Thus we have said repeatedly that the ego is formed to a great extent out of identifications which take the place of abandoned cathexes by the id; that the first of these identifications always behave as a special agency in the ego and stand apart from the ego in the form of a super-ego, while later on, as it grows stronger, the ego may become more resistant to the influences of such identifications. The super-ego owes its special position in the ego, or in relation to the ego, to a factor which must be considered from two sides: on the one hand it was the first identification and one which took place while the ego was still feeble, and on the other hand it is the heir to the Oedipus complex and has thus introduced the most momentous objects into the ego. The super-ego's relation to the later alterations of the ego is roughly similar to that of the primary sexual phase of childhood to later sexual life after puberty. Although it is accessible to all later influences, it nevertheless preserves throughout life the character given to it by its derivation from the father-complex - namely, the capacity to stand apart from the ego and to master it. It is a memorial of the former weakness and dependence of the ego, and the mature ego remains subject to its domination. As the child was once under a compulsion to obey its parents, so the ego submits to the categorical imperative of its super-ego.

[1923b, 3982]

But the derivation of the super-ego from the first object-cathexes of the id, from the Oedipus complex, signifies even more for it. This derivation, as we have already shown, brings it into relation with the phylogenetic acquisitions of the id and makes it a reincarnation of former ego-structures which have left their precipitates behind in the id. Thus the super-ego is always close to the id and can act as its representative vis-à-vis the ego. It reaches deep down into the id and for that reason is farther from consciousness than the ego is.¹

[1923b, 3982]

One may go further and venture the hypothesis that a great part of the sense of guilt must normally remain unconscious, because the origin of conscience is intimately connected with the Oedipus complex, which belongs to the unconscious. If anyone were inclined to put forward the paradoxical proposition that the normal man is not only far more immoral than he believes but also far more moral than he knows, psycho-analysis, on whose findings the first half of the assertion rests, would have no objection to raise against the second half.¹

[1923b, 3986]

I cannot go further in my consideration of these questions without introducing a fresh hypothesis. The super-ego arises, as we know, from an identification with the father taken as a model. Every such identification is in the nature of a desexualization or even of a sublimation. It now seems as though when a transformation of this kind takes place, an instinctual defusion occurs at the same time. After sublimation the erotic component no longer has the power to bind the whole of the destructiveness that was combined with it, and this is released in the form of an inclination to aggression and destruction. This defusion would be the source of the general character of harshness and cruelty exhibited by the ideal - its dictatorial 'Thou shalt'.

[1923b, 3988]
We have said that the function of the ego is to unite and to reconcile the claims of the three agencies which it serves; and we may add that in doing so it also possesses in the super-ego a model which it can strive to follow. For this super-ego is as much a representative of the id as of the external world. It came into being through the introjection into the ego of the first objects of the id's libidinal impulses - namely, the two parents. In this process the relation to those objects was desexualized; it was diverted from its direct sexual aims. Only in this way was it possible for the Oedipus complex to be surmounted. The super-ego retained essential features of the introjected persons - their strength, their severity, their inclination to supervise and to punish. As I have said elsewhere,¹ it is easily conceivable that, thanks to the defusion of instinct which occurs along with this introduction into the ego, the severity was increased. The super-ego - the conscience at work in the ego - may then become harsh, cruel and inexorable against the ego which is in its charge. Kant's Categorical Imperative is thus the direct heir of the Oedipus complex.

But the same figures who continue to operate in the super-ego as the agency we know as conscience after they have ceased to be objects of the libidinal impulses of the id - these same figures also belong to the real external world. It is from there that they were drawn; their power, behind which lie hidden all the influences of the past and of tradition, was one of the most strongly-felt manifestations of reality. In virtue of this concurrence, the super-ego, the substitute for the Oedipus complex, becomes a representative of the real external world as well and thus also becomes a model for the endeavours of the ego.

In this way the Oedipus complex proves to be - as has already been conjectured in a historical sense¹ - the source of our individual ethical sense, our morality. The course of childhood development leads to an ever-increasing detachment from parents, and their personal significance for the super-ego recedes into the background. To the imagos they leave behind there are then linked the influences of teachers and authorities, self-chosen models and publicly recognized heroes, whose figures need no longer be introjected by an ego which has become more resistant. The last figure in the series that began with the parents is the dark power of Destiny which only the fewest of us are able to look upon as impersonal. There is little to be said against the Dutch writer Multatuli² when he replaces the Μοία [Destiny] of the Greeks by the divine pair 'Λόγος χαί Ανάγκη [Reason and necessity]; but all who transfer the guidance of the world to Providence, to God, or to God and Nature, arouse a suspicion that they still look upon these ultimate and remotest powers as a parental couple, in a mythological sense, and believe themselves linked to them by libidinal ties. In *The Ego and the Id* I made an attempt to derive mankind's realistic fear of death, too, from the same parental view of fate. It seems very hard to free oneself from it.

¹[1924c, 4079]
²[1924c, 4079]
³[1924c, 4080]
The fact that moral masochism is unconscious leads us to an obvious clue. We were able to translate the expression 'unconscious sense of guilt' as meaning a need for punishment at the hands of a parental power. We now know that the wish, which so frequently appears in phantasies, to be beaten by the father stands very close to the other wish, to have a passive (feminine) sexual relation to him and is only a regressive distortion of it. If we insert this explanation into the content of moral masochism, its hidden meaning becomes clear to us. Conscience and morality have arisen through the overcoming, the desexualization, of the Oedipus complex; but through moral masochism morality becomes sexualized once more, the Oedipus complex is revived and the way is opened for a regression from morality to the Oedipus complex. This is to the advantage neither of morality nor of the person concerned. An individual may, it is true, have preserved the whole or some measure of ethical sense alongside of his masochism; but, alternatively, a large part of his conscience may have vanished into his masochism. Again, masochism creates a temptation to perform 'sinful' actions, which must then be expiated by the reproaches of the sadistic conscience (as is exemplified in so many Russian character-types) or by chastisement from the great parental power of Destiny. In order to provoke punishment from this last representative of the parents, the masochist must do what is inexpedient, must act against his own interests, must ruin the prospects which open out to him in the real world and must, perhaps, destroy his own real existence.

[1924c, 4081]

I have described elsewhere how this turning away takes place. The object-cathexes are given up and replaced by identifications. The authority of the father or the parents is introjected into the ego, and there it forms the nucleus of the super-ego, which takes over the severity of the father and perpetuates his prohibition against incest, and so secures the ego from the return of the libidinal object-cathexis. The libidinal trends belonging to the Oedipus complex are in part desexualized and sublimated (a thing which probably happens with every transformation into an identification) and in part inhibited in their aim and changed into impulses of affection. The whole process has, on the one hand, preserved the genital organ - has averted the danger of its loss - and, on the other, has paralysed it - has removed its function. This process ushers in the latency period, which now interrupts the child's sexual development.

[1924d, 4088]

Analytic observation enables us to recognize or guess these connections between the phallic organization, the Oedipus complex, the threat of castration, the formation of the super-ego and the latency period. These connections justify the statement that the destruction of the Oedipus complex is brought about by the threat of castration. But this does not dispose of the problem; there is room for a theoretical speculation which may upset the results we have come to or put them in a new light. Before we start along this new path, however, we must turn to a question which has arisen in the course of this discussion and has so far been left on one side. The process which has been described refers, as has been expressly said, to male children only. How does the corresponding development take place in little girls?

[1924d, 4089]
At this point our material - for some incomprehensible reason - becomes far more obscure and full of gaps. The female sex, too, develops an Oedipus complex, a super-ego and a latency period. May we also attribute a phallic organization and a castration complex to it? The answer is in the affirmative; but these things cannot be the same as they are in boys. Here the feminist demand for equal rights for the sexes does not take us far, for the morphological distinction is bound to find expression in differences of psychical development. 'Anatomy is Destiny', to vary a saying of Napoleon's. The little girl's clitoris behaves just like a penis to begin with; but, when she makes a comparison with a playfellow of the other sex, she perceives that she has 'come off badly' and she feels this as a wrong done to her and as a ground for inferiority. For a while still she consoles herself with the expectation that later on, when she grows older, she will acquire just as big an appendage as the boy's. Here the masculinity complex of women branches off. A female child, however, does not understand her lack of a penis as being a sex character; she explains it by assuming that at some earlier date she had possessed an equally large organ and had then lost it by castration. She seems not to extend this inference from herself to other, adult females, but, entirely on the lines of the phallic phase, to regard them as possessing large and complete - that is to say, male - genitals. The essential difference thus comes about that the girl accepts castration as an accomplished fact, whereas the boy fears the possibility of its occurrence.

I have no doubt that the chronological and causal relations described here between the Oedipus complex, sexual intimidation (the threat of castration), the formation of the super-ego and the beginning of the latency period are of a typical kind; but I do not wish to assert that this type is the only possible one. Variations in the chronological order and in the linking-up of these events are bound to have a very important bearing on the development of the individual.

The Oedipus complex, however, is such an important thing that the manner in which one enters and leaves it cannot be without its effects. In boys (as I have shown at length in the paper to which I have just referred and to which all of my present remarks are closely related) the complex is not simply repressed, it is literally smashed to pieces by the shock of threatened castration. Its libidinal cathexes are abandoned, desexualized and in part sublimated; its objects are incorporated into the ego, where they form the nucleus of the super-ego and give that new structure its characteristic qualities. In normal, or, it is better to say, in ideal cases, the Oedipus complex exists no longer, even in the unconscious; the super-ego has become its heir. Since the penis (to follow Ferenczi) owes its extraordinarily high narcissistic cathexis to its organic significance for the propagation of the species, the catastrophe to the Oedipus complex (the abandonment of incest and the institution of conscience and morality) may be regarded as a victory of the race over the individual. This is an interesting point of view when one considers that neurosis is based upon a struggle of the ego against the demands of the sexual function. But to leave the standpoint of individual psychology is not of any immediate help in clarifying this complicated situation.
In girls the motive for the demolition of the Oedipus complex is lacking. Castration has already had its effect, which was to force the child into the situation of the Oedipus complex. Thus the Oedipus complex escapes the fate which it meets with in boys: it may be slowly abandoned or dealt with by repression, or its effects may persist far into women's normal mental life. I cannot evade the notion (though I hesitate to give it expression) that for women the level of what is ethically normal is different from what it is in men. Their super-ego is never so inexorable, so impersonal, so independent of its emotional origins as we require it to be in men. Character-traits which critics of every epoch have brought up against women - that they show less sense of justice than men, that they are less ready to submit to the great exigencies of life, that they are more often influenced in their judgements by feelings of affection or hostility - all these would be amply accounted for by the modification in the formation of their super-ego which we have inferred above. We must not allow ourselves to be deflected from such conclusions by the denials of the feminists, who are anxious to force us to regard the two sexes as completely equal in position and worth; but we shall, of course, willingly agree that the majority of men are also far behind the masculine ideal and that all human individuals, as a result of their bisexual disposition and of cross-inheritance, combine in themselves both masculine and feminine characteristics, so that pure masculinity and femininity remain theoretical constructions of uncertain content.

[1925j, 4155]

In enforcing regression, the ego scores its first success in its defensive struggle against the demands of the libido. (In this connection it is of advantage to distinguish the more general notion of 'defence' from 'repression'. Repression is only one of the mechanisms which defence makes use of.) It is perhaps in obsessional cases more than in normal or hysterical ones that we can most clearly recognize that the motive force of defence is the castration complex and that what is being fended off are the trends of the Oedipus complex. We are at present dealing with the beginning of the latency period, a period which is characterized by the dissolusion of the Oedipus complex, the creation or consolidation of the super-ego and the erection of ethical and aesthetic barriers in the ego. In obsessional neuroses these processes are carried further than is normal. In addition to the destruction of the Oedipus complex a regressive degradation of the libido takes place, the super-ego becomes exceptionally severe and unkind, and the ego, in obedience to the super-ego, produces strong reaction-formations in the shape of conscientiousness, pity and cleanliness. Implacable, though not always on that account successful, severity is shown in condemning the temptation to continue early infantile masturbation, which now attaches itself to regressive (sadistic-anal) ideas but which nevertheless represents the unsubjugated part of the phallic organization. There is an inherent contradiction about this state of affairs, in which, precisely in the interests of masculinity (that is to say, from fear of castration), every activity belonging to masculinity is stopped. But here, too, obsessional neurosis is only overdoing the normal method of getting rid of the Oedipus complex. We once more find here an illustration of the truth that every exaggeration contains the seed of its own undoing. For, under the guise of obsessional acts, the masturbation that has been suppressed approaches ever more closely to satisfaction.

[1926d, 4273]

The most important conflict with which a small child is faced is his relation to his parents, the 'Oedipus complex'; it is in attempting to grapple with this problem that those destined to suffer from a neurosis habitually come to grief. The reactions against the instinctual demands of the Oedipus complex are the source of the most precious and socially important achievements of the human mind; and this holds true not only in the life of individuals but probably also in the history of the human species as a whole. The super-ego, too, the moral agency which dominates the ego, has its origin in the process of overcoming the Oedipus complex.

[1926f, 4406]
The contradiction between this statement and what we have previously said about the genesis of conscience is in point of fact not so very great, and we see a way of further reducing it. In order to make our exposition easier, let us take as our example the aggressive instinct, and let us assume that the renunciation in question is always a renunciation of aggression. (This, of course, is only to be taken as a temporary assumption.) The effect of instinctual renunciation on the conscience then is that every piece of aggression whose satisfaction the subject gives up is taken over by the super-ego and increases the latter's aggressiveness (against the ego). This does not harmonize well with the view that the original aggressiveness of conscience is a continuance of the severity of the external authority and therefore has nothing to do with renunciation. But the discrepancy is removed if we postulate a different derivation for this first instalment of the super-ego's aggressivity. A considerable amount of aggressiveness must be developed in the child against the authority which prevents him from having his first, but none the less his most important, satisfactions, whatever the kind of instinctual deprivation that is demanded of him may be; but he is obliged to renounce the satisfaction of this revengeful aggressiveness. He finds his way out of this economically difficult situation with the help of familiar mechanisms. By means of identification he takes the unattackable authority into himself. The authority now turns into his super-ego and enters into possession of all the aggressiveness which a child would have liked to exercise against it. The child's ego has to content itself with the unhappy role of the authority - the father - who has been thus degraded. Here, as so often, the situation is reversed: 'If I were the father and you were the child, I should treat you badly.' The relationship between the super-ego and the ego is a return, distorted by a wish, of the real relationships between the ego, as yet undivided, and an external object. That is typical, too. But the essential difference is that the original severity of the super-ego does not - or does not so much - represent the severity which one has experienced from it, or which one attributes to it; it represents rather one's own aggressiveness towards it. If this is correct, we may assert truly that in the beginning conscience arises through the suppression of an aggressive impulse, and that it is subsequently reinforced by fresh suppressions of the same kind.

[1930a, 4519]

Which of these two views is correct? The earlier one, which genetically seemed so unassailable, or the newer one, which rounds off the theory in such a welcome fashion? Clearly, and by the evidence, too, of direct observations, both are justified. They do not contradict each other, and they even coincide at one point, for the child's revengeful aggressiveness will be in part determined by the amount of punitive aggression which he expects from his father. Experience shows, however, that the severity of the super-ego which a child develops in no way corresponds to the severity of treatment which he has himself met with. The severity of the former seems to be independent of that of the latter. A child who has been very leniently brought up can acquire a very strict conscience. But it would also be wrong to exaggerate this independence; it is not difficult to convince oneself that severity of upbringing does also exert a strong influence on the formation of the child's super-ego. What it amounts to is that in the formation of the super-ego and the emergence of a conscience innate constitutional factors and influences from the real environment act in combination. This is not at all surprising; on the contrary, it is a universal aetiological condition for all such processes.

[1930a, 4520]
The two main types of pathogenic methods of upbringing - over-strictness and spoiling - have been accurately assessed by Franz Alexander in his book *The Psychoanalysis of the Total Personality* (1927) in connection with Aichhorn's study of delinquency. The 'unduly lenient and indulgent father' is the cause of children's forming an over-severe super-ego, because, under the impression of the love that they receive, they have no other outlet for their aggressiveness but turning it inwards. In delinquent children, who have been brought up without love, the tension between ego and super-ego is lacking, and the whole of their aggressiveness can be directed outwards. Apart from a constitutional factor which may be supposed to be present, it can be said, therefore, that a severe conscience arises from the joint operation of two factors: the frustration of instinct, which unleashes aggressiveness, and the experience of being loved, which turns the aggressiveness inwards and hands it over to the super-ego.

It can also be asserted that when a child reacts to his first great instincual frustrations with excessively strong aggressiveness and with a correspondingly severe super-ego, he is following a phylogenetic model and is going beyond the response that would be currently justified; for the father of prehistoric times was undoubtedly terrible, and an extreme amount of aggressiveness may be attributed to him. Thus, if one shifts over from individual to phylogenetic development, the differences between the two theories of the genesis of conscience are still further diminished. On the other hand, a new and important difference makes its appearance between these two developmental processes. We cannot get away from the assumption that man's sense of guilt springs from the Oedipus complex and was acquired at the killing of the father by the brothers banded together. On that occasion an act of aggression was not suppressed but carried out; but it was the same act of aggression whose suppression in the child is supposed to be the source of his sense of guilt. At this point I should not be surprised if the reader were to exclaim angrily: 'So it makes no difference whether one kills one's father or not - one gets a feeling of guilt in either case! We may take leave to raise a few doubts here. Either it is not true that the sense of guilt comes from suppressed aggressiveness, or else the whole story of the killing of the father is a fiction and the children of primaeval man did not kill their fathers any more often than children do nowadays. Besides, if it is not fiction but a plausible piece of history, it would be a case of something happening which everyone expects to happen - namely, of a person feeling guilty because he really has done something which cannot be justified. And of this event, which is after all an everyday occurrence, psycho-analysis has not yet given any explanation.'

[1930a, 4521]
But if the human sense of guilt goes back to the killing of the primal father, that was after all a case of 'remorse'. Are we to assume that a conscience and a sense of guilt were not, as we have presupposed, in existence before the deed? If not, where, in this case, did the remorse come from? There is no doubt that this case should explain the secret of the sense of guilt to us and put an end to our difficulties. And I believe it does. This remorse was the result of the primordial ambivalence of feeling towards the father. His sons hated him, but they loved him, too. After their hatred had been satisfied by their act of aggression, their love came to the fore in their remorse for the deed. It set up the super-ego by identification with the father; it gave that agency the father's power, as though as a punishment for the deed of aggression they had carried out against him, and it created the restrictions which were intended to prevent a repetition of the deed. And since the inclination to aggressiveness against the father was repeated in the following generations, the sense of guilt, too, persisted, and it was reinforced once more by every piece of aggressiveness that was suppressed and carried over to the super-ego. Now, I think, we can at last grasp two things perfectly clearly: the part played by love in the origin of conscience and the fatal inevitability of the sense of guilt. Whether one has killed one's father or has abstained from doing so is not really the decisive thing. One is bound to feel guilty in either case, for the sense of guilt is an expression of the conflict due to ambivalence, of the eternal struggle between Eros and the instinct of destruction or death. This conflict is set going as soon as men are faced with the task of living together. So long as the community assumes no other form than that of the family, the conflict is bound to express itself in the Oedipus complex, to establish the conscience and to create the first sense of guilt. When an attempt is made to widen the community, the same conflict is continued in forms which are dependent on the past; and it is strengthened and results in a further intensification of the sense of guilt. Since civilization obeys an internal erotic impulse which causes human beings to unite in a closely-knit group, it can only achieve this aim through an ever-increasing reinforcement of the sense of guilt. What began in relation to the father is completed in relation to the group. If civilization is a necessary course of development from the family to humanity as a whole, then - as a result of the inborn conflict arising from ambivalence, of the eternal struggle between the trends of love and death - there is inextricably bound up with it an increase of the sense of guilt, which will perhaps reach heights that the individual finds hard to tolerate. One is reminded of the great poet's moving arraignment of the 'Heavenly Powers':-

[1930a, 4522]

But what has been said so far does not exhaust the consequences of the repression of the hatred of the father in the Oedipus complex. There is something fresh to be added: namely that in spite of everything the identification with the father finally makes a permanent place for itself in the ego. It is received into the ego, but establishes itself there as a separate agency in contrast to the rest of the content of the ego. We then give it the name of super-ego and ascribe to it, the inheritor of the parental influence, the most important functions. If the father was hard, violent and cruel, the super-ego takes over those attributes from him and, in the relations between the ego and it, the passivity which was supposed to have been repressed is re-established. The super-ego has become sadistic, and the ego becomes masochistic - that is to say, at bottom passive in a feminine way. A great need for punishment develops in the ego, which in part offers itself as a victim to Fate, and in part finds satisfaction in ill-treatment by the super-ego (that is, in the sense of guilt). For every punishment is ultimately castration and, as such, a fulfilment of the old passive attitude towards the father. Even Fate is, in the last resort, only a later projection of the father.

[1928b, 4561]
We have already learned, too, that there is yet another difference between the sexes, which relates to the Oedipus complex. We have an impression here that what we have said about the Oedipus complex applies with complete strictness to the male child only and that we are right in rejecting the term 'Electra complex' which seeks to emphasize the analogy between the attitude of the two sexes. It is only in the male child that we find the fateful combination of love for the one parent and simultaneous hatred for the other as a rival. In his case it is the discovery of the possibility of castration, as proved by the sight of the female genitals, which forces on him the transformation of his Oedipus complex, and which leads to the creation of his super-ego and thus initiates all the processes that are designed to make the individual find a place in the cultural community. After the paternal agency has been internalized and become a super-ego, the next task is to detach the latter from the figures of whom it was originally the psychical representative. In this remarkable course of development it is precisely the boy's narcissistic interest in his genitals - his interest in preserving his penis - which is turned round into a curtailing of his infantile sexuality.

[1931b, 4593]

I myself am far from satisfied with these remarks on identification; but it will be enough if you can grant me that the installation of the super-ego can be described as a successful instance of identification with the parental agency. The fact that speaks decisively for this view is that this new creation of a superior agency within the ego is most intimately linked with the destiny of the Oedipus complex, so that the super-ego appears as the heir of that emotional attachment which is of such importance for childhood. With his abandonment of the Oedipus complex a child must, as we can see, renounce the intense object-cathexes which he has deposited with his parents, and it is as a compensation for this loss of objects that there is such a strong intensification of the identifications with his parents which have probably long been present in his ego. Identifications of this kind as precipitates of object-cathexes that have been given up will be repeated often enough later in the child's life; but it is entirely in accordance with the emotional importance of this first instance of such a transformation that a special place in the ego should be found for its outcome. Close investigation has shown us, too, that the super-ego is stunted in its strength and growth if the surmounting of the Oedipus complex is only incompletely successful. In the course of development the super-ego also takes on the influences of those who have stepped into the place of parents - educators, teachers, people chosen as ideal models. Normally it departs more and more from the original parental figures; it becomes, so to say, more impersonal. Nor must it be forgotten that a child has a different estimate of its parents at different periods of its life. At the time at which the Oedipus complex gives place to the super-ego they are something quite magnificent; but later they lose much of this. Identifications then come about with these later parents as well, and indeed they regularly make important contributions to the formation of character; but in that case they only affect the ego, they no longer influence the super-ego, which has been determined by the earliest parental imagos.

[1933a, 4673]
But let us return to the super-ego. We have allotted it the functions of self-observation, of conscience and of the ideal. It follows from what we have said about its origin that it presupposes an immensely important biological fact and a fateful psychological one: namely, the human child's long dependence on its parents and the Oedipus complex, both of which, again, are intimately interconnected. The super-ego is the representative for us of every moral restriction, the advocate of a striving towards perfection - it is, in short, as much as we have been able to grasp psychologically of what is described as the higher side of human life. Since it itself goes back to the influence of parents, educators and so on, we learn still more of its significance if we turn to those who are its sources. As a rule parents and authorities analogous to them follow the precepts of their own super-egos in educating children. Whatever understanding their ego may have come to with their super-ego, they are severe and exacting in educating children. They have forgotten the difficulties of their own childhood and they are glad to be able now to identify themselves fully with their own parents who in the past laid such severe restrictions upon them. Thus a child's super-ego is in fact constructed on the model not of its parents but of its parents' super-ego; the contents which fill it are the same and it becomes the vehicle of tradition and of all the time-resisting judgements of value which have propagated themselves in this manner from generation to generation. You may easily guess what important assistance taking the super-ego into account will give us in our understanding of the social behaviour of mankind - in the problem of delinquency, for instance - and perhaps even what practical hints on education. It seems likely that what are known as materialistic views of history sin in under-estimating this factor. They brush it aside with the remark that human 'ideologies' are nothing other than the product and superstructure of their contemporary economic conditions. That is true, but very probably not the whole truth. Mankind never lives entirely in the present. The past, the tradition of the race and of the people, lives on in the ideologies of the super-ego, and yields only slowly to the influences of the present and to new changes; and so long as it operates through the super-ego it plays a powerful part in human life, independently of economic conditions.

[1933a, 4676]

With the transference of the wish for a penis-baby on to her father, the girl has entered the situation of the Oedipus complex. Her hostility to her mother, which did not need to be freshly created, is now greatly intensified, for she becomes the girl's rival, who receives from her father everything that she desires from him. For a long time the girl's Oedipus complex concealed her pre-Oedipus attachment to her mother from our view, though it is nevertheless so important and leaves such lasting fixations behind it. For girls the Oedipus situation is the outcome of a long and difficult development; it is a kind of preliminary solution, a position of rest which is not soon abandoned, especially as the beginning of the latency period is not far distant. And we are now struck by a difference between the two sexes, which is probably momentous, in regard to the relation of the Oedipus complex to the castration complex. In a boy the Oedipus complex, in which he desires his mother and would like to get rid of his father as being a rival, develops naturally from the phase of his phallic sexuality. The threat of castration compels him, however, to give up that attitude. Under the impression of the danger of losing his penis, the Oedipus complex is abandoned, repressed and, in the most normal cases, entirely destroyed, and a severe super-ego is set up as its heir. What happens with a girl is almost the opposite. The castration complex prepares for the Oedipus complex instead of destroying it; the girl is driven out of her attachment to her mother through the influence of her envy for the penis and she enters the Oedipus situation as though into a haven of refuge. In the absence of fear of castration the chief motive is lacking which leads boys to surmount the Oedipus complex. Girls remain in it for an indeterminate length of time; they demolish it late and, even so, incompletely. In these circumstances the formation of the super-ego must suffer; it cannot attain the strength and independence which give it its cultural significance, and feminists are not pleased when we point out to them the effects of this factor upon the average feminine character.

[1933a, 4731]
The picture of an ego which mediates between the id and the external world, which takes over the instinctual demands of the former in order to lead them to satisfaction, which derives perceptions from the latter and uses them as memories, which, intent on its self-preservation, puts itself in defence against excessively strong claims from both sides and which, at the same time, is guided in all its decisions by the injunctions of a modified pleasure principle - this picture in fact applies to the ego only up to the end of the first period of childhood, till about the age of five. At about that time an important change has taken place. A portion of the external world has, at least partially, been abandoned as an object and has instead, by identification, been taken into the ego and thus become an integral part of the internal world. This new psychical agency continues to carry on the functions which have hitherto been performed by the people in the external world: it observes the ego, gives it orders, judges it and threatens it with punishments, exactly like the parents whose place it has taken. We call this agency the super-ego and are aware of it in its judicial functions as our conscience. It is a remarkable thing that the super-ego often displays a severity for which no model has been provided by the real parents, and moreover that it calls the ego to account not only for its deeds but equally for its thoughts and unexecuted intentions, of which the super-ego seems to have knowledge. This reminds us that the hero of the Oedipus legend too felt guilty for his deeds and submitted himself to self-punishment, although the coercive power of the oracle should have acquitted him of guilt in our judgement and his own. The super-ego is in fact the heir to the Oedipus complex and is only established after that complex has been disposed of. For that reason its excessive severity does not follow a real model but corresponds to the strength of the defence used against the temptation of the Oedipus complex. Some suspicion of this state of things lies, no doubt, at the bottom of the assertion made by philosophers and believers that the moral sense is not instilled into men by education or acquired by them in their social life but is implanted in them from a higher source.

[1940a [1938], 5010]
It is a surprising thing that the tragedy of Sophocles does not call up indignant repudiation in his audience - a reaction similar to that of our simple-minded army doctor but far better justified. For fundamentally it is an amoral work: it absolves men from moral responsibility, exhibits the gods as promoters of crime and shows the impotence of the moral impulses of men which struggle against crime. It might easily be supposed that the material of the legend had in view an indictment of the gods and of fate; and in the hands of Euripides, the critic and enemy of the gods, it would probably have become such an indictment. But with the devout Sophocles there is no question of an application of that kind. The difficulty is overcome by the pious sophistry that to bow to the will of the gods is the highest morality even when it promotes crime. I cannot think that this morality is a strong point of the play, but it has no influence on its effect. It is not to it that the auditor reacts but to the secret sense and content of the legend. He reacts as though by self-analysis he had recognized the Oedipus complex in himself and had unveiled the will of the gods and the oracle as exalted disguises of his own unconscious. It is as though he was obliged to remember the two wishes - to do away with his father and in place of him to take his mother to wife - and to be horrified at them. And he understands the dramatist's voice as though it were saying to him: 'You are struggling in vain against your responsibility and are protesting in vain of what you have done in opposition to these criminal intentions. You are guilty, for you have not been able to destroy them; they still persist in you unconsciously.' And there is psychological truth contained in this. Even if a man has repressed his evil impulses into the unconscious and would like to tell himself afterwards that he is not responsible for them, he is nevertheless bound to be aware of this responsibility as a sense of guilt whose basis is unknown to him.

There can be no doubt that the Oedipus complex may be looked upon as one of the most important sources of the sense of guilt by which neurotics are so often tormented. But more than this: in a study of the beginnings of human religion and morality which I published in 1913 under the title of Totem and Taboo I put forward a suggestion that mankind as a whole may have acquired its sense of guilt, the ultimate source of religion and morality, at the beginning of its history, in connection with the Oedipus complex. I should be very glad to tell you more about this, but I had better leave it on one side. Once one has begun on that topic it is hard to break off; and we must go back to individual psychology.

His identification of his father with the castrator became important as being the source of an intense unconscious hostility towards him (which reached the pitch of a death-wish) and of a sense of guilt which reacted against it. Up to this point, however, he was behaving normally - that is to say, like every neurotic who is possessed by a positive Oedipus complex. But the astonishing thing was that even against this there was a counter-current working in him, which, on the contrary, regarded his father as the one who had been castrated and as calling, therefore, for his sympathy.
But the time comes when this early blossoming is nipped by the frost. None of these incestuous loves can avoid the fate of repression. They may succumb to it on the occasion of some discoverable external event which leads to disillusionment - such as unexpected slights, the unwelcome birth of a new brother or sister (which is felt as faithlessness), etc.; or the same thing may happen owing to internal conditions apart from any such events, perhaps simply because their yearning remains unsatisfied too long. It is unquestionably true that such events are not the effective causes, but that these love-affairs are bound to come to grief sooner or later, though we cannot say on what particular stumbling block. Most probably they pass away because their time is over, because the children have entered upon a new phase of development in which they are compelled to recapitulate from the history of mankind the repression of an incestuous object-choice, just as at an earlier stage they were obliged to effect an object-choice of that very sort.¹ In the new phase no mental product of the incestuous love-impulses that is present unconsciously is taken over by consciousness; and anything that has already come into consciousness is expelled from it. At the same time as this process of repression takes place, a sense of guilt appears. This is also of unknown origin, but there is no doubt whatever that it is connected with the incestuous wishes, and that it is justified by the persistence of those wishes in the unconscious.²

We may note too in passing that the analysis of the infantile perversion dealt with here is also of help in solving an old riddle - one which, it is true, has always troubled those who have not accepted psycho-analysis more than analysts themselves. Yet quite recently even Bleuler regarded it as a remarkable and inexplicable fact that neurotics make masturbation the central point of their sense of guilt. We have long assumed that this sense of guilt relates to the masturbation of early childhood and not to that of puberty, and that in the main it is to be connected not with the act of masturbation but with the phantasy which, although unconscious, lies at its root - that is to say, with the Oedipus complex.

One may go further and venture the hypothesis that a great part of the sense of guilt must normally remain unconscious, because the origin of conscience is intimately connected with the Oedipus complex, which belongs to the unconscious. If anyone were inclined to put forward the paradoxical proposition that the normal man is not only far more immoral than he believes but also far more moral than he knows, psycho-analysis, on whose findings the first half of the assertion rests, would have no objection to raise against the second half.¹
By its theory of the instincts psycho-analysis offended the feelings of individuals in so far as they regarded themselves as members of the social community; another branch of its theory was calculated to hurt every single person at the tenderest point of his own psychical development. Psycho-analysis disposed once and for all of the fairy tale of an asexual childhood. It demonstrated the fact that sexual interests and activities occur in small children from the beginning of their lives. It showed what transformations those activities pass through, how at about the age of five they succumb to inhibition and how from puberty onwards they enter the service of the reproductive function. It recognized that early infantile sexual life reaches its peak in what is known as the Oedipus complex (an emotional attachment of the child to the parent of the opposite sex accompanied by an attitude of rivalry to the parent of the same sex) and that at that period of life this impulsion extends uninhibited into a straightforward sexual desire. This can be confirmed so easily that only the greatest efforts could make it possible to overlook it. Every individual has in fact gone through this phase but has afterwards energetically repressed its purport and succeeded in forgetting it. A horror of incest and an enormous sense of guilt are left over from this prehistoric epoch of the individual's existence. It may be that something quite similar occurred in the prehistoric epoch of the human species as a whole and that the beginnings of morality, religion and social order were intimately connected with the surmounting of that primaeval era. To adults their prehistory seems so inglorious that they refuse to allow themselves to be reminded of it: they were infuriated when psycho-analysis tried to lift the veil of amnesia from their years of childhood. There was only one way out: what psycho-analysis asserted must be false and what posed as a new science must be a tissue of fancies and distortions.

[1925e, 4128]

It can also be asserted that when a child reacts to his first great instinctual frustrations with excessively strong aggressiveness and with a correspondingly severe super-ego, he is following a phylogenetic model and is going beyond the response that would be currently justified; for the father of prehistoric times was undoubtedly terrible, and an extreme amount of aggressiveness may be attributed to him. Thus, if one shifts over from individual to phylogenetic development, the differences between the two theories of the genesis of conscience are still further diminished. On the other hand, a new and important difference makes its appearance between these two developmental processes. We cannot get away from the assumption that man's sense of guilt springs from the Oedipus complex and was acquired at the killing of the father by the brothers banded together. On that occasion an act of aggression was not suppressed but carried out; but it was the same act of aggression whose suppression in the child is supposed to be the source of his sense of guilt. At this point I should not be surprised if the reader were to exclaim angrily: 'So it makes no difference whether one kills one's father or not - one gets a feeling of guilt in either case! We may take leave to raise a few doubts here. Either it is not true that the sense of guilt comes from suppressed aggressiveness, or else the whole story of the killing of the father is a fiction and the children of primaeval man did not kill their fathers any more often than children do nowadays. Besides, if it is not fiction but a plausible piece of history, it would be a case of something happening which everyone expects to happen - namely, of a person feeling guilty because he really has done something which cannot be justified. And of this event, which is after all an everyday occurrence, psycho-analysis has not yet given any explanation.'

[1930a, 4521]
But if the human sense of guilt goes back to the killing of the primal father, that was after all a case of 'remorse'. Are we to assume that a conscience and a sense of guilt were not, as we have presupposed, in existence before the deed? If not, where, in this case, did the remorse come from? There is no doubt that this case should explain the secret of the sense of guilt to us and put an end to our difficulties. And I believe it does. This remorse was the result of the primordial ambivalence of feeling towards the father. His sons hated him, but they loved him, too. After their hatred had been satisfied by their act of aggression, their love came to the fore in their remorse for the deed. It set up the super-ego by identification with the father; it gave that agency the father's power, as though as a punishment for the deed of aggression they had carried out against him, and it created the restrictions which were intended to prevent a repetition of the deed. And since the inclination to aggressiveness against the father was repeated in the following generations, the sense of guilt, too, persisted, and it was reinforced once more by every piece of aggressiveness that was suppressed and carried over to the super-ego. Now, I think, we can at last grasp two things perfectly clearly: the part played by love in the origin of conscience and the fatal inevitability of the sense of guilt. Whether one has killed one's father or has abstained from doing so is not really the decisive thing. One is bound to feel guilty in either case, for the sense of guilt is an expression of the conflict due to ambivalence, of the eternal struggle between Eros and the instinct of destruction or death. This conflict is set going as soon as men are faced with the task of living together. So long as the community assumes no other form than that of the family, the conflict is bound to express itself in the Oedipus complex, to establish the conscience and to create the first sense of guilt. When an attempt is made to widen the community, the same conflict is continued in forms which are dependent on the past; and it is strengthened and results in a further intensification of the sense of guilt. Since civilization obeys an internal erotic impulsion which causes human beings to unite in a closely-knit group, it can only achieve this aim through an ever-increasing reinforcement of the sense of guilt. What began in relation to the father is completed in relation to the group. If civilization is a necessary course of development from the family to humanity as a whole, then - as a result of the inborn conflict arising from ambivalence, of the eternal struggle between the trends of love and death - there is inextricably bound up with it an increase of the sense of guilt, which will perhaps reach heights that the individual finds hard to tolerate. One is reminded of the great poet's moving arraignment of the 'Heavenly Powers':-

Parricide, according to a well-known view, is the principal and primal crime of humanity as well as of the individual. (See my Totem and Taboo 1912-13.) It is in any case the main source of the sense of guilt, though we do not know if it is the only one: researches have not yet been able to establish with certainty the mental origin of guilt and the need for expiation. But it is not necessary for it to be the only one. The psychological situation is complicated and requires elucidation. The relation of a boy to his father is, as we say, an 'ambivalent' one. In addition to the hate which seeks to get rid of the father as a rival, a measure of tenderness for him is also habitually present. The two attitudes of mind combine to produce identification with the father; the boy wants to be in his father's place because he admires him and wants to be like him, and also because he wants to put him out of the way. This whole development now comes up against a powerful obstacle. At a certain moment the child comes to understand that an attempt to remove his father as a rival would be punished by him with castration. So from fear of castration - that is, in the interests of preserving his masculinity - he gives up his wish to possess his mother and get rid of his father. In so far as this wish remains in the unconscious it forms the basis of the sense of guilt. We believe that what we have here been describing are normal processes, the normal fate of the so-called 'Oedipus complex'; nevertheless it requires an important amplification.
Everyone who is familiar with the complicated transformation of meaning undergone by hysterical symptoms will understand that no attempt can be made here to follow out the meaning of Dostoevsky's attacks beyond this beginning.¹ It is enough that we may assume that their original meaning remained unchanged behind all later accretions. We can safely say that Dostoevsky never got free from the feelings of guilt arising from his intention of murdering his father. They also determined his attitude in the two other spheres in which the father-relation is the decisive factor, his attitude towards the authority of the State and towards belief in God. In the first of these he ended up with complete submission to his Little Father, the Tsar, who had once performed with him in reality the comedy of killing which his attacks had so often represented in play. Here penitence gained the upper hand. In the religious sphere he retained more freedom: according to apparently trustworthy reports he wavered, up to the last moment of his life, between faith and atheism. His great intellect made it impossible for him to overlook any of the intellectual difficulties to which faith leads. By an individual recapitulation of a development in world-history he hoped to find a way out and a liberation from guilt in the Christ ideal, and even to make use of his sufferings as a claim to be playing a Christ-like role. If on the whole he did not achieve freedom and became a reactionary, that was because the filial guilt, which is present in human beings generally and on which religious feeling is built, had in him attained a super-individual intensity and remained insurmountable even to his great intelligence. In writing this we are laying ourselves open to the charge of having abandoned the impartiality of analysis and of subjecting Dostoevsky to judgements that can only be justified from the partisan standpoint of a particular Weltanschauung. A conservative would take the side of the Grand Inquisitor and would judge Dostoevsky differently. The objection is just; and one can only say in extenuation that Dostoevsky's decision has every appearance of having been determined by an intellectual inhibition due to his neurosis.

[1928b, 4563]

But here we come upon the solution of the little problem of why it was that already at Trieste we interfered with our enjoyment of the voyage to Athens. It must be that a sense of guilt was attached to the satisfaction in having gone such a long way: there was something about it that was wrong, that from earliest times had been forbidden. It was something to do with a child's criticism of his father, with the undervaluation which took the place of the overvaluation of earlier childhood. It seems as though the essence of success was to have got further than one's father, and as though to excel one's father was still something forbidden.

[1936a, 4831]

As an addition to this generally valid motive there was a special factor present in our particular case. The very theme of Athens and the Acropolis in itself contained evidence of the son's superiority. Our father had been in business, he had had no secondary education, and Athens could not have meant much to him. Thus what interfered with our enjoyment of the journey to Athens was a feeling filial piety. And now you will no longer wonder that the recollection of this incident on the Acropolis should have troubled me so often since I myself have grown old and stand in need of forbearance and can travel no more.

[1936a, 4831]
Let us first consider the relation of children to their brothers and sisters. I do not know why we presuppose that that relation must be a loving one; for instances of hostility between adult brothers and sisters force themselves upon everyone’s experience and we can often establish the fact that the disunity originated in childhood or has always existed. But it is further true that a great many adults, who are on affectionate terms with their brothers and sisters and are ready to stand by them to-day, passed their childhood on almost unbroken terms of enmity with them. The elder child ill-treats the younger, maligns him and robs him of his toys; while the younger is consumed with impotent rage against the elder, envies and fears him, or meets his oppressor with the first stirrings of a love of liberty and a sense of justice. Their parents complain that the children do not get on with one another, but cannot discover why. It is easy to see that the character of even a good child is not what we should wish to find it in an adult. Children are completely egoistic; they feel their needs intensely and strive ruthlessly to satisfy them—especially as against the rivals, other children, and first and foremost as against their brothers and sisters. But we do not on that account call a child ‘bad’, we call him ‘naughty’; he is no more answerable for his evil deeds in our judgement than in the eyes of the law. And it is right that this should be so; for we may expect that, before the end of the period which we count as childhood, altruistic impulses and morality will awaken in the little egoist and (to use Meynert’s terms) a secondary ego will overlay and inhibit the primary one. It is true, no doubt, that morality does not set in simultaneously all along the line and that the length of non-moral childhood varies in different individuals. If this morality fails to develop, we like to talk of ‘degeneracy’, though what in fact faces us is an inhibition in development. After the primary character has already been overlaid by later development, it can still be laid bare again, at all events in part, in cases of hysterical illness. There is a really striking resemblance between what is known as the hysterical character and that of a naughty child. Obsessional neurosis, on the contrary, corresponds to a super-morality imposed as a reinforcing weight upon fresh stirrings of the primary character.

Many people, therefore, who love their brothers and sisters and would feel bereaved if they were to die, harbour evil wishes against them in their unconscious, dating from earlier times; and these are capable of being realized in dreams.

It is of quite particular interest, however, to observe the behaviour of small children up to the age of two or three or a little older towards their younger brothers and sisters. Here, for instance, was a child who had so far been the only one; and now he was told that the stork had brought a new baby. He looked the new arrival up and down and then declared decisively: ‘The stork can take him away again!’¹ I am quite seriously of the opinion that a child can form a just estimate of the set-back he has to expect at the hands of the little stranger. A lady of my acquaintance, who is on very good terms to-day with a sister four years her junior, tells me that she greeted the news of her first arrival with this qualification: ‘But all the same I shan’t give her my red cap!’ Even if a child only comes to realize the situation later on, his hostility will date from that moment. I know of a case in which a little girl of less than three tried to strangle an infant in its cradle because she felt that its continued presence boded her no good. Children at that time of life are capable of jealousy of any degree of intensity and obviousness. Again, if it should happen that the baby sister does in fact disappear after a short while, the elder child will find the whole affection of the household once more concentrated upon himself. If after that the stork should bring yet another baby, it seems only logical that the little favourite should nourish a wish that his new competitor may meet with the same fate as the earlier one, so that he himself may be as happy as he was originally and during the interval.² Normally, of course, this attitude of a child towards a younger brother or sister is a simple function of the difference between their ages. Where the gap in time is sufficiently long, an elder girl will already begin to feel the stirring of her maternal instincts towards the helpless new born baby.
Hostile feelings towards brothers and sisters must be far more frequent in childhood than the unseeing eye of the adult observer can perceive.¹
[1900a, 731]

In the case of my own children, who followed each other in rapid succession, I neglected the opportunity of carrying out observations of this kind; but I am now making up for this neglect by observing a small nephew, whose autocratic rule was upset, after lasting for fifteen months, by the appearance of a female rival. I am told, it is true, that the young man behaves in the most chivalrous manner to his little sister, that he kisses her hand and strokes her; but I have been able to convince myself that even before the end of his second year he made use of his powers of speech for the purpose of criticizing someone whom he could not fail to regard as superfluous. Whenever the conversation touched upon her he used to intervene in it and exclaim petulantly: 'Too 'ickle! too 'ickle!' During the last few months the baby's growth has made enough progress to place her beyond this particular ground for contempt, and the little boy has found a different basis for his assertion that she does not deserve so much attention: at every suitable opportunity he draws attention to the fact that she has no teeth.² We all of us recollect how the eldest girl of another of my sisters, who was then a child of six, spent half an hour in insisting upon each of her aunts in succession agreeing with her: 'Lucie can't understand that yet, can she?' she kept asking. Lucie was her rival - two and a half years her junior.
[1900a, 731]

¹ [Footnote added 1914:] Since this was written, a large number of observations have been made and recorded in the literature of psycho-analysis upon the originally hostile attitude of children towards their brothers and sisters and one of their parents. The author and poet Spitteler has given us a particularly genuine and naïve account of this childish attitude, derived from his own childhood: 'Moreover there was a second Adolf there: a little creature who they alleged was my brother, though I could not see what use he was and still less why they made as much fuss of him as of me myself. I was sufficient so far as I was concerned; why should I want a brother? And he was not merely useless, he was positively in the way. When I pestered my grandmother, he wanted to pester her too. When I was taken out in the perambulator, he sat opposite to me and took up half the space, so that we were bound to kick each other with our feet.'
[1900a, 731]

At this point someone will perhaps interrupt: 'Granted that children have hostile impulses towards their brothers and sisters, how can a child's mind reach such a pitch of depravity as to wish for the death of his rivals or of playmates stronger than himself, as though the death penalty were the only punishment for every crime?' Anyone who talks like this has failed to bear in mind that a child's idea of being 'dead' has nothing much in common with ours apart from the word. Children know nothing of the horrors of corruption, of freezing in the ice-cold grave, of the terrors of eternal nothingness - ideas which grown-up people find it so hard to tolerate, as is proved by all the myths of a future life. The fear of death has no meaning to a child; hence it is that he will play with the dreadful word and use it as a threat against a playmate: 'If you do that again, you'll die, like Franz!' Meanwhile the poor mother gives a shudder and remembers, perhaps, that the greater half of the human race fail to survive their childhood years. It was actually possible for a child, who was over eight years old at the time, coming home from a visit to the Natural History Museum, to say to his mother: 'I'm so fond of you, Mummy: when you die I'll have you stuffed and I'll keep you in this room, so that I can see you all the time.' So little resemblance is there between a child's idea of being dead and our own!'
To children, who, moreover, are spared the sight of the scenes of suffering which precede death, being 'dead' means approximately the same as being 'gone' - not troubling the survivors any longer. A child makes no distinction as to how this absence is brought about: whether it is due to a journey, to a dismissal, to an estrangement, or to death.¹ If, during a child's prehistoric epoch, his nurse has been dismissed, and if soon afterwards his mother has died, the two events are superimposed on each other in a single series in his memory as revealed in analysis. When people are absent, children do not miss them with any great intensity; many mothers have learnt this to their sorrow when, after being away from home for some weeks on a summer holiday, they are met on their return by the news that the children have not once asked after their mummy. If their mother does actually make the journey to that 'undiscover'd country, from whose bourn no traveller returns', children seem at first to have forgotten her, and it is only later on that they begin to call their dead mother to mind.

