process' ending in the picture.

But the distinction between foreconscious and unconscious activity, and the recognition of the barrier which keeps them asunder, is not the last or the most important result of the psycho-analytic investigation of psychical life. There is one psychical product to be met with in the most normal persons, which yet presents a very striking analogy to the wildest productions of insanity, and was no more intelligible to philosophers than insanity itself. I refer to dreams. Psycho-analysis is founded upon the analysis of dreams; the interpretation of dreams is the most complete piece of work the young science has done up to the present. One of the most common types of dream-formation may be described as follows: a train of thoughts has been aroused by the working of the mind in the daytime, and retained some of its activity, escaping from the general inhibition of interests which introduces sleep and constitutes the psychical preparation for sleeping. During the night this train of thoughts succeeds in finding connections with one of the unconscious tendencies present ever since his childhood in the mind of the dreamer, but ordinarily repressed and excluded from his conscious life. By the borrowed force of this unconscious help, the thoughts, the residue of the day's work, now become active again, and emerge into consciousness in the shape of the dream. Now three things have happened:
Before going any further, let us state the important, though inconvenient, fact that the attribute of being unconscious is only one feature that is found in the psychical and is by no means sufficient fully to characterize it. There are psychical acts of very varying value which yet agree in possessing the characteristic of being unconscious. The unconscious comprises, on the one hand, acts which are merely latent, temporarily unconscious, but which differ in no other respect from conscious ones and, on the other hand, processes such as repressed ones, which if they were to become conscious would be bound to stand out in the crudest contrast to the rest of the conscious processes. It would put an end to all misunderstandings if, from now on, in describing the various kinds of psychical acts we were to disregard the question of whether they were conscious or unconscious, and were to classify and correlate them only according to their relation to instincts and aims, according to their composition and according to which of the hierarchy of psychical systems they belong to. This, however, is for various reasons impracticable, so that we cannot escape the ambiguity of using the words 'conscious' and 'unconscious' sometimes in a descriptive and sometimes in a systematic sense, in which latter they signify inclusion in particular systems and possession of certain characteristics. We might attempt to avoid confusion by giving the psychical systems which we have distinguished certain arbitrarily chosen names which have no reference to the attribute of being conscious. Only we should first have to specify what the grounds are on which we distinguish the systems, and in doing this we should not be able to evade the attribute of being conscious, seeing that it forms the point of departure for all our investigations. Perhaps we may look for some assistance from the proposal to employ, at any rate in writing, the abbreviation Cs. for consciousness and Ucs. for what is unconscious, when we are using the two words in the systematic sense.

[1915e, 2996]

Proceeding now to an account of the positive findings of psycho-analysis, we may say that in general a psychical act goes through two phases as regards its state, between which is interposed a kind of testing (censorship). In the first phase the psychical act is unconscious and belongs to the system Ucs.; if, on testing, it is rejected by the censorship, it is not allowed to pass into the second phase; it is then said to be 'repressed' and must remain unconscious. If, however, it passes this testing, it enters the second phase and thenceforth belongs to the second system, which we will call the system Cs. But the fact that it belongs to that system does not yet unequivocally determine its relation to consciousness. It is not yet conscious, but it is certainly capable of becoming conscious (to use Breuer's expression) - that is, it can now, given certain conditions, become an object of consciousness without any special resistance. In consideration of this capacity for becoming conscious we also call the system Cs. the 'preconscious'. If it should turn out that a certain censorship also plays a part in determining whether the preconscious becomes conscious, we shall discriminate more sharply between the systems Pcs. and Cs. For the present let it suffice us to bear in mind that the system Pcs. shares the characteristics of the system Cs. and that the rigorous censorship exercises its office at the point of transition from the Ucs. to the Pcs. (or Cs.).

[1915e, 2997]

By accepting the existence of these two (or three) psychical systems, psycho-analysis has departed a step further from the descriptive 'psychology of consciousness' and has raised new problems and acquired a new content. Up till now, it has differed from that psychology mainly by reason of its dynamic view of mental processes; now in addition it seems to take account of psychical topography as well, and to indicate in respect of any given mental act within what system or between what systems it takes place. On account of this attempt, too, it has been given the name of 'depth-psychology'. We shall hear that it can be further enriched by taking yet another point of view into account.

[1915e, 2997]
If we are to take the topography of mental acts seriously we must direct our interest to a doubt which arises at this point. When a psychical act (let us confine ourselves here to one which is in the nature of an idea) is transposed from the system $\text{Ucs.}$ into the system $\text{Cs.}$ (or $\text{Pcs.}$), are we to suppose that this transposition involves a fresh record - as it were, a second registration - of the idea in question, which may thus be situated as well in a fresh psychical locality, and alongside of which the original unconscious registration continues to exist? Or are we rather to believe that the transposition consists in a change in the state of the idea, a change involving the same material and occurring in the same locality? This question may appear abstruse, but it must be raised if we wish to form a more definite conception of psychical topography, of the dimension of depth in the mind. It is a difficult one because it goes beyond pure psychology and touches on the relations of the mental apparatus to anatomy. We know that in the very roughest sense such relations exist. Research has given irrefutable proof that mental activity is bound up with the function of the brain as it is with no other organ. We are taken a step further - we do not know how much - by the discovery of the unequal importance of the different parts of the brain and their special relations to particular parts of the body and to particular mental activities. But every attempt to go on from there to discover a localization of mental processes, every endeavour to think of ideas as stored up in nerve-cells and of excitations as travelling along nerve-fibres, has miscarried completely. The same fate would await any theory which attempted to recognize, let us say, the anatomical position of the system $\text{Cs.}$ - conscious mental activity - as being in the cortex, and to localize the unconscious processes in the sub-cortical parts of the brain. There is a hiatus here which at present cannot be filled, nor is it one of the tasks of psychology to fill it. Our psychical topography has for the present nothing to do with anatomy; it has reference not to anatomical localities, but to regions in the mental apparatus, wherever they may be situated in the body.

[1915e, 2998]

In this respect, then, our work is untrammelled and may proceed according to its own requirements. It will, however, be useful to remind ourselves that as things stand our hypotheses set out to be no more than graphic illustrations. The first of the two possibilities which we considered - namely, that the $\text{Cs.}$ phase of an idea implies a fresh registration of it, which is situated in another place - is doubtless the cruder but also the more convenient. The second hypothesis - that of a merely functional change of state - is a priori more probable, but it is less plastic, less easy to manipulate. With the first, or topographical, hypothesis is bound up that of a topographical separation of the systems $\text{Ucs.}$ and $\text{Cs.}$ and also the possibility that an idea may exist simultaneously in two places in the mental apparatus indeed, that if it is not inhibited by the censorship, it regularly advances from the one position to the other, possibly without losing its first location or registration.

[1915e, 2999]
But it would be unfair if we neglected at this point to emphasize sufficiently another outcome of our investigations. The dream-wishes which seek to disturb us in our sleep are unknown to us and indeed we only learnt of them through dream-interpretation. They are thus to be described, in the sense we have discussed, as unconscious for the time being. But we must reflect that they are unconscious too for more than the time being. The dreamer also disavows them, as we have seen in so many instances, after he has come to know them through the interpretation of his dream. We are then faced once again with the position we first came across in the 'hiccoughing' slip of the tongue, where the proposer of the toast protested indignantly that neither then nor at any earlier time had he become conscious of any disrespectful impulse towards his Chief. Already at the time we felt some doubts about the weight of an assurance of this kind, and suggested instead the hypothesis that the speaker was permanently unaware of the presence of this impulse in him. This situation is repeated now with every interpretation of a strongly distorted dream and consequently gains an increased importance in its bearing on the view we have taken. We are now prepared to assume that there are in the mind processes and purposes of which one knows nothing at all has known nothing for a long time, and has even perhaps never known anything. With this the unconscious acquires a new sense for us; the characteristic of 'for the time being' or 'temporary' disappears from its essential nature. It can mean permanently unconscious and not merely 'latent at the time'. We shall of course have to hear more about this on some other occasion.

[1916-1917, 3242]

The crudest idea of these systems is the most convenient for us - a spatial one. Let us therefore compare the system of the unconscious to a large entrance hall, in which the mental impulses jostle one another like separate individuals. Adjoining this entrance hall there is a second, narrower, room - a kind of drawing-room - in which consciousness, too, resides. But on the threshold between these two rooms a watchman performs his function: he examines the different mental impulses, acts as a censor, and will not admit them into the drawing-room if they displease him. You will see at once that it does not make much difference if the watchman turns away a particular impulse at the threshold itself or if he pushes it back across the threshold after it has entered the drawing-room. This is merely a question of the degree of his watchfulness and of how early he carries out his act of recognition. If we keep to this picture, we shall be able to extend our nomenclature further. The impulses in the entrance hall of the unconscious are out of sight of the conscious, which is in the other room; to begin with they must remain unconscious. If they have already pushed their way forward to the threshold and have been turned back by the watchman, then they are inadmissible to consciousness; we speak of them as repressed. But even the impulses which the watchman has allowed to cross the threshold are not on that account necessarily conscious as well; they can only become so if they succeed in catching the eye of consciousness. We are therefore justified in calling this second room the system of the preconscious. In that case becoming conscious retains its purely descriptive sense. For any particular impulse, however, the vicissitude of repression consists in its not being allowed by the watchman to pass from the system of the unconscious into that of the preconscious. It is the same watchman whom we get to know as resistance when we try to lift the repression by means of the analytic treatment.

[1916-1917, 3369]
Now I know you will say that these ideas are both crude and fantastic and quite impermissible in a scientific account. I know that they are crude: and, more than that, I know that they are incorrect, and, if I am not very much mistaken, I already have something better to take their place. Whether it will seem to you equally fantastic I cannot tell. They are preliminary working hypotheses, like Ampère’s manikin swimming in the electric current, and they are not to be despised in so far as they are of service in making our observations intelligible. I should like to assure you that these crude hypotheses of the two rooms, the watchman at the threshold between them and consciousness as a spectator at the end of the second room, must nevertheless be very far-reaching approximations to the real facts. And I should like to hear you admit that our terms, ‘unconscious’, ‘preconscious’ and ‘conscious’, prejudge things far less and are far easier to justify than others which have been proposed or are in use, such as ‘subconscious’, ‘paraconscious’, ‘intraconscious’ and the like.

[1916-1917, 3369]

But we have arrived at the term or concept of the unconscious along another path, by considering certain experiences in which mental dynamics play a part. We have found - that is, we have been obliged to assume - that very powerful mental processes or ideas exist (and here a quantitative or economic factor comes into question for the first time) which can produce all the effects in mental life that ordinary ideas do (including effects that can in their turn become conscious as ideas), though they themselves do not become conscious. It is unnecessary to repeat in detail here what has been explained so often before. It is enough to say that at this point psycho-analytic theory steps in and asserts that the reason why such ideas cannot become conscious is that a certain force opposes them, that otherwise they could become conscious, and that it would then be apparent how little they differ from other elements which are admittedly psychical. The fact that in the technique of psycho-analysis a means has been found by which the opposing force can be removed and the ideas in question made conscious renders this theory irrefutable. The state in which the ideas existed before being made conscious is called by us repression, and we assert that the force which instituted the repression and maintains it is perceived as resistance during the work of analysis.
[1923b, 3948]

Thus we obtain our concept of the unconscious from the theory of repression. The repressed is the prototype of the unconscious for us. We see, however, that we have two kinds of unconscious - the one which is latent but capable of becoming conscious, and the one which is repressed and which is not, in itself and without more ado, capable of becoming conscious. This piece of insight into psychical dynamics cannot fail to affect terminology and description. The latent, which is unconscious only descriptively, not in the dynamic sense, we call preconscious; we restrict the term unconscious to the dynamically unconscious repressed; so that now we have three terms, conscious (Cs.), preconscious (Pcs.), and unconscious (Ucs.), whose sense is no longer purely descriptive. The Pcs. is presumably a great deal closer to the Cs. than is the Ucs., and since we have called the Ucs. psychical we shall with even less hesitation call the latent Pcs. psychical. But why do we not rather, instead of this, remain in agreement with the philosophers and, in a consistent way, distinguish the Pcs. as well as the Ucs. from the conscious psychical? The philosophers would then propose that the Pcs. and the Ucs. should be described as two species or stages of the ‘psychoid’, and harmony would be established. But endless difficulties in exposition would follow; and the one important fact, that these two kinds of ‘psychoid’ coincide in almost every other respect with what is admittedly psychical, would be forced into the background in the interests of a prejudice dating from a period in which these psychoids, or the most important part of them, were still unknown.
[1923b, 3949]
We can now play about comfortably with our three terms, $Cs_\text{.}$, $Pcs_\text{.}$, and $Ucs_\text{.}$, so long as we do not forget that in the descriptive sense there are two kinds of unconscious, but in the dynamic sense only one. For purposes of exposition this distinction can in some cases be ignored, but in others it is of course indispensable. At the same time, we have become more or less accustomed to this ambiguity of the unconscious and have managed pretty well with it. As far as I can see, it is impossible to avoid this ambiguity; the distinction between conscious and unconscious is in the last resort a question of perception, which must be answered 'yes' or 'no', and the act of perception itself tells us nothing of the reason why a thing is or is not perceived. No one has a right to complain because the actual phenomenon expresses the dynamic factor ambiguously.¹

For our conception of the unconscious, however, the consequences of our discovery are even more important. Dynamic considerations caused us to make our first correction; our insight into the structure of the mind leads to the second. We recognize that the $Ucs_\text{.}$ does not coincide with the repressed; it is still true that all that is repressed is $Ucs_\text{.}$, but not all that is $Ucs_\text{.}$ is repressed. A part of the ego, too - and Heaven knows how important a part - may be $Ucs_\text{.}$, undoubtedly is $Ucs_\text{.}$ And this $Ucs_\text{.}$ belonging to the ego is not latent like the $Pcs_\text{.}$; for if it were, it could not be activated without becoming $Cs_\text{.}$, and the process of making it conscious would not encounter such great difficulties. When we find ourselves thus confronted by the necessity of postulating a third $Ucs_\text{.}$, which is not repressed, we must admit that the characteristic of being unconscious begins to lose significance for us. It becomes a quality which can have many meanings, a quality which we are unable to make, as we should have hoped to do, the basis of far-reaching and inevitable conclusions. Nevertheless we must beware of ignoring this characteristic, for the property of being conscious or not is in the last resort our one beacon-light in the darkness of depth-psychology.

It would be more difficult to explain concisely how it came about that psycho-analysis made a further distinction in the unconscious, and separated it into a preconscious and an unconscious proper. It will be sufficient to say that it appeared a legitimate course to supplement the theories that were a direct expression of experience with hypotheses that were designed to facilitate the handling of the material and related to matters which could not be a subject of immediate observation. The very same procedure is adopted by the older sciences. The subdivision of the unconscious is part of an attempt to picture the apparatus of the mind as being built up of a number of agencies or systems whose relations to one another are expressed in spatial terms, without, however, implying any connection with the actual anatomy of the brain. (I have described this as the topographical method of approach.) Such ideas as these are part of a speculative superstructure of psycho-analysis, any portion of which can be abandoned or changed without loss or regret the moment its inadequacy has been proved. But there is still plenty to be described that lies closer to actual experience.

¹ [1923b, 3950]
There is no need to discuss what is to be called conscious: it is removed from all doubt. The oldest and best meaning of the word 'unconscious' is the descriptive one; we call a psychical process unconscious whose existence we are obliged to assume - for some such reason as that we infer it from its effects -, but of which we know nothing. In that case we have the same relation to it as we have to a psychical process in another person, except that it is in fact one of our own. If we want to be still more correct, we shall modify our assertion by saying that we call a process unconscious if we are obliged to assume that it is being activated at the moment, though at the moment we know nothing about it. This qualification makes us reflect that the majority of conscious processes are conscious only for a short time; very soon they become latent, but can easily become conscious again. We might also say that they had become unconscious, if it were at all certain that in the condition of latency they are still something psychical. So far we should have learnt nothing new; nor should we have acquired the right to introduce the concept of an unconscious into psychology. But then comes the new observation that we were already able to make in parapraxes. In order to explain a slip of the tongue, for instance, we find ourselves obliged to assume that the intention to make a particular remark was present in the subject. We infer it with certainty from the interference with his remark which has occurred; but the intention did not put itself through and was thus unconscious. If, when we subsequently put it before the speaker, he recognizes it as one familiar to him, then it was only temporarily unconscious to him; but if he repudiates it as something foreign to him, then it was permanently unconscious. From this experience we retrospectively obtain the right also to pronounce as something unconscious what had been described as latent. A consideration of these dynamic relations permits us now to distinguish two kinds of unconscious - one which is easily, under frequently occurring circumstances, transformed into something conscious, and another with which this transformation is difficult and takes place only subject to a considerable expenditure of effort or possibly never at all. In order to escape the ambiguity as to whether we mean the one or the other unconscious, whether we are using the word in the descriptive or in the dynamic sense, we make use of a permissible and simple way out. We call the unconscious which is only latent, and thus easily becomes conscious, the 'preconscious' and retain the term 'unconscious' for the other. We now have three terms, 'conscious', 'preconscious' and 'unconscious', with which we can get along in our description of mental phenomena. Once again: the preconscious is also unconscious in the purely descriptive sense, but we do not give it that name, except in talking loosely or when we have to make a defence of the existence in mental life of unconscious processes in general.

[1933a, 4679]
You will admit, I hope, that so far that is not too bad and allows of convenient handling. Yes, but unluckily the work of psycho-analysis has found itself compelled to use the word 'unconscious' in yet another, third, sense, and this may, to be sure, have led to confusion. Under the new and powerful impression of there being an extensive and important field of mental life which is normally withdrawn from the ego's knowledge so that the processes occurring in it have to be regarded as unconscious in the truly dynamic sense, we have come to understand the term 'unconscious' in a topographical or systematic sense as well; we have come to speak of a 'system' of the preconscious and a 'system' of the unconscious, of a conflict between the ego and the system \( Ucs \), and have used the word more and more to denote a mental province rather than a quality of what is mental. The discovery, actually an inconvenient one, that portions of the ego and super-ego as well are unconscious in the dynamic sense, operates at this point as a relief - it makes possible the removal of a complication. We perceive that we have no right to name the mental region that is foreign to the ego 'the system \( Ucs \)', since the characteristic of being unconscious is not restricted to it. Very well; we will no longer use the term 'unconscious' in the systematic sense and we will give what we have hitherto so described a better name and one no longer open to misunderstanding. Following a verbal usage of Nietzsche's and taking up a suggestion by Georg Groddeck, we will in future call it the 'id'. This impersonal pronoun seems particularly well suited for expressing the main characteristic of this province of the mind - the fact of its being alien to the ego. The super-ego, the ego and the id - these, then, are the three realms, regions, provinces, into which we divide an individual's mental apparatus, and with the mutual relations of which we shall be concerned in what follows.

[1933a, 4680]

The difference between whether a psychical process is conscious or unconscious has served us as a criterion and a means of finding our bearings. The repressed is unconscious. Now it would simplify things agreeably if this sentence admitted of reversal - if, that is, the difference between the qualities of conscious (\( Cs \)) and unconscious (\( Ucs \)) coincided with the distinction between 'belonging to the ego' and 'repressed'. The fact of there being isolated and unconscious things like this in our mental life would be sufficiently novel and important. But in reality the position is more complicated. It is true that everything repressed is unconscious, but it is not true that everything belonging to the ego is conscious. We notice that consciousness is a transient quality which attaches to a psychical process only in passing. For our purposes therefore we must replace 'conscious' by 'capable of being conscious' and we call this quality 'preconscious' (\( Pcs \)). We then say, more correctly, that the ego is mainly preconscious (virtually conscious) but that portions of the ego are unconscious.

[1939a, 4918]

The repressed is to be counted as belonging to the id and is subject to the same mechanisms; it is distinguished from it only in respect to its genesis. The differentiation is accomplished in the earliest period of life, while the ego is developing out of the id. At that time a portion of the contents of the id is taken into the ego and raised to the preconscious state; another portion is not affected by this translation and remains behind in the id as the unconscious proper. In the further course of the formation of the ego, however, certain psychical impressions and processes in the ego are excluded from it by a defensive process; the characteristic of being preconscious is withdrawn from them, so that they are once more reduced to being component portions of the id. Here then is the 'repressed' in the id. So far as intercourse between the two mental provinces is concerned, we therefore assume that, on the one hand, unconscious processes in the id are raised to the level of the preconscious and incorporated into the ego, and that, on the other hand, preconscious material in the ego can follow the opposite path and be put back into the id. The fact that later on a special region - that of the 'super-ego' - is separated off in the ego lies outside our present interest.

[1939a, 4919]
All of this may appear to be far from simple. But when one has grown reconciled to this
unusual spatial view of the mental apparatus, it can present no particular difficulties to the
imagination. I will add the further comment that the psychical topography that I have developed
here has nothing to do with the anatomy of the brain, and actually only touches it at one point.
What is unsatisfactory in this picture - and I am aware of it as clearly as anyone - is due to our
complete ignorance of the \textit{dynamic} nature of the mental processes. We tell ourselves that what
distinguishes a conscious idea from a preconscious one, and the latter from an unconscious
one, can only be a modification, or perhaps a different distribution, of psychical energy. We talk
of cathexes and hypercathexes, but beyond this we are without any knowledge on the subject
or even any starting-point for a serviceable working hypothesis. Of the phenomenon of
consciousness we can at least say that it was originally attached to perception. All sensations
which originate from the perception of painful, tactile, auditory or visual stimuli are what are
most readily conscious. Thought-processes, and whatever may be analogous to them in the id,
are in themselves unconscious and obtain access to consciousness by becoming linked to the
mnemonic residues of visual and auditory perceptions along the path of the function of speech. In
animals, which lack speech, these conditions must be of a simpler kind.
[1939a, 4919]

In the course of this work the distinctions which we describe as psychical qualities force
themselves on our notice. There is no need to characterize what we call 'conscious': it is the
same as the consciousness of philosophers and of everyday opinion. Everything else psychical
is in our view 'the unconscious'. We are soon led to make an important division in this
unconscious. Some processes become conscious easily; they may then cease to be conscious,
but can become conscious once more without any trouble: as people say, they can be
reproduced or remembered. This reminds us that consciousness is in general a highly fugitive
state. What is conscious is conscious only for a moment. If our perceptions do not confirm this,
the contradiction is only an apparent one; it is explained by the fact that the stimuli which lead to
perception may persist for considerable periods, so that meanwhile the perception of them may
be repeated. The whole position is made clear in connection with the conscious perception of
our thought-processes: these too may persist for some time, but they may just as well pass in a
flash. Everything unconscious that behaves in this way, that can thus easily exchange the
unconscious state for the conscious one, is therefore preferably described as 'capable of
becoming conscious' or as \textit{preconscious}. Experience has taught us that there is hardly a
psychical process, however complicated it may be, which cannot on occasion remain
preconscious, even though as a rule it will, as we say, push its way forward into consciousness.
There are other psychical processes and psychical material which have no such easy access to
becoming conscious but must be inferred, recognized and translated into conscious form in the
manner described. For such material we reserve the name of the unconscious proper.
[1940a [1938], 4969]
The sole prevailing quality in the id is that of being unconscious. Id and unconscious are as intimately linked as ego and preconscious: indeed, in the former case the connection is even more exclusive. If we look back at the developmental history of an individual and of his psychical apparatus, we shall be able to perceive an important distinction in the id. Originally, to be sure, everything was id; the ego was developed out of the id by the continual influence of the external world. In the course of this slow development certain of the contents of the id were transformed into the preconscious state and so taken into the ego; others of its contents remained in the id unchanged, as its scarcely accessible nucleus. During this development, however, the young and feeble ego put back into the unconscious state some of the material it had already taken in, dropped it, and behaved in the same way to some fresh impressions which it might have taken in, so that these, having been rejected, could leave a trace only in the id. In consideration of its origin we speak of this latter portion of the id as the repressed. It is of little importance that we are not always able to draw a sharp line between these two categories of contents in the id. They coincide approximately with the distinction between what was innately present originally and what was acquired in the course of the ego's development.

[1940a [1938], 4973]
We will describe the last of the systems at the motor end as 'the preconscious', to indicate that the excitatory processes occurring in it can enter consciousness without further impediment provided that certain other conditions are fulfilled: for instance, that they reach a certain degree of intensity, that the function which can only be described as 'attention' is distributed in a particular way, and so on. This is at the same time the system which holds the key to voluntary movement. We will describe the system that lies behind it as 'the unconscious', because it has no access to consciousness except via the preconscious, in passing through which its excitatory process is obliged to submit to modifications.¹

[1900a, 974]

It is not without intention that I speak of 'our' unconscious. For what I thus describe is not the same as the unconscious of the philosophers or even the unconscious of Lipps. By them the term is used merely to indicate a contrast with the conscious: the thesis which they dispute with so much heat and defend with so much energy is the thesis that apart from conscious there are also unconscious psychical processes. Lipps carries things further with his assertion that the whole of what is psychical exists unconsciously and that a part of it also exists consciously. But it is not in order to establish this thesis that we have summoned up the phenomena of dreams and of the formation of hysterical symptoms; the observation of normal waking life would by itself suffice to prove it beyond any doubt. The new discovery that we have been taught by the analysis of psychopathological structures and of the first member of that class - the dream - lies in the fact that the unconscious (that is, the psychical) is found as a function of two separate systems and that this is the case in normal as well as in pathological life. Thus there are two kinds of unconscious, which have not yet been distinguished by psychologists. Both of them are unconscious in the sense used by psychology; but in our sense one of them, which we term the **Ucs.**, is also inadmissible to consciousness, while we term the other the **Pcs.** because its excitations - after observing certain rules, it is true, and perhaps only after passing a fresh censorship, though nonetheless without regard to the **Ucs.** - are able to reach consciousness. The fact that excitations in order to reach consciousness must pass through a fixed series or hierarchy of agencies (which is revealed to us by the modifications made in them by censorship) has enabled us to construct a spatial analogy. We have described the relations of the two systems to each other and to consciousness by saying that the system **Pcs.** stands like a screen between the system **Ucs.** and consciousness. The system **Pcs.** not merely bars access to consciousness, it also controls access to the power of voluntary movement and has at its disposal for distribution a mobile cathectic energy, a part of which is familiar to us in the form of attention.²

[1900a, 1039]

² [Footnote added 1923:] I am here using the word 'consciousness' in a sense which I later avoided, namely, to describe our normal processes of thought - such, that is, as are capable of consciousness. We know that thought processes of this kind may also take place preconsciously; and it is wiser to regard their actual 'consciousness' from a purely phenomenological standpoint. By this I do not, of course, mean to contradict the expectation that consciousness in this more limited sense of the word must also fulfil some biological function.

[1909b, 2121]
Proceeding now to an account of the positive findings of psycho-analysis, we may say that in general a psychical act goes through two phases as regards its state, between which is interposed a kind of testing (censorship). In the first phase the psychical act is unconscious and belongs to the system Ucs.; if, on testing, it is rejected by the censorship, it is not allowed to pass into the second phase; it is then said to be 'repressed' and must remain unconscious. If, however, it passes this testing, it enters the second phase and thenceforth belongs to the second system, which we will call the system Cs. But the fact that it belongs to that system does not yet unequivocally determine its relation to consciousness. It is not yet conscious, but it is certainly capable of becoming conscious (to use Breuer's expression) - that is, it can now, given certain conditions, become an object of consciousness without any special resistance. In consideration of this capacity for becoming conscious we also call the system Cs. the 'preconscious'. If it should turn out that a certain censorship also plays a part in determining whether the preconscious becomes conscious, we shall discriminate more sharply between the systems Pcs. and Cs. For the present let it suffice us to bear in mind that the system Pcs. shares the characteristics of the system Cs. and that the rigorous censorship exercises its office at the point of transition from the Ucs. to the Pcs. (or Cs.).

In order to make it easier to understand this 'compulsion to repeat', which emerges during the psycho-analytic treatment of neurotics, we must above all get rid of the mistaken notion that what we are dealing with in our struggle against resistances is resistance on the part of the unconscious. The unconscious - that is to say, the 'repressed' - offers no resistance whatever to the efforts of the treatment. Indeed, it itself has no other endeavour than to break through the pressure weighing down on it and force its way either to consciousness or to a discharge through some real action. Resistance during treatment arises from the same higher strata and systems of the mind which originally carried out repression. But the fact that, as we know from experience, the motives of the resistances, and indeed the resistances themselves, are unconscious at first during the treatment, is a hint to us that we should correct a shortcoming in our terminology. We shall avoid a lack of clarity if we make our contrast not between the conscious and the unconscious but between the coherent ego and the repressed. It is certain that much of the ego is itself unconscious, and notably what we may describe as its nucleus; only a small part of it is covered by the term 'preconscious'. Having replaced a purely descriptive terminology by one which is systematic or dynamic, we can say that the patient's resistance arises from his ego, and we then at once perceive that the compulsion to repeat must be ascribed to the unconscious repressed. It seems probable that the compulsion can only express itself after the work of treatment has gone half-way to meet it and has loosened the repression.¹

¹ [1920g, 3724]
Thus we obtain our concept of the unconscious from the theory of repression. The repressed is the prototype of the unconscious for us. We see, however, that we have two kinds of unconscious - the one which is latent but capable of becoming conscious, and the one which is repressed and which is not, in itself and without more ado, capable of becoming conscious. This piece of insight into psychical dynamics cannot fail to affect terminology and description. The latent, which is unconscious only descriptively, not in the dynamic sense, we call preconscious; we restrict the term unconscious to the dynamically unconscious repressed; so that now we have three terms, conscious (Cs.), preconscious (Pcs.), and unconscious (Ucs.), whose sense is no longer purely descriptive. The Pcs. is presumably a great deal closer to the Cs. than is the Ucs., and since we have called the Ucs. psychical we shall with even less hesitation call the latent Pcs. psychical. But why do we not rather, instead of this, remain in agreement with the philosophers and, in a consistent way, distinguish the Pcs. as well as the Ucs. from the conscious psychical? The philosophers would then propose that the Pcs. and the Ucs. should be described as two species or stages of the 'psychoid', and harmony would be established. But endless difficulties in exposition would follow; and the one important fact, that these two kinds of 'psychoid' coincide in almost every other respect with what is admittedly psychical, would be forced into the background in the interests of a prejudice dating from a period in which these psychoids, or the most important part of them, were still unknown.