¹ [Footnote added 1924:] Anyone who is interested in the mental life of these years of childhood will find it easy to guess the deeper determinant of the demand made on the big brother. The child of not yet three had understood that the little sister who had recently arrived had grown inside his mother. He was very far from approving of this addition to the family, and was full of mistrust and anxiety that his mother's inside might conceal still more children. The wardrobe or cupboard was a symbol for him of his mother's inside. So he insisted on looking into this cupboard, and turned for this to his big brother, who (as is clear from other material) had taken his father's place as the child's rival. Besides the well-founded suspicion that this brother had had the lost nurse 'boxed up', there was a further suspicion against him - namely that he had in some way introduced the recently born baby into his mother's inside. The affect of disappointment when the cupboard was found to be empty derived, therefore, from the superficial motivation for the child's demand. As regards the deeper trend of thought, the affect was in the wrong place. On the other hand, his great satisfaction over his mother's slimness on her return can only be fully understood in the light of this deeper layer.
Her other reproach against her father was that his ill-health was only a pretext and that he exploited it for his own purposes. This reproach, too, concealed a whole section of her own secret history. One day she complained of a professedly new symptom, which consisted of piercing gastric pains. 'Whom are you copying now?' I asked her, and found I had hit the mark. The day before she had visited her cousins, the daughters of the aunt who had died. The younger one had become engaged, and this had given occasion to the elder one for falling ill with gastric pains, and she was to be sent off to Semmering. Dora thought it was all just envy on the part of the elder sister; she always got ill when she wanted something, and what she wanted now was to be away from home so as not to have to look on at her sister's happiness.¹ But Dora's own gastric pains proclaimed the fact that she identified herself with her cousin, who, according to her, was a malingerer. Her grounds for this identification were either that she too envied the luckier girl her love, or that she saw her own story reflected in that of the elder sister, who had recently had a love-affair which had ended unhappily.² But she had also learned from observing Frau K. what useful things illnesses could become. Herr K. spent part of the year travelling. Whenever he came back, he used to find his wife in bad health, although, as Dora knew, she had been quite well only the day before. Dora realized that the presence of the husband had the effect of making his wife ill, and that she was glad to be ill so as to be able to escape the conjugal duties which she so much detested. At this point in the discussion Dora suddenly brought in an allusion to her own alternations between poor and bad health during the first years of her girlhood at B--; and I was thus driven to suspect that her states of health were to be regarded as depending upon something else, in the same way as Frau K.'s. (It is a rule of psycho-analytic technique that an internal connection which is still undisclosed will announce its presence by means of a contiguity - a temporal proximity of associations; just as in writing, if 'a' and 'b' are put side by side, it means that the syllable 'ab' is to be formed out of them.) Dora had had a very large number of attacks of coughing accompanied by loss of voice. Could it be that the presence or absence of the man she loved had had an influence upon the appearance and disappearance of the symptoms of her illness? If this were so, it must be possible to discover some coincidence or other which would betray the fact. I asked her what the average length of these attacks had been. 'From three to six weeks, perhaps.' How long had Herr K.'s absences lasted? 'Three to six weeks, too,' she was obliged to admit. Her illness was therefore a demonstration of her love for K., just as his wife's was a demonstration of her dislike. It was only necessary to suppose that her behaviour had been the opposite of Frau K.'s and that she had been ill when he was absent and well when he had come back. And this really seemed to have been so, at least during the first period of the attacks. Later on it no doubt became necessary to obscure the coincidence between her attacks of illness and the absence of the man she secretly loved, lest its regularity should betray her secret. The length of the attacks would then remain as a trace of their original significance.

¹[1905e, 1376]
The motives for being ill often begin to be active even in childhood. A little girl in her greed for love does not enjoy having to share the affection of her parents with her brothers and sisters; and she notices that the whole of their affection is lavished on her once more whenever she arouses their anxiety by falling ill. She has now discovered a means of enticing out her parents' love, and will make use of that means as soon as she has the necessary psychical material at her disposal for producing an illness. When such a child has grown up to be a woman she may find all the demands she used to make in her childhood countered owing to her marriage with an inconsiderate husband, who may subjugate her will, mercilessly exploit her capacity for work, and lavish neither his affection nor his money upon her. In that case ill-health will be her one weapon for maintaining her position. It will procure her the care she longs for; it will force her husband to make pecuniary sacrifices for her and to show her consideration, as he would never have done while she was well; and it will compel him to treat her with solicitude if she recovers, for otherwise a relapse will threaten. Her state of ill-health will have every appearance of being objective and involuntary - the very doctor who treats her will bear witness to the fact; and for that reason she will no need to feel any conscious self-reproaches at making such successful use of a means which she had found effective in her years of childhood.

The second great problem which exercises a child's mind - only at a somewhat later age, no doubt - is the question of the origin of babies. This is usually started by the unwelcome arrival of a small brother or sister. It is the oldest and most burning question that confronts immature humanity. Those who understand how to interpret myths and legends can detect it in the riddle which the Theban Sphinx set to Oedipus. The customary answers given to the child in the nursery damage his genuine instinct of research and as a rule deal the first blow, too, at his confidence in his parents. From that time on he usually begins to mistrust grown-up people, and to keep his most intimate interests secret from them. The following little document shows how tormenting this curiosity can become in older children. It is a letter written by a motherless girl of eleven and a half who had been speculating on the problem with her younger sister.

If we could divest ourselves of our corporeal existence, and could view the things of this earth with a fresh eye as purely thinking beings, from another planet for instance, nothing perhaps would strike our attention more forcibly than the fact of the existence of two sexes among human beings, who, though so much alike in other respects, yet mark the difference between them with such obvious external signs. But it does not seem that children choose this fundamental fact in the same way as the starting-point of their researches into sexual problems. Since they have known a father and mother as far back as they can remember in life, they accept their existence as a reality which needs no further enquiry, and a boy has the same attitude towards a little sister from whom he is separated by only a slight difference of age of one or two years. A child's desire for knowledge on this point does not in fact awaken spontaneously, prompted perhaps by some inborn need for established causes; it is aroused under the goad of the self-seeking instincts that dominate him, when - perhaps after the end of his second year - he is confronted with the arrival of a new baby. And a child whose own nursery has received no such addition is able, from observations made in other homes, to put himself in the same situation. The loss of his parents' care, which he actually experiences or justly fears, and the presentiment that from now on he must for evermore share all his possessions with the newcomer, have the effect of awakening his emotions and sharpening his capacities for thought. The elder child expresses unconcealed hostility towards his rival, which finds vent in unfriendly criticisms of it, in wishes that "the stork should take it away again" and occasionally even in small attacks upon the creature lying helpless in the cradle. A wider difference in age usually softens the expression of this primary hostility. In the same way, at a rather later age, if no small brother or sister has appeared, the child's wish for a playmate, such as he has seen in other families, may gain the upper hand.
For a small child his parents are at first the only authority and the, source of all belief. The child's most intense and most momentous wish during these early years is to be like his parents (that is, the parent of his own sex) and to be big like his father and mother. But as intellectual growth increases, the child cannot help discovering by degrees the category to which his parents belong. He gets to know other parents and compares them with his own, and so acquires the right to doubt the incomparable and unique quality which he had attributed to them. Small events in the child's life which make him feel dissatisfied afford him provocation for beginning to criticize his parents, and for using, in order to support his critical attitude, the knowledge which he has acquired that other parents are in some respects preferable to them. The psychology of the neuroses teaches us that, among other factors, the most intense impulses of sexual rivalry contribute to this result. A feeling of being slighted is obviously what constitutes the subject-matter of such provocations. There are only too many occasions on which a child is slighted, or at least feels he has been slighted, on which he feels he is not receiving the whole of his parents' love, and, most of all, of which he feels regrets at having to share it with brothers and sisters. His sense that his own affection is not being fully reciprocated then finds a vent in the idea, often consciously recollected later from early childhood, of being a step-child or an adopted child. People who have not developed neuroses very frequently remember such occasions, on which - usually as a result of something they have read - they interpreted and responded to their parent's hostile behaviour in this fashion. But here the influence of sex is already in evidence, for a boy is far more inclined to feel hostile impulses towards his father than towards his mother and has a far more intense desire to get free from him than from her. In this respect the imagination of girls is apt to show itself much weaker. These consciously remembered mental impulses of childhood embody the factor which enables us to understand the nature of myths.

A younger child is very specially inclined to use imaginative stories such as these in order to rob those born before him of their prerogatives - in a way which reminds one of historical intrigues; and he often has no hesitation in attributing to his mother as many fictitious love-affairs as he himself has competitors. An interesting variant of the family romance may then appear, in which the hero and author returns to legitimacy himself while his brothers and sisters are eliminated by being bastardized. So too if there are any other particular interests at work they can direct the course to be taken by the family romance; for its many-sidedness and its great range of applicability enable it to meet every sort of requirement. In this way, for instance, the young phantasy-builder can get rid of his forbidden degree of kinship with one of his sisters if he finds himself sexually attracted by her.

² Hans is very jealous of the new arrival, and whenever any one praises her, says she is a lovely baby, and so on, he at once declares scornfully: "But she's not got any teeth yet." And in fact when he saw her for the first time he was very much surprised that she was unable to speak, and decided that this was because she had no teeth. During the first few days he was naturally put very much in the background. He was suddenly taken ill with a sore throat. In his fever he was heard saying: "But I don't want a baby sister!"

² This again is a typical mode of behaviour. Another little boy, only two years his sister's senior, used to parry similar remarks with an angry cry of 'Too 'ickle! too 'ickle!' 

² Some six months later he had got over his jealousy, and his brotherly affection for the baby was only equalled by his sense of his own superiority over her.
¹ Another child, rather older than Hans, welcomed his younger brother with the words: 'The stork can take him away again.' Compare in this connection my remarks in The Interpretation of Dreams on dreams of the death of loved relatives.

[1909b, 2007]

'I: "When you were watching Mummy giving Hanna her bath, perhaps you wished she would let go of her so that Hanna should fall in?"

[1909b, 2054]

Hans's father, we cannot help thinking, had made a very good guess.

[1909b, 2054]

'In the evening my wife told me that Hans had been out on the balcony and had said: "I thought to myself Hanna was on the balcony and fell down off it." I had once or twice told him to be careful that Hanna did not get too near the balustrade when she was out on the balcony; for the railing was designed in the most unpractical way (by a metal-worker of the Secessionist movement) and had big gaps in it which I had to have filled in with wire netting. Hans's repressed wish was very transparent. His mother asked him if he would rather Hanna were not there, to which he said "Yes".

[1909b, 2054]

April 14th. The theme of Hanna is uppermost. As you may remember from earlier records, Hans felt a strong aversion to the new-born baby that robbed him of a part of his parents' love. This dislike has not entirely disappeared and is only partly overcompensated by an exaggerated affection.¹ He has already several times expressed a wish that the stork should bring no more babies and that we should pay him money not to bring any more "out of the big box" where babies are. (Compare his fear of furniture-vans. Does not a bus look like a big box?) Hanna screams such a lot, he says, and that's a nuisance to him.

[1909b, 2054]

¹ The 'Hanna' theme immediately succeeded the 'lumf' theme, and the explanation of this at length begins to dawn upon us: Hanna was a lumf herself - babies were lumfs.

[1909b, 2055]

I had predicted to his father that it would be possible to trace back Hans's phobia to thoughts and wishes occasioned by the birth of his baby sister. But I had omitted to point out that according to the sexual theory of children a baby is a 'lumf', so that Hans's path would lie through the excremental complex. It was owing to this neglect on my part that the progress of the case became temporarily obscured. Now that the matter had been cleared up, Hans's father attempted to examine the boy a second time upon this important point.

[1909b, 2061]

'Hans: "Oh yes. Why not? I should like to have one, but Mummy mustn't have one; I don't like that."

[1909b, 2072]

(He has often expressed this view before. He is afraid of losing still more of his position if a third child arrives.)

[1909b, 2072]
The most important influence upon the course of Hans's psychosexual development was the birth of a baby sister when he was three and a half years old. That event accentuated his relations to his parents and gave him some insoluble problems to think about; and later, as he watched the way in which the infant was looked after, the memory-traces of his own earliest experiences of pleasure were revived in him. This influence, too, is a typical one: in an unexpectedly large number of life-histories, normal as well as pathological, we find ourselves obliged to take as our starting-point an outburst of sexual pleasure and sexual curiosity connected, like this one, with the birth of the next child. Hans's behaviour towards the new arrival was just what I have described in *The Interpretation of Dreams*. In his fever a few days later he betrayed how little he liked the addition to the family. Affection for his sister might come later,¹ but his first attitude was hostility. From that time forward fear that yet another baby might arrive found a place among his conscious thoughts. In the neurosis, his hostility, already suppressed, was represented by a special fear - a fear of the bath. In the analysis he gave undisguised expression to his death-wish against his sister, and was not content with allusions which required supplementing by his father. His inner conscience did not consider this wish so wicked as the analogous one against his father; but it is clear that in his unconscious he treated both persons in the same way, because they both took his mummy away from him, and interfered with his being alone with her.

[1909b, 2098]

The arrival of his sister brought into Hans's life many new elements, which from that time on gave him no rest. In the first place he was obliged to submit to a certain degree of privation: to begin with, a temporary separation from his mother, and later a permanent diminution in the amount of care and attention which he had received from her and which thenceforward he had to grow accustomed to sharing with his sister. In the second place, he experienced a revival of the pleasures he had enjoyed when he was looked after as an infant; for they were called up by all that he saw his mother doing for the baby. As a result of these two influences his erotic needs became intensified, while at the same time they began to obtain insufficient satisfaction. He made up for the loss which his sister's arrival had entailed on him by imagining that he had children of his own; and so long as he was at Gmunden - on his second visit there - and could really play with these children, he found a sufficient outlet for his affections. But after his return to Vienna he was once more alone, and set all his hopes upon his mother. He had meanwhile suffered another privation, having been exiled from his parents' bedroom at the age of four and a half. His intensified erotic excitability now found expression in phantasies, by which in his loneliness he conjured up his playmates of the past summer, and in regular auto-erotic satisfaction obtained by a masturbatory stimulation of his genitals.

[1909b, 2112]
He then went on to say that he would like to speak of a criminal act, whose author he did not recognize as himself, though he quite clearly recollected committing it. He quoted a saying of Nietzsche's:² "I did this," says my Memory. "I cannot have done this," says my Pride and remains inexorable. In the end - Memory yields.' 'Well,' he continued, 'my memory has not yielded on this point.' - 'That is because you derive pleasure from your self-reproaches as a means of self-punishment.' - 'My younger brother - I am really very fond of him now, and he is causing me a great deal of worry just at present, for he wants to make what I consider a preposterous match; I have thought before now of going and killing the person concerned so as to prevent his marrying her - well, my younger brother and I used to fight a lot when we were children. We were very fond of each other at the same time, and were inseparable; but I was plainly filled with jealousy, as he was the stronger and better-looking of the two and consequently the favourite.' - 'Yes. You have already given me a description of a scene of jealousy in connection with Fräulein Lina.' - 'Very well then, on some such occasion (it was certainly before I was eight years old, for I was not going to school yet, which I began to do when I was eight) - on some such occasion, this is what I did. We both had toy guns of the usual make. I loaded mine with the ram rod and told him that if he looked up the barrel he would see something. Then, while he was looking in, I pulled the trigger. He was hit on the forehead and not hurt; but I had meant to hurt him very much indeed. Afterwards I was quite beside myself, and threw myself on the ground and asked myself however I could have done such a thing. But I did do it.' - I took the opportunity of urging my case. If he had preserved the recollection of an action so foreign to him as this, he could not, I maintained, deny the possibility of something similar, which he had now forgotten entirely, having happened at a still earlier age in relation to his father. - He then told me he was aware of having felt other vindictive impulses, this time towards the lady he admired so much, of whose character he painted a glowing picture. It might be true, he said, that she could not love easily; but she was reserving her whole self for the one man to whom she would some day belong. She did not love him. When he had become certain of that, a conscious phantasy had taken shape in his mind of how he should grow very rich and marry some one else, and should then take her to call on the lady in order to hurt her feelings. But at that point the phantasy had broken down, for he had been obliged to own to himself that the other woman, his wife, was completely indifferent to him; then his thoughts had become confused, till finally it had been clearly borne in upon him that this other woman would have to die. In this phantasy, just as in his attempt upon his brother, he recognized the quality of cowardice which was so particularly horrible to him.³ - In the further course of our conversation I pointed out to him that he ought logically to consider himself as in no way responsible for any of these traits in his character; for all of these reprehensible impulses originated from his infancy, and were only derivatives of his infantile character surviving in his unconscious; and he must know that moral responsibility could not be applied to children. It was only by a process of development, I added, that a man, with his moral responsibility, grew up out of the sum of his infantile predispositions.⁴ He expressed a doubt, however, whether all his evil impulses had originated from that source. But I promised to prove it to him in the course of the treatment.

[1909d, 2146]
Let us return to the sexual development of children. We have some arrears to make up owing to our having paid more attention to the somatic than to the mental phenomena of sexual life. The child's first choice of an object, which derives from its need for help, claims our further interest. Its choice is directed in the first instance to all those who look after it, but these soon give place to its parents. Children's relations to their parents, as we learn alike from direct observations of children and from later analytic examination of adults, are by no means free from elements of accompanying sexual excitation. The child takes both of its parents, and more particularly one of them, as the object of its erotic wishes. In so doing, it usually follows some indication from its parents, whose affection bears the clearest characteristics of a sexual activity, even though of one that is inhibited in its aims. As a rule a father prefers his daughter and a mother her son; the child reacts to this by wishing, if he is a son, to take his father's place, and, if she is a daughter, her mother's. The feelings which are aroused in these relations between parents and children and in the resulting ones between brothers and sisters are not only of a positive or affectionate kind but also of a negative or hostile one. The complex which is thus formed is doomed to early repression; but it continues to exercise a great and lasting influence from the unconscious. It is to be suspected that, together with its extensions, it constitutes the nuclear complex of every neurosis, and we may expect to find it no less actively at work in other regions of mental life. The myth of King Oedipus, who killed his father and took his mother to wife, reveals, with little modification, the infantile wish, which is later opposed and repudiated by the barrier against incest. Shakespeare's Hamlet is equally rooted in the soil of the incest-complex, but under a better disguise.

Psycho-analytic studies of psychical impotence have already been carried out and published by several writers.¹ Every analyst can confirm the explanations provided by them from his own clinical experience. It is in fact a question of the inhibitory influence of certain psychical complexes which are withdrawn from the subject's knowledge. An incestuous fixation on mother or sister, which has never been surmounted, plays a prominent part in this pathogenic material and is its most universal content. In addition there is the influence to be considered of accidental distressing impressions connected with infantile sexual activity, and also those factors which in a general way reduce the libido that is to be directed on to the female sexual object.²

However, this motive does not go deep enough either; besides, being bound up with civilized conditions, it fails to provide a satisfactory connection with the state of affairs among primitive people. All the more important, therefore, is the next factor, which is based on the evolution of the libido. We have learnt from analytic researches how universal and how powerful the earliest allocations of libido are. In these we are concerned with infantile sexual wishes which are clung to (in women usually a fixation of the libido on the father or a brother who takes his place) - wishes which frequently enough were directed towards other things than intercourse, or included it only as a dimly perceived goal. The husband is almost always so to speak only a substitute, never the right man; it is another man - in typical cases the father - who has first claim to a woman's love, the husband at most takes second place. It depends on how intense this fixation is and on how obstinately it is maintained whether the substitute is rejected as unsatisfying. Frigidity is thus among the genetic determinants of neuroses. The more powerful the psychical element in a woman's sexual life is, the greater will be the capacity for resistance shown by her distribution of libido to the upheaval of the first sexual act, and the less overpowering will be the effect which bodily possession of her can produce. Frigidity may then become established as a neurotic inhibition or provide the foundation for the development of other neuroses and even a moderate diminution of potency in the man will greatly contribute to help this process.

¹ [1910a, 2232]
² [1912d, 2338]
³ [1918a, 2358]
When other children appear on the scene the Oedipus complex is enlarged into a family complex. This, with fresh support from the egoistic sense of injury, gives grounds for receiving the new brothers or sisters with repugnance and for unhesitatingly getting rid of them by a wish. It is even true that as a rule children are far readier to give verbal expression to these feelings of hate than to those arising from the parental complex. If a wish of this kind is fulfilled and the undesired addition to the family is removed again shortly afterwards by death, we can discover from a later analysis what an important experience this death has been to the child, even though it need not have remained fixed in his memory. A child who has been put into second place by the birth of a brother or sister, and who is now for the first time almost isolated from his mother, does not easily forgive her this loss of place; feelings which in an adult would be described as greatly embittered arise in him and are often the basis of a permanent estrangement. We have already mentioned that the child's sexual researches, with all their consequences, usually follow from this vital experience of his. As these brothers and sisters grow up, the boy's attitude to them undergoes very significant transformations. He may take his sister as a love-object by way of substitute for his faithless mother. Where there are several brothers, all of them courting a younger sister, situations of hostile rivalry, which are so important for later life, arise already in the nursery. A little girl may find in her elder brother a substitute for her father who no longer takes an affectionate interest in her as he did in her earliest years. Or she may take a younger sister as a substitute for the baby she has vainly wished for from her father.

This and very much else of a similar nature will be shown to you by the direct observation of children and by the consideration of clearly retained memories from childhood uninfluenced by analysis. From this you will conclude among other things that the position of a child in the family order is a factor of extreme importance in determining the shape of his later life and should deserve consideration in every life-history. But, what is more important, in view of this information which can be so easily obtained, you will not be able to recall without a smile the pronouncements of science in explanation of the prohibition of incest. There is no end to what has been invented on the subject. It has been said that sexual inclination is diverted from members of the same family who are of the opposite sex by the fact of having lived together from childhood; or, again, that a biological purpose of avoiding inbreeding is represented psychically by an innate horror of incest. In all this the fact is entirely overlooked that such an inexorable prohibition of it in law and custom would not be needed if there were any reliable natural barriers against the temptation to incest. The truth is just the opposite. A human being's first choice of an object is regularly an incestuous one, aimed, in the case of the male, at his mother and sister; and it calls for the severest prohibitions to deter this persistent infantile tendency from realization. Among the primitive races still living to-day, among savages, the prohibitions against incest are even very much stricter than among ourselves, and Theodor Reik has only recently shown in a brilliant work that the puberty rites of savages, which represent a re-birth, have the sense of releasing the boy from his incestuous bond with his mother and of reconciling him with his father.
The deeper significance of our patient's early screen memory, to the effect that he had his first fit of rage because he was not given enough presents one Christmas, is now revealed to us. What he was feeling the want of was sexual satisfaction, which he had taken as being anal. His sexual researches came during the course of the dream to understand what they had been prepared for finding before the dream, namely, that the sexual act solved the problem of the origin of babies. Even before the dream he had disliked babies. Once, when he had come upon a small unfledged bird that had fallen out of its nest, he had taken it for a human baby and been horrified at it. The analysis showed that all small animals, such as caterpillars and insects, that he had been so enraged with, had had the meaning of babies to him.¹ His position in regard to his elder sister had given him every opportunity for reflecting upon the relation between elder and younger children. His Nanya had once told him that his mother was so fond of him because he was the youngest, and this gave him good grounds for wishing that no younger child might come after him. His dread of this youngest child was revived under the influence of the dream which brought up before him his parents' intercourse.

Goethe's next youngest sister, Cornelia Friederica Christiana, was born on December 7, 1750, when he was fifteen months old. This slight difference in age almost excludes the possibility of her having been an object of jealousy. It is known that, when their passions awake, children never develop such violent reactions against the brothers and sisters they find already in existence, but direct their hostility against the newcomers. Nor is the scene we are endeavouring to interpret reconcilable with Goethe's tender age at the time of, or shortly after, Cornelia's birth.

After hearing this statement I threw all doubts to the winds. When in analysis two things are brought out one immediately after the other, as though in one breath, we have to interpret this proximity as a connection of thought. It was, therefore, as if the patient had said, 'Because I found that I had got a new brother, I shortly afterwards threw these things into the street.' The act of flinging the brushes, shoes and so on, out of the window must be recognized as a reaction to the birth of the brother. Nor is it a matter for regret that in this instance the objects thrown out were not crockery but other things, probably, anything the child could reach at the moment. - The hurling out (through the window into the street) thus proves to be the essential thing in the act, while the pleasure in the smashing and the noise, and the class of object on which 'execution is done', are variable and unessential points.

These two cases scarcely call for a commentary. They establish without further analytic effort that the bitterness children feel about the expected or actual appearance of a rival finds expression in throwing objects out of the window and in other acts of naughtiness and destructiveness. In the first case the 'heavy objects' probably symbolized the mother herself, against whom the child's anger was directed so long as the new baby had not yet appeared. The three-and-a-half-year-old boy knew about his mother's pregnancy and had no doubt that she had got the baby in her body. 'Little Hans'² and his special dread of heavily loaded carts may be recalled here.² In the second case the very youthful age of the child, two and a half years, is noteworthy.
The affections of the little girl are fixed on her father, who has probably done all he could to win her love, and in this way has sown the seeds of an attitude of hatred and rivalry towards her mother. This attitude exists side by side with a current of affectionate dependence on her, and as years go on it may be destined to come into consciousness more and more clearly and forcibly, or else to give an impetus to an excessive reaction of devotion to her. But it is not with the girl's relation to her mother that the beating-phantasy is connected. There are other children in the nursery, only a few years older or younger, who are disliked on all sorts of other grounds, but chiefly because the parents' love has to be shared with them, and for this reason they are repelled with all the wild energy characteristic of the emotional life of those years. If the child in question is a younger brother or sister (as in three of my four cases) it is despised as well as hated; yet it attracts to itself the share of affection which the blinded parents are always ready to give the youngest child, and this is a spectacle the sight of which cannot be avoided. One soon learns that being beaten, even if it does not hurt very much, signifies a deprivation of love and a humiliation. And many children who believed themselves securely enthroned in the unshakable affection of their parents have by a single blow been cast down from all the heavens of their imaginary omnipotence. The idea of the father beating this hateful child is therefore an agreeable one, quite apart from whether he has actually been seen doing so. It means: 'My father does not love this other child, he loves only me.'

[1919e, 3649]

The early efflorescence of infantile sexual life is doomed to extinction because its wishes are incompatible with reality and with the inadequate stage of development which the child has reached. That efflorescence comes to an end in the most distressing circumstances and to the accompaniment of the most painful feelings. Loss of love and failure leave behind them a permanent injury to self-regard in the form of a narcissistic scar, which in my opinion, as well as in Marcinowski's (1918), contributes more than anything to the 'sense of inferiority' which is so common in neurotics. The child's sexual researches, on which limits are imposed by his physical development, lead to no satisfactory conclusion; hence such later complaints as 'I can't accomplish anything; I can't succeed in anything'. The tie of affection, which binds the child as a rule to the parent of the opposite sex, succumbs to disappointment, to a vain expectation of satisfaction or to jealousy over the birth of a new baby - unmistakable proof of the infidelity of the object of the child's affections. His own attempt to make a baby himself, carried out with tragic seriousness, fails shamefully. The lessening amount of affection he receives, the increasing demands of education, hard words and an occasional punishment - these show him at last the full extent to which he has been scorned. These are a few typical and constantly recurring instances of the ways in which the love characteristic of the age of childhood is brought to a conclusion.

[1920g, 3725]
It is naturally no easy matter to trace the ontogenesis of the herd instinct. The fear which is shown by small children when they are left alone, and which Trotter claims as being already a manifestation of the instinct, nevertheless suggests more readily another interpretation. The fear relates to the child's mother, and later to other familiar people, and it is the expression of an unfulfilled desire, which the child does not yet know how to deal with in any way except by turning it into anxiety.¹ Nor is the child's fear when it is alone pacified by the sight of any haphazard 'member of the herd', but on the contrary it is brought into existence by the approach of a 'stranger' of this sort. Then for a long time nothing in the nature of herd instinct or group feeling is to be observed in children. Something like it first grows up, in a nursery containing many children, out of the children's relation to their parents, and it does so as a reaction to the initial envy with which the elder child receives the younger one. The elder child would certainly like to put his successor jealously aside, to keep it away from the parents, and to rob it of all its privileges; but in the face of the fact that this younger child (like all that come later) is loved by the parents as much as he himself is, and in consequence of the impossibility of his maintaining his hostile attitude without damaging himself, he is forced into identifying himself with the other children. So there grows up in the troop of children a communal or group feeling, which is then further developed at school. The first demand made by this reaction-formation is for justice, for equal treatment for all. We all know how loudly and implacably this claim is put forward at school. If one cannot be the favourite oneself, at all events nobody else shall be the favourite. This transformation - the replacing of jealousy by a group feeling in the nursery and classroom - might be considered improbable, if the same process could not later on be observed again in other circumstances. We have only to think of the troop of women and girls, all of them in love in an enthusiastically sentimental way, who crowd round a singer or pianist after his performance. It would certainly be easy for each of them to be jealous of the rest; but, in the face of their numbers and the consequent impossibility of their reaching the aim of their love, they renounce it, and, instead of pulling out one another's hair, they act as a united group, do homage to the hero of the occasion with their common actions, and would probably be glad to have a share of his flowing locks. Originally rivals, they have succeeded in identifying themselves with one another by means of a similar love for the same object. When, as is usual, an instinctual situation is capable of various outcomes, we shall not be surprised that the actual outcome is one which brings with it the possibility of a certain amount of satisfaction, whereas some other outcome, in itself more obvious, is passed over because the circumstances of life prevent its leading to any such satisfaction.

[1921c, 3812]
The little series of reminiscences must engage our attention for a while longer. I have stated elsewhere that such scenes of childhood are 'screen memories' selected at a later period, put together, and not infrequently falsified in the process. This subsequent remodelling serves a purpose that is sometimes easy to guess. In our case one can almost hear the writer's ego glorifying or soothing itself by means of this series of recollections. 'I was from infancy a particularly noble and compassionate creature. I learnt quite early that animals have souls as we have, and could not endure cruelty to animals. The sins of the flesh were far from me and I preserved my chastity till late in life.' With declarations such as these she was loudly contradicting the inferences that we have to make about her early childhood on the basis of our analytical experience, namely, that she had an abundance of premature sexual impulses and violent feelings of hatred for her mother and her younger brothers and sisters. (Besides the genital significance I have just assigned to it, the little bird may also be a symbol of a child, like all small animals; her recollection thus accentuated very insistently the fact that this small creature had the same right to exist as she herself.) Hence the short series of recollections furnishes a very nice example of a mental structure with a twofold aspect. Viewed superficially, we may find in it the expression of an abstract idea, here, as usually, with an ethical reference. In Silberer's nomenclature the structure has an anagogic content. On deeper investigation it reveals itself as a chain of phenomena belonging to the region of the repressed life of the instincts - it displays its psycho-analytic content. As you know, Silberer, who was among the first to issue a warning to us not to lose sight of the nobler side of the human soul, has put forward the view that all or nearly all dreams permit such a twofold interpretation, a purer, anagogic one beside the ignoble, psycho-analytic one. This is, however, unfortunately not so. On the contrary, an over-interpretation of this kind is rarely possible. To my knowledge no valid example of such a dream-analysis with a double meaning has been published up to the present time. But observations of this kind can often be made upon the series of associations that our patients produce during analytic treatment. On the one hand the successive ideas are linked by a line of association which is plain to the eye, while on the other hand you become aware of an underlying theme which is kept secret but which at the same time plays a part in all these ideas. The contrast between the two themes that dominate the same series of ideas is not always one between the lofty anagogic and the low psycho-analytic, but one rather between offensive and respectable or indifferent ideas - a fact that easily explains why such a chain of associations with a twofold determination arises. In our present example it is of course not accidental that the anagogic and the psycho-analytic interpretations stood in such a sharp contrast to each other; both related to the same material, and the later trend was no other than that of the reaction-formations which had been erected against the disowned instinctual impulses. [1922a, 3894]

The dead brother, however, was not only our correspondent's imaginary child; he also represented a rival whom she had regarded with hatred from the time of his birth. By far the greater number of all telepathic intimations relate to death or the possibility of death; when patients under analysis keep telling us of the frequency and infallibility of their gloomy forebodings, we can with equal regularity show them that they are fostering particularly strong death-wishes in their unconscious against their nearest relations and have long been thus suppressing them. The patient whose history I related in 1909 was an example to the point; he was called a 'carrion crow' by his relations. But when this kindly and highly intelligent man - who has since himself perished in the war - began to make progress towards recovery, he himself gave me considerable assistance in clearing up his own psychological conjuring tricks. In the same way, the account given in our first correspondent's letter, of how he and his three brothers had received the news of their youngest brother's death as a thing they had long been inwardly aware of, appears to need no other explanation. The elder brothers would all have been equally convinced of the superfluousness of the youngest arrival. [1922a, 3896]
There is not much to be said from the analytic point of view. It is easy to see that essentially it is compounded of grief, the pain caused by the thought of losing the loved object, and of the narcissistic wound, in so far as this is distinguishable from the other wound; further, of feelings of enmity against the successful rival, and of a greater or lesser amount of self-criticism which tries to hold the subject's own ego accountable for his loss. Although we may call it normal, this jealousy is by no means completely rational, that is, derived from the actual situation, proportionate to the real circumstances and under the complete control of the conscious ego; for it is rooted deep in the unconscious, it is a continuation of the earliest stirrings of the child's affective life, and it originates in the Oedipus or brother-and-sister complex of the first sexual period. Moreover, it is noteworthy that in some people it is experienced bisexual. That is to say, a man will not only feel pain about the woman he loves and hatred of the man who is his rival, but also grief about the man, whom he loves unconsciously, and hatred of the woman as his rival; and this latter set of feelings will add to the intensity of his jealousy. I even know of a man who suffered exceedingly during his attacks of jealousy and who, according to his own account, went through unendurable torments by consciously imagining himself in the position of the faithless woman. The sensation of helplessness which then came over him and the images he used to describe his condition - exposed to the vulture's beak like Prometheus, or thrown bound into a nest of serpents - were referred by him to impressions received during several homosexual acts of aggression to which he had been subjected as a boy.

Among these factors are some which are determined by the circumstances of infantile sexuality in general, and so hold good equally for the erotic life of boys. First and foremost we may mention jealousy of other people - of brothers and sisters, rivals, among whom the father too has a place. Childhood love is boundless; it demands exclusive possession, it is not content with less than all. But it has a second characteristic: it has, in point of fact, no aim and is incapable of obtaining complete satisfaction; and principally for that reason it is doomed to end in disappointment and to give place to a hostile attitude. Later on in life the lack of an ultimate satisfaction may favour a different result. This very factor may ensure the uninterrupted continuance of the libidinal cathexis, as happens with love-relations that are inhibited in their aim. But in the stress of the processes of development it regularly happens that the libido abandons its unsatisfying position in order to find a new one.

Fenichel (1930) rightly emphasizes the difficulty of recognizing in the material produced in analysis what parts of it represent the unchanged content of the pre-Oedipus phase and what parts have been distorted by regression (or in other ways). He does not accept Jeanne Lampl-de Groot's assertion of the little girl's active attitude in the phallic phase. He also rejects the 'displacement backwards' of the Oedipus complex proposed by Melanie Klein (1928), who places its beginnings as early as the commencement of the second year of life. This dating of it, which would also necessarily imply a modification of our view of all the rest of the child's development, does not in fact correspond to what we learn from the analyses of adults, and it is especially incompatible with my findings as to the long duration of the girl's pre-Oedipus attachment to her mother. A means of softening this contradiction is afforded by the reflection that we are not as yet able to distinguish in this field between what is rigidly fixed by biological laws and what is open to movement and change under the influence of accidental experience. The effect of seduction has long been familiar to us and in just the same way other factors - such as the date at which the child's brothers and sisters are born or the time when it discovers the difference between the sexes, or again its direct observations of sexual intercourse or its parents' behaviour in encouraging or repelling it - may hasten the child's sexual development and bring it to maturity.
The next accusation against the child's mother flares up when the next baby appears in the nursery. If possible the connection with oral frustration is preserved: the mother could not or would not give the child any more milk because she needed the nourishment for the new arrival. In cases in which the two children are so close in age that lactation is prejudiced by the second pregnancy, this reproach acquires a real basis, and it is a remarkable fact that a child, even with an age difference of only 11 months, is not too young to take notice of what is happening. But what the child grudges the unwanted intruder and rival is not only the suckling but all the other signs of maternal care. It feels that it has been dethroned, despoiled, prejudiced in its rights; it casts a jealous hatred upon the new baby and develops a grievance against the faithless mother which often finds expression in a disagreeable change in its behaviour. It becomes 'naughty', perhaps, irritable and disobedient and goes back on the advances it has made towards controlling its excretions. All of this has been very long familiar and is accepted as self-evident; but we rarely form a correct idea of the strength of these jealous impulses, of the tenacity with which they persist and of the magnitude of their influence on later development. Especially as this jealousy is constantly receiving fresh nourishment in the later years of childhood and the whole shock is repeated with the birth of each new brother or sister. Nor does it make much difference if the child happens to remain the mother's preferred favourite. A child's demands for love are immoderate, they make exclusive claims and tolerate no sharing. [1933a, 4725]
Very different are the dreams of the other class - those in which the dreamer imagines the death of a loved relative and is at the same time painfully affected. The meaning of such dreams, as their content indicates, is a wish that the person in question may die. And since I must expect that the feelings of all of my readers and any others who have experienced similar dreams will rebel against my assertion, I must try to base my evidence for it on the broadest possible foundation.

I have already discussed a dream which taught us that the wishes which are represented in dreams as fulfilled are not always present-day wishes. They may also be wishes of the past which have been abandoned, overlaid and repressed, and to which we have to attribute some sort of continued existence only because of their re-emergence in a dream. They are not dead in our sense of the word but only like the shades in the Odyssey, which awoke to some sort of life as soon as they had tasted blood. In the dream of the dead child in the 'case' (p. 154) what was involved was a wish which had been an immediate one fifteen years earlier and was frankly admitted as having existed at that time. I may add - and this may not be without its bearing upon the theory of dreams - that even behind this wish there lay a memory from the dreamer's earliest childhood. When she was a small child - the exact date could not be fixed with certainty - she had heard that her mother had fallen into a deep depression during the pregnancy of which she had been the fruit and had passionately wished that the child she was bearing might die. When the dreamer herself was grown-up and pregnant, she merely followed her mother's example.

If anyone dreams, with every sign of pain, that his father or mother or brother or sister has died, I should never use the dream as evidence that he wishes for that person's death of at the present time. The theory of dreams does not require as much as that; it is satisfied with the inference that this death has been wished for at some time or other during the dreamer's childhood. I fear, however, that this reservation will not appease the objectors; they will deny the possibility of their ever having had such a thought with just as much energy as they insist that they harbour no such wishes now. I must therefore reconstruct a portion of the vanished mental life of children on the basis of the evidence of the present.¹

If, then, a child's death-wishes against his brothers and sisters are explained by the childish egoism which makes him regard them as his rivals, how are we to explain his death-wishes against his parents, who surround him with love and fulfil his needs and whose preservation that same egoism should lead him to desire?

A solution of this difficulty is afforded by the observation that dreams of the death of parents apply with preponderant frequency to the parent who is of the same sex as the dreamer: that men, that is, dream mostly of their father's death and women of their mother's. I cannot pretend that this is universally so, but the preponderance in the direction I have indicated is so evident that it requires to be explained by a factor of general importance.¹ It is as though - to put it bluntly - a sexual preference were making itself felt at an early age: as though boys regarded their fathers and girls their mothers as their rivals in love, whose elimination could not fail to be to their advantage.
If a furious raging against one's own integrity and one's own life can be hidden in this way behind apparently accidental clumsiness and motor inefficiency, it is not a very large step to find it possible to transfer the same view to mistakes that seriously endanger the lives and health of other people. What evidence I have to show that this view is a valid one is drawn from my experience with neurotics, and thus does not wholly meet the demands of the situation. I will give an account of a case in which something that was not strictly a faulty action but that rather deserves the name of a symptomatic or chance action gave me the clue which subsequently made it possible to resolve the patient's conflict. I once undertook the task of bringing an improvement to the marriage of a very intelligent man, whose disagreements with his fondly attached young wife could undoubtedly be shown to have a real basis, but could not, as he himself admitted, be completely accounted for in that way. He was continually occupied with the thought of a divorce, which he then dismissed once more because of his warm love for his two small children. In spite of this he constantly returned to his intention and made no attempt to find a way of making the situation tolerable to himself. Such inability to deal with a conflict is taken by me as proof that unconscious and repressed motives have lent a hand in strengthening the conscious ones which are struggling against each other, and I undertake in such cases to end the conflict by psychical analysis. One day the man told me of a small incident which had frightened him extremely. He was romping with his elder child, who was by far his favourite; he was swinging him high in the air and down again, and once he swung him so high while he was standing at a particular spot that the top of the child's head almost struck the heavy gas chandelier that was hanging there. Almost, but not quite - or perhaps just! No harm came to the child, but it was made giddy with fright. The father stood horrified with the child in his arms, and the mother had a hysterical attack. The peculiar adroitness of this imprudent movement and the violence of the parents' reaction prompted me to look for a symptomatic act in this accident - one which aimed at expressing an evil intention directed against the beloved child. I was able to remove the contradiction between this and the father's contemporary affection for his child by shifting the impulse to injure it back to the time when this child had been the only one and had been so small that its father had not yet had any reason to take an affectionate interest in it. It was then easy for me to suppose that, as he was getting little satisfaction from his wife, he may at that time have had a thought or formed a decision of this kind: 'If this little creature that means nothing at all to me dies, I shall be free and able to get a divorce.' A wish for the death of the creature that he now loved so dearly must therefore have persisted unconsciously. From this point it was easy to find the path by which this wish had become unconsciously fixated. A powerful determinant was in fact provided by a memory from the patient's childhood: namely that the death of a small brother, for which his mother blamed his father's negligence, had led to violent quarrels between the parents and threats of a divorce. The subsequent course of my patient's marriage, as well as my therapeutic success, confirmed my conjecture.

[1901b, 1266]
The most important influence upon the course of Hans's psychosexual development was the birth of a baby sister when he was three and a half years old. That event accentuated his relations to his parents and gave him some insoluble problems to think about; and later, as he watched the way in which the infant was looked after, the memory-traces of his own earliest experiences of pleasure were revived in him. This influence, too, is a typical one: in an unexpectedly large number of life-histories, normal as well as pathological, we find ourselves obliged to take as our starting-point an outburst of sexual pleasure and sexual curiosity connected, like this one, with the birth of the next child. Hans's behaviour towards the new arrival was just what I have described in *The Interpretation of Dreams*. In his fever a few days later he betrayed how little he liked the addition to the family. Affection for his sister might come later,¹ but his first attitude was hostility. From that time forward fear that yet another baby might arrive found a place among his conscious thoughts. In the neurosis, his hostility, already suppressed, was represented by a special fear - a fear of the bath. In the analysis he gave undisguised expression to his death-wish against his sister, and was not content with allusions which required supplementing by his father. His inner conscience did not consider this wish so wicked as the analogous one against his father; but it is clear that in his unconscious he treated both persons in the same way, because they both took his mummy away from him, and interfered with his being alone with her.

[1909b, 2098]

(8) The strangest characteristic of unconscious (repressed) processes, to which no investigator can become accustomed without the exercise of great self-discipline, is due to their entire disregard of reality-testing; they equate reality of thought with external actuality, and wishes with their fulfilment - with the event - just as happens automatically under the dominance of the ancient pleasure principle. Hence also the difficulty of distinguishing unconscious phantasies from memories which have become unconscious. But one must never allow oneself to be misled into applying the standards of reality to repressed psychical structures, and on that account, perhaps, into undervaluing the importance of phantasies in the formation of symptoms on the ground that they are not actualities, or into tracing a neurotic sense of guilt back to some other source because there is no evidence that any actual crime has been committed. One is bound to employ the currency that is in use in the country one is exploring - in our case a neurotic currency. Suppose, for instance, that one is trying to solve a dream such as this. A man who had once nursed his father through a long and painful mortal illness, told me that in the months following his father's death he had repeatedly dreamt that *his father was alive once more and that he was talking to him in his usual way*. But he felt it exceedingly painful that *his father had really died, only without knowing it*. The only way of understanding this apparently nonsensical dream is by adding 'as the dreamer wished' or 'in consequence of his wish' after the words 'that his father had really died', and by further adding 'that he wished it' to the last words. The dream-thought then runs: it was a painful memory for him that he had been obliged to wish for his father's death (as a release) while he was still alive, and how terrible it would have been if his father had had any suspicion of it! What we have here is thus the familiar case of self-reproaches after the loss of someone loved, and in this instance the self-reproach went back to the infantile significance of death-wishes against the father.

[1911b, 2557]
Suppose, on the other hand, that we were to take into account the finding arrived at by psycho-analysis from the dreams of normal people, to the effect that we ourselves are subject, more strongly and more often than we suspect, to a temptation to kill someone and that that temptation produces psychical effects even though it remains out of sight of our consciousness. Suppose, again, that we were to recognize the compulsive observances of certain neurotics as being guarantees against an intensified impulse to murder or as being self-punishments on account of it. In that case we should have to attach still greater importance to our thesis that where there is a prohibition there must be an underlying desire. We should have to suppose that the desire to murder is actually present in the unconscious and that neither taboos nor moral prohibitions are psychologically superfluous but that on the contrary they are explained and justified by the existence of an ambivalent attitude towards the impulse to murder.

[1912-1913, 2714]

On the other hand, for strangers and for enemies we do acknowledge death, and consign them to it quite as readily and unhesitatingly as did primaeval man. There is, it is true, a distinction here which will be pronounced decisive so far as real life is concerned. Our unconscious does not carry out the killing; it merely thinks it and wishes it. But it would be wrong so completely to undervalue this psychical reality as compared with factual reality. It is significant and momentous enough. In our unconscious impulses we daily and hourly get rid of anyone who stands in our way, of anyone who has offended or injured us. The expression 'Devil take him!', which so often comes to people's lips in joking anger and which really means 'Death take him!', is in our unconscious a serious and powerful death-wish. Indeed, our unconscious will murder even for trifles; like the ancient Athenian code of Draco, it knows no other punishment for crime than death. And this has a certain consistency, for every injury to our almighty and autocratic ego is at bottom a crime of lèse-majesté.

[1915b, 3089]

Psycho-analysis finds as a rule no credence among laymen for assertions such as these. They reject them as calumnies which are confuted by conscious experience, and they adroitly overlook the faint indications by which even the unconscious is apt to betray itself to consciousness. It is therefore relevant to point out that many thinkers who could not have been influenced by psycho-analysis have quite definitely accused our unspoken thoughts of being ready, heedless of the prohibition against murder, to get rid of anything which stands in our way. From many examples of this I will choose one that has become famous:

[1915b, 3090]

Just as for primaeval man, so also for our unconscious, there is one case in which the two opposing attitudes towards death, the one which acknowledges it as the annihilation of life and the other which denies it as unreal, collide and come into conflict. This case is the same as in primal ages: the death, or the risk of death, of someone we love, a parent or a partner in marriage, a brother or sister, a child or a dear friend. These loved ones are on the one hand an inner possession, components of our own ego; but on the other hand they are partly strangers, even enemies. With the exception of only a very few situations, there adheres to the tenderest and most intimate of our love-relations a small portion of hostility which can excite an unconscious death-wish. But this conflict due to ambivalence does not now, as it did then, lead to the doctrine of the soul and to ethics, but to neurosis, which affords us deep insight into normal mental life as well. How often have physicians who practise psycho-analysis had to deal with the symptom of an exaggerated worry over the well-being of relatives, or with entirely unfounded self-reproaches after the death of a loved person. The study of such phenomena has left them in no doubt about the extent and importance of unconscious death-wishes.

[1915b, 3090]
To sum up: our unconscious is just as inaccessible to the idea of our own death, just as murderously inclined towards strangers, just as divided (that is, ambivalent) towards those we love, as was primaeval man. But how far we have moved from this primal state in our conventional and cultural attitude towards death!
[1915b, 3091]

The ego, freed from all ethical bonds, also finds itself at one with all the demands of sexual desire, even those which have long been condemned by our aesthetic upbringing and those which contradict all the requirements of moral restraint. The desire for pleasure - the 'libido', as we call it - chooses its objects without inhibition, and by preference, indeed, the forbidden ones: not only other men's wives, but above all incestuous objects, objects sanctified by the common agreement of mankind, a man's mother and sister, a woman's father and brother. (The dream of our fifty-year-old lady, too, was incestuous; her libido was unmistakably directed to her son.) Lusts which we think of as remote from human nature show themselves strong enough to provoke dreams. Hatred, too, rages without restraint. Wishes for revenge and death directed against those who are nearest and dearest in waking life, against the dreamer's parents, brothers and sisters, husband or wife, and his own children are nothing unusual. These censored wishes appear to rise up out of a positive Hell; after they have been interpreted when we are awake, no censorship of them seems to us too severe.
[1916-1917, 3237]

I do not doubt that this was really his attitude towards his father during the tedious illness and that his boastful assurances of his filial piety were meant to distract him from these memories. Under such conditions the death-wish against a father is apt to become active and to hide itself under the mask of such sympathetic reflections as that 'it would be a happy release for him'. But please observe that here we have passed a barrier in the latent dream-thoughts themselves. No doubt the first portion of them was unconscious only temporarily - that is, during the construction of the dream; but his hostile impulses against his father must have been permanently unconscious. They may have originated from scenes in his childhood and have occasionally slipped into consciousness, timidly and disguised, during his father's illness. We can assert this with greater certainty of other latent thoughts which have made unmistakable contributions to the content of the dream. Nothing, indeed, is to be discovered in the dream of his hostile impulses towards his father. But if we look for the roots of such hostility to a father in childhood, we shall recall that fear of a father is set up because, in the very earliest years, he opposes a boy's sexual activities, just as he is bound to do once more from social motives after the age of puberty. This relation to his father applies to our dreamer as well: his love for him included a fair admixture of awe and anxiety, which had their source in his having been early deterred by threats from sexual activity.
[1916-1917, 3280]
This same piece of information can be further applied to another of the riddles we have come up against. You recall the amazement which was caused by our discovery that what instigates dreams are actively evil and extravagantly sexual wishes, which have made the censorship and distortion of dreams necessary. When we have interpreted a dream of this sort to the dreamer and if, to take the most favourable case, he does not actually attack the interpretation, he nevertheless regularly raises the question of where these wishes come from, since they feel alien to him and their opposite is what he is conscious of. We need have no hesitation in pointing out their origin. These evil wishful impulses arise from the past, and often from a past that is not very remote. It can be shown that there was a time when they were familiar and conscious, even if they are no longer so to-day. A woman, whose dream meant that she would like to see her only daughter, now seventeen years old, dead before her eyes, found under our guidance that she had indeed at one time harboured this death wish. The child was the fruit of an unhappy marriage which was soon dissolved. Once, while she still bore her daughter in her womb, in a fit of rage after a violent scene with her husband she had beaten with her fists on her body in order to kill the child inside it. How many mothers, who love their children tenderly, perhaps over-tenderly, to-day, conceived them unwillingly and wished at that time that the living thing within them might not develop further! They may even have expressed that wish in various, fortunately harmless, actions. Thus their death-wish against someone they love, which is later so mysterious, originates from the earliest days of their relationship to that person. [1916-1917, 3291]

In the same way, a father had a dream which justified the interpretation that he wished for the death of his favourite eldest child. He too was led to remember that there had been a time when this wish was not strange to him. When the child was still an infant in arms, the father, discontented with his choice of a wife, often thought that if the little creature, who meant nothing to him, were to die, he would be free once more and would make better use of his freedom. The same origin can be shown in the case of a great number of similar impulses of hatred; they are recollections of something belonging to the past, which was once conscious and played its part in mental life. You will be inclined to conclude from this that such wishes and such dreams ought not to arise in cases where transformations of this kind in one's relation to someone never occurred, where the relation was of the same kind from the first. I am prepared to admit this; but I must remind you that what you must take into consideration is not the wording of the dream but its sense after it has been interpreted. It is possible that a manifest dream of the death of someone loved has merely assumed a horrifying mask and may mean something quite different, or that the loved person is intended as a misleading substitute for someone else. [1916-1917, 3291]
We will keep to wishes forgetting rid of someone, which may for the most part be attributed to the dreamer's unrestricted egoism. A wish of this kind can very often be pointed to as the constructor of a dream. Whenever anyone in the course of one's life gets in one's way - and how often this must happen in view of the complication of one's relationships in life! - a dream is promptly ready to kill that person, even if it be father or mother, brother or sister, husband or wife. This wickedness of human nature came as a great surprise to us and we were decidedly disinclined to accept this outcome of dream-interpretation without question. But as soon as we were led to look for the origin of these wishes in the past, we discovered the period of the individual's past in which there was no longer anything strange in such egoism and such wishful impulses, directed even against his closest relatives. It is children, and precisely in those earliest years which are later veiled by amnesia, who often exhibit this egoism to an extremely marked degree and who invariably show clear rudiments or, more correctly speaking, residues of it. Children love themselves first, and it is only later that they learn to love others and to sacrifice something of their own ego to others. Even those people whom a child seems to love from the beginning are loved by him at first because he needs them and cannot do without them - once again from egoistic motives. Not until later does the impulse to love make itself independent of egoism. It is literally true that his egoism has taught him to love.

In this connection it will be interesting to compare the child's attitude to his brothers and sisters with that towards his parents. A small child does not necessarily love his brothers and sisters; often he obviously does not. There is no doubt that he hates them as his competitors, and it is a familiar fact that this attitude often persists for long years, till maturity is reached or even later, without interruption. Quite often, it is true, it is succeeded, or let us rather say overlaid, by a more affectionate attitude; but the hostile one seems very generally to be the earlier. This hostile attitude can be observed most easily in children between two and a half and four or five, when a new baby brother or sister appears. It usually meets with a very unfriendly reception. Such remarks as 'I don't like him; the stork can take him away again!' are quite common. After this, every opportunity is taken of disparaging the new arrival and attempts to injure him and even murderous assaults are not unknown. If the difference in age is less, by the time the child's mental activity has awakened to some degree of intensity he finds his competitor already there and adjusts himself to him. If the difference is greater, the new baby may from the first arouse a certain sympathy as an interesting object, a sort of live doll; and where the difference in age is of eight or more years, solicitous, maternal impulses may already come into play, especially in girls. But, honestly speaking, if one comes upon a wish for the death of a brother or sister behind a dream, there is seldom need to find it puzzling and one can trace its prototype without any trouble in early childhood and often enough in later years of companionship as well.

There is probably no nursery without violent conflicts between its inmates. The motives for these are rivalry for parental love, for common possessions, for living space. The hostile impulses are directed against older as well as against younger members of the family. It was, I believe, Bernard Shaw who remarked: 'As a rule there is only one person an English girl hates more than she hates her mother; and that's her eldest sister.' But there is something in this remark that strikes us as strange. We might at a pinch find hatred and competition with brothers and sisters intelligible. But how can we suppose that feelings of hatred can make their way into the relation between daughter and mother, between parents and children?
This relation is undoubtedly a more favourable one, from the children's point of view as well. That is what our expectations demand; we find an absence of love far more repellent between parents and children than between brothers and sisters. In the former case we have, as it were, made something sacred which in the latter we have left profane. Yet daily observation can show us how frequently the emotional relations between parents and their grown-up children fall behind the ideal set up by society, how much hostility is ready to hand and would be expressed if it were not held back by admixtures of filial piety and affectionate impulses. The motives for this hostility are generally known and their tendency is to divide those of the same sex - the daughter from the mother and the father from the son. The daughter finds in her mother the authority which restricts her will and which is entrusted with the task of imposing on her the renunciation of sexual freedom which society demands; in a few instances she even finds in her a competitor who struggles against being supplanted. The same thing is repeated between the son and his father still more glaringly. In the son's eyes his father embodies every unwillingly tolerated social restraint; his father prevents him from exercising his will, from early sexual pleasure and, where there is common property in the family, from enjoying it. In the case of an heir to the throne this waiting for a father's death reaches an almost tragic height. There seems less danger to the relation between father and daughter or mother and son. This last provides the purest examples of an unchangeable affection, unimpaired by any egoistic considerations.

[1916-1917, 3294]

There is no need to feel surprised, therefore, if, in a large number of people, dreams disclose their wish to get rid of their parents and especially of the parent of their own sex. We may assume that this wish is also present in waking life and is even conscious sometimes, if it can be masked by some other motive, as was the case with our dreamer in Example 3, where it was replaced by pity for his father's useless sufferings. It is rarely that the hostility alone dominates the relationship; far oftener it is in the background of more affectionate impulses by which it is suppressed, and it must wait until a dream isolates it, as it were. What seems to us of enormous size in a dream, on account of this isolation, shrinks up once more when our interpretation has given it its place in the context of real life (Hanns Sachs). But we come upon this dream-wish, too, where it has no relevance in real life, and where the adult need never confess to it in his waking life. The reason for this is that the deepest and most invariable motive for estrangement, especially between two people of the same sex, has already made itself felt in early childhood.

[1916-1917, 3295]

The deeper significance of our patient's early screen memory, to the effect that he had his first fit of rage because he was not given enough presents one Christmas, is now revealed to us. What he was feeling the want of was sexual satisfaction, which he had taken as being anal. His sexual researches came during the course of the dream to understand what they had been prepared for finding before the dream, namely, that the sexual act solved the problem of the origin of babies. Even before the dream he had disliked babies. Once, when he had come upon a small unfledged bird that had fallen out of its nest, he had taken it for a human baby and been horrified at it. The analysis showed that all small animals, such as caterpillars and insects, that he had been so enraged with, had had the meaning of babies to him.¹ His position in regard to his elder sister had given him every opportunity for reflecting upon the relation between elder and younger children. His Nanya had once told him that his mother was so fond of him because he was the youngest, and this gave him good grounds for wishing that no younger child might come after him. His dread of this youngest child was revived under the influence of the dream which brought up before him his parents' intercourse.

[1918b, 3564]
His identification of his father with the castrator¹ became important as being the source of an intense unconscious hostility towards him (which reached the pitch of a death-wish) and of a sense of guilt which reacted against it. Up to this point, however, he was behaving normally - that is to say, like every neurotic who is possessed by a positive Oedipus complex. But the astonishing thing was that even against this there was a counter-current working in him, which, on the contrary, regarded his father as the one who had been castrated and as calling, therefore, for his sympathy.

[1918b, 3569]

We are led into quite another realm of explanation by the analysis of the attempt at suicide, which I must regard as seriously intended, and which, incidentally, considerably improved her position both with her parents and with the lady she loved. She went for a walk with her one day in a part of the town and at an hour at which she was not unlikely to meet her father on his way from his office. So it turned out. Her father passed them in the street and cast a furious look at her and her companion, about whom he had by that time come to know. A few moments later she flung herself into the railway cutting. The explanation she gave of the immediate reasons determining her decision sounded quite plausible. She had confessed to the lady that the man who had given them such an irate glance was her father, and that he had absolutely forbidden their friendship. The lady became incensed at this and ordered the girl to leave her then and there, and never again to wait for her or to address her - the affair must now come to an end. In her despair at having thus lost her loved one for ever, she wanted to put an end to herself. The analysis, however, was able to disclose another and deeper interpretation behind the one she gave, which was confirmed by the evidence of her own dreams. The attempted suicide was, as might have been expected, determined by two other motives besides the one she gave: it was the fulfilment of a punishment (self-punishment), and the fulfilment of a wish. As the latter it meant the attainment of the very wish which, when frustrated, had driven her into homosexuality - namely, the wish to have a child by her father, for now she 'fell' through her father's fault.¹ The fact that at that moment the lady had spoken in just the same terms as her father, and had uttered the same prohibition, forms the connecting link between this deep interpretation and the superficial one of which the girl herself was conscious. From the point of view of self-punishment the girl's action shows us that she had developed in her unconscious strong death-wishes against one or other of her parents - perhaps against her father, out of revenge for impeding her love, but more probably against her mother too, when she was pregnant with the little brother. For analysis has explained the enigma of suicide in the following way: probably no one finds the mental energy required to kill himself unless, in the first place, in doing so he is at the same time killing an object with whom he has identified himself, and, in the second place, is turning against himself a death-wish which had been directed against someone else. Nor need the regular discovery of these unconscious death-wishes in those who have attempted suicide surprise us (any more than it ought to make us think that it confirms our deductions), since the unconscious of all human beings is full enough of such death-wishes, even against those they love.² Since the girl identified herself with her mother, who should have died at the birth of the child denied to herself, this punishment-fulfilment itself was once again a wish-fulfilment. Finally, the discovery that several quite different motives, all of great strength, must have co-operated to make such a deed possible is only in accordance with what we should expect.

[1920a, 3851]
The dead brother, however, was not only our correspondent’s imaginary child; he also represented a rival whom she had regarded with hatred from the time of his birth. By far the greater number of all telepathic intimations relate to death or the possibility of death; when patients under analysis keep telling us of the frequency and infallibility of their gloomy forebodings, we can with equal regularity show them that they are fostering particularly strong death-wishes in their unconscious against their nearest relations and have long been thus suppressing them. The patient whose history I related in 1909¹ was an example to the point; he was called a ‘carrion crow’ by his relations. But when this kindly and highly intelligent man - who has since himself perished in the war - began to make progress towards recovery, he himself gave me considerable assistance in clearing up his own psychological conjuring tricks. In the same way, the account given in our first correspondent’s letter, of how he and his three brothers had received the news of their youngest brother’s death as a thing they had long been inwardly aware of, appears to need no other explanation. The elder brothers would all have been equally convinced of the superfluousness of the youngest arrival.

[1922a, 3896]
Obsessional prohibitions involve just as extensive renunciations and restrictions in the lives of those who are subject to them as do taboo prohibitions; but some of them can be lifted if certain actions are performed. Thereafter, these actions must be performed: they become compulsive or obsessive acts, and there can be no doubt that they are in the nature of expiation, penance, defensive measures and purification. The commonest of these obsessive acts is washing in water ('washing mania'). Some taboo prohibitions can be replaced in just the same way; or rather their violation can be made good by a similar 'ceremonial'; and here again lustration with water is the preferred method.
[1912-1913, 2676]

In the accepted explanation of all these observances of appeasement, restriction, expiation and purification, two principles are combined: the extension of the taboo from the slain man on to everything that has come in contact with him, and the fear of the slain man's ghost. How these two factors are to be combined with each other to explain the ceremonial, whether they are to be regarded as of equal weight, whether one is primary and the other secondary, and if so which - none of these questions receives an answer, and indeed it would be hard to find one. We, on the other hand, can lay stress on the unity of our view, which derives all of these observances from emotional ambivalence towards the enemy.
[1912-1913, 2688]

Our space will not allow nor does our interest require us to enter further into a description of the taboos associated with the dignity of kings and priests. I will only add that the principal part is played in them by restrictions upon freedom of movement and upon diet. Two examples of taboo ceremonial occurring in civilized communities of a far higher level of culture will serve to show, however, what a conservative effect upon ancient usages is exercised by contact with these privileged personages.
[1912-1913, 2691]
If we take instinctual repression as a measure of the level of civilization that has been reached, we shall have to admit that even under the animistic system advances and developments took place which are unjustly despised on account of their superstitious basis. When we are told that the warriors in a savage tribe practise the greatest continence and cleanliness when they go on the war-path, the explanation is put forward that their motive is ‘a fear lest the enemy should obtain the refuse of their persons, and thus be enabled to work their destruction by magic’ (Frazer, 1911b, 157); and an analogous superstitious reason could be suggested for their continence. None the less the fact remains that they have made an instinctual renunciation; and we can understand the position better if we suppose that the savage warrior submits to these restrictions as a counter-measure because he is on the point of yielding completely to the satisfaction of cruel and hostile impulses which are as a rule prohibited to him. The same is true of the numerous cases of sexual restrictions being imposed on anyone who is engaged on difficult or responsible work (ibid., 200 f.). Though the grounds alleged for these prohibitions may belong to a magical context, yet the fundamental idea of gaining greater strength by renouncing some instinctual satisfaction remains unmistakable; and the hygienic root of the prohibition which lies alongside its magical rationalization must not be overlooked. When the men of a savage tribe go out on an expedition to hunt, to fish, to fight or to gather precious plants, their wives left at home are subjected to many oppressive restrictions, to which the savages themselves ascribe a favourable influence, operating at a distance upon the success of the expedition. But it requires very little penetration to see that this factor which operates at a distance is nothing other than the absent men's longing thoughts of home, and that behind these disguises lies a sound piece of psychological insight that the men will only do their best if they feel completely secure about the women whom they have left behind them unguarded. Sometimes they will even themselves declare, without alleging any magical reasons, that a wife's infidelity in marriage will bring to nothing the efforts of an absent husband engaged on some responsible work.
[1912-1913, 2739]

Another difficulty might actually be brought forward from psycho-analytic quarters. The earliest moral precepts and restrictions in primitive society have been explained by us as reactions to a deed which gave those who performed it the concept of 'crime'. They felt remorse for the deed and decided that it should never be repeated and that its performance should bring no advantage. This creative sense of guilt still persists among us. We find it operating in an asocial manner in neurotics, and producing new moral precepts and persistent restrictions, as an atonement for crimes that have been committed and as a precaution against the committing of new ones.' If, however, we inquire among these neurotics to discover what were the deeds which provoked these reactions, we shall be disappointed. We find no deeds, but only impulses and emotions, set upon evil ends but held back from their achievement. What lie behind the sense of guilt of neurotics are always *psychical* realities and never *factual* ones. What characterizes neurotics is that they prefer psychical to factual reality and react just as seriously to thoughts as normal people do to realities.
[1912-1913, 2798]
When other children appear on the scene the Oedipus complex is enlarged into a family complex. This, with fresh support from the egoistic sense of injury, gives grounds for receiving the new brothers or sisters with repugnance and for unhesitatingly getting rid of them by a wish. It is even true that as a rule children are far readier to give verbal expression to these feelings of hate than to those arising from the parental complex. If a wish of this kind is fulfilled and the undesired addition to the family is removed again shortly afterwards by death, we can discover from a later analysis what an important experience this death has been to the child, even though it need not have remained fixed in his memory. A child who has been put into second place by the birth of a brother or sister, and who is now for the first time almost isolated from his mother, does not easily forgive her this loss of place; feelings which in an adult would be described as greatly embittered arise in him and are often the basis of a permanent estrangement. We have already mentioned that the child's sexual researches, with all their consequences, usually follow from this vital experience of his. As these brothers and sisters grow up, the boy's attitude to them undergoes very significant transformations. He may take his sister as a love-object by way of substitute for his faithless mother. Where there are several brothers, all of them courting a younger sister, situations of hostile rivalry, which are so important for later life, arise already in the nursery. A little girl may find in her elder brother a substitute for her father who no longer takes an affectionate interest in her as he did in her earliest years. Or she may take a younger sister as a substitute for the baby she has vainly wished for from her father.

The subsequent history of this identification with the father may easily be lost sight of. It may happen that the Oedipus complex becomes inverted, and that the father is taken as the object of a feminine attitude, an object from which the directly sexual instincts look for satisfaction; in that event the identification with the father has become the precursor of an object-tie with the father. The same holds good, with the necessary substitutions, of the baby daughter as well.

The whole subject, however, is so complicated that it will be necessary to go into it in greater detail. The intricacy of the problem is due to two factors: the triangular character of the Oedipus situation and the constitutional bisexuality of each individual.

It would appear, therefore, that in both sexes the relative strength of the masculine and feminine sexual dispositions is what determines whether the outcome of the Oedipus situation shall be an identification with the father or with the mother. This is one of the ways in which bisexuality takes a hand in the subsequent vicissitudes of the Oedipus complex. The other way is even more important. For one gets an impression that the simple Oedipus complex is by no means its commonest form, but rather represents a simplification or schematization which, to be sure, is often enough justified for practical purposes. Closer study usually discloses the more complete Oedipus complex, which is twofold, positive and negative, and is due to the bisexuality originally present in children: that is to say, a boy has not merely an ambivalent attitude towards his father and an affectionate object-choice towards his mother, but at the same time he also behaves like a girl and displays an affectionate feminine attitude to his father and a corresponding jealousy and hostility towards his mother. It is this complicating element introduced by bisexuality that makes it so difficult to obtain a clear view of the facts in connection with the earliest object-choices and identifications, and still more difficult to describe them intelligibly. It may even be that the ambivalence displayed in the relations to the parents should be attributed entirely to bisexuality and that it is not, as I have represented above, developed out of identification in consequence of rivalry.
In my opinion it is advisable in general, and quite especially where neurotics are concerned, to assume the existence of the complete Oedipus complex. Analytic experience then shows that in a number of cases one or the other constituent disappears, except for barely distinguishable traces; so that the result is a series with the normal positive Oedipus complex at one end and the inverted negative one at the other, while its intermediate members exhibit the complete form with one or other of its two components preponderating. At the dissolution of the Oedipus complex the four trends of which it consists will group themselves in such a way as to produce a father-identification and a mother-identification. The father-identification will preserve the object-relation to the mother which belonged to the positive complex and will at the same time replace the object-relation to the father which belonged to the inverted complex: and the same will be true, *mutatis mutandis*, of the mother-identification. The relative intensity of the two identifications in any individual will reflect the preponderance in him of one or other of the two sexual dispositions.
[1923b, 3967]

I have no doubt that the chronological and causal relations described here between the Oedipus complex, sexual intimidation (the threat of castration), the formation of the super-ego and the beginning of the latency period are of a typical kind; but I do not wish to assert that this type is the only possible one. Variations in the chronological order and in the linking-up of these events are bound to have a very important bearing on the development of the individual.
[1924d, 4091]

In boys the situation of the Oedipus complex is the first stage that can be recognized with certainty. It is easy to understand, because at that stage a child retains the same object which he previously cathexed with his libido - not as yet a genital one - during the preceding period while he was being suckled and nursed. The fact, too, that in this situation he regards his father as a disturbing rival and would like to get rid of him and take his place is a straightforward consequence of the actual state of affairs. I have shown elsewhere¹ how the Oedipus attitude in little boys belongs to the phallic phase, and how its destruction is brought about by the fear of castration - that is, by narcissistic interest in their genitals. The matter is made more difficult to grasp by the complicating circumstance that even in boys the Oedipus complex has a double orientation, active and passive, in accordance with their bisexual constitution; a boy also wants to take his *mother's* place as the love-object of his *father* - a fact which we describe as the feminine attitude.
[1925j, 4147]
As regards the prehistory of the Oedipus complex in boys we are far from complete clarity. We know that that period includes an identification of an affectionate sort with the boy's father, an identification which is still free from any sense of rivalry in regard to his mother. Another element of that stage is invariably, I believe, a masturbatory activity in connection with the genitals, the masturbation of early childhood, the more or less violent suppression of which by those in charge of the child sets the castration complex in action. It is to be assumed that this masturbation is attached to the Oedipus complex and serves as a discharge for the sexual excitation belonging to it. It is, however, uncertain whether the masturbation has this character from the first, or whether on the contrary it makes its first appearance spontaneously as an activity of a bodily organ and is only brought into relation with the Oedipus complex at some later date; this second possibility is by far the more probable. Another doubtful question is the part played by bed-wetting and by the breaking of that habit through the intervention of training measures. We are inclined to make the simple connection that continued bed-wetting is a result of masturbation and that its suppression is regarded by boys as an inhibition of their genital activity - that is, as having the meaning of a threat of castration; but whether we are always right in supposing this remains to be seen. Finally, analysis shows us in a shadowy way how the fact of a child at a very early age listening to his parents copulating may set up his first sexual excitation, and how that event may, owing to its after-effects, act as a starting-point for the child's whole sexual development. Masturbation, as well as the two attitudes in the Oedipus complex, later on become attached to this early experience, the child having subsequently interpreted its meaning. It is impossible, however, to suppose that these observations of coitus are of universal occurrence, so that at this point we are faced with the problem of 'primal phantasies'. Thus the prehistory of the Oedipus complex, even in boys, raises all of these questions for sifting and explanation; and there is the further problem of whether we are to suppose that the process invariably follows the same course, or whether a great variety of different preliminary stages may not converge upon the same terminal situation.

[1925j, 4148]
The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-erotism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother's organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors' own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child's first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child's life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child's early years become reanimated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of 'male' or 'female' but of 'possessing a penis' or 'castrated'. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses.

¹ (Footnote added 1935:) The information about infantile sexuality was obtained from the study of men and the theory deduced from it was concerned with male children. It was natural enough to expect to find a complete parallel between the two sexes; but this turned out not to hold. Further investigations and reflections revealed profound differences between the sexual development of men and women. The first sexual object of a baby girl (just as of a baby boy) is her mother; and before a woman can reach the end of her normal development she has to change not only her sexual object but also her leading genital zone. From this circumstance difficulties arise and possibilities of inhibition which are not present in the case of men.

² [1925d, 4212]
The case of the 'Wolf Man' and the somewhat less complicated one of 'Little Hans' raise a number of further considerations. But we have already made two unexpected discoveries. There can be no doubt that the instinctual impulse which was repressed in both phobias was a hostile one against the father. One might say that that impulse had been repressed by the process of being transformed into its opposite. Instead of aggressiveness on the part of the subject towards his father, there appeared aggressiveness (in the shape of revenge) on the part of his father towards the subject. Since this aggressiveness is in any case rooted in the sadistic phase of the libido, only a certain amount of degradation is needed to reduce it to the oral stage. This stage, while only hinted at in 'Little Hans's' fear of being bitten, was blatantly exhibited in the 'Wolf Man's' terror of being devoured. But, besides this, the analysis has demonstrated, beyond a shadow of doubt, the presence of another instinctual impulse of an opposite nature which had succumbed to repression. This was a tender, passive impulse directed towards the father, which had already reached the genital (phallic) level of libidinal organization. As regards the final outcome of the process of repression, this impulse seems, indeed, to have been the more important of the two; it underwent a more far-reaching regression and had a decisive influence upon the content of the phobia. In following up a single instinctual repression we have thus had to recognize a convergence of two such processes. The two instinctual impulses that have been overtaken by repression - sadistic aggressiveness towards the father and a tender passive attitude to him - form a pair of opposites. Furthermore, a full appreciation of 'Little Hans's' case shows that the formation of his phobia had had the effect of abolishing his affectionate object-cathexis of his mother as well, though the actual content of his phobia betrayed no sign of this. The process of repression had attacked almost all the components of his Oedipus complex - both his hostile and his tender impulses towards his father and his tender impulses towards his mother. In my Russian patient this state of affairs was much less obvious. [1926d, 4266]
These are unwelcome complications, considering that we only set out to study simple cases of symptom-formation due to repression, and with that intention selected the earliest and to all appearances, most transparent neuroses of childhood. Instead of a single repression we have found a collection of them and have become involved with regression into the bargain. Perhaps we have added to the confusion by treating the two cases of animal phobia at our disposal - 'Little Hans' and the 'Wolf Man' - as though they were cast in the same mould. As a matter of fact, certain differences between them stand out. It is only with regard to 'Little Hans' that we can say with certainty that what his phobia disposed of were the two main impulses of the Oedipus complex - his aggressiveness towards his father and his over-fondness for his mother. A tender feeling for his father was undoubtedly there too and played a part in repressing the opposite feeling; but we can prove neither that it was strong enough to draw repression upon itself nor that it disappeared afterwards. 'Hans' seems, in fact, to have been a normal boy with what is called a 'positive' Oedipus complex. It is possible that the factors which we do not find were actually at work in him, but we cannot demonstrate their existence. Even the most exhaustive analysis has gaps in its data and is insufficiently documented. In the case of the Russian the deficiency lies elsewhere. His attitude to female objects had been disturbed by an early seduction and his passive, feminine side was strongly developed. The analysis of his wolf-dream revealed very little intentional aggressiveness towards his father, but it brought forward unmistakable proof that what repression overtook was his passive tender attitude to his father. In his case, too, the other factors may have been operative as well; but they were not in evidence. How is it that, in spite of these differences in the two cases, almost amounting to an antithesis, the final outcome - a phobia - was approximately the same? The answer must be sought in another quarter. I think it will be found in the second fact which emerges from our brief comparative examination. It seems to me that in both cases we can detect what the motive force of the repression was and can substantiate our view of its nature from the line of development which the two children subsequently pursued. This motive force was the same in both of them. It was the fear of impending castration. 'Little Hans' gave up his aggressiveness towards his father from fear of being castrated. His fear that a horse would bite him can, without any forcing, be given the full sense of a fear that a horse would bite off his genitals, would castrate him. But it was from fear of being castrated, too, that the little Russian relinquished his wish to be loved by his father, for he thought that a relation of that sort presupposed a sacrifice of his genitals - of the organ which distinguished him from a female. As we see, both forms of the Oedipus complex, the normal, active form and the inverted one, came to grief through the castration complex. The Russian boy's anxiety-idea of being devoured by a wolf contained, it is true, no suggestion of castration, for the oral regression it had undergone had removed it too far from the phallic stage. But the analysis of his dream rendered further proof superfluous. It was a triumph of repression that the form in which his phobia was expressed should no longer have contained any allusion to castration.

[1926d, 4267]
Let us go back again to infantile phobias of animals; for, when all is said and done, we understand them better than any other cases. In animal phobias, then, the ego has to oppose a libidinal object-cathexis coming from the id - a cathexis that belongs either to the positive or the negative Oedipus complex - because it believes that to give way to it would entail the danger of castration. This question has already been discussed, but there still remains a doubtful point to clear up. In 'Little Hans's' case - that is, in the case of a positive Oedipus complex - was it his fondness for his mother or was it his aggressiveness towards his father which called out the defence by the ego? In practice it seems to make no difference, especially as each set of feelings implies the other; but the question has a theoretical interest, since it is only the feeling of affection for the mother which can count as a purely erotic one. The aggressive impulse flows mainly from the destructive instinct; and we have always believed that in a neurosis it is against the demands of the libido and not against those of any other instinct that the ego is defending itself. In point of fact we know that after 'Hans's' phobia had been formed, his tender attachment to his mother seemed to disappear, having been completely disposed of by repression, while the formation of the symptom (the substitutive formation) took place in relation to his aggressive impulses. In the 'Wolf Man' the situation was simpler. The impulse that was repressed - his feminine attitude towards his father - was a genuinely erotic one; and it was in relation to that impulse that the formation of his symptoms took place.

Nothing, however, deserves more notice than the fact that children regularly direct their sexual wishes towards their nearest relatives - in the first place, therefore, towards their father and mother, and afterwards towards their brothers and sisters. The first object of a boy's love is his mother, and of a girl's her father (except in so far as an innate bisexual disposition favours the simultaneous presence of the contrary attitude). The other parent is felt as a disturbing rival and not infrequently viewed with strong hostility. You must understand me aright. What I mean to say is not that the child wants to be treated by its favourite parent merely with the kind of affection which we adults like to regard as the essence of the parent-child relation. No, analysis leaves us in no doubt that the child's wishes extend beyond such affection to all that we understand by sensual satisfaction - so far, that is, as the child's powers of imagination allow. It is easy to see that the child never guesses the actual facts of sexual intercourse; he replaces them by other notions derived from his own experience and feelings. As a rule his wishes culminate in the intention to bear, or in some in definable way, to procreate a baby. Boys, too, in their ignorance, do not exclude themselves from the wish to bear a baby. We give the whole of this mental structure the name of 'Oedipus complex', after the familiar Greek legend. With the end of the early sexual period it should normally be given up, should radically disintegrate and become transformed; and the results of this transformation are destined for important functions in later mental life. But as a rule this is not effected radically enough, in which case puberty brings about a revival of the complex, which may have serious consequences.

A further complication arises when the constitutional factor we call bisexuality is comparatively strongly developed in a child. For then, under the threat to the boy's masculinity by castration, his inclination becomes strengthened to diverge in the direction of femininity, to put himself instead in his mother's place and take over her role as object of his father's love. But the fear of castration makes this solution impossible as well. The boy understands that he must also submit to castration if he wants to be loved by his father as a woman. Thus both impulses, hatred of the father and being in love with the father, undergo repression. There is a certain psychological distinction in the fact that the hatred of the father is given up on account of fear of an external danger (castration), while the being in love with the father is treated as an internal instinctual danger, though fundamentally it goes back to the same external danger.
What makes hatred of the father unacceptable is fear of the father; castration is terrible, whether as a punishment or as the price of love. Of the two factors which repress hatred of the father, the first, the direct fear of punishment and castration, may be called the normal one; its pathogenic intensification seems to come only with the addition of the second factor, the fear of the feminine attitude. Thus a strong innate bisexual disposition becomes one of the preconditions or reinforcements of neurosis. Such a disposition must certainly be assumed in Dostoevsky, and it shows itself in a viable form (as latent homosexuality) in the important part played by male friendships in his life, in his strangely tender attitude towards rivals in love and in his remarkable understanding of situations which are explicable only by repressed homosexuality, as many examples from his novels show.

[1928b, 4560]

During the phase of the normal Oedipus complex we find the child tenderly attached to the parent of the opposite sex, while its relation to the parent of its own sex is predominantly hostile. In the case of a boy there is no difficulty in explaining this. His first love-object was his mother. She remains so; and, with the strengthening of his erotic desires and his deeper insight into the relations between his father and mother, the former is bound to become his rival. With the small girl it is different. Her first object, too, was her mother. How does she find her way to her father? How, when and why does she detach herself from her mother? We have long understood that the development of female sexuality is complicated by the fact that the girl has the task of giving up what was originally her leading genital zone the clitoris - in favour of a new zone - the vagina. But it now seems to us that there is a second change of the same sort which is no less characteristic and important for the development of the female: the exchange of her original object - her mother - for her father. The way in which the two tasks are connected with each other is not yet clear to us.

[1931b, 4590]

Since this phase allows room for all the fixations and repressions from which we trace the origin of the neuroses, it would seem as though we must retract the universality of the thesis that the Oedipus complex is the nucleus of the neuroses. But if anyone feels reluctant about making this correction, there is no need for him to do so. On the one hand, we can extend the content of the Oedipus complex to include all the child's relations to both parents; or, on the other, we can take due account of our new findings by saying that the female only reaches the normal positive Oedipus situation after she has surmounted a period before it that is governed by the negative complex. And indeed during that phase a little girl's father is not much else for her than a troublesome rival, although her hostility towards him never reaches the pitch which is characteristic of boys. We have, after all, long given up any expectation of a neat parallelism between male and female sexual development.

[1931b, 4591]

Our insight into this early, pre-Oedipus, phase in girls comes to us as a surprise, like the discovery, in another field, of the Minoan-Mycenean civilization behind the civilization of Greece.

[1931b, 4591]
Everything in the sphere of this first attachment to the mother seemed to me so difficult to grasp in analysis - so grey with age and shadowy and almost impossible to revivify - that it was as if it had succumbed to an especially inexorable repression. But perhaps I gained this impression because the women who were in analysis with me were able to cling to the very attachment to the father in which they had taken refuge from the early phase that was in question. It does indeed appear that women analysts - as, for instance, Jeanne Lampl-de Groot and Helene Deutsch - have been able to perceive these facts more easily and clearly because they were helped in dealing with those under their treatment by the transference to a suitable mother-substitute. Nor have I succeeded in seeing my way through any case completely, and I shall therefore confine myself to reporting the most general findings and shall give only a few examples of the new ideas which I have arrived at. Among these is a suspicion that this phase of attachment to the mother is especially intimately related to the aetiology of hysteria, which is not surprising when we reflect that both the phase and the neurosis are characteristically feminine, and further, that in this dependence on the mother we have the germ of later paranoia in women.¹ For this germ appears to be the surprising, yet regular, fear of being killed (?) devoured) by the mother. It is plausible to assume that this fear corresponds to a hostility which develops in the child towards her mother in consequence of the manifold restrictions imposed by the latter in the course of training and bodily care and that the mechanism of projection is favoured by the early age of the child's psychical organization.

[1931b, 4591]
If *Oedipus Rex* moves a modern audience no less than it did the contemporary Greek one, the explanation can only be that its effect does not lie in the contrast between destiny and human will, but is to be looked for in the particular nature of the material on which that contrast is exemplified. There must be something which makes a voice within us ready to recognize the compelling force of destiny in the *Oedipus*, while we can dismiss as merely arbitrary such dispositions as are laid down in *Die Ahnfrau* or other modern tragedies of destiny. And a factor of this kind is in fact involved in the story of King Oedipus. His destiny moves us only because it might have been ours - because the oracle laid the same curse upon us before our birth as upon him. It is the fate of all of us, perhaps, to direct our first sexual impulse towards our mother and our first hatred and our first murderous wish against our father. Our dreams convince us that that is so. King Oedipus, who slew his father Laïus and married his mother Jocasta, merely shows us the fulfilment of our own childhood wishes. But, more fortunate than he, we have meanwhile succeeded, in so far as we have not become psychoneurotics, in detaching our sexual impulses from our mothers and in forgetting our jealousy of our fathers. Here is one in whom these primateval wishes of our childhood have been fulfilled, and we shrink back from him with the whole force of the repression by which those wishes have since that time been held down within us. While the poet, as he unravels the past, brings to light the guilt of Oedipus, he is at the same time compelling us to recognize our own inner minds, in which those same impulses, though suppressed, are still to be found. The contrast with which the closing Chorus leaves us confronted -

[1900a, 741]

I have learnt to look upon unconscious love relations like this (which are marked by their abnormal consequences) - between a father and a daughter, or between a mother and a son - as a revival of germs of feeling in infancy. I have shown at length elsewhere at what an early age sexual attraction makes itself felt between parents and children, and I have explained that the legend of Oedipus is probably to be regarded as a poetical rendering of what is typical in these relations. Distinct traces are probably to be found in most people of an early partiality of this kind - on the part of a daughter for her father, or on the part of a son for his mother; but it must be assumed to be more intense from the very first in the case of those children whose constitution marks them down for a neurosis, who develop prematurely and have a craving for love. At this point certain other influences, which need not be discussed here, come into play, and lead to a fixation of this rudimentary feeling of love or to a reinforcement of it; so that it turns into something (either while the child is still young or not until it has reached the age of puberty) which must be put on a par with a sexual inclination and which, like the latter, has the forces of the libido at its command. The nature of her disposition had always drawn her towards her father, and his numerous illnesses were bound to have increased her affection for him. In some of these illnesses he would allow no one but her to discharge the lighter duties of nursing. He had been so proud of the early growth of her intelligence that he had made her his confidante while she was still a child. It was really she and not her mother whom Frau K.'s appearance had driven out of more than one position.

[1905e, 1393]
It is in the world of ideas, however, that the choice of an object is accomplished at first; and the sexual life of maturing youth is almost entirely restricted to indulging in phantasies, that is, in ideas that are not destined to be carried into effect.¹ In these phantasies the infantile tendencies invariably emerge once more, but this time with intensified pressure from somatic sources. Among these tendencies the first place is taken with uniform frequency by the child's sexual impulses towards his parents, which are as a rule already differentiated owing to the attraction of the opposite sex - the son being drawn towards his mother and the daughter towards her father.² At the same time as these plainly incestuous phantasies are overcome and repudiated, one of the most significant, but also one of the most painful, psychical achievements of the pubertal period is completed: detachment from parental authority, a process that alone makes possible the opposition, which is so important for the progress of civilization, between the new generation and the old. At every stage in the course of development through which all human beings ought by rights to pass, a certain number are held back; so there are some who have never got over their parents' authority and have withdrawn their affection from them either very incompletely or not at all. They are mostly girls, who, to the delight of their parents, have persisted in all their childish love far beyond puberty. It is most instructive to find that it is precisely these girls who in their later marriage lack the capacity to give their husbands what is due to them; they make cold wives and remain sexually anaesthetic. We learn from this that sexual love and what appears to be non-sexual love for parents are fed from the same sources; the latter, that is to say, merely corresponds to an infantile fixation of the libido.

[1905d, 1539]

The closer one comes to the deeper disturbances of psychosexual development, the more unmistakably the importance of incestuous object-choice emerges. In psychoneurotics a large portion or the whole of their psychosexual activity in finding an object remains in the unconscious as a result of their repudiation of sexuality. Girls with an exaggerated need for affection and an equally exaggerated horror of the real demands made by sexual life have an irresistible temptation on the one hand to realize the ideal of asexual love in their lives and on the other hand to conceal their libido behind an affection which they can express without self-reproaches, by holding fast throughout their lives to their infantile fondness, revived at puberty, for their parents or brothers and sisters. Psycho-analysis has no difficulty in showing persons of this kind that they are in love, in the everyday sense of the word, with these blood-relations of theirs; for, with the help of their symptoms and other manifestations of their illness, it traces their unconscious thoughts and translates them into conscious ones. In cases in which someone who has previously been healthy falls ill after an unhappy experience in love it is also possible to show with certainty that the mechanism of his illness consists in a turning-back of his libido on to those whom he preferred in his infancy.

[1905d, 1539]

It has justly been said that the Oedipus complex is the nuclear complex of the neuroses, and constitutes the essential part of their content. It represents the peak of infantile sexuality, which, through its after-effects, exercises a decisive influence on the sexuality of adults. Every new arrival on this planet is faced by the task of mastering the Oedipus complex; anyone who fails to do so falls a victim to neurosis. With the progress of psycho-analytic studies the importance of the Oedipus complex has become more and more clearly evident; its recognition has become the shibboleth that distinguishes the adherents of psycho-analysis from its opponents.

[1905d, 1539]
In his subsequent development, however, it was not to homosexuality that our young libertine proceeded, but to an energetic masculinity with traits of polygamy; he knew how to vary his behaviour, too, with his varying feminine objects - audaciously aggressive in one case, languishing and bashful in another. His affection had moved from his mother on to other objects of love, but at a time when there was a scarcity of these it returned to her, only to break down in a neurosis. It was not until this happened that it became evident to what a pitch of intensity his love for his mother had developed and through what vicissitudes it had passed. The sexual aim which he pursued with his girl playmates, of sleeping with them, had originated in relation to his mother. It was expressed in words which might be retained in maturity, though they would then bear a richer connotation.¹ The boy had found his way to object-love in the usual manner from the care he had received when he was an infant; and a new pleasure had now become the most important for him - that of sleeping beside his mother. I should like to emphasize the importance of pleasure derived from cutaneous contact as a component in this new aim of Hans's, which, according to the nomenclature (artificial to my mind) of Moll, would have to be described as satisfaction of the instinct of contrectation.

[1909b, 2095]

There are not many more mysteries ahead of us now. An obscure phantasy of missing a train seems to have been a forerunner of the later notion of handing over Hans's father to his grandmother at Lainz, for the phantasy dealt with a visit to Lainz, and his grandmother appeared in it. Another phantasy, in which a boy gave the guard 50,000 florins to let him ride on the truck, almost sounds like a plan of buying his mother from his father, part of whose power, of course, lay in his wealth. At about this time, too, he confessed, with a degree of openness which he had never before reached, that he wished to get rid of his father, and that the reason he wished it was that his father interfered with his own intimacy with his mother. We must not be surprised to find the same wishes constantly reappearing in the course of an analysis. The monotony only attaches to the analyst's interpretations of these wishes. For Hans they were not mere repetitions, but steps in a progressive development from timid hinting to fully conscious, undistorted perspicuity.

[1909b, 2111]

Let us return to the sexual development of children. We have some arrears to make up owing to our having paid more attention to the somatic than to the mental phenomena of sexual life. The child's first choice of an object, which derives from its need for help, claims our further interest. Its choice is directed in the first instance to all those who look after it, but these soon give place to its parents. Children's relations to their parents, as we learn alike from direct observations of children and from later analytic examination of adults, are by no means free from elements of accompanying sexual excitation. The child takes both of its parents, and more particularly one of them, as the object of its erotic wishes. In so doing, it usually follows some indication from its parents, whose affection bears the clearest characteristics of a sexual activity, even though of one that is inhibited in its aims. As a rule a father prefers his daughter and a mother her son; the child reacts to this by wishing, if he is a son, to take his father's place, and, if she is a daughter, her mother's. The feelings which are aroused in these relations between parents and children and in the resulting ones between brothers and sisters are not only of a positive or affectionate kind but also of a negative or hostile one. The complex which is thus formed is doomed to early repression; but it continues to exercise a great and lasting influence from the unconscious. It is to be suspected that, together with its extensions, it constitutes the nuclear complex of every neurosis, and we may expect to find it no less actively at work in other regions of mental life. The myth of King Oedipus, who killed his father and took his mother to wife, reveals, with little modification, the infantile wish, which is later opposed and repudiated by the barrier against incest. Shakespeare's Hamlet is equally rooted in the soil of the incest-complex, but under a better disguise.

[1910a, 2232]
A young man who has hitherto satisfied his libido by means of phantasies ending in masturbation, and who now seeks to replace a régime approximating to auto-erotism by the choice of a real object - or a girl who has given her whole affection to her father or brother and who must now, for the sake of a man who is courting her, allow her hitherto unconscious incestuous libidinal wishes to become conscious - or a married woman who would like to renounce her polygamous inclinations and phantasies of prostitution so as to become a faithful consort to her husband and a perfect mother to her child - all of these fall ill from the most laudable efforts, if the earlier fixations of their libido are powerful enough to resist a displacement; and this point will be decided, once again, by the factors of disposition, constitution and infantile experience. All of them, it might be said, meet with the fate of the little tree in the Grimms' fairy tale, which wished it had different leaves. From the hygienic point of view - which, to be sure, is not the only one to be taken into account - one could only wish for them that they had continued to be as undeveloped, as inferior and as useless as they were before they fell ill. The change which the patients strive after, but bring about only imperfectly or not at all, invariably has the value of a step forward from the point of view of real life. It is otherwise if we apply ethical standards: we see people falling ill just as often when they discard an ideal as when they seek to attain it.

[1912c, 2562]

There has been little opportunity in the preceding pages for showing how new light can be thrown upon the facts of social psychology by the adoption of a psycho-analytic method of approach: for the horror of incest displayed by savages has long been recognized as such and stands in need of no further interpretation. All that I have been able to add to our understanding of it is to emphasize the fact that it is essentially an infantile feature and that it reveals a striking agreement with the mental life of neurotic patients. Psycho-analysis has taught us that a boy's earliest choice of objects for his love is incestuous and that those objects are forbidden ones - his mother and his sister. We have learnt, too, the manner in which, as he grows up, he liberates himself from this incestuous attraction. A neurotic, on the other hand, invariably exhibits some degree of psychical infantilism. He has either failed to get free from the psychosexual conditions that prevailed in his childhood or he has returned to them - two possibilities which may be summed up as developmental inhibition and regression. Thus incestuous fixations of libido continue to play (or begin once more to play) the principal part in his unconscious mental life. We have arrived at the point of regarding a child's relation to his parents, dominated as it is by incestuous longings, as the nuclear complex of neurosis. This revelation of the importance of incest in neurosis is naturally received with universal scepticism by adults and normal people. Similar expressions of disbelief, for instance, inevitably greet the writings of Otto Rank, which have brought more and more evidence to show the extent to which the interest of creative writers centres round the theme of incest and how the same theme, in countless variations and distortions, provides the subject-matter of poetry. We are driven to believe that this rejection is principally a product of the distaste which human beings feel for their early incestuous wishes, now over taken by repression. It is therefore of no small importance that we are able to show that these same incestuous wishes, which are later destined to become unconscious, are still regarded by savage peoples as immediate perils against which the most severe measures of defence must be enforced.

[1912-1913, 2665]
She found out the central meaning of her ceremonial one day when she suddenly understood the meaning of the rule that the pillow must not touch the back of the bedstead. The pillow, she said, had always been a woman to her and the upright wooden back a man. Thus she wanted - by magic, we must interpolate - to keep the man and woman apart - that is, to separate her parents from each other, not to allow them to have sexual intercourse. In earlier years, before she had established the ceremonial, she had tried to achieve the same aim in a more direct way. She had simulated fear (or had exploited a tendency to fear which was already present) in order that the connecting doors between her parents' bedroom and the nursery should not be shut. This rule had, indeed, been retained in her present ceremonial. In that way she gave herself the opportunity of listening to her parents, but in making use of it she brought on an insomnia which lasted for months. Not satisfied with disturbing her parents by this means, she contrived to be allowed from time to time to sleep in her parents' bed between them. The 'pillow' and the 'wooden back' were thus really unable to come together. Finally, when she was so big that it became physically uncomfortable for her to find room in the bed between her parents, she managed, by a conscious simulation of anxiety, to arrange for her mother to exchange places with her for the night and to leave her own place so that the patient could sleep beside her father. This situation no doubt became the starting-point of phantasies whose after-effect was to be seen in the ceremonial.

[1916-1917, 3347]

The processes of finding an object are fairly complex and no comprehensive account has hitherto been given of them. For our purposes it may be specially pointed out that when, in the years of childhood before puberty, the process has in some respects reached a conclusion, the object that has been found turns out to be almost identical with the first object of the oral pleasure-instinct, which was reached by attachment. Though it is not actually the mother's breast, at least it is the mother. We call the mother the first love-object. For we speak of love when we bring the mental side of the sexual trends into the foreground and want to force back the underlying physical or 'sensual' instinctual demands or to forget them for a moment. At the time at which the child's mother becomes his love-object the psychical work of repression has already begun in him, which is withdrawing from his knowledge awareness of a part of his sexual aims. To his choice of his mother as a love-object everything becomes attached which, under the name of the 'Oedipus complex', has attained so much importance in the psychoanalytic explanation of the neuroses and has played no less a part, perhaps, in the resistance to psycho-analysis.