[1923b, 3949]

For our conception of the unconscious, however, the consequences of our discovery are even more important. Dynamic considerations caused us to make our first correction; our insight into the structure of the mind leads to the second. We recognize that the Ucs. does not coincide with the repressed; it is still true that all that is repressed is Ucs., but not all that is Ucs. is repressed. A part of the ego, too - and Heaven knows how important a part - may be Ucs., undoubtedly is Ucs. And this Ucs. belonging to the ego is not latent like the Pcs.; for if it were, it could not be activated without becoming Cs., and the process of making it conscious would not encounter such great difficulties. When we find ourselves thus confronted by the necessity of postulating a third Ucs., which is not repressed, we must admit that the characteristic of being unconscious begins to lose significance for us. It becomes a quality which can have many meanings, a quality which we are unable to make, as we should have hoped to do, the basis of far-reaching and inevitable conclusions. Nevertheless we must beware of ignoring this characteristic, for the property of being conscious or not is in the last resort our one beacon-light in the darkness of depth-psychology.

[1923b, 3952]

I have already, in another place,' suggested that the real difference between a Ucs. and a Pcs. idea (thought) consists in this: that the former is carried out on some material which remains unknown, whereas the latter (the Pcs.) is in addition brought into connection with word-presentations. This is the first attempt to indicate distinguishing marks for the two systems, the Pcs. and the Ucs., other than their relation to consciousness. The question, 'How does a thing become conscious?' would thus be more advantageously stated: 'How does a thing become preconscious?' And the answer would be: 'Through becoming connected with the word-presentations corresponding to it.'

[1923b, 3954]
But from here our interest proceeds to the question whether the latent dream-thoughts that have to be arrived at by interpretation can also be influenced or suggested by the analyst. And to this the answer must once more be that they obviously can be. For a portion of these latent dream-thoughts correspond to preconscious thought-formations, perfectly capable of being conscious, with which the dreamer might quite well have reacted to the physician's remarks in his waking state too - whether the patient's reactions were in harmony with those remarks or in opposition to them. In fact, if we replace the dream by the dream-thoughts which it contains, the question of how far one can suggest dreams coincides with the more general question of how far a patient in analysis is accessible to suggestion.

[1923c, 4035]

There is no need to discuss what is to be called conscious: it is removed from all doubt. The oldest and best meaning of the word 'unconscious' is the descriptive one; we call a psychical process unconscious whose existence we are obliged to assume - for some such reason as that we infer it from its effects -, but of which we know nothing. In that case we have the same relation to it as we have to a psychical process in another person, except that it is in fact one of our own. If we want to be still more correct, we shall modify our assertion by saying that we call a process unconscious if we are obliged to assume that it is being activated at the moment, though at the moment we know nothing about it. This qualification makes us reflect that the majority of conscious processes are conscious only for a short time; very soon they become latent, but can easily become conscious again. We might also say that they had become unconscious, if it were at all certain that in the condition of latency they are still something psychical. So far we should have learnt nothing new; nor should we have acquired the right to introduce the concept of an unconscious into psychology. But then comes the new observation that we were already able to make in parapraxes. In order to explain a slip of the tongue, for instance, we find ourselves obliged to assume that the intention to make a particular remark has occurred; but the intention did not put itself through and was thus unconscious. If, when we subsequently put it before the speaker, he recognizes it as one familiar to him, then it was only temporarily unconscious to him; but if he repudiates it as something foreign to him, then it was permanently unconscious. From this experience we retrospectively obtain the right also to pronounce as something unconscious what had been described as latent. A consideration of these dynamic relations permits us now to distinguish two kinds of unconscious - one which is easily, under frequently occurring circumstances, transformed into something conscious, and another with which this transformation is difficult and takes place only subject to a considerable expenditure of effort or possibly never at all. In order to escape the ambiguity as to whether we mean the one or the other unconscious, whether we are using the word in the descriptive or in the dynamic sense, we make use of a permissible and simple way out. We call the unconscious which is only latent, and thus easily becomes conscious, the 'preconscious' and retain the term 'unconscious' for the other. We now have three terms, 'conscious', 'preconscious' and 'unconscious', with which we can get along in our description of mental phenomena. Once again: the preconscious is also unconscious in the purely descriptive sense, but we do not give it that name, except in talking loosely or when we have to make a defence of the existence in mental life of unconscious processes in general.

[1933a, 4679]
You will admit, I hope, that so far that is not too bad and allows of convenient handling. Yes, but unluckily the work of psycho-analysis has found itself compelled to use the word 'unconscious' in yet another, third, sense, and this may, to be sure, have led to confusion. Under the new and powerful impression of there being an extensive and important field of mental life which is normally withdrawn from the ego's knowledge so that the processes occurring in it have to be regarded as unconscious in the truly dynamic sense, we have come to understand the term 'unconscious' in a topographical or systematic sense as well; we have come to speak of a 'system' of the preconscious and a 'system' of the unconscious, of a conflict between the ego and the system Ucs., and have used the word more and more to denote a mental province rather than a quality of what is mental. The discovery, actually an inconvenience, that portions of the ego and super-ego as well are unconscious in the dynamic sense, operates at this point as a relief - it makes possible the removal of a complication. We perceive that we have no right to name the mental region that is foreign to the ego 'the system Ucs', since the characteristic of being unconscious is not restricted to it. Very well; we will no longer use the term 'unconscious' in the systematic sense and we will give what we have hitherto so described a better name and one no longer open to misunderstanding. Following a verbal usage of Nietzsche's and taking up a suggestion by Georg Groddeck, we will in future call it the 'id'. This impersonal pronoun seems particularly well suited for expressing the main characteristic of this province of the mind - the fact of its being alien to the ego. The super-ego, the ego and the id - these, then, are the three realms, regions, provinces, into which we divide an individual's mental apparatus, and with the mutual relations of which we shall be concerned in what follows.

The difference between whether a psychical process is conscious or unconscious has served us as a criterion and a means of finding our bearings. The repressed is unconscious. Now it would simplify things agreeably if this sentence admitted of reversal - if, that is, the difference between the qualities of conscious (Cs.) and unconscious (Ucs.) coincided with the distinction between 'belonging to the ego' and 'repressed'. The fact of there being isolated and unconscious things like this in our mental life would be sufficiently novel and important. But in reality the position is more complicated. It is true that everything repressed is unconscious, but it is not true that everything belonging to the ego is conscious. We notice that consciousness is a transient quality which attaches to a psychical process only in passing. For our purposes therefore we must replace 'conscious' by 'capable of being conscious' and we call this quality 'preconscious' (Pcs.). We then say, more correctly, that the ego is mainly preconscious (virtually conscious) but that portions of the ego are unconscious.
In the course of this work the distinctions which we describe as psychical qualities force themselves on our notice. There is no need to characterize what we call 'conscious': it is the same as the consciousness of philosophers and of everyday opinion. Everything else psychical is in our view 'the unconscious'. We are soon led to make an important division in this unconscious. Some processes become conscious easily; they may then cease to be conscious, but can become conscious once more without any trouble: as people say, they can be reproduced or remembered. This reminds us that consciousness is in general a highly fugitive state. What is conscious is conscious only for a moment. If our perceptions do not confirm this, the contradiction is only an apparent one; it is explained by the fact that the stimuli which lead to perception may persist for considerable periods, so that meanwhile the perception of them may be repeated. The whole position is made clear in connection with the conscious perception of our thought-processes: these too may persist for some time, but they may just as well pass in a flash. Everything unconscious that behaves in this way, that can thus easily exchange the unconscious state for the conscious one, is therefore preferably described as 'capable of becoming conscious' or as preconscious. Experience has taught us that there is hardly a psychical process, however complicated it may be, which cannot on occasion remain preconscious, even though as a rule it will, as we say, push its way forward into consciousness. There are other psychical processes and psychical material which have no such easy access to becoming conscious but must be inferred, recognized and translated into conscious form in the manner described. For such material we reserve the name of the unconscious proper.

Thus we have attributed three qualities to psychical processes: they are either conscious, preconscious or unconscious. The division between the three classes of material which possess these qualities is neither absolute nor permanent. What is preconscious becomes conscious, as we have seen, without any assistance from us; what is unconscious can, through our efforts, be made conscious, and in the process we may have a feeling that we are often overcoming very strong resistances. When we attempt to do this with someone else, we should not forget that the conscious filling-in of the gaps in his perceptions - the construction we are presenting him with - does not mean as yet that we have made the unconscious material in question conscious to him. All that is true so far is that the material is present in him in two records, once in the conscious reconstruction he has been given, and besides this in its original unconscious state. Our continued efforts usually succeed eventually in making this unconscious material conscious to him himself, as a result of which the two records are brought to coincide. The amount of effort we have to use, by which we estimate the resistance against the material becoming conscious, varies in magnitude in individual cases. For instance, what comes about in an analytic treatment as a result of our efforts can also occur spontaneously: material which is ordinarily unconscious can transform itself into preconscious material and then becomes conscious - a thing that happens to a large extent in psychotic states. From this we infer that the maintenance of certain internal resistances is a sine qua non of normality. A relaxation of resistances such as this, with a consequent pushing forward of unconscious material, takes place regularly in the state of sleep, and thus brings about a necessary precondition for the construction of dreams. Conversely, preconscious material can become temporarily inaccessible and cut off by resistances, as happens when something is temporarily forgotten or escapes the memory; or a preconscious thought can even be temporarily put back into the unconscious state, as seems to be a precondition in the case of jokes. We shall see that a similar transformation back of preconscious material or processes into the unconscious state plays a great part in the causation of neurotic disorders.
The inside of the ego, which comprises above all the thought-processes, has the quality of being preconscious. This is characteristic of the ego and belongs to it alone. It would not be correct, however, to think that connection with the mnemonic residues of speech is a necessary precondition of the preconscious state. On the contrary, that state is independent of a connection with them, though the presence of that connection makes it safe to infer the preconscious nature of a process. The preconscious state, characterized on the one hand by having access to consciousness and on the other hand by its connection with the speech-residues, is nevertheless something peculiar, the nature of which is not exhausted by these two characteristics. The evidence for this is the fact that large portions of the ego, and particularly of the super-ego, which cannot be denied the characteristic of preconsciousness, none the less remain for the most part unconscious in the phenomenological sense of the word. We do not know why this must be so. We shall attempt presently to attack the problem of the true nature of the preconscious.

[1940a [1938], 4972]

The sole prevailing quality in the id is that of being unconscious. Id and unconscious are as intimately linked as ego and preconscious: indeed, in the former case the connection is even more exclusive. If we look back at the developmental history of an individual and of his psychical apparatus, we shall be able to perceive an important distinction in the id. Originally, to be sure, everything was id; the ego was developed out of the id by the continual influence of the external world. In the course of this slow development certain of the contents of the id were transformed into the preconscious state and so taken into the ego; others of its contents remained in the id unchanged, as its scarcely accessible nucleus. During this development, however, the young and feeble ego put back into the unconscious state some of the material it had already taken in, dropped it, and behaved in the same way to some fresh impressions which it might have taken in, so that these, having been rejected, could leave a trace only in the id. In consideration of its origin we speak of this latter portion of the id as the repressed. It is of little importance that we are not always able to draw a sharp line between these two categories of contents in the id. They coincide approximately with the distinction between what was innately present originally and what was acquired in the course of the ego's development.

[1940a [1938], 4973]
The other agency of the mind, which we believe we know best and in which we recognize ourselves most easily - what is known as the ego - has been developed out of the id's cortical layer, which, through being adapted to the reception and exclusion of stimuli, is in direct contact with the external world (reality). Starting from conscious perception it has subjected to its influence ever larger regions and deeper strata of the id, and, in the persistence with which it maintains its dependence on the external world, it bears the indelible stamp of its origin (as it might be 'Made in Germany'). Its psychological function consists in raising the passage in the id to a higher dynamic level (perhaps by transforming freely mobile energy into bound energy, such as corresponds to the preconscious state); its constructive function consists in interpolating, between the demand made by an instinct and the action that satisfies it, the activity of thought which, after taking its bearings in the present and assessing earlier experiences, endeavours by means of experimental actions to calculate the consequences of the course of action proposed. In this way the ego comes to a decision on whether the attempt to obtain satisfaction is to be carried out or postponed or whether it may not be necessary for the demand by the instinct to be suppressed altogether as being dangerous. (Here we have the reality principle.) Just as the id is directed exclusively to obtaining pleasure, so the ego is governed by considerations of safety. The ego has set itself the task of self-preservation, which the id appears to neglect. It makes use of the sensations of anxiety as a signal to give a warning of dangers that threaten its integrity. Since memory traces can become conscious just as perceptions do, especially through their association with residues of speech, the possibility arises of a confusion which would lead to a mistaking of reality. The ego guards itself against this possibility by the institution of reality-testing, which is allowed to fall into abeyance in dreams on account of the conditions prevailing in the state of sleep. The ego, which seeks to maintain itself in an environment of overwhelming mechanical forces, is threatened by dangers which come in the first instance from external reality; but dangers do not threaten it from there alone. Its own id is a source of similar dangers, and that for two different reasons. In the first place, an excessive strength of instinct can damage the ego in a similar way to an excessive 'stimulus' from the external world. It is true that the former cannot destroy it; but it can destroy its characteristic dynamic organization and change the ego back into a portion of the id. In the second place, experience may have taught the ego that the satisfaction of some instinctual demand which is not in itself intolerable would involve dangers in the external world, so that an instinctual demand of that kind itself becomes a danger. Thus the ego is fighting on two fronts: it has to defend its existence against an external world which threatens it with annihilation as well as against an internal world that makes excessive demands. It adopts the same methods of defence against both, but its defence against the internal enemy is particularly inadequate. As a result of having originally been identical with this latter enemy and of having lived with it since on the most intimate terms, it has great difficulty in escaping from the internal dangers. They persist as threats, even if they can be temporarily held down.

[1940a [1938], 5005]
It became necessary to elaborate and modify this view after it was recognized that the essential feature of a preconscious idea was the fact of its being connected with the residues of verbal presentations. Cf. ‘The Unconscious’ (1915e).

I should like to point out at what an early date we already possessed the insight which to-day enables us to understand one of the most striking characteristics of schizophrenia. In the last few pages of The Interpretation of Dreams, which was published in 1900, the view was developed that thought-processes, i.e. those acts of cathexis which are comparatively remote from perception, are in themselves without quality and unconscious, and that they attain their capacity to become conscious only through being linked with the residues of perceptions of words. But word-presentations, for their part too, are derived from sense-perceptions, in the same way as thing-presentations are; the question might therefore be raised why presentations of objects cannot become conscious through the medium of their own perceptual residues. Probably, however, thought proceeds in systems so far remote from the original perceptual residues that they have no longer retained anything of the qualities of those residues, and, in order to become conscious, need to be reinforced by new qualities. Moreover, by being linked with words, cathexes can be provided with quality even when they represent only relations between presentations of objects and are thus unable to derive any quality from perceptions. Such relations, which become comprehensible only through words, form a major part of our thought-processes. As we can see, being linked with word-presentations is not yet the same thing as becoming conscious, but only makes it possible to become so; it is therefore characteristic of the system Pcs. and of that system alone. With these discussions, however, we have evidently departed from our subject proper and find ourselves plunged into problems concerning the preconscious and the conscious, which for good reasons we are reserving for separate treatment.

I have already, in another place, suggested that the real difference between a Ucs. and a Pcs. idea (thought) consists in this: that the former is carried out on some material which remains unknown, whereas the latter (the Pcs.) is in addition brought into connection with word-presentations. This is the first attempt to indicate distinguishing marks for the two systems, the Pcs. and the Ucs., other than their relation to consciousness. The question, ‘How does a thing become conscious?’ would thus be more advantageously stated: ‘How does a thing become preconscious?’ And the answer would be: ‘Through becoming connected with the word-presentations corresponding to it.’

These word-presentations are residues of memories; they were at one time perceptions, and like all mnemonic residues they can become conscious again. Before we concern ourselves further with their nature, it dawns upon us like a new discovery that only something which has once been a Cs. perception can become conscious, and that anything arising from within (apart from feelings) that seeks to become conscious must try to transform itself into external perceptions: this becomes possible by means of memory-traces.
We think of the mnemic residues as being contained in systems which are directly adjacent to the system $Pcpt.-Cs.$, so that the cathexes of those residues can readily extend from within on to the elements of the latter system. We immediately think here of hallucinations, and of the fact that the most vivid memory is always distinguishable both from a hallucination and from an external perception; but it will also occur to us at once that when a memory is revived the cathexis remains in the mnemic system, whereas a hallucination, which is not distinguishable from a perception, can arise when the cathexis does not merely spread over from the memory-trace on to the $Pcpt.$ element, but passes over to it entirely.

[1923b, 3954]

Verbal residues are derived primarily from auditory perceptions, so that the system $Pcs.$ has, as it were, a special sensory source. The visual components of word-presentations are secondary, acquired through reading, and may to begin with be left on one side; so may the motor images of words, which, except with deaf-mutes, play the part of auxiliary indications. In essence a word is after all the mnemic residue of a word that has been heard.

[1923b, 3955]

In all these situations the super-ego displays its independence of the conscious ego and its intimate relations with the unconscious id. Having regard, now, to the importance we have ascribed to preconscious verbal residues in the ego, the question arises whether it can be the case that the super-ego, in so far as it is $Ucs.$, consists in such word-presentations and, if it does not, what else it consists in. Our tentative answer will be that it is as impossible for the super-ego as for the ego to disclaim its origin from things heard; for it is a part of the ego and remains accessible to consciousness by way of these word-presentations (concepts, abstractions). But the cathectic energy does not reach these contents of the super-ego from auditory perception (instruction or reading) but from sources in the id.

[1923b, 3986]

The inside of the ego, which comprises above all the thought-processes, has the quality of being preconscious. This is characteristic of the ego and belongs to it alone. It would not be correct, however, to think that connection with the mnemic residues of speech is a necessary precondition of the preconscious state. On the contrary, that state is independent of a connection with them, though the presence of that connection makes it safe to infer the preconscious nature of a process. The preconscious state, characterized on the one hand by having access to consciousness and on the other hand by its connection with the speech-residues, is nevertheless something peculiar, the nature of which is not exhausted by these two characteristics. The evidence for this is the fact that large portions of the ego, and particularly of the super-ego, which cannot be denied the characteristic of preconsciousness, none the less remain for the most part unconscious in the phenomenological sense of the word. We do not know why this must be so. We shall attempt presently to attack the problem of the true nature of the preconscious.

[1940a [1938], 4972]
We will describe the last of the systems at the motor end as 'the preconscious', to indicate that the excitatory processes occurring in it can enter consciousness without further impediment provided that certain other conditions are fulfilled: for instance, that they reach a certain degree of intensity, that the function which can only be described as 'attention' is distributed in a particular way, and so on. This is at the same time the system which holds the key to voluntary movement. We will describe the system that lies behind it as 'the unconscious', because it has no access to consciousness except via the preconscious, in passing through which its excitatory process is obliged to submit to modifications.¹ [1900a, 974]

As the outcome of our whole enquiry, let us grasp two discoveries, though they only signify the beginning of fresh enigmas and fresh doubts. First, the regression of the dream-work is not only a formal but also a material one. It not only translates our thoughts into a primitive form of expression; but it also revives the characteristics of our primitive mental life - the old dominance of the ego, the initial impulses of our sexual life, and even, indeed, our old intellectual endowment, if symbolic connections may be regarded as such. And secondly, all this, which is old and infantile and was once dominant and alone dominant, must to-day be ascribed to the unconscious, our ideas of which are now becoming altered and extended. 'Unconscious' is no longer the name of what is latent at the moment; the unconscious is a particular realm of the mind with its own wishful impulses, its own mode of expression and its peculiar mental mechanisms which are not in force elsewhere. But the latent dream-thoughts which we have discovered by interpreting dreams do not belong to this realm; they are on the contrary thoughts just as we might have thought them in waking life. Nevertheless, they are unconscious. How, then, is this contradiction to be solved? We begin to suspect that a distinction is to be drawn here. Something which is derived from our conscious life and shares its characteristics - we call it 'the day's residues' - combines with something else coming from the realm of the unconscious in order to construct a dream. The dream-work is accomplished between these two components. The influence exercised upon the day's residues by the addition of the unconscious is no doubt among the determinants of regression. This is the deepest insight that we can reach here into the essential nature of dreams - until we have investigated further regions of the mind. But the time will soon have come to provide another name for the unconscious character of the latent dream-thoughts in order to distinguish it from the unconscious which comes from the realm of the infantile. [1916-1917, 3299]
There is no need to discuss what is to be called conscious: it is removed from all doubt. The oldest and best meaning of the word 'unconscious' is the descriptive one; we call a psychical process unconscious whose existence we are obliged to assume - for some such reason as that we infer it from its effects -, but of which we know nothing. In that case we have the same relation to it as we have to a psychical process in another person, except that it is in fact one of our own. If we want to be still more correct, we shall modify our assertion by saying that we call a process unconscious if we are obliged to assume that it is being activated at the moment, though at the moment we know nothing about it. This qualification makes us reflect that the majority of conscious processes are conscious only for a short time; very soon they become latent, but can easily become conscious again. We might also say that they had become unconscious, if it were at all certain that in the condition of latency they are still something psychical. So far we should have learnt nothing new; nor should we have acquired the right to introduce the concept of an unconscious into psychology. But then comes the new observation that we were already able to make in parapraxes. In order to explain a slip of the tongue, for instance, we find ourselves obliged to assume that the intention to make a particular remark was present in the subject. We infer it with certainty from the interference with his remark which has occurred; but the intention did not put itself through and was thus unconscious. If, when we subsequently put it before the speaker, he recognizes it as one familiar to him, then it was only temporarily unconscious to him; but if he repudiates it as something foreign to him, then it was permanently unconscious. From this experience we retrospectively obtain the right also to pronounce as something unconscious what had been described as latent. A consideration of these dynamic relations permits us now to distinguish two kinds of unconscious - one which is easily, under frequently occurring circumstances, transformed into something conscious, and another with which this transformation is difficult and takes place only subject to a considerable expenditure of effort or possibly never at all. In order to escape the ambiguity as to whether we mean the one or the other unconscious, whether we are using the word in the descriptive or in the dynamic sense, we make use of a permissible and simple way out. We call the unconscious which is only latent, and thus easily becomes conscious, the 'preconscious' and retain the term 'unconscious' for the other. We now have three terms, 'conscious', 'preconscious' and 'unconscious', with which we can get along in our description of mental phenomena. Once again: the preconscious is also unconscious in the purely descriptive sense, but we do not give it that name, except in talking loosely or when we have to make a defence of the existence in mental life of unconscious processes in general.

[1933a, 4679]
In the course of this work the distinctions which we describe as psychical qualities force themselves on our notice. There is no need to characterize what we call 'conscious': it is the same as the consciousness of philosophers and of everyday opinion. Everything else psychical is in our view 'the unconscious'. We are soon led to make an important division in this unconscious. Some processes become conscious easily; they may then cease to be conscious, but can become conscious once more without any trouble: as people say, they can be reproduced or remembered. This reminds us that consciousness is in general a highly fugitive state. What is conscious is conscious only for a moment. If our perceptions do not confirm this, the contradiction is only an apparent one; it is explained by the fact that the stimuli which lead to perception may persist for considerable periods, so that meanwhile the perception of them may be repeated. The whole position is made clear in connection with the conscious perception of our thought-processes: these too may persist for some time, but they may just as well pass in a flash. Everything unconscious that behaves in this way, that can thus easily exchange the unconscious state for the conscious one, is therefore preferably described as 'capable of becoming conscious' or as preconscious. Experience has taught us that there is hardly a psychical process, however complicated it may be, which cannot on occasion remain preconscious, even though as a rule it will, as we say, push its way forward into consciousness. There are other psychical processes and psychical material which have no such easy access to becoming conscious but must be inferred, recognized and translated into conscious form in the manner described. For such material we reserve the name of the unconscious proper.

Thus we have attributed three qualities to psychical processes: they are either conscious, preconscious or unconscious. The division between the three classes of material which possess these qualities is neither absolute nor permanent. What is preconscious becomes conscious, as we have seen, without any assistance from us; what is unconscious can, through our efforts, be made conscious, and in the process we may have a feeling that we are often overcoming very strong resistances. When we attempt to do this with someone else, we should not forget that the conscious filling-in of the gaps in his perceptions - the construction we are presenting him with - does not mean as yet that we have made the unconscious material in question conscious to him. All that is true so far is that the material is present in him in two records, once in the conscious reconstruction he has been given, and besides this in its original unconscious state. Our continued efforts usually succeed eventually in making this unconscious material conscious to him himself, as a result of which the two records are brought to coincide. The amount of effort we have to use, by which we estimate the resistance against the material becoming conscious, varies in magnitude in individual cases. For instance, what comes about in an analytic treatment as a result of our efforts can also occur spontaneously: material which is ordinarily unconscious can transform itself into preconscious material and then becomes conscious - a thing that happens to a large extent in psychotic states. From this we infer that the maintenance of certain internal resistances is a sine qua non of normality. A relaxation of resistances such as this, with a consequent pushing forward of unconscious material, takes place regularly in the state of sleep, and thus brings about a necessary precondition for the construction of dreams. Conversely, preconscious material can become temporarily inaccessible and cut off by resistances, as happens when something is temporarily forgotten or escapes the memory; or a preconscious thought can even be temporarily put back into the unconscious state, as seems to be a precondition in the case of jokes. We shall see that a similar transformation back of preconscious material or processes into the unconscious state plays a great part in the causation of neurotic disorders.

[1940a [1938], 4970]
It is not without intention that I speak of 'our' unconscious. For what I thus describe is not the same as the unconscious of the philosophers or even the unconscious of Lipps. By them the term is used merely to indicate a contrast with the conscious: the thesis which they dispute with so much heat and defend with so much energy is the thesis that apart from conscious there are also unconscious psychical processes. Lipps carries things further with his assertion that the whole of what is psychical exists unconsciously and that a part of it also exists consciously. But it is not in order to establish this thesis that we have summoned up the phenomena of dreams and of the formation of hysterical symptoms; the observation of normal waking life would by itself suffice to prove it beyond any doubt. The new discovery that we have been taught by the analysis of psychopathological structures and of the first member of that class - the dream - lies in the fact that the unconscious (that is, the psychical) is found as a function of two separate systems and that this is the case in normal as well as in pathological life. Thus there are two kinds of unconscious, which have not yet been distinguished by psychologists. Both of them are unconscious in the sense used by psychology; but in our sense one of them, which we term the Ucs., is also inadmissible to consciousness, while we term the other the Pcs. because its excitations - after observing certain rules, it is true, and perhaps only after passing a fresh censorship, though nonetheless without regard to the Ucs. - are able to reach consciousness. The fact that excitations in order to reach consciousness must pass through a fixed series or hierarchy of agencies (which is revealed to us by the modifications made in them by censorship) has enabled us to construct a spatial analogy. We have described the relations of the two systems to each other and to consciousness by saying that the system Pcs. stands like a screen between the system Ucs. and consciousness. The system Pcs. not merely bars access to consciousness, it also controls access to the power of voluntary movement and has at its disposal for distribution a mobile cathectic energy, a part of which is familiar to us in the form of attention.²

We said a little earlier that Norbert Hanold's memories of his childhood relations with Zoe were in a state of 'repression'; and here we have called them 'unconscious' memories. So we must now pay a little attention to the relation between these two technical terms, which, indeed, appear to coincide in their meaning. It is not difficult to make the matter plain. 'Unconscious' is the wider concept; 'repressed' is the narrower one. Everything that is repressed is unconscious; but we cannot assert that everything unconscious is repressed. If when Hanold saw the relief he had remembered his Zoe's gait, what had earlier been an unconscious memory of his would have become simultaneously active and conscious, and this would have shown that it had not earlier been repressed. 'Unconscious' is a purely descriptive term, one that is indefinite in some respects and, as we might say, static. 'Repressed' is a dynamic expression, which takes account of the interplay of mental forces; it implies that there is a force present which is seeking to bring about all kinds of psychical effects, including that of becoming conscious, but that there is also an opposing force which is able to obstruct some of these psychical effects, once more including that of becoming conscious. The mark of something repressed is precisely that in spite of its intensity it is unable to enter consciousness. In Hanold's case, therefore, from the moment of the appearance of the relief onwards, we are concerned with something unconscious that is repressed, or, more briefly with something repressed.

[1900a, 1039]

[1907a, 1847]
We have learnt from psycho-analysis that the essence of the process of repression lies, not in putting an end to, in annihilating, the idea which represents an instinct, but in preventing it from becoming conscious. When this happens we say of the idea that it is in a state of being ‘unconscious’, and we can produce good evidence to show that even when it is unconscious it can produce effects, even including some which finally reach consciousness. Everything that is repressed must remain unconscious; but let us state at the very outset that the repressed does not cover everything that is unconscious. The unconscious has the wider compass: the repressed is a part of the unconscious.

We cannot advance any further here, for you have probably long been disturbed by a doubt which deserves to be given a hearing. ‘Are the day’s residues,’ you will ask, ‘really unconscious in the same sense as the unconscious wish which must be added to them in order to make them capable of producing a dream?’ Your suspicion is correct. This is the salient point of the whole business. They are not unconscious in the same sense. The dream-wish belongs to a different unconscious - to the one which we have already recognized as being of infantile origin and equipped with peculiar mechanisms. It would be highly opportune to distinguish these two kinds of unconscious by different names. But we would prefer to wait till we have become familiar with the field of phenomena of the neuroses. People consider a single unconscious as something fantastic. What will they say when we confess that we cannot make shift without two of them?

¹ There is some difference between Le Bon’s view and ours owing to his concept of the unconscious not quite coinciding with the one adopted by psycho-analysis. Le Bon’s unconscious more especially contains the most deeply buried features of the racial mind, which as a matter of fact lies outside the scope of psycho-analysis. We do not fail to recognize, indeed, that the ego’s nucleus, which comprises the ‘archaic heritage’ of the human mind, is unconscious; but in addition to this we distinguish the ‘unconscious repressed’, which arose from a portion of that heritage. This concept of the repressed is not to be found in Le Bon.