[1916-1917, 3397]
But let us now turn from the direct observation of children to the analytic examination of adults who have become neurotic. What help does analysis give towards a further knowledge of the Oedipus complex? That can be answered in a word. Analysis confirms all that the legend describes. It shows that each of these neurotics has himself been an Oedipus or, what comes to the same thing, has, as a reaction to the complex, become a Hamlet. The analytic account of the Oedipus complex is, of course, a magnification and coarsening of the infantile sketch. The hatred of the father, the death-wishes against him, are no longer hinted at timidly, the affection for the mother admits that its aim is to possess her as a woman. Should we really attribute such blatant and extreme emotional impulses to the tender years of childhood, or is analysis deceiving us by an admixture of some new factor? It is not hard to find one. Whenever someone gives an account of a past event, even if he is a historian, we must take into account what he unintentionally puts back into the past from the present or from some intermediate time, thus falsifying his picture of it. In the case of a neurotic it is even a question whether this putting back is an entirely unintentional one; later on we shall have to discover reasons for this and have to do justice in general to the fact of 'retrospective phantasying'. We can easily see, too, that hatred of the father is reinforced by a number of factors arising from later times and circumstances and that the sexual desires towards the mother are cast into forms which must have been alien as yet to a child. But it would be a vain effort to seek to explain the whole Oedipus complex by retrospective phantasying and to attach it to later times. Its infantile core and more or less of its accessories remain as they were confirmed by the direct observation of children.

The clinical fact which meets us behind the form of the Oedipus complex as it is established by analysis is of the highest practical significance. We learn that at puberty, when the sexual instinct first makes its demands in full strength, the old familiar incestuous objects are taken up again and freshly cathedected with libido. The infantile object-choice was only a feeble one, but it was a prelude, pointing the direction for the object-choice at puberty. At this point, then, very intense emotional processes come into play, following the direction of the Oedipus complex or reacting against it, processes which, however, since their premisses have become intolerable, must to a large extent remain apart from consciousness. From this time onwards, the human individual has to devote himself to the great task of detaching himself from his parents, and not until that task is achieved can he cease to be a child and become a member of the social community. For the son this task consists in detaching his libidinal wishes from his mother and employing them for the choice of a real outside love-object, and in reconciling himself with his father if he has remained in opposition to him, or in freeing himself from his pressure if, as a reaction to his infantile rebelliousness, he has become subservient to him. These tasks are set to everyone; and it is remarkable how seldom they are dealt with in an ideal manner - that is, in one which is correct both psychologically and socially. By neurotics, however, no solution at all is arrived at: the son remains all his life bowed beneath his father's authority and he is unable to transfer his libido to an outside sexual object. With the relationship changed round, the same fate can await the daughter. In this sense the Oedipus complex may justly be regarded as the nucleus of the neuroses.

[1916-1917, 3401]

[1916-1917, 3402]
For the moment we will dwell a little longer on regression. After what you have learnt of the development of the libidinal function, you will be prepared to hear that there are regressions of two sorts: a return to the objects first cathectified by the libido, which, as we know, are of an incestuous nature, and a return of the sexual organization as a whole to earlier stages. Both sorts are found in the transference neuroses and play a great part in their mechanism. In particular, a return to the first incestuous objects of the libido is a feature that is found in neurotics with positively fatiguing regularity. There is much more to be said about regressions of the libido itself when we take into account as well another group of neuroses, the narcissistic ones, which, for the time being we do not intend to do. These disorders give us access to other developmental processes of the libidinal function which we have not yet mentioned, and show us correspondingly new sorts of regression as well. But above all I think I ought to warn you now not to confuse regression with repression and help you to form a clear idea of the relations between the two processes. Repression, as you will recall, is the process by which an act which is admissible to consciousness, one, therefore, which belongs to the system \( Pcs. \), is made unconscious - is pushed back, therefore, into the system \( Ucs. \). And we equally speak of repression if the unconscious mental act is altogether forbidden access to the neighbouring preconscious system and is turned back at the threshold by the censorship. Thus the concept of repression involves no relation to sexuality: I must ask you to take special note of that. It indicates a purely psychological process, which we can characterize still better if we call it a 'topographical' one. By this we intend to say that it is concerned with the psychical regions which we have assumed to exist, or, if we drop this clumsy working hypothesis, with the construction of the mental apparatus out of distinct psychical systems.

If, however, the derivation of perversions from the Oedipus complex can be generally established, our estimate of its importance will have gained added strength. For in our opinion the Oedipus complex is the actual nucleus of neuroses, and the infantile sexuality which culminates in this complex is the true determinant of neuroses. What remains of the complex in the unconscious represents the disposition to the later development of neuroses in the adult. In this way the beating-phantasy and other analogous perverse fixations would also only be precipitates of the Oedipus complex, scars, so to say, left behind after the process has ended, just as the notorious 'sense of inferiority' corresponds to a narcissistic scar of the same sort. In taking this view of the matter I must express my unreserved agreement with Marcinowski (1918), who has recently put it forward most happily. As is well known, this neurotic delusion of inferiority is only a partial one, and is completely compatible with the existence of a self-overvaluation derived from other sources. The origin of the Oedipus complex itself, and the destiny which compels man, probably alone among all animals, to begin his sexual life twice over, first like all other creatures in his early childhood, and then after a long interruption once more at the age of puberty - all the problems that are connected with man's 'archaic heritage' - have been discussed by me elsewhere, and I have no intention of going into them in this place.

[1916-1917, 3405]

[1919e, 3654]
The theory of psycho-analysis (a theory based on observation) holds firmly to the view that the motive forces of repression must not be sexualized. Man's archaic heritage forms the nucleus of the unconscious mind; and whatever part of that heritage has to be left behind in the advance to later phases of development, because it is unserviceable or incompatible with what is new and harmful to it, falls a victim to the process of repression. This selection is made more successfully with one group of instincts than with the other. In virtue of special circumstances which have often been pointed out already, the latter group, that of the sexual instincts, are able to defeat the intentions of repression, and to enforce their representation by substitutive formations of a disturbing kind. For this reason infantile sexuality, which is held under repression, acts as the chief motive force in the formation of symptoms; and the essential part of its content, the Oedipus complex, is the nuclear complex of neuroses. I hope that in this paper I have raised an expectation that the sexual aberrations of childhood, as well as those of mature life, are ramifications of the same complex.

[1919e, 3662]

In 1913 Otto Rank and Hanns Sachs, in an extremely interesting work, brought together the results which had been achieved up to that time in the application of psycho-analysis to the mental sciences. The most easily accessible branches of those sciences seem to be mythology and the history of literature and religion. No final formula has yet been found enabling us to give an appropriate place to myths in this connection. Otto Rank, in a large volume on the incest complex (1912), has produced evidence of the surprising fact that the choice of subject matter, especially for dramatic works, is principally determined by the ambit of what psycho-analysis has termed the 'Oedipus complex'. By working it over with the greatest variety of modifications, distortions and disguises, the dramatist seeks to deal with his own most personal relations to this emotional theme. It is in attempting to master the Oedipus complex - that is to say, a person's emotional attitude towards his family, or in a narrower sense towards his father and mother - that individual neurotics come to grief, and for this reason that complex habitually forms the nucleus of their neuroses. It does not owe its importance to any unintelligible conjunction; the emphasis laid upon the relation of children to their parents is an expression of the biological facts that the young of the human race pass through a long period of dependence and are slow in reaching maturity, as well as that their capacity for love undergoes a complicated course of development. Consequently, the overcoming of the Oedipus complex coincides with the most efficient way of mastering the archaic, animal heritage of humanity. It is true that that heritage comprises all the forces that are required for the subsequent cultural development of the individual, but they must first be sorted out and worked over. This archaic heirloom is not fit to be used for the purposes of civilized social life in the form in which it is inherited by the individual.

[1919g, 3704]
But it became ever clearer that the aim which had been set up - the aim that what was unconscious should become conscious - is not completely attainable by that method. The patient cannot remember the whole of what is repressed in him, and what he cannot remember may be precisely the essential part of it. Thus he acquires no sense of conviction of the correctness of the construction that has been communicated to him. He is obliged to repeat the repressed material as a contemporary experience instead of, as the physician would prefer to see, remembering it as something belonging to the past.¹ These reproductions, which emerge with such unwished-for exactitude, always have as their subject some portion of infantile sexual life - of the Oedipus complex, that is, and its derivatives; and they are invariably acted out in the sphere of the transference, of the patient's relation to the physician. When things have reached this stage, it may be said that the earlier neurosis has now been replaced by a fresh, 'transference neurosis'. It has been the physician's endeavour to keep this transference neurosis within the narrowest limits: to force as much as possible into the channel of memory and to allow as little as possible to emerge as repetition. The ratio between what is remembered and what is reproduced varies from case to case. The physician cannot as a rule spare his patient this phase of the treatment. He must get him to re-experience some portion of his forgotten life, but must see to it, on the other hand, that the patient retains some degree of aloofness, which will enable him, in spite of everything, to recognize that what appears to be reality is in fact only a reflection of a forgotten past. If this can be successfully achieved, the patient's sense of conviction is won, together with the therapeutic success that is dependent on it.

¹[1920g, 3723]

In the very earliest years of childhood (approximately between the ages of two and five) a convergence of the sexual impulses occurs of which, in the case of boys, the object is the mother. This choice of an object, in conjunction with a corresponding attitude of rivalry and hostility towards the father, provides the content of what is known as the Oedipus complex, which in every human being is of the greatest importance in determining the final shape of his erotic life. It has been found to be characteristic of a normal individual that he learns to master his Oedipus complex, whereas the neurotic subject remains involved in it.

¹[1923a, 3922]

In my opinion it is advisable in general, and quite especially where neurotics are concerned, to assume the existence of the complete Oedipus complex. Analytic experience then shows that in a number of cases one or the other constituent disappears, except for barely distinguishable traces; so that the result is a series with the normal positive Oedipus complex at one end and the inverted negative one at the other, while its intermediate members exhibit the complete form with one or other of its two components preponderating. At the dissolution of the Oedipus complex the four trends of which it consists will group themselves in such a way as to produce a father-identification and a mother-identification. The father-identification will preserve the object-relation to the mother which belonged to the positive complex and will at the same time replace the object-relation to the father which belonged to the inverted complex: and the same will be true, mutatis mutandis, of the mother-identification. The relative intensity of the two identifications in any individual will reflect the preponderance in him of one or other of the two sexual dispositions.

¹[1923b, 3967]
I see no reason for denying the name of a 'repression' to the ego's turning away from the Oedipus complex, although later repressions come about for the most part with the participation of the super-ego, which in this case is only just being formed. But the process we have described is more than a repression. It is equivalent, if it is ideally carried out, to a destruction and an abolition of the complex. We may plausibly assume that we have here come upon the borderline - never a very sharply drawn one - between the normal and the pathological. If the ego has in fact not achieved much more than a repression of the complex, the latter persists in an unconscious state in the id and will later manifest its pathogenic effect.

[1924d, 4089]

After hypnosis was replaced by the technique of free association, Breuer's cathartic procedure turned into psycho-analysis, which for more than a decade was developed by the author (Freud) alone. During that time psycho-analysis gradually acquired a theory which appeared to give a satisfactory account of the origin, meaning and purpose of neurotic symptoms and provided a rational basis for medical attempts at curing the complaint. I will once again enumerate the factors that go to make up this theory. They are: emphasis on instinctual life (affectivity), on mental dynamics, on the fact that even the apparently most obscure and arbitrary mental phenomena invariably have a meaning and a causation, the theory of psychical conflict and of the pathogenic nature of repression, the view that symptoms are substitutive satisfactions, the recognition of the aetiological importance of sexual life, and in particular of the beginnings of infantile sexuality. From a philosophical standpoint this theory was bound to adopt the view that the mental does not coincide with the conscious, that mental processes are in themselves unconscious and are only made conscious by the functioning of special organs (agencies or systems). By way of completing this list, I will add that among the affective attitudes of childhood the complicated emotional relation of children to their parents - what is known as the Oedipus complex - came into prominence. It became ever clearer that this was the nucleus of every case of neurosis, and in the patient's behaviour towards his analyst certain phenomena of his emotional transference emerged which came to be of great importance for theory and technique alike.

[1924f, 4107]
Before going further into the question of infantile sexuality I must mention an error into which I fell for a while and which might well have had fatal consequences for the whole of my work. Under the influence of the technical procedure which I used at that time, the majority of my patients reproduced from their childhood scenes in which they were sexually seduced by some grown-up person. With female patients the part of seducer was almost always assigned to their father. I believed these stories, and consequently supposed that I had discovered the roots of the subsequent neurosis in these experiences of sexual seduction in childhood. My confidence was strengthened by a few cases in which relations of this kind with a father, uncle, or elder brother had continued up to an age at which memory was to be trusted. If the reader feels inclined to shake his head at my credulity, I cannot altogether blame him; though I may plead that this was at a time when I was intentionally keeping my critical faculty in abeyance so as to preserve an unprejudiced and receptive attitude towards the many novelties which were coming to my notice every day. When, however, I was at last obliged to recognize that these scenes of seduction had never taken place, and that they were only phantasies which my patients had made up or which I myself had perhaps forced on them, I was for some time completely at a loss. My confidence alike in my technique and in its results suffered a severe blow; it could not be disputed that I had arrived at these scenes by a technical method which I considered correct, and their subject-matter was unquestionably related to the symptoms from which my investigation had started. When I had pulled myself together, I was able to draw the right conclusions from my discovery: namely, that the neurotic symptoms were not related directly to actual events but to wishful phantasies, and that as far as the neurosis was concerned psychical reality was of more importance than material reality. I do not believe even now that I forced the seduction-phantasies on my patients, that I 'suggested' them. I had in fact stumbled for the first time upon the *Oedipus complex*, which was later to assume such an overwhelming importance, but which I did not recognize as yet in its disguise of phantasy. Moreover, seduction during childhood retained a certain share, though a humbler one, in the aetiology of neuroses. But the seducers turned out as a rule to have been older children.

I must begin by adding that increasing experience showed more and more plainly that the *Oedipus complex* was the nucleus of the neurosis. It was at once the climax of infantile sexual life and the point of junction from which all of its later developments proceeded. But if so, it was no longer possible to expect analysis to discover a factor that was specific in the aetiology of the neuroses. It must be true, as Jung expressed it so well in the early days when he was still an analyst, that neuroses have no peculiar content which belongs exclusively to them but that neurotics break down at the same difficulties that are successfully overcome by normal people. This discovery was very far from being a disappointment. It was in complete harmony with another one: that the depth-psychology revealed by psycho-analysis was in fact the psychology of the normal mind. Our path had been like that of chemistry: the great qualitative differences between substances were traced back to quantitative variations in the proportions in which the same elements were combined.
A number of suggestions came to me out of the Oedipus complex, the ubiquity of which gradually dawned on me. The poet's choice, or his invention, of such a terrible subject seemed puzzling; and so too did the overwhelming effect of its dramatic treatment, and the general nature of such tragedies of destiny. But all of this became intelligible when one realized that a universal law of mental life had here been captured in all its emotional significance. Fate and the oracle were no more than materializations of an internal necessity; and the fact of the hero's sinning without his knowledge and against his intentions was evidently a right expression of the unconscious nature of his criminal tendencies. From understanding this tragedy of destiny it was only a step further to understanding a tragedy of character - *Hamlet*, which had been admired for three hundred years without its meaning being discovered or its author's motives guessed. It could scarcely be a chance that this neurotic creation of the poet should have come to grief, like his numberless fellows in the real world, over the Oedipus complex. For Hamlet was faced with the task of taking vengeance on another for the two deeds which are the subject of the Oedipus desires; and before that task his arm was paralysed by his own obscure sense of guilt. Shakespeare wrote *Hamlet* very soon after his father's death.¹ The suggestions made by me for the analysis of this tragedy were fully worked out later on by Ernest Jones. And the same example was afterwards used by Otto Rank as the starting-point for his investigation of the choice of material made by dramatists. In his large volume on the incest theme (Rank, 1912) he was able to show how often imaginative writers have taken as their subject the themes of the Oedipus situation, and traced in the different literatures of the world the way in which the material has been transformed, modified, and softened. [1925d, 4237]

The case of the 'Wolf Man' and the somewhat less complicated one of 'Little Hans' raise a number of further considerations. But we have already made two unexpected discoveries. There can be no doubt that the instinctual impulse which was repressed in both phobias was a hostile one against the father. One might say that that impulse had been repressed by the process of being transformed into its opposite. Instead of aggressiveness on the part of the subject towards his father, there appeared aggressiveness (in the shape of revenge) on the part of his father towards the subject. Since this aggressiveness is in any case rooted in the sadistic phase of the libido, only a certain amount of degradation is needed to reduce it to the oral stage. This stage, while only hinted at in 'Little Hans's' fear of being bitten, was blatantly exhibited in the 'Wolf Man's' terror of being devoured. But, besides this, the analysis has demonstrated, beyond a shadow of doubt, the presence of another instinctual impulse of an opposite nature which had succumbed to repression. This was a tender, passive impulse directed towards the father, which had already reached the genital (phallic) level of libidinal organization. As regards the final outcome of the process of repression, this impulse seems, indeed, to have been the more important of the two; it underwent a more far-reaching regression and had a decisive influence upon the content of the phobia. In following up a single instinctual repression we have thus had to recognize a convergence of two such processes. The two instinctual impulses that have been overtaken by repression - sadistic aggressiveness towards the father and a tender passive attitude to him - form a pair of opposites. Furthermore, a full appreciation of 'Little Hans's' case shows that the formation of his phobia had had the effect of abolishing his affectionate object-cathexis of his mother as well, though the actual content of his phobia betrayed no sign of this. The process of repression had attacked almost all the components of his Oedipus complex - both his hostile and his tender impulses towards his father and his tender impulses towards his mother. In my Russian patient this state of affairs was much less obvious. [1926d, 4266]
These are unwelcome complications, considering that we only set out to study simple cases of symptom-formation due to repression, and with that intention selected the earliest and to all appearances, most transparent neuroses of childhood. Instead of a single repression we have found a collection of them and have become involved with regression into the bargain. Perhaps we have added to the confusion by treating the two cases of animal phobia at our disposal - 'Little Hans' and the 'Wolf Man' - as though they were cast in the same mould. As a matter of fact, certain differences between them stand out. It is only with regard to 'Little Hans' that we can say with certainty that what his phobia disposed of were the two main impulses of the Oedipus complex - his aggressiveness towards his father and his over-fondness for his mother. A tender feeling for his father was undoubtedly there too and played a part in repressing the opposite feeling; but we can prove neither that it was strong enough to draw repression upon itself nor that it disappeared afterwards. 'Hans' seems, in fact, to have been a normal boy with what is called a 'positive' Oedipus complex. It is possible that the factors which we do not find were actually at work in him, but we cannot demonstrate their existence. Even the most exhaustive analysis has gaps in its data and is insufficiently documented. In the case of the Russian the deficiency lies elsewhere. His attitude to female objects had been disturbed by an early seduction and his passive, feminine side was strongly developed. The analysis of his wolf-dream revealed very little intentional aggressiveness towards his father, but it brought forward unmistakable proof that what repression overtook was his passive tender attitude to his father. In his case, too, the other factors may have been operative as well; but they were not in evidence. How is it that, in spite of these differences in the two cases, almost amounting to an antithesis, the final outcome - a phobia - was approximately the same? The answer must be sought in another quarter. I think it will be found in the second fact which emerges from our brief comparative examination. It seems to me that in both cases we can detect what the motive force of the repression was and can substantiate our view of its nature from the line of development which the two children subsequently pursued. This motive force was the same in both of them. It was the fear of impending castration. 'Little Hans' gave up his aggressiveness towards his father from fear of being castrated. His fear that a horse would bite him can, without any forcing, be given the full sense of a fear that a horse would bite off his genitals, would castrate him. But it was from fear of being castrated, too, that the little Russian relinquished his wish to be loved by his father, for he thought that a relation of that sort presupposed a sacrifice of his genitals - of the organ which distinguished him from a female. As we see, both forms of the Oedipus complex, the normal, active form and the inverted one, came to grief through the castration complex. The Russian boy's anxiety-idea of being devoured by a wolf contained, it is true, no suggestion of castration, for the oral regression it had undergone had removed it too far from the phallic stage. But the analysis of his dream rendered further proof superfluous. It was a triumph of repression that the form in which his phobia was expressed should no longer have contained any allusion to castration.

Obsessional neurosis is unquestionably the most interesting and repaying subject of analytic research. But as a problem it has not yet been mastered. It must be confessed that, if we endeavour to penetrate more deeply into its nature, we still have to rely upon doubtful assumptions and unconfirmed suppositions. Obsessional neurosis originates, no doubt, in the same situation as hysteria, namely, the necessity of fending off the libidinal demands of the Oedipus complex. Indeed, every obsessional neurosis seems to have a substratum of hysterical symptoms that have been formed at a very early stage. But it is subsequently shaped along quite different lines owing to a constitutional factor. The genital organization of the libido turns out to be feeble and insufficiently resistant, so that when the ego begins its defensive efforts the first thing it succeeds in doing is to throw back the genital organization (of the phallic phase), in whole or in part, to the earlier sadistic-anal level. This fact of regression is decisive for all that follows.

[1926d, 4267]
In enforcing regression, the ego scores its first success in its defensive struggle against the demands of the libido. (In this connection it is of advantage to distinguish the more general notion of 'defence' from 'repression'. Repression is only one of the mechanisms which defence makes use of.) It is perhaps in obsessional cases more than in normal or hysterical ones that we can most clearly recognize that the motive force of defence is the castration complex and that what is being fended off are the trends of the Oedipus complex. We are at present dealing with the beginning of the latency period, a period which is characterized by the dissolution of the Oedipus complex, the creation or consolidation of the super-ego and the erection of ethical and aesthetic barriers in the ego. In obsessional neuroses these processes are carried further than is normal. In addition to the destruction of the Oedipus complex a regressive degradation of the libido takes place, the super-ego becomes exceptionally severe and unkind, and the ego, in obedience to the super-ego, produces strong reaction-formations in the shape of conscientiousness, pity and cleanliness. Implacable, though not always on that account successful, severity is shown in condemning the temptation to continue early infantile masturbation, which now attaches itself to regressive (sadistic-anal) ideas but which nevertheless represents the unsubjugated part of the phallic organization. There is an inherent contradiction about this state of affairs, in which, precisely in the interests of masculinity (that is to say, from fear of castration), every activity belonging to masculinity is stopped. But here, too, obsessional neurosis is only overdoing the normal method of getting rid of the Oedipus complex. We once more find here an illustration of the truth that every exaggeration contains the seed of its own undoing. For, under the guise of obsessional acts, the masturbation that has been suppressed approaches ever more closely to satisfaction.

[1926d, 4273]

This is as far as our investigations into the formation of symptoms take us. It is hardly worth while summing them up, for the results they have yielded are scanty and incomplete and tell us scarcely anything that we do not already know. It would be fruitless to turn our attention to symptom-formation in other disorders besides phobias, conversion hysteria and obsessional neurosis, for too little is known about them. But in reviewing those three neuroses together we are brought up against a very serious problem the consideration of which can no longer be put off. All three have as their outcome the destruction of the Oedipus complex; and in all three the motive force of the ego's opposition is, we believe, the fear of castration. Yet it is only in the phobias that this fear comes to the surface and is acknowledged. What has become of it in the other two neuroses? How has the ego spared itself this fear? The problem becomes accentuated when we recall the possibility, already referred to, that anxiety arises directly, by a kind of fermentation, from a libidinal cathexis whose processes have been disturbed. Furthermore, is it absolutely certain that fear of castration is the only motive force of repression (or defence)? If we think of neuroses in women we are bound to doubt it. For though we can with certainty establish in them the presence of a castration complex, we can hardly speak with propriety of castration anxiety where castration has already taken place.

[1926d, 4281]
Let us go back again to infantile phobias of animals; for, when all is said and done, we understand them better than any other cases. In animal phobias, then, the ego has to oppose a libidinal object-cathexis coming from the id - a cathexis that belongs either to the positive or the negative Oedipus complex - because it believes that to give way to it would entail the danger of castration. This question has already been discussed, but there still remains a doubtful point to clear up. In 'Little Hans's' case - that is, in the case of a positive Oedipus complex - was it his fondness for his mother or was it his aggressiveness towards his father which called out the defence by the ego? In practice it seems to make no difference, especially as each set of feelings implies the other; but the question has a theoretical interest, since it is only the feeling of affection for the mother which can count as a purely erotic one. The aggressive impulse flows mainly from the destructive instinct; and we have always believed that in a neurosis it is against the demands of the libido and not against those of any other instinct that the ego is defending itself. In point of fact we know that after 'Hans's' phobia had been formed, his tender attachment to his mother seemed to disappear, having been completely disposed of by repression, while the formation of the symptom (the substitutive formation) took place in relation to his aggressive impulses. In the 'Wolf Man' the situation was simpler. The impulse that was repressed - his feminine attitude towards his father - was a genuinely erotic one; and it was in relation to that impulse that the formation of his symptoms took place.

[1926d, 4282]

Nothing, however, deserves more notice than the fact that children regularly direct their sexual wishes towards their nearest relatives - in the first place, therefore, towards their father and mother, and afterwards towards their brothers and sisters. The first object of a boy's love is his mother, and of a girl's her father (except in so far as an innate bisexual disposition favours the simultaneous presence of the contrary attitude). The other parent is felt as a disturbing rival and not infrequently viewed with strong hostility. You must understand me aright. What I mean to say is not that the child wants to be treated by its favourite parent merely with the kind of affection which we adults like to regard as the essence of the parent-child relation. No, analysis leaves us in no doubt that the child's wishes extend beyond such affection to all that we understand by sensual satisfaction - so far, that is, as the child's powers of imagination allow. It is easy to see that the child never guesses the actual facts of sexual intercourse; he replaces them by other notions derived from his own experience and feelings. As a rule his wishes culminate in the intention to bear, or in some in definable way, to procreate a baby. Boys, too, in their ignorance, do not exclude themselves from the wish to bear a baby. We give the whole of this mental structure the name of 'Oedipus complex', after the familiar Greek legend. With the end of the early sexual period it should normally be given up, should radically disintegrate and become transformed; and the results of this transformation are destined for important functions in later mental life. But as a rule this is not effected radically enough, in which case puberty brings about a revival of the complex, which may have serious consequences.

[1926e, 4355]

In his childhood: as a rule in his relation with one of his parents. You will remember what importance we had to attribute to these earliest emotional ties. So here the circle closes.

[1926e, 4369]

The most important conflict with which a small child is faced is his relation to his parents, the 'Oedipus complex'; it is in attempting to grapple with this problem that those destined to suffer from a neurosis habitually come to grief. The reactions against the instinctual demands of the Oedipus complex are the source of the most precious and socially important achievements of the human mind; and this holds true not only in the life of individuals but probably also in the history of the human species as a whole. The super-ego, too, the moral agency which dominates the ego, has its origin in the process of overcoming the Oedipus complex.

[1926f, 4406]
We now observe that the store of religious ideas includes not only wish-fulfilments but important historical recollections. This concurrent influence of past and present must give religion a truly incomparable wealth of power. But perhaps with the help of an analogy yet another discovery may begin to dawn on us. Though it is not a good plan to transplant ideas far from the soil in which they grew up, yet here is a conformity which we cannot avoid pointing out. We know that a human child cannot successfully complete its development to the civilized stage without passing through a phase of neurosis sometimes of greater and sometimes of less distinctness. This is because so many instinctual demands which will later be unserviceable cannot be suppressed by the rational operation of the child's intellect but have to be tamed by acts of repression, behind which, as a rule, lies the motive of anxiety. Most of these infantile neuroses are overcome spontaneously in the course of growing up, and this is especially true of the obsessional neuroses of childhood. The remainder can be cleared up later still by psychoanalytic treatment. In just the same way, one might assume, humanity as a whole, in its development through the ages, fell into states analogous to the neuroses, and for the same reasons - namely because in the times of its ignorance and intellectual weakness the instinctual renunciations indispensable for man's communal existence had only been achieved by it by means of purely affective forces. The precipitates of these processes resembling repression which took place in prehistoric times still remained attached to civilization for long periods. Religion would thus be the universal obsessional neurosis of humanity; like the obsessional neuroses of children, it arose out of the Oedipus complex, out of the relation to the father. If this view is right, it is to be supposed that a turning-away from religion is bound to occur with the fatal inevitability of a process of growth, and that we find ourselves at this very juncture in the middle of that phase of development. Our behaviour should therefore be modelled on that of a sensible teacher who does not oppose an impending new development but seeks to ease its path and mitigate the violence of its irruption. Our analogy does not, to be sure, exhaust the essential nature of religion. If, on the one hand, religion brings with it obsessional restrictions, exactly as an individual obsessional neurosis does, on the other hand it comprises a system of wishful illusions together with a disavowal of reality, such as we find in an isolated form nowhere else but in amnesia, in a state of blissful hallucinatory confusion. But these are only analogies, by the help of which we endeavour to understand a social phenomenon; the pathology of the individual does not supply us with a fully valid counterpart.

I am sorry, though I cannot alter the facts, if this exposition of the attitudes of hatred and love towards the father and their transformations under the influence of the threat of castration seems to readers unfamiliar with psycho-analysis unsavoury and incredible. I should myself expect that it is precisely the castration complex that would be bound to arouse the most general repudiation. But I can only insist that psycho-analytic experience has put these matters in particular beyond the reach of doubt and has taught us to recognize in them the key to every neurosis. This key, then, we must apply to our author's so-called epilepsy. So alien to our consciousness are the things by which our unconscious mental life is governed!
Since this phase allows room for all the fixations and repressions from which we trace the origin of the neuroses, it would seem as though we must retract the universality of the thesis that the Oedipus complex is the nucleus of the neuroses. But if anyone feels reluctant about making this correction, there is no need for him to do so. On the one hand, we can extend the content of the Oedipus complex to include all the child's relations to both parents; or, on the other, we can take due account of our new findings by saying that the female only reaches the normal positive Oedipus situation after she has surmounted a period before it that is governed by the negative complex. And indeed during that phase a little girl's father is not much else for her than a troublesome rival, although her hostility towards him never reaches the pitch which is characteristic of boys. We have, after all, long given up any expectation of a neat parallelism between male and female sexual development.
[1931b, 4591]

For we have recently been examining the way in which anxiety is generated in certain phobias which we class as anxiety hysteria, and have chosen cases in which we were dealing with the typical repression of wishful impulses arising from the Oedipus complex. We should have expected to find that it was a libidinal cathexis of the boy's mother as object which, as a result of repression, had been changed into anxiety and which now emerged, expressed in symptomatic terms, attached to a substitute for his father. I cannot present you with the detailed steps of an investigation such as this; it will be enough to say that the surprising result was the opposite of what we expected. It was not the repression that created the anxiety; the anxiety was there earlier; it was the anxiety that made the repression. But what sort of anxiety can it have been? Only anxiety in the face of a threatening external danger - that is to say, a realistic anxiety. It is true that the boy felt anxiety in the face of a demand by his libido - in this instance, anxiety at being in love with his mother; so the case was in fact one of neurotic anxiety. But this being in love only appeared to him as an internal danger, which he must avoid by renouncing that object, because it conjured up an external situation of danger. And in every case we examine we obtain the same result. It must be confessed that we were not prepared to find that internal instinctual danger would turn out to be a determinant and preparation for an external, real, situation of danger.
[1933a, 4692]

But we have not made any mention at all so far of what the real danger is that the child is afraid of as a result of being in love with his mother. The danger is the punishment of being castrated, of losing his genital organ. You will of course object that after all that is not a real danger. Our boys are not castrated because they are in love with their mothers during the phase of the Oedipus complex. But the matter cannot be dismissed so simply. Above all, it is not a question of whether castration is really carried out; what is decisive is that the danger is one that threatens from outside and that the child believes in it. He has some ground for this, for people threaten him often enough with cutting off his penis during the phallic phase, at the time of his early masturbation, and hints at that punishment must regularly find a phylogenetic reinforcement in him. It is our suspicion that during the human family's primaeval period castration used actually to be carried out by a jealous and cruel father upon growing boys, and that circumcision, which so frequently plays a part in puberty rites among primitive peoples, is a clearly recognizable relic of it. We are aware that here we are diverging widely from the general opinion; but we must hold fast to the view that fear of castration is one of the commonest and strongest motives for repression and thus for the formation of neuroses. The analysis of cases in which circumcision, though not, it is true, castration, has been carried out on boys as a cure or punishment for masturbation (a far from rare occurrence in Anglo-American society) has given our conviction a last degree of certainty. It is very tempting at this point to go more deeply into the castration complex, but I will stick to our subject.
[1933a, 4693]
None of the findings of psycho-analytic research has provoked such embittered denials, such fierce opposition - or such amusing contortions - on the part of critics as this indication of the childhood impulses towards incest which persist in the unconscious. An attempt has even been made recently to make out, in the face of all experience, that the incest should only be taken as 'symbolic'. Ferenczi (1912) has proposed an ingenious 'over-interpretation' of the Oedipus myth, based on a passage in one of Schopenhauer's letters.

Later studies have shown that the 'Oedipus complex', which was touched upon for the first time in the above paragraphs in the Interpretation of Dreams, throws a light of undreamt-of importance on the history of the human race and the evolution of religion and morality - (See my Totem and Taboo, 1912-13.)

These, then, must be the oldest and most powerful of human desires. We cannot hope to understand this or test our hypothesis on these two examples, so long as we are totally ignorant of the meaning and origin of the totemic system. But the wording of these two taboos and the fact of their concurrence will remind anyone acquainted with the findings of psycho-analytic investigations on individuals of something quite definite, which psycho-analysts regard as the centre-point of childhood wishes and as the nucleus of neuroses.

At the conclusion, then, of this exceedingly condensed inquiry, I should like to insist that its outcome shows that the beginnings of religion, morals, society and art converge in the Oedipus complex. This is in complete agreement with the psycho-analytic finding that the same complex constitutes the nucleus of all neuroses, so far as our present knowledge goes. It seems to me a most surprising discovery that the problems of social psychology, too, should prove soluble on the basis of one single concrete point - man's relation to his father. It is even possible that yet another psychological problem belongs in this same connection. I have often had occasion to point out that emotional ambivalence in the proper sense of the term - that is, the simultaneous existence of love and hate towards the same object - lies at the root of many important cultural institutions. We know nothing of the origin of this ambivalence. One possible assumption is that it is a fundamental phenomenon of our emotional life. But it seems to me quite worth considering another possibility, namely that originally it formed no part of our emotional life but was acquired by the human race in connection with their father-complex, precisely where the psycho-analytic examination of modern individuals still finds it revealed at its strongest.

Mythology will teach you that incest, which is supposed to be so much detested by humans, is unhesitatingly allowed to the gods. And you may learn from ancient history that incestuous sister marriage was a sanctified injuction upon the person of the Ruler (among the Egyptian Pharaohs and the Incas of Peru). What was in question was thus a privilege forbidden to the common herd.

Mother-incest was one of the crimes of Oedipus, parricide was the other. It may be remarked in passing that they are also the two great crimes proscribed by totemism, the first socio-religious institution of mankind.
Any estimate of psychoanalysis would be incomplete if it failed to make clear that, alone among the medical disciplines, it has the most extensive relations with the mental sciences, and that it is in a position to play a part of the same importance in the studies of religious and cultural history and in the sciences of mythology and literature as it is in psychiatry. This may seem strange when we reflect that originally its only object was the understanding and improvement of neurotic symptoms. But it is easy to indicate the starting-point of the bridge that leads over to the mental sciences. The analysis of dreams gave us an insight into the unconscious processes of the mind and showed us that the mechanisms which produce pathological symptoms are also operative in the normal mind. Thus psychoanalysis became a depth-psychology and capable as such of being applied to the mental sciences, and it was able to answer a good number of questions with which the academic psychology of consciousness was helpless to deal. At quite an early stage problems of human phylogenesis arose. It became clear that pathological function was often nothing more than a regression to an earlier stage in the development of normal function. C. G. Jung was the first to draw explicit attention to the striking similarity between the disordered phantasies of sufferers from dementia praecox and the myths of primitive peoples; while the present writer pointed out that the two wishes which combine to form the Oedipus complex coincide precisely with the two principal prohibitions imposed by totemism (not to kill the tribal ancestor and not to marry any woman belonging to one's own clan) and drew far-reaching conclusions from this fact. The significance of the Oedipus complex began to grow to gigantic proportions and it looked as though social order, morals, justice and religion had arisen together in the primaeval ages of mankind as reaction-formations against the Oedipus complex. Otto Rank threw a brilliant light upon mythology and the history of literature by the application of psycho-analytic views, as did Theodor Reik upon the history of morals and religions, while Dr. Pfister, of Zurich, aroused the interest of religious and secular teachers and demonstrated the importance of the psycho-analytic standpoint for education. Further discussion of these applications of psycho-analysis would be out of place here, and it is enough to say that the limits of their influence are not yet in sight.

In this way the Oedipus complex proves to be - as has already been conjectured in a historical sense¹ - the source of our individual ethical sense, our morality. The course of childhood development leads to an ever-increasing detachment from parents, and their personal significance for the super-ego recedes into the background. To the imagos they leave behind there are then linked the influences of teachers and authorities, self-chosen models and publicly recognized heroes, whose figures need no longer be introjected by an ego which has become more resistant. The last figure in the series that began with the parents is the dark power of Destiny which only the fewest of us are able to look upon as impersonal. There is little to be said against the Dutch writer Multatuli² when he replaces the Μοία [Destiny] of the Greeks by the divine pair Ἀλόγος ἄλογος· [Reason and necessity]; but all who transfer the guidance of the world to Providence, to God, or to God and Nature, arouse a suspicion that they still look upon these ultimate and remotest powers as a parental couple, in a mythological sense, and believe themselves linked to them by libidinal ties. In The Ego and the Id I made an attempt to derive mankind's realistic fear of death, too, from the same parental view of fate. It seems very hard to free oneself from it.

[1923a, 3929]

[1924c, 4080]
And now, as a third point, psycho-analysis has shown us, to our growing astonishment, the enormously important part played by what is known as the 'Oedipus complex' - that is, the emotional relation of a child to its two parents - in the mental life of human beings. Our astonishment diminishes when we realize that the Oedipus complex is the psychical correlate of two fundamental biological facts: the long period of the human child's dependence, and the remarkable way in which its sexual life reaches a first climax in the third to fifth years of life, and then, after a period of inhibition, sets in again at puberty. And here, the discovery was made that a third and extremely serious part of human intellectual activity, the part which has created the great institutions of religion, law, ethics, and all forms of civic life, has as its fundamental aim the enabling of the individual to master his Oedipus complex and to divert his libido from its infantile attachments into the social ones that are ultimately desired. The applications of psycho-analysis to the science of religion and sociology (e. g. by the present writer, Theodor Reik and Oskar Pfister), which have led to these findings, are still young and insufficiently appreciated; but it cannot be doubted that further studies will only confirm the certainty of these important conclusions.

[1924f, 4117]

The chief literary sources of my studies in this field were the well-known works of J. G. Frazer (Totemism and Exogamy and The Golden Bough), a mine of valuable facts and opinions. But Frazer effected little towards elucidating the problems of totemism; he had several times fundamentally altered his views on the subject, and the other ethnologists and prehistorians seemed in equal uncertainty and disagreement. My starting-point was the striking correspondence between the two taboo-ordinances of totemism (not to kill the totem and not to have sexual relations with any woman of the same totem-clan) and the two elements of the Oedipus complex (getting rid of the father and taking the mother to wife). I was therefore tempted to equate the totem-animal with the father; and in fact primitive peoples themselves do this explicitly, by honouring it as the forefather of the clan. There next came to my help two facts from psycho-analysis, a lucky observation of a child made by Ferenczi, which enabled me to speak of an 'infantile return of totemism', and the analysis of early animal-phobias in children, which so often showed that the animal was a substitute for the father, a substitute on to which the fear of the father derived from the Oedipus complex had been displaced. Not much was lacking to enable me to recognize the killing of the father as the nucleus of totemism and the starting-point in the formation of religion.

[1925d, 4240]
This missing element was supplied when I became acquainted with W. Robertson Smith's work, *The Religion of the Semites*. Its author (a man of genius who was both a physicist and an expert in biblical researches) introduced the so-called 'totem meal' as an essential part of the totemic religion. Once a year the totem animal, which was at other times regarded as sacred, was solemnly killed in the presence of all the members of the clan, was devoured and was then mourned over. The mourning was followed by a great festival. When I further took into account Darwin's conjecture that men originally lived in hordes, each under the domination of a single powerful, violent and jealous male, there rose before me out of all these components the following hypothesis, or, I would rather say, vision. The father of the primal horde, since he was an unlimited despot, had seized all the women for himself; his sons, being dangerous to him as rivals, had been killed or driven away. One day, however, the sons came together and united to overwhelm, kill, and devour their father, who had been their enemy but also their ideal. After the deed they were unable to take over their heritage since they stood in one another's way. Under the influence of failure and remorse they learned to come to an agreement among themselves; they banded themselves into a clan of brothers by the help of the ordinances of totemism, which aimed at preventing a repetition of such a deed, and they jointly undertook to forgo the possession of the women on whose account they had killed their father. They were then driven to finding strange women, and this was the origin of the exogamy which is so closely bound up with totemism. The totem meal was the festival commemorating the fearful deed from which sprang man's sense of guilt (or 'original sin') and which was the beginning at once of social organization, of religion and of ethical restrictions.

[1925d, 4240]

Nothing, however, deserves more notice than the fact that children regularly direct their sexual wishes towards their nearest relatives - in the first place, therefore, towards their father and mother, and afterwards towards their brothers and sisters. The first object of a boy's love is his mother, and of a girl's her father (except in so far as an innate bisexual disposition favours the simultaneous presence of the contrary attitude). The other parent is felt as a disturbing rival and not infrequently viewed with strong hostility. You must understand me aright. What I mean to say is not that the child wants to be treated by its favourite parent merely with the kind of affection which we adults like to regard as the essence of the parent-child relation. No, analysis leaves us in no doubt that the child's wishes extend beyond such affection to all that we understand by sensual satisfaction - so far, that is, as the child's powers of imagination allow. It is easy to see that the child never guesses the actual facts of sexual intercourse; he replaces them by other notions derived from his own experience and feelings. As a rule his wishes culminate in the intention to bear, or in some in definable way, to procreate a baby. Boys, too, in their ignorance, do not exclude themselves from the wish to bear a baby. We give the whole of this mental structure the name of 'Oedipus complex', after the familiar Greek legend. With the end of the early sexual period it should normally be given up, should radically disintegrate and become transformed; and the results of this transformation are destined for important functions in later mental life. But as a rule this is not effected radically enough, in which case puberty brings about a revival of the complex, which may have serious consequences.

[1926e, 4355]

The most important conflict with which a small child is faced is his relation to his parents, the 'Oedipus complex'; it is in attempting to grapple with this problem that those destined to suffer from a neurosis habitually come to grief. The reactions against the instinctual demands of the Oedipus complex are the source of the most precious and socially important achievements of the human mind; and this holds true not only in the life of individuals but probably also in the history of the human species as a whole. The super-ego, too, the moral agency which dominates the ego, has its origin in the process of overcoming the Oedipus complex.

[1926f, 4406]
We now observe that the store of religious ideas includes not only wish-fulfilments but important historical recollections. This concurrent influence of past and present must give religion a truly incomparable wealth of power. But perhaps with the help of an analogy yet another discovery may begin to dawn on us. Though it is not a good plan to transplant ideas far from the soil in which they grew up, yet here is a conformity which we cannot avoid pointing out. We know that a human child cannot successfully complete its development to the civilized stage without passing through a phase of neurosis sometimes of greater and sometimes of less distinctness. This is because so many instinctual demands which will later be unserviceable cannot be suppressed by the rational operation of the child's intellect but have to be tamed by acts of repression, behind which, as a rule, lies the motive of anxiety. Most of these infantile neuroses are overcome spontaneously in the course of growing up, and this is especially true of the obsessional neuroses of childhood. The remainder can be cleared up later still by psychoanalytic treatment. In just the same way, one might assume, humanity as a whole, in its development through the ages, fell into states analogous to the neuroses, and for the same reasons - namely because in the times of its ignorance and intellectual weakness the instinctual renunciations indispensable for man's communal existence had only been achieved by it by means of purely affective forces. The precipitates of these processes resembling repression which took place in prehistoric times still remained attached to civilization for long periods. Religion would thus be the universal obsessional neurosis of humanity; like the obsessional neurosis of children, it arose out of the Oedipus complex, out of the relation to the father. If this view is right, it is to be supposed that a turning-away from religion is bound to occur with the fatal inevitability of a process of growth, and that we find ourselves at this very juncture in the middle of that phase of development. Our behaviour should therefore be modelled on that of a sensible teacher who does not oppose an impending new development but seeks to ease its path and mitigate the violence of its irruption. Our analogy does not, to be sure, exhaust the essential nature of religion. If, on the one hand, religion brings with it obsessional restrictions, exactly as an individual obsessional neurosis does, on the other hand it comprises a system of wishful illusions together with a disavowal of reality, such as we find in an isolated form nowhere else but in amentia, in a state of blissful hallucinatory confusion. But these are only analogies, by the help of which we endeavour to understand a social phenomenon; the pathology of the individual does not supply us with a fully valid counterpart.

[1927c, 4452]

We may suppose, therefore, that this was the way in which things happened. The sight of a woman's dead body, naked or on the point of being stripped, reminded the young man of his mother. It roused in him a longing for his mother which sprang from his Oedipus complex, and this was immediately completed by a feeling of indignation against his father. His ideas of 'father' and 'God' had not yet become widely separated; so that his desire to destroy his father could become conscious as doubt in the existence of God and could seek to justify itself in the eyes of reason as indignation about the ill-treatment of a mother object. It is of course typical for a child to regard what his father does to his mother in sexual intercourse as ill-treatment. The new impulse, which was displaced into the sphere of religion, was only a repetition of the Oedipus situation and consequently soon met with a similar fate. It succumbed to a powerful opposing current. During the actual conflict the level of displacement was not maintained: there is no mention of arguments in justification of God, nor are we told what the infallible signs were by which God proved his existence to the doubter. The conflict seems to have been unfolded in the form of a hallucinatory psychosis: inner voices were heard which uttered warnings against resistance to God. But the outcome of the struggle was displayed once again in the sphere of religion and it was of a kind predetermined by the fate of the Oedipus complex: complete submission to the will of God the Father. The young man became a believer and accepted everything he had been taught since his childhood about God and Jesus Christ. He had had a religious experience and had undergone a conversion.

[1928a, 4550]
All of this is so simple and straightforward that we cannot but ask ourselves whether by understanding this case we have thrown any light at all on the psychology of conversion in general. I may refer the reader to an admirable volume on the subject by Sante de Sanctis (1924), which incidentally takes all the findings of psycho-analysis into account. Study of this work confirms our expectation that by no means every case of conversion can be understood so easily as this one. In no respect, however, does our case contradict the views arrived at on the subject by modern research. The point which our present observation throws into relief is the manner in which the conversion was attached to a particular determining event, which caused the subject's scepticism to flare up for a last time before being finally extinguished.

[1928a, 4550]

The picture of an ego which mediates between the id and the external world, which takes over the instinctual demands of the former in order to lead them to satisfaction, which derives perceptions from the latter and uses them as memories, which, intent on its self-preservation, puts itself in defence against excessively strong claims from both sides and which, at the same time, is guided in all its decisions by the injunctions of a modified pleasure principle - this picture in fact applies to the ego only up to the end of the first period of childhood, till about the age of five. At about that time an important change has taken place. A portion of the external world has, at least partially, been abandoned as an object and has instead, by identification, been taken into the ego and thus become an integral part of the internal world. This new psychical agency continues to carry on the functions which have hitherto been performed by the people in the external world: it observes the ego, gives it orders, judges it and threatens it with punishments, exactly like the parents whose place it has taken. We call this agency the super-ego and are aware of it in its judicial functions as our conscience. It is a remarkable thing that the super-ego often displays a severity for which no model has been provided by the real parents, and moreover that it calls the ego to account not only for its deeds but equally for its thoughts and unexecuted intentions, of which the super-ego seems to have knowledge. This reminds us that the hero of the Oedipus legend too felt guilty for his deeds and submitted himself to self-punishment, although the coercive power of the oracle should have acquitted him of guilt in our judgement and his own. The super-ego is in fact the heir to the Oedipus complex and is only established after that complex has been disposed of. For that reason its excessive severity does not follow a real model but corresponds to the strength of the defence used against the temptation of the Oedipus complex. Some suspicion of this state of things lies, no doubt, at the bottom of the assertion made by philosophers and believers that the moral sense is not instilled into men by education or acquired by them in their social life but is implanted in them from a higher source.