Thus we obtain our concept of the unconscious from the theory of repression. The repressed is the prototype of the unconscious for us. We see, however, that we have two kinds of unconscious - the one which is latent but capable of becoming conscious, and the one which is repressed and which is not, in itself and without more ado, capable of becoming conscious. This piece of insight into psychical dynamics cannot fail to affect terminology and description. The latent, which is unconscious only descriptively, not in the dynamic sense, we call preconscious; we restrict the term unconscious to the dynamically unconscious repressed; so that now we have three terms, conscious (Cs.), preconscious (Pcs.), and unconscious (Ucs.), whose sense is no longer purely descriptivé. The Pcs. is presumably a great deal closer to the Cs. than is the Ucs., and since we have called the Ucs. psychical we shall with even less hesitation call the latent Pcs. psychical. But why do we not rather, instead of this, remain in agreement with the philosophers and, in a consistent way, distinguish the Pcs. as well as the Ucs. from the conscious psychical? The philosophers would then propose that the Pcs. and the Ucs. should be described as two species or stages of the ‘psychoïd’. and harmony would be established. But endless difficulties in exposition would follow; and the one important fact, that these two kinds of ‘psychoïd’ coincide in almost every other respect with what is admittedly psychical, would be forced into the background in the interests of a prejudice dating from a period in which these psychoïds, or the most important part of them, were still unknown.
For our conception of the unconscious, however, the consequences of our discovery are even more important. Dynamic considerations caused us to make our first correction; our insight into the structure of the mind leads to the second. We recognize that the Ucs. does not coincide with the repressed; it is still true that all that is repressed is Ucs., but not all that is Ucs. is repressed. A part of the ego, too - and Heaven knows how important a part - may be Ucs., undoubtedly is Ucs. And this Ucs. belonging to the ego is not latent like the Pcs.; for if it were, it could not be activated without becoming Cs., and the process of making it conscious would not encounter such great difficulties. When we find ourselves thus confronted by the necessity of postulating a third Ucs., which is not repressed, we must admit that the characteristic of being unconscious begins to lose significance for us. It becomes a quality which can have many meanings, a quality which we are unable to make, as we should have hoped to do, the basis of far-reaching and inevitable conclusions. Nevertheless we must beware of ignoring this characteristic, for the property of being conscious or not is in the last resort our one beacon-light in the darkness of depth-psychology.

[1923b, 3952]

There is no need to discuss what is to be called conscious: it is removed from all doubt. The oldest and best meaning of the word ‘unconscious’ is the descriptive one; we call a psychical process unconscious whose existence we are obliged to assume - for some such reason as that we infer it from its effects -, but of which we know nothing. In that case we have the same relation to it as we have to a psychical process in another person, except that it is in fact one of our own. If we want to be still more correct, we shall modify our assertion by saying that we call a process unconscious if we are obliged to assume that it is being activated at the moment, though at the moment we know nothing about it. This qualification makes us reflect that the majority of conscious processes are conscious only for a short time; very soon they become latent, but can easily become conscious again. We might also say that they had become unconscious, if it were at all certain that in the condition of latency they are still something psychical. So far we should have learnt nothing new; nor should we have acquired the right to introduce the concept of an unconscious into psychology. But then comes the new observation that we were already able to make in parapraxes. In order to explain a slip of the tongue, for instance, we find ourselves obliged to assume that the intention to make a particular remark was present in the subject. We infer it with certainty from the interference with his remark which has occurred; but the intention did not put itself through and was thus unconscious. If, when we subsequently put it before the speaker, he recognizes it as one familiar to him, then it was only temporarily unconscious to him; but if he repudiates it as something foreign to him, then it was permanently unconscious. From this experience we retrospectively obtain the right also to pronounce as something unconscious what had been described as latent. A consideration of these dynamic relations permits us now to distinguish two kinds of unconscious - one which is easily, under frequently occurring circumstances, transformed into something conscious, and another with which this transformation is difficult and takes place only subject to a considerable expenditure of effort or possibly never at all. In order to escape the ambiguity as to whether we mean the one or the other unconscious, whether we are using the word in the descriptive or in the dynamic sense, we make use of a permissible and simple way out. We call the unconscious which is only latent, and thus easily becomes conscious, the 'preconscious' and retain the term 'unconscious' for the other. We now have three terms, 'conscious', 'preconscious' and 'unconscious', with which we can get along in our description of mental phenomena. Once again: the preconscious is also unconscious in the purely descriptive sense, but we do not give it that name, except in talking loosely or when we have to make a defence of the existence in mental life of unconscious processes in general.

[1933a, 4679]
You will admit, I hope, that so far that is not too bad and allows of convenient handling. Yes, but unluckily the work of psycho-analysis has found itself compelled to use the word 'unconscious' in yet another, third, sense, and this may, to be sure, have led to confusion. Under the new and powerful impression of there being an extensive and important field of mental life which is normally withdrawn from the ego's knowledge so that the processes occurring in it to have to be regarded as unconscious in the truly dynamic sense, we have come to understand the term 'unconscious' in a topographical or systematic sense as well; we have come to speak of a 'system' of the preconscious and a 'system' of the unconscious, of a conflict between the ego and the system Ucs., and have used the word more and more to denote a mental province rather than a quality of what is mental. The discovery, actually an inconvenient one, that portions of the ego and super-ego as well are unconscious in the dynamic sense, operates at this point as a relief - it makes possible the removal of a complication. We perceive that we have no right to name the mental region that is foreign to the ego 'the system Ucs', since the characteristic of being unconscious is not restricted to it. Very well; we will no longer use the term 'unconscious' in the systematic sense and we will give what we have hitherto so described a better name and one no longer open to misunderstanding. Following a verbal usage of Nietzsche's and taking up a suggestion by Georg Groddeck, we will in future call it the 'id'. This impersonal pronoun seems particularly well suited for expressing the main characteristic of this province of the mind - the fact of its being alien to the ego. The super-ego, the ego and the id - these, then, are the three realms, regions, provinces, into which we divide an individual's mental apparatus, and with the mutual relations of which we shall be concerned in what follows.

The difference between whether a psychical process is conscious or unconscious has served us as a criterion and a means of finding our bearings. The repressed is unconscious. Now it would simplify things agreeably if this sentence admitted of reversal - if, that is, the difference between the qualities of conscious (Cs.) and unconscious (Ucs.) coincided with the distinction between 'belonging to the ego' and 'repressed'. The fact of there being isolated and unconscious things like this in our mental life would be sufficiently novel and important. But in reality the position is more complicated. It is true that everything repressed is unconscious, but it is not true that everything belonging to the ego is conscious. We notice that consciousness is a transient quality which attaches to a psychical process only in passing. For our purposes therefore we must replace 'conscious' by 'capable of being conscious' and we call this quality 'preconscious' (Pcs.). We then say, more correctly, that the ego is mainly preconscious (virtually conscious) but that portions of the ego are unconscious.

The repressed is to be counted as belonging to the id and is subject to the same mechanisms; it is distinguished from it only in respect to its genesis. The differentiation is accomplished in the earliest period of life, while the ego is developing out of the id. At that time a portion of the contents of the id is taken into the ego and raised to the preconscious state; another portion is not affected by this translation and remains behind in the id as the unconscious proper. In the further course of the formation of the ego, however, certain psychical impressions and processes in the ego are excluded from it by a defensive process; the characteristic of being preconscious is withdrawn from them, so that they are once more reduced to being component portions of the id. Here then is the 'repressed' in the id. So far as intercourse between the two mental provinces is concerned, we therefore assume that, on the one hand, unconscious processes in the id are raised to the level of the preconscious and incorporated into the ego, and that, on the other hand, preconscious material in the ego can follow the opposite path and be put back into the id. The fact that later on a special region - that of the 'super-ego' - is separated off in the ego lies outside our present interest.
The sole prevailing quality in the id is that of being unconscious. Id and unconscious are as intimately linked as ego and preconscious: indeed, in the former case the connection is even more exclusive. If we look back at the developmental history of an individual and of his psychical apparatus, we shall be able to perceive an important distinction in the id. Originally, to be sure, everything was id; the ego was developed out of the id by the continual influence of the external world. In the course of this slow development certain of the contents of the id were transformed into the preconscious state and so taken into the ego; others of its contents remained in the id unchanged, as its scarcely accessible nucleus. During this development, however, the young and feeble ego put back into the unconscious state some of the material it had already taken in, dropped it, and behaved in the same way to some fresh impressions which it might have taken in, so that these, having been rejected, could leave a trace only in the id. In consideration of its origin we speak of this latter portion of the id as the repressed. It is of little importance that we are not always able to draw a sharp line between these two categories of contents in the id. They coincide approximately with the distinction between what was innately present originally and what was acquired in the course of the ego’s development.
[1940a [1938], 4973]
There is some difference between Le Bon's view and ours owing to his concept of the unconscious not quite coinciding with the one adopted by psycho-analysis. Le Bon's unconscious more especially contains the most deeply buried features of the racial mind, which as a matter of fact lies outside the scope of psycho-analysis. We do not fail to recognize, indeed, that the ego's nucleus, which comprises the 'archaic heritage' of the human mind, is unconscious; but in addition to this we distinguish the 'unconscious repressed', which arose from a portion of that heritage. This concept of the repressed is not to be found in Le Bon.

For our conception of the unconscious, however, the consequences of our discovery are even more important. Dynamic considerations caused us to make our first correction; our insight into the structure of the mind leads to the second. We recognize that the $Ucs.$ does not coincide with the repressed; it is still true that all that is repressed is $Ucs.$, but not all that is $Ucs.$ is repressed. A part of the ego, too - and Heaven knows how important a part - may be $Ucs.$, undoubtedly is $Ucs.$ And this $Ucs.$ belonging to the ego is not latent like the $Pcs.$; for if it were, it could not be activated without becoming $Cs.$, and the process of making it conscious would not encounter such great difficulties. When we find ourselves thus confronted by the necessity of postulating a third $Ucs.$, which is not repressed, we must admit that the characteristic of being unconscious begins to lose significance for us. It becomes a quality which can have many meanings, a quality which we are unable to make, as we should have hoped to do, the basis of far-reaching and inevitable conclusions. Nevertheless we must beware of ignoring this characteristic, for the property of being conscious or not is in the last resort our one beacon-light in the darkness of depth-psychology.
There is no need to discuss what is to be called conscious: it is removed from all doubt. The oldest and best meaning of the word 'unconscious' is the descriptive one; we call a psychical process unconscious whose existence we are obliged to assume - for some such reason as that we infer it from its effects -, but of which we know nothing. In that case we have the same relation to it as we have to a psychical process in another person, except that it is in fact one of our own. If we want to be still more correct, we shall modify our assertion by saying that we call a process unconscious if we are obliged to assume that it is being activated at the moment, though at the moment we know nothing about it. This qualification makes us reflect that the majority of conscious processes are conscious only for a short time; very soon they become latent, but can easily become conscious again. We might also say that they had become unconscious, if it were at all certain that in the condition of latency they are still something psychical. So far we should have learnt nothing new; nor should we have acquired the right to introduce the concept of an unconscious into psychology. But then comes the new observation that we were already able to make in parapraxes. In order to explain a slip of the tongue, for instance, we find ourselves obliged to assume that the intention to make a particular remark was present in the subject. We infer it with certainty from the interference with his remark which has occurred; but the intention did not put itself through and was thus unconscious. If, when we subsequently put it before the speaker, he recognizes it as one familiar to him, then it was only temporarily unconscious to him; but if he repudiates it as something foreign to him, then it was permanently unconscious. From this experience we retrospectively obtain the right also to pronounce as something unconscious what had been described as latent. A consideration of these dynamic relations permits us now to distinguish two kinds of unconscious - one which is easily, under frequently occurring circumstances, transformed into something conscious, and another with which this transformation is difficult and takes place only subject to a considerable expenditure of effort or possibly never at all. In order to escape the ambiguity as to whether we mean the one or the other unconscious, whether we are using the word in the descriptive or in the dynamic sense, we make use of a permissible and simple way out. We call the unconscious which is only latent, and thus easily becomes conscious, the 'preconscious' and retain the term 'unconscious' for the other. We now have three terms, 'conscious', 'preconscious' and 'unconscious', with which we can get along in our description of mental phenomena. Once again: the preconscious is also unconscious in the purely descriptive sense, but we do not give it that name, except in talking loosely or when we have to make a defence of the existence in mental life of unconscious processes in general.

[1933a, 4679]
You will admit, I hope, that so far that is not too bad and allows of convenient handling. Yes, but unluckily the work of psycho-analysis has found itself compelled to use the word 'unconscious' in yet another, third, sense, and this may, to be sure, have led to confusion. Under the new and powerful impression of there being an extensive and important field of mental life which is normally withdrawn from the ego's knowledge so that the processes occurring in it have to be regarded as unconscious in the truly dynamic sense, we have come to understand the term 'unconscious' in a topographical or systematic sense as well; we have come to speak of a 'system' of the preconscious and a 'system' of the unconscious, of a conflict between the ego and the system Ucs., and have used the word more and more to denote a mental province rather than a quality of what is mental. The discovery, actually an inconvenient one, that portions of the ego and super-ego as well are unconscious in the dynamic sense, operates at this point as a relief - it makes possible the removal of a complication. We perceive that we have no right to name the mental region that is foreign to the ego 'the system Ucs', since the characteristic of being unconscious is not restricted to it. Very well; we will no longer use the term 'unconscious' in the systematic sense and we will give what we have hitherto so described a better name and one no longer open to misunderstanding. Following a verbal usage of Nietzsche's and taking up a suggestion by Georg Groddeck, we will in future call it the 'id'. This impersonal pronoun seems particularly well suited for expressing the main characteristic of this province of the mind - the fact of its being alien to the ego. The super-ego, the ego and the id - these, then, are the three realms, regions, provinces, into which we divide an individual's mental apparatus, and with the mutual relations of which we shall be concerned in what follows.

[1933a, 4680]

The repressed is to be counted as belonging to the id and is subject to the same mechanisms; it is distinguished from it only in respect to its genesis. The differentiation is accomplished in the earliest period of life, while the ego is developing out of the id. At that time a portion of the contents of the id is taken into the ego and raised to the preconscious state; another portion is not affected by this translation and remains behind in the id as the unconscious proper. In the further course of the formation of the ego, however, certain psychical impressions and processes in the ego are excluded from it by a defensive process; the characteristic of being preconscious is withdrawn from them, so that they are once more reduced to being component portions of the id. Here then is the 'repressed' in the id. So far as intercourse between the two mental provinces is concerned, we therefore assume that, on the one hand, unconscious processes in the id are raised to the level of the preconscious and incorporated into the ego, and that, on the other hand, preconscious material in the ego can follow the opposite path and be put back into the id. The fact that later on a special region - that of the 'super-ego' - is separated off in the ego lies outside our present interest.

[1939a, 4919]
The sole prevailing quality in the id is that of being unconscious. Id and unconscious are as intimately linked as ego and preconscious: indeed, in the former case the connection is even more exclusive. If we look back at the developmental history of an individual and of his psychical apparatus, we shall be able to perceive an important distinction in the id. Originally, to be sure, everything was id; the ego was developed out of the id by the continual influence of the external world. In the course of this slow development certain of the contents of the id were transformed into the preconscious state and so taken into the ego; others of its contents remained in the id unchanged, as its scarcely accessible nucleus. During this development, however, the young and feeble ego put back into the unconscious state some of the material it had already taken in, dropped it, and behaved in the same way to some fresh impressions which it might have taken in, so that these, having been rejected, could leave a trace only in the id. In consideration of its origin we speak of this latter portion of the id as the repressed. It is of little importance that we are not always able to draw a sharp line between these two categories of contents in the id. They coincide approximately with the distinction between what was innately present originally and what was acquired in the course of the ego's development. [1940a [1938], 4973]
The crudest idea of these systems is the most convenient for us - a spatial one. Let us therefore compare the system of the unconscious to a large entrance hall, in which the mental impulses jostle one another like separate individuals. Adjoining this entrance hall there is a second, narrower, room - a kind of drawing-room - in which consciousness, too, resides. But on the threshold between these two rooms a watchman performs his function: he examines the different mental impulses, acts as a censor, and will not admit them into the drawing-room if they displease him. You will see at once that it does not make much difference if the watchman turns away a particular impulse at the threshold itself or if he pushes it back across the threshold after it has entered the drawing-room. This is merely a question of the degree of his watchfulness and of how early he carries out his act of recognition. If we keep to this picture, we shall be able to extend our nomenclature further. The impulses in the entrance hall of the unconscious are out of sight of the conscious, which is in the other room; to begin with they must remain unconscious. If they have already pushed their way forward to the threshold and have been turned back by the watchman, then they are inadmissible to consciousness; we speak of them as repressed. But even the impulses which the watchman has allowed to cross the threshold are not on that account necessarily conscious as well; they can only become so if they succeed in catching the eye of consciousness. We are therefore justified in calling this second room the system of the preconscious. In that case becoming conscious retains its purely descriptive sense. For any particular impulse, however, the vicissitude of repression consists in its not being allowed by the watchman to pass from the system of the unconscious into that of the preconscious. It is the same watchman whom we get to know as resistance when we try to lift the repression by means of the analytic treatment.

[1916-1917, 3369]

For a time psycho-analysis seemed fated to merge into psychology without being able to show why the psychology of the sick differed from that of the normal. In the course of its advance, however, it came up against the problem of dreams, which are abnormal products of the mind created by normal men under regularly recurrent physiological conditions. When psycho-analysis had solved the problem of dreams, it had discovered in unconscious psychical processes the common ground in which the highest and the lowest of mental impulses have their roots and from which spring the most normal as well as the most morbid and erratic of mental productions. The new picture of the workings of the mind began to grow ever clearer and more complete. It was a picture of obscure instinctual forces organic in origin, striving towards inborn aims, and, above them, of an agency comprising more highly organized mental structures - acquisitions of human evolution made under the impact of human history - an agency which has taken over portions of the instinctual impulses, has developed them further or has even directed them towards higher aims, but which in any case binds them firmly and manipulates their energy to suit its own purposes. This higher organization, however, which is known to us as the ego, has rejected another portion of these same elementary instinctual impulses as being unserviceable because they cannot be fitted into the organic unity of the individual or because they rebel against the individual's cultural aims. The ego is not in a position to exterminate these unsubdued mental powers, but it turns its back on them, lets them remain at the lowest psychological level, defends itself from their demands by the energetic erection of protective and antithetical barriers or seeks to come to terms with them by means of substitutive satisfactions. These instincts which have fallen victim to repression - untamed and indestructible, yet inhibited from any kind of activity - together with their primitive mental representatives, constitute the mental underworld, the nucleus of the true unconscious, and are at every moment ready to assert their demands and, by hook or by crook, to force their way forward to satisfaction. To this is due the instability of the proud superstructure of the mind, the emergence at night of the proscribed and repressed material in the form of dreams, and the tendency to fall ill with neuroses and psychoses as soon as the balance of power between the ego and the repressed shifts to the disadvantage of the ego.

[1919g, 3703]
There is some difference between Le Bon's view and ours owing to his concept of the unconscious not quite coinciding with the one adopted by psycho-analysis. Le Bon's unconscious more especially contains the most deeply buried features of the racial mind, which as a matter of fact lies outside the scope of psycho-analysis. We do not fail to recognize, indeed, that the ego's nucleus, which comprises the 'archaic heritage' of the human mind, is unconscious; but in addition to this we distinguish the 'unconscious repressed', which arose from a portion of that heritage. This concept of the repressed is not to be found in Le Bon.

[1921c, 3769]

In this place I shall only follow up one of the consequences which seem possible from this point of view, thus resuming the discussion of a problem which I was obliged to leave unsolved elsewhere.¹ Each of the mental differentiations that we have become acquainted with represents a fresh aggravation of the difficulties of mental functioning, increases its instability, and may become the starting-point for its breakdown, that is, for the onset of a disease. Thus, by being born we have made the step from an absolutely self-sufficient narcissism to the perception of a changing external world and the beginnings of the discovery of objects. And with this is associated the fact that we cannot endure the new state of things for long, that we periodically revert from it, in our sleep, to our former condition of absence of stimulation and avoidance of objects. It is true, however, that in this we are following a hint from the external world, which, by means of the periodical change of day and night, temporarily withdraws the greater part of the stimuli that affect us. The second example of such a step, pathologically more important, is subject to no such qualification. In the course of development we have effected a separation of our mental existence into a coherent ego and into an unconscious and repressed portion which is left outside it; and we know that the stability of this new acquisition is exposed to constant shocks. In dreams and in neuroses what is thus excluded knocks for admission at the gates, guarded though they are by resistances; and in our waking health we make use of special artifices for allowing what is repressed to circumvent the resistances and for receiving it temporarily into our ego to the increase of our pleasure. Jokes and humour, and to some extent the comic in general, may be regarded in this light. Everyone acquainted with the psychology of the neuroses will think of similar examples of less importance; but I hasten on to the application I have in view.

[1921c, 3821]

This first configuration of the child's love, which in typical cases takes the shape of the Oedipus complex, succumbs, as we know, from the beginning of the period of latency onwards to a wave of repression. Such of it as is left over shows itself as a purely affectionate emotional tie, relating to the same people, but no longer to be described as 'sexual'. Psycho-analysis, which illuminates the depths of mental life, has no difficulty in showing that the sexual ties of the earliest years of childhood also persist, though repressed and unconscious. It gives us courage to assert that wherever we come across an affectionate feeling it is successor to a completely 'sensual' object-tie with the person in question or rather with that person's prototype (or imago). It cannot indeed disclose to us without a special investigation whether in a given case this former complete sexual current still exists under repression or whether it has already been exhausted. To speak still more precisely: it is quite certain that this current is still there as a form and possibility, and can always be cathected and put into activity again by means of regression; the only question is (and it cannot always be answered) what degree of cathexis and operative force it still has at the present moment. Equal care must be taken in this connection to avoid two sources of error - the Scylla of underestimating the importance of the repressed unconscious, and the Charybdis of judging the normal entirely by the standards of the pathological.

[1921c, 3829]
Neurosis stands outside this series. It also is based upon a peculiarity in the development of the human libido - the twice repeated start made by the directly sexual function, with an intervening period of latency.¹ To this extent it resembles hypnosis and group formation in having the character of a regression, which is absent from being in love. It makes its appearance wherever the advance from directly sexual instincts to those that are inhibited in their aims has not been wholly successful; and it represents a conflict between those portions of the instincts which have been received into the ego after having passed through this development and those portions of them which, springing from the repressed unconscious, strive - as do other, completely repressed, instinctual impulses - to attain direct satisfaction. Neuroses are extraordinarily rich in content, for they embrace all possible relations between the ego and the object - both those in which the object is retained and others in which it is abandoned or erected inside the ego itself - and also the conflicting relations between the ego and its ego ideal.

[1921c, 3834]

But we have arrived at the term or concept of the unconscious along another path, by considering certain experiences in which mental dynamics play a part. We have found - that is, we have been obliged to assume - that very powerful mental processes or ideas exist (and here a quantitative or economic factor comes into question for the first time) which can produce all the effects in mental life that ordinary ideas do (including effects that can in their turn become conscious as ideas), though they themselves do not become conscious. It is unnecessary to repeat in detail here what has been explained so often before. It is enough to say that at this point psycho-analytic theory steps in and asserts that the reason why such ideas cannot become conscious is that a certain force opposes them, that otherwise they could become conscious, and that it would then be apparent how little they differ from other elements which are admittedly psychical. The fact that in the technique of psycho-analysis a means has been found by which the opposing force can be removed and the ideas in question made conscious renders this theory irrefutable. The state in which the ideas existed before being made conscious is called by us repression, and we assert that the force which instituted the repression and maintains it is perceived as resistance during the work of analysis.

[1923b, 3948]

Thus we obtain our concept of the unconscious from the theory of repression. The repressed is the prototype of the unconscious for us. We see, however, that we have two kinds of unconscious - the one which is latent but capable of becoming conscious, and the one which is repressed and which is not, in itself and without more ado, capable of becoming conscious. This piece of insight into psychical dynamics cannot fail to affect terminology and description. The latent, which is unconscious only descriptively, not in the dynamic sense, we call preconscious; we restrict the term unconscious to the dynamically unconscious repressed; so that now we have three terms, conscious (Cs.), preconscious (Pcs.), and unconscious (Ucs.), whose sense is no longer purely descriptive. The Pcs. is presumably a great deal closer to the Cs. than is the Ucs., and since we have called the Ucs. psychical we shall with even less hesitation call the latent Pcs. psychical. But why do we not rather, instead of this, remain in agreement with the philosophers and, in a consistent way, distinguish the Pcs. as well as the Ucs. from the conscious psychical? The philosophers would then propose that the Pcs. and the Ucs. should be described as two species or stages of the 'psychoid', and harmony would be established. But endless difficulties in exposition would follow; and the one important fact, that these two kinds of 'psychoid' coincide in almost every other respect with what is admittedly psychical, would be forced into the background in the interests of a prejudice dating from a period in which these psychoids, or the most important part of them, were still unknown.

[1923b, 3949]
For our conception of the unconscious, however, the consequences of our discovery are even more important. Dynamic considerations caused us to make our first correction; our insight into the structure of the mind leads to the second. We recognize that the Ucs does not coincide with the repressed; it is still true that all that is repressed is Ucs., but not all that is Ucs. is repressed. A part of the ego, too - and Heaven knows how important a part - may be Ucs., undoubtedly is Ucs. And this Ucs. belonging to the ego is not latent like the Pcs.; for if it were, it could not be activated without becoming Cs., and the process of making it conscious would not encounter such great difficulties. When we find ourselves thus confronted by the necessity of postulating a third Ucs., which is not repressed, we must admit that the characteristic of being unconscious begins to lose significance for us. It becomes a quality which can have many meanings, a quality which we are unable to make, as we should have hoped to do, the basis of far-reaching and inevitable conclusions. Nevertheless we must beware of ignoring this characteristic, for the property of being conscious or not is in the last resort our one beacon-light in the darkness of depth-psychology.

[1923b, 3952]

There is no need to discuss what is to be called conscious: it is removed from all doubt. The oldest and best meaning of the word 'unconscious' is the descriptive one; we call a psychical process unconscious whose existence we are obliged to assume - for some such reason as that we infer it from its effects -, but of which we know nothing. In that case we have the same relation to it as we have to a psychical process in another person, except that it is in fact one of our own. If we want to be still more correct, we shall modify our assertion by saying that we call a process unconscious if we are obliged to assume that it is being activated at the moment, though at the moment we know nothing about it. This qualification makes us reflect that the majority of conscious processes are conscious only for a short time; very soon they become latent, but can easily become conscious again. We might also say that they had become unconscious, if it were at all certain that in the condition of latency they are still something psychical. So far we should have learnt nothing new; nor should we have acquired the right to introduce the concept of an unconscious into psychology. But then comes the new observation that we were already able to make in parapraxes. In order to explain a slip of the tongue, for instance, we find ourselves obliged to assume that the intention to make a particular remark was present in the subject. We infer it with certainty from the interference with his remark which has occurred; but the intention did not put itself through and was thus unconscious. If, when we subsequently put it before the speaker, he recognizes it as one familiar to him, then it was only temporarily unconscious to him; but if he repudiates it as something foreign to him, then it was permanently unconscious. From this experience we retrospectively obtain the right also to pronounce as something unconscious what had been described as latent. A consideration of these dynamic relations permits us now to distinguish two kinds of unconscious - one which is easily, under frequently occurring circumstances, transformed into something conscious, and another with which this transformation is difficult and takes place only subject to a considerable expenditure of effort or possibly never at all. In order to escape the ambiguity as to whether we mean the one or the other unconscious, whether we are using the word in the descriptive or in the dynamic sense, we make use of a permissible and simple way out. We call the unconscious which is only latent, and thus easily becomes conscious, the 'preconscious' and retain the term 'unconscious' for the other. We now have three terms, 'conscious', 'preconscious' and 'unconscious', with which we can get along in our description of mental phenomena. Once again: the preconscious is also unconscious in the purely descriptive sense, but we do not give it that name, except in talking loosely or when we have to make a defence of the existence in mental life of unconscious processes in general.

[1933a, 4679]
You will admit, I hope, that so far that is not too bad and allows of convenient handling. Yes, but unluckily the work of psycho-analysis has found itself compelled to use the word 'unconscious' in yet another, third, sense, and this may, to be sure, have led to confusion. Under the new and powerful impression of there being an extensive and important field of mental life which is normally withdrawn from the ego's knowledge so that the processes occurring in it have to be regarded as unconscious in the truly dynamic sense, we have come to understand the term 'unconscious' in a topographical or systematic sense as well; we have come to speak of a 'system' of the preconscious and a 'system' of the unconscious, of a conflict between the ego and the system $Ucs.$, and have used the word more and more to denote a mental province rather than a quality of what is mental. The discovery, actually an inconvenient one, that portions of the ego and super-ego as well are unconscious in the dynamic sense, operates at this point as a relief - it makes possible the removal of a complication. We perceive that we have no right to name the mental region that is foreign to the ego 'the system $Ucs.$', since the characteristic of being unconscious is not restricted to it. Very well; we will no longer use the term 'unconscious' in the systematic sense and we will give what we have hitherto so described a better name and one no longer open to misunderstanding. Following a verbal usage of Nietzsche's and taking up a suggestion by Georg Groddeck, we will in future call it the 'id'. This impersonal pronoun seems particularly well suited for expressing the main characteristic of this province of the mind - the fact of its being alien to the ego. The super-ego, the ego and the id - these, then, are the three realms, regions, provinces, into which we divide an individual's mental apparatus, and with the mutual relations of which we shall be concerned in what follows.

[1933a, 4680]

There is one portion of the id from which the ego has separated itself by resistances due to repression. But the repression is not carried over into the id: the repressed merges into the remainder of the id.

[1933a, 4685]

The difference between whether a psychical process is conscious or unconscious has served us as a criterion and a means of finding our bearings. The repressed is unconscious. Now it would simplify things agreeably if this sentence admitted of reversal - if, that is, the difference between the qualities of conscious ($Cs.$) and unconscious ($Ucs.$) coincided with the distinction between 'belonging to the ego' and 'repressed'. The fact of there being isolated and unconscious things like this in our mental life would be sufficiently novel and important. But in reality the position is more complicated. It is true that everything repressed is unconscious, but it is not true that everything belonging to the ego is conscious. We notice that consciousness is a transient quality which attaches to a psychical process only in passing. For our purposes therefore we must replace 'conscious' by 'capable of being conscious' and we call this quality 'preconscious' ($Pcs.$). We then say, more correctly, that the ego is mainly preconscious (virtually conscious) but that portions of the ego are unconscious.

[1939a, 4918]
The *repressed* is to be counted as belonging to the id and is subject to the same mechanisms; it is distinguished from it only in respect to its genesis. The differentiation is accomplished in the earliest period of life, while the ego is developing out of the id. At that time a portion of the contents of the id is taken into the ego and raised to the preconscious state; another portion is not affected by this translation and remains behind in the id as the unconscious proper. In the further course of the formation of the ego, however, certain psychical impressions and processes in the ego are excluded from it by a defensive process; the characteristic of being preconscious is withdrawn from them, so that they are once more reduced to being component portions of the id. Here then is the 'repressed' in the id. So far as intercourse between the two mental provinces is concerned, we therefore assume that, on the one hand, unconscious processes in the id are raised to the level of the preconscious and incorporated into the ego, and that, on the other hand, preconscious material in the ego can follow the opposite path and be put back into the id. The fact that later on a special region - that of the 'super-ego' - is separated off in the ego lies outside our present interest.

[1939a, 4919]

The sole prevailing quality in the id is that of being unconscious. Id and unconscious are as intimately linked as ego and preconscious: indeed, in the former case the connection is even more exclusive. If we look back at the developmental history of an individual and of his psychical apparatus, we shall be able to perceive an important distinction in the id. Originally, to be sure, everything was id; the ego was developed out of the id by the continual influence of the external world. In the course of this slow development certain of the contents of the id were transformed into the preconscious state and so taken into the ego; others of its contents remained in the id unchanged, as its scarcely accessible nucleus. During this development, however, the young and feeble ego put back into the unconscious state some of the material it had already taken in, dropped it, and behaved in the same way to some fresh impressions which it might have taken in, so that these, having been rejected, could leave a trace only in the id. In consideration of its origin we speak of this latter portion of the id as the *repressed*. It is of little importance that we are not always able to draw a sharp line between these two categories of contents in the id. They coincide approximately with the distinction between what was innately present originally and what was acquired in the course of the ego's development.

[1940a [1938], 4973]
The crudest idea of these systems is the most convenient for us - a spatial one. Let us therefore compare the system of the unconscious to a large entrance hall, in which the mental impulses jostle one another like separate individuals. Adjoining this entrance hall there is a second, narrower, room - a kind of drawing-room - in which consciousness, too, resides. But on the threshold between these two rooms a watchman performs his function: he examines the different mental impulses, acts as a censor, and will not admit them into the drawing-room if they displease him. You will see at once that it does not make much difference if the watchman turns away a particular impulse at the threshold itself or if he pushes it back across the threshold after it has entered the drawing-room. This is merely a question of the degree of his watchfulness and of how early he carries out his act of recognition. If we keep to this picture, we shall be able to extend our nomenclature further. The impulses in the entrance hall of the unconscious are out of sight of the conscious, which is in the other room; to begin with they must remain unconscious. If they have already pushed their way forward to the threshold and have been turned back by the watchman, then they are inadmissible to consciousness; we speak of them as repressed. But even the impulses which the watchman has allowed to cross the threshold are not on that account necessarily conscious as well; they can only become so if they succeed in catching the eye of consciousness. We are therefore justified in calling this second room the system of the preconscious. In that case becoming conscious retains its purely descriptive sense. For any particular impulse, however, the vicissitude of repression consists in its not being allowed by the watchman to pass from the system of the unconscious into that of the preconscious. It is the same watchman whom we get to know as resistance when we try to lift the repression by means of the analytic treatment.

What, then, must we do in order to replace what is unconscious in our patients by what is conscious? There was a time when we thought this was a very simple matter: all that was necessary was for us to discover this unconscious material and communicate it to the patient. But we know already that this was a short-sighted error. Our knowledge about the unconscious material is not equivalent to his knowledge; if we communicate our knowledge to him, he does not receive it instead of his unconscious material but beside it; and that makes very little change in it. We must rather picture this unconscious material topographically, we must look for it in his memory at the place where it became unconscious owing to a repression. The repression must be got rid of - after which the substitution of the conscious material for the unconscious can proceed smoothly. How, then, do we lift a repression of this kind? Here our task enters a second phase. First, the search for the repression and then the removal of the resistance which maintains the repression.

But we have arrived at the term or concept of the unconscious along another path, by considering certain experiences in which mental dynamics play a part. We have found - that is, we have been obliged to assume - that very powerful mental processes or ideas exist (and here a quantitative or economic factor comes into question for the first time) which can produce all the effects in mental life that ordinary ideas do (including effects that can in their turn become conscious as ideas), though they themselves do not become conscious. It is unnecessary to repeat in detail here what has been explained so often before. It is enough to say that at this point psycho-analytic theory steps in and asserts that the reason why such ideas cannot become conscious is that a certain force opposes them, that otherwise they could become conscious, and that it would then be apparent how little they differ from other elements which are admittedly psychical. The fact that in the technique of psycho-analysis a means has been found by which the opposing force can be removed and the ideas in question made conscious renders this theory irrefutable. The state in which the ideas existed before being made conscious is called by us repression, and we assert that the force which instituted the repression and maintains it is perceived as resistance during the work of analysis.
Thus we obtain our concept of the unconscious from the theory of repression. The repressed is the prototype of the unconscious for us. We see, however, that we have two kinds of unconscious - the one which is latent but capable of becoming conscious, and the one which is repressed and which is not, in itself and without more ado, capable of becoming conscious. This piece of insight into psychical dynamics cannot fail to affect terminology and description. The latent, which is unconscious only descriptively, not in the dynamic sense, we call preconscious; we restrict the term unconscious to the dynamically unconscious repressed; so that now we have three terms, conscious (Cs.), preconscious (Pcs.), and unconscious (Ucs.), whose sense is no longer purely descriptive. The Pcs. is presumably a great deal closer to the Cs. than is the Ucs., and since we have called the Ucs. psychical we shall with even less hesitation call the latent Pcs. psychical. But why do we not rather, instead of this, remain in agreement with the philosophers and, in a consistent way, distinguish the Pcs. as well as the Ucs. from the conscious psychical? The philosophers would then propose that the Pcs. and the Ucs. should be described as two species or stages of the 'psychoid', and harmony would be established. But endless difficulties in exposition would follow; and the one important fact, that these two kinds of 'psychoid' coincide in almost every other respect with what is admittedly psychical, would be forced into the background in the interests of a prejudice dating from a period in which these psychoids, or the most important part of them, were still unknown.

[1923b, 3949]

In so far as it is possible to influence by arguments the decision of a question of this kind which depends either on convention or on emotional factors, we may make the following comments. The reference to gradations of clarity in consciousness is in no way conclusive and has no more evidential value than such analogous statements as: 'There are so very many gradations in illumination - from the most glaring and dazzling light to the dimmest glimmer - therefore there is no such thing as darkness at all'; or, 'There are varying degrees of vitality, therefore there is no such thing as death.' Such statements may in a certain way have a meaning, but for practical purposes they are worthless. This will be seen if one tries to draw particular conclusions from them, such as, 'there is therefore no need to strike a light', or, 'therefore all organisms are immortal'. Further, to include 'what is unnoticeable' under the concept of 'what is conscious' is simply to play havoc with the one and only piece of direct and certain knowledge that we have about the mind. And after all, a consciousness of which one knows nothing seems to me a good deal more absurd than something mental that is unconscious. Finally, this attempt to equate what is unnoticed with what is unconscious is obviously made without taking into account the dynamic conditions involved, which were the decisive factors in forming the psycho-analytic view. For it ignores two facts: first, that it is exceedingly difficult and requires very great effort to concentrate enough attention on something unnoticed of this kind; and secondly, that when this has been achieved the thought which was previously unnoticed is not recognized by consciousness, but often seems entirely alien and opposed to it and is promptly disavowed by it. Thus, seeking refuge from the unconscious in what is scarcely noticed or unnoticed is after all only a derivative of the preconceived belief which regards the identity of the psychical and the conscious as settled once and for all.

[1923b, 3950]
For our conception of the unconscious, however, the consequences of our discovery are even more important. Dynamic considerations caused us to make our first correction; our insight into the structure of the mind leads to the second. We recognize that the Ucs. does not coincide with the repressed; it is still true that all that is repressed is Ucs., but not all that is Ucs. is repressed. A part of the ego, too - and Heaven knows how important a part - may be Ucs., undoubtedly is Ucs. And this Ucs. belonging to the ego is not latent like the Pcs.; for if it were, it could not be activated without becoming Cs., and the process of making it conscious would not encounter such great difficulties. When we find ourselves thus confronted by the necessity of postulating a third Ucs., which is not repressed, we must admit that the characteristic of being unconscious begins to lose significance for us. It becomes a quality which can have many meanings, a quality which we are unable to make, as we should have hoped to do, the basis of far-reaching and inevitable conclusions. Nevertheless we must beware of ignoring this characteristic, for the property of being conscious or not is in the last resort our one beacon-light in the darkness of depth-psychology.

There is no need to discuss what is to be called conscious: it is removed from all doubt. The oldest and best meaning of the word 'unconscious' is the descriptive one; we call a psychical process unconscious whose existence we are obliged to assume - for some such reason as that we infer it from its effects -, but of which we know nothing. In that case we have the same relation to it as we have to a psychical process in another person, except that it is in fact one of our own. If we want to be still more correct, we shall modify our assertion by saying that we call a process unconscious if we are obliged to assume that it is being activated at the moment, though at the moment we know nothing about it. This qualification makes us reflect that the majority of conscious processes are conscious only for a short time; very soon they become latent, but can easily become conscious again. We might also say that they had become unconscious, if it were at all certain that in the condition of latency they are still something psychical. So far we should have learnt nothing new; nor should we have acquired the right to introduce the concept of an unconscious into psychology. But then comes the new observation that we were already able to make in parapraxes. In order to explain a slip of the tongue, for instance, we find ourselves obliged to assume that the intention to make a particular remark was present in the subject. We infer it with certainty from the interference with his remark which has occurred; but the intention did not put itself through and was thus unconscious. If, when we subsequently put it before the speaker, he recognizes it as one familiar to him, then it was only temporarily unconscious to him; but if he repudiates it as something foreign to him, then it was permanently unconscious. From this experience we retrospectively obtain the right also to pronounce as something unconscious what had been described as latent. A consideration of these dynamic relations permits us now to distinguish two kinds of unconscious - one which is easily, under frequently occurring circumstances, transformed into something conscious, and another with which this transformation is difficult and takes place only subject to a considerable expenditure of effort or possibly never at all. In order to escape the ambiguity as to whether we mean the one or the other unconscious, whether we are using the word in the descriptive or in the dynamic sense, we make use of a permissible and simple way out. We call the unconscious which is only latent, and thus easily becomes conscious, the 'preconscious' and retain the term 'unconscious' for the other. We now have three terms, 'conscious', 'preconscious' and 'unconscious', with which we can get along in our description of mental phenomena. Once again: the preconscious is also unconscious in the purely descriptive sense, but we do not give it that name, except in talking loosely or when we have to make a defence of the existence in mental life of unconscious processes in general.

[1923b, 3952]

[1933a, 4679]
Thus we have attributed three qualities to psychical processes: they are either conscious, preconscious or unconscious. The division between the three classes of material which possess these qualities is neither absolute nor permanent. What is preconscious becomes conscious, as we have seen, without any assistance from us; what is unconscious can, through our efforts, be made conscious, and in the process we may have a feeling that we are often overcoming very strong resistances. When we attempt to do this with someone else, we should not forget that the conscious filling-in of the gaps in his perceptions - the construction we are presenting him with - does not mean as yet that we have made the unconscious material in question conscious to him. All that is true so far is that the material is present in him in two records, once in the conscious reconstruction he has been given, and besides this in its original unconscious state. Our continued efforts usually succeed eventually in making this unconscious material conscious to him himself, as a result of which the two records are brought to coincide. The amount of effort we have to use, by which we estimate the resistance against the material becoming conscious, varies in magnitude in individual cases. For instance, what comes about in an analytic treatment as a result of our efforts can also occur spontaneously: material which is ordinarily unconscious can transform itself into preconscious material and then becomes conscious - a thing that happens to a large extent in psychotic states. From this we infer that the maintenance of certain internal resistances is a sine qua non of normality. A relaxation of resistances such as this, with a consequent pushing forward of unconscious material, takes place regularly in the state of sleep, and thus brings about a necessary precondition for the construction of dreams. Conversely, preconscious material can become temporarily inaccessible and cut off by resistances, as happens when something is temporarily forgotten or escapes the memory; or a preconscious thought can even be temporarily put back into the unconscious state, as seems to be a precondition in the case of jokes. We shall see that a similar transformation back of preconscious material or processes into the unconscious state plays a great part in the causation of neurotic disorders.

[1940a (1938), 4970]
Thus we obtain our concept of the unconscious from the theory of repression. The repressed is the prototype of the unconscious for us. We see, however, that we have two kinds of unconscious - the one which is latent but capable of becoming conscious, and the one which is repressed and which is not, in itself and without more ado, capable of becoming conscious. This piece of insight into psychical dynamics cannot fail to affect terminology and description. The latent, which is unconscious only descriptively, not in the dynamic sense, we call preconscious; we restrict the term unconscious to the dynamically unconscious repressed; so that now we have three terms, conscious (Cs.), preconscious (Pcs.), and unconscious (Ucs.), whose sense is no longer purely descriptive. The Pcs. is presumably a great deal closer to the Cs. than is the Ucs., and since we have called the Ucs. psychical we shall with even less hesitation call the latent Pcs. psychical. But why do we not rather, instead of this, remain in agreement with the philosophers and, in a consistent way, distinguish the Pcs. as well as the Ucs. from the conscious psychical? The philosophers would then propose that the Pcs. and the Ucs. should be described as two species or stages of the 'psychoid', and harmony would be established. But endless difficulties in exposition would follow; and the one important fact, that these two kinds of 'psychoid' coincide in almost every other respect with what is admittedly psychical, would be forced into the background in the interests of a prejudice dating from a period in which these psychoids, or the most important part of them, were still unknown.

[1923b, 3949]

For our conception of the unconscious, however, the consequences of our discovery are even more important. Dynamic considerations caused us to make our first correction; our insight into the structure of the mind leads to the second. We recognize that the Ucs. does not coincide with the repressed; it is still true that all that is repressed is Ucs., but not all that is Ucs. is repressed. A part of the ego, too - and Heaven knows how important a part - may be Ucs., undoubtedly is Ucs. And this Ucs. belonging to the ego is not latent like the Pcs.; for if it were, it could not be activated without becoming Cs., and the process of making it conscious would not encounter such great difficulties. When we find ourselves thus confronted by the necessity of postulating a third Ucs., which is not repressed, we must admit that the characteristic of being unconscious begins to lose significance for us. It becomes a quality which can have many meanings, a quality which we are unable to make, as we should have hoped to do, the basis of far-reaching and inevitable conclusions. Nevertheless we must beware of ignoring this characteristic, for the property of being conscious or not is in the last resort our one beacon-light in the darkness of depth-psychology.

[1923b, 3952]
There is no need to discuss what is to be called conscious: it is removed from all doubt. The oldest and best meaning of the word ‘unconscious’ is the descriptive one; we call a psychical process unconscious whose existence we are obliged to assume - for some such reason as that we infer it from its effects -, but of which we know nothing. In that case we have the same relation to it as we have to a psychical process in another person, except that it is in fact one of our own. We might also say that they had become unconscious, if it were at all certain that in the condition of latency they are still something psychical. So far we should have learnt nothing new; nor should we have acquired the right to introduce the concept of an unconscious into psychology. But then comes the new observation that we were already able to make in parapraxises. In order to explain a slip of the tongue, for instance, we find ourselves obliged to assume that the intention to make a particular remark was present in the subject. We infer it with certainty from the interference with his remark which has occurred; but the intention did not put itself through and was thus unconscious. If, when we subsequently put it before the speaker, he recognizes it as one familiar to him, then it was only temporarily unconscious to him; but if he repudiates it as something foreign to him, then it was permanently unconscious. From this experience we retrospectively obtain the right also to pronounce as something unconscious what had been described as latent. A consideration of these dynamic relations permits us now to distinguish two kinds of unconscious - one which is easily, under frequently occurring circumstances, transformed into something conscious, and another with which this transformation is difficult and takes place only subject to a considerable expenditure of effort or possibly never at all. In order to escape the ambiguity as to whether we mean the one or the other unconscious, whether we are using the word in the descriptive or in the dynamic sense, we make use of a permissible and simple way out. We call the unconscious which is only latent, and thus easily becomes conscious, the ‘preconscious’ and retain the term ‘unconscious’ for the other. We now have three terms, ‘conscious’, ‘preconscious’ and ‘unconscious’, with which we can get along in our description of mental phenomena. Once again: the preconscious is also unconscious in the purely descriptive sense, but we do not give it that name, except in talking loosely or when we have to make a defence of the existence in mental life of unconscious processes in general.

[1933a, 4679]
You will admit, I hope, that so far that is not too bad and allows of convenient handling. Yes, but unluckily the work of psycho-analysis has found itself compelled to use the word 'unconscious' in yet another, third, sense, and this may, to be sure, have led to confusion. Under the new and powerful impression of there being an extensive and important field of mental life which is normally withdrawn from the ego's knowledge so that the processes occurring in it have to be regarded as unconscious in the truly dynamic sense, we have come to understand the term 'unconscious' in a topographical or systematic sense as well; we have come to speak of a 'system' of the preconscious and a 'system' of the unconscious, of a conflict between the ego and the system Ucs., and have used the word more and more to denote a mental province rather than a quality of what is mental. The discovery, actually an inconvenient one, that portions of the ego and super-ego as well are unconscious in the dynamic sense, operates at this point as a relief - it makes possible the removal of a complication. We perceive that we have no right to name the mental region that is foreign to the ego 'the system Ucs', since the characteristic of being unconscious is not restricted to it. Very well; we will no longer use the term 'unconscious' in the systematic sense and we will give what we have hitherto so described a better name and one no longer open to misunderstanding. Following a verbal usage of Nietzsche's and taking up a suggestion by Georg Groddeck, we will in future call it the 'id'. This impersonal pronoun seems particularly well suited for expressing the main characteristic of this province of the mind - the fact of its being alien to the ego. The super-ego, the ego and the id - these, then, are the three realms, regions, provinces, into which we divide an individual's mental apparatus, and with the mutual relations of which we shall be concerned in what follows.

The difference between whether a psychical process is conscious or unconscious has served us as a criterion and a means of finding our bearings. The repressed is unconscious. Now it would simplify things agreeably if this sentence admitted of reversal - if, that is, the difference between the qualities of conscious (Cs.) and unconscious (Ucs.) coincided with the distinction between 'belonging to the ego' and 'repressed'. The fact of there being isolated and unconscious things like this in our mental life would be sufficiently novel and important. But in reality the position is more complicated. It is true that everything repressed is unconscious, but it is not true that everything belonging to the ego is conscious. We notice that consciousness is a transient quality which attaches to a psychical process only in passing. For our purposes therefore we must replace 'conscious' by 'capable of being conscious' and we call this quality 'preconscious' (Pcs.). We then say, more correctly, that the ego is mainly preconscious (virtually conscious) but that portions of the ego are unconscious.

The repressed is to be counted as belonging to the id and is subject to the same mechanisms; it is distinguished from it only in respect to its genesis. The differentiation is accomplished in the earliest period of life, while the ego is developing out of the id. At that time a portion of the contents of the id is taken into the ego and raised to the preconscious state; another portion is not affected by this translation and remains behind in the id as the unconscious proper. In the further course of the formation of the ego, however, certain psychical impressions and processes in the ego are excluded from it by a defensive process; the characteristic of being preconscious is withdrawn from them, so that they are once more reduced to being component portions of the id. Here then is the 'repressed' in the id. So far as intercourse between the two mental provinces is concerned, we therefore assume that, on the one hand, unconscious processes in the id are raised to the level of the preconscious and incorporated into the ego, and that, on the other hand, preconscious material in the ego can follow the opposite path and be put back into the id. The fact that later on a special region - that of the 'super-ego' - is separated off in the ego lies outside our present interest.
The sole prevailing quality in the id is that of being unconscious. Id and unconscious are as intimately linked as ego and preconscious: indeed, in the former case the connection is even more exclusive. If we look back at the developmental history of an individual and of his psychical apparatus, we shall be able to perceive an important distinction in the id. Originally, to be sure, everything was id; the ego was developed out of the id by the continual influence of the external world. In the course of this slow development certain of the contents of the id were transformed into the preconscious state and so taken into the ego; others of its contents remained in the id unchanged, as its scarcely accessible nucleus. During this development, however, the young and feeble ego put back into the unconscious state some of the material it had already taken in, dropped it, and behaved in the same way to some fresh impressions which it might have taken in, so that these, having been rejected, could leave a trace only in the id. In consideration of its origin we speak of this latter portion of the id as the repressed. It is of little importance that we are not always able to draw a sharp line between these two categories of contents in the id. They coincide approximately with the distinction between what was innately present originally and what was acquired in the course of the ego’s development. [1940a [1938], 4973]
Nor will it be out of place here to utter a warning against any over-hasty generalization of what we have brought to light concerning the distribution of the various mental functions between the two systems. We are describing the state of affairs as it appears in the adult human being, in whom the system Ucs. operates, strictly speaking, only as a preliminary stage of the higher organization. The question of what the content and connections of that system are during the development of the individual, and of what significance it possesses in animals - these are points on which no conclusion can be deduced from our description: they must be investigated independently. Moreover, in human beings we must be prepared to find possible pathological conditions under which the two systems alter, or even exchange, both their content and their characteristics.

[1915e, 3012]

The repressed retains its upward urge, its effort to force its way to consciousness. It achieves its aim under three conditions: (1) if the strength of the anticathexis is diminished by pathological processes which overtake the other part, what we call the ego, or by a different distribution of the cathectic energies in that ego, as happens regularly in the state of sleep; (2) if the instinctual elements attaching to the repressed receive a special reinforcement (of which the best example is the processes during puberty); and (3) if at any time in recent experience impressions or experiences occur which resemble the repressed so closely that they are able to awaken it. In the last case the recent experience is reinforced by the latent energy of the repressed, and the repressed comes into operation behind the recent experience and with its help. In none of these three alternatives does what has hitherto been repressed enter consciousness smoothly and unaltered; it must always put up with distortions which testify to the influence of the resistance (not entirely overcome) arising from the anticathexis, or to the modifying influence of the recent experience or to both.

[1939a, 4918]
The repressed retains its upward urge, its effort to force its way to consciousness. It achieves its aim under three conditions: (1) if the strength of the anticathexis is diminished by pathological processes which overtake the other part, what we call the ego, or by a different distribution of the cathetic energies in that ego, as happens regularly in the state of sleep; (2) if the instinctual elements attaching to the repressed receive a special reinforcement (of which the best example is the processes during puberty); and (3) if at any time in recent experience impressions or experiences occur which resemble the repressed so closely that they are able to awaken it. In the last case the recent experience is reinforced by the latent energy of the repressed, and the repressed comes into operation behind the recent experience and with its help. [1939a, 4918]

Thus we have attributed three qualities to psychical processes: they are either conscious, preconscious or unconscious. The division between the three classes of material which possess these qualities is neither absolute nor permanent. What is preconscious becomes conscious, as we have seen, without any assistance from us; what is unconscious can, through our efforts, be made conscious, and in the process we may have a feeling that we are often overcoming very strong resistances. When we attempt to do this with someone else, we should not forget that the conscious filling-in of the gaps in his perceptions - the construction we are presenting him with - does not mean as yet that we have made the unconscious material in question conscious to him. All that is true so far is that the material is present in him in two records, once in the conscious reconstruction he has been given, and besides this in its original unconscious state. Our continued efforts usually succeed eventually in making this unconscious material conscious to him himself, as a result of which the two records are brought to coincide. The amount of effort we have to use, by which we estimate the resistance against the material becoming conscious, varies in magnitude in individual cases. For instance, what comes about in an analytic treatment as a result of our efforts can also occur spontaneously: material which is ordinarily unconscious can transform itself into preconscious material and then becomes conscious - a thing that happens to a large extent in psychotic states. From this we infer that the maintenance of certain internal resistances is a sine qua non of normality. A relaxation of resistances such as this, with a consequent pushing forward of unconscious material, takes place regularly in the state of sleep, and thus brings about a necessary precondition for the construction of dreams.

Conversely, preconscious material can become temporarily inaccessible and cut off by resistances, as happens when something is temporarily forgotten or escapes the memory; or a preconscious thought can even be temporarily put back into the unconscious state, as seems to be a precondition in the case of jokes. We shall see that a similar transformation back of preconscious material or processes into the unconscious state plays a great part in the causation of neurotic disorders.

[1940a [1938], 4970]
An investigation of normal, stable states, in which the frontiers of the ego are safeguarded against the id by resistances (anticathexes) and have held firm, and in which the super-ego is not distinguished from the ego, because they work together harmoniously - an investigation of that kind would teach us little. The only thing that can help us are states of conflict and uproar, when the contents of the unconscious id have a prospect of forcing their way into the ego and into consciousness and the ego puts itself once more on the defensive against this invasion. It is only under these conditions that we can make such observations as will confirm or correct our statements about the two partners. Now, our nightly sleep is precisely a state of this sort, and for that reason psychical activity during sleep, which we perceive as dreams, is our most favourable object of study. In that way, too, we avoid the familiar reproach that we base our constructions of normal mental life on pathological findings; for dreams are regular events in the life of a normal person, however much their characteristics may differ from the productions of our waking life. Dreams, as everyone knows, may be confused, unintelligible or positively nonsensical, what they say may contradict all that we know of reality, and we behave in them like insane people, since, so long as we are dreaming, we attribute objective reality to the contents of the dream.

[1940a [1938], 4975]

We find our way to the understanding ('interpretation') of a dream by assuming that what we recollect as the dream after we have woken up is not the true dream-process but only a façade behind which that process lies concealed. Here we have our distinction between the manifest content of a dream and the latent dream-thoughts. The process which produces the former out of the latter is described as the dream-work. The study of the dream-work teaches us by an excellent example the way in which unconscious material from the id (originally unconscious and repressed unconscious alike) forces its way into the ego, becomes preconscious and, as a result of the ego's opposition, undergoes the changes which we know as dream-distortion. There are no features of a dream which cannot be explained in this way.

[1940a [1938], 4975]

But what makes dreams so invaluable in giving us insight is the circumstance that, when the unconscious material makes its way into the ego, it brings its own modes of working along with it. This means that the preconscious thoughts in which the unconscious material has found its expression are handled in the course of the dream-work as though they were unconscious portions of the id; and, in the case of the alternative method of dream-formation, the preconscious thoughts which have obtained reinforcement from an unconscious instinctual impulse are brought down to the unconscious state. It is only in this way that we learn the laws which govern the passage of events in the unconscious and the respects in which they differ from the rules that are familiar to us in waking thought. Thus the dream-work is essentially an instance of the unconscious working-over of preconscious thought-processes. To take an analogy from history: invading conquerors govern a conquered country, not according to the judicial system which they find in force there, but according to their own. It is, however, an unmistakable fact that the outcome of the dream-work is a compromise. The ego-organization is not yet paralysed, and its influence is to be seen in the distortion imposed on the unconscious material and in what are often very ineffective attempts at giving the total result a form not too unacceptable to the ego (secondary revision). In our analogy this would be an expression of the continued resistance of the defeated people.

[1940a [1938], 4977]
Thus we have attributed three qualities to psychical processes: they are either conscious, preconscious or unconscious. The division between the three classes of material which possess these qualities is neither absolute nor permanent. What is preconscious becomes conscious, as we have seen, without any assistance from us; what is unconscious can, through our efforts, be made conscious, and in the process we may have a feeling that we are often overcoming very strong resistances. When we attempt to do this with someone else, we should not forget that the conscious filling-in of the gaps in his perceptions - the construction we are presenting him with - does not mean as yet that we have made the unconscious material in question conscious to him. All that is true so far is that the material is present in him in two records, once in the conscious reconstruction he has been given, and besides this in its original unconscious state.

Our continued efforts usually succeed eventually in making this unconscious material conscious to him himself, as a result of which the two records are brought to coincide. The amount of effort we have to use, by which we estimate the resistance against the material becoming conscious, varies in magnitude in individual cases. For instance, what comes about in an analytic treatment as a result of our efforts can also occur spontaneously: material which is ordinarily unconscious can transform itself into preconscious material and then becomes conscious - a thing that happens to a large extent in psychotic states. From this we infer that the maintenance of certain internal resistances is a sine qua non of normality. A relaxation of resistances such as this, with a consequent pushing forward of unconscious material, takes place regularly in the state of sleep, and thus brings about a necessary precondition for the construction of dreams.

Conversely, preconscious material can become temporarily inaccessible and cut off by resistances, as happens when something is temporarily forgotten or escapes the memory; or a preconscious thought can even be temporarily put back into the unconscious state, as seems to be a precondition in the case of jokes. We shall see that a similar transformation back of preconscious material or processes into the unconscious state plays a great part in the causation of neurotic disorders.

[1940a [1938], 4970]

[1940a [1938], 4970]
But you must not take this warning of mine to mean that I propose to give you dogmatic lectures and to insist on your unqualified belief. Such a misunderstanding would do me a grave injustice. I do not wish to arouse conviction; I wish to stimulate thought and to upset prejudices. If as a result of lack of knowledge of the material you are not in a position to form a judgement, you should neither believe nor reject. You should listen and allow what I tell you to work on you. It is not so easy to arrive at convictions, or, if they are reached easily, they soon turn out to be worthless and incapable of resistance. The only person who has a right to a conviction is someone who, like me, has worked for many years at the same material and who, in doing so, has himself had the same new and surprising experiences. What is the good, then, in the sphere of the intellect, of these sudden convictions, these lightning-like conversions, these instantaneous rejections? Is it not clear that the ‘coup de foudre’, love at first sight, is derived from quite another sphere, from that of the emotions? We do not even require of our patients that they should bring a conviction of the truth of psycho-analysis into the treatment or be adherents of it. Such an attitude often raises our suspicions. The attitude that we find the most desirable in them is a benevolent scepticism. So you too should endeavour to allow the psycho-analytic view to grow up quietly in you alongside of the popular or psychiatric one, till opportunities arise for the two to influence each other, to compete with each other and to unite in leading to a conclusion.

[1916-1917, 3326]

The repressed retains its upward urge, its effort to force its way to consciousness. It achieves its aim under three conditions: (1) if the strength of the anticathexis is diminished by pathological processes which overtake the other part, what we call the ego, or by a different distribution of the cathectic energies in that ego, as happens regularly in the state of sleep; (2) if the instinctual elements attaching to the repressed receive a special reinforcement (of which the best example is the processes during puberty); and (3) if at any time in recent experience impressions or experiences occur which resemble the repressed so closely that they are able to awaken it. In the last case the recent experience is reinforced by the latent energy of the repressed, and the repressed comes into operation behind the recent experience and with its help. In none of these three alternatives does what has hitherto been repressed enter consciousness smoothly and unaltered; it must always put up with distortions which testify to the influence of the resistance (not entirely overcome) arising from the anticathexis, or to the modifying influence of the recent experience or to both.

[1939a, 4918]
Thus we have attributed three qualities to psychical processes: they are either conscious, preconscious or unconscious. The division between the three classes of material which possess these qualities is neither absolute nor permanent. What is preconscious becomes conscious, as we have seen, without any assistance from us; what is unconscious can, through our efforts, be made conscious, and in the process we may have a feeling that we are often overcoming very strong resistances. When we attempt to do this with someone else, we should not forget that the conscious filling-in of the gaps in his perceptions - the construction we are presenting him with - does not mean as yet that we have made the unconscious material in question conscious to him. All that is true so far is that the material is present in him in two records, once in the conscious reconstruction he has been given, and besides this in its original unconscious state. Our continued efforts usually succeed eventually in making this unconscious material conscious to him himself, as a result of which the two records are brought to coincide. The amount of effort we have to use, by which we estimate the resistance against the material becoming conscious, varies in magnitude in individual cases. For instance, what comes about in an analytic treatment as a result of our efforts can also occur spontaneously: material which is ordinarily unconscious can transform itself into preconscious material and then becomes conscious - a thing that happens to a large extent in psychotic states. From this we infer that the maintenance of certain internal resistances is a sine qua non of normality. A relaxation of resistances such as this, with a consequent pushing forward of unconscious material, takes place regularly in the state of sleep, and thus brings about a necessary precondition for the construction of dreams. Conversely, preconscious material can become temporarily inaccessible and cut off by resistances, as happens when something is temporarily forgotten or escapes the memory; or a preconscious thought can even be temporarily put back into the unconscious state, as seems to be a precondition in the case of jokes. We shall see that a similar transformation back of preconscious material or processes into the unconscious state plays a great part in the causation of neurotic disorders.