[1940a [1938], 5010]
Let us consider first the relation between father and son. The sanctity which we attribute to the rules laid down in the Decalogue has, I think, blunted our powers of perceiving the real facts. We seem scarcely to venture to observe that the majority of mankind disobey the Fifth Commandment. Alike in the lowest and in the highest strata of human society filial piety is wont to give way to other interests. The obscure information which is brought to us by mythology and legend from the primaeval ages of human society gives an unpleasing picture of the father's despotic power and of the ruthlessness with which he made use of it. Kronos devoured his children, just as the wild boar devours the sow's litter; while Zeus emasculated his father² and made himself ruler in his place. The more unrestricted was the rule of the father in the ancient family, the more must the son, as his destined successor, have found himself in the position of an enemy, and the more impatient must he have been to become ruler himself though his father's death. Even in our middle-class families fathers are as a rule inclined to refuse their sons independence and the means necessary to secure it and thus to foster the growth of the germ of hostility which is inherent in their relation. A physician will often be in a position to notice how a son's grief at the loss of his father cannot suppress his satisfaction at having at length won his freedom. In our society to-day fathers are apt to cling desperately to what is left of a now sadly antiquated protestas patris familias; and an author who, like Ibsen, brings the immemorial struggle between fathers and sons into prominence in his writings may be certain of producing his effect.

[1900a, 735]
Another of the great creations of tragic poetry, Shakespeare's *Hamlet*, has its roots in the same soil as *Oedipus Rex*. But the changed treatment of the same material reveals the whole difference in the mental life of these two widely separated epochs of civilization: the secular advance of repression in the emotional life of mankind. In *Oedipus* the child's wishful phantasy that underlies it is brought into the open and realized as it would be in a dream. In *Hamlet* it remains repressed; and - just as in the case of a neurosis - we only learn of its existence from its inhibiting consequences. Strangely enough, the overwhelming effect produced by the more modern tragedy has turned out to be compatible with the fact that people have remained completely in the dark as to the hero's character. The play is built up on Hamlet's hesitations over fulfilling the task of revenge that is assigned to him; but its text offers no reasons or motives for these hesitations and an immense variety of attempts at interpreting them have failed to produce a result. According to the view which was originated by Goethe and is still the prevailing one to-day, Hamlet represents the type of man whose power of direct action is paralysed by an excessive development of his intellect. (He is 'sicklied o'er with the pale cast of thought'.) According to another view, the dramatist has tried to portray a pathologically irresolute character which might be classed as neurasthenic. The plot of the drama shows us, however, that Hamlet is far from being represented as a person incapable of taking any action. We see him doing so on two occasions: first in a sudden outburst of temper, when he runs his sword through the eavesdropper behind the arras, and secondly in a premeditated and even crafty fashion, when, with all the callousness of a Renaissance prince, he sends the two courtiers to the death that had been planned for himself. What is it, then, that inhibits him in fulfilling the task set him by his father's ghost? The answer, once again, is that it is the peculiar nature of the task. Hamlet is able to do anything - except take vengeance on the man who did away with his father and took that father's place with his mother, the man who shows him the repressed wishes of his own childhood realized. Thus the loathing which should drive him on to revenge is replaced in him by self-reproaches, by scruples of conscience, which remind him that he himself is literally no better than the sinner whom he is to punish. Here I have translated into conscious terms what was bound to remain unconscious in Hamlet's mind; and if any one is inclined to call him a hyster, I can only accept the fact as one that is implied by my interpretation. The distaste for sexuality expressed by Hamlet in his conversation with Ophelia fits in very well with this: the same distaste which was destined to take possession of the poet's mind more and more during the years that followed, and which reached its extreme expression in *Timon of Athens*. For it can of course only be the poet's own mind which confronts us in Hamlet. I observe in a book on Shakespeare by Georg Brandes (1896) a statement that *Hamlet* was written immediately after the death of Shakespeare's father (in 1601), that is, under the immediate impact of his bereavement and, as we may well assume, while his childhood feelings about his father had been freshly revived. It is known, too, that Shakespeare's own son who died at an early age bore the name of 'Hamnet', which is identical with 'Hamlet'. Just as *Hamlet* deals with the relation of a son to his parents, so *Macbeth* (written at approximately the same period) is concerned with the subject of childlessness. But just as all neurotic symptoms, and, for that matter, dreams, are capable of being 'over-interpreted' and indeed need to be, if they are to be fully understood, so all genuinely creative writings are the product of more than a single motive and more than a single impulse in the poet's mind, and are open to more than a single interpretation. In what I have written I have only attempted to interpret the deepest layer of impulses in the mind of the creative writer.¹

¹ [Footnote added 1919:] The above indications of a psycho-analytic explanation of *Hamlet* have since been amplified by Ernest Jones and defended against the alternative views put forward in the literature of the subject. (See Jones, 1910a.) - [Added 1930:] Incidentally, I have in the meantime ceased to believe that the author of Shakespeare's works was the man from Stratford. - [Added 1919:] Further attempts at an analysis of *Macbeth* will be found in a paper of mine and in one by Jekels (1917). [1900a, 743]
Dreams, then, are often most profound when they seem most crazy. In every epoch of history those who have had something to say but could not say it without peril have eagerly assumed a fool's cap. The audience at whom their forbidden speech was aimed tolerated it more easily if they could at the same time laugh and flatter themselves with the reflection that the unwelcome words were clearly nonsensical. The Prince in the play, who had to disguise himself as a madman, was behaving just as dreams do in reality; so that we can say of dreams what Hamlet said of himself, concealing the true circumstances under a cloak of wit and unintelligibility: 'I am but mad north-north-west: when the wind is southerly, I know a hawk from a hand-saw!'

I do not propose at this point to discuss how it is that in such circumstances as these a recent occasion for the generation of an affect can hark back to an infantile situation and be replaced by that situation as far as the production of affect is concerned. This question forms part of the psychology of unconscious thinking, and would find its proper place in a psychological elucidation of the neuroses. For the purposes of dream-interpretation let us assume that a childhood memory arose, or was constructed in phantasy, with some such content as the following. The two children had a dispute about some object. (What the object was may be left an open question, though the memory or pseudo-memory had a quite specific one in view.) Each of them claimed to have *got there before the other* and therefore to have a better right to it. They came to blows and might prevailed over right. On the evidence of the dream, I may myself have been aware that I was in the wrong ('*I myself noticed the mistake*'). However, this time I was the stronger and remained in possession of the field. The vanquished party hurried to his grandfather - my father - and complained about me, and I defended myself in the words which I know from my father's account: 'I hit him 'cos he hit me.' This memory, or more probably phantasy, which came into my mind while I was analysing the dream - without further evidence I myself could not tell how - constituted an intermediate element in the dream-thoughts, which gathered up the emotions raging in them as a well collects the water that flows into it. From this point the dream-thoughts proceeded along some such lines as these: 'It serves you right if you had to make way for me. Why did you try to push *me* out of the way? I don't need you, I can easily find someone else to play with', and so on. These thoughts now entered upon the paths which led to their representation in the dream. There had been a time when I had had to reproach my friend Josef for an attitude of this same kind: 'Ôte-toi que je m'y mette!' He had followed in my footsteps as demonstrator in Brücke's laboratory, but promotion there was slow and tedious. Neither of Brücke's two assistants was inclined to budge from his place, and youth was impatient. My friend, who knew that he could not expect to live long, and whom no bonds of intimacy attached to his immediate superior, sometimes gave loud expression to his impatience, and, since this superior was seriously ill, P.'s wish to have him out of the way might have an uglier meaning than the mere hope for the man's promotion. Not unnaturally, a few years earlier, I myself had nourished a still livelier wish to fill a vacancy. Wherever there is rank and promotion the way lies open for wishes that call for suppression. Shakespeare's Prince Hal could not, even at his father's sick-bed, resist the temptation of trying on the crown. But, as was to be expected, the dream punished my friend, and not me, for this callous wish.
(b) It seems to me that there is a widespread and erroneous impression among my colleagues that this technique of searching for the origins of an illness and removing its manifestations by that means is an easy one which can be practised off-hand, as it were. I conclude this from the fact that not one of all the people who have shown an interest in my therapy and passed definite judgements upon it has ever asked me how I actually go about it. There can be only one reason for this: that they think there is nothing to enquire about, that the thing is perfectly self-evident. Again, I am now and then astonished to hear that in this or that department of a hospital a young assistant has received an order from his chief to undertake a 'psycho-analysis' of a hysterical patient. I am sure he would not be allowed to examine an extirpated tumour unless he had convinced his chiefs that he was conversant with histological technique. Similarly, reports reach my ears that this or that colleague has arranged appointments with a patient in order to undertake a mental treatment of the case, though I am certain he knows nothing of the technique of any such therapy. His expectation must be therefore that the patient will make him a present of his secrets, or perhaps that he is looking for salvation in some sort of confession or confidence. I should not be surprised if a patient were injured rather than benefited by being treated in such a fashion. For it is not so easy to play upon the instrument of the mind. I am reminded on such occasions of the words of a world-famous neurotic - though it is true that he was never treated by a physician but existed only in a poet's imagination - Hamlet, Prince of Denmark. The King has ordered two courtiers, Rosenkranz and Guildenstern, to follow him, to question him and drag the secret of his depression out of him. He wards them off. Then some recorders are brought on the stage and Hamlet, taking one of them, begs one of his tormentors to play upon it, telling him that it is as easy as lying. The courtier excuses himself, for he knows no touch of the instrument, and when he cannot be persuaded to try it, Hamlet finally breaks out with these words: 'Why, look you now, how unworthy a thing you make of me! You would play upon me; . . . you would pluck out the heart of my mystery; you would sound me from my lowest note to the top of my compass; and there is much music, excellent voice, in this little organ; yet you cannot make it speak. 'Sblood, do you think I am easier to be played on than a pipe? Call me what instrument you will, though you can fret me, you cannot play upon me.' (Act III, Scene 2.)

[1905a, 1567]

The first of these modern dramas is Hamlet. It has as its subject the way in which a man who has so far been normal becomes neurotic owing to the peculiar nature of the task by which he is faced, a man, that is, in whom an impulse that has hitherto been successfully suppressed endeavours to make its way into action. Hamlet is distinguished by three characteristics which seem important in connection with our present discussion. (1) The hero is not psychopathic, but only becomes psychopathic in the course of the action of the play. (2) The repressed impulse is one of those which are similarly repressed in all of us, and the repression of which is part and parcel of the foundations of our personal evolution. It is this repression which is shaken up by the situation in the play. As a result of these two characteristics it is easy for us to recognize ourselves in the hero: we are susceptible to the same conflict as he is, since 'a person who does not lose his reason under certain conditions can have no reason to lose'. (3) It appears as a necessary precondition of this form of art that the impulse that is struggling into consciousness, however clearly it is recognizable, is never given a definite name; so that in the spectator too the process is carried through with his attention averted, and he is in the grip of his emotions instead of taking stock of what is happening. A certain amount of resistance is no doubt saved in this way, just as, in an analytic treatment, we find derivatives of the repressed material reaching consciousness, owing to a lower resistance, while the repressed material itself is unable to do so. After all, the conflict in Hamlet is so effectively concealed that it was left to me to unearth it.

[1942a [1905], 1611]
It may be in consequence of disregarding these three preconditions that so many other psychopathic characters are as unserviceable on the stage as they are in real life. For the victim of a neurosis is someone into whose conflict we can gain no insight if we first meet it in a fully established state. But, per contra, if we recognize the conflict, we forget that he is a sick man, just as, if he himself recognizes it, he ceases to be ill. It would seem to be the dramatist's business to induce the same illness in us; and this can best be achieved if we are made to follow the development of the illness along with the sufferer. This will be especially necessary where the repression does not already exist in us but has first to be set up; and this represents a step further than Hamlet in the use of neurosis on the stage. If we are faced by an unfamiliar and fully established neurosis, we shall be inclined to send for the doctor (just as we do in reality) and pronounce the character inadmissible to the stage.

At this point the tension in which the author has hitherto held us grows for a moment into a painful sense of bewilderment. It is not only our hero who has evidently lost his balance; we too have lost our bearings in the face of the apparition of Gradiva, who was first a marble figure and then an imaginary one. Is she a hallucination of our hero, led astray by his delusions? Is she a 'real' ghost? or a living person? Not that we need believe in ghosts when we draw up this list. The author, who has called his story a 'phantasy', has found no occasion so far for informing us whether he intends to leave us in our world, decried for being prosaic and governed by the laws of science, or whether he wishes to transport us into another and imaginary world, in which spirits and ghosts are given reality. As we know from the examples of Hamlet and Macbeth, we are prepared to follow him there without hesitation. If so, the imaginative archaeologist's delusion would have to be measured by another standard. Indeed, when we consider how improbable it must be that a real person could exist who bore an exact resemblance to the antique sculpture, our list of alternatives shrinks to two: a hallucination or a mid-day ghost. A small detail in the account soon cancels the first possibility. A large lizard was lying motionless, stretched out in the sunshine, but fled at the approach of Gradiva's foot and darted away across the lava paving-stones. So it was no hallucination, but something outside our dreamer's mind. But could the reality of a rediviva startle a lizard?

Let us return to the sexual development of children. We have some arrears to make up owing to our having paid more attention to the somatic than to the mental phenomena of sexual life. The child's first choice of an object, which derives from its need for help, claims our further interest. Its choice is directed in the first instance to all those who look after it, but these soon give place to its parents. Children's relations to their parents, as we learn alike from direct observations of children and from later analytic examination of adults, are by no means free from elements of accompanying sexual excitation. The child takes both of its parents, and more particularly one of them, as the object of its erotic wishes. In so doing, it usually follows some indication from its parents, whose affection bears the clearest characteristics of a sexual activity, even though of one that is inhibited in its aims. As a rule a father prefers his daughter and a mother her son; the child reacts to this by wishing, if he is a son, to take his father's place, and, if she is a daughter, her mother's. The feelings which are aroused in these relations between parents and children and in the resulting ones between brothers and sisters are not only of a positive or affectionate kind but also of a negative or hostile one. The complex which is thus formed is doomed to early repression; but it continues to exercise a great and lasting influence from the unconscious. It is to be suspected that, together with its extensions, it constitutes the nuclear complex of every neurosis, and we may expect to find it no less actively at work in other regions of mental life. The myth of King Oedipus, who killed his father and took his mother to wife, reveals, with little modification, the infantile wish, which is later opposed and repudiated by the barrier against incest. Shakespeare's Hamlet is equally rooted in the soil of the incest-complex, but under a better disguise.

There has been little opportunity in the preceding pages for showing how new light can be thrown upon the facts of social psychology by the adoption of a psycho-analytic method of approach: for the horror of incest displayed by savages has long been recognized as such and stands in need of no further interpretation. All that I have been able to add to our understanding of it is to emphasize the fact that it is essentially an infantile feature and that it reveals a striking agreement with the mental life of neurotic patients. Psycho-analysis has taught us that a boy’s earliest choice of objects for his love is incestuous and that those objects are forbidden ones - his mother and his sister. We have learnt, too, the manner in which, as he grows up, he liberates himself from this incestuous attraction. A neurotic, on the other hand, invariably exhibits some degree of psychical infantilism. He has either failed to get free from the psychosexual conditions that prevailed in his childhood or he has returned to them - two possibilities which may be summed up as developmental inhibition and regression. Thus incestuous fixations of libido continue to play (or begin once more to play) the principal part in his unconscious mental life. We have arrived at the point of regarding a child’s relation to his parents, dominated as it is by incestuous longings, as the nuclear complex of neurosis. This revelation of the importance of incest in neurosis is naturally received with universal scepticism by adults and normal people. Similar expressions of disbelief, for instance, inevitably greet the writings of Otto Rank, which have brought more and more evidence to show the extent to which the interest of creative writers centres round the theme of incest and how the same theme, in countless variations and distortions, provides the subject-matter of poetry. We are driven to believe that this rejection is principally a product of the distaste which human beings feel for their early incestuous wishes, now over taken by repression. It is therefore of no small importance that we are able to show that these same incestuous wishes, which are later destined to become unconscious, are still regarded by savage peoples as immediate perils against which the most severe measures of defence must be enforced.

[1912-1913, 2665]

Let us consider Shakespeare’s masterpiece, Hamlet, a play, now over three centuries old.¹ I have followed the literature of psycho-analysis closely, and I accept its claim that it was not until the material of the tragedy had been traced back by psycho-analysis to the Oedipus theme that the mystery of its effect was at last explained. But before this was done, what a mass of differing and contradictory interpretative attempts, what a variety of opinions about the hero’s character and the dramatist’s intentions! Does Shakespeare claim our sympathies on behalf of a sick man, or of an ineffectual weakling, or of an idealist who is merely too good for the real world? And how many of these interpretations leave us cold! - so cold that they do nothing to explain the effect of the play and rather incline us to the view that its magical appeal rests solely upon the impressive thoughts in it and the splendour of its language. And yet, do not those very endeavours speak for the fact that we feel the need of discovering in it some source of power beyond them alone?

[1914b, 2846]
It would be equally fruitless from a scientific and a therapeutic point of view to contradict a patient who brings these accusations against his ego. He must surely be right in some way and be describing something that is as it seems to him to be. Indeed, we must at once confirm some of his statements without reservation. He really is as lacking in interest and as incapable of love and achievement as he says. But that, as we know, is secondary; it is the effect of the internal work which is consuming his ego work which is unknown to us but which is comparable to the work of mourning. He also seems to us justified in certain other self-accusations; it is merely that he has a keener eye for the truth than other people who are not melancholic. When in his heightened self-criticism he describes himself as petty, egoistic, dishonest, lacking in independence, one whose sole aim has been to hide the weaknesses of his own nature, it may be, so far as we know, that he has come pretty near to understanding himself; we only wonder why a man has to be ill before he can be accessible to a truth of this kind. For there can be no doubt that if anyone holds and expresses to others an opinion of himself such as this (an opinion which Hamlet held both of himself and of everyone else ¹), he is ill, whether he is speaking the truth or whether he is being more or less unfair to himself. Nor is it difficult to see that there is no correspondence, so far as we can judge, between the degree of self-abasement and its real justification. A good, capable, conscientious woman will speak no better of herself after she develops melancholia than one who is in fact worthless; indeed, the former is perhaps more likely to fall ill of the disease than the latter, of whom we too should have nothing good to say. Finally, it must strike us that after all the melancholic does not behave in quite the same way as a person who is crushed by remorse and self-reproach in a normal fashion. Feelings of shame in front of other people, which would more than anything characterize this latter condition, are lacking in the melancholic, or at least they are not prominent in him. One might emphasize the presence in him of an almost opposite trait of insistent communicativeness which finds satisfaction in self-exposure.

¹ The presence of the theme of incest in Rosmersholm has already been demonstrated by the same arguments as mine in Otto Rank's extremely comprehensive Das Inzest-Motiv in Dichtung und Sage (1912).

It cannot be said that the world has shown much gratitude to psycho-analytic research for its revelation of the Oedipus complex. On the contrary, the discovery has provoked the most violent opposition among adults; and those who had neglected to take part in the repudiation of this proscribed and tabooed emotional relationship made up for their fault later by depriving the complex of its value through twisted re-interpretations. It is my unaltered conviction that there is nothing in this to be disavowed or glossed over. We must reconcile ourselves to the fact which was recognized by the Greek legend itself as an inevitable fate. It is once again an interesting fact that the Oedipus complex, which has been rejected from real life, has been left to imaginative writing, has been placed freely, as it were, at its disposal. Otto Rank has shown in a careful study how the Oedipus complex has provided dramatic authors with a wealth of themes in endless modifications, softenings and disguises - in distortions, that is to say, of the kind which we are already familiar with as the work of a censorship. We may therefore also ascribe this Oedipus complex to dreamers who have been fortunate enough to escape conflicts with their parents in later life. And, intimately linked with it, we find what we call the 'castration complex', the reaction to the threats against the child aimed at putting a stop to his early sexual activities and attributed to his father.

[1916-1917, 3296]
As you may imagine, Gentlemen, I have passed very cursorily over a great number of considerations of both practical and theoretical importance connected with the Oedipus complex. Nor shall I enter into its variations or its possible reversal. Among its remoter connections I will only give you a further hint that it has turned out to have a highly important effect on literary production. In a valuable work Otto Rank has shown that dramatists of every period have chosen their material in the main from the Oedipus and incest complex and its variations and disguises. Nor should it be allowed to pass unnoticed that the two criminal wishes of the Oedipus complex were recognized as the true representatives of the uninhibited life of the instincts long before the time of psycho-analysis. Among the writings of the Encyclopaedist Diderot you will find a celebrated dialogue, *Le neveu Rameau*, which was rendered into German by no less a person than Goethe. There you may read this remarkable sentence: 'Si le petit sauvage était abandonné à lui-même, qu'il conservât toute son imbécillité, et qu'il réunît au peu de raison de l'enfant au berceau la violence des passions de l'homme de trente ans, il tordrait le col à son père et coucherait avec sa mère.'¹

A number of suggestions came to me out of the Oedipus complex, the ubiquity of which gradually dawned on me. The poet's choice, or his invention, of such a terrible subject seemed puzzling; and so too did the overwhelming effect of its dramatic treatment, and the general nature of such tragedies of destiny. But all of this became intelligible when one realized that a universal law of mental life had here been captured in all its emotional significance. Fate and the oracle were no more than materializations of an internal necessity; and the fact of the hero's sinning without his knowledge and against his intentions was evidently a right expression of the unconscious nature of his criminal tendencies. From understanding this tragedy of destiny it was only a step further to understanding a tragedy of character - *Hamlet*, which had been admired for three hundred years without its meaning being discovered or its author's motives guessed. It could scarcely be a chance that this neurotic creation of the poet should have come to grief, like his numberless fellows in the real world, over the Oedipus complex. For Hamlet was faced with the task of taking vengeance on another for the two deeds which are the subject of the Oedipus desires; and before that task his arm was paralysed by his own obscure sense of guilt. Shakespeare wrote *Hamlet* very soon after his father's death.¹ The suggestions made by me for the analysis of this tragedy were fully worked out later on by Ernest Jones. And the same example was afterwards used by Otto Rank as the starting-point for his investigation of the choice of material made by dramatists. In his large volume on the incest theme (Rank, 1912) he was able to show how often imaginative writers have taken as their subject the themes of the Oedipus situation, and traced in the different literatures of the world the way in which the material has been transformed, modified, and softened.

It can scarcely be owing to chance that three of the masterpieces of the literature of all time - the *Oedipus Rex* of Sophocles, Shakespeare's *Hamlet* and Dostoevsky's *The Brothers Kamarazov* - should all deal with the same subject, parricide. In all three, moreover, the motive for the deed, sexual rivalry for a woman, is laid bare.
The most straightforward is certainly the representation in the drama derived from the Greek legend. In this it is still the hero himself who commits the crime. But poetic treatment is impossible without softening and disguise. The naked admission of an intention to commit parricide, as we arrive at it in analysis, seems intolerable without analytic preparation. The Greek drama, while retaining the crime, introduces the indispensable toning-down in a masterly fashion by projecting the hero's unconscious motive into reality in the form of a compulsion by a destiny which is alien to him. The hero commits the deed unintentionally and apparently uninfluenced by the woman; this latter element is however taken into account in the circumstance that the hero can only obtain possession of the queen mother after he has repeated his deed upon the monster who symbolizes the father. After his guilt has been revealed and made conscious, the hero makes no attempt to exculpate himself by appealing to the artificial expedient of the compulsion of destiny. His crime is acknowledged and punished as though it were a full and conscious one - which is bound to appear unjust to our reason, but which psychologically is perfectly correct.

[1928b, 4564]

In the English play the presentation is more indirect; the hero does not commit the crime himself; it is carried out by someone else, for whom it is not parricide. The forbidden motive of sexual rivalry for the woman does not need, therefore, to be disguised. Moreover, we see the hero's Oedipus complex, as it were, in a reflected light, by learning the effect upon him of the other's crime. He ought to avenge the crime, but finds himself, strangely enough, incapable of doing so. We know that it is his sense of guilt that is paralysing him; but, in a manner entirely in keeping with neurotic processes, the sense of guilt is displaced on to the perception of his inadequacy for fulfilling his task. There are signs that the hero feels this guilt as a superindividual one. He despises others no less than himself: 'Use every man after his desert, and who should 'scape whipping?'

[1928b, 4564]
The Russian novel goes a step further in the same direction. There also the murder is committed by someone else. This other person, however, stands to the murdered man in the same filial relation as the hero, Dmitri; in this other person's case the motive of sexual rivalry is openly admitted; he is a brother of the hero's, and it is a remarkable fact that Dostoevsky has attributed to him his own illness, the alleged epilepsy, as though he were seeking to confess that the epileptic, the neurotic, in himself was a parricide. Then, again, in the speech for the defence at the trial, there is the famous mockery of psychology - it is a 'knife that cuts both ways': a splendid piece of disguise, for we have only to reverse it in order to discover the deepest meaning of Dostoevsky's view of things. It is not psychology that deserves the mockery, but the procedure of judicial enquiry. It is a matter of indifference who actually committed the crime; psychology is only concerned to know who desired it emotionally and who welcomed it when it was done. And for that reason all of the brothers, except the contrasted figure of Alyosha, are equally guilty - the impulsive sensualist, the sceptical cynic and the epileptic criminal. In The Brothers Karamazov there is one particularly revealing scene. In the course of his talk with Dmitri, Father Zossima recognizes that Dmitri is prepared to commit parricide, and he bows down at his feet. It is impossible that this can be meant as an expression of admiration; it must mean that the holy man is rejecting the temptation to despise or detest the murderer and for that reason humbles himself before him. Dostoevsky's sympathy for the criminal is, in fact, boundless; it goes far beyond the pity which the unhappy wretch has a right to, and reminds us of the 'holy awe' with which epileptics and lunatics were regarded in the past. A criminal is to him almost a Redeemer, who has taken on himself the guilt which must else have been borne by others. There is no longer any need for one to murder, since he has already murdered; and one must be grateful to him, for, except for him, one would have been obliged oneself to murder. That is not kindly pity alone, it is identification on the basis of similar murderous impulses - in fact, a slightly displaced narcissism. (In saying this, we are not disputing the ethical value of this kindliness.) This may perhaps be quite generally the mechanism of kindly sympathy with other people, a mechanism which one can discern with especial ease in this extreme case of a guilt-ridden novelist. There is no doubt that this sympathy by identification was a decisive factor in determining Dostoevsky's choice of material. He dealt first with the common criminal (whose motives are egotistical) and the political and religious criminal; and not until the end of his life did he come back to the primal criminal, the parricide, and use him, in a work of art, for making his confession. [1928b, 4565]

In Dostoevsky's great novel, The Brothers Karamazov, the Oedipus situation stands at the focal point of interest. Old Karamazov has made himself detested by his sons through heartless oppression; in the eyes of one of them he is, in addition, a powerful rival for the woman he desires. This son, Dmitri, makes no secret of his intention to avenge himself on his father by force. It is therefore natural that after his father has been murdered and robbed he should be accused as his murderer and, despite all protestations of his innocence, condemned. And yet Dmitri is innocent; another of the brothers has done the deed. A dictum that has become famous occurs during the trial scene in this novel: 'Psychology is a knife that cuts both ways.' [1931d, 4610]
That the redeemer had sacrificed himself without guilt was evidently a tendentious distortion, which offered difficulties to logical understanding. For how could someone guiltless of the act of murder take on himself the guilt of the murderers by allowing himself to be killed? In the historical reality there was no such contradiction. The 'redeemer' could be none other than the most guilty person, the ringleader of the company of brothers who had overpowered their father. We must in my judgement leave it undecided whether there was such a chief rebel and ringleader. That is possible; but we must also bear in mind that each one of the company of brothers certainly had a wish to commit the deed by himself alone and so to create an exceptional position for himself and to find a substitute for his identification with the father which was having to be given up and which was becoming merged in the community. If there was no such ringleader, then Christ was the heir to a wishful phantasy which remained unfulfilled; if there was one, then he was his successor and his reincarnation. But no matter whether what we have here is a phantasy or the return of a forgotten reality, in any case the origin of the concept of a hero is to be found at this point - the hero who always rebels against his father and kills him in some shape or other.¹ Here too is the true basis for the 'tragic guilt' of the hero of drama, which is otherwise hard to explain. It can scarcely be doubted that the hero and chorus in Greek drama represent the same rebellious hero and company of brothers; and it is not without significance that in the Middle Ages what the theatre started with afresh was the representation of the story of the Passion.
[1939a, 4911]

It is no doubt true that the impact of the threat of castration upon a boy's budding sexual life does not always have these dreaded consequences. It will depend once again on quantitative relations how much damage is done and how much avoided. The whole occurrence, which may probably be regarded as the central experience of the years of childhood, the greatest problem of early life and the strongest source of later inadequacy, is so completely forgotten that its reconstruction during the work of analysis is met in adults by the most decided disbelief. Indeed, aversion to it is so great that people try to silence any mention of the proscribed subject and the most obvious reminders of it are overlooked by a strange intellectual blindness. One may hear it objected, for instance, that the legend of King Oedipus has in fact no connection with the construction made by analysis: the cases are quite different, since Oedipus did not know that it was his father that he killed and his mother that he married. What is overlooked in this is that a distortion of this kind is inevitable if an attempt is made at a poetic handling of the material, and that there is no introduction of extraneous material but only a skilful employment of the factors presented by the theme. The ignorance of Oedipus is a legitimate representation of the unconscious state into which, for adults, the whole experience has fallen; and the coercive power of the oracle, which makes or should make the hero innocent, is a recognition of the inevitability of the fate which has condemned every son to live through the Oedipus complex. Again it was pointed out from psycho-analytic quarters how easily the riddle of another dramatic hero, Shakespeare's procrastinator, Hamlet, can be solved by reference to the Oedipus complex, since the prince came to grief over the task of punishing someone else for what coincided with the substance of his own Oedipus wish - whereupon the general lack of understanding on the part of the literary world showed how ready is the mass of mankind to hold fast to its infantile repressions.¹
[1940a [1938], 4999]
Yet more than a century before the emergence of psycho-analysis the French philosopher Diderot bore witness to the importance of the Oedipus complex by expressing the difference between the primitive and civilized worlds in this sentence: ‘Si le petit sauvage était abandonné à lui-même, qu’il conservât toute son imbécillité, et qu’il réunît au peu de raison de l’enfant au berceau la violence des passions de l’homme de trente ans, il tordrait le col à son père et coucherait avec sa mère.’² I venture to say that if psycho-analysis could boast of no other achievement than the discovery of the repressed Oedipus complex, that alone would give it a claim to be included among the precious new acquisitions of mankind.

[1940a [1938], 4999]

² ["If the little savage were left to himself, preserving all his foolishness and adding to the small sense of a child in the cradle the violent passions of a man of thirty, he would strangle his father and lie with his mother."]

[1940a [1938], 4999]
Under analysis, these perversions - and indeed most others - reveal a surprising variety of motives and determinants. The compulsion to exhibit, for instance, is also closely dependent on the castration complex: it is a means of constantly insisting upon the integrity of the subject's own (male) genitals and it reiterates his infantile satisfaction at the absence of a penis in those of women.

Similarly, the term masochism comprises any passive attitude towards sexual life and the sexual object, the extreme instance of which appears to be that in which satisfaction is conditional upon suffering physical or mental pain at the hands of the sexual object. Masochism, in the form of a perversion, seems to be further removed from the normal sexual aim than its counterpart; it may be doubted at first whether it can ever occur as a primary phenomenon or whether, on the contrary, it may not invariably arise from a transformation of sadism.¹ It can often be shown that masochism is nothing more than an extension of sadism turned round upon the subject's own self, which thus, to begin with, takes the place of the sexual object. Clinical analysis of extreme cases of masochistic perversion show that a great number of factors (such as the castration complex and the sense of guilt) have combined to exaggerate and fixate the original passive sexual attitude.

Castration Complex and Penis Envy This conviction is energetically maintained by boys, is obstinately defended against the contradictions which soon result from observation, and is only abandoned after severe internal struggles (the castration complex). The substitutes for this penis which they feel is missing in women play a great part in determining the form taken by many perversions.¹

¹ [Footnote added 1920:] We are justified in speaking of a castration complex in women as well. Both male and female children form a theory that women no less than men originally had a penis, but that they have lost it by castration. The conviction which is finally reached by males that women have no penis often leads them to an enduringly low opinion of the other sex.

He made this reply without having any sense of guilt as yet. But this was the occasion of his acquiring the 'castration complex', the presence of which we are so often obliged to infer in analysing neurotics, though they one and all struggle violently against recognizing it. There is much of importance to be said upon the significance of this element in the life of a child. The 'castration complex' has left marked traces behind it in myths (and not only in Greek myths); in a passage in my Interpretation of Dreams, and elsewhere, I have touched upon the part it plays.¹

¹ [Footnote added 1920:]
¹ [Footnote added 1923:] - Since this was written, the study of the castration complex has been further developed in contributions to the subject by Lou Andreas-Salomé, A. Stärcke, F. Alexander, and others. It has been urged that every time his mother’s breast is withdrawn from a baby he is bound to feel it as castration (that is to say, as the loss of what he regards as an important part of his own body); that, further, he cannot fail to be similarly affected by the regular loss of his faeces; and, finally, that the act of birth itself (consisting as it does in the separation of the child from his mother, with whom he has hitherto been united) is the prototype of all castration. While recognizing all of these roots of the complex, I have nevertheless put forward the view that the term ‘castration complex’ ought to be confined to those excitations and consequences which are bound up with the loss of the penis. Any one who, in analysing adults, has become convinced of the invariable presence of the castration complex, will of course find difficulty in ascribing its origin to a chance threat - of a kind which is not, after all, of such universal occurrence; he will be driven to assume that children construct this danger for themselves out of the slightest hints, which will never be wanting. This circumstance is also the motive, indeed, that has stimulated the search for those deeper roots of the complex which are universally forthcoming. But this makes it all the more valuable that in the case of little Hans the threat of castration is reported by his parents themselves, and moreover at a date before there was any question of his phobia.

[1909b, 2004]

Hans’s last words of comfort throw a light upon the situation and allow us to make some small corrections in his father’s assertions. It is true that he was afraid of big animals because he was obliged to think of their big widdlers; but it cannot really be said that he was afraid of big widdlers themselves. Formerly the idea of them had been decidedly pleasurable to him, and he used to make every effort to get a glimpse of one. Since that time this enjoyment had been spoiled for him, owing to the general reversal of pleasure into unpleasure which had come over the whole of his sexual researches - in a way which has not yet been explained - and also owing to something which is clearer to us, namely, to certain experiences and reflections which had led to distressing conclusions. We may infer from his self-consolatory words (‘my widdler will get bigger as I get bigger’) that during his observations he had constantly been making comparisons, and that he had remained extremely dissatisfied with the size of his own widdler. Big animals reminded him of his defect, and were for that reason disagreeable to him. But since the whole train of thought was probably incapable of becoming clearly conscious, this distressing feeling, too, was transformed into anxiety, so that his present anxiety was erected both upon his former pleasure and his present unpleasure. When once a state of anxiety establishes itself, the anxiety swallows up all other feelings; with the progress of repression, and the more those ideas which are charged with affect and which have been conscious move down into the unconscious, all affects are capable of being changed into anxiety.

[1909b, 2025]

The piece of enlightenment which Hans had been given a short time before to the effect that women really do not possess a widdler was bound to have had a shattering effect upon his self-confidence and to have aroused his castration complex. For this reason he resisted the information, and for this reason it had no therapeutic results. Could it be that living beings really did exist which did not possess widdlers? If so, it would no longer be so incredible that they could take his own widdler away, and, as it were, make him into a woman!

[1909b, 2026]

¹ I cannot interrupt the discussion so far as to demonstrate the typical character of the unconscious train of thought which I think there is here reason for attributing to little Hans. The castration complex is the deepest unconscious root of anti-semitism; for even in the nursery little boys hear that a Jew has something cut off his penis - a piece of his penis, they think - and this gives them a right to despise Jews. And there is no stronger unconscious root for the sense of superiority over women. Weininger (the young philosopher who, highly gifted but sexually deranged, committed suicide after producing his remarkable book, Geschlecht und Charakter), in a chapter that attracted much attention, treated Jews and women with equal hostility and overwhelmed them with the same insults. Being a neurotic, Weininger was completely under the sway of his infantile complexes; and from that standpoint what is common to Jews and women is their relation to the castration complex.

[1909b, 2026]
Crawley, in language which differs only slightly from the current terminology of psycho-analysis, declares that each individual is separated from the others by a 'taboo of personal isolation', and that it is precisely the minor differences in people who are otherwise alike that form the basis of feelings of strangeness and hostility between them. It would be tempting to pursue this idea and to derive from this 'narcissism of minor differences' the hostility which in every human relation we see fighting successfully against feelings of fellowship and overpowering the commandment that all men should love one another. Psycho-analysis believes that it has discovered a large part of what underlies the narcissistic rejection of women by men, which is so much mixed up with despising them, in drawing attention to the castration complex and its influence on the opinion in which women are held.

[1918a, 2355]

In this story the tree appears, upon which the wolves were sitting in the dream. But it also contains an unmistakable allusion to the castration complex. The old wolf was docked of his tail by the tailor. The fox-tails of the wolves in the dream were probably compensations for this taillessness.

[1913d, 2600]

It may fairly be said that in these children's phobias some of the features of totemism reappear, but reversed into their negative. We are, however, indebted to Ferenczi (1913a) for an interesting history of a single case which can only be described as an instance of positive totemism in a child. It is true that in the case of little Árpád (the subject of Ferenczi's report) his totemic interests did not arise in direct relation with his Oedipus complex but on the basis of its narcissistic precondition, the fear of castration. But any attentive reader of the story of little Hans will find abundant evidence that he, too, admired his father as possessing a big penis and feared him as threatening his own. The same part is played by the father alike in the Oedipus and the castration complexes - the part of a dreaded enemy to the sexual interests of childhood. The punishment which he threatens is castration, or its substitute, blinding.¹

[1912-1913, 2770]

We soon agreed that, in spite of what he had thought, he could not have told me the story of this vision or hallucination before. He was very well aware that I could not have failed to exploit such evidence as this of his having had a fear of castration at the age of five. The episode broke down his resistance to assuming the existence of a castration complex; but he raised the question: 'Why did I feel so certain of having told you this recollection before?'

[1914a, 2840]

It seems unnecessary to add anything in the way of an interpretation of this little occurrence, so far as it throws light upon the phenomenon of 'fausse reconnaissance'. As regards the subject-matter of the patient's vision, I may remark that, particularly in relation to the castration complex, similar hallucinatory falsifications are of not infrequent occurrence, and that they can just as easily serve the purpose of correcting unwelcome perceptions.

[1914a, 2840]
In connection with the attempt, which psycho-analysis has made necessary, to correlate the fundamental principle of its theory with the mental life of children, Adler exhibits the most serious departures from actual observation and the most fundamental confusion in his concepts. The biological, social and psychological meanings of 'masculine' and 'feminine' are here hopelessly mixed. It is impossible, and is disproved by observation, that a child, whether male or female, should found the plan of its life on an original depreciation of the female sex and take the wish to be a real man as its 'guiding line'. Children have, to begin with, no idea of the significance of the distinction between the sexes; on the contrary, they start with the assumption that the same genital organ (the male one) is possessed by both sexes; they do not begin their sexual researches with the problem of the distinction between the sexes, while the social underestimation of women is completely foreign to them. There are women in whose neurosis the wish to be a man has played no part. Whatever in the nature of a masculine protest can be shown to exist is easily traceable to a disturbance in primary narcissism due to threats of castration or to the earliest interferences with sexual activities. All disputes about the psychogenesis of the neuroses must eventually be decided in the field of the neuroses of childhood. Careful dissection of a neurosis in early childhood puts an end to all misapprehensions about the aetiology of the neuroses and to all doubts about the part played by the sexual instincts in them. That is why, in his criticism of Jung's paper 'Conflicts in the Mind of the Child', Adler was obliged to resort to the imputation that the facts of the case had been one-sidedly arranged, 'no doubt by the father'.

[1914d, 2918]

The disturbances to which a child's original narcissism is exposed, the reactions with which he seeks to protect himself from them and the paths into which he is forced in doing so - these are themes which I propose to leave on one side, as an important field of work which still awaits exploration. The most significant portion of it, however, can be singled out in the shape of the 'castration complex' (in boys, anxiety about the penis - in girls, envy for the penis) and treated in connection with the effect of early deterrence from sexual activity. Psycho-analytic research ordinarily enables us to trace the vicissitudes undergone by the libidinal instincts when these, isolated from the ego-instincts, are placed in opposition to them; but in the particular field of the castration complex, it allows us to infer the existence of an epoch and a psychical situation in which the two groups of instincts, still operating in unison and inseparably mingled, make their appearance as narcissistic interests. It is from this context that Adler has derived his concept of the 'masculine protest', which he has elevated almost to the position of the sole motive force in the formation of character and neurosis alike and which he bases not on a narcissistic, and therefore still a libidinal, trend, but on a social valuation. Psycho-analytic research has from the very beginning recognized the existence and importance of the 'masculine protest', but it has regarded it, in opposition to Adler, as narcissistic in nature and derived from the castration complex. The 'masculine protest' is concerned in the formation of character, into the genesis of which it enters along with many other factors, but it is completely unsuited for explaining the problems of the neuroses, with regard to which Adler takes account of nothing but the manner in which they serve the ego-instincts. I find it quite impossible to place the genesis of neurosis upon the narrow basis of the castration complex, however powerfully it may come to the fore in men among their resistances to the cure of a neurosis. Incidentally, I know of cases of neurosis in which the 'masculine protest', or, as we regard it, the castration complex, plays no pathogenic part, and even fails to appear at all.

[1914c, 2946]
Another symbol of the female genitals which deserves mention is a jewel-case. Jewel and treasure are used in dreams as well as in waking life to describe someone who is loved. Sweets frequently represent sexual enjoyment. Satisfaction obtained from a person's own genitals is indicated by all kinds of playing, including piano-playing. Symbolic representations par excellence of masturbation are gliding or sliding and pulling off a branch. The falling out of a tooth or the pulling out of a tooth is a particularly notable dream-symbol. Its first meaning is undoubtedly castration as a punishment for masturbating. We come across special representations of sexual intercourse less often than might be expected from what has been said so far. Rhythmic activities such as dancing, riding and climbing must be mentioned here, as well as violent experiences such as being run over; so, too, certain manual crafts, and, of course, threatening with weapons.

It cannot be said that the world has shown much gratitude to psycho-analytic research for its revelation of the Oedipus complex. On the contrary, the discovery has provoked the most violent opposition among adults; and those who had neglected to take part in the repudiation of this proscribed and tabooed emotional relationship made up for their fault later by depriving the complex of its value through twisted re-interpretations. It is my unaltered conviction that there is nothing in this to be disavowed or glossed over. We must reconcile ourselves to the fact which was recognized by the Greek legend itself as an inevitable fate. It is once again an interesting fact that the Oedipus complex, which has been rejected from real life, has been left to imaginative writing, has been placed freely, as it were, at its disposal. Otto Rank has shown in a careful study how the Oedipus complex has provided dramatic authors with a wealth of themes in endless modifications, softenings and disguises - in distortions, that is to say, of the kind which we are already familiar with as the work of a censorship. We may therefore also ascribe this Oedipus complex to dreamers who have been fortunate enough to escape conflicts with their parents in later life. And, intimately linked with it, we find what we call the 'castration complex', the reaction to the threats against the child aimed at putting a stop to his early sexual activities and attributed to his father.
Among the occurrences which recur again and again in the youthful history of neurotics - which are scarcely ever absent - there are a few of particular importance, which also deserve, on that account, I think, to be brought into greater prominence than the rest. As specimens of this class I will enumerate these: observation of parental intercourse, seduction by an adult and threat of being castrated. It would be a mistake to suppose that they are never characterized by material reality; on the contrary, this is often established incontestably through enquiries from older members of the patient's family. It is by no means a rare thing, for instance, for a little boy, who is beginning to play with his penis in a naughty way and is not yet aware that one must conceal such activities, to be threatened by a parent or nurse with having his penis or his sinful hand cut off. Parents will often admit this when they are asked, since they think they have done something useful in making such a threat; a number of people have a correct conscious memory of such a threat, especially if it was made at a somewhat later period. If the threat is delivered by the mother or some other female she usually shifts its performance on to the father or the doctor. In Struwwelpeter, the famous work of the Frankfurt paediatrician Hoffmann (which owes its popularity precisely to an understanding of the sexual and other complexes of childhood), you will find castration softened into a cutting-off of the thumbs as a punishment for obstinate sucking. But it is highly improbable that children are threatened with castration as often as it appears in the analyses of neurotics. We shall be satisfied by realizing that the child puts a threat of this kind together in his imagination on the basis of hints, helped out by a knowledge that auto-erotic satisfaction is forbidden and under the impression of his discovery of the female genitals. Nor is it only in proletarian families that it is perfectly possible for a child, while he is not yet credited with possessing an understanding or a memory, to be a witness of the sexual act between his parents or other grown-up people; and the possibility cannot be rejected that he will be able to understand and react to the impression in retrospect. If, however, the intercourse is described with the most minute details, which would be difficult to observe, or if, as happens most frequently, it turns out to have been intercourse from behind more ferarum [in the manner of animals], there can be no remaining doubt that the phantasy is based on an observation of intercourse between animals (such as dogs) and that its motive was the child's unsatisfied scopophilia during puberty. The extreme achievement on these lines is a phantasy of observing parental intercourse while one is still an unborn baby in the womb. Phantasies of being seduced are of particular interest, because so often they are not phantasies but real memories. Fortunately, however, they are nevertheless not real as often as seemed at first to be shown by the findings of analysis. Seduction by an older child or by one of the same age is even more frequent than by an adult; and if in the case of girls who produce such an event in the story of their childhood their father figures fairly regularly as the seducer, there can be no doubt either of the imaginary nature of the accusation or of the motive that has led to it. A phantasy of being seduced when no seduction has occurred is usually employed by a child to screen the auto-erotic period of his sexual activity. He spares himself shame about masturbation by retrospectively phantasying a desired object into these earliest times. You must not suppose, however, that sexual abuse of a child by its nearest male relatives belongs entirely to the realm of phantasy. Most analysts will have treated cases in which such events were real and could be unimpeachably established; but even so they related to the later years of childhood and had been transposed into earlier times.

[1916-1917, 3426]
The only impression we gain is that these events of childhood are somehow demanded as a necessity, that they are among the essential elements of a neurosis. If they have occurred in reality, so much to the good; but if they have been withheld by reality, they are put together from hints and supplemented by phantasy. The outcome is the same, and up to the present we have not succeeded in pointing to any difference in the consequences, whether phantasy or reality has had the greater share in these events of childhood. Here we simply have once again one of the complemental relations that I have so often mentioned; moreover it is the strangest of all we have met with. Whence comes the need for these phantasies and the material for them? There can be no doubt that their sources lie in the instincts; but it has still to be explained why the same phantasies with the same content are created on every occasion. I am prepared with an answer which I know will seem daring to you. I believe these primal phantasies, as I should like to call them, and no doubt a few others as well, are a phylogenetic endowment. In them the individual reaches beyond his own experience into primaeval experience at points where his own experience as been too rudimentary. It seems to me quite possible that all the things that are told to us to-day in analysis as phantasy - the seduction of children, the inflaming of sexual excitement by observing parental intercourse, the threat of castration (or rather castration itself) - were once real occurrences in the primaeval times of the human family, and that children in their phantasies are simply filling in the gaps in individual truth with prehistoric truth. I have repeatedly been led to suspect that the psychology of the neuroses has stored up in it more of the antiquities of human development than any other source.