[1940a [1938], 4970]
It is not without intention that I speak of 'our' unconscious. For what I thus describe is not the same as the unconscious of the philosophers or even the unconscious of Lipps. By the term is used merely to indicate a contrast with the conscious: the thesis which they dispute with so much heat and defend with so much energy is the thesis that apart from conscious there are also unconscious psychical processes. Lipps carries things further with his assertion that the whole of what is psychical exists unconsciously and that a part of it also exists consciously. But it is not in order to establish this thesis that we have summoned up the phenomena of dreams and of the formation of hysterical symptoms; the observation of normal waking life would by itself suffice to prove it beyond any doubt. The new discovery that we have been taught by the analysis of psychopathological structures and of the first member of that class - the dream - lies in the fact that the unconscious (that is, the psychical) is found as a function of two separate systems and that this is the case in normal as well as in pathological life. Thus there are two kinds of unconscious, which have not yet been distinguished by psychologists. Both of them are unconscious in the sense used by psychology; but in our sense one of them, which we term the *Ucs*, is also *inadmissible to consciousness*, while we term the other the *Pcs*. because its excitations - after observing certain rules, it is true, and perhaps only after passing a fresh censorship, though nonetheless without regard to the *Ucs* - are able to reach consciousness. The fact that excitations in order to reach consciousness must pass through a fixed series or hierarchy of agencies (which is revealed to us by the modifications made in them by censorship) has enabled us to construct a spatial analogy. We have described the relations of the two systems to each other and to consciousness by saying that the system *Pcs* stands like a screen between the system *Ucs* and consciousness. The system *Pcs* not merely bars access to consciousness, it also controls access to the power of voluntary movement and has at its disposal for distribution a mobile cathetic energy, a part of which is familiar to us in the form of attention.²

Thus we obtain our concept of the unconscious from the theory of repression. The repressed is the prototype of the unconscious for us. We see, however, that we have two kinds of unconscious - the one which is latent but capable of becoming conscious, and the one which is repressed and which is not, in itself and without more ado, capable of becoming conscious. This piece of insight into psychical dynamics cannot fail to affect terminology and description. The latent, which is unconscious only descriptively, not in the dynamic sense, we call *preconscious*; we restrict the term *unconscious* to the dynamically unconscious repressed; so that now we have three terms, conscious (*Cs*), preconscious (*Pcs*), and unconscious (*Ucs*), whose sense is no longer purely descriptive. The *Pcs* is presumably a great deal closer to the *Cs* than is the *Ucs*, and since we have called the *Ucs* psychical we shall with even less hesitation call the latent *Pcs* psychical. But why do we not rather, instead of this, remain in agreement with the philosophers and, in a consistent way, distinguish the *Pcs* as well as the *Ucs* from the conscious psychical? The philosophers would then propose that the *Pcs* and the *Ucs* should be described as two species or stages of the 'psychoid', and harmony would be established. But endless difficulties in exposition would follow; and the one important fact, that these two kinds of 'psychoid' coincide in almost every other respect with what is admittedly psychical, would be forced into the background in the interests of a prejudice dating from a period in which these psychoids, or the most important part of them, were still unknown.²

[1900a, 1039]

[1923b, 3949]
For our conception of the unconscious, however, the consequences of our discovery are even more important. Dynamic considerations caused us to make our first correction; our insight into the structure of the mind leads to the second. We recognize that the Ucs. does not coincide with the repressed; it is still true that all that is repressed is Ucs., but not all that is Ucs. is repressed. A part of the ego, too - and Heaven knows how important a part - may be Ucs., undoubtedly is Ucs. And this Ucs. belonging to the ego is not latent like the Pcs.; for if it were, it could not be activated without becoming Cs., and the process of making it conscious would not encounter such great difficulties. When we find ourselves thus confronted by the necessity of postulating a third Ucs., which is not repressed, we must admit that the characteristic of being unconscious begins to lose significance for us. It becomes a quality which can have many meanings, a quality which we are unable to make, as we should have hoped to do, the basis of far-reaching and inevitable conclusions. Nevertheless we must beware of ignoring this characteristic, for the property of being conscious or not is in the last resort our one beacon-light in the darkness of depth-psychology.

[1923b, 3952]

There is no need to discuss what is to be called conscious: it is removed from all doubt. The oldest and best meaning of the word 'unconscious' is the descriptive one; we call a psychical process unconscious whose existence we are obliged to assume - for some such reason as that we infer it from its effects -, but of which we know nothing. In that case we have the same relation to it as we have to a psychical process in another person, except that it is in fact one of our own. If we want to be still more correct, we shall modify our assertion by saying that we call a process unconscious if we are obliged to assume that it is being activated at the moment, though at the moment we know nothing about it. This qualification makes us reflect that the majority of conscious processes are conscious only for a short time; very soon they become latent, but can easily become conscious again. We might also say that they had become unconscious, if it were at all certain that in the condition of latency they are still something psychical. So far we should have learnt nothing new; nor should we have acquired the right to introduce the concept of an unconscious into psychology. But then comes the new observation that we were already able to make in parapraxes. In order to explain a slip of the tongue, for instance, we find ourselves obliged to assume that the intention to make a particular remark was present in the subject. We infer it with certainty from the interference with his remark which has occurred; but the intention did not put itself through and was thus unconscious. If, when we subsequently put it before the speaker, he recognizes it as one familiar to him, then it was only temporarily unconscious to him; but if he repudiates it as something foreign to him, then it was permanently unconscious. From this experience we retrospectively obtain the right also to pronounce as something unconscious what had been described as latent. A consideration of these dynamic relations permits us now to distinguish two kinds of unconscious - one which is easily, under frequently occurring circumstances, transformed into something conscious, and another with which this transformation is difficult and takes place only subject to a considerable expenditure of effort or possibly never at all. In order to escape the ambiguity as to whether we mean the one or the other unconscious, whether we are using the word in the descriptive or in the dynamic sense, we make use of a permissible and simple way out. We call the unconscious which is only latent, and thus easily becomes conscious, the 'preconscious' and retain the term 'unconscious' for the other. We now have three terms, 'conscious', 'preconscious' and 'unconscious', with which we can get along in our description of mental phenomena. Once again: the preconscious is also unconscious in the purely descriptive sense, but we do not give it that name, except in talking loosely or when we have to make a defence of the existence in mental life of unconscious processes in general.

[1933a, 4679]
You will admit, I hope, that so far that is not too bad and allows of convenient handling. Yes, but unluckily the work of psycho-analysis has found itself compelled to use the word 'unconscious' in yet another, third, sense, and this may, to be sure, have led to confusion. Under the new and powerful impression of there being an extensive and important field of mental life which is normally withdrawn from the ego's knowledge so that the processes occurring in it have to be regarded as unconscious in the truly dynamic sense, we have come to understand the term 'unconscious' in a topographical or systematic sense as well; we have come to speak of a 'system' of the preconscious and a 'system' of the unconscious, of a conflict between the ego and the system Ucs., and have used the word more and more to denote a mental province rather than a quality of what is mental. The discovery, actually an inconvenient one, that portions of the ego and super-ego as well are unconscious in the dynamic sense, operates at this point as a relief - it makes possible the removal of a complication. We perceive that we have no right to name the mental region that is foreign to the ego 'the system Ucs', since the characteristic of being unconscious is not restricted to it. Very well; we will no longer use the term 'unconscious' in the systematic sense and we will give what we have hitherto so described a better name and one no longer open to misunderstanding. Following a verbal usage of Nietzsche's and taking up a suggestion by Georg Groddeck, we will in future call it the 'id'. This impersonal pronoun seems particularly well suited for expressing the main characteristic of this province of the mind - the fact of its being alien to the ego. The super-ego, the ego and the id - these, then, are the three realms, regions, provinces, into which we divide an individual's mental apparatus, and with the mutual relations of which we shall be concerned in what follows.

[1933a, 4680]
If we have made a true assessment of the nature of the Ucs. and have correctly defined the difference between an unconscious and a preconscious presentation, then our researches will inevitably bring us back from many other points to this same piece of insight.
[1915e, 3024]

Thus we obtain our concept of the unconscious from the theory of repression. The repressed is the prototype of the unconscious for us. We see, however, that we have two kinds of unconscious - the one which is latent but capable of becoming conscious, and the one which is repressed and which is not, in itself and without more ado, capable of becoming conscious. This piece of insight into psychical dynamics cannot fail to affect terminology and description. The latent, which is unconscious only descriptively, not in the dynamic sense, we call preconscious; we restrict the term unconscious to the dynamically unconscious repressed; so that now we have three terms, conscious (Cs.), preconscious (Pcs.), and unconscious (Ucs.), whose sense is no longer purely descriptive. The Pcs. is presumably a great deal closer to the Cs. than is the Ucs., and since we have called the Ucs. psychical we shall with even less hesitation call the latent Pcs. psychical. But why do we not rather, instead of this, remain in agreement with the philosophers and, in a consistent way, distinguish the Pcs. as well as the Ucs. from the conscious psychical? The philosophers would then propose that the Pcs. and the Ucs. should be described as two species or stages of the 'psychoid', and harmony would be established. But endless difficulties in exposition would follow; and the one important fact, that these two kinds of 'psychoid' coincide in almost every other respect with what is admittedly psychical, would be forced into the background in the interests of a prejudice dating from a period in which these psychoids, or the most important part of them, were still unknown.
[1923b, 3949]

For our conception of the unconscious, however, the consequences of our discovery are even more important. Dynamic considerations caused us to make our first correction; our insight into the structure of the mind leads to the second. We recognize that the Ucs. does not coincide with the repressed; it is still true that all that is repressed is Ucs., but not all that is Ucs. is repressed. A part of the ego, too - and Heaven knows how important a part - may be Ucs., undoubtedly is Ucs. And this Ucs. belonging to the ego is not latent like the Pcs.; for if it were, it could not be activated without becoming Cs., and the process of making it conscious would not encounter such great difficulties. When we find ourselves thus confronted by the necessity of postulating a third Ucs., which is not repressed, we must admit that the characteristic of being unconscious begins to lose significance for us. It becomes a quality which can have many meanings, a quality which we are unable to make, as we should have hoped to do, the basis of far-reaching and inevitable conclusions. Nevertheless we must beware of ignoring this characteristic, for the property of being conscious or not is in the last resort our one beacon-light in the darkness of depth-psychology.
[1923b, 3952]

I have already, in another place,¹ suggested that the real difference between a Ucs. and a Pcs. idea (thought) consists in this: that the former is carried out on some material which remains unknown, whereas the latter (the Pcs.) is in addition brought into connection with word-presentations. This is the first attempt to indicate distinguishing marks for the two systems, the Pcs. and the Ucs., other than their relation to consciousness. The question, 'How does a thing become conscious?' would thus be more advantageously stated: 'How does a thing become preconscious?' And the answer would be: 'Through becoming connected with the word-presentations corresponding to it.'
[1923b, 3954]
There is no need to discuss what is to be called conscious: it is removed from all doubt. The oldest and best meaning of the word 'unconscious' is the descriptive one; we call a psychical process unconscious whose existence we are obliged to assume - for some such reason as that we infer it from its effects -, but of which we know nothing. In that case we have the same relation to it as we have to a psychical process in another person, except that it is in fact one of our own. We now have three terms, 'conscious', 'preconscious' and 'unconscious', with which we can get along in our description of mental phenomena. Once again: the preconscious is also unconscious in the purely descriptive sense, but we do not give it that name, except in talking loosely or when we have to make a defence of the existence in mental life of unconscious processes in general.

[1933a, 4679]
You will admit, I hope, that so far that is not too bad and allows of convenient handling. Yes, but unluckily the work of psycho-analysis has found itself compelled to use the word 'unconscious' in yet another, third, sense, and this may, to be sure, have led to confusion. Under the new and powerful impression of there being an extensive and important field of mental life which is normally withdrawn from the ego's knowledge so that the processes occurring in it have to be regarded as unconscious in the truly dynamic sense, we have come to understand the term 'unconscious' in a topographical or systematic sense as well; we have come to speak of a 'system' of the preconscious and a 'system' of the unconscious, of a conflict between the ego and the system $\text{Ucs}$, and have used the word more and more to denote a mental province rather than a quality of what is mental. The discovery, actually an inconvenient one, that portions of the ego and super-ego as well are unconscious in the dynamic sense, operates at this point as a relief - it makes possible the removal of a complication. We perceive that we have no right to name the mental region that is foreign to the ego 'the system $\text{Ucs}$', since the characteristic of being unconscious is not restricted to it. Very well; we will no longer use the term 'unconscious' in the systematic sense and we will give what we have hitherto so described a better name and one no longer open to misunderstanding. Following a verbal usage of Nietzsche's and taking up a suggestion by Georg Groddeck, we will in future call it the 'id'. This impersonal pronoun seems particularly well suited for expressing the main characteristic of this province of the mind - the fact of its being alien to the ego. The super-ego, the ego and the id - these, then, are the three realms, regions, provinces, into which we divide an individual's mental apparatus, and with the mutual relations of which we shall be concerned in what follows.

[1933a, 4680]

The difference between whether a psychical process is conscious or unconscious has served us as a criterion and a means of finding our bearings. The repressed is unconscious. Now it would simplify things agreeably if this sentence admitted of reversal - if, that is, the difference between the qualities of conscious ($\text{Cs}$.) and unconscious ($\text{Ucs}$.) coincided with the distinction between 'belonging to the ego' and 'repressed'. The fact of there being isolated and unconscious things like this in our mental life would be sufficiently novel and important. But in reality the position is more complicated. It is true that everything repressed is unconscious, but it is not true that everything belonging to the ego is conscious. We notice that consciousness is a transient quality which attaches to a psychical process only in passing. For our purposes therefore we must replace 'conscious' by 'capable of being conscious' and we call this quality 'preconscious' ($\text{Pcs}$.). We then say, more correctly, that the ego is mainly preconscious (virtually conscious) but that portions of the ego are unconscious.

[1939a, 4918]
All of this may appear to be far from simple. But when one has grown reconciled to this unusual spatial view of the mental apparatus, it can present no particular difficulties to the imagination. I will add the further comment that the psychical topography that I have developed here has nothing to do with the anatomy of the brain, and actually only touches it at one point. What is unsatisfactory in this picture - and I am aware of it as clearly as anyone - is due to our complete ignorance of the dynamic nature of the mental processes. We tell ourselves that what distinguishes a conscious idea from a preconscious one, and the latter from an unconscious one, can only be a modification, or perhaps a different distribution, of psychical energy. We talk of cathexes and hypercathexes, but beyond this we are without any knowledge on the subject or even any starting-point for a serviceable working hypothesis. Of the phenomenon of consciousness we can at least say that it was originally attached to perception. All sensations which originate from the perception of painful, tactile, auditory or visual stimuli are what are most readily conscious. Thought-processes, and whatever may be analogous to them in the id, are in themselves unconscious and obtain access to consciousness by becoming linked to the mnemonic residues of visual and auditory perceptions along the path of the function of speech. In animals, which lack speech, these conditions must be of a simpler kind.

[1939a, 4919]

In the course of this work the distinctions which we describe as psychical qualities force themselves on our notice. There is no need to characterize what we call 'conscious': it is the same as the consciousness of philosophers and of everyday opinion. Everything else psychical is in our view 'the unconscious'. We are soon led to make an important division in this unconscious. Some processes become conscious easily; they may then cease to be conscious, but can become conscious once more without any trouble: as people say, they can be reproduced or remembered. This reminds us that consciousness is in general a highly fugitive state. What is conscious is conscious only for a moment. If our perceptions do not confirm this, the contradiction is only an apparent one; it is explained by the fact that the stimuli which lead to perception may persist for considerable periods, so that meanwhile the perception of them may be repeated. The whole position is made clear in connection with the conscious perception of our thought-processes: these too may persist for some time, but they may just as well pass in a flash. Everything unconscious that behaves in this way, that can thus easily exchange the unconscious state for the conscious one, is therefore preferably described as 'capable of becoming conscious' or as preconscious. Experience has taught us that there is hardly a psychical process, however complicated it may be, which cannot on occasion remain preconscious, even though as a rule it will, as we say, push its way forward into consciousness. There are other psychical processes and psychical material which have no such easy access to becoming conscious but must be inferred, recognized and translated into conscious form in the manner described. For such material we reserve the name of the unconscious proper.

[1940a [1938], 4969]
Thus we have attributed three qualities to psychical processes: they are either conscious, preconscious or unconscious. The division between the three classes of material which possess these qualities is neither absolute nor permanent. What is preconscious becomes conscious, as we have seen, without any assistance from us; what is unconscious can, through our efforts, be made conscious, and in the process we may have a feeling that we are often overcoming very strong resistances. When we attempt to do this with someone else, we should not forget that the conscious filling-in of the gaps in his perceptions - the construction we are presenting him with - does not mean as yet that we have made the unconscious material in question conscious to him. All that is true so far is that the material is present in him in two records, once in the conscious reconstruction he has been given, and besides this in its original unconscious state. Our continued efforts usually succeed eventually in making this unconscious material conscious to him himself, as a result of which the two records are brought to coincide. The amount of effort we have to use, by which we estimate the resistance against the material becoming conscious, varies in magnitude in individual cases. For instance, what comes about in an analytic treatment as a result of our efforts can also occur spontaneously: material which is ordinarily unconscious can transform itself into preconscious material and then becomes conscious - a thing that happens to a large extent in psychotic states. From this we infer that the maintenance of certain internal resistances is a *sine qua non* of normality. A relaxation of resistances such as this, with a consequent pushing forward of unconscious material, takes place regularly in the state of sleep, and thus brings about a necessary precondition for the construction of dreams. Conversely, preconscious material can become temporarily inaccessible and cut off by resistances, as happens when something is temporarily forgotten or escapes the memory; or a preconscious thought can even be temporarily put back into the unconscious state, as seems to be a precondition in the case of jokes. We shall see that a similar transformation back of preconscious material or processes into the unconscious state plays a great part in the causation of neurotic disorders.

[1940a [1938], 4970]

The inside of the ego, which comprises above all the thought-processes, has the quality of being preconscious. This is characteristic of the ego and belongs to it alone. It would not be correct, however, to think that connection with the mnemic residues of speech is a necessary precondition of the preconscious state. On the contrary, that state is independent of a connection with them, though the presence of that connection makes it safe to infer the preconscious nature of a process. The preconscious state, characterized on the one hand by having access to consciousness and on the other hand by its connection with the speech-residues, is nevertheless something peculiar, the nature of which is not exhausted by these two characteristics. The evidence for this is the fact that large portions of the ego, and particularly of the super-ego, which cannot be denied the characteristic of preconsciousness, none the less remain for the most part unconscious in the phenomenological sense of the word. We do not know why this must be so. We shall attempt presently to attack the problem of the true nature of the preconscious.

[1940a [1938], 4972]
If we have made a true assessment of the nature of the Ucs. and have correctly defined the difference between an unconscious and a preconscious presentation, then our researches will inevitably bring us back from many other points to this same piece of insight. [1915e, 3024]

Thus we obtain our concept of the unconscious from the theory of repression. The repressed is the prototype of the unconscious for us. We see, however, that we have two kinds of unconscious - the one which is latent but capable of becoming conscious, and the one which is repressed and which is not, in itself and without more ado, capable of becoming conscious. This piece of insight into psychical dynamics cannot fail to affect terminology and description. The latent, which is unconscious only descriptively, not in the dynamic sense, we call preconscious; we restrict the term unconscious to the dynamically unconscious repressed; so that now we have three terms, conscious (Cs.), preconscious (Pcs.), and unconscious (Ucs.), whose sense is no longer purely descriptive. The Pcs. is presumably a great deal closer to the Cs. than is the Ucs., and since we have called the Ucs. psychical we shall with even less hesitation call the latent Pcs. psychical. But why do we not rather, instead of this, remain in agreement with the philosophers and, in a consistent way, distinguish the Pcs. as well as the Ucs. from the conscious psychical? The philosophers would then propose that the Pcs. and the Ucs. should be described as two species or stages of the 'psychoid', and harmony would be established. But endless difficulties in exposition would follow; and the one important fact, that these two kinds of 'psychoid' coincide in almost every other respect with what is admittedly psychical, would be forced into the background in the interests of a prejudice dating from a period in which these psychoids, or the most important part of them, were still unknown. [1923b, 3949]

For our conception of the unconscious, however, the consequences of our discovery are even more important. Dynamic considerations caused us to make our first correction; our insight into the structure of the mind leads to the second. We recognize that the Ucs. does not coincide with the repressed; it is still true that all that is repressed is Ucs., but not all that is Ucs. is repressed. A part of the ego, too - and Heaven knows how important a part - may be Ucs., undoubtedly is Ucs. And this Ucs. belonging to the ego is not latent like the Pcs.; for if it were, it could not be activated without becoming Cs., and the process of making it conscious would not encounter such great difficulties. When we find ourselves thus confronted by the necessity of postulating a third Ucs., which is not repressed, we must admit that the characteristic of being unconscious begins to lose significance for us. It becomes a quality which can have many meanings, a quality which we are unable to make, as we should have hoped to do, the basis of far-reaching and inevitable conclusions. Nevertheless we must beware of ignoring this characteristic, for the property of being conscious or not is in the last resort our one beacon-light in the darkness of depth-psychology. [1923b, 3952]

I have already, in another place,¹ suggested that the real difference between a Ucs. and a Pcs. idea (thought) consists in this: that the former is carried out on some material which remains unknown, whereas the latter (the Pcs.) is in addition brought into connection with word-presentations. This is the first attempt to indicate distinguishing marks for the two systems, the Pcs. and the Ucs., other than their relation to consciousness. The question, 'How does a thing become conscious?' would thus be more advantageously stated: 'How does a thing become preconscious?' And the answer would be: 'Through becoming connected with the word-presentations corresponding to it.' [1923b, 3954]
There is no need to discuss what is to be called conscious: it is removed from all doubt. The oldest and best meaning of the word ‘unconscious’ is the descriptive one; we call a psychical process unconscious whose existence we are obliged to assume - for some such reason as that we infer it from its effects - , but of which we know nothing. In that case we have the same relation to it as we have to a psychical process in another person, except that it is in fact one of our own. If we want to be still more correct, we shall modify our assertion by saying that we call a process unconscious if we are obliged to assume that it is being activated at the moment, though at the moment we know nothing about it. This qualification makes us reflect that the majority of conscious processes are conscious only for a short time; very soon they become latent, but can easily become conscious again. We might also say that they had become unconscious, if it were at all certain that in the condition of latency they are still something psychical. So far we should have learnt nothing new; nor should we have acquired the right to introduce the concept of an unconscious into psychology. But then comes the new observation that we were already able to make in parapraxes. In order to explain a slip of the tongue, for instance, we find ourselves obliged to assume that the intention to make a particular remark was present in the subject. We infer it with certainty from the interference with his remark which has occurred; but the intention did not put itself through and was thus unconscious. If, when we subsequently put it before the speaker, he recognizes it as one familiar to him, then it was only temporarily unconscious to him; but if he repudiates it as something foreign to him, then it was permanently unconscious. From this experience we retrospectively obtain the right also to pronounce as something unconscious what had been described as latent. A consideration of these dynamic relations permits us now to distinguish two kinds of unconscious - one which is easily, under frequently occurring circumstances, transformed into something conscious, and another with which this transformation is difficult and takes place only subject to a considerable expenditure of effort or possibly never at all. In order to escape the ambiguity as to whether we mean the one or the other unconscious, whether we are using the word in the descriptive or in the dynamic sense, we make use of a permissible and simple way out. We call the unconscious which is only latent, and thus easily becomes conscious, the ‘preconscious’ and retain the term ‘unconscious’ for the other. We now have three terms, ‘conscious’, ‘preconscious’ and ‘unconscious’, with which we can get along in our description of mental phenomena. Once again: the preconscious is also unconscious in the purely descriptive sense, but we do not give it that name, except in talking loosely or when we have to make a defence of the existence in mental life of unconscious processes in general.
[1933a, 4679]
You will admit, I hope, that so far that is not too bad and allows of convenient handling. Yes, but unluckily the work of psycho-analysis has found itself compelled to use the word 'unconscious' in yet another, third, sense, and this may, to be sure, have led to confusion. Under the new and powerful impression of there being an extensive and important field of mental life which is normally withdrawn from the ego's knowledge so that the processes occurring in it have to be regarded as unconscious in the truly dynamic sense, we have come to understand the term 'unconscious' in a topographical or systematic sense as well; we have come to speak of a 'system' of the preconscious and a 'system' of the unconscious, of a conflict between the ego and the system Ucs., and have used the word more and more to denote a mental province rather than a quality of what is mental. The discovery, actually an inconvenient one, that portions of the ego and super-ego as well are unconscious in the dynamic sense, operates at this point as a relief - it makes possible the removal of a complication. We perceive that we have no right to name the mental region that is foreign to the ego 'the system Ucs', since the characteristic of being unconscious is not restricted to it. Very well; we will no longer use the term 'unconscious' in the systematic sense and we will give what we have hitherto so described a better name and one no longer open to misunderstanding. Following a verbal usage of Nietzsche's and taking up a suggestion by Georg Groddeck, we will in future call it the 'id'. This impersonal pronoun seems particularly well suited for expressing the main characteristic of this province of the mind - the fact of its being alien to the ego. The super-ego, the ego and the id - these, then, are the three realms, regions, provinces, into which we divide an individual's mental apparatus, and with the mutual relations of which we shall be concerned in what follows.

[1933a, 4680]

The difference between whether a psychical process is conscious or unconscious has served us as a criterion and a means of finding our bearings. The repressed is unconscious. Now it would simplify things agreeably if this sentence admitted of reversal - if, that is, the difference between the qualities of conscious (Cs.) and unconscious (Ucs.) coincided with the distinction between 'belonging to the ego' and 'repressed'. The fact of there being isolated and unconscious things like this in our mental life would be sufficiently novel and important. But in reality the position is more complicated. It is true that everything repressed is unconscious, but it is not true that everything belonging to the ego is conscious. We notice that consciousness is a transient quality which attaches to a psychical process only in passing. For our purposes therefore we must replace 'conscious' by 'capable of being conscious' and we call this quality 'preconscious' (Pcs.). We then say, more correctly, that the ego is mainly preconscious (virtually conscious) but that portions of the ego are unconscious.

[1939a, 4918]
In the course of this work the distinctions which we describe as psychical qualities force themselves on our notice. There is no need to characterize what we call 'conscious': it is the same as the consciousness of philosophers and of everyday opinion. Everything else psychical is in our view 'the unconscious'. We are soon led to make an important division in this unconscious. Some processes become conscious easily; they may then cease to be conscious, but can become conscious once more without any trouble: as people say, they can be reproduced or remembered. This reminds us that consciousness is in general a highly fugitive state. What is conscious is conscious only for a moment. If our perceptions do not confirm this, the contradiction is only an apparent one; it is explained by the fact that the stimuli which lead to perception may persist for considerable periods, so that meanwhile the perception of them may be repeated. The whole position is made clear in connection with the conscious perception of our thought-processes: these too may persist for some time, but they may just as well pass in a flash. Everything unconscious that behaves in this way, that can thus easily exchange the unconscious state for the conscious one, is therefore preferably described as 'capable of becoming conscious' or as preconscious. Experience has taught us that there is hardly a psychical process, however complicated it may be, which cannot on occasion remain preconscious, even though as a rule it will, as we say, push its way forward into consciousness. There are other psychical processes and psychical material which have no such easy access to becoming conscious but must be inferred, recognized and translated into conscious form in the manner described. For such material we reserve the name of the unconscious proper.

Thus we have attributed three qualities to psychical processes: they are either conscious, preconscious or unconscious. The division between the three classes of material which possess these qualities is neither absolute nor permanent. What is preconscious becomes conscious, as we have seen, without any assistance from us; what is unconscious can, through our efforts, be made conscious, and in the process we may have a feeling that we are often overcoming very strong resistances. When we attempt to do this with someone else, we should not forget that the conscious filling-in of the gaps in his perceptions - the construction we are presenting him with - does not mean as yet that we have made the unconscious material in question conscious to him. All that is true so far is that the material is present in him in two records, once in the conscious reconstruction he has been given, and besides this in its original unconscious state. Our continued efforts usually succeed eventually in making this unconscious material conscious to him himself, as a result of which the two records are brought to coincide. The amount of effort we have to use, by which we estimate the resistance against the material becoming conscious, varies in magnitude in individual cases. For instance, what comes about in an analytic treatment as a result of our efforts can also occur spontaneously: material which is ordinarily unconscious can transform itself into preconscious material and then becomes conscious - a thing that happens to a large extent in psychotic states. From this we infer that the maintenance of certain internal resistances is a sine qua non of normality. A relaxation of resistances such as this, with a consequent pushing forward of unconscious material, takes place regularly in the state of sleep, and thus brings about a necessary precondition for the construction of dreams. Conversely, preconscious material can become temporarily inaccessible and cut off by resistances, as happens when something is temporarily forgotten or escapes the memory; or a preconscious thought can even be temporarily put back into the unconscious state, as seems to be a precondition in the case of jokes. We shall see that a similar transformation back of preconscious material or processes into the unconscious state plays a great part in the causation of neurotic disorders.

[1940a [1938], 4969]

Thus we have attributed three qualities to psychical processes: they are either conscious, preconscious or unconscious. The division between the three classes of material which possess these qualities is neither absolute nor permanent. What is preconscious becomes conscious, as we have seen, without any assistance from us; what is unconscious can, through our efforts, be made conscious, and in the process we may have a feeling that we are often overcoming very strong resistances. We shall see that a similar transformation back of preconscious material or processes into the unconscious state plays a great part in the causation of neurotic disorders.