[1916-1917, 3427]

It is easy to understand that the first suspicion fell upon the English governess, for the change in the boy made its appearance while she was there. Two screen memories had persisted, which were incomprehensible in themselves, and which related to her. On one occasion, as she was walking along in front of them, she said: 'Do look at my little tail!' Another time, when they were on a drive, her hat flew away, to the two children's great satisfaction. This pointed to the castration complex, and might permit of a construction being made to the effect that a threat uttered by her against the boy had been largely responsible for originating his abnormal conduct. There is no danger at all in communicating constructions of this kind to the person under analysis; they never do any damage to the analysis if they are mistaken; but at the same time they are not put forward unless there is some prospect of reaching a nearer approximation to the truth by means of them. The first effect of this supposition was the appearance of some dreams, which it was not possible to interpret completely, but all of which seemed to centre around the same material. As far as they could be understood, they were concerned with aggressive actions on the boy's part against his sister or against the governess and with energetic reproofs and punishments on account of them. It was as though . . . after her bath . . . he had tried . . . to undress his sister . . . to tear off her coverings . . . or veils - and so on. But it was not possible to get at any firm content from the interpretation; and since these dreams gave an impression of always working over the same material in various different ways, the correct reading of these ostensible reminiscences became assured: it could only be a question of phantasies, which the dreamer had made on the subject of his childhood at some time or other, probably at the age of puberty, and which had now come to the surface again in this unrecognizable form.

[1918b, 3512]
How did the boy react to the allurements of his elder sister? By a refusal, is the answer, but by a refusal which applied to the person and not to the thing. His sister was not agreeable to him as a sexual object, probably because his relation to her had already been determined in a hostile direction owing to their rivalry for their parents' love. He held aloof from her, and, moreover, her solicitations soon ceased. But he tried to win, instead of her, another person of whom he was fonder; and the information which his sister herself had given him, and in which the had claimed his Nanya as a model, turned his choice in that direction. He therefore began to play with his penis in his Nanya's presence, and this, like so many other instances in which children do not conceal their masturbation, must be regarded as an attempt at seduction. His Nanya disillusioned him; she made a serious face, and explained that that wasn't good; children who did that, she added, got a 'wound' in the place.

[1918b, 3515]

It agrees entirely with our anticipations when we learn that, after his first genital excitations, his sexual researches began, and that he soon came upon the problem of castration. At this time he succeeded in observing two girls - his sister and a friend of hers - while they were micturating. His acumen might well have enabled him to gather the true facts from this spectacle, but he behaved as we know other male children behave in these circumstances. He rejected the idea that he saw before him a confirmation of the wound with which his Nanya had threatened him, and he explained to himself that this was the girls' 'front bottom'. The theme of castration was not settled by this decision; he found new allusions to it in everything that he heard. Once when the children were given some coloured sugar-sticks, the governess, who was inclined to disordered fancies, pronounced that they were pieces of chopped-up snakes. He remembered afterwards that his father had once met a snake while he was walking along a footpath, and had beaten it to pieces with his stick. He heard the story (out of Reynard the Fox) read aloud, of how the wolf wanted to go fishing in the winter, and used his tail as a bait, and how in that way his tail was broken off in the ice. He learned the different names by which horses are distinguished, according to whether their sexual organs are intact or not. Thus he was occupied with thoughts about castration, but as yet he had no belief in it and no dread of it. Other sexual problems arose for him out of the fairy tales with which he became familiar at this time. In 'Little Red Riding-Hood' and 'The Seven Little Goats' the children were taken out of the wolf's body. Was the wolf a female creature, then, or could men have children in their bodies as well? At this time the question was not yet settled. Moreover, at the time of these enquiries he had as yet no fear of wolves.

[1918b, 3516]

There is no doubt whatever that at this time his father was turning into the terrifying figure that threatened him with castration. The cruel God with whom he was then struggling - who made men sinful, only to punish them afterwards, who sacrificed his own son and the sons of men - this God threw back his character on to the patient's father, though, on the other hand, the boy was at the same time trying to defend his father against the God. At this point the boy had to fit into a phylogenetic pattern, and he did so, although his personal experiences may not have agreed with it. Although the threats or hints of castration which had come his way had emanated from women,¹ this could not hold up the final result for long. In spite of everything it was his father from whom in the end he came to fear castration. In this respect heredity triumphed over accidental experience; in man's prehistory it was unquestionably the father who practised castration as a punishment and who later softened it down into circumcision. The further the patient went in repressing sensuality during the course of the development of the obsessional neurosis,² the more natural it must have become to him to attribute these evil intentions to his father, who was the true representative of sensual activity.

[1918b, 3568]
Moreover, I would not recommend any opponent of the psycho-analytic view to select this particular story of the Sand-Man with which to support his argument that anxiety about the eyes has nothing to do with the castration complex. For why does Hoffmann bring the anxiety about eyes into such intimate connection with the father's death? And why does the Sand-Man always appear as a disturber of love? He separates the unfortunate Nathaniel from his betrothed and from her brother, his best friend; he destroys the second object of his love, Olympia, the lovely doll; and he drives him into suicide at the moment when he has won back his Clara and is about to be happily united to her. Elements in the story like these, and many others, seem arbitrary and meaningless so long as we deny all connection between fears about the eye and castration; but they become intelligible as soon as we replace the Sand-Man by the dreaded father at whose hands castration is expected.¹

¹ It has been quite correctly pointed out that a child gets the idea of a narcissistic injury through a bodily loss from the experience of losing his mother's breast after sucking, from the daily surrender of his faeces and, indeed, even from his separation from the womb at birth. Nevertheless, one ought not to speak of a castration complex until this idea of a loss has become connected with the male genitals.

[1923e, 4060]

In the course of these researches the child arrives at the discovery that the penis is not a possession which is common to all creatures that are like himself. An accidental sight of the genitals of a little sister or playmate provides the occasion for this discovery. In unusually intelligent children, the observation of girls urinating will even earlier have aroused a suspicion that there is something different here. For they will have seen a different posture and heard a different sound, and will have made attempts to repeat their observations so as to obtain enlightenment. We know how children react to their first impressions of the absence of a penis. They disavow the fact and believe that they do see a penis, all the same. They gloss over the contradiction between observation and preconception by telling themselves that the penis is still small and will grow bigger presently; and they then slowly come to the emotionally significant conclusion that after all the penis had at least been there before and been taken away afterwards. The lack of a penis is regarded as a result of castration, and so now the child is faced with the task of coming to terms with castration in relation to himself. The further developments are too well known generally to make it necessary to recapitulate them here. But it seems to me that the significance of the castration complex can only be rightly appreciated if its origin in the phase of phallic primacy is also taken into account.¹

¹ Erotogenic masochism accompanies the libido through all its developmental phases and derives from them its changing psychical coatings. The fear of being eaten up by the totem animal (the father) originates from the primitive oral organization; the wish to be beaten by the father comes from the sadistic-anal phase which follows it; castration, although it is later disavowed, enters into the content of masochistic phantasies as a precipitate of the phallic stage or organization;¹ and from the final genital organization there arise, of course, the situations of being copulated with and of giving birth, which are characteristic of femaleness. The part played in masochism by the nates, too, is easily understandable, apart from its obvious basis in reality. The nates are the part of the body which is given erotogenic preference in the sadistic-anal phase, like the breast in the oral phase and the penis in the genital phase.

[1924c, 4077]
I have now said the essence of what I had to say: I will stop, therefore, and cast an eye over our findings. We have gained some insight into the prehistory of the Oedipus complex in girls. The corresponding period in boys is more or less unknown. In girls the Oedipus complex is a secondary formation. The operations of the castration complex precede it and prepare for it. As regards the relation between the Oedipus and castration complexes there is a fundamental contrast between the two sexes. *Whereas in boys the Oedipus complex is destroyed by the castration complex, in girls it is made possible and led up to by the castration complex.* This contradiction is cleared up if we reflect that the castration complex always operates in the sense implied in its subject-matter: it inhibits and limits masculinity and encourages femininity. The difference between the sexual development of males and females at the stage we have been considering is an intelligible consequence of the anatomical distinction between their genitals and of the psychical situation involved in it; it corresponds to the difference between a castration that has been carried out and one that has merely been threatened. In their essentials, therefore, our findings are self-evident and it should have been possible to foresee them.

[1925j, 4154]

Probably no male human being is spared the fright of castration at the sight of a female genital. Why some people become homosexual as a consequence of that impression, while others fend it off by creating a fetish, and the great majority surmount it, we are frankly not able to explain. It is possible that, among all the factors at work, we do not yet know those which are decisive for the rare pathological results. We must be content if we can explain what has happened, and may for the present leave on one side the task of explaining why something has not happened.

[1927e, 4537]

An investigation of fetishism is strongly recommended to any one who still doubts the existence of the castration complex or who can still believe that fright at the sight of the female genital has some other ground - for instance, that it is derived from a supposed recollection of the trauma of birth.

[1927e, 4537]

But what has been said so far does not exhaust the consequences of the repression of the hatred of the father in the Oedipus complex. There is something fresh to be added: namely that in spite of everything the identification with the father finally makes a permanent place for itself in the ego. It is received into the ego, but establishes itself there as a separate agency in contrast to the rest of the content of the ego. We then give it the name of super-ego and ascribe to it, the inheritor of the parental influence, the most important functions. If the father was hard, violent and cruel, the super-ego takes over those attributes from him and, in the relations between the ego and it, the passivity which was supposed to have been repressed is re-established. The super-ego has become sadistic, and the ego becomes masochistic - that is to say, at bottom passive in a feminine way. A great need for punishment develops in the ego, which in part offers itself as a victim to Fate, and in part finds satisfaction in ill-treatment by the super-ego (that is, in the sense of guilt). For every punishment is ultimately castration and, as such, a fulfillment of the old passive attitude towards the father. Even Fate is, in the last resort, only a later projection of the father.

[1928b, 4561]
It is no doubt true that the impact of the threat of castration upon a boy's budding sexual life does not always have these dreaded consequences. It will depend once again on quantitative relations how much damage is done and how much avoided. The whole occurrence, which may probably be regarded as the central experience of the years of childhood, the greatest problem of early life and the strongest source of later inadequacy, is so completely forgotten that its reconstruction during the work of analysis is met in adults by the most decided disbelief. Indeed, aversion to it is so great that people try to silence any mention of the proscribed subject and the most obvious reminders of it are overlooked by a strange intellectual blindness. One may hear it objected, for instance, that the legend of King Oedipus has in fact no connection with the construction made by analysis: the cases are quite different, since Oedipus did not know that it was his father that he killed and his mother that he married. What is overlooked in this is that a distortion of this kind is inevitable if an attempt is made at a poetic handling of the material, and that there is no introduction of extraneous material but only a skilful employment of the factors presented by the theme. The ignorance of Oedipus is a legitimate representation of the unconscious state into which, for adults, the whole experience has fallen; and the coercive power of the oracle, which makes or should make the hero innocent, is a recognition of the inevitability of the fate which has condemned every son to live through the Oedipus complex. Again it was pointed out from psycho-analytic quarters how easily the riddle of another dramatic hero, Shakespeare's procrastinator, Hamlet, can be solved by reference to the Oedipus complex, since the prince came to grief over the task of punishing someone else for what coincided with the substance of his own Oedipus wish - whereupon the general lack of understanding on the part of the literary world showed how ready is the mass of mankind to hold fast to its infantile repressions.¹

[1940a [1938], 4999]
Infantile sexual theories provide the explanation. There was once a time when the male genital was found compatible with the picture of the mother. When a male child first turns his curiosity to the riddles of sexual life, he is dominated by his interest in his own genital. He finds that part of his body too valuable and too important for him to be able to believe that it could be missing in other people whom he feels he resembles so much. As he cannot guess that there exists another type of genital structure of equal worth, he is forced to make the assumption that all human beings, women as well as men, possess a penis like his own. This preconception is so firmly planted in the youthful investigator that it is not destroyed even when he first observes the genitals of little girls. His perception tells him, it is true, that there is something different from what there is in him, but he is incapable of admitting to himself that the content of this perception is that he cannot find a penis in girls. That the penis could be missing strikes him as an uncanny and intolerable idea, and so in an attempt at a compromise he comes to the conclusion that little girls have a penis as well, only it is still very small; it will grow later.¹ If it seems from later observations that this expectation is not realized, he has another remedy at his disposal: little girls too had a penis, but it was cut off and in its place was left a wound. This theoretical advance already makes use of personal experiences of a distressing kind: the boy in the meantime has heard the threat that the organ which is so dear to him will be taken away from him if he shows his interest in it too plainly. Under the influence of this threat of castration he now sees the notion he has gained of the female genitals in a new light; henceforth he will tremble for his masculinity, but at the same time he will despise the unhappy creatures on whom the cruel punishment has, as he supposes, already fallen.²

[1910c, 2270]

Though I am anxious to cut short this discussion still further, I must nevertheless tell you a little about the sexual researches of children: they are too characteristic of infantile sexuality and of too great significance for the symptomatology of the neuroses to be passed over. Infantile sexual researches begin very early, sometimes before the third year of life. They do not relate to the distinction between the sexes, for this means nothing to children, since they (or at any rate boys) attribute the same male genital to both sexes. If, afterwards, a boy makes the discovery of the vagina from seeing his little sister or a girl playmate, he tries, to begin with, to disavow the evidence of his senses, for he cannot imagine a human creature like himself who is without such a precious portion. Later on, he takes fright at the possibility thus presented to him; and any threats that may have been made to him earlier, because he took too intense an interest in his little organ, now produce a deferred effect. He comes under the sway of the castration complex, the form taken by which plays a great part in the construction of his character if he remains normal, in his neurosis if he falls ill, and in his resistances if he comes into analytic treatment. As regards little girls, we can say of them that they feel greatly at a disadvantage owing to their lack of a big, visible penis, that they envy boys for possessing one and that, in the main for this reason, they develop a wish to be a man - a wish that re-emerges later on, in any neurosis that may arise if they meet with a mishap in playing a feminine part. In her childhood, moreover, a girl's clitoris takes on the role of a penis entirely: it is characterized by special excitability and is the area in which auto-erotic satisfaction is obtained. The process of a girl's becoming a woman depends very much on the clitoris passing on this sensitivity to the vaginal orifice in good time and completely. In cases of what is known as sexual anaesthesia in women the clitoris has obstinately retained its sensitivity.

[1916-1917, 3387]
It agrees entirely with our anticipations when we learn that, after his first genital excitations, his sexual researches began, and that he soon came upon the problem of castration. At this time he succeeded in observing two girls - his sister and a friend of hers - while they were micturating. His acumen might well have enabled him to gather the true facts from this spectacle, but he behaved as we know other male children behave in these circumstances. He rejected the idea that he saw before him a confirmation of the wound with which his Nanya had threatened him, and he explained to himself that this was the girls' 'front bottom'. The theme of castration was not settled by this decision; he found new allusions to it in everything that he heard. Once when the children were given some coloured sugar-sticks, the governess, who was inclined to disordered fancies, pronounced that they were pieces of chopped-up snakes. He remembered afterwards that his father had once met a snake while he was walking along a footpath, and had beaten it to pieces with his stick. He heard the story (out of *Reynard the Fox*) read aloud, of how the wolf wanted to go fishing in the winter, and used his tail as a bait, and how in that way his tail was broken off in the ice. He learned the different names by which horses are distinguished, according to whether their sexual organs are intact or not. Thus he was occupied with thoughts about castration, but as yet he had no belief in it and no dread of it. Other sexual problems arose for him out of the fairy tales with which he became familiar at this time. In 'Little Red Riding-Hood' and 'The Seven Little Goats' the children were taken out of the wolf's body. Was the wolf a female creature, then, or could men have children in their bodies as well? At this time the question was not yet settled. Moreover, at the time of these enquiries he had as yet no fear of wolves.

[1918b, 3516]

When the patient entered more deeply into the situation of the primal scene, he brought to light the following pieces of self-observation. He assumed to begin with, he said, that the event of which he was a witness was an act of violence, but the expression of enjoyment which he saw on his mother's face did not fit in with this; he was obliged to recognize that the experience was one of gratification.¹ What was essentially new for him in his observation of his parents' intercourse was the conviction of the reality of castration - a possibility with which his thoughts had already been occupied previously. (The sight of the two girls micturating, his Nanya's threat, the governess' interpretation of the sugar-sticks, the recollection of his father having beaten a snake to pieces.) For now he saw with his own eyes the wound of which his Nanya had spoken, and understood that its presence was a necessary condition of intercourse with his father. He could no longer confuse it with the bottom, as he had in his observation of the little girls.²

[1918b, 3533]
We now observe that at this point in our narrative we must make an alteration in our terminology. During the dream he had reached a new phase in his sexual organization. Up to then the sexual opposites had been for him active and passive. Since his seduction his sexual aim had been a passive one, of being touched on the genitals; it was then transformed, by regression to the earlier stage of the sadistic-anal organization, into the masochistic aim of being beaten or punished. It was a matter of indifference to him whether he reached this aim with a man or with a woman. He had travelled, without considering the difference of sex, from his Nanya to his father; he had longed to have his penis touched by his Nanya, and had tried to provoke a beating from his father. Here his genitals were left out of account; though the connection with them which had been concealed by the regression was still expressed in his phantasy of being beaten on the penis. The activation of the primal scene in the dream now brought him back to the genital organization. He discovered the vagina and the biological significance of masculine and feminine. He understood now that active was the same as masculine, while passive was the same as feminine. His passive sexual aim should now have been transformed into a feminine one, and have expressed itself as 'being copulated with by his father' instead of 'being beaten by him on the genitals or on the bottom'. This feminine aim, however, underwent repression and was obliged to let itself be replaced by fear of the wolf.

At this point we must consider an objection, the discussion of which may contribute much to the elucidation of the apparent confusion of the circumstances. We have been driven to assume that during the process of the dream he understood that women are castrated, that instead of a male organ they have a wound which serves for sexual intercourse, and that castration is the necessary condition of femininity; we have been driven to assume that the threat of this loss induced him to repress his feminine attitude towards men, and that he awoke from his homosexual enthusiasm in anxiety. Now how can this comprehension of sexual intercourse, this recognition of the vagina, be brought into harmony with the selection of the bowel for the purpose of identification with women? Are not the intestinal symptoms based on what is probably an older notion, and one which in any case completely contradicts the dread of castration - the notion, namely, that sexual intercourse takes place at the anus?
When his Christmas dream, with its excitement and expectancy, conjured up before him the picture of the sexual intercourse of his parents as it had once been observed (or construed) by him, there can be no doubt that the first view of it to come up was the old one, according to which the part of the female body which received the male organ was the anus. And, indeed, what else could he have supposed when at the age of one and a half he was a spectator of the scene? But now came the new event that occurred when he was four years old. What he had learnt in the meantime, the allusions which he had heard to castration, awoke and cast a doubt on the 'cloacal theory'; they brought to his notice the difference between the sexes and the sexual part played by women. In this contingency he behaved as children in general behave when they are given an unwished for piece of information - whether sexual or of any other kind. He rejected what was new (in our case from motives connected with his fear of castration) and clung fast to what was old. He decided in favour of the intestine and against the vagina, just as, for similar motives, he later on took his father's side against God. He rejected the new information and clung to the old theory. The latter must have provided the material for his identification with women, which made its appearance later as a dread of death in connection with the bowels, and for his first religious scruples, about whether Christ had had a behind, and so on. It is not that his new insight remained without any effect; quite the reverse. It developed an extraordinarily powerful effect, for it became a motive for keeping the whole process of the dream under repression and for excluding it from being worked over later in consciousness. But with that its effect was exhausted; it had no influence in deciding the sexual problem. That it should have been possible from that time onwards for a fear of castration to exist side by side with an identification with women by means of the bowel admittedly involved a contradiction. But it was only a logical contradiction - which is not saying much. On the contrary, the whole process is characteristic of the way in which the unconscious works. A repression is something very different from a condemning judgement.

[1918b, 3561]

Another part of the nexus of relations can be observed much more clearly in the male. It arises when the boy's sexual researches lead him to the discovery of the absence of a penis in women. He concludes that the penis must be a detachable part of the body, something analogous to faeces, the first piece of bodily substance the child had to part with. Thus the old anal defiance enters into the composition of the castration complex. The organic analogy which enabled the intestinal contents to be the forerunner of the penis during the pregenital phase cannot come into account as a motive; but the boy's sexual researches lead him to a psychical substitute for it. When a baby appears on the scene he regards it as 'lumf', in accordance with those researches, and he cathects it with powerful anal-erotic interest. When social experiences teach that a baby is to be regarded as a love-token, a gift, the wish for a baby receives a second contribution from the same source. Faeces, penis and baby are all three solid bodies; they all three, by forcible entry or expulsion, stimulate a membranous passage, i.e. the rectum and the vagina, the latter being as it were 'taken on lease' from the rectum, as Lou Andreas-Salomé aptly remarks. Infantile sexual researches can only lead to the conclusion that the baby follows the same route as the faecal mass. The function of the penis is not usually discovered by those researches. But it is interesting to note that after so many detours an organic correspondence reappears in the psychical sphere as an unconscious identity.

[1917c, 3605]
After this highly discursive introduction I am only able to present a very concise summary of the sexual history of the case under consideration. In childhood the girl had passed through the normal attitude characteristic of the feminine Oedipus complex¹ in a way that was not at all remarkable, and had later also begun to substitute for her father a brother slightly older than herself. She did not remember any sexual traumas in early life, nor were any discovered by the analysis. Comparison of her brother's genital organs and her own, which took place about the beginning of the latency period (at five years old or perhaps a little earlier), left a strong impression on her and had far-reaching after-effects. There were very few signs pointing to infantile masturbation, or else the analysis did not go far enough to throw light on this point. The birth of a second brother when she was between five and six years old exercised no special influence upon her development. During the pre-pubertal years at school she gradually became acquainted with the facts of sex, and she received this knowledge with mixed feelings of lasciviousness and frightened aversion, in a way which may be called normal and was not exaggerated in degree. This amount of information about her seems meagre enough, nor can I guarantee that it is complete. It may be that the history of her youth was much richer in experiences; I do not know. As I have already said, the analysis was broken off after a short time, and therefore yielded an anamnesis not much more reliable than the other anamneses of homosexuals, which there is good cause to question. Further, the girl had never been neurotic, and came to the analysis without even one hysterical symptom, so that opportunities for investigating the history of her childhood did not present themselves so readily as usual.

[1920a, 3845]

To decapitate = to castrate. The terror of Medusa is thus a terror of castration that is linked to the sight of something. Numerous analyses have made us familiar with the occasion for this: it occurs when a boy, who has hitherto been unwilling to believe the threat of castration, catches sight of the female genitals, probably those of an adult, surrounded by hair, and essentially those of his mother.

[1940c [1922], 3943]

¹ Perhaps it would be safer to say 'with the parents'; for before a child has arrived at definite knowledge of the difference between the sexes, the lack of a penis, it does not distinguish in value between its father and its mother. I recently came across the instance of a young married woman whose story showed that, after noticing the lack of a penis in herself, she had supposed it to be absent not in all women, but only in those whom she regarded as inferior, and had still supposed that her mother possessed one. In order to simplify my presentation I shall discuss only identification with the father.

[1923b, 3965]

Unfortunately we can describe this state of things only as it affects the male child; the corresponding processes in the little girl are not known to us. The small boy undoubtedly perceives the distinction between men and women, but to begin with he has no occasion to connect it with a difference in their genitals. It is natural for him to assume that all other living beings, humans and animals, possess a genital like his own; indeed, we know that he looks for an organ analogous to his own in inanimate things as well.¹ This part of the body, which is easily excitable, prone to changes and so rich in sensations, occupies the boy's interest to a high degree and is constantly setting new tasks to his instinct for research. He wants to see it in other people as well, so as to compare it with his own; and he behaves as though he had a vague idea that this organ could and should be bigger. The driving force which this male portion of the body will develop later at puberty expresses itself at this period of life mainly as an urge to investigate, as sexual curiosity. Many of the acts of exhibitionism and aggression which children commit, and which in later years would be judged without hesitation to be expressions of lust, prove in analysis to be experiments undertaken in the service of sexual research.

[1923e, 4059]
It is, incidentally, remarkable what a small degree of attention the other part of the male genitals, the little sac with its contents, attracts in children. From all one hears in analyses, one would not guess that the male genitals consisted of anything more than the penis.

In the course of these researches the child arrives at the discovery that the penis is not a possession which is common to all creatures that are like himself. An accidental sight of the genitals of a little sister or playmate provides the occasion for this discovery. In unusually intelligent children, the observation of girls urinating will even earlier have aroused a suspicion that there is something different here. For they will have seen a different posture and heard a different sound, and will have made attempts to repeat their observations so as to obtain enlightenment. We know how children react to their first impressions of the absence of a penis. They disavow the fact and believe that they do see a penis, all the same. They gloss over the contradiction between observation and preconception by telling themselves that the penis is still small and will grow bigger presently; and they then slowly come to the emotionally significant conclusion that after all the penis had at least been there before and been taken away afterwards. The lack of a penis is regarded as a result of castration, and so now the child is faced with the task of coming to terms with castration in relation to himself. The further developments are too well known generally to make it necessary to recapitulate them here. But it seems to me that the significance of the castration complex can only be rightly appreciated if its origin in the phase of phallic primacy is also taken into account.

We know, too, to what a degree depreciation of women, horror of women, and a disposition to homosexuality are derived from the final conviction that women have no penis. Ferenczi (1923) has recently, with complete justice, traced back the mythological symbol of horror - Medusa's head - to the impression of the female genitals devoid of a penis.

It should not be supposed, however, that the child quickly and readily makes a generalization from his observation that some women have no penis. He is in any case debarred from doing so by his assumption that the lack of a penis is the result of having been castrated as a punishment. On the contrary, the child believes that it is only unworthy female persons that have lost their genitals - females who, in all probability, were guilty of inadmissible impulses similar to his own. Women whom he respects, like his mother, retain a penis for a long time. For him, being a woman is not yet synonymous with being without a penis. It is not till later, when the child takes up the problems of the origin and birth of babies, and when he guesses that only women can give birth to them - it is only then that the mother, too, loses her penis. And, along with this, quite complicated theories are built up to explain the exchange of the penis for a baby. In all this, the female genitals never seem to be discovered. The baby, we know, is supposed to live inside the mother’s body (in her bowel) and to be born through the intestinal outlet. These last theories carry us beyond the stretch of time covered by the infantile sexual period.
It is not unimportant to bear in mind what transformations are undergone, during the sexual
development of childhood, by the polarity of sex with which we are familiar. A first antithesis is
introduced with the choice of object, which, of course, presupposes a subject and an object. At
the stage of the pregenital sadistic-anal organization, there is as yet no question of male and
female; the antithesis between active and passive is the dominant one.¹ At the following stage
of infantile genital organization, which we now know about, maleness exists, but not
femaleness. The antithesis here is between having a male genital and being castrated. It is not
until development has reached its completion at puberty that the sexual polarity coincides with
male and female. Maleness combines subject, activity and possession of the penis; femaleness
takes over object and passivity. The vagina is now valued as a place of shelter for the penis; it
enters into the heritage of the womb.
[1923e, 4062]

The observation which finally breaks down his unbelief is the sight of the female genitals.
Sooner or later the child, who is so proud of his possession of a penis, has a view of the genital
region of a little girl, and cannot help being convinced of the absence of a penis in a creature
who is so like himself. With this, the loss of his own penis becomes imaginable, and the threat
of castration takes its deferred effect.
[1924d, 4087]

We should not be as short-sighted as the person in charge of the child who threatens him with
castration, and we must not overlook the fact that at this time masturbation by no means
represents the whole of his sexual life. As can be clearly shown, he stands in the Oedipus
attitude to his parents; his masturbation is only a genital discharge of the sexual excitation
belonging to the complex, and throughout his later years will owe its importance to that
relationship. The Oedipus complex offered the child two possibilities of satisfaction, an active
and a passive one. He could put himself in his father's place in a masculine fashion and have
intercourse with his mother as his father did, in which case he would soon have felt the latter as
a hindrance; or he might want to take the place of his mother and be loved by his father, in
which case his mother would become superfluous. The child may have had only very vague
notions as to what constitutes a satisfying erotic intercourse; but certainly the penis must play a
part in it, for the sensations in his own organ were evidence of that. So far he had had no
occasion to doubt that women possessed a penis. But now his acceptance of the possibility of
castration, his recognition that women were castrated, made an end of both possible ways of
obtaining satisfaction from the Oedipus complex. For both of them entailed the loss of his penis
- the masculine one as a resulting punishment and the feminine one as a precondition. If the
satisfaction of love in the field of the Oedipus complex is to cost the child his penis, a conflict is
bound to arise between his narcissistic interest in that part of his body and the libidinal cathexis
of his parental objects. In this conflict the first of these forces normally triumphs: the child's ego
turns away from the Oedipus complex.
[1924d, 4088]
At this point our material - for some incomprehensible reason - becomes far more obscure and full of gaps. The female sex, too, develops an Oedipus complex, a super-ego and a latency period. May we also attribute a phallic organization and a castration complex to it? The answer is in the affirmative; but these things cannot be the same as they are in boys. Here the feminist demand for equal rights for the sexes does not take us far, for the morphological distinction is bound to find expression in differences of psychical development. 'Anatomy is Destiny', to vary a saying of Napoleon's. The little girl's clitoris behaves just like a penis to begin with; but, when she makes a comparison with a playfellow of the other sex, she perceives that she has 'come off badly' and she feels this as a wrong done to her and as a ground for inferiority. For a while still she consoles herself with the expectation that later on, when she grows older, she will acquire just as big an appendage as the boy's. Here the masculinity complex of women branches off. A female child, however, does not understand her lack of a penis as being a sex character; she explains it by assuming that at some earlier date she had possessed an equally large organ and had then lost it by castration. She seems not to extend this inference from herself to other, adult females, but, entirely on the lines of the phallic phase, to regard them as possessing large and complete - that is to say, male - genitals. The essential difference thus comes about that the girl accepts castration as an accomplished fact, whereas the boy fears the possibility of its occurrence.

The old paediatrician Lindner once remarked that a child discovers the genital zones (the penis or the clitoris) as a source of pleasure while indulging in sensual sucking (thumb sucking).¹ I shall leave it an open question whether it is really true that the child takes the newly found source of pleasure in exchange for the recent loss of the mother's nipple - a possibility to which later phantasies (fellatio) seem to point. Be that as it may, the genital zone is discovered at some time or other, and there seems no justification for attributing any psychical content to the first activities in connection with it. But the first step in the phallic phase which begins in this way is not the linking-up of the masturbation with the object-cathexes of the Oedipus complex, but a momentous discovery which little girls are destined to make. They notice the penis of a brother or playmate, strikingly visible and of large proportions, at once recognize it as the superior counterpart of their own small and inconspicuous organ, and from that time forward fall a victim to envy for the penis.

There is an interesting contrast between the behaviour of the two sexes. In the analogous situation, when a little boy first catches sight of a girl's genital region, he begins by showing irresolution and lack of interest; he sees nothing or disavows what he has seen, he softens it down or looks about for expedients for bringing it into line with his expectations. It is not until later, when some threat of castration has obtained a hold upon him, that the observation becomes important to him: if he then recollects or repeats it, it arouses a terrible storm of emotion in him and forces him to believe in the reality of the threat which he has hitherto laughed at. This combination of circumstances leads to two reactions, which may become fixed and will in that case, whether separately or together or in conjunction with other factors, permanently determine the boy's relations to women: horror of the mutilated creature or triumph and contempt for her. These developments, however, belong to the future, though not to a very remote one.

A little girl behaves differently. She makes her judgement and her decision in a flash. She has seen it and knows that she is without it and wants to have it.¹
This is an opportunity for correcting a statement which I made many years ago. I believed that the sexual interest of children, unlike that of pubescents, was aroused, not by the difference between the sexes, but by the problem of where babies come from. We now see that, at all events with girls, this is certainly not the case. With boys it may no doubt happen sometimes one way and sometimes the other; or with both sexes chance experiences may determine the event.

A third consequence of penis-envy seems to be a loosening of the girl's relation with her mother as a love-object. The situation as a whole is not very clear, but it can be seen that in the end the girl's mother, who sent her into the world so insufficiently equipped, is almost always held responsible for her lack of a penis. The way in which this comes about historically is often that soon after the girl has discovered that her genitals are unsatisfactory she begins to show jealousy of another child on the ground that her mother is fonder of it than of her, which serves as a reason for her giving up her affectionate relation to her mother. It will fit in with this if the child which has been preferred by her mother is made into the first object of the beating-phantasy which ends in masturbation.

There is yet another surprising effect of penis-envy, or of the discovery of the inferiority of the clitoris, which is undoubtedly the most important of all. In the past I had often formed an impression that in general women tolerate masturbation worse than men, that they more frequently fight against it and that they are unable to make use of it in circumstances in which a man would seize upon it as a way of escape without any hesitation. Experience would no doubt elicit innumerable exceptions to this statement, if we attempted to turn it into a rule. The reactions of human individuals of both sexes are of course made up of masculine and feminine traits. But it appeared to me nevertheless as though masturbation were further removed from the nature of women than of men, and the solution of the problem could be assisted by the reflection that masturbation, at all events of the clitoris, is a masculine activity and that the elimination of clitoridal sexuality is a necessary precondition for the development of femininity. Analyses of the remote phallic period have now taught me that in girls, soon after the first signs of penis-envy, an intense current of feeling against masturbation makes its appearance, which cannot be attributed exclusively to the educational influence of those in charge of the child. This impulse is clearly a forerunner of the wave of repression which at puberty will do away with a large amount of the girl's masculine sexuality in order to make room for the development of her femininity. It may happen that this first opposition to auto-erotic activity fails to attain its end. And this was in fact the case in the instances which I analysed. The conflict continued, and both then and later the girl did everything she could to free herself from the compulsion to masturbate. Many of the later manifestations of sexual life in women remain unintelligible unless this powerful motive is recognized.

I cannot explain the opposition which is raised in this way by little girls to phallic masturbation except by supposing that there is some concurrent factor which turns her violently against that pleasurable activity. Such a factor lies close at hand. It cannot be anything else than her narcissistic sense of humiliation which is bound up with penis-envy, the reminder that after all this is a point on which she cannot compete with boys and that it would therefore be best for her to give up the idea of doing so. Thus the little girl's recognition of the anatomical distinction between the sexes forces her away from masculinity and masculine masturbation on to new lines which lead to the development of femininity.
So far there has been no question of the Oedipus complex, nor has it up to this point played any part. But now the girl's libido slips into a new position along the line - there is no other way of putting it - of the equation 'penis-child'. She gives up her wish for a penis and puts in place of it a wish for a child: and with that purpose in view she takes her father as a love object. Her mother becomes the object of her jealousy. The girl has turned into a little woman. If I am to credit a single analytic instance, this new situation can give rise to physical sensations which would have to be regarded as a premature awakening of the female genital apparatus. When the girl's attachment to her father comes to grief later on and has to be abandoned, it may give place to an identification with him and the girl may thus return to her masculinity complex and perhaps remain fixated in it.

[1925j, 4154]

The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-eroticism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother's organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors' own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child's first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child's life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child's early years become re-animated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of 'male' or 'female' but of 'possessing a penis' or 'castrated'. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses.

[1925d, 4212]
Another, much more specific motive for turning away from the mother arises from the effect of the castration complex on the creature who is without a penis. At some time or other the little girl makes the discovery of her organic inferiority - earlier and more easily, of course, if there are brothers or other boys about. We have already taken note of the three paths which diverge from this point: (a) the one which leads to a cessation of her whole sexual life, (b) the one which leads to a defiant over-emphasis of her masculinity, and (c) the first steps towards definitive femininity. It is not easy to determine the exact timing here or the typical course of events. Even the point of time when the discovery of castration is made varies, and a number of other factors seem to be inconstant and to depend on chance. The state of the girl's own phallic activity plays a part; and so too does the question whether this activity was found out or not, and how much interference with it she experienced afterwards.

[1931b, 4596]

When the little girl discovers her own deficiency, from seeing a male genital, it is only with hesitation and reluctance that she accepts the unwelcome knowledge. As we have seen, she clings obstinately to the expectation of one day having a genital of the same kind too, and her wish for it survives long after her hope has expired. The child invariably regards castration in the first instance as a misfortune peculiar to herself; only later does she realize that it extends to certain other children and lastly to certain grown-ups. When she comes to understand the general nature of this characteristic, it follows that femaleness - and with it, of course, her mother - suffers a great depreciation in her eyes.

[1931b, 4597]

This account of how girls respond to the impression of castration and the prohibition against masturbation will very probably strike the reader as confused and contradictory. This is not entirely the author's fault. In truth, it is hardly possible to give a description which has general validity. We find the most different reactions in different individuals, and in the same individual the contrary attitudes exist side by side. With the first intervention of the prohibition, the conflict is there, and from now on it will accompany the development of the sexual function. Insight into what takes place is made particularly difficult by the fact of its being so hard to distinguish the mental processes of this first phase from later ones by which they are overlaid and are distorted in memory. Thus, for instance, a girl may later construe the fact of castration as a punishment for her masturbatory activity, and she will attribute the carrying out of this punishment to her father, but neither of these ideas can have been a primary one. Similarly, boys regularly fear castration from their father, although in their case, too, the threat most usually comes from their mother.

[1931b, 4597]
Fenichel (1930) rightly emphasizes the difficulty of recognizing in the material produced in analysis what parts of it represent the unchanged content of the pre-Oedipus phase and what parts have been distorted by regression (or in other ways). He does not accept Jeanne Lampl-de Groot's assertion of the little girl's active attitude in the phallic phase. He also rejects the 'displacement backwards' of the Oedipus complex proposed by Melanie Klein (1928), who places its beginnings as early as the commencement of the second year of life. This dating of it, which would also necessarily imply a modification of our view of all the rest of the child's development, does not in fact correspond to what we learn from the analyses of adults, and it is especially incompatible with my findings as to the long duration of the girl's pre-Oedipus attachment to her mother. A means of softening this contradiction is afforded by the reflection that we are not as yet able to distinguish in this field between what is rigidly fixed by biological laws and what is open to movement and change under the influence of accidental experience. The effect of seduction has long been familiar to us and in just the same way other factors - such as the date at which the child's brothers and sisters are born or the time when it discovers the difference between the sexes, or again its direct observations of sexual intercourse or its parents' behaviour in encouraging or repelling it - may hasten the child's sexual development and bring it to maturity.

[1931b, 4606]

We have been able to study transformations of instinct and similar processes particularly in anal erotism, the excitations arising from the sources of the erotogenic anal zone, and we were surprised at the multiplicity of uses to which these instinctual impulses are put. It may not be easy, perhaps, to get free from the contempt into which this particular zone has fallen in the course of evolution. Let us therefore allow ourselves to be reminded by Abraham that embryologically the anus corresponds to the primitive mouth, which has migrated down to the end of the bowel. We have learnt, then, that after a person's own faeces, his excrement, has lost its value for him, this instinctual interest derived from the anal source passes over on to objects that can be presented as gifts. And this is rightly so, for faeces were the first gift that an infant could make, something he could part with out of love for whoever was looking after him. After this, corresponding exactly to analogous changes of meaning that occur in linguistic development, this ancient interest in faeces is transformed into the high valuation of gold and money but also makes a contribution to the affective cathexis of baby and penis. It is a universal conviction among children, who long retain the cloaca theory, that babies are born from the bowel like a piece of faeces: defaecation is the model of the act of birth. But the penis too has its fore-runner in the column of faeces which fills and stimulates the mucous membrane of the bowel. When a child, unwillingly enough, comes to realize that there are human creatures who do not possess a penis, that organ appears to him as something detachable from the body and becomes unmistakably analogous to the excrement, which was the first piece of bodily material that had to be renounced. A great part of anal erotism is thus carried over into a cathexis of the penis. But the interest in that part of the body has, in addition to its anal-erotic root, an oral one which is perhaps more powerful still: for when sucking has come to an end, the penis also becomes heir of the mother's nipple.

[1933a, 4705]

I believe we have found this specific factor, and indeed where we expected to find it, even though in a surprising form. Where we expected to find it, I say, for it lies in the castration complex. After all, the anatomical distinction must express itself in psychical consequences. It was, however, a surprise to learn from analyses that girls hold their mother responsible for their lack of a penis and do not forgive her for their being thus put at a disadvantage.

[1933a, 4726]
As you hear, then, we ascribe a castration complex to women as well. And for good reasons, though its content cannot be the same as with boys. In the latter the castration complex arises after they have learnt from the sight of the female genitals that the organ which they value so highly need not necessarily accompany the body. At this the boy recalls to mind the threats he brought on himself by his doings with that organ, he begins to give credence to them and falls under the influence of fear of castration, which will be the most powerful motive force in his subsequent development. The castration complex of girls is also started by the sight of the genitals of the other sex. They at once notice the difference and, it must be admitted, its significance too. They feel seriously wronged, often declare that they want to 'have something like it too', and fall a victim to 'envy for the penis', which will leave ineradicable traces on their development and the formation of their character and which will not be surmounted in even the most favourable cases without a severe expenditure of psychical energy. The girl's recognition of the fact of her being without a penis does not by any means imply that she submits to the fact easily. On the contrary, she continues to hold on for a long time to the wish to get something like it herself and she believes in that possibility for improbably long years; and analysis can show that, at a period when knowledge of reality has long since rejected the fulfilment of the wish as unattainable, it persists in the unconscious and retains a considerable cathexis of energy. The wish to get the longed-for penis eventually in spite of everything may contribute to the motives that drive a mature woman to analysis, and what she may reasonably expect from analysis - a capacity, for instance, to carry on an intellectual profession - may often be recognized as a sublimated modification of this repressed wish.

The discovery that she is castrated is a turning-point in a girl's growth. Three possible lines of development start from it: one leads to sexual inhibition or to neurosis, the second to change of character in the sense of a masculinity complex, the third, finally, to normal femininity. We have learnt a fair amount, though not everything, about all three.

The essential content of the first is as follows: the little girl has hitherto lived in a masculine way, has been able to get pleasure by the excitation of her clitoris and has brought this activity into relation with her sexual wishes directed towards her mother, which are often active ones; now, owing to the influence of her penis-envy, she loses her enjoyment in her phallic sexuality. Her self-love is mortified by the comparison with the boy's far superior equipment and in consequence she renounces her masturbatory satisfaction from her clitoris, repudiates her love for her mother and at the same time not infrequently represses a good part of her sexual trends in general. No doubt her turning away from her mother does not occur all at once, for to begin with the girl regards her castration as an individual misfortune, and only gradually extends it to other females and finally to her mother as well. Her love was directed to her phallic mother; with the discovery that her mother is castrated it becomes possible to drop her as an object, so that the motives for hostility, which have long been accumulating, gain the upper hand. This means, therefore, that as a result of the discovery of women's lack of a penis they are debased in value for girls just as they are for boys and later perhaps for men.
To go back a little. We mentioned as the second possible reaction to the discovery of female castration the development of a powerful masculinity complex. By this we mean that the girl refuses, as it were, to recognize the unwelcome fact and, defiantly rebellious, even exaggerates her previous masculinity, clings to her clitoral activity and takes refuge in an identification with her phallic mother or her father. What can it be that decides in favour of this outcome? We can only suppose that it is a constitutional factor, a greater amount of activity, such as is ordinarily characteristic of a male. However that may be, the essence of this process is that at this point in development the wave of passivity is avoided which opens the way to the turn towards femininity. The extreme achievement of such a masculinity complex would appear to be the influencing of the choice of an object in the sense of manifest homosexuality. Analytic experience teaches us, to be sure, that female homosexuality is seldom or never a direct continuation of infantile masculinity. Even for a girl of this kind it seems necessary that she should take her father as an object for some time and enter the Oedipus situation. But afterwards, as a result of her inevitable disappointments from her father, she is driven to regress into her early masculinity complex. The significance of these disappointments must not be exaggerated; a girl who is destined to become feminine is not spared them, though they do not have the same effect. The predominance of the constitutional factor seems indisputable; but the two phases in the development of female homosexuality are well mirrored in the practices of homosexuals, who play the parts of mother and baby with each other as often and as clearly as those of husband and wife.

With the phallic phase and in the course of it the sexuality of early childhood reaches its height and approaches its dissolution. Thereafter boys and girls have different histories. Both have begun to put their intellectual activity at the service of sexual researches; both start off from the premiss of the universal presence of the penis. But now the paths of the sexes diverge. The boy enters the Oedipus phase; he begins to manipulate his penis and simultaneously has phantasies of carrying out some sort of activity with it in relation to his mother, till, owing to the combined effect of a threat of castration and the sight of the absence of a penis in females, he experiences the greatest trauma of his life and this introduces the period of latency with all its consequences. The girl, after vainly attempting to do the same as the boy, comes to recognize her lack of a penis or rather the inferiority of her clitoris, with permanent effects on the development of her character; as a result of this first disappointment in rivalry, she often begins by turning away altogether from sexual life.

At this point we must give separate accounts of the development of boys and girls (of males and females), for it is now that the difference between the sexes finds psychological expression for the first time. We are faced here by the great enigma of the biological fact of the duality of the sexes: it is an ultimate fact for our knowledge, it defies every attempt to trace it back to something else. Psycho-analysis has contributed nothing to clearing up this problem, which clearly falls wholly within the province of biology. In mental life we only find reflections of this great antithesis; and their interpretation is made more difficult by the fact, long suspected, that no individual is limited to the modes of reaction of a single sex but always finds some room for those of the opposite one, just as his body bears, alongside of the fully developed organs of one sex, atrophied and often useless rudiments of those of the other. For distinguishing between male and female in mental life we make use of what is obviously an inadequate empirical and conventional equation: we call everything that is strong and active male, and everything that is weak and passive female. This fact of psychological bisexuality, too, embarrasses all our enquiries into the subject and makes them harder to describe.
The boy's mother has understood quite well that his sexual excitation relates to herself. Sooner or later she reflects that it is not right to allow it to continue. She thinks she is doing the correct thing in forbidding him to handle his genital organ. Her prohibition has little effect; at the most it brings about some modification in his method of obtaining satisfaction. At last his mother adopts the severest measures; she threatens to take away from him the thing he is defying her with. Usually, in order to make the threat more frightening and more credible, she delegates its execution to the boy's father, saying that she will tell him and that he will cut the penis off. Strange to say, this threat operates only if another condition is fulfilled before or afterwards. In itself it seems too inconceivable to the boy that such a thing could happen. But if at the time of the threat he can recall the appearance of female genitals or if shortly afterwards he has a sight of them - of genitals, that is to say, which really lack this supremely valued part, then he takes what he has heard seriously and, coming under the influence of the castration complex, experiences the severest trauma of his young life.¹

[1940a [1938], 4997]
In the course of these researches the child arrives at the discovery that the penis is not a possession which is common to all creatures that are like himself. An accidental sight of the genitals of a little sister or playmate provides the occasion for this discovery. In unusually intelligent children, the observation of girls urinating will even earlier have aroused a suspicion that there is something different here. For they will have seen a different posture and heard a different sound, and will have made attempts to repeat their observations so as to obtain enlightenment. We know how children react to their first impressions of the absence of a penis. They disavow the fact and believe that they do see a penis, all the same. They gloss over the contradiction between observation and preconception by telling themselves that the penis is still small and will grow bigger presently; and they then slowly come to the emotionally significant conclusion that after all the penis had at least been there before and been taken away afterwards. The lack of a penis is regarded as a result of castration, and so now the child is faced with the task of coming to terms with castration in relation to himself. The further developments are too well known generally to make it necessary to recapitulate them here. But it seems to me that the significance of the castration complex can only be rightly appreciated if its origin in the phase of phallic primacy is also taken into account.¹

We know, too, to what a degree depreciation of women, horror of women, and a disposition to homosexuality are derived from the final conviction that women have no penis. Ferenczi (1923) has recently, with complete justice, traced back the mythological symbol of horror - Medusa's head - to the impression of the female genitals devoid of a penis.¹

Analytic observation enables us to recognize or guess these connections between the phallic organization, the Oedipus complex, the threat of castration, the formation of the super-ego and the latency period. These connections justify the statement that the destruction of the Oedipus complex is brought about by the threat of castration. But this does not dispose of the problem; there is room for a theoretical speculation which may upset the results we have come to or put them in a new light. Before we start along this new path, however, we must turn to a question which has arisen in the course of this discussion and has so far been left on one side. The process which has been described refers, as has been expressly said, to male children only. How does the corresponding development take place in little girls?

[1923e, 4055]
[1923e, 4060]

[1923e, 4061]

[1924d, 4089]
The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-erotism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother's organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors' own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child's first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child's life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child's early years become re-animated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of 'male' or 'female' but of 'possessing a penis' or 'castrated'. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses.
[1925d, 4212]
There is really very little difficulty in inferring: (1) that the boy had masturbated when he was younger, that he had probably denied it, and that he had been threatened with severe punishment for his bad habit (cf. his admission: ‘Je ne le ferais plus’, and his denial: ‘Albert n'a jamais fait ça’); (2) that with the onset of puberty the temptation to masturbate had revived with the tickling in his genitals; but (3) that a struggle for repression had broken out in him, which had suppressed his libido and transformed it into anxiety, and that the anxiety had taken over the punishments with which he had been threatened earlier.