[1940a [1938], 4970]
Having now decided upon the topographical dissection of the psychical apparatus into an ego and an id, with which the difference in quality between preconscious and unconscious runs parallel, and having agreed that this quality is to be regarded only as an indication of the difference and not as its essence, a further question faces us. What, if this is so, is the true nature of the state which is revealed in the id by the quality of being unconscious and in the ego by that of being preconscious and in what does the difference between them consist? [1940a [1938], 4973]

But of that we know nothing. And the profound obscurity of the background of our ignorance is scarcely illuminated by a few glimmers of insight. Here we have approached the still shrouded secret of the nature of the psychical. We assume, as other natural sciences have led us to expect, that in mental life some kind of energy is at work; but we have nothing to go upon which will enable us to come nearer to a knowledge of it by analogies with other forms of energy. We seem to recognize that nervous or psychical energy occurs in two forms, one freely mobile and another, by comparison, bound; we speak of cathexes and hypercathexes of psychical material, and even venture to suppose that a hypercathexis brings about a kind of synthesis of different processes - a synthesis in the course of which free energy is transformed into bound energy. Further than this we have not advanced. At any rate, we hold firmly to the view that the distinction between the unconscious and the preconscious state lies in dynamic relations of this kind, which would explain how it is that, whether spontaneously or with our assistance, the one can be changed into the other. [1940a [1938], 4973]
Thus we have attributed three qualities to psychical processes: they are either conscious, preconscious or unconscious. The division between the three classes of material which possess these qualities is neither absolute nor permanent. What is preconscious becomes conscious, as we have seen, without any assistance from us; what is unconscious can, through our efforts, be made conscious, and in the process we may have a feeling that we are often overcoming very strong resistances. When we attempt to do this with someone else, we should not forget that the conscious filling-in of the gaps in his perceptions - the construction we are presenting him with - does not mean as yet that we have made the unconscious material in question conscious to him. All that is true so far is that the material is present in him in two records, once in the conscious reconstruction he has been given, and besides this in its original unconscious state. Our continued efforts usually succeed eventually in making this unconscious material conscious to him himself, as a result of which the two records are brought to coincide. The amount of effort we have to use, by which we estimate the resistance against the material becoming conscious, varies in magnitude in individual cases. For instance, what comes about in an analytic treatment as a result of our efforts can also occur spontaneously: material which is ordinarily unconscious can transform itself into preconscious material and then becomes conscious - a thing that happens to a large extent in psychotic states. From this we infer that the maintenance of certain internal resistances is a sine qua non of normality. A relaxation of resistances such as this, with a consequent pushing forward of unconscious material, takes place regularly in the state of sleep, and thus brings about a necessary precondition for the construction of dreams. Conversely, preconscious material can become temporarily inaccessible and cut off by resistances, as happens when something is temporarily forgotten or escapes the memory; or a preconscious thought can even be temporarily put back into the unconscious state, as seems to be a precondition in the case of jokes. We shall see that a similar transformation back of preconscious material or processes into the unconscious state plays a great part in the causation of neurotic disorders.

[1940a [1938], 4970]
In this respect, then, our work is untrammelled and may proceed according to its own requirements. It will, however, be useful to remind ourselves that as things stand our hypotheses set out to be no more than graphic illustrations. The first of the two possibilities which we considered - namely, that the Cs. phase of an idea implies a fresh registration of it, which is situated in another place - is doubtless the cruder but also the more convenient. The second hypothesis - that of a merely functional change of state - is a priori more probable, but it is less plastic, less easy to manipulate. With the first, or topographical, hypothesis is bound up that of a topographical separation of the systems Ucs. and Cs. and also the possibility that an idea may exist simultaneously in two places in the mental apparatus indeed, that if it is not inhibited by the censorship, it regularly advances from the one position to the other, possibly without losing its first location or registration.

[1915e, 2999]

This view may seem odd, but it can be supported by observations from psycho-analytic practice. If we communicate to a patient some idea which he has at one time repressed but which we have discovered in him, our telling him makes at first no change in his mental condition. Above all, it does not remove the repression nor undo its effects, as might perhaps be expected from the fact that the previously unconscious idea has now become conscious. On the contrary, all that we shall achieve at first will be a fresh rejection of the repressed idea. But now the patient has in actual fact the same idea in two forms indifferent places in his mental apparatus: first, he has the conscious memory of the auditory trace of the idea, conveyed in what we told him; and secondly, he also has - as we know for certain - the unconscious memory of his experience as it was in its earlier form. Actually there is no lifting of the repression until the conscious idea, after the resistances have been overcome, has entered into connection with the unconscious memory-trace. It is only through the making conscious of the latter itself that success is achieved. On superficial consideration this would seem to show that conscious and unconscious ideas are distinct registrations, topographically separated, of the same content. But a moment's reflection shows that the identity of the information given to the patient with his repressed memory is only apparent. To have heard something and to have experienced something are in their psychological nature two quite different things, even though the content of both is the same.

[1915e, 2999]
Thus we have attributed three qualities to psychical processes: they are either conscious, preconscious or unconscious. The division between the three classes of material which possess these qualities is neither absolute nor permanent. What is preconscious becomes conscious, as we have seen, without any assistance from us; what is unconscious can, through our efforts, be made conscious, and in the process we may have a feeling that we are often overcoming very strong resistances. When we attempt to do this with someone else, we should not forget that the conscious filling-in of the gaps in his perceptions - the construction we are presenting him with - does not mean as yet that we have made the unconscious material in question conscious to him. All that is true so far is that the material is present in him in two records, once in the conscious reconstruction he has been given, and besides this in its original unconscious state. Our continued efforts usually succeed eventually in making this unconscious material conscious to him himself, as a result of which the two records are brought to coincide. The amount of effort we have to use, by which we estimate the resistance against the material becoming conscious, varies in magnitude in individual cases. For instance, what comes about in an analytic treatment as a result of our efforts can also occur spontaneously: material which is ordinarily unconscious can transform itself into preconscious material and then becomes conscious - a thing that happens to a large extent in psychotic states. From this we infer that the maintenance of certain internal resistances is a sine qua non of normality. A relaxation of resistances such as this, with a consequent pushing forward of unconscious material, takes place regularly in the state of sleep, and thus brings about a necessary precondition for the construction of dreams. Conversely, preconscious material can become temporarily inaccessible and cut off by resistances, as happens when something is temporarily forgotten or escapes the memory; or a preconscious thought can even be temporarily put back into the unconscious state, as seems to be a precondition in the case of jokes. We shall see that a similar transformation back of preconscious material or processes into the unconscious state plays a great part in the causation of neurotic disorders.

[1940a [1938], 4970]
Conscious processes on the periphery of the ego and everything else in the ego unconscious - such would be the simplest state of affairs that we might picture. And such may in fact be the state that prevails in animals. But in men there is an added complication through which internal processes in the ego may also acquire the quality of consciousness. This is the work of the function of speech, which brings material in the ego into a firm connection with mnemonic residues of visual, but more particularly of auditory, perceptions. Thenceforward the perceptual periphery of the cortical layer can be excited to a much greater extent from inside as well, internal events such as passages of ideas and thought-processes can become conscious, and a special device is called for in order to distinguish between the two possibilities - a device known as reality-testing. The equation 'perception = reality (external world)' no longer holds. Errors, which can now easily arise and do so regularly in dreams, are called hallucinations.

[1940a [1938], 4972]
We are now well on the way to proceeding further with the erection of the psychological scaffolding, which we stopped at the point at which we introduced the two systems $Ucs$ and $Pcs$. But there are reasons for continuing a little with our consideration of wishes as the sole psychical motive force for the construction of dreams. We have accepted the idea that the reason why dreams are invariably wish-fulfilments is that they are products of the system $Ucs$, whose activity knows no other aim than the fulfilment of wishes and which has at its command no other forces than wishful impulses. If we insist, for even a moment longer, upon our right to base such far-reaching psychological speculations upon the interpretation of dreams, we are in duty found to prove that those speculations have enabled us to insert dreams into a nexus which can include other psychical structures as well. If such a thing as a system $Ucs$ exists (or something analogous to it for the purposes of our discussion), dreams cannot be its only manifestation; every dream may be a wish-fulfilment, but apart from dreams there must be other forms of abnormal wish-fulfilments. And it is a fact that the theory governing all psychoneurotic symptoms culminates in a single proposition, which asserts that they too are to be regarded as fulfilments of unconscious wishes.¹ Our explanation makes the dream only the first member of a class which is of the greatest significance to psychiatrists and an understanding of which implies the solution of the purely psychological side of the problem of psychiatry.²

Now I think we shall gain a great deal by following the suggestion of a writer who, from personal motives, vainly asserts that he has nothing to do with the rigours of pure science. I am speaking of Georg Groddeck, who is never tired of insisting that what we call our ego behaves essentially passively in life, and that, as he expresses it, we are 'lived' by unknown and uncontrollable forces.¹ We have all had impressions of the same kind, even though they may not have overwhelmed us to the exclusion of all others, and we need feel no hesitation in finding a place for Groddeck's discovery in the structure of science. I propose to take it into account by calling the entity which starts out from the system $Pcpt$ and begins by being $Pcs$ the 'ego', and by following Groddeck in calling the other part of the mind, into which this entity extends and which behaves as though it were $Ucs$, the 'id'.²

But to proceed. Putting ourselves on the footing of everyday knowledge, we recognize in human beings a mental organization which is interpolated between their sensory stimuli and the perception of their somatic needs on the one hand and their motor acts on the other, and which mediates between them for a particular purpose. We call this organization their 'Ich'. Now there is nothing new in this. Each one of us makes this assumption without being a philosopher, and some people even in spite of being philosophers. But this does not, in our opinion, exhaust the description of the mental apparatus. Besides this 'I', we recognize another mental region, more extensive, more imposing and more obscure than the 'I', and this we call the 'Es'. The relation between the two must be our immediate concern.
Now I think we shall gain a great deal by following the suggestion of a writer who, from personal motives, mainly asserts that he has nothing to do with the rigours of pure science. I am speaking of Georg Groddeck, who is never tired of insisting that what we call our ego behaves essentially passively in life, and that, as he expresses it, we are 'lived' by unknown and uncontrollable forces.¹ We have all had impressions of the same kind, even though they may not have overwhelmed us to the exclusion of all others, and we need feel no hesitation in finding a place for Groddeck's discovery in the structure of science. I propose to take it into account by calling the entity which starts out from the system Pcpt. and begins by being Pcs. the 'ego', and by following Groddeck in calling the other part of the mind, into which this entity extends and which behaves as though it were Ucs., the 'id'.²

[1923b, 3957]

You will probably protest at our having chosen simple pronouns to describe our two agencies or provinces instead of giving them orotund Greek names. In psycho-analysis, however, we like to keep in contact with the popular mode of thinking and prefer to make its concepts scientifically serviceable rather than to reject them. There is no merit in this; we are obliged to take this line; for our theories must be understood by our patients, who are often very intelligent, but not always learned. The impersonal 'it' is immediately connected with certain forms of expression used by normal people. 'It shot through me,' people say; 'there was something in me at that moment that was stronger than me.' 'C'était plus fort que moi.'

[1926e, 4338]

You will admit, I hope, that so far that is not too bad and allows of convenient handling. Yes, but unluckily the work of psycho-analysis has found itself compelled to use the word 'unconscious' in yet another, third, sense, and this may, to be sure, have led to confusion. Under the new and powerful impression of there being an extensive and important field of mental life which is normally withdrawn from the ego's knowledge so that the processes occurring in it have to be regarded as unconscious in the truly dynamic sense, we have come to understand the term 'unconscious' in a topographical or systematic sense as well; we have come to speak of a 'system' of the preconscious and a 'system' of the unconscious, of a conflict between the ego and the system Ucs., and have used the word more and more to denote a mental province rather than a quality of what is mental. The discovery, actually an inconvenient one, that portions of the ego and super-ego as well are unconscious in the dynamic sense, operates at this point as a relief - it makes possible the removal of a complication. We perceive that we have no right to name the mental region that is foreign to the ego 'the system Ucs', since the characteristic of being unconscious is not restricted to it. Very well; we will no longer use the term 'unconscious' in the systematic sense and we will give what we have hitherto so described a better name and one no longer open to misunderstanding. Following a verbal usage of Nietzsche's and taking up a suggestion by Georg Groddeck, we will in future call it the 'id'. This impersonal pronoun seems particularly well suited for expressing the main characteristic of this province of the mind - the fact of its being alien to the ego. The super-ego, the ego and the id - these, then, are the three realms, regions, provinces, into which we divide an individual's mental apparatus, and with the mutual relations of which we shall be concerned in what follows.

[1933a, 4680]
You will not expect me to have much to tell you that is new about the id apart from its new name. It is the dark, inaccessible part of our personality; what little we know of it we have learnt from our study of the dream-work and of the construction of neurotic symptoms, and most of that is of a negative character and can be described only as a contrast to the ego. We approach the id with analogies: we call it a chaos, a cauldron full of seething excitations. We picture it as being open at its end to somatic influences, and as there taking up into itself instinctual needs which find their psychical expression in it, but we cannot say in what substratum. It is filled with energy reaching it from the instincts, but it has no organization, produces no collective will, but only a striving to bring about the satisfaction of the instinctual needs subject to the observance of the pleasure principle. The logical laws of thought do not apply in the id, and this is true above all of the law of contradiction. Contrary impulses exist side by side, without cancelling each other out or diminishing each other: at the most they may converge to form compromises under the dominating economic pressure towards the discharge of energy. There is nothing in the id that could be compared with negation; and we perceive with surprise an exception to the philosophical theorem that space and time are necessary forms of our mental acts. There is nothing in the id that corresponds to the idea of time; there is no recognition of the passage of time, and - a thing that is most remarkable and awaits consideration in philosophical thought - no alteration in its mental processes is produced by the passage of time. Wishful impulses which have never passed beyond the id, but impressions, too, which have been sunk into the id by repression, are virtually immortal; after the passage of decades they behave as though they had just occurred. They can only be recognized as belonging to the past, can only lose their importance and be deprived of their cathexis of energy, when they have been made conscious by the work of analysis, and it is on this that the therapeutic effect of analytic treatment rests to no small extent.

[1933a, 4682]
The establishment of this latter fact shows us that the qualities on which we have hitherto relied are insufficient to give us our bearings in the obscurity of mental life. We must introduce another distinction which is no longer qualitative but topographical and - what gives it special value - at the same time genetic. We now distinguish in our mental life (which we regard as an apparatus compounded of several agencies, districts or provinces) one region which we call the ego proper and another which we name the id. The id is the older of the two; the ego has developed out of it, like a cortical layer, through the influence of the external world. It is in the id that all our primary instincts are at work, all the processes in the id take place unconsciously. The ego, as we have already said, coincides with the region of the preconscious; it includes portions which normally remain unconscious. The course of events in the id, and their mutual interaction, are governed by quite other laws than those prevailing in the ego. It is in fact the discovery of these differences that has led to our new view and justifies it.

[1939a, 4919]

We have arrived at our knowledge of this psychical apparatus by studying the individual development of human beings. To the oldest of these psychical provinces or agencies we give the name of id. It contains everything that is inherited, that is present at birth, that is laid down in the constitution - above all, therefore, the instincts, which originate from the somatic organization and which find a first psychical expression here in forms unknown to us.¹

[1940a [1938], 4957]

¹ This oldest portion of the psychical apparatus remains the most important throughout life; moreover, the investigations of psycho-analysis started with it.

[1940a [1938], 4957]
The sole prevailing quality in the id is that of being unconscious. Id and unconscious are as intimately linked as ego and preconscious: indeed, in the former case the connection is even more exclusive. If we look back at the developmental history of an individual and of his psychical apparatus, we shall be able to perceive an important distinction in the id. Originally, to be sure, everything was id; the ego was developed out of the id by the continual influence of the external world. In the course of this slow development certain of the contents of the id were transformed into the preconscious state and so taken into the ego; others of its contents remained in the id unchanged, as its scarcely accessible nucleus. During this development, however, the young and feeble ego put back into the unconscious state some of the material it had already taken in, dropped it, and behaved in the same way to some fresh impressions which it might have taken in, so that these, having been rejected, could leave a trace only in the id. In consideration of its origin we speak of this latter portion of the id as the repressed. It is of little importance that we are not always able to draw a sharp line between these two categories of contents in the id. They coincide approximately with the distinction between what was innately present originally and what was acquired in the course of the ego's development. [1940a [1938], 4973]
We will describe the last of the systems at the motor end as 'the preconscious', to indicate that the excitatory processes occurring in it can enter consciousness without further impediment provided that certain other conditions are fulfilled: for instance, that they reach a certain degree of intensity, that the function which can only be described as 'attention' is distributed in a particular way, and so on. This is at the same time the system which holds the key to voluntary movement. We will describe the system that lies behind it as 'the unconscious', because it has no access to consciousness except via the preconscious, in passing through which its excitatory process is obliged to submit to modifications.¹

Hitherto philosophers have had no occasion to concern themselves with a psychology of repression. We may therefore be permitted to make a first approach to this hitherto unknown topic by constructing a pictorial image of the course of events in dream-formation. It is true that the schematic picture we have arrived at - not only from the study of dreams - is a fairly complicated one; but we cannot manage with anything simpler. Our hypothesis is that in our mental apparatus there are two thought-constructing agencies, of which the second enjoys the privilege of having free access to consciousness for its products whereas the activity of the first is in itself unconscious and can only reach consciousness by way of the second. On the frontier between the two agencies, where the first passes over to the second, there is a censorship, which only allows what is agreeable to it to pass through and holds back everything else. According to our definition, then, what is rejected by the censorship is in a state of repression. Under certain conditions, of which the state of sleep is one, the relation between the strength of the two agencies is modified in such a way that what is repressed can no longer be held back. In the state of sleep this probably occurs owing to a relaxation of the censorship; when this happens it becomes possible for what has hitherto been repressed to make a path for itself to consciousness. Since, however, the censorship is never completely eliminated but merely reduced, the repressed material must submit to certain alterations which mitigate its offensive features. What becomes conscious in such cases is a compromise between the intentions of one agency and the demands of the other. Repression - relaxation of the censorship - the formation of a compromise, this is the fundamental pattern for the generation not only of dreams but of many other psychopathological structures; and in the latter cases too we may observe that the formation of compromises is accompanied by processes of condensation and displacement and by the employment of superficial associations, which we have become familiar with in the dream-work.

We have no reason to disguise the fact that in the hypothesis which we have set up in order to explain the dream-work a part is played by what might be described as a 'daemonic' element. We have gathered an impression that the formation of obscure dreams occurs as though one person who was dependent upon a second person had to make a remark which was bound to be disagreeable in the ears of this second one; and it is on the basis of this simile that we have arrived at the concepts of dream-distortion and censorship, and have endeavoured to translate our impression into a psychological theory which is no doubt crude but is at least lucid. Whatever it may be with which a further investigation of the subject may enable us to identify our first and second agencies, we may safely expect to find a confirmation of some correlate of our hypothesis that the second agency controls access to consciousness and can bar the first agency from such access.
Now I think we shall gain a great deal by following the suggestion of a writer who, from personal motives, vainly asserts that he has nothing to do with the rigours of pure science. I am speaking of Georg Groddeck, who is never tired of insisting that what we call our ego behaves essentially passively in life, and that, as he expresses it, we are 'lived' by unknown and uncontrollable forces.¹ We have all had impressions of the same kind, even though they may not have overwhelmed us to the exclusion of all others, and we need feel no hesitation in finding a place for Groddeck's discovery in the structure of science. I propose to take it into account by calling the entity which starts out from the system $Pcpt.$ and begins by being $Pcs.$ the 'ego', and by following Groddeck in calling the other part of the mind, into which this entity extends and which behaves as though it were $Ucs.$, the 'id'.²

[1923b, 3957]

We shall soon see whether we can derive any advantage from this view for purposes either of description or of understanding. We shall now look upon an individual as a psychical id, unknown and unconscious, upon whose surface rests the ego, developed from its nucleus the $Pcpt.$ system. If we make an effort to represent this pictorially, we may add that the ego does not completely envelop the id, but only does so to the extent to which the system $Pcpt.$ forms its surface, more or less as the germinal disc rests upon the ovum. The ego is not sharply separated from the id; its lower portion merges into it.

[1923b, 3958]

Thus we may express our expectation that psycho-analysis, whose development and achievements hitherto have been briefly and inadequately related in these pages, will enter into the cultural development of the next decades as a significant ferment, and will help to deepen our understanding of the world and to fight against some things in life which are recognized as injurious. It must not be forgotten, however, that psycho-analysis alone cannot offer a complete picture of the world. If we accept the distinction which I have recently proposed of dividing the mental apparatus into an ego, turned towards the external world and equipped with consciousness, and an unconscious id, dominated by its instinctual needs, then psycho-analysis is to be described as a psychology of the id (and of its effects upon the ego). In each field of knowledge, therefore, it can make only contributions, which require to be completed from the psychology of the ego. If these contributions often contain the essence of the facts, this only corresponds to the important part which, it may be claimed, is played in our lives by the mental unconscious that has so long remained unknown.

[1924f, 4118]

It is not masquerading. The other names are of no use. And do not try to give me literature instead of science. If someone talks of subconsciousness, I cannot tell whether he means the term topographically - to indicate something lying in the mind beneath consciousness - or qualitatively - to indicate another consciousness, a subterranean one, as it were. He is probably not clear about any of it. The only trustworthy antithesis is between conscious and unconscious. But it would be a serious mistake to think that this antithesis coincides with the distinction between ego and id. Of course it would be delightful if it were as simple as that: our theory would have a smooth passage. But things are not so simple. All that is true is that everything that happens in the id is and remains unconscious, and that processes in the ego, and they alone, can become conscious. But not all of them are, nor always, nor necessarily; and large portions of the ego can remain permanently unconscious.

[1926e, 4341]
Topographically, psycho-analysis regards the mental apparatus as a compound instrument, and endeavours to determine at what points in it the various mental processes take place. According to the most recent psycho-analytic views, the mental apparatus is composed of an 'id', which is the repository of the instinctual impulses, of an 'ego', which is the most superficial portion of the id and one which has been modified by the influence of the external world, and of a 'super-ego', which develops out of the id, dominates the ego and represents the inhibitions of instinct that are characteristic of man. The quality of consciousness, too, has a topographical reference; for processes in the id are entirely unconscious, while consciousness is the function of the ego's outermost layer, which is concerned with the perception of the external world.

As you see here, the super-ego merges into the id; indeed, as heir to the Oedipus complex it has intimate relations with the id; it is more remote than the ego from the perceptual system. The id has intercourse with the external world only through the ego - at least, according to this diagram. It is certainly hard to say to-day how far the drawing is correct. In one respect it is undoubtedly not. The space occupied by the unconscious id ought to have been incomparably greater than that of the ego or the preconscious. I must ask you to correct it in your thoughts.

The establishment of this latter fact shows us that the qualities on which we have hitherto relied are insufficient to give us our bearings in the obscurity of mental life. We must introduce another distinction which is no longer qualitative but topographical and - what gives it special value - at the same time genetic. We now distinguish in our mental life (which we regard as an apparatus compounded of several agencies, districts or provinces) one region which we call the ego proper and another which we name the id. The id is the older of the two; the ego has developed out of it, like a cortical layer, through the influence of the external world. It is in the id that all our primary instincts are at work, all the processes in the id take place unconsciously. The ego, as we have already said, coincides with the region of the preconscious; it includes portions which normally remain unconscious. The course of events in the id, and their mutual interaction, are governed by quite other laws than those prevailing in the ego. It is in fact the discovery of these differences that has led to our new view and justifies it.

The sole prevailing quality in the id is that of being unconscious. Id and unconscious are as intimately linked as ego and preconscious: indeed, in the former case the connection is even more exclusive. If we look back at the developmental history of an individual and of his psychical apparatus, we shall be able to perceive an important distinction in the id. Originally, to be sure, everything was id; the ego was developed out of the id by the continual influence of the external world. In the course of this slow development certain of the contents of the id were transformed into the preconscious state and so taken into the ego; others of its contents remained in the id unchanged, as its scarcely accessible nucleus. During this development, however, the young and feeble ego put back into the unconscious state some of the material it had already taken in, dropped it, and behaved in the same way to some fresh impressions which it might have taken in, so that these, having been rejected, could leave a trace only in the id. In consideration of its origin we speak of this latter portion of the id as the repressed. It is of little importance that we are not always able to draw a sharp line between these two categories of contents in the id. They coincide approximately with the distinction between what was innately present originally and what was acquired in the course of the ego's development.
But to proceed. Putting ourselves on the footing of everyday knowledge, we recognize in human beings a mental organization which is interpolated between their sensory stimuli and the perception of their somatic needs on the one hand and their motor acts on the other, and which mediates between them for a particular purpose. We call this organization their 'Ich'. Now there is nothing new in this. Each one of us makes this assumption without being a philosopher, and some people even in spite of being philosophers. But this does not, in our opinion, exhaust the description of the mental apparatus. Besides this 'I', we recognize another mental region, more extensive, more imposing and more obscure than the 'I', and this we call the 'Es'. The relation between the two must be our immediate concern.

[1926e, 4338]

As you see here, the super-ego merges into the id; indeed, as heir to the Oedipus complex it has intimate relations with the id; it is more remote than the ego from the perceptual system. The id has intercourse with the external world only through the ego - at least, according to this diagram. It is certainly hard to say to-day how far the drawing is correct. In one respect it is undoubtedly not. The space occupied by the unconscious id ought to have been incomparably greater than that of the ego or the preconscious. I must ask you to correct it in your thoughts.

[1933a, 4687]
It would nevertheless be wrong to imagine that the *Ucs.* remains at rest while the whole work of the mind is performed by the *Pcs.* - that the *Ucs.* is something finished with, a vestigial organ, a residuum from the process of development. It is wrong also to suppose that communication between the two systems is confined to the act of repression, with the *Pcs.* casting everything that seems disturbing to it into the abyss of the *Ucs.* On the contrary, the *Ucs.* is alive and capable of development and maintains a number of other relations with the *Pcs.*, amongst them that of co-operation. In brief, it must be said that the *Ucs.* is continued into what are known as derivatives, that it is accessible to the impressions of life, that it constantly influences the *Pcs.*, and is even, for its part, subjected to influences from the *Pcs.*

[1915e, 3013]

The content of the *Ucs.* may be compared with an aboriginal population in the mind. If inherited mental formations exist in the human being - something analogous to instinct¹ in animals - these constitute the nucleus of the *Ucs.* Later there is added to them what is discarded during childhood development as unserviceable; and this need not differ in its nature from what is inherited. A sharp and final division between the content of the two systems does not, as a rule, take place till puberty.

[1915e, 3017]

Let us now leave primaeval man, and turn to the unconscious in our own mental life. Here we depend entirely upon the psycho-analytic method of investigation, the only one which reaches to such depths. What, we ask, is the attitude of our unconscious towards the problem of death? The answer must be: almost exactly the same as that of primaeval man. In this respect, as in many others, the man of prehistoric times survives unchanged in our unconscious. Our unconscious, then, does not believe in its own death; it behaves as if it were immortal. What we call our 'unconscious' - the deepest strata of our minds, made up of instinctual impulses - knows nothing that is negative, and no negation; in it contradictories coincide. For that reason it does not know its own death, for to that we can give only a negative content. Thus there is nothing instinctual in us which responds to a belief in death. This may even be the secret of heroism. The rational grounds for heroism rest on a judgement that the subject's own life cannot be so precious as certain abstract and general goods. But more frequent, in my view, is the instinctive and impulsive heroism which knows no such reasons, and flouts danger in the spirit of Anzengruber's *Steinklopferrhans*: 'Nothing can happen to me'. Or else those reasons only serve to clear away the hesitations which might hold back the heroic reaction that corresponds to the unconscious. The fear of death, which dominates us oftener than we know, is on the other hand something secondary, and is usually the outcome of a sense of guilt.

[1915b, 3088]
The crudest idea of these systems is the most convenient for us - a spatial one. Let us therefore compare the system of the unconscious to a large entrance hall, in which the mental impulses jostle one another like separate individuals. Adjoining this entrance hall there is a second, narrower, room - a kind of drawing-room - in which consciousness, too, resides. But on the threshold between these two rooms a watchman performs his function: he examines the different mental impulses, acts as a censor, and will not admit them into the drawing-room if they displease him. You will see at once that it does not make much difference if the watchman turns away a particular impulse at the threshold itself or if he pushes it back across the threshold after it has entered the drawing-room. This is merely a question of the degree of his watchfulness and of how early he carries out his act of recognition. If we keep to this picture, we shall be able to extend our nomenclature further. The impulses in the entrance hall of the unconscious are out of sight of the conscious, which is in the other room; to begin with they must remain unconscious. If they have already pushed their way forward to the threshold and have been turned back by the watchman, then they are inadmissible to consciousness; we speak of them as repressed. But even the impulses which the watchman has allowed to cross the threshold are not on that account necessarily conscious as well; they can only become so if they succeed in catching the eye of consciousness. We are therefore justified in calling this second room the system of the preconscious. In that case becoming conscious retains its purely descriptive sense. For any particular impulse, however, the vicissitude of repression consists in its not being allowed by the watchman to pass from the system of the unconscious into that of the preconscious. It is the same watchman whom we get to know as resistance when we try to lift the repression by means of the analytic treatment.

[1916-1917, 3369]

Although thus humbled in his external relations, man feels himself to be supreme within his own mind. Somewhere in the core of his ego he has developed an organ of observation to keep a watch on his impulses and actions and see whether they harmonize with its demands. If they do not, they are ruthlessly inhibited and withdrawn. His internal perception, consciousness, gives the ego news of all the important occurrences in the mind's working, and the will, directed by these reports, carries out what the ego orders and modifies anything that seeks to accomplish itself spontaneously. For this mind is not a simple thing; on the contrary, it is a hierarchy of superordinated and subordinated agencies, a labyrinth of impulses striving independently of one another towards action, corresponding with the multiplicity of instincts and of relations with the external world, many of which are antagonistic to one another and incompatible. For proper functioning it is necessary that the highest of these agencies should have knowledge of all that is going forward and that its will should penetrate everywhere, so as to exert its influence. And in fact the ego feels secure both as to the completeness and trustworthiness of the reports it receives and as to the openness of the channels through which it enforces its commands.

[1917a, 3612]
For a time psycho-analysis seemed fated to merge into psychology without being able to show why the psychology of the sick differed from that of the normal. In the course of its advance, however, it came up against the problem of dreams, which are abnormal products of the mind created by normal men under regularly recurrent physiological conditions. When psycho-analysis had solved the problem of dreams, it had discovered in unconscious psychical processes the common ground in which the highest and the lowest of mental impulses have their roots and from which spring the most normal as well as the most morbid and erratic of mental productions. The new picture of the workings of the mind began to grow ever clearer and more complete. It was a picture of obscure instinctual forces organic in origin, striving towards inborn aims, and, above them, of an agency comprising more highly organized mental structures - acquisitions of human evolution made under the impact of human history - , an agency which has taken over portions of the instinctual impulses, has developed them further or has even directed them towards higher aims, but which in any case binds them firmly and manipulates their energy to suit its own purposes. This higher organization, however, which is known to us as the ego, has rejected another portion of these same elementary instinctual impulses as being unserviceable because they cannot be fitted into the organic unity of the individual or because they rebel against the individual's cultural aims. The ego is not in a position to exterminate these subdued mental powers, but it turns its back on them, lets them remain at the lowest psychological level, defends itself from their demands by the energetic erection of protective and antithetical barriers or seeks to come to terms with them by means of substitutive satisfactions. These instincts which have fallen victim to repression - untamed and indestructible, yet inhibited from any kind of activity - together with their primitive mental representatives, constitute the mental underworld, the nucleus of the true unconscious, and are at every moment ready to assert their demands and, by hook or by crook, to force their way forward to satisfaction. To this is due the instability of the proud superstructure of the mind, the emergence at night of the proscribed and repressed material in the form of dreams, and the tendency to fall ill with neuroses and psychoses as soon as the balance of power between the ego and the repressed shifts to the disadvantage of the ego.

[1919g, 3703]

But the repressed merges into the id as well, and is merely a part of it. The repressed is only cut off sharply from the ego by the resistances of repression; it can communicate with the ego through the id. We at once realize that almost all the lines of demarcation we have drawn at the instigation of pathology relate only to the superficial strata of the mental apparatus - the only ones known to us. The state of things which we have been describing can be represented diagrammatically (Fig. 1); though it must be remarked that the form chosen has no pretensions to any special applicability, but is merely intended to serve for purposes of exposition.

[1923b, 3958]

It is easy to see that the ego is that part of the id which has been modified by the direct influence of the external world through the medium of the Pcpt.-Cs.; in a sense it is an extension of the surface-differentiation. Moreover, the ego seems to bring the influence of the external world to bear upon the id and its tendencies, and endeavours to substitute the reality principle for the pleasure principle which reigns unrestrictedly in the id. For the ego, perception plays the part which in the id falls to instinct. The ego represents what may be called reason and common sense, in contrast to the id, which contains the passions. All this falls into line with popular distinctions which we are all familiar with; at the same time, however, it is only to be regarded as holding good on the average or ‘ideally’.

[1923b, 3959]
We have already said that, if the differentiation we have made of the mind into an id, an ego, and a super-ego represents any advance in our knowledge, it ought to enable us to understand more thoroughly the dynamic relations within the mind and to describe them more clearly. We have also already concluded that the ego is especially under the influence of perception, and that, speaking broadly, perceptions may be said to have the same significance for the ego as instincts have for the id. At the same time the ego is subject to the influence of the instincts, too, like the id, of which it is, as we know, only a specially modified part.

Thus we may express our expectation that psycho-analysis, whose development and achievements hitherto have been briefly and inadequately related in these pages, will enter into the cultural development of the next decades as a significant ferment, and will help to deepen our understanding of the world and to fight against some things in life which are recognized as injurious. It must not be forgotten, however, that psycho-analysis alone cannot offer a complete picture of the world. If we accept the distinction which I have recently proposed of dividing the mental apparatus into an ego, turned towards the external world and equipped with consciousness, and an unconscious id, dominated by its instinctual needs, then psycho-analysis is to be described as a psychology of the id (and of its effects upon the ego). In each field of knowledge, therefore, it can make only contributions, which require to be completed from the psychology of the ego. If these contributions often contain the essence of the facts, this only corresponds to the important part which, it may be claimed, is played in our lives by the mental unconscious that has so long remained unknown.

In psychology we can only describe things by the help of analogies. There is nothing peculiar in this; it is the case elsewhere as well. But we have constantly to keep changing these analogies, for none of them lasts us long enough. Accordingly, in trying to make the relation between the ego and the id clear, I must ask you to picture the ego as a kind of façade of the id, as a frontage, like an external, cortical, layer of it. We can hold on to this last analogy. We know that cortical layers owe their peculiar characteristics to the modifying influence of the external medium on which they abut. Thus we suppose that the ego is the layer of the mental apparatus (of the id) which has been modified by the influence of the external world (of reality). This will show you how in psycho-analysis we take spatial ways of looking at things seriously. For us the ego is really something superficial and the id something deeper - looked at from outside, of course. The ego lies between reality and the id, which is what is truly mental.

I hope not. You will soon find your way about in it. Well then, we assume that the forces which drive the mental apparatus into activity are produced in the bodily organs as an expression of the major somatic needs. You will recollect the words of our poet-philosopher: 'Hunger and love.' Incidentally, quite a formidable pair of forces! We give these bodily needs, in so far as they represent an instigation to mental activity, the name of 'Trieb', a word for which we are envied by many modern languages. Well, these instincts fill the id: all the energy in the id, as we may put it briefly, originates from them. Nor have the forces in the ego any other origin; they are derived from those in the id. What, then, do these instincts want? Satisfaction - that is, the establishment of situations in which the bodily needs can be extinguished. A lowering of the tension of need is felt by our organ of consciousness as pleasurable; an increase of it is soon felt as unpleasure. From these oscillations arises the series of feelings of pleasure-unpleasure, in accordance with which the whole mental apparatus regulates its activity. In this connection we speak of a 'dominance of the pleasure principle'.

[1923b, 3974]
[1924f, 4118]
[1926e, 4338]
[1926e, 4343]
I come now to a question the discussion of which seems to me more important. Is the practice of psycho-analysis a matter which should in general be subject to official interference, or would it be more expedient to leave it to follow its natural development? I shall certainly not come to any decision on this point here and now, but I shall take the liberty of putting the problem before you for your consideration. In our country from of old a positive *furor prohibendi* has been the rule, a tendency to keep people under tutelage, to interfere and to forbid, which, as we all know, has not borne particularly good fruit. In our new republican Austria, it seems, things have not yet changed very much. I fancy you will have an important word to say in deciding the case of psycho-analysis which we are now considering; I do not know whether you have the wish or the influence with which to oppose these bureaucratic tendencies. At all events, I shall not spare you my unauthoritative thoughts on the subject. In my opinion a superabundance of regulations and prohibitions injures the authority of the law. It can be observed that where only a few prohibitions exist they are carefully observed, but where one is accompanied by prohibitions at every step, one feels definitely tempted to disregard them. Moreover, it does not mean one is quite an anarchist if one is prepared to realize that laws and regulations cannot from their origin claim to possess the attribute of being sacred and untransgressable, that they are often inadequately framed and offend our sense of justice, or will do so after a time, and that, in view of the sluggishness of the authorities, there is often no other means of correcting such inexpedient laws than by boldly violating them. Furthermore, if one desires to maintain respect for laws and regulations it is advisable not to enact any where a watch cannot easily be kept on whether they are obeyed or transgressed. Much of what I have quoted above on the practice of analysis by doctors could be repeated here in regard to genuine analysis by laymen which the law is seeking to suppress. The course of an analysis is most inconspicuous, it employs neither medicines nor instruments and consists only in talking and an exchange of information; it will not be easy to prove that a layman is practising 'analysis', if he asserts that he is merely giving encouragement and explanations and trying to establish a healthy human influence on people who are in search of mental assistance. It would surely not be possible to forbid that merely because doctors sometimes do the same thing. In English-speaking countries the practices of Christian Science have become very widespread: a kind of dialectical denial of the evils in life, based on an appeal to the doctrines of the Christian religion. I do not hesitate to assert that that procedure represents a regrettable aberration of the human spirit; but who in America or England would dream of forbidding it and making it punishable? Are the authorities so certain of the right path to salvation that they venture to prevent each man from trying 'to be saved after his own fashion'. And granted that many people if they are left to themselves run into danger and come to grief, would not the authorities do better carefully to mark the limits of the regions which are to be regarded as not to be trespassed upon, and for the rest, so far as possible, to allow human beings to be educated by experience and mutual influence? Psycho-analysis is something so new in the world, the mass of mankind is so little instructed about it, the attitude of official science to it is still so vacillating, that it seems to me over-hasty to intervene in its development with legislative regulations. Let us allow patients themselves to discover that it is damaging to them to look for mental assistance to people who have not learnt how to give it. If we explain this to them and warn them against it, we shall have spared ourselves the need to forbid it. On the main roads of Italy the pylons that carry high-tension cables bear the brief and impressive inscription: 'Chi tocca, muore.' This is perfectly calculated to regulate the behaviour of passers-by to any wires that may be hanging down. The corresponding German notices exhibit an unnecessary and offensive verbosity: 'Das Berühren der Leitungsdrähte ist, weil lebensgefährlich, strengstens verboten.' Why the prohibition? Anyone who holds his life dear will make the prohibition for himself; and anyone who wants to kill himself in that way will not ask for permission.

[1926e, 4377]
You will not expect me to have much to tell you that is new about the id apart from its new name. It is the dark, inaccessible part of our personality; what little we know of it we have learnt from our study of the dream-work and of the construction of neurotic symptoms, and most of that is of a negative character and can be described only as a contrast to the ego. We approach the id with analogies: we call it a chaos, a cauldron full of seething excitations. We picture it as being open at its end to somatic influences, and as there taking up into itself instinctual needs which find their psychical expression in it, but we cannot say in what substratum. It is filled with energy reaching it from the instincts, but it has no organization, produces no collective will, but only a striving to bring about the satisfaction of the instinctual needs subject to the observance of the pleasure principle. The logical laws of thought do not apply in the id, and this is true above all of the law of contradiction. Contrary impulses exist side by side, without cancelling each other out or diminishing each other: at the most they may converge to form compromises under the dominating economic pressure towards the discharge of energy. There is nothing in the id that could be compared with negation; and we perceive with surprise an exception to the philosophical theorem that space and time are necessary forms of our mental acts. There is nothing in the id that corresponds to the idea of time; there is no recognition of the passage of time, and - a thing that is most remarkable and awaits consideration in philosophical thought - no alteration in its mental processes is produced by the passage of time. Wishful impulses which have never passed beyond the id, but impressions, too, which have been sunk into the id by repression, are virtually immortal; after the passage of decades they behave as though they had just occurred. They can only be recognized as belonging to the past, can only lose their importance and be deprived of their cathexis of energy, when they have been made conscious by the work of analysis, and it is on this that the therapeutic effect of analytic treatment rests to no small extent.

[1933a, 4682]

The id of course knows no judgements of value: no good and evil, no morality. The economic or, if you prefer, the quantitative factor, which is intimately linked to the pleasure principle, dominates all its processes. Instinctual cathexes seeking discharge - that, in our view, is all there is in the id. It even seems that the energy of these instinctual impulses is in a state different from that in the other regions of the mind, far more mobile and capable of discharge; otherwise the displacements and condensations would not occur which are characteristic of the id and which so completely disregard the quality of what is cathected - what in the ego we should call an idea. We would give much to understand more about these things! You can see, incidentally, that we are in a position to attribute to the id characteristics other than that of its being unconscious, and you can recognize the possibility of portions of the ego and super-ego being unconscious without possessing the same primitive and irrational characteristics.

[1933a, 4683]

The relation to time, which is so hard to describe, is also introduced into the ego by the perceptual system; it can scarcely be doubted that the mode of operation of that system is what provides the origin of the idea of time. But what distinguishes the ego from the id quite especially is a tendency to synthesis in its contents, to a combination and unification in its mental processes which are totally lacking in the id. When presently we come to deal with the instincts in mental life we shall, I hope, succeed in tracing this essential characteristic of the ego back to its source. It alone produces the high degree of organization which the ego needs for its best achievements. The ego develops from perceiving the instincts to controlling them; but this last is only achieved by the representative of the instinct being allotted its proper place in a considerable assemblage, by its being taken up into a coherent context. To adopt a popular mode of speaking, we might say that the ego stands for reason and good sense while the id stands for the untamed passions.

[1933a, 4685]
The therapeutic effect depends on making conscious what is repressed, in the widest sense of the word, in the id. We prepare the way for this making conscious by interpretations and constructions, but we have interpreted only for ourselves not for the patient so long as the ego holds on to its earlier defences and does not give up its resistances. Now these resistances, although they belong to the ego, are nevertheless unconscious and in some sense separated off within the ego. The analyst recognizes them more easily than he does the hidden material in the id. One might suppose that it would be sufficient to treat them like portions of the id and, by making them conscious, bring them into connection with the rest of the ego. In this way, we should suppose, one half of the task of analysis would be accomplished; we should not reckon on meeting with a resistance against the uncovering of resistances. But what happens is this. During the work on the resistances the ego withdraws - with a greater or less degree of seriousness - from the agreement on which the analytic situation is founded. The ego ceases to support our efforts at uncovering the id; it opposes them, disobeys the fundamental rule of analysis, and allows no further derivatives of the repressed to emerge. We cannot expect the patient to have a strong conviction of the curative power of analysis. He may have brought along with him a certain amount of confidence in his analyst, which will be strengthened to an effective point by the factors of the positive transference which will be aroused in him. Under the influence of the unpleasurable impulses which he feels as a result of the fresh activation of his defensive conflicts, negative transferences may now gain the upper hand and completely annul the analytic situation. The patient now regards the analyst as no more than a stranger who is making disagreeable demands on him, and he behaves towards him exactly like a child who does not like the stranger and does not believe anything he says. If the analyst tries to explain to the patient one of the distortions made by him for the purposes of defence, and to correct it, he finds him uncomprehending and inaccessible to sound arguments. Thus we see that there is a resistance against the uncovering of resistances, and the defensive mechanisms really do deserve the name which we gave them originally, before they had been more closely examined. They are resistances not only to the making conscious of contents of the id, but also to the analysis as a whole, and thus to recovery.

[1937c, 5034]
The nucleus of the Ucs. consists of instinctual representatives which seek to discharge their cathexis; that is to say, it consists of wishful impulses. These instinctual impulses are coordinate with one another, exist side by side without being influenced by one another, and are exempt from mutual contradiction. When two wishful impulses whose aims must appear to us incompatible become simultaneously active, the two impulses do not diminish each other or cancel each other out, but combine to form an intermediate aim, a compromise.
[1915e, 3009]

There are in this system no negation, no doubt, no degrees of certainty; all this is only introduced by the work of the censorship between the Ucs. and the Pcs. Negation is a substitute, at a higher level, for repression. In the Ucs. there are only contents, cathected with greater or lesser strength.
[1915e, 3009]

The cathectic intensities are much more mobile. By the process of displacement one idea may surrender to another its whole quota of cathexis; by the process of condensation it may appropriate the whole cathexis of several other ideas. I have proposed to regard these two processes as distinguishing marks of the so-called primary psychical process. In the system Pcs. the secondary process¹ is dominant. When a primary process is allowed to take its course in connection with elements belonging to the system Pcs., it appears 'comic' and excites laughter.
[1915e, 3009]

The Ucs. processes pay just as little regard to reality. They are subject to the pleasure principle; their fate depends only on how strong they are and on whether they fulfil the demands of the pleasure-unpleasure regulation.
[1915e, 3010]

To sum up: exemption from mutual contradiction, primary process (mobility of cathexes), timelessness, and replacement of external by psychical reality - these are the characteristics which we may expect to find in processes belonging to the system Ucs.¹
[1915e, 3010]

Unconscious processes only become cognizable by us under the conditions of dreaming and of neurosis - that is to say, when processes of the higher, Pcs., system are set back to an earlier stage by being lowered (by regression). In themselves they cannot be cognized, indeed are even incapable of carrying on their existence; for the system Ucs. is at a very early moment overlaid by the Pcs. which has taken over access to consciousness and to motility. Discharge from the system Ucs. passes into somatic innervation that leads to development of affect; but even this path of discharge is, as we have seen, contested by the Pcs. By itself, the system Ucs. would not in normal conditions be able to bring about any expedient muscular acts, with the exception of those already organized as reflexes.
[1915e, 3010]

The full significance of the characteristics of the system Ucs. described above could only be appreciated by us if we were to contrast and compare them with those of the system Pcs. But this would take us so far afield that I propose that we should once more call a halt and not undertake the comparison of the two till we can do so in connection with our discussion of the higher system. Only the most pressing points of all will be mentioned at this stage.
[1915e, 3011]
The processes of the system \textit{Pcs.} display - no matter whether they are already conscious or only capable of becoming conscious - an inhibition of the tendency of cathected ideas towards discharge. When a process passes from one idea to another, the first idea retains a part of its cathexis and only a small portion undergoes displacement. Displacements and condensations such as happen in the primary process are excluded or very much restricted. This circumstance caused Breuer to assume the existence of two different states of cathectic energy in mental life: one in which the energy is tonically 'bound' and the other in which it is freely mobile and presses towards discharge. In my opinion this distinction represents the deepest insight we have gained up to the present into the nature of nervous energy, and I do not see how we can avoid making it. A metapsychological presentation would most urgently call for further discussion at this point, though perhaps that would be too daring an undertaking as yet. [1915e, 3011]

The possibility mentioned above - that some of the preconscious thoughts of the day may also prove resistant and retain a part of their cathexis - must be recognized as a second breach in narcissism. At bottom, the two cases may be identical. The resistance of the day's residues may originate in a link with unconscious impulses which is already in existence during waking life; or the process may be somewhat less simple, and the day's residues which have not been wholly emptied of cathexis may establish a connection with the repressed material only after the state of sleep has set in, thanks to the easing of communication between the \textit{Pcs.} and the \textit{Ucs.} In both cases there follows the same decisive step in dream-formation: the preconscious dream-wish is formed, which gives expression to the unconscious impulse in the material of the preconscious day's residues. This dream-wish must be sharply distinguished from the day's residues; it need not have existed in waking life and it may already display the irrational character possessed by everything that is unconscious when we translate it into the conscious. Again, the dream-wish must not be confused with the wishful impulses which may have been present, though they certainly need not necessarily be present, amongst the preconscious (latent) dream-thoughts. If, however, there were any such preconscious wishes, the dream-wish associates itself with them, as a most effective reinforcement of them. [1917d, 3031]

We may, however, obtain a deeper insight than this into the change brought about by the war in our former compatriots, and at the same time receive a warning against doing them an injustice. For the development of the mind shows a peculiarity which is present in no other developmental process. When a village grows into a town or a child into a man, the village and the child become lost in the town and the man. Memory alone can trace the old features in the new picture; and in fact the old materials or forms have been got rid of and replaced by new ones. It is otherwise with the development of the mind. Here one can describe the state of affairs, which has nothing to compare with it, only by saying that in this case every earlier stage of development persists alongside the later stage which has arisen from it; here succession also involves co-existence, although it is to the same materials that the whole series of transformations has applied. The earlier mental state may not have manifested itself for years, but none the less it is so far present that it may at any time again become the mode of expression of the forces in the mind, and indeed the only one, as though all later developments had been annulled or undone. This extraordinary plasticity of mental developments is not unrestricted as regards direction; it may be described as a special capacity for involution - for regression - since it may well happen that a later and higher stage of development, once abandoned, cannot be reached again. But the primitive stages can always be re-established; the primitive mind is, in the fullest meaning of the word, imperishable. [1915b, 3077]
Let us now leave primaeval man, and turn to the unconscious in our own mental life. Here we depend entirely upon the psycho-analytic method of investigation, the only one which reaches to such depths. What, we ask, is the attitude of our unconscious towards the problem of death? The answer must be: almost exactly the same as that of primaeval man. In this respect, as in many others, the man of prehistoric times survives unchanged in our unconscious. Our unconscious, then, does not believe in its own death; it behaves as if it were immortal. What we call our 'unconscious' - the deepest strata of our minds, made up of instinctual impulses - knows nothing that is negative, and no negation; in it contradictories coincide. For that reason it does not know its own death, for to that we can give only a negative content. Thus there is nothing instinctual in us which responds to a belief in death. This may even be the secret of heroism. The rational grounds for heroism rest on a judgement that the subject's own life cannot be so precious as certain abstract and general goods. But more frequent, in my view, is the instinctive and impulsive heroism which knows no such reasons, and flouts danger in the spirit of Anzengruber's *Steinklopfershans*: 'Nothing can happen to me'. Or else those reasons only serve to clear away the hesitations which might hold back the heroic reaction that corresponds to the unconscious. The fear of death, which dominates us oftener than we know, is on the other hand something secondary, and is usually the outcome of a sense of guilt.

It will perhaps not be thought too rash to suppose that the impulses arising from the instincts do not belong to the type of bound nervous processes but of freely mobile processes which press towards discharge. The best part of what we know of these processes is derived from our study of the dream-work. We there discovered that the processes in the unconscious systems were fundamentally different from those in the preconscious (or conscious) systems. In the unconscious, cathexes can easily be completely transferred, displaced and condensed. Such treatment, however, could produce only invalid results if it were applied to preconscious material; and this accounts for the familiar peculiarities exhibited by manifest dreams after the preconscious residues of the preceding day have been worked over in accordance with the laws operating in the unconscious. I described the type of process found in the unconscious as the 'primary' psychical process, in contradistinction to the 'secondary' process which is the one obtaining in our normal waking life. Since all instinctual impulses have the unconscious systems as their point of impact, it is hardly an innovation to say that they obey the primary process. Again, it is easy to identify the primary psychical process with Breuer's freely mobile cathexis and the secondary process with changes in his bound or tonic cathexis.¹ If so, it would be the task of the higher strata of the mental apparatus to bind the instinctual excitation reaching the primary process. A failure to effect this binding would provoke a disturbance analogous to a traumatic neurosis; and only after the binding has been accomplished would it be possible for the dominance of the pleasure principle (and of its modification, the reality principle) to proceed unhindered. Till then the other task of the mental apparatus, the task of mastering or binding excitations, would have precedence - not, indeed, in opposition to the pleasure principle, but independently of it and to some extent in disregard of it.

We shall soon see whether we can derive any advantage from this view for purposes either of description or of understanding. We shall now look upon an individual as a psychical id, unknown and unconscious, upon whose surface rests the ego, developed from its nucleus the *Pcpt.* system. If we make an effort to represent this pictorially, we may add that the ego does not completely envelop the id, but only does so to the extent to which the system *Pcpt.* forms its surface, more or less as the germinal disc rests upon the ovum. The ego is not sharply separated from the id; its lower portion merges into it.
It is easy to see that the ego is that part of the id which has been modified by the direct influence of the external world through the medium of the Pcpt.-Cs.; in a sense it is an extension of the surface-differentiation. Moreover, the ego seems to bring the influence of the external world to bear upon the id and its tendencies, and endeavours to substitute the reality principle for the pleasure principle which reigns unrestrictedly in the id. For the ego, perception plays the part which in the id falls to instinct. The ego represents what may be called reason and common sense, in contrast to the id, which contains the passions. All this falls into line with popular distinctions which we are all familiar with; at the same time, however, it is only to be regarded as holding good on the average or 'ideally'.

[1923b, 3959]

In the present discussion, moreover, I am only putting forward a hypothesis; I have no proof to offer. It seems a plausible view that this displaceable and neutral energy, which is no doubt active in both in the ego and in the id, proceeds from the narcissistic store of libido - that it is desexualized Eros. (The erotic instincts appear to be altogether more plastic, more readily diverted and displaced than the destructive instincts.) From this we can easily go on to assume that this displaceable libido is employed in the service of the pleasure principle to obviate blockages and to facilitate discharge. In this connection it is easy to observe a certain indifference as to the path along which the discharge takes place, so long as it takes place somehow. We know this trait; it is characteristic of the cathetic processes in the id. It is found in erotic cathexes, where a peculiar indifference in regard to the object displays itself; and it is especially evident in the transfersences arising in analysis, which develop inevitably, irrespective of the persons who are their object. Not long ago Rank published some good examples of the way in which neurotic acts of revenge can be directed against the wrong people. Such behaviour on the part of the unconscious reminds one of the comic story of the three village tailors, one of whom had to be hanged because the only village blacksmith had committed a capital offence. Punishment must be exacted even if it does not fall upon the guilty. It was in studying the dream-work that we first came upon this kind of looseness in the displacements brought about by the primary process. In that case it was the objects that were thus relegated to a position of no more than secondary importance, just as in the case we are now discussing it is the paths of discharge. It would be characteristic of the ego to be more particular about the choice both of an object and of a path of discharge.

[1923b, 3979]

From the point of view of instinctual control, of morality, it may be said of the id that it is totally non-moral, of the ego that it strives to be moral, and of the super-ego that it can be super-moral and then become as cruel as only the id can be. It is remarkable that the more a man checks his aggressiveness towards the exterior the more severe - that is aggressive - he becomes in his ego ideal. The ordinary view sees the situation the other way round: the standard set up by the ego ideal seems to be the motive for the suppression of aggressiveness. The fact remains, however, as we have stated it: the more a man controls his aggressiveness, the more intense becomes his ideal's inclination to aggressiveness against his ego. It is like a displacement, a turning round upon his own ego. But even ordinary normal morality has a harshly restraining, cruelly prohibiting quality. It is from this, indeed, that the conception arises of a higher being who deals out punishment inexorably.

[1923b, 3988]
Your question shows me the right way to proceed. For the important and valuable thing is to know that the ego and the id differ greatly from each other in several respects. The rules governing the course of mental acts are different in the ego and the id; the ego pursues different purposes and by other methods. A great deal could be said about this; but perhaps you will be content with a fresh analogy and an example. Think of the difference between 'the front' and 'behind the lines', as things were during the war. We were not surprised then that some things were different at the front from what they were behind the lines, and that many things were permitted behind the lines which had to be forbidden at the front. The determining influence was, of course, the proximity of the enemy; in the case of mental life it is the proximity of the external world. There was a time when 'outside', 'strange' and 'hostile' were identical concepts. And now we come to the example. In the id there are no conflicts; contradictions and antitheses persist side by side in it unconcernedly, and are often adjusted by the formation of compromises. In similar circumstances the ego feels a conflict which must be decided; and the decision lies in one urge being abandoned in favour of the other. The ego is an organization characterized by a very remarkable trend towards unification, towards synthesis. This characteristic is lacking in the id; it is, as we might say, 'all to pieces'; its different urges pursue their own purposes independently and regardless of one another.

[1926e, 4339]

You will not expect me to have much to tell you that is new about the id apart from its new name. It is the dark, inaccessible part of our personality; what little we know of it we have learnt from our study of the dream-work and of the construction of neurotic symptoms, and most of that is of a negative character and can be described only as a contrast to the ego. We approach the id with analogies: we call it a chaos, a cauldron full of seething excitations. We picture it as being open at its end to somatic influences, and as there taking up into itself instinctual needs which find their psychical expression in it, but we cannot say in what substratum. It is filled with energy reaching it from the instincts, but it has no organization, produces no collective will, but only a striving to bring about the satisfaction of the instinctual needs subject to the observance of the pleasure principle. The logical laws of thought do not apply in the id, and this is true above all of the law of contradiction. Contrary impulses exist side by side, without cancelling each other out or diminishing each other: at the most they may converge to form compromises under the dominating economic pressure towards the discharge of energy. There is nothing in the id that could be compared with negation; and we perceive with surprise an exception to the philosophical theorem that space and time are necessary forms of our mental acts. There is nothing in the id that corresponds to the idea of time; there is no recognition of the passage of time, and - a thing that is most remarkable and awaits consideration in philosophical thought - no alteration in its mental processes is produced by the passage of time. Wishful impulses which have never passed beyond the id, but impressions, too, which have been sunk into the id by repression, are virtually immortal; after the passage of decades they behave as though they had just occurred. They can only be recognized as belonging to the past, can only lose their importance and be deprived of their cathexis of energy, when they have been made conscious by the work of analysis, and it is on this that the therapeutic effect of analytic treatment rests to no small extent.

[1933a, 4682]
The id of course knows no judgements of value: no good and evil, no morality. The economic or, if you prefer, the quantitaive factor, which is intimately linked to the pleasure principle, dominates all its processes. Instinctual cathexes seeking discharge - that, in our view, is all there is in the id. It even seems that the energy of these instinctual impulses is in a state different from that in the other regions of the mind, far more mobile and capable of discharge; otherwise the displacements and condensations would not occur which are characteristic of the id and which so completely disregard the quality of what is cathected - what in the ego we should call an idea. We would give much to understand more about these things! You can see, incidentally, that we are in a position to attribute to the id characteristics other than that of its being unconscious, and you can recognize the possibility of portions of the ego and super-ego being unconscious without possessing the same primitive and irrational characteristics.

[1933a, 4683]

The relation to time, which is so hard to describe, is also introduced into the ego by the perceptual system; it can scarcely be doubted that the mode of operation of that system is what provides the origin of the idea of time. But what distinguishes the ego from the id quite especially is a tendency to synthesis in its contents, to a combination and unification in its mental processes which are totally lacking in the id. When presently we come to deal with the instincts in mental life we shall, I hope, succeed in tracing this essential characteristic of the ego back to its source. It alone produces the high degree of organization which the ego needs for its best achievements. The ego develops from perceiving the instincts to controlling them; but this last is only achieved by the representative of the instinct being allotted its proper place in a considerable assemblage, by its being taken up into a coherent context. To adopt a popular mode of speaking, we might say that the ego stands for reason and good sense while the id stands for the untamed passions.

[1933a, 4685]

The laws that govern the passage of events in the unconscious, which come to light in this manner, are remarkable enough and suffice to explain most of what seems strange to us about dreams. Above all there is a striking tendency to condensation, an inclination to form fresh unities out of elements which in our waking thought we should certainly have kept separate. As a consequence of this, a single element of the manifest dream often stands for a whole number of latent dream-thoughts as though it were a combined allusion to all of them; and in general the compass of the manifest dream is extraordinarily small in comparison with the wealth of material from which it has sprung. Another peculiarity of the dream-work, not entirely independent of the former one, is the ease with which psychical intensities (cathexes) are displaced from one element to another, so that it often happens that an element which was of little importance in the dream-thoughts appears as the clearest and accordingly most important feature of the manifest dream, and, vice versa, that essential elements of the dream-thoughts are represented in the manifest dream only by slight allusions. Moreover, as a rule the existence of quite insignificant points in common between two elements is enough to allow the dream-work to replace one by the other in all further operations. It will easily be imagined how greatly these mechanisms of condensation and displacement can increase the difficulty of interpreting a dream and of revealing the relations between the manifest dream and the latent dream-thoughts. From the evidence of the existence of these two tendencies to condensation and displacement our theory infers that in the unconscious id the energy is in a freely mobile state and that the id sets more store by the possibility of discharging quantities of excitation than by any other consideration;¹ and our theory makes use of these two peculiarities in defining the character of the primary process we have attributed to the id.

[1940a [1938], 4978]
The study of the dream-work has taught us many other characteristics of the processes in the unconscious which are as remarkable as they are important; but we must only mention a few of them here. The governing rules of logic carry no weight in the unconscious; it might be called the Realm of the Illogical. Urges with contrary aims exist side by side in the unconscious without any need arising for an adjustment between them. Either they have no influence whatever on each other, or, if they have, no decision is reached, but a compromise comes about which is nonsensical since it embraces mutually incompatible details. With this is connected the fact that contraries are not kept apart but treated as though they were identical, so that in the manifest dream any element may also have the meaning of its opposite. Certain philologists have found that the same held good in the most ancient languages and that contraries such as 'strong-weak', 'light-dark' and 'high-deep' were originally expressed by the same roots, until two different modifications of the primitive word distinguished between the two meanings. Residues of this original double meaning seem to have survived even in a highly developed language like Latin in its use of words such as ‘altus’ ('high' and 'deep') and ‘sacer’ ('sacred' and 'infamous').