[1900a, 1014]

Here is another example. A fourteen-year-old boy came to me for psycho-analytic treatment suffering from tic convulsif, hysterical vomiting, headaches, etc. I began the treatment by assuring him that if he shut his eyes he would see pictures or have ideas, which he was then to communicate to me. He replied in pictures. His last impression before coming to me was revived visually in his memory. He had been playing at draughts with his uncle and saw the board in front of him. He thought of various positions, favourable or unfavourable, and of moves that one must not make. He then saw a dagger lying on the board - an object that belonged to his father but which his imagination placed on the board. Then there was a sickle lying on the board and next a scythe. And there now appeared a picture of an old peasant mowing the grass in front of the patient's distant home with a scythe. After a few days I discovered the meaning of this series of pictures. The boy had been upset by an unhappy family situation. He had a father who was a hard man, liable to fits of rage, who had been unhappily married to the patient's mother, and whose educational methods had consisted of threats. His father had been divorced from his mother, a tender and affectionate woman, had married again and had one day brought a young woman home with him who was to be the boy's new mother. It was during the first few days after this that the fourteen-year-old boy's illness had come on. His suppressed rage against his father was what had constructed this series of pictures with their understandable allusions. The material for them was provided by a recollection from mythology. The sickle was the one with which Zeus castrated his father; the scythe and the picture of the old peasant represented Kronos, the violent old man who devoured his children and on whom Zeus took such unfilial vengeance. His father's marriage gave the boy an opportunity of repaying the reproaches and threats which he had heard from his father long before because he had played with his genitals. (Cf. the playing at draughts; the forbidden moves; the dagger which could be used to kill.) In this case long-repressed memories and derivatives from them which had remained unconscious slipped into consciousness by a roundabout path in the form of apparently meaningless pictures.

[1900a, 1043]

CASTRATION COMPLEX AND PENIS ENVY This conviction is energetically maintained by boys, is obstinately defended against the contradictions which soon result from observation, and is only abandoned after severe internal struggles (the castration complex). The substitutes for this penis which they feel is missing in women play a great part in determining the form taken by many perversions.¹

[1905d, 1514]

¹ [Footnote added 1920:] We are justified in speaking of a castration complex in women as well. Both male and female children form a theory that women no less than men originally had a penis, but that they have lost it by castration. The conviction which is finally reached by males that women have no penis often leads them to an enduringly low opinion of the other sex.

[1905d, 1514]
The phantasies of the pubertal period have as their starting-point the infantile sexual researches that were abandoned in childhood. No doubt, too, they are also present before the end of the latency period. They may persist wholly, or to a great extent, unconsciously and for that reason it is often impossible to date them accurately. They are of great importance in the origin of many symptoms, since they precisely constitute preliminary stages of these symptoms and thus lay down the forms in which the repressed libidinal components find satisfaction. In the same way, they are the prototypes of the nocturnal phantasies which become conscious as dreams. Dreams are often nothing more than revivals of pubertal phantasies of this kind under the influence of, and in relation to, some stimulus left over from the waking life of the previous day (the 'day's residues'). Some among the sexual phantasies of the pubertal period are especially prominent, and are distinguished by their very general occurrence and by being to a great extent independent of individual experience. Such are the adolescent's phantasies of overhearing his parents in sexual intercourse, of having been seduced at an early age by someone he loves and of having been threatened with castration; such, too, are his phantasies of being in the womb, and even of experiences there, and the so-called 'Family Romance', in which he reacts to the difference between his attitude towards his parents now and in his childhood. The close relations existing between these phantasies and myths has been demonstrated in the case of the last instance by Otto Rank (1909).

If this idea of a woman with a penis becomes 'fixated' in an individual when he is a child, resisting all the influences of later life and making him as a man unable to do without a penis in his sexual object, then, although in other respects he may lead a normal sexual life, he is bound to become a homosexual, and will seek his sexual object among men who, owing to some other physical and mental characteristics, remind him of women. Real women, when he comes to know them later, remain impossible as sexual objects for him, because they lack the essential sexual attraction; indeed, in connection with another impression of his childhood life, they may even become abhorrent to him. The child, having been mainly dominated by excitations in the penis, will usually have obtained pleasure by stimulating it with his hand; he will have been detected in this by his parents or nurse and terrorized by the threat of having his penis cut off. The effect of this 'threat of castration' is proportionate to the value set upon that organ and is quite extraordinarily deep and persistent. Legends and myths testify to the upheaval in the child's emotional life and to the horror which is linked with the castration complex - a complex which is subsequently remembered by consciousness with corresponding reluctance. The woman's genitalia, when seen later on, are regarded as a mutilated organ and recall this threat, and they therefore arouse horror instead of pleasure in the homosexual. This reaction cannot be altered in any way when the homosexual comes to learn from science that his childish assumption that women had a penis too was not so far wrong after all. Anatomy has recognized the clitoris within the female pudenda as being an organ that is homologous to the penis; and the physiology of the sexual processes has been able to add that this small penis which does not grow any bigger behaves in fact during childhood like a real and genuine penis - that it becomes the seat of excitations which lead to its being touched, that its excitability gives the little girl's sexual activity a masculine character and that a wave of repression in the years of puberty is needed in order for this masculine sexuality to be discarded and the woman to emerge. Since the sexual function of many women is crippled, whether by their obstinate clinging on to this excitability of the clitoris so that they remain anaesthetic in intercourse, or by such excessive repression occurring that its operation is partly replaced by hysterical compensatory formations - all this seems to show that there is some truth in the infantile sexual theory that women, like men, possess a penis.

Meanwhile his interest in widdlers was by no means a purely theoretical one; as might have been expected, it also impelled him to touch his member. When he was three and a half his mother found him with his hand on his penis. She threatened him in these words: 'If you do that, I shall send for Dr. A. to cut off your widdler. And then what'll you widdle with?'
He made this reply without having any sense of guilt as yet. But this was the occasion of his
acquiring the 'castration complex', the presence of which we are so often obliged to infer in
analysing neurotics, though they one and all struggle violently against recognizing it. There is
much of importance to be said upon the significance of this element in the life of a child. The
'castration complex' has left marked traces behind it in myths (and not only in Greek myths); in a
passage in my *Interpretation of Dreams*, and elsewhere, I have touched upon the part it plays.¹

Hans's last words of comfort throw a light upon the situation and allow us to make some small
corrections in his father's assertions. It is true that he was afraid of big animals because he was
obliged to think of their big widdlers; but it cannot really be said that he was afraid of big
widdlers themselves. Formerly the idea of them had been decidedly pleasurable to him, and he
used to make every effort to get a glimpse of one. Since that time this enjoyment had been
spoiled for him, owing to the general reversal of pleasure into unpleasure which had come over
the whole of his sexual researches - in a way which has not yet been explained - and also
owing to something which is clearer to us, namely, to certain experiences and reflections which
had led to distressing conclusions. We may infer from his self-consolatory words ('my widdler
will get bigger as I get bigger') that during his observations he had constantly been making
comparisons, and that he had remained extremely dissatisfied with the size of his own widdler.
Big animals reminded him of his defect, and were for that reason disagreeable to him. But since
the whole train of thought was probably incapable of becoming clearly conscious, this
distressing feeling, too, was transformed into anxiety, so that his present anxiety was erected
both upon his former pleasure and his present unpleasure. When once a state of anxiety
establishes itself, the anxiety swallows up all other feelings; with the progress of repression, and
the more those ideas which are charged with affect and which have been conscious move down
into the unconscious, all affects are capable of being changed into anxiety.²

Hans's singular remark, 'it's fixed in, of course', makes it possible to guess many things in
connection with his consolatory speech which he could not express in words and did not
express during the course of the analysis. I shall bridge the gap for a little distance by means of
my experiences in the analyses of grown-up people; but I hope the interpolation will not be
considered arbitrary or capricious. 'It's fixed in, of course': if the motives of the thought were
solace and defiance, we are reminded of his mother's old threat that she should have his
widdler cut off if he went on playing with it. At the time it was made, when he was three and a
half, this threat had no effect. He calmly replied that then he should widdle with his bottom. It
would be the most completely typical procedure if the threat of castration were to have a
deferred effect, and if he were now, a year and a quarter later, oppressed by the fear of having
to lose this precious piece of his ego. In other cases of illness we can observe a similar deferred
operation of commands and threats made in childhood, where the interval covers as many
decades or more. I even know cases in which a 'deferred obedience' under the influence of
repression has had a principal share in determining the symptoms of the disease.²

The piece of enlightenment which Hans had been given a short time before to the effect that
women really do not possess a widdler was bound to have had a shattering effect upon his self-
confidence and to have aroused his castration complex. For this reason he resisted the
information, and for this reason it had no therapeutic results. Could it be that living beings really
did exist which did not possess widdlers? If so, it would no longer be so incredible that they
could take his own widdler away, and, as it were, make him into a woman!²
¹ I cannot interrupt the discussion so far as to demonstrate the typical character of the unconscious train of thought which I think there is here reason for attributing to little Hans. The castration complex is the deepest unconscious root of anti-semitism; for even in the nursery little boys hear that a Jew has something cut off his penis - a piece of his penis, they think - and this gives them a right to despise Jews. And there is no stronger unconscious root for the sense of superiority over women. Weininger (the young philosopher who, highly gifted but sexually deranged, committed suicide after producing his remarkable book, Geschlecht und Charakter), in a chapter that attracted much attention, treated Jews and women with equal hostility and overwhelmed them with the same insults. Being a neurotic, Weininger was completely under the sway of his infantile complexes; and from that standpoint what is common to Jews and women is their relation to the castration complex.

[1909b, 2026]

And yet, even during the analysis, the small patient gave evidence of enough independence to acquit him upon the charge of 'suggestion'. Like all other children, he applied his childish sexual theories to the material before him without having received any encouragement to do so. These theories are extremely remote from the adult mind. Indeed, in this instance I actually omitted to warn Hans's father that the boy would be bound to approach the subject of childbirth by way of the excretory complex. This negligence on my part, though it led to an obscure phase in the analysis, was nevertheless the means of producing a good piece of evidence of the genuineness and independence of Hans's mental processes. He suddenly became occupied with 'lumf', without his father, who is supposed to have been practising suggestion upon him, having the least idea how he had arrived at that subject or what was going to come of it. Nor can his father be saddled with any responsibility for the production of the two plumber phantasies, which arose out of Hans's early acquired 'castration complex'. And I must here confess that, out of theoretical interest, I entirely concealed from Hans's father my expectation that there would turn out to be some such connection, so as not to interfere with the value of a piece of evidence such as does not often come within one's grasp.

[1909b, 2090]

The first trait in little Hans which can be regarded as part of his sexual life was a quite peculiarly lively interest in his 'widdler' - an organ deriving its name from that one of its two functions which, scarcely the less important of the two, is not to be eluded in the nursery. This interest aroused in him the spirit of enquiry, and he thus discovered that the presence or absence of a widdler made it possible to differentiate between animate and inanimate objects. He assumed that all animate objects were like himself, and possessed this important bodily organ; he observed that it was present in the larger animals, suspected that this was so too in both his parents, and was not deterred by the evidence of his own eyes from authenticating the fact in his new-born sister. One might almost say that it would have been too shattering a blow to his 'Weltanschauung' if he had had to make up his mind to forgo the presence of this organ in a being similar to him; it would have been as though it were being torn away from himself. It was probably on this account that a threat of his mother's, which was concerned precisely with the loss of his widdler, was hastily dismissed from his thoughts and only succeeded in making its effects apparent at a later period. The reason for his mother's intervention had been that he used to like giving himself feelings of pleasure by touching his member: the little boy had begun to practise the commonest - and most normal - form of auto-erotic sexual activity.

[1909b, 2091]
I had expressed a suspicion that Hans's repressed wish might now be that he wanted at all costs to see his mother's widdler. As his behaviour to a new maid fitted in with this hypothesis, his father gave him his first piece of enlightenment, namely, that women have no widdlers. He reacted to this first effort at helping him by producing a phantasy that he had seen his mother showing her widdler.¹ This phantasy and a remark made by him in conversation, to the effect that his widdler was 'fixed in, of course', allow us our first glimpse into the patient's unconscious mental processes. The fact was that the threat of castration made to him by his mother some fifteen months earlier was now having a deferred effect upon him. For his phantasy that his mother was doing the same as he had done (the familiar *tu quoque* repartee of inculpated children) was intended to serve as a piece of self-justification; it was a protective or defensive phantasy. At the same time we must remark that it was Hans's parents who had extracted from the pathogenic material operating in him the particular theme of his interest in widdlers. Hans followed their lead in this matter, but he had not yet taken any line of his own in the analysis. And no therapeutic success was to be observed. The analysis had passed far away from the subject of horses; and the information that women have no widdlers was calculated, if anything, to increase his concern for the preservation of his own.

[1909b, 2102]

It deserves to be noticed that the ideational content of Hans's phobia as it then stood had to be submitted to one further process of distortion and substitution before his consciousness took cognizance of it. Hans's first formulation of his anxiety was: 'the horse will bite me'; and this was derived from another episode at Gmunden, which was on the one hand related to his hostile wishes towards his father and on the other hand was reminiscent of the warning he had been given against masturbation. Some interfering influence, emanating from his parents perhaps, had made itself felt. I am not certain whether the reports upon Hans were at that time drawn up with sufficient care to enable us to decide whether he expressed his anxiety in this form before or not until after his mother had taken him to task on the subject of masturbating. I should be inclined to suspect that it was not until afterwards, though this would contradict the account given in the case history. At any rate, it is evident that at every point Hans's hostile complex against his father screened his lustful one about his mother, just as it was the first to be disclosed and dealt with in the analysis.

[1909b, 2116]
Infantile sexual theories provide the explanation. There was once a time when the male genital was found compatible with the picture of the mother. When a male child first turns his curiosity to the riddles of sexual life, he is dominated by his interest in his own genital. He finds that part of his body too valuable and too important for him to be able to believe that it could be missing in other people whom he feels he resembles so much. As he cannot guess that there exists another type of genital structure of equal worth, he is forced to make the assumption that all human beings, women as well as men, possess a penis like his own. This preconception is so firmly planted in the youthful investigator that it is not destroyed even when he first observes the genitals of little girls. His perception tells him, it is true, that there is something different from what there is in him, but he is incapable of admitting to himself that the content of this perception is that he cannot find a penis in girls. That the penis could be missing strikes him as an uncanny and intolerable idea, and so in an attempt at a compromise he comes to the conclusion that little girls have a penis as well, only it is still very small; it will grow later.¹ If it seems from later observations that this expectation is not realized, he has another remedy at his disposal: little girls too had a penis, but it was cut off and in its place was left a wound. This theoretical advance already makes use of personal experiences of a distressing kind: the boy in the meantime has heard the threat that the organ which is so dear to him will be taken away from him if he shows his interest in it too plainly. Under the influence of this threat of castration he now sees the notion he has gained of the female genitals in a new light; henceforth he will tremble for his masculinity, but at the same time he will despise the unhappy creatures on whom the cruel punishment has, as he supposes, already fallen.²

Before the child comes under the dominance of the castration-complex - at a time when he still holds women at full value - he begins to display an intense desire to look, as an erotic instinctual activity. He wants to see other people's genitals, at first in all probability to compare them with his own. The erotic attraction that comes from his mother soon culminates in a longing for her genital organ, which he takes to be a penis. With the discovery, which is not made till later, that women do not have a penis, this longing often turns into its opposite and gives place to a feeling of disgust which in the years of puberty can become the cause of psychical impotence, misogyny and permanent homosexuality. But the fixation on the object that was once strongly desired, the woman's penis, leaves indelible traces on the mental life of the child, who has pursued that portion of his infantile sexual researches with particular thoroughness. Fetishistic reverence for a woman's foot and shoe appears to take the foot merely as a substitutive symbol for the woman's penis which was once revered and later missed; without knowing it, 'coupeurs de nattes'¹ play the part of people who carry out an act of castration on the female genital organ.

Crawley, in language which differs only slightly from the current terminology of psycho-analysis, declares that each individual is separated from the others by a 'taboo of personal isolation', and that it is precisely the minor differences in people who are otherwise alike that form the basis of feelings of strangeness and hostility between them. It would be tempting to pursue this idea and to derive from this 'narcissism of minor differences' the hostility which in every human relation we see fighting successfully against feelings of fellowship and overpowering the commandment that all men should love one another. Psycho-analysis believes that it has discovered a large part of what underlies the narcissistic rejection of women by men, which is so much mixed up with despising them, in drawing attention to the castration complex and its influence on the opinion in which women are held.

[1910c, 2270]

[1910c, 2271]

[1918a, 2355]
Thus in the case of Schreber we find ourselves once again on the familiar ground of the father-complex.¹ The patient's struggle with Flechsig became revealed to him as a conflict with God, and we must therefore construe it as an infantile conflict with the father whom he loved; the details of that conflict (of which we know nothing) are what determined the content of his delusions. None of the material which in other cases of the sort is brought to light by analysis is absent in the present one: every element is hinted at in one way or another. In infantile experiences such as this the father appears as an interferer with the satisfaction which the child is trying to obtain; this is usually of an auto-erotic character, though at a later date it is often replaced in phantasy by some other satisfaction of a less inglorious kind.² In the final stage of Schreber's delusion a magnificent victory was scored by the infantile sexual urge; for voluptuousness became God-fearing, and God Himself (his father) never tired of demanding it from him. His father's most dreaded threat, castration, actually provided the material for his wishful phantasy (at first resisted but later accepted) of being transformed into a woman. His allusion to an offence covered by the surrogate idea 'soul-murder' could not be more transparent. The chief attendant was discovered to be identical with his neighbour von W., who, according to the voices, had falsely accused him of masturbation (108). The voices said, as though giving grounds for the threat of castration: 'For you are to be represented as being given over to voluptuous excesses.'³ (127-8.) Finally, we come to the enforced thinking which the patient submitted himself because he supposed that God would believe he had become an idiot and would withdraw from him if he ceased thinking for a moment. This is a reaction (with which we are also familiar in other connections) to the threat or fear of losing one's reason⁴ as a result of indulging in sexual practices and especially in masturbation. Considering the enormous number of delusional ideas of a hypochondriacal nature which the patient developed, no great importance should perhaps be attached to the fact that some of them coincide word for word with the hypochondriacal fears of masturbators.⁵

¹ Fear of castration plays an extremely large part, in the case of the youthful neurotics whom we come across, as an interference in their relations with their father. The illuminating instance reported by Ferenczi (1913a) has shown us how a little boy took as his totem the beast that had pecked at his little penis. When our children come to hear of ritual circumcision, they equate it with castration. The parallel in social psychology to this reaction by children has not yet been worked out, so far as I am aware. In primeval times and in primitive races, where circumcision is so frequent, it is performed at the age of initiation into manhood and it is at that age that its significance is to be found; it was only as a secondary development that it was shifted back to the early years of life. It is of very great interest to find that among primitive peoples circumcision is combined with cutting the hair and knocking out teeth or is replaced by them, and that our children, who cannot possibly have any knowledge of this, in fact treat these two operations, in the anxiety with which they react to them, as equivalents of castration.

² [1912-1913, 2792]

³ We soon agreed that, in spite of what he had thought, he could not have told me the story of this vision or hallucination before. He was very well aware that I could not have failed to exploit such evidence as this of his having had a fear of castration at the age of five. The episode broke down his resistance to assuming the existence of a castration complex; but he raised the question: 'Why did I feel so certain of having told you this recollection before?'

⁴ [1914a, 2840]
'Once when my uncle went away on a journey he asked me and my sister what we should like him to bring us back. My sister asked for a book, and I asked for a pocket-knife.' We now understood that this association which had emerged months before had in reality been a screen memory for the repressed recollection, and had been an attempt (rendered abortive by resistance) at telling the story of his imagined loss of his little finger - an unmistakable equivalent for his penis. The knife which his uncle did in fact bring him back was, as he clearly remembered, the same one that made its appearance in the episode which had been suppressed for so long. [1914a, 2840]

The disturbances to which a child's original narcissism is exposed, the reactions with which he seeks to protect himself from them and the paths into which he is forced in doing so - these are themes which I propose to leave on one side, as an important field of work which still awaits exploration. The most significant portion of it, however, can be singled out in the shape of the 'castration complex' (in boys, anxiety about the penis - in girls, envy for the penis) and treated in connection with the effect of early deterrence from sexual activity. Psycho-analytic research ordinarily enables us to trace the vicissitudes undergone by the libidinal instincts when these, isolated from the ego-instincts, are placed in opposition to them; but in the particular field of the castration complex, it allows us to infer the existence of an epoch and a psychical situation in which the two groups of instincts, still operating in unison and inseparably mingled, make their appearance as narcissistic interests. It is from this context that Adler has derived his concept of the 'masculine protest', which he has elevated almost to the position of the sole motive force in the formation of character and neurosis alike and which he bases not on a narcissistic, and therefore still a libidinal, trend, but on a social valuation. Psycho-analytic research has from the very beginning recognized the existence and importance of the 'masculine protest', but it has regarded it, in opposition to Adler, as narcissistic in nature and derived from the castration complex. The 'masculine protest' is concerned in the formation of character, into the genesis of which it enters along with many other factors, but it is completely unsuited for explaining the problems of the neuroses, with regard to which Adler takes account of nothing but the manner in which they serve the ego-instincts. I find it quite impossible to place the genesis of neurosis upon the narrow basis of the castration complex, however powerfully it may come to the fore in men among their resistances to the cure of a neurosis. Incidentally, I know of cases of neurosis in which the 'masculine protest', or, as we regard it, the castration complex, plays no pathogenic part, and even fails to appear at all. [1914c, 2946]
Though I am anxious to cut short this discussion still further, I must nevertheless tell you a little about the sexual researches of children: they are too characteristic of infantile sexuality and of too great significance for the symptomatology of the neuroses to be passed over. Infantile sexual researches begin very early, sometimes before the third year of life. They do not relate to the distinction between the sexes, for this means nothing to children, since they (or at any rate boys) attribute the same male genital to both sexes. If, afterwards, a boy makes the discovery of the vagina from seeing his little sister or a girl playmate, he tries, to begin with, to disavow the evidence of his senses, for he cannot imagine a human creature like himself who is without such a precious portion. Later on, he takes fright at the possibility thus presented to him; and any threats that may have been made to him earlier, because he took too intense an interest in his little organ, now produce a deferred effect. He comes under the sway of the castration complex, the form taken by which plays a great part in the construction of his character if he remains normal, in his neurosis if he falls ill, and in his resistances if he comes into analytic treatment. As regards little girls, we can say of them that they feel greatly at a disadvantage owing to their lack of a big, visible penis, that they envy boys for possessing one and that, in the main for this reason, they develop a wish to be a man - a wish that re-emerges later on, in any neurosis that may arise if they meet with a mishap in playing a feminine part. In her childhood, moreover, a girl's clitoris takes on the role of a penis entirely: it is characterized by special excitability and is the area in which auto-erotic satisfaction is obtained. The process of a girl's becoming a woman depends very much on the clitoris passing on this sensitivity to the vaginal orifice in good time and completely. In cases of what is known as sexual anaesthesia in women the clitoris has obstinately retained its sensitivity.

[1916-1917, 3387]

It agrees entirely with our anticipations when we learn that, after his first genital excitations, his sexual researches began, and that he soon came upon the problem of castration. At this time he succeeded in observing two girls - his sister and a friend of hers - while they were micturating. His acumen might well have enabled him to gather the true facts from this spectacle, but he behaved as we know other male children behave in these circumstances. He rejected the idea that he saw before him a confirmation of the wound with which his Nanya had threatened him, and he explained to himself that this was the girls' 'front bottom'. The theme of castration was not settled by this decision; he found new allusions to it in everything that he heard. Once when the children were given some coloured sugar-sticks, the governess, who was inclined to disordered fancies, pronounced that they were pieces of chopped-up snakes. He remembered afterwards that his father had once met a snake while he was walking along a footpath, and had beaten it to pieces with his stick. He heard the story (out of Reynard the Fox) read aloud, of how the wolf wanted to go fishing in the winter, and used his tail as a bait, and how in that way his tail was broken off in the ice. He learned the different names by which horses are distinguished, according to whether their sexual organs are intact or not. Thus he was occupied with thoughts about castration, but as yet he had no belief in it and no dread of it. Other sexual problems arose for him out of the fairy tales with which he became familiar at this time. In 'Little Red Riding-Hood' and 'The Seven Little Goats' the children were taken out of the wolf's body. Was the wolf a female creature, then, or could men have children in their bodies as well? At this time the question was not yet settled. Moreover, at the time of these enquiries he had as yet no fear of wolves.

[1918b, 3516]
One of the patient's pieces of information will make it easier for us to understand the alteration in his character which appeared during his parents' absence as a somewhat indirect consequence of his seduction. He said that he gave up masturbating very soon after his Nanya's refusal and threat. His sexual life, therefore, which was beginning to come under the sway of the genital zone, gave way before an external obstacle, and was thrown back by its influence into an earlier phase of pregenital organization. As a result of the suppression of his masturbation, the boy's sexual life took on a sadistic-anal character. He became irritable and a tormentor, and gratified himself in this way at the expense of animals and humans. His principal object was his beloved Nanya, and he knew how to torment her till she burst into tears. In this way he revenged himself on her for the refusal he had met with, and at the same time gratified his sexual lust in the form which corresponded to his present regressive phase. He began to be cruel to small animals, to catch flies and pull off their wings, to crush beetles underfoot; in his imagination he liked beating large animals (horses) as well. All of these, then, were active and sadistic proceedings; we shall discuss his anal impulses at this period in a later connection.

When the patient entered more deeply into the situation of the primal scene, he brought to light the following pieces of self-observation. He assumed to begin with, he said, that the event of which he was a witness was an act of violence, but the expression of enjoyment which he saw on his mother's face did not fit in with this; he was obliged to recognize that the experience was one of gratification.¹ What was essentially new for him in his observation of his parents' intercourse was the conviction of the reality of castration - a possibility with which his thoughts had already been occupied previously. (The sight of the two girls micturating, his Nanya's threat, the governess' interpretation of the sugar-sticks, the recollection of his father having beaten a snake to pieces.) For now he saw with his own eyes the wound of which his Nanya had spoken, and understood that its presence was a necessary condition of intercourse with his father. He could no longer confuse it with the bottom, as he had in his observation of the little girls.²

And the driving force of this repression? The circumstances of the case show that it can only have been his narcissistic genital libido which, in the form of concern for his male organ, was fighting against a satisfaction whose attainment seemed to involve the renunciation of that organ. And it was from his threatened narcissism that he derived the masculinity with which he defended himself against his passive attitude towards his father.

This other view which I have in mind is that the state of affairs can be explained in the following manner. It is true that we cannot dispense with the assumption that the child observed a copulation, the sight of which gave him a conviction that castration might be more than an empty threat. Moreover, the significance which he subsequently came to attach to the postures of men and women, in connection with the development of anxiety on the one hand, and as a condition upon which his falling in love depended on the other hand, leaves us no choice but to conclude that it must have been a coitus a tergo, more ferarum. But there is another factor which is not so irreplaceable and which may be dropped. Perhaps what the child observed was not copulation between his parents but copulation between animals, which he then displaced on to his parents, as though he had inferred that his parents did things in the same way.
At this point we must consider an objection, the discussion of which may contribute much to
the elucidation of the apparent confusion of the circumstances. We have been driven to assume
that during the process of the dream he understood that women are castrated, that instead of a
male organ they have a wound which serves for sexual intercourse, and that castration is the
necessary condition of femininity; we have been driven to assume that the threat of this loss
induced him to repress his feminine attitude towards men, and that he awoke from his
homosexual enthusiasm in anxiety. Now how can this comprehension of sexual intercourse, this
recognition of the vagina, be brought into harmony with the selection of the bowel for the
purpose of identification with women? Are not the intestinal symptoms based on what is
probably an older notion, and one which in any case completely contradicts the dread of
castration - the notion, namely, that sexual intercourse takes place at the anus?
[1918b, 3560]

When his Christmas dream, with its excitement and expectancy, conjured up before him the
picture of the sexual intercourse of his parents as it had once been observed (or construed) by
him, there can be no doubt that the first view of it to come up was the old one, according to
which the part of the female body which received the male organ was the anus. And, indeed,
what else could he have supposed when at the age of one and a half he was a spectator of the
scene?¹ But now came the new event that occurred when he was four years old. What he had
learnt in the meantime, the allusions which he had heard to castration, awoke and cast a doubt
on the 'cloacal theory'; they brought to his notice the difference between the sexes and the
sexual part played by women. In this contingency he behaved as children in general behave
when they are given an unwished for piece of information - whether sexual or of any other kind.
He rejected what was new (in our case from motives connected with his fear of castration) and
clung fast to what was old. He decided in favour of the intestine and against the vagina, just as,
for similar motives, he later on took his father's side against God. He rejected the new
information and clung to the old theory. The latter must have provided the material for his
identification with women, which made its appearance later as a dread of death in connection
with the bowels, and for his first religious scruples, about whether Christ had had a behind, and
so on. It is not that his new insight remained without any effect; quite the reverse. It developed
an extraordinarily powerful effect, for it became a motive for keeping the whole process of the
dream under repression and for excluding it from being worked over later in consciousness. But
with that its effect was exhausted; it had no influence in deciding the sexual problem. That it
should have been possible from that time onwards for a fear of castration to exist side by side
with an identification with women by means of the bowel admittedly involved a contradiction. But
it was only a logical contradiction - which is not saying much. On the contrary, the whole
process is characteristic of the way in which the unconscious works. A repression is something
very different from a condemning judgement.
[1918b, 3561]

His hallucination of the severed finger was instigated, as he reported later on, by the story that
a female relation of his had been born with six toes and that the extra one had immediately
afterwards been chopped off with an axe. Women, then, had no penis because it was taken
away from them at birth. In this manner he came, at the period of the obsessional neurosis, to
accept what he had already learned during the dream but had at the time rejected by
repression. He must also have become acquainted, during the readings and discussions of the
sacred story, with the ritual circumcision of Christ and of the Jews in general.
[1918b, 3568]
There is no doubt whatever that at this time his father was turning into the terrifying figure that threatened him with castration. The cruel God with whom he was then struggling - who made men sinful, only to punish them afterwards, who sacrificed his own son and the sons of men - this God threw back his character on to the patient's father, though, on the other hand, the boy was at the same time trying to defend his father against the God. At this point the boy had to fit into a phylogenetic pattern, and he did so, although his personal experiences may not have agreed with it. Although the threats or hints of castration which had come his way had emanated from women,¹ this could not hold up the final result for long. In spite of everything it was his father from whom in the end he came to fear castration. In this respect heredity triumphed over accidental experience; in man's prehistory it was unquestionably the father who practised castration as a punishment and who later softened it down into circumcision. The further the patient went in repressing sensuality during the course of the development of the obsessional neurosis,² the more natural it must have become to him to attribute these evil intentions to his father, who was the true representative of sensual activity.

¹ [1918b, 3568]

His identification of his father with the castrator¹ became important as being the source of an intense unconscious hostility towards him (which reached the pitch of a death-wish) and of a sense of guilt which reacted against it. Up to this point, however, he was behaving normally - that is to say, like every neurotic who is possessed by a positive Oedipus complex. But the astonishing thing was that even against this there was a counter-current working in him, which, on the contrary, regarded his father as the one who had been castrated and as calling, therefore, for his sympathy.

² [1918b, 3569]

The analysis of the anxiety-dream shows us that the repression was connected with his recognition of the existence of castration. The new element was rejected because its acceptance would have cost him his penis. Closer consideration leads us to some such conclusion as the following. What was repressed was the homosexual attitude understood in the genital sense, an attitude which had been formed under the influence of this recognition of castration. But that attitude was retained as regards the unconscious and set up as a dissociated and deeper stratum. The motive force of the repression seems to have been the narcissistic masculinity which attached to the boy's genitals, and which had come into a long-prepared conflict with the passivity of his homosexual sexual aim. The repression was thus a result of his masculinity.

³ [1918b, 3586]
Another part of the nexus of relations can be observed much more clearly in the male. It arises when the boy's sexual researches lead him to the discovery of the absence of a penis in women. He concludes that the penis must be a detachable part of the body, something analogous to faeces, the first piece of bodily substance the child had to part with. Thus the old anal defiance enters into the composition of the castration complex. The organic analogy which enabled the intestinal contents to be the forerunner of the penis during the pregenital phase cannot come into account as a motive; but the boy's sexual researches lead him to a psychical substitute for it. When a baby appears on the scene he regards it as 'lumf', in accordance with those researches, and he cathects it with powerful anal-erotic interest. When social experiences teach that a baby is to be regarded as a love-token, a gift, the wish for a baby receives a second contribution from the same source. Faeces, penis and baby are all three solid bodies; they all three, by forcible entry or expulsion, stimulate a membranous passage, i.e. the rectum and the vagina, the latter being as it were 'taken on lease' from the rectum, as Lou Andreas-Salomé aptly remarks.¹ Infantile sexual researches can only lead to the conclusion that the baby follows the same route as the faecal mass. The function of the penis is not usually discovered by those researches. But it is interesting to note that after so many detours an organic correspondence reappears in the psychical sphere as an unconscious identity.

[1917c, 3605]

Moreover, I would not recommend any opponent of the psycho-analytic view to select this particular story of the Sand-Man with which to support his argument that anxiety about the eyes has nothing to do with the castration complex. For why does Hoffmann bring the anxiety about eyes into such intimate connection with the father's death? And why does the Sand-Man always appear as a disturber of love? He separates the unfortunate Nathaniel from his betrothed and from her brother, his best friend; he destroys the second object of his love, Olympia, the lovely doll; and he drives him into suicide at the moment when he has won back his Clara and is about to be happily united to her. Elements in the story like these, and many others, seem arbitrary and meaningless so long as we deny all connection between fears about the eye and castration; but they become intelligible as soon as we replace the Sand-Man by the dreaded father at whose hands castration is expected.¹

[1919h, 3684]

To decapitate = to castrate. The terror of Medusa is thus a terror of castration that is linked to the sight of something. Numerous analyses have made us familiar with the occasion for this: it occurs when a boy, who has hitherto been unwilling to believe the threat of castration, catches sight of the female genitals, probably those of an adult, surrounded by hair, and essentially those of his mother.

[1940c [1922], 3943]
But why should his father, after being reduced to the status of a Devil, bear this physical mark of a woman? The feature seems at first hard to interpret; but soon we find two explanations which compete with each other without being mutually exclusive. A boy's feminine attitude to his father undergoes repression as soon as he understands that his rivalry with a woman for his father's love has as a precondition the loss of his own male genitals - in other words, castration. Repudiation of the feminine attitude is thus the result of a revolt against castration. It regularly finds its strongest expression in the converse phantasy of castrating the father, of turning him into a woman. Thus the Devil's breasts would correspond to a projection of the subject's own femininity on to the father-substitute. The second explanation of these female additions to the Devil's body no longer has a hostile meaning but an affectionate one. It sees in the adoption of this shape an indication that the child's tender feelings towards his mother have been displaced on to his father; and this suggests that there has previously been a strong fixation on the mother, which, in its turn, is responsible for part of the child's hostility towards his father. Large breasts are the positive sexual characteristics of the mother even at a time when the negative characteristic of the female - her lack of a penis - is as yet unknown to the child.¹

In the course of these researches the child arrives at the discovery that the penis is not a possession which is common to all creatures that are like himself. An accidental sight of the genitals of a little sister or playmate provides the occasion for this discovery. In unusually intelligent children, the observation of girls urinating will even earlier have aroused a suspicion that there is something different here. For they will have seen a different posture and heard a different sound, and will have made attempts to repeat their observations so as to obtain enlightenment. We know how children react to their first impressions of the absence of a penis. They disavow the fact and believe that they do see a penis, all the same. They gloss over the contradiction between observation and preconception by telling themselves that the penis is still small and will grow bigger presently; and they then slowly come to the emotionally significant conclusion that after all the penis had at least been there before and been taken away afterwards. The lack of a penis is regarded as a result of castration, and so now the child is faced with the task of coming to terms with castration in relation to himself. The further developments are too well known generally to make it necessary to recapitulate them here. But it seems to me that the significance of the castration complex can only be rightly appreciated if its origin in the phase of phallic primacy is also taken into account.¹

We know, too, to what a degree depreciation of women, horror of women, and a disposition to homosexuality are derived from the final conviction that women have no penis. Ferenczi (1923) has recently, with complete justice, traced back the mythological symbol of horror - Medusa's head - to the impression of the female genitals devoid of a penis.¹
It should not be supposed, however, that the child quickly and readily makes a generalization from his observation that some women have no penis. He is in any case debarred from doing so by his assumption that the lack of a penis is the result of having been castrated as a punishment. On the contrary, the child believes that it is only unworthy female persons that have lost their genitals - females who, in all probability, were guilty of inadmissible impulses similar to his own. Women whom he respects, like his mother, retain a penis for a long time. For him, being a woman is not yet synonymous with being without a penis.² It is not till later, when the child takes up the problems of the origin and birth of babies, and when he guesses that only women can give birth to them - it is only then that the mother, too, loses her penis. And, along with this, quite complicated theories are built up to explain the exchange of the penis for a baby. In all this, the female genitals never seem to be discovered. The baby, we know, is supposed to live inside the mother's body (in her bowel) and to be born through the intestinal outlet. These last theories carry us beyond the stretch of time covered by the infantile sexual period.

² [1923e, 4061]

When the (male) child's interest turns to his genitals he betrays the fact by manipulating them frequently; and he then finds that the adults do not approve of this behaviour. More or less plainly, more or less brutally, a threat is pronounced that this part of him which he values so highly will be taken away from him. Usually it is from women that the threat emanates; very often they seek to strengthen their authority by a reference to the father or the doctor, who, so they say, will carry out the punishment. In a number of cases the women will themselves mitigate the threat in a symbolic manner by telling the child that what is to be removed is not his genital, which actually plays a passive part, but his hand, which is the active culprit. It happens particularly often that the little boy is threatened with castration, not because he plays with his penis with his hand, but because he wets his bed every night and cannot be got to be clean. Those in charge of him behave as if this nocturnal incontinence was the result and the proof of his being unduly concerned with his penis, and they are probably right. In any case, long-continued bed-wetting is to be equated with the emissions of adults. It is an expression of the same excitation of the genitals which has impelled the child to masturbate at this period.

³ [1924d, 4086]

Now it is my view that what brings about the destruction of the child's phallic genital organization is this threat of castration. Not immediately, it is true, and not without other influences being brought to bear as well. For to begin with the boy does not believe in the threat or obey it in the least. Psycho-analysis has recently attached importance to two experiences which all children go through and which, it is suggested, prepare them for the loss of highly valued parts of the body. These experiences are the withdrawal of the mother's breast - at first intermittently and later for good - and the daily demand on them to give up the contents of the bowel. But there is no evidence to show that, when the threat of castration takes place, those experiences have any effect. It is not until a fresh experience comes his way that the child begins to reckon with the possibility of being castrated, and then only hesitantly and unwillingly, and not without making efforts to depreciate the significance of something he has himself observed.

⁴ [1924d, 4087]

The observation which finally breaks down his unbelief is the sight of the female genitals. Sooner or later the child, who is so proud of his possession of a penis, has a view of the genital region of a little girl, and cannot help being convinced of the absence of a penis in a creature who is so like himself. With this, the loss of his own penis becomes imaginable, and the threat of castration takes its deferred effect.

⁵ [1924d, 4087]
We should not be as short-sighted as the person in charge of the child who threatens him with castration, and we must not overlook the fact that at this time masturbation by no means represents the whole of his sexual life. As can be clearly shown, he stands in the Oedipus attitude to his parents; his masturbation is only a genital discharge of the sexual excitation belonging to the complex, and throughout his later years will owe its importance to that relationship. The Oedipus complex offered the child two possibilities of satisfaction, an active and a passive one. He could put himself in his father's place in a masculine fashion and have intercourse with his mother as his father did, in which case he would soon have felt the latter as a hindrance; or he might want to take the place of his mother and be loved by his father, in which case his mother would become superfluous. The child may have had only very vague notions as to what constitutes a satisfying erotic intercourse; but certainly the penis must play a part in it, for the sensations in his own organ were evidence of that. So far he had had no occasion to doubt that women possessed a penis. But now his acceptance of the possibility of castration, his recognition that women were castrated, made an end of both possible ways of obtaining satisfaction from the Oedipus complex. For both of them entailed the loss of his penis - the masculine one as a resulting punishment and the feminine one as a precondition. If the satisfaction of love in the field of the Oedipus complex is to cost the child his penis, a conflict is bound to arise between his narcissistic interest in that part of his body and the libidinal cathexis of his parental objects. In this conflict the first of these forces normally triumphs: the child's ego turns away from the Oedipus complex.

I have described elsewhere how this turning away takes place. The object-cathexes are given up and replaced by identifications. The authority of the father or the parents is introjected into the ego, and there it forms the nucleus of the super-ego, which takes over the severity of the father and perpetuates his prohibition against incest, and so secures the ego from the return of the libidinal object-cathexis. The libidinal trends belonging to the Oedipus complex are in part desexualized and sublimated (a thing which probably happens with every transformation into an identification) and in part inhibited in their aim and changed into impulses of affection. The whole process has, on the one hand, preserved the genital organ - has averted the danger of its loss - and, on the other, has paralysed it - has removed its function. This process ushers in the latency period, which now interrupts the child's sexual development.

Analytic observation enables us to recognize or guess these connections between the phallic organization, the Oedipus complex, the threat of castration, the formation of the super-ego and the latency period. These connections justify the statement that the destruction of the Oedipus complex is brought about by the threat of castration. But this does not dispose of the problem; there is room for a theoretical speculation which may upset the results we have come to or put them in a new light. Before we start along this new path, however, we must turn to a question which has arisen in the course of this discussion and has so far been left on one side. The process which has been described refers, as has been expressly said, to male children only. How does the corresponding development take place in little girls?
At this point our material - for some incomprehensible reason - becomes far more obscure and full of gaps. The female sex, too, develops an Oedipus complex, a super-ego and a latency period. May we also attribute a phallic organization and a castration complex to it? The answer is in the affirmative; but these things cannot be the same as they are in boys. Here the feminist demand for equal rights for the sexes does not take us far, for the morphological distinction is bound to find expression in differences of psychological development. 'Anatomy is Destiny', to vary a saying of Napoleon's. The little girl's clitoris behaves just like a penis to begin with; but, when she makes a comparison with a playfellow of the other sex, she perceives that she has 'come off badly' and she feels this as a wrong done to her and as a ground for inferiority. For a while still she consoles herself with the expectation that later on, when she grows older, she will acquire just as big an appendage as the boy's. Here the masculinity complex of women branches off. A female child, however, does not understand her lack of a penis as being a sex character; she explains it by assuming that at some earlier date she had possessed an equally large organ and had then lost it by castration. She seems not to extend this inference from herself to other, adult females, but, entirely on the lines of the phallic phase, to regard them as possessing large and complete - that is to say, male - genitals. The essential difference thus comes about that the girl accepts castration as an accomplished fact, whereas the boy fears the possibility of its occurrence.

[1924d, 4090]

In boys the situation of the Oedipus complex is the first stage that can be recognized with certainty. It is easy to understand, because at that stage a child retains the same object which he previously cathected with his libido - not as yet a genital one - during the preceding period while he was being suckled and nursed. The fact, too, that in this situation he regards his father as a disturbing rival and would like to get rid of him and take his place is a straightforward consequence of the actual state of affairs. I have shown elsewhere how the Oedipus attitude in little boys belongs to the phallic phase, and how its destruction is brought about by the fear of castration - that is, by narcissistic interest in their genitals. The matter is made more difficult to grasp by the complicating circumstance that even in boys the Oedipus complex has a double orientation, active and passive, in accordance with their bisexual constitution; a boy also wants to take his mother's place as the love-object of his father - a fact which we describe as the feminine attitude.

[1925j, 4147]
As regards the prehistory of the Oedipus complex in boys we are far from complete clarity. We know that that period includes an identification of an affectionate sort with the boy's father, an identification which is still free from any sense of rivalry in regard to his mother. Another element of that stage is invariably, I believe, a masturbatory activity in connection with the genitals, the masturbation of early childhood, the more or less violent suppression of which by those in charge of the child sets the castration complex in action. It is to be assumed that this masturbation is attached to the Oedipus complex and serves as a discharge for the sexual excitation belonging to it. It is, however, uncertain whether the masturbation has this character from the first, or whether on the contrary it makes its first appearance spontaneously as an activity of a bodily organ and is only brought into relation with the Oedipus complex at some later date; this second possibility is by far the more probable. Another doubtful question is the part played by bed-wetting and by the breaking of that habit through the intervention of training measures. We are inclined to make the simple connection that continued bed-wetting is a result of masturbation and that its suppression is regarded by boys as an inhibition of their genital activity - that is, as having the meaning of a threat of castration; but whether we are always right in supposing this remains to be seen. Finally, analysis shows us in a shadowy way how the fact of a child at a very early age listening to his parents copulating may set up his first sexual excitation, and how that event may, owing to its after-effects, act as a starting-point for the child's whole sexual development. Masturbation, as well as the two attitudes in the Oedipus complex, later on become attached to this early experience, the child having subsequently interpreted its meaning. It is impossible, however, to suppose that these observations of coitus are of universal occurrence, so that at this point we are faced with the problem of 'primal phantasies'. Thus the prehistory of the Oedipus complex, even in boys, raises all of these questions for sifting and explanation; and there is the further problem of whether we are to suppose that the process invariably follows the same course, or whether a great variety of different preliminary stages may not converge upon the same terminal situation.

[1925j, 4148]

There is an interesting contrast between the behaviour of the two sexes. In the analogous situation, when a little boy first catches sight of a girl's genital region, he begins by showing irresolution and lack of interest; he sees nothing or disavows what he has seen, he softens it down or looks about for expedients for bringing it into line with his expectations. It is not until later, when some threat of castration has obtained a hold upon him, that the observation becomes important to him: if he then recollects or repeats it, it arouses a terrible storm of emotion in him and forces him to believe in the reality of the threat which he has hitherto laughed at. This combination of circumstances leads to two reactions, which may become fixed and will in that case, whether separately or together or in conjunction with other factors, permanently determine the boy's relations to women: horror of the mutilated creature or triumph and contempt for her. These developments, however, belong to the future, though not to a very remote one.

[1925j, 4150]

¹ This is an opportunity for correcting a statement which I made many years ago. I believed that the sexual interest of children, unlike that of pubescents, was aroused, not by the difference between the sexes, but by the problem of where babies come from. We now see that, at all events with girls, this is certainly not the case. With boys it may no doubt happen sometimes one way and sometimes the other; or with both sexes chance experiences may determine the event.