The id, cut off from the external world, has a world of perception of its own. It detects with extraordinary acuteness certain changes in its interior, especially oscillations in the tension of its instinctual needs, and these changes become conscious as feelings in the pleasure-unpleasure series. It is hard to say, to be sure, by what means and with the help of what sensory terminal organs these perceptions come about. But it is an established fact that self-perceptions - coenaesthetic feelings and feelings of pleasure-unpleasure - govern the passage of events in the id with despotic force. The id obeys the inexorable pleasure principle. But not the id alone. It seems that the activity of the other psychical agencies too is able only to modify the pleasure principle but not to nullify it; and it remains a question of the highest theoretical importance, and one that has not yet been answered, when and how it is ever possible for the pleasure principle to be overcome. The consideration that the pleasure principle demands a reduction, at bottom the extinction perhaps, of the tensions of instinctual needs (that is, Nirvana) leads to the still unassessed relations between the pleasure principle and the two primal forces, Eros and the death instinct.
As you see here, the super-ego merges into the id; indeed, as heir to the Oedipus complex it has intimate relations with the id; it is more remote than the ego from the perceptual system. The id has intercourse with the external world only through the ego - at least, according to this diagram. It is certainly hard to say to-day how far the drawing is correct. In one respect it is undoubtedly not. The space occupied by the unconscious id ought to have been incomparably greater than that of the ego or the preconscious. I must ask you to correct it in your thoughts. [1933a, 4687]

The core of our being, then, is formed by the obscure id, which has no direct communication with the external world and is accessible even to our own knowledge only though the medium of another agency. Within this id the organic instincts operate, which are themselves compounded of fusions of two primal forces (Eros and destructiveness) in varying proportions and are differentiated from one another by their relation to organs or systems of organs. The one and only urge of these instincts is towards satisfaction, which is expected to arise from certain changes in the organs with the help of objects in the external world. But immediate and unheeding satisfaction of the instincts, such as the id demands, would often lead to perilous conflicts with the external world and to extinction. The id knows no solicitude about ensuring survival and no anxiety; or it would perhaps be more correct to say that, though it can generate the sensory elements of anxiety, it cannot make use of them. The processes which are possible in and between the assumed psychical elements in the id (the primary process) differ widely from those which are familiar to us through conscious perception in our intellectual and emotional life; nor are they subject to the critical restrictions of logic, which repudiates some of these processes as invalid and seeks to undo them. [1940a [1938], 5004]

The id, cut off from the external world, has a world of perception of its own. It detects with extraordinary acuteness certain changes in its interior, especially oscillations in the tension of its instincual needs, and these changes become conscious as feelings in the pleasure-unpleasure series. It is hard to say, to be sure, by what means and with the help of what sensory terminal organs these perceptions come about. But it is an established fact that self-perceptions - coenaesthetic feelings and feelings of pleasure-unpleasure - govern the passage of events in the id with despotic force. The id obeys the inexorable pleasure principle. But not the id alone. It seems that the activity of the other psychical agencies too is able only to modify the pleasure principle but not to nullify it; and it remains a question of the highest theoretical importance, and one that has not yet been answered, when and how it is ever possible for the pleasure principle to be overcome. The consideration that the pleasure principle demands a reduction, at bottom the extinction perhaps, of the tensions of instincual needs (that is, Nirvana) leads to the still unassessed relations between the pleasure principle and the two primal forces, Eros and the death instinct. [1940a [1938], 5005]
The sole prevailing quality in the id is that of being unconscious. Id and unconscious are as intimately linked as ego and preconscious: indeed, in the former case the connection is even more exclusive. If we look back at the developmental history of an individual and of his psychical apparatus, we shall be able to perceive an important distinction in the id. Originally, to be sure, everything was id; the ego was developed out of the id by the continual influence of the external world. In the course of this slow development certain of the contents of the id were transformed into the preconscious state and so taken into the ego; others of its contents remained in the id unchanged, as its scarcely accessible nucleus. During this development, however, the young and feeble ego put back into the unconscious state some of the material it had already taken in, dropped it, and behaved in the same way to some fresh impressions which it might have taken in, so that these, having been rejected, could leave a trace only in the id. In consideration of its origin we speak of this latter portion of the id as the repressed. It is of little importance that we are not always able to draw a sharp line between these two categories of contents in the id. They coincide approximately with the distinction between what was innately present originally and what was acquired in the course of the ego's development. [1940a [1938], 4973]
The content of the *Ucs.* may be compared with an aboriginal population in the mind. If inherited mental formations exist in the human being - something analogous to instinct¹ in animals - these constitute the nucleus of the *Ucs.* Later there is added to them what is discarded during childhood development as unserviceable; and this need not differ in its nature from what is inherited. A sharp and final division between the content of the two systems does not, as a rule, take place till puberty.

[1915e, 3017]

The theory of psycho-analysis (a theory based on observation) holds firmly to the view that the motive forces of repression must not be sexualized. Man's archaic heritage forms the nucleus of the unconscious mind; and whatever part of that heritage has to be left behind in the advance to later phases of development, because it is unserviceable or incompatible with what is new and harmful to it, falls a victim to the process of repression. This selection is made more successfully with one group of instincts than with the other. In virtue of special circumstances which have often been pointed out already, the latter group, that of the sexual instincts, are able to defeat the intentions of repression, and to enforce their representation by substitutive formations of a disturbing kind. For this reason infantile sexuality, which is held under repression, acts as the chief motive force in the formation of symptoms; and the essential part of its content, the Oedipus complex, is the nuclear complex of neuroses. I hope that in this paper I have raised an expectation that the sexual aberrations of childhood, as well as those of mature life, are ramifications of the same complex.

[1919e, 3662]

Let us answer first what is easiest to answer. The differentiation between ego and id must be attributed not only to primitive man but even to much simpler organisms, for it is the inevitable expression of the influence of the external world. The super-ego, according to our hypothesis, actually originated from the experiences that led to totemism. The question whether it was the ego or the id that experienced and acquired these things soon comes to nothing. Reflection at once shows us that no external vicissitudes can be experienced or undergone by the id, except by way of the ego, which is the representative of the external world to the id. Nevertheless it is not possible to speak of direct inheritance in the ego. It is here that the gulf between an actual individual and the concept of a species becomes evident. Moreover, one must not take the difference between ego and id in too hard-and-fast a sense, nor forget that the ego is a specially differentiated part of the id. The experiences of the ego seem at first to be lost for inheritance; but, when they have been repeated often enough and with sufficient strength in many individuals in successive generations, they transform themselves, so to say, into experiences of the id, the impressions of which are preserved by heredity. Thus in the id, which is capable of being inherited, are harboured residues of the existences of countless egos; and, when the ego forms its super-ego out of the id, it may perhaps only be reviving shapes of former egos and be bringing them to resurrection.

[1923b, 3972]

We have arrived at our knowledge of this psychical apparatus by studying the individual development of human beings. To the oldest of these psychical provinces or agencies we give the name of *id.* It contains everything that is inherited, that is present at birth, that is laid down in the constitution - above all, therefore, the instincts, which originate from the somatic organization and which find a first psychical expression here in forms unknown to us.

[1940a [1938], 4957]
An action by the ego is as it should be if it satisfies simultaneously the demands of the id, of the super-ego and of reality - that is to say, if it is able to reconcile their demands with one another. The details of the relation between the ego and the super-ego become completely intelligible when they are traced back to the child's attitude to its parents. This parental influence of course includes in its operation not only the personalities of the actual parents but also the family, racial and national traditions handed on through them, as well as the demands of the immediate social milieu which they represent. In the same way, the super-ego, in the course of an individual's development, receives contributions from later successors and substitutes of his parents, such as teachers and models in public life of admired social ideals. It will be observed that, for all their fundamental difference, the id and the super-ego have one thing in common: they both represent the influences of the past - the id the influence of heredity, the super-ego the influence, essentially, of what is taken over from other people - whereas the ego is principally determined by the individual's own experience, that is by accidental and contemporary events.
[1940a [1938], 4958]
If human beings too possessed an instinctive endowment such as this, it would not be surprising that it should be very particularly concerned with the processes of sexual life, even though it could not be by any means confined to them. This instinctive factor would then be the nucleus of the unconscious, a primitive kind of mental activity, which would later be dethroned and overlaid by human reason, when that faculty came to be acquired, but which in some people, perhaps in every one, would retain the power of drawing down to it the higher mental processes. Repression would be the return to this instinctive stage, and man would thus be paying for his great new acquisition with his liability to neurosis, and would be bearing witness by the possibility of the neuroses to the existence of those earlier, instinct-like, preliminary stages. The significance of the traumas of early childhood would lie in their contributing material to this unconscious which would save it from being worn away by the subsequent course of development.

[1918b, 3595]

Let us answer first what is easiest to answer. The differentiation between ego and id must be attributed not only to primitive man but even to much simpler organisms, for it is the inevitable expression of the influence of the external world. The super-ego, according to our hypothesis, actually originated from the experiences that led to totemism. The question whether it was the ego or the id that experienced and acquired these things soon comes to nothing. Reflection at once shows us that no external vicissitudes can be experienced or undergone by the id, except by way of the ego, which is the representative of the external world to the id. Nevertheless it is not possible to speak of direct inheritance in the ego. It is here that the gulf between an actual individual and the concept of a species becomes evident. Moreover, one must not take the difference between ego and id in too hard-and-fast a sense, nor forget that the ego is a specially differentiated part of the id. The experiences of the ego seem at first to be lost for inheritance; but, when they have been repeated often enough and with sufficient strength in many individuals in successive generations, they transform themselves, so to say, into experiences of the id, the impressions of which are preserved by heredity. Thus in the id, which is capable of being inherited, are harboured residues of the existences of countless egos; and, when the ego forms its super-ego out of the id, it may perhaps only be reviving shapes of former egos and be bringing them to resurrection.

[1923b, 3972]

Our ideas about the ego are beginning to clear, and its various relationships are gaining distinctness. We now see the ego in its strength and in its weaknesses. It is entrusted with important functions. By virtue of its relation to the perceptual system it gives mental processes an order in time and submits them to 'reality-testing'. By interposing the processes of thinking, it secures a postponement of motor discharges and controls the access to motility. This last power is, to be sure, a question more of form than of fact; in the matter of action the ego's position is like that of a constitutional monarch, without whose sanction no law can be passed but who hesitates long before imposing his veto on any measure put forward by Parliament. All the experiences of life that originate from without enrich the ego; the id, however, is its second external world, which it strives to bring into subjection to itself. It withdraws libido from the id and transforms the object-cathexes of the id into ego-structures. With the aid of the super-ego, in a manner that is still obscure to us, it draws upon the experiences of past ages stored in the id.

[1923b, 3989]
An action by the ego is as it should be if it satisfies simultaneously the demands of the id, of the super-ego and of reality - that is to say, if it is able to reconcile their demands with one another. The details of the relation between the ego and the super-ego become completely intelligible when they are traced back to the child's attitude to its parents. This parental influence of course includes in its operation not only the personalities of the actual parents but also the family, racial and national traditions handed on through them, as well as the demands of the immediate social milieu which they represent. In the same way, the super-ego, in the course of an individual's development, receives contributions from later successors and substitutes of his parents, such as teachers and models in public life of admired social ideals. It will be observed that, for all their fundamental difference, the id and the super-ego have one thing in common: they both represent the influences of the past - the id the influence of heredity, the super-ego the influence, essentially, of what is taken over from other people - whereas the ego is principally determined by the individual's own experience, that is by accidental and contemporary events.

[1940a [1938], 4958]

We have heard how the weak and immature ego of the first period of childhood is permanently damaged by the stresses put upon it in its efforts to fend off the dangers that are peculiar to that period of life. Children are protected against the dangers that threaten them from the external world by the solicitude of their parents; they pay for this security by a fear of loss of love which would deliver them over helpless to the dangers of the external world. This factor exerts a decisive influence on the outcome of the conflict when a boy finds himself in the situation of the Oedipus complex, in which the threat to his narcissism by the danger of castration, reinforced from primaeval sources, takes possession of him. Driven by the combined operation of these two influences, the contemporary real danger and the remembered one with its phylogenetic basis, the child embarks on his attempts at defence - repressions - which are effective for the moment but nevertheless turn out to be psychologically inadequate when the later re-animation of sexual life brings a reinforcement to the instinctual demands which have been repudiated in the past. If this is so, it would have to be said from a biological standpoint that the ego comes to grief over the task of mastering the excitations of the early sexual period, at a time when its immaturity makes it incompetent to do so. It is in this lagging of ego development behind libidinal development that we see the essential precondition of neurosis; and we cannot escape the conclusion that neuroses could be avoided if the childish ego were spared this task - if, that is to say, the child's sexual life were allowed free play, as happens among many primitive peoples. It may be that the aetiology of neurotic illnesses is more complicated than we have here described it; if so, we have at least brought out one essential part of the aetiological complex. Nor should we forget the phylogenetic influences, which are represented in some way in the id in forms that we are not yet able to grasp, and which must certainly act upon the ego more powerfully in that early period than later. On the other hand, the realization dawns on us that such an early attempt at damming up the sexual instinct, so decided a partisanship by the young ego in favour of the external as opposed to the internal world, brought about by the prohibition of infantile sexuality, cannot be without its effect on the individual's later readiness for culture. The instinctual demands forced away from direct satisfaction are compelled to enter on new paths leading to substitutive satisfaction, and in the course of these détours they may become desexualized and their connection with their original instinctual aims may become looser. And at this point we may anticipate the thesis that many of the highly valued assets of our civilization were acquired at the cost of sexuality and by the restriction of sexual motive forces.

[1940a [1938], 5006]
So long as the ego works in full harmony with the super-ego it is not easy to distinguish between their manifestations; but tensions and estrangements between them make themselves very plainly visible. The torments caused by the reproaches of conscience correspond precisely to a child's fear of loss of love, a fear the place of which has been taken by the moral agency. On the other hand, if the ego has successfully resisted a temptation to do something which would be objectionable to the super-ego, it feels raised in its self-esteem and strengthened in its pride, as though it had made some precious acquisition. In this way the super-ego continues to play the part of an external world for the ego, although it has become a portion of the internal world. Throughout later life it represents the influence of a person's childhood, of the care and education given him by his parents and of his dependence on them - a childhood which is prolonged so greatly in human beings by a family life in common. And in all this it is not only the personal qualities of these parents that is making itself felt, but also everything that had a determining effect on them themselves, the tastes and standards of the social class in which they lived and the innate dispositions and traditions of the race from which they sprang. Those who have a liking for generalizations and sharp distinctions may say that the external world, in which the individual finds himself exposed after being detached from his parents, represents the power of the present; that his id, with its inherited trends, represents the organic past; and that the super-ego, which comes to join them later, represents more than anything the cultural past, which a child has, as it were, to repeat as an after-experience during the few years of his early life. It is unlikely that such generalizations can be universally correct. Some portion of the cultural acquisitions have undoubtedly left a precipitate behind them in the id; much of what is contributed by the super-ego will awaken an echo in the id; not a few of the child's new experiences will be intensified because they are repetitions of some primaeval phylogenetic experience.

[1940a [1938], 5011]
I hope not. You will soon find your way about in it. Well then, we assume that the forces which drive the mental apparatus into activity are produced in the bodily organs as an expression of the major somatic needs. You will recollect the words of our poet-philosopher: 'Hunger and love.' Incidentally, quite a formidable pair of forces! We give these bodily needs, in so far as they represent an instigation to mental activity, the name of 'Triebе', a word for which we are envied by many modern languages. Well, these instincts fill the id: all the energy in the id, as we may put it briefly, originates from them. Nor have the forces in the ego any other origin; they are derived from those in the id. What, then, do these instincts want? Satisfaction - that is, the establishment of situations in which the bodily needs can be extinguished. A lowering of the tension of need is felt by our organ of consciousness as pleasurable; an increase of it is soon felt as unpleasure. From these oscillations arises the series of feelings of pleasure-unpleasure, in accordance with which the whole mental apparatus regulates its activity. In this connection we speak of a 'dominance of the pleasure principle'.
[1926e, 4343]
It will perhaps not be thought too rash to suppose that the impulses arising from the instincts do not belong to the type of bound nervous processes but of freely mobile processes which press towards discharge. The best part of what we know of these processes is derived from our study of the dream-work. We there discovered that the processes in the unconscious systems were fundamentally different from those in the preconscious (or conscious) systems. In the unconscious, cathexes can easily be completely transferred, displaced and condensed. Such treatment, however, could produce only invalid results if it were applied to preconscious material; and this accounts for the familiar peculiarities exhibited by manifest dreams after the preconscious residues of the preceding day have been worked over in accordance with the laws operating in the unconscious. I described the type of process found in the unconscious as the ‘primary’ psychical process, in contradistinction to the ‘secondary’ process which is the one obtaining in our normal waking life. Since all instinctual impulses have the unconscious systems as their point of impact, it is hardly an innovation to say that they obey the primary process. Again, it is easy to identify the primary psychical process with Breuer’s freely mobile cathexis and the secondary process with changes in his bound or tonic cathexis.¹ If so, it would be the task of the higher strata of the mental apparatus to bind the instinctual excitation reaching the primary process. A failure to effect this binding would provoke a disturbance analogous to a traumatic neurosis; and only after the binding has been accomplished would it be possible for the dominance of the pleasure principle (and of its modification, the reality principle) to proceed unhindered. Till then the other task of the mental apparatus, the task of mastering or binding excitations, would have precedence - not, indeed, in opposition to the pleasure principle, but independently of it and to some extent in disregard of it.

I hope not. You will soon find your way about in it. Well then, we assume that the forces which drive the mental apparatus into activity are produced in the bodily organs as an expression of the major somatic needs. You will recollect the words of our poet-philosopher: ‘Hunger and love.’ Incidentally, quite a formidable pair of forces! A lowering of the tension of need is felt by our organ of consciousness as pleasurable; an increase of it is soon felt as unpleasure. From these oscillations arises the series of feelings of pleasure-unpleasure, in accordance with which the whole mental apparatus regulates its activity. In this connection we speak of a ‘dominance of the pleasure principle’.

¹[1920g, 3737]

[1926e, 4343]
You will not expect me to have much to tell you that is new about the id apart from its new name. It is the dark, inaccessible part of our personality; what little we know of it we have learnt from our study of the dream-work and of the construction of neurotic symptoms, and most of that is of a negative character and can be described only as a contrast to the ego. We approach the id with analogies: we call it a chaos, a cauldron full of seething excitations. We picture it as being open at its end to somatic influences, and as there taking up into itself instinctual needs which find their psychical expression in it, but we cannot say in what substratum. It is filled with energy reaching it from the instincts, but it has no organization, produces no collective will, but only a striving to bring about the satisfaction of the instinctual needs subject to the observance of the pleasure principle. The logical laws of thought do not apply in the id, and this is true above all of the law of contradiction. Contrary impulses exist side by side, without cancelling each other out or diminishing each other: at the most they may converge to form compromises under the dominating economic pressure towards the discharge of energy. There is nothing in the id that could be compared with negation; and we perceive with surprise an exception to the philosophical theorem that space and time are necessary forms of our mental acts. There is nothing in the id that corresponds to the idea of time; there is no recognition of the passage of time, and - a thing that is most remarkable and awaits consideration in philosophical thought - no alteration in its mental processes is produced by the passage of time. Wishful impulses which have never passed beyond the id, but impressions, too, which have been sunk into the id by repression, are virtually immortal; after the passage of decades they behave as though they had just occurred. They can only be recognized as belonging to the past, can only lose their importance and be deprived of their cathexis of energy, when they have been made conscious by the work of analysis, and it is on this that the therapeutic effect of analytic treatment rests to no small extent.

[1933a, 4682]

[1933a, 4682]
We have arrived at our knowledge of this psychical apparatus by studying the individual development of human beings. To the oldest of these psychical provinces or agencies we give the name of id. It contains everything that is inherited, that is present at birth, that is laid down in the constitution - above all, therefore, the instincts, which originate from the somatic organization and which find a first psychical expression here in forms unknown to us.¹

[1940a [1938], 4957]
Let us now leave primaeval man, and turn to the unconscious in our own mental life. Here we depend entirely upon the psycho-analytic method of investigation, the only one which reaches to such depths. What, we ask, is the attitude of our unconscious towards the problem of death? The answer must be: almost exactly the same as that of primaeval man. In this respect, as in many others, the man of prehistoric times survives unchanged in our unconscious. Our unconscious, then, does not believe in its own death; it behaves as if it were immortal. What we call our 'unconscious' - the deepest strata of our minds, made up of instinctual impulses - knows nothing that is negative, and no negation; in it contradictories coincide. For that reason it does not know its own death, for to that we can give only a negative content. Thus there is nothing instinctual in us which responds to a belief in death. This may even be the secret of heroism. The rational grounds for heroism rest on a judgement that the subject's own life cannot be so precious as certain abstract and general goods. But more frequent, in my view, is the instinctive and impulsive heroism which knows no such reasons, and flouts danger in the spirit of Anzengruber's Steinklopfershans: 'Nothing can happen to me'. Or else those reasons only serve to clear away the hesitations which might hold back the heroic reaction that corresponds to the unconscious. The fear of death, which dominates us oftener than we know, is on the other hand something secondary, and is usually the outcome of a sense of guilt.

It is easy to see that the ego is that part of the id which has been modified by the direct influence of the external world through the medium of the Pcnt.-Cs.; in a sense it is an extension of the surface-differentiation. Moreover, the ego seems to bring the influence of the external world to bear upon the id and its tendencies, and endeavours to substitute the reality principle for the pleasure principle which reigns unrestrainedly in the id. For the ego, perception plays the part which in the id falls to instinct. The ego represents what may be called reason and common sense, in contrast to the id, which contains the passions. All this falls into line with popular distinctions which we are all familiar with; at the same time, however, it is only to be regarded as holding good on the average or 'ideally'.

We have already said that, if the differentiation we have made of the mind into an id, an ego, and a super-ego represents any advance in our knowledge, it ought to enable us to understand more thoroughly the dynamic relations within the mind and to describe them more clearly. We have also already concluded that the ego is especially under the influence of perception, and that, speaking broadly, perceptions may be said to have the same significance for the ego as instincts have for the id. At the same time the ego is subject to the influence of the instincts, too, like the id, of which it is, as we know, only a specially modified part.

Thus we may express our expectation that psycho-analysis, whose development and achievements hitherto have been briefly and inadequately related in these pages, will enter into the cultural development of the next decades as a significant ferment, and will help to deepen our understanding of the world and to fight against some things in life which are recognized as injurious. It must not be forgotten, however, that psycho-analysis alone cannot offer a complete picture of the world. If we accept the distinction which I have recently proposed of dividing the mental apparatus into an ego, turned towards the external world and equipped with consciousness, and an unconscious id, dominated by its instinctual needs, then psycho-analysis is to be described as a psychology of the id (and of its effects upon the ego). In each field of knowledge, therefore, it can make only contributions, which require to be completed from the psychology of the ego. If these contributions often contain the essence of the facts, this only corresponds to the important part which, it may be claimed, is played in our lives by the mental unconscious that has so long remained unknown.
I hope not. You will soon find your way about in it. Well then, we assume that the forces which drive the mental apparatus into activity are produced in the bodily organs as an expression of the major somatic needs. You will recollect the words of our poet-philosopher: 'Hunger and love.' Incidentally, quite a formidable pair of forces! We give these bodily needs, in so far as they represent an instigation to mental activity, the name of 'Trieb', a word for which we are envied by many modern languages. Well, these instincts fill the id: all the energy in the id, as we may put it briefly, originates from them. Nor have the forces in the ego any other origin; they are derived from those in the id. What, then, do these instincts want? Satisfaction - that is, the establishment of situations in which the bodily needs can be extinguished. A lowering of the tension of need is felt by our organ of consciousness as pleasurable; an increase of it is soon felt as unpleasure. From these oscillations arises the series of feelings of pleasure-unpleasure, in accordance with which the whole mental apparatus regulates its activity. In this connection we speak of a 'dominance of the pleasure principle'.

Topographically, psycho-analysis regards the mental apparatus as a compound instrument, and endeavours to determine at what points in it the various mental processes take place. According to the most recent psycho-analytic views, the mental apparatus is composed of an 'id', which is the repository of the instinctual impulses, of an 'ego', which is the most superficial portion of the id and one which has been modified by the influence of the external world, and of a 'super-ego', which develops out of the id, dominates the ego and represents the inhibitions of instinct that are characteristic of man. The quality of consciousness, too, has a topographical reference; for processes in the id are entirely unconscious, while consciousness is the function of the ego's outermost layer, which is concerned with the perception of the external world.

You will not expect me to have much to tell you that is new about the id apart from its new name. It is the dark, inaccessible part of our personality; what little we know of it we have learnt from our study of the dream-work and of the construction of neurotic symptoms, and most of that is of a negative character and can be described only as a contrast to the ego. We approach the id with analogies: we call it a chaos, a cauldron full of seething excitations. We picture it as being open at its end to somatic influences, and as there taking up into itself instinctual needs which find their psychical expression in it, but we cannot say in what substratum. It is filled with energy reaching it from the instincts, but it has no organization, produces no collective will, but only a striving to bring about the satisfaction of the instinctual needs subject to the observance of the pleasure principle. The logical laws of thought do not apply in the id, and this is true above all of the law of contradiction. Contrary impulses exist side by side, without cancelling each other out or diminishing each other: at the most they may converge to form compromises under the dominating economic pressure towards the discharge of energy. There is nothing in the id that could be compared with negation; and we perceive with surprise an exception to the philosophical theorem that space and time are necessary forms of our mental acts. There is nothing in the id that corresponds to the idea of time; there is no recognition of the passage of time, and - a thing that is most remarkable and awaits consideration in philosophical thought - no alteration in its mental processes is produced by the passage of time. Wishful impulses which have never passed beyond the id, but impressions, too, which have been sunk into the id by repression, are virtually immortal; after the passage of decades they behave as though they had just occurred. They can only be recognized as belonging to the past, can only lose their importance and be deprived of their cathexis of energy, when they have been made conscious by the work of analysis, and it is on this that the therapeutic effect of analytic treatment rests to no small extent.

[1926e, 4343]
[1926f, 4404]
[1933a, 4682]
Secondly, the acquisition of fire was a crime; it was accomplished by robbery or theft. This is a constant feature in all the legends about the acquiring of control over fire. It is found among the most different and widely separated peoples and not merely in the Greek myth of Prometheus the Bringer of Fire. Here, then, must be the essential content of mankind’s distorted recollection. But why is the acquisition of fire inseparably connected with the idea of a crime? Who is it that was injured or defrauded by it? The Promethean myth in Hesiod gives us a straight answer; for, in another story, not itself directly connected with fire, Prometheus so arranged the sacrifices to the gods as to give men the advantage over Zeus. It is the gods, then, who were defrauded. We know that in myths the gods are granted the satisfaction of all the desires which human creatures have to renounce, as we have learnt from the case of incest. Speaking in analytic terms, we should say that instinctual life - the id - is the god who is defrauded when the quenching of fire is renounced: in the legend, a human desire is transformed into a divine privilege. But in the legend the deity possesses nothing of the characteristics of a super-ego, he is still the representative of the paramount life of the instincts.

[1932a, 4782]

The establishment of this latter fact shows us that the qualities on which we have hitherto relied are insufficient to give us our bearings in the obscurity of mental life. We must introduce another distinction which is no longer qualitative but topographical and - what gives it special value - at the same time genetic. We now distinguish in our mental life (which we regard as an apparatus compounded of several agencies, districts or provinces) one region which we call the ego proper and another which we name the id. The id is the older of the two; the ego has developed out of it, like a cortical layer, through the influence of the external world. It is in the id that all our primary instincts are at work, all the processes in the id take place unconsciously. The ego, as we have already said, coincides with the region of the preconscious; it includes portions which normally remain unconscious. The course of events in the id, and their mutual interaction, are governed by quite other laws than those prevailing in the ego. It is in fact the discovery of these differences that has led to our new view and justifies it.

[1939a, 4919]
If the id in a human being gives rise to an instinctual demand of an erotic or aggressive nature, the simplest and most natural thing is that the ego, which has the apparatus of thought and the muscular apparatus at its disposal, should satisfy the demand by an action. This satisfaction of the instinct is felt by the ego as pleasure, just as its non-satisfaction would undoubtedly have become a source of unpleasure. Now a case may arise in which the ego abstains from satisfying the instinct in view of external obstacles - namely, if it perceives that the action in question would provoke a serious danger to the ego. An abstention from satisfaction of this kind, the renunciation of an instinct on account of an external hindrance - or, as we say, in obedience to the reality principle - is not pleasurable in any event. The renunciation of the instinct would lead to a lasting tension owing to unpleasure, if it were not possible to reduce the strength of the instinct itself by displacements of energy. Instinctual renunciation can, however, also be imposed for other reasons, which we correctly describe as internal. In the course of an individual's development a portion of the inhibiting forces in the external world are internalized and an agency is constructed in the ego which confronts the rest of the ego in an observing, criticizing and prohibiting sense. We call this new agency the super-ego. Thenceforward the ego, before putting to work the instinctual satisfactions demanded by the id, has to take into account not merely the dangers of the external world but also the objections of the super-ego, and it will have all the more grounds for abstaining from satisfying the instinct. But whereas instinctual renunciation, when it is for external reasons, is only unpleasurable, when it is for internal reasons, in obedience to the super-ego, it has a different economic effect. In addition to the inevitable unpleasurable consequences it also brings the ego a yield of pleasure - a substitutive satisfaction, as it were. The ego feels elevated; it is proud of the instinctual renunciation, as though it were a valuable achievement. We believe we can understand the mechanism of this yield of pleasure. The super-ego is the successor and representative of the individual's parents (and educators) who had supervised his actions in the first period of his life; it carries on their functions almost unchanged. It keeps the ego in a permanent state of dependence and exercises a constant pressure on it. Just as in childhood, the ego is apprehensive about risking the love of its supreme master; it feels his approval as liberation and satisfaction and his reproaches as pangs of conscience. When the ego has brought the super-ego the sacrifice of an instinctual renunciation, it expects to be rewarded by receiving more love from it. The consciousness of deserving this love is felt by it as pride. At the time when the authority had not yet been internalized as a super-ego, there could be the same relation between the threat of loss of love and the claims of instinct: there was a feeling of security and satisfaction when one had achieved an instinctual renunciation out of love for one's parents. But this happy feeling could only assume the peculiar narcissistic character of pride after the authority had itself become a portion of the ego.