[1925j, 4150]
I have now said the essence of what I had to say: I will stop, therefore, and cast an eye over our findings. We have gained some insight into the prehistory of the Oedipus complex in girls. The corresponding period in boys is more or less unknown. In girls the Oedipus complex is a secondary formation. The operations of the castration complex precede it and prepare for it. As regards the relation between the Oedipus and castration complexes there is a fundamental contrast between the two sexes. Whereas in boys the Oedipus complex is destroyed by the castration complex, in girls it is made possible and led up to by the castration complex. This contradiction is cleared up if we reflect that the castration complex always operates in the sense implied in its subject-matter: it inhibits and limits masculinity and encourages femininity. The difference between the sexual development of males and females at the stage we have been considering is an intelligible consequence of the anatomical distinction between their genitals and of the psychical situation involved in it; it corresponds to the difference between a castration that has been carried out and one that has merely been threatened. In their essentials, therefore, our findings are self-evident and it should have been possible to foresee them. [1925], 4154

The Oedipus complex, however, is such an important thing that the manner in which one enters and leaves it cannot be without its effects. In boys (as I have shown at length in the paper to which I have just referred and to which all of my present remarks are closely related) the complex is not simply repressed, it is literally smashed to pieces by the shock of threatened castration. Its libidinal cathexes are abandoned, desexualized and in part sublimated; its objects are incorporated into the ego, where they form the nucleus of the super-ego and give that new structure its characteristic qualities. In normal, or, it is better to say, in ideal cases, the Oedipus complex exists no longer, even in the unconscious; the super-ego has become its heir. Since the penis (to follow Ferenczi) owes its extraordinarily high narcissistic cathexis to its organic significance for the propagation of the species, the catastrophe to the Oedipus complex (the abandonment of incest and the institution of conscience and morality) may be regarded as a victory of the race over the individual. This is an interesting point of view when one considers that neurosis is based upon a struggle of the ego against the demands of the sexual function. But to leave the standpoint of individual psychology is not of any immediate help in clarifying this complicated situation. [1925], 4155
These are unwelcome complications, considering that we only set out to study simple cases of symptom-formation due to repression, and with that intention selected the earliest and to all appearances, most transparent neuroses of childhood. Instead of a single repression we have found a collection of them and have become involved with regression into the bargain. Perhaps we have added to the confusion by treating the two cases of animal phobia at our disposal - 'Little Hans' and the 'Wolf Man' - as though they were cast in the same mould. As a matter of fact, certain differences between them stand out. It is only with regard to 'Little Hans' that we can say with certainty that what his phobia disposed of were the two main impulses of the Oedipus complex - his aggressiveness towards his father and his over-fondness for his mother. A tender feeling for his father was undoubtedly there too and played a part in repressing the opposite feeling; but we can prove neither that it was strong enough to draw repression upon itself nor that it disappeared afterwards. 'Hans' seems, in fact, to have been a normal boy with what is called a 'positive' Oedipus complex. It is possible that the factors which we do not find were actually at work in him, but we cannot demonstrate their existence. Even the most exhaustive analysis has gaps in its data and is insufficiently documented. In the case of the Russian the deficiency lies elsewhere. His attitude to female objects had been disturbed by an early seduction and his passive, feminine side was strongly developed. The analysis of his wolf-dream revealed very little intentional aggressiveness towards his father, but it brought forward unmistakable proof that what repression overtook was his passive tender attitude to his father. In his case, too, the other factors may have been operative as well; but they were not in evidence. How is it that, in spite of these differences in the two cases, almost amounting to an antithesis, the final outcome - a phobia - was approximately the same? The answer must be sought in another quarter. I think it will be found in the second fact which emerges from our brief comparative examination. It seems to me that in both cases we can detect what the motive force of the repression was and can substantiate our view of its nature from the line of development which the two children subsequently pursued. This motive force was the same in both of them. It was the fear of impending castration. 'Little Hans' gave up his aggressiveness towards his father from fear of being castrated. His fear that a horse would bite him can, without any forcing, be given the full sense of a fear that a horse would bite off his genitals, would castrate him. But it was from fear of being castrated, too, that the little Russian relinquished his wish to be loved by his father, for he thought that a relation of that sort presupposed a sacrifice of his genitals - of the organ which distinguished him from a female. As we see, both forms of the Oedipus complex, the normal, active form and the inverted one, came to grief through the castration complex. The Russian boy's anxiety-idea of being devoured by a wolf contained, it is true, no suggestion of castration, for the oral regression it had undergone had removed it too far from the phallic stage. But the analysis of his dream rendered further proof superfluous. It was a triumph of repression that the form in which his phobia was expressed should no longer have contained any allusion to castration.

[1926d, 4267]
The significance of the loss of object as a determinant of anxiety extends considerably further. For the next transformation of anxiety, viz. the castration anxiety belonging to the phallic phase, is also a fear of separation and is thus attached to the same determinant. In this case the danger is of being separated from one's genitals. Ferenczi has traced, quite correctly, I think, a clear line of connection between this fear and the fears contained in the earlier situations of danger. The high degree of narcissistic value which the penis possesses can appeal to the fact that that organ is a guarantee to its owner that he can be once more united to his mother - i.e. to a substitute for her - in the act of copulation. Being deprived of it amounts to a renewed separation from her, and this in its turn means being helplessly exposed to an unpleasurable tension due to instinctual need, as was the case at birth. But the need whose increase is feared is now a specific one belonging to the genital libido and is no longer an indeterminate one, as it was in the period of infancy. It may be added that for a man who is impotent (that is, who is inhibited by the threat of castration) the substitute for copulation is a phantasy of returning into his mother's womb. Following Ferenczi's line of thought, we might say that the man in question, having tried to bring about his return into his mother's womb by using his genital organ to represent him, is now replacing that organ regressively by his whole person.

[1926d, 4294]

This study of the determinants of anxiety has, as it were, shown the defensive behaviour of the ego transfigured in a rational light. Each situation of danger corresponds to a particular period of life or a particular developmental phase of the mental apparatus and appears to be justifiable for it. In early infancy the individual is really not equipped to master psychically the large sums of excitation that reach him whether from without or from within. Again, at a certain period of life his most important interest really is that the people he is dependent on should not withdraw their loving care of him. Later on in his boyhood, when he feels that his father is a powerful rival in regard to his mother and becomes aware of his own aggressive inclinations towards him and of his sexual intentions towards his mother, he really is justified in being afraid of his father; and his fear of being punished by him can find expression through phylogenetic reinforcement in the fear of being castrated. Finally, as he enters into social relationships, it really is necessary for him to be afraid of his super-ego, to have a conscience; and the absence of that factor would give rise to severe conflicts, dangers and so on.

[1926d, 4301]

There is much to be told, for which our expectations have not prepared us, about the contents, manifestations and achievements of this early period of sexuality. For instance, you will no doubt be surprised to hear how often little boys are afraid of being eaten up by their father. (And you may also be surprised at my including this fear among the phenomena of sexual life.) But I may remind you of the mythological tale which you may still recall from your schooldays of how the god Kronos swallowed his children. How strange this must have sounded to you when you first heard it! But I suppose none of us thought about it at the time. To-day we can also call to mind a number of fairy tales in which some ravenous animal like a wolf appears, and we shall recognize it as a disguise of the father. And this is an opportunity of assuring you that it was only through the knowledge of infantile sexuality that it became possible to understand mythology and the world of fairy tales. Here then something has been gained as a by-product of analytic studies.

[1926e, 4354]
You will be no less surprised to hear that male children suffer from a fear of being robbed of their sexual organ by their father, so that this fear of being castrated has a most powerful influence on the development of their character and in deciding the direction to be followed by their sexuality. And here again mythology may give you the courage to believe psycho-analysis. The same Kronos who swallowed his children also emasculated his father Uranus, and was afterwards himself emasculated in revenge by his son Zeus, who had been rescued though his mother's cunning. If you have felt inclined to suppose that all that psycho-analysis reports about the early sexuality of children is derived from the disordered imagination of the analysts, you must at least admit that their imagination has created the same product as the imaginative activities of primitive man, of which myths and fairy tales are the precipitate. The alternative friendlier, and probably also the more pertinent view would be that in the mental life of children to-day we can still detect the same archaic factors which were once dominant generally in the primaeval days of human civilization. In his mental development the child would be repeating the history of his race in an abbreviated form, just as embryology long since recognized was the case with somatic development.

Returning to my description of fetishism, I may say that there are many and weighty additional proofs of the divided attitude of fetishists to the question of the castration of women. In very subtle instances both the disavowal and the affirmation of the castration have found their way into the construction of the fetish itself. This was so in the case of a man whose fetish was an athletic support-belt which could also be worn as bathing drawers. This piece of clothing covered up the genitals entirely and concealed the distinction between them. Analysis showed that it signified that women were castrated and that they were not castrated; and it also allowed of the hypothesis that men were castrated, for all these possibilities could equally well be concealed under the belt - the earliest rudiment of which in his childhood had been the fig-leaf on a statue. A fetish of this sort, doubly derived from contrary ideas, is of course especially durable. In other instances the divided attitude shows itself in what the fetishist does with his fetish, whether in reality or in his imagination. To point out that he reveres his fetish is not the whole story; in many cases he treats it in a way which is obviously equivalent to a representation of castration. This happens particularly if he has developed a strong identification with his father and plays the part of the latter; for it is to him that as a child he ascribed the woman's castration. Affection and hostility in the treatment of the fetish - which run parallel with the disavowal and the acknowledgement of castration - are mixed in unequal proportions in different cases, so that the one or the other is more clearly recognizable. We seem here to approach an understanding, even if a distant one, of the behaviour of the 'coupeur de nattes'. In him the need to carry out the castration which he disavows has come to the front. His action contains in itself the two mutually incompatible assertions: 'the woman has still got a penis' and 'my father has castrated the woman'. Another variant, which is also a parallel to fetishism in social psychology, might be seen in the Chinese custom of mutilating the female foot and then revering it like a fetish after it has been mutilated. It seems as though the Chinese male wants to thank the woman for having submitted to being castrated.

[1926e, 4354]

[1927e, 4538]
Parricide, according to a well-known view, is the principal and primal crime of humanity as well as of the individual. (See my Totem and Taboo 1912-13.) It is in any case the main source of the sense of guilt, though we do not know if it is the only one: researches have not yet been able to establish with certainty the mental origin of guilt and the need for expiation. But it is not necessary for it to be the only one. The psychological situation is complicated and requires elucidation. The relation of a boy to his father is, as we say, an 'ambivalent' one. In addition to the hate which seeks to get rid of the father as a rival, a measure of tenderness for him is also habitually present. The two attitudes of mind combine to produce identification with the father; the boy wants to be in his father's place because he admires him and wants to be like him, and also because he wants to put him out of the way. This whole development now comes up against a powerful obstacle. At a certain moment the child comes to understand that an attempt to remove his father as a rival would be punished by him with castration. So from fear of castration - that is, in the interests of preserving his masculinity - he gives up his wish to possess his mother and get rid of his father. In so far as this wish remains in the unconscious it forms the basis of the sense of guilt. We believe that what we have here been describing are normal processes, the normal fate of the so-called 'Oedipus complex'; nevertheless it requires an important amplification.

[1928b, 4559]

A further complication arises when the constitutional factor we call bisexuality is comparatively strongly developed in a child. For then, under the threat to the boy's masculinity by castration, his inclination becomes strengthened to diverge in the direction of femininity, to put himself instead in his mother's place and take over her role as object of his father's love. But the fear of castration makes this solution impossible as well. The boy understands that he must also submit to castration if he wants to be loved by his father as a woman. Thus both impulses, hatred of the father and being in love with the father, undergo repression. There is a certain psychological distinction in the fact that the hatred of the father is given up on account of fear of an external danger (castration), while the being in love with the father is treated as an internal instinctual danger, though fundamentally it goes back to the same external danger.

[1928b, 4559]

What makes hatred of the father unacceptable is fear of the father; castration is terrible, whether as a punishment or as the price of love. Of the two factors which repress hatred of the father, the first, the direct fear of punishment and castration, may be called the normal one; its pathogenic intensification seems to come only with the addition of the second factor, the fear of the feminine attitude. Thus a strong innate bisexual disposition becomes one of the preconditions or reinforcements of neurosis. Such a disposition must certainly be assumed in Dostoevsky, and it shows itself in a viable form (as latent homosexuality) in the important part played by male friendships in his life, in his strangely tender attitude towards rivals in love and in his remarkable understanding of situations which are explicable only by repressed homosexuality, as many examples from his novels show.

[1928b, 4560]

I am sorry, though I cannot alter the facts, if this exposition of the attitudes of hatred and love towards the father and their transformations under the influence of the threat of castration seems to readers unfamiliar with psycho-analysis unsavoury and incredible. I should myself expect that it is precisely the castration complex that would be bound to arouse the most general repudiation. But I can only insist that psycho-analytic experience has put these matters in particular beyond the reach of doubt and has taught us to recognize in them the key to every neurosis. This key, then, we must apply to our author's so-called epilepsy. So alien to our consciousness are the things by which our unconscious mental life is governed!

[1928b, 4560]
We have already learned, too, that there is yet another difference between the sexes, which relates to the Oedipus complex. We have an impression here that what we have said about the Oedipus complex applies with complete strictness to the male child only and that we are right in rejecting the term 'Electra complex' which seeks to emphasize the analogy between the attitude of the two sexes. It is only in the male child that we find the fateful combination of love for the one parent and simultaneous hatred for the other as a rival. In his case it is the discovery of the possibility of castration, as proved by the sight of the female genitals, which forces on him the transformation of his Oedipus complex, and which leads to the creation of his super-ego and thus initiates all the processes that are designed to make the individual find a place in the cultural community. After the paternal agency has been internalized and become a super-ego, the next task is to detach the latter from the figures of whom it was originally the psychical representative. In this remarkable course of development it is precisely the boy's narcissistic interest in his genitals - his interest in preserving his penis - which is turned round into a curtailing of his infantile sexuality.

This account of how girls respond to the impression of castration and the prohibition against masturbation will very probably strike the reader as confused and contradictory. This is not entirely the author's fault. In truth, it is hardly possible to give a description which has general validity. We find the most different reactions in different individuals, and in the same individual the contrary attitudes exist side by side. With the first intervention of the prohibition, the conflict is there, and from now on it will accompany the development of the sexual function. Insight into what takes place is made particularly difficult by the fact of its being so hard to distinguish the mental processes of this first phase from later ones by which they are overlaid and are distorted in memory. Thus, for instance, a girl may later construe the fact of castration as a punishment for her masturbatory activity, and she will attribute the carrying out of this punishment to her father, but neither of these ideas can have been a primary one. Similarly, boys regularly fear castration from their father, although in their case, too, the threat most usually comes from their mother.

But we have not made any mention at all so far of what the real danger is that the child is afraid of as a result of being in love with his mother. The danger is the punishment of being castrated, of losing his genital organ. You will of course object that after all that is not a real danger. Our boys are not castrated because they are in love with their mothers during the phase of the Oedipus complex. But the matter cannot be dismissed so simply. Above all, it is not a question of whether castration is really carried out; what is decisive is that the danger is one that threatens from outside and that the child believes in it. He has some ground for this, for people threaten him often enough with cutting off his penis during the phallic phase, at the time of his early masturbation, and hints at that punishment must regularly find a phylogenetic reinforcement in him. It is our suspicion that during the human family's primaeval period castration used actually to be carried out by a jealous and cruel father upon growing boys, and that circumcision, which so frequently plays a part in puberty rites among primitive peoples, is a clearly recognizable relic of it. We are aware that here we are diverging widely from the general opinion; but we must hold fast to the view that fear of castration is one of the commonest and strongest motives for repression and thus for the formation of neuroses. The analysis of cases in which circumcision, though not, it is true, castration, has been carried out on boys as a cure or punishment for masturbation (a far from rare occurrence in Anglo-American society) has given our conviction a last degree of certainty. It is very tempting at this point to go more deeply into the castration complex, but I will stick to our subject.
Fear of castration is not, of course, the only motive for repression: indeed, it finds no place in women, for though they have a castration complex they cannot have a fear of being castrated. Its place is taken in their sex by a fear of loss of love, which is evidently a later prolongation of the infant's anxiety if it finds its mother absent. You will realize how real a situation of danger is indicated by this anxiety. If a mother is absent or has withdrawn her love from her child, it is no longer sure of the satisfaction of its needs and is perhaps exposed to the most distressing feelings of tension. Do not reject the idea that these determinants of anxiety may at bottom repeat the situation of the original anxiety at birth, which, to be sure, also represented a separation from the mother. Indeed, if you follow a train of thought suggested by Ferenczi, you may add the fear of castration to this series, for a loss of the male organ results in an inability to unite once more with the mother (or a substitute for her) in the sexual act. I may mention to you incidentally that the very frequent phantasy of returning into the mother's womb is a substitute for this wish to copulate. There would be many interesting things and surprising connections to tell you at this point, but I cannot go outside the framework of an introduction to psycho-analysis. I will only draw your attention to the fact that here psychological researches trench upon the facts of biology.

[1933a, 4694]

As you hear, then, we ascribe a castration complex to women as well. And for good reasons, though its content cannot be the same as with boys. In the latter the castration complex arises after they have learnt from the sight of the female genitals that the organ which they value so highly need not necessarily accompany the body. At this the boy recalls to mind the threats he brought on himself by his doings with that organ; he begins to give credence to them and falls under the influence of fear of castration, which will be the most powerful motive force in his subsequent development. The castration complex of girls is also started by the sight of the genitals of the other sex. They at once notice the difference and, it must be admitted, its significance too. They feel seriously wronged, often declare that they want to 'have something like it too', and fall a victim to 'envy for the penis', which will leave ineradicable traces on their development and the formation of their character and which will not be surmounted in even the most favourable cases without a severe expenditure of psychical energy. The girl's recognition of the fact of her being without a penis does not by any means imply that she submits to the fact easily. On the contrary, she continues to hold on for a long time to the wish to get something like it herself and she believes in that possibility for improbably long years; and analysis can show that, at a period when knowledge of reality has long since rejected the fulfilment of the wish as unattainable, it persists in the unconscious and retains a considerable cathexis of energy. The wish to get the longed-for penis eventually in spite of everything may contribute to the motives that drive a mature woman to analysis, and what she may reasonably expect from analysis - a capacity, for instance, to carry on an intellectual profession - may often be recognized as a sublimated modification of this repressed wish.

[1933a, 4727]
The essential content of the first is as follows: the little girl has hitherto lived in a masculine way, has been able to get pleasure by the excitation of her clitoris and has brought this activity into relation with her sexual wishes directed towards her mother, which are often active ones; now, owing to the influence of her penis-envy, she loses her enjoyment in her phallic sexuality. Her self-love is mortified by the comparison with the boy's far superior equipment and in consequence she renounces her masturbatory satisfaction from her clitoris, repudiates her love for her mother and at the same time not infrequently represses a good part of her sexual trends in general. No doubt her turning away from her mother does not occur all at once, for to begin with the girl regards her castration as an individual misfortune, and only gradually extends it to other females and finally to her mother as well. Her love was directed to her phallic mother; with the discovery that her mother is castrated it becomes possible to drop her as an object, so that the motives for hostility, which have long been accumulating, gain the upper hand. This means, therefore, that as a result of the discovery of women's lack of a penis they are debased in value for girls just as they are for boys and later perhaps for men.

[1933a, 4728]

With the transference of the wish for a penis-baby on to her father, the girl has entered the situation of the Oedipus complex. Her hostility to her mother, which did not need to be freshly created, is now greatly intensified, for she becomes the girl's rival, who receives from her father everything that she desires from him. For a long time the girl's Oedipus complex concealed her pre-Oedipus attachment to her mother from our view, though it is nevertheless so important and leaves such lasting fixations behind it. For girls the Oedipus situation is the outcome of a long and difficult development; it is a kind of preliminary solution, a position of rest which is not soon abandoned, especially as the beginning of the latency period is not far distant. And we are now struck by a difference between the two sexes, which is probably momentous, in regard to the relation of the Oedipus complex to the castration complex. In a boy the Oedipus complex, in which he desires his mother and would like to get rid of his father as being a rival, develops naturally from the phase of his phallic sexuality. The threat of castration compels him, however, to give up that attitude. Under the impression of the danger of losing his penis, the Oedipus complex is abandoned, repressed and, in the most normal cases, entirely destroyed, and a severe super-ego is set up as its heir. What happens with a girl is almost the opposite. The castration complex prepares for the Oedipus complex instead of destroying it; the girl is driven out of her attachment to her mother through the influence of her envy for the penis and she enters the Oedipus situation as though into a haven of refuge. In the absence of fear of castration the chief motive is lacking which leads boys to surmount the Oedipus complex. Girls remain in it for an indeterminate length of time; they demolish it late and, even so, incompletely. In these circumstances the formation of the super-ego must suffer; it cannot attain the strength and independence which give it its cultural significance, and feminists are not pleased when we point out to them the effects of this factor upon the average feminine character.

[1933a, 4731]

With the phallic phase and in the course of it the sexuality of early childhood reaches its height and approaches its dissolution. Thereafter boys and girls have different histories. Both have begun to put their intellectual activity at the service of sexual researches; both start off from the premiss of the universal presence of the penis. But now the paths of the sexes diverge. The boy enters the Oedipus phase; he begins to manipulate his penis and simultaneously has phantasies of carrying out some sort of activity with it in relation to his mother, till, owing to the combined effect of a threat of castration and the sight of the absence of a penis in females, he experiences the greatest trauma of his life and this introduces the period of latency with all its consequences. The girl, after vainly attempting to do the same as the boy, comes to recognize her lack of a penis or rather the inferiority of her clitoris, with permanent effects on the development of her character; as a result of this first disappointment in rivalry, she often begins by turning away altogether from sexual life.

[1940a [1938], 4965]
The boy’s mother has understood quite well that his sexual excitation relates to herself. Sooner or later she reflects that it is not right to allow it to continue. She thinks she is doing the correct thing in forbidding him to handle his genital organ. Her prohibition has little effect; at the most it brings about some modification in his method of obtaining satisfaction. At last his mother adopts the severest measures; she threatens to take away from him the thing he is defying her with. Usually, in order to make the threat more frightening and more credible, she delegates its execution to the boy’s father, saying that she will tell him and that he will cut the penis off. Strange to say, this threat operates only if another condition is fulfilled before or afterwards. In itself it seems too inconceivable to the boy that such a thing could happen. But if at the time of the threat he can recall the appearance of female genitals or if shortly afterwards he has a sight of them - of genitals, that is to say, which really lack this supremely valued part, then he takes what he has heard seriously and, coming under the influence of the castration complex, experiences the severest trauma of his young life.¹

[1940a [1938], 4997]

The results of the threat of castration are multifarious and incalculable; they affect the whole of a boy’s relations with his father and mother and subsequently with men and women in general. As a rule the child’s masculinity is unable to stand up to this first shock. In order to preserve his sexual organ he renounces the possession of his mother more or less completely; his sexual life often remains permanently encumbered by the prohibition. If a strong feminine component, as we call it, is present in him, its strength is increased by this intimidation of his masculinity. He falls into a passive attitude to his father, such as he attributes to his mother. It is true that as a result of the threat he has given up masturbation, but not the activities of his imagination accompanying it. On the contrary, since these are now the only form of sexual satisfaction remaining to him, he indulges in them more than before and in these phantasies, though he still continues to identify himself with his father, he also does so, simultaneously and perhaps predominantly, with his mother. Derivatives and modified products of these early masturbatory phantasies usually make their way into his later ego and play a part in the formation of his character. Apart from this encouragement of his femininity, fear and hatred of his father gain greatly in intensity. The boy’s masculinity withdraws, as it were, into a defiant attitude towards his father, which will dominate his later behaviour in human society in a compulsive fashion. A residue of his erotic fixation to his mother is often left in the form of an excessive dependence on her, and this persists as a kind of bondage to women. He no longer ventures to love his mother, but he cannot risk not being loved by her, for in that case he would be in danger of being betrayed by her to his father and handed over to castration. The whole experience, with all its antecedents and consequences, of which my account has only been able to give a selection, is subjected to a highly energetic repression, and, as is made possible by the laws operating in the unconscious id, all the mutually contending emotional impulses and reactions which are set going at that time are preserved in the unconscious and ready to disturb the later development of the ego after puberty. When the somatic process of sexual maturation puts fresh life into the old libidinal fixations which had apparently been surmounted, sexual life will turn out to be inhibited, without homogeneity and fallen apart into mutually conflicting urges. [1940a [1938], 4998]
It is no doubt true that the impact of the threat of castration upon a boy's budding sexual life does not always have these dreaded consequences. It will depend once again on quantitative relations how much damage is done and how much avoided. The whole occurrence, which may probably be regarded as the central experience of the years of childhood, the greatest problem of early life and the strongest source of later inadequacy, is so completely forgotten that its reconstruction during the work of analysis is met in adults by the most decided disbelief. Indeed, aversion to it is so great that people try to silence any mention of the proscribed subject and the most obvious reminders of it are overlooked by a strange intellectual blindness. One may hear it objected, for instance, that the legend of King Oedipus has in fact no connection with the construction made by analysis: the cases are quite different, since Oedipus did not know that it was his father that he killed and his mother that he married. What is overlooked in this is that a distortion of this kind is inevitable if an attempt is made at a poetic handling of the material, and that there is no introduction of extraneous material but only a skilful employment of the factors presented by the theme. The ignorance of Oedipus is a legitimate representation of the unconscious state into which, for adults, the whole experience has fallen; and the coercive power of the oracle, which makes or should make the hero innocent, is a recognition of the inevitability of the fate which has condemned every son to live through the Oedipus complex. Again it was pointed out from psycho-analytic quarters how easily the riddle of another dramatic hero, Shakespeare's procrastinator, Hamlet, can be solved by reference to the Oedipus complex, since the prince came to grief over the task of punishing someone else for what coincided with the substance of his own Oedipus wish - whereupon the general lack of understanding on the part of the literary world showed how ready is the mass of mankind to hold fast to its infantile repressions.¹

It is an interesting thing that the relation between the Oedipus complex and the castration complex should take such a different shape - an opposite one, in fact - in the case of females as compared to that of males. In males, as we have seen, the threat of castration brings the Oedipus complex to an end; in females we find that, on the contrary, it is their lack of a penis that forces them into their Oedipus complex. It does little harm to a woman if she remains in her feminine Oedipus attitude. (The term 'Electra complex' has been proposed for it.) She will in that case choose her husband for his paternal characteristics and be ready to recognize his authority. Her longing to possess a penis, which is in fact unappeasable, may find satisfaction if she can succeed in completing her love for the organ by extending it to the bearer of the organ, just as happened earlier when she progressed from her mother's breast to her mother as a whole person.

¹[1940a [1938], 5001]
We have heard how the weak and immature ego of the first period of childhood is permanently damaged by the stresses put upon it in its efforts to fend off the dangers that are peculiar to that period of life. Children are protected against the dangers that threaten them from the external world by the solicitude of their parents; they pay for this security by a fear of loss of love which would deliver them over helpless to the dangers of the external world. This factor exerts a decisive influence on the outcome of the conflict when a boy finds himself in the situation of the Oedipus complex, in which the threat to his narcissism by the danger of castration, reinforced from primaeval sources, takes possession of him. Driven by the combined operation of these two influences, the contemporary real danger and the remembered one with its phylogenetic basis, the child embarks on his attempts at defence - repressions - which are effective for the moment but nevertheless turn out to be psychologically inadequate when the later re-animation of sexual life brings a reinforcement to the instinctual demands which have been repudiated in the past. If this is so, it would have to be said from a biological standpoint that the ego comes to grief over the task of mastering the excitations of the early sexual period, at a time when its immaturity makes it incompetent to do so. It is in this lagging of ego development behind libidinal development that we see the essential precondition of neurosis; and we cannot escape the conclusion that neuroses could be avoided if the childish ego were spared this task - if, that is to say, the child's sexual life were allowed free play, as happens among many primitive peoples. It may be that the aetiology of neurotic illnesses is more complicated than we have here described it; if so, we have at least brought out one essential part of the aetiological complex. Nor should we forget the phylogenetic influences, which are represented in some way in the id in forms that we are not yet able to grasp, and which must certainly act upon the ego more powerfully in that early period than later. On the other hand, the realization dawns on us that such an early attempt at damming up the sexual instinct, so decided a partisanship by the young ego in favour of the external as opposed to the internal world, brought about by the prohibition of infantile sexuality, cannot be without its effect on the individual's later readiness for culture. The instinctual demands forced away from direct satisfaction are compelled to enter on new paths leading to substitutive satisfaction, and in the course of these détours they may become desexualized and their connection with their original instinctual aims may become looser. And at this point we may anticipate the thesis that many of the highly valued assets of our civilization were acquired at the cost of sexuality and by the restriction of sexual motive forces.

[1940a [1938], 5006]

In trying to introduce this factor into the structure of our theory, we must not overlook the fact that it cannot, by its very nature, occupy the same position in both sexes. In males the striving to be masculine is completely ego-syntonic from the first; the passive attitude, since it presupposes an acceptance of castration, is energetically repressed, and often its presence is only indicated by excessive overcompensations. In females, too, the striving to be masculine is ego-syntonic at a certain period - namely in the phallic phase, before the development to femininity has set in. But it then succumbs to the momentous process of repression whose outcome, as has so often been shown, determines the fortunes of a woman's femininity. A great deal depends on whether a sufficient amount of her masculinity complex escapes repression and exercises a permanent influence on her character. Normally, large portions of the complex are transformed and contribute to the construction of her femininity: the appeased wish for a penis is destined to be converted into a wish for a baby and for a husband, who possesses a penis. It is strange, however, how often we find that the wish for masculinity has been retained in the unconscious and, from out of its state of repression, exercises a disturbing influence.

[1937c, 5044]
It will assist if I introduce an individual case history into this schematic disquisition. A little boy, while he was between three and four years of age, had become acquainted with the female genitals through being seduced by an older girl. After these relations had been broken off, he carried on the sexual stimulation set going in this way by zealously practising manual masturbation; but he was soon caught at it by his energetic nurse and was threatened with castration, the carrying out of which was, as usual, ascribed to his father. There were thus present in this case conditions calculated to produce a tremendous effect of fright. A threat of castration by itself need not produce a great impression. A child will refuse to believe in it, for he cannot easily imagine the possibility of losing such a highly prized part of his body. His sight of the female genitals might have convinced our child of that possibility. But he drew no such conclusion from it, since his disinclination to doing so was too great and there was no motive present which could compel him to. On the contrary, whatever uneasiness he may have felt was calmed by the reflection that what was missing would yet make its appearance: she would grow one (a penis) later. Anyone who has observed enough small boys will be able to recollect having come across some such remark at the sight of a baby sister's genitals. But it is different if both factors are present together. In that case the threat revives the memory of the perception which had hitherto been regarded as harmless and finds in that memory a dreaded confirmation. The little boy now thinks he understands why the girl's genitals showed no sign of a penis and no longer ventures to doubt that his own genitals may meet with the same fate. Thenceforward he cannot help believing in the reality of the danger of castration.

The usual result of the fright of castration, the result that passes as the normal one, is that, either immediately or after some considerable struggle, the boy gives way to the threat and obeys the prohibition either wholly or at least in part (that is, by no longer touching his genitals with his hand). In other words, he gives up, in whole or in part, the satisfaction of the instinct. We are prepared to hear, however, that our present patient found another way out. He created a substitute for the penis which he missed in females - that is to say, a fetish. In so doing, it is true that he had disavowed reality, but he had saved his own penis. So long as he was not obliged to acknowledge that females have lost their penis, there was no need for him to believe the threat that had been made against him: he need have no fears for his own penis, so he could proceed with his masturbation undisturbed. This behaviour on the part of our patient strikes us forcibly as being a turning away from reality - a procedure which we should prefer to reserve for psychoses. And it is in fact not very different. Yet we will suspend our judgement, for upon closer inspection we shall discover a not unimportant distinction. The boy did not simply contradict his perceptions and hallucinate a penis where there was none to be seen; he effected no more than a displacement of value - he transferred the importance of the penis to another part of the body, a procedure in which he was assisted by the mechanism of regression (in a manner which need not here be explained). This displacement, it is true, related only to the female body; as regards his own penis nothing was changed.
This way of dealing with reality, which almost deserves to be described as artful, was decisive as regards the boy's practical behaviour. He continued with his masturbation as though it implied no danger to his penis; but at the same time, in complete contradiction to his apparent boldness or indifference, he developed a symptom which showed that he nevertheless did recognize the danger. He had been threatened with being castrated by his father, and immediately afterwards, simultaneously with the creation of his fetish, he developed an intense fear of his father punishing him, which it required the whole force of his masculinity to master and overcompensate. This fear of his father, too, was silent on the subject of castration: by the help of regression to an oral phase, it assumed the form of a fear of being eaten by his father. At this point it is impossible to forget a primitive fragment of Greek mythology which tells how Kronos, the old Father God, swallowed his children and sought to swallow his youngest son Zeus like the rest, and how Zeus was saved by the craft of his mother and later on castrated his father. But we must return to our case history and add that the boy produced yet another symptom, though it was a slight one, which he has retained to this day. This was an anxious susceptibility against either of his little toes being touched, as though, in all the to and fro between disavowal and acknowledgement, it was nevertheless castration that found the clearer expression. . . .

[1940e [1938], 5064]
CASTRATION COMPLEX AND PENIS ENVY

This conviction is energetically maintained by boys, is obstinately defended against the contradictions which soon result from observation, and is only abandoned after severe internal struggles (the castration complex). The substitutes for this penis which they feel is missing in women play a great part in determining the form taken by many perversions.¹

[1905d, 1514]

Little girls do not resort to denial of this kind when they see that boys' genitals are formed differently from their own. They are ready to recognize them immediately and are overcome by envy for the penis - an envy culminating in the wish, which is so important in its consequences, to be boys themselves.

[1905d, 1514]

¹ [Footnote added 1920:] We are justified in speaking of a castration complex in women as well. Both male and female children form a theory that women no less than men originally had a penis, but that they have lost it by castration. The conviction which is finally reached by males that women have no penis often leads them to an enduringly low opinion of the other sex.

[1905d, 1514]

We have learnt from the analysis of many neurotic women that they go through an early age in which they envy their brothers their sign of masculinity and feel at a disadvantage and humiliated because of the lack of it (actually because of its diminished size) in themselves. We include this 'envy for the penis' in the 'castration complex'. If we understand 'masculine' as including the idea of wishing to be masculine, then the designation 'masculine protest' fits this behaviour; the phrase was coined by Adler with the intention of proclaiming this factor as being responsible for neurosis in general. During this phase, little girls often make no secret of their envy, nor of the hostility towards their favoured brothers which arises from it. They even try to urinate standing upright like their brothers in order to prove the equality which they lay claim to. In the case already described in which the woman used to show uncontrolled aggression after intercourse towards her husband, whom otherwise she loved, I was able to establish that this phase had existed before that of object-choice. Only later was the little girl's libido directed towards her father, and then, instead of wanting to have a penis, she wanted - a child.²

[1918a, 2359]

I should not be surprised if in other cases the order in which these impulses occurred were reversed and this part of the castration complex only became effective after a choice of object had been successfully made. But the masculine phase in the girl in which she envies the boy for his penis is in any case developmentally the earlier, and it is closer to the original narcissism than it is to object-love.

[1918a, 2360]
Some time ago I chanced to have an opportunity of obtaining insight into a dream of a newly-married woman which was recognizable as a reaction to the loss of her virginity. It betrayed spontaneously the woman's wish to castrate her young husband and to keep his penis for herself. Certainly there was also room for the more innocent interpretation that what she wished for was the prolongation and repetition of the act, but several details of the dream did not fit into this meaning and the character as well as the subsequent behaviour of the woman who had the dream gave evidence in favour of the more serious view. Behind this envy for the penis, there comes to light the woman's hostile bitterness against the man, which never completely disappears in the relations between the sexes, and which is clearly indicated in the strivings and in the literary productions of 'emancipated' women. In a palaeo-biological speculation, Ferenczi has traced back this hostility of women - I do not know if he is the first to do so - to the period in time when the sexes became differentiated. At first, in his opinion, copulation took place between two similar individuals, one of which, however, developed into the stronger and forced the weaker one to submit to sexual union. The feelings of bitterness arising from this subjection still persist in the present-day disposition of women. I do not think there is any harm in employing such speculations, so long as one avoids setting too much value on them.

[1918a, 2360]

Rumpelstiltskin was connected with the contemporary thoughts underlying the dream - the day's residues - by a neat antithetic relation. In the fairy tale he comes in order to take away the queen's first child. In the dream the little man comes in the shape of a father, because he had presumably brought a second child. But Rumpelstiltskin also gave access to the deeper, infantile stratum of the dream-thoughts. The droll little fellow, whose very name is unknown, whose secret is so eagerly canvassed, who can perform such extraordinary tricks - in the fairy tale he turns straw into gold - the fury against him, or rather against his possessor, who is envied for possessing him (the girl's envy for the penis) - all of these were elements whose relation to the foundations of the patient's neurosis can, as I have said, barely be touched upon in this paper. The short-cut hair of the manikin in the dream was no doubt also connected with the subject of castration.

[1913d, 2598]

After several days of resistance the patient reported that she had felt very much snubbed because a young man whom she met regularly near the doctor's house, and who used as a rule to look at her admiringly, had on the last occasion looked contemptuously at her feet. In fact she had no reason to be ashamed of her feet. She produced the explanation herself after admitting that she had regarded the young man as the doctor's son, who thus (by way of the transference) stood for her elder brother. There now followed a memory of having been in the habit of accompanying her brother to the lavatory when she was about five years old and of watching him micturate. She was overcome with envy at not being able to do it in the same way as he did and one day tried to copy him (envy for the penis). But in doing so she wetted her shoes and got very angry when her brother teased her about it. For a long time afterwards her anger recurred whenever her brother looked contemptuously at her shoes with the object of reminding her of her misfortune. She added that this experience had determined her later behaviour at school. If she was unsuccessful in anything at the first attempt she could never bring herself to try again, so that in many subjects she failed completely. This is a good example of the way in which sexual life acts as a model and influences character.

[1913h, 2832]
The disturbances to which a child's original narcissism is exposed, the reactions with which he seeks to protect himself from them and the paths into which he is forced in doing so - these are themes which I propose to leave on one side, as an important field of work which still awaits exploration. The most significant portion of it, however, can be singled out in the shape of the 'castration complex' (in boys, anxiety about the penis - in girls, envy for the penis) and treated in connection with the effect of early deterrence from sexual activity. Psycho-analytic research ordinarily enables us to trace the vicissitudes undergone by the libidinal instincts when these, isolated from the ego-instincts, are placed in opposition to them; but in the particular field of the castration complex, it allows us to infer the existence of an epoch and a psychical situation in which the two groups of instincts, still operating in unison and inseparably mingled, make their appearance as narcissistic interests. It is from this context that Adler has derived his concept of the 'masculine protest', which he has elevated almost to the position of the sole motive force in the formation of character and neurosis alike and which he bases not on a narcissistic, and therefore still a libidinal, trend, but on a social valuation. Psycho-analytic research has from the very beginning recognized the existence and importance of the 'masculine protest', but it has regarded it, in opposition to Adler, as narcissistic in nature and derived from the castration complex. The 'masculine protest' is concerned in the formation of character, into the genesis of which it enters along with many other factors, but it is completely unsuited for explaining the problems of the neuroses, with regard to which Adler takes account of nothing but the manner in which they serve the ego-instincts. I find it quite impossible to place the genesis of neurosis upon the narrow basis of the castration complex, however powerfully it may come to the fore in men among their resistances to the cure of a neurosis. Incidentally, I know of cases of neurosis in which the 'masculine protest', or, as we regard it, the castration complex, plays no pathogenic part, and even fails to appear at all.

[1914c, 2946]

Though I am anxious to cut short this discussion still further, I must nevertheless tell you a little about the sexual researches of children: they are too characteristic of infantile sexuality and of too great significance for the symptomatology of the neuroses to be passed over. Infantile sexual researches begin very early, sometimes before the third year of life. They do not relate to the distinction between the sexes, for this means nothing to children, since they (or at any rate boys) attribute the same male genital to both sexes. If, afterwards, a boy makes the discovery of the vagina from seeing his little sister or a girl playmate, he tries, to begin with, to disavow the evidence of his senses, for he cannot imagine a human creature like himself who is without such a precious portion. Later on, he takes fright at the possibility thus presented to him; and any threats that may have been made to him earlier, because he took too intense an interest in his little organ, now produce a deferred effect. He comes under the sway of the castration complex, the form taken by which plays a great part in the construction of his character if he remains normal, in his neurosis if he falls ill, and in his resistances if he comes into analytic treatment. As regards little girls, we can say of them that they feel greatly at a disadvantage owing to their lack of a big, visible penis, that they envy boys for possessing one and that, in the main for this reason, they develop a wish to be a man - a wish that re-emerges later on, in any neurosis that may arise if they meet with a mishap in playing a feminine part. In her childhood, moreover, a girl's clitoris takes on the role of a penis entirely: it is characterized by special excitability and is the area in which auto-erotic satisfaction is obtained. The process of a girl's becoming a woman depends very much on the clitoris passing on this sensitivity to the vaginal orifice in good time and completely. In cases of what is known as sexual anaesthesia in women the clitoris has obstinately retained its sensitivity.

[1916-1917, 3387]
If we penetrate deeply enough into the neurosis of a woman, we not infrequently meet with the repressed wish to possess a penis like a man. We call this wish 'envy for a penis' and include it in the castration complex. Chance mishaps in the life of such a woman, mishaps which are themselves frequently the result of a very masculine disposition, have re-activated this infantile wish and, through the backward flow of libido, made it the chief vehicle of her neurotic symptoms. In other women we find no evidence of this wish for a penis; it is replaced by the wish for a baby, the frustration of which in real life can lead to the outbreak of a neurosis. It looks as if such women had understood (although this could not possibly have acted as a motive) that nature has given babies to women as a substitute for the penis that has been denied them. With other women, again, we learn that both wishes were present in their childhood and that one replaced the other. At first they had wanted a penis like a man; then at a later, though still childish, stage there appeared instead the wish for a baby. The impression is forced upon us that this variety in our findings is caused by accidental factors during childhood (e.g. the presence or absence of brothers or the birth of a new baby at some favourable time of life), so that the wish for a penis and the wish for a baby would be fundamentally identical.

[1917c, 3601]

---

Anal erotism finds a narcissistic application in the production of defiance, which constitutes an important reaction on the part of the ego against demands made by other people. Interest in faeces is carried over first to interest in gifts, and then to interest in money. In girls, the discovery of the penis gives rise to envy for it, which later changes into the wish for a man as the possessor of a penis. Even before this the wish for a penis has changed into the wish for a baby, or the latter wish has taken the place of the former one. An organic analogy between penis and baby (dotted line) is expressed by the existence of a symbol ('little one') common to both. A rational wish (double line) then leads from the wish for a baby to the wish for a man: we have already appreciated the importance of this instinctual transformation.

[1917c, 3604]
After this highly discursive introduction I am only able to present a very concise summary of the sexual history of the case under consideration. In childhood the girl had passed through the normal attitude characteristic of the feminine Oedipus complex¹ in a way that was not at all remarkable, and had later also begun to substitute for her father a brother slightly older than herself. She did not remember any sexual traumas in early life, nor were any discovered by the analysis. Comparison of her brother's genital organs and her own, which took place about the beginning of the latency period (at five years old or perhaps a little earlier), left a strong impression on her and had far-reaching after-effects. There were very few signs pointing to infantile masturbation, or else the analysis did not go far enough to throw light on this point. The birth of a second brother when she was between five and six years old exercised no special influence upon her development. During the pre-pubertal years at school she gradually became acquainted with the facts of sex, and she received this knowledge with mixed feelings of lasciviousness and frightened aversion, in a way which may be called normal and was not exaggerated in degree. This amount of information about her seems meagre enough, nor can I guarantee that it is complete. It may be that the history of her youth was much richer in experiences; I do not know. As I have already said, the analysis was broken off after a short time, and therefore yielded an anamnesis not much more reliable than the other anamneses of homosexuals, which there is good cause to question. Further, the girl had never been neurotic, and came to the analysis without even one hysterical symptom, so that opportunities for investigating the history of her childhood did not present themselves so readily as usual. [1920a, 3845]

The analysis showed, further, that the girl had brought along with her from her childhood a strongly marked 'masculinity complex'. A spirited girl, always ready for romping and fighting, she was not at all prepared to be second to her slightly older brother; after inspecting his genital organs she had developed a pronounced envy for the penis, and the thoughts derived from this envy still continued to fill her mind. She was in fact a feminist; she felt it to be unjust that girls should not enjoy the same freedom as boys, and rebelled against the lot of woman in general. At the time of the analysis the idea of pregnancy and child-birth was disagreeable to her, partly, I surmise, on account of the bodily disfigurement connected with them. Her girlish narcissism had fallen back on this defence,¹ and ceased to express itself as pride in her good looks. Various clues indicated that she must formerly have had strong exhibitionist and scopophilic tendencies. Anyone who is anxious that the claims of acquired as opposed to hereditary factors should not be under-estimated in aetiology will call attention to the fact that the girl's behaviour, as described above, was exactly what would follow from the combined effect in a person with a strong mother-fixation of the two influences of her mother's neglect and her comparison of her genital organs with her brother's. It is possible here to attribute to the impress of the operation of external influence in early life something which one would have liked to regard as a constitutional peculiarity. On the other hand, a part even of this acquired disposition (if it was really acquired) has to be ascribed to inborn constitution. So we see in practice a continual mingling and blending of what in theory we should try to separate into a pair of opposites - namely, inherited and acquired characters. [1920a, 3858]
In the course of these researches the child arrives at the discovery that the penis is not a possession which is common to all creatures that are like himself. An accidental sight of the genitals of a little sister or playmate provides the occasion for this discovery. In unusually intelligent children, the observation of girls urinating will even earlier have aroused a suspicion that there is something different here. For they will have seen a different posture and heard a different sound, and will have made attempts to repeat their observations so as to obtain enlightenment. We know how children react to their first impressions of the absence of a penis. They disavow the fact and believe that they do see a penis, all the same. They gloss over the contradiction between observation and preconception by telling themselves that the penis is still small and will grow bigger presently; and they then slowly come to the emotionally significant conclusion that after all the penis had at least been there before and been taken away afterwards. The lack of a penis is regarded as a result of castration, and so now the child is faced with the task of coming to terms with castration in relation to himself. The further developments are too well known generally to make it necessary to recapitulate them here. But it seems to me that the significance of the castration complex can only be rightly appreciated if its origin in the phase of phallic primacy is also taken into account.¹

Analytic observation enables us to recognize or guess these connections between the phallic organization, the Oedipus complex, the threat of castration, the formation of the super-ego and the latency period. These connections justify the statement that the destruction of the Oedipus complex is brought about by the threat of castration. But this does not dispose of the problem; there is room for a theoretical speculation which may upset the results we have come to or put them in a new light. Before we start along this new path, however, we must turn to a question which has arisen in the course of this discussion and has so far been left on one side. The process which has been described refers, as has been expressly said, to male children only. How does the corresponding development take place in little girls?

At this point our material - for some incomprehensible reason - becomes far more obscure and full of gaps. The female sex, too, develops an Oedipus complex, a super-ego and a latency period. May we also attribute a phallic organization and a castration complex to it? The answer is in the affirmative; but these things cannot be the same as they are in boys. Here the feminist demand for equal rights for the sexes does not take us far, for the morphological distinction is bound to find expression in differences of psychical development. 'Anatomy is Destiny,' to vary a saying of Napoleon's. The little girl's clitoris behaves just like a penis to begin with; but, when she makes a comparison with a playfellow of the other sex, she perceives that she has 'come off badly' and she feels this as a wrong done to her and as a ground for inferiority. For a while still she consoles herself with the expectation that later on, when she grows older, she will acquire just as big an appendage as the boy's. Here the masculinity complex of women branches off. A female child, however, does not understand her lack of a penis as being a sex character; she explains it by assuming that at some earlier date she had possessed an equally large organ and had then lost it by castration. She seems not to extend this inference from herself to other, adult females, but, entirely on the lines of the phallic phase, to regard them as possessing large and complete - that is to say, male - genitals. The essential difference thus comes about that the girl accepts castration as an accomplished fact, whereas the boy fears the possibility of its occurrence.

¹ [1923e, 4060]

² [1924d, 4089]

³ [1924d, 4090]
The fear of castration being thus excluded in the little girl, a powerful motive also drops out for the setting-up of a super-ego and for the breaking-off of the infantile genital organization. In her, far more than in the boy, these changes seem to be the result of upbringing and of intimidation from outside which threatens her with a loss of love. The girl's Oedipus complex is much simpler than that of the small bearer of the penis; in my experience, it seldom goes beyond the taking of her mother's place and the adopting of a feminine attitude towards her father. Renunciation of the penis is not tolerated by the girl without some attempt at compensation. She slips - along the line of a symbolic equation, one might say - from the penis to a baby. Her Oedipus complex culminates in a desire, which is long retained, to receive a baby from her father as a gift - to bear him a child. One has an impression that the Oedipus complex is then gradually given up because this wish is never fulfilled. The two wishes - to possess a penis and a child - remain strongly cathected in the unconscious and help to prepare the female creature for her later sexual role. The comparatively lesser strength of the sadistic contribution to her sexual instinct, which we may no doubt connect with the stunted growth of her penis, makes it easier in her case for the direct sexual trends to be transformed into aim-inhibited trends of an affectionate kind. It must be admitted, however, that in general our insight into these developmental processes in girls is unsatisfactory, incomplete and vague.

The old paediatrician Lindner once remarked that a child discovers the genital zones (the penis or the clitoris) as a source of pleasure while indulging in sensual sucking (thumb sucking).¹ I shall leave it an open question whether it is really true that the child takes the newly found source of pleasure in exchange for the recent loss of the mother's nipple - a possibility to which later phantasies (fellatio) seem to point. Be that as it may, the genital zone is discovered at some time or other, and there seems no justification for attributing any psychical content to the first activities in connection with it. But the first step in the phallic phase which begins in this way is not the linking-up of the masturbation with the object-cathexes of the Oedipus complex, but a momentous discovery which little girls are destined to make. They notice the penis of a brother or playmate, strikingly visible and of large proportions, at once recognize it as the superior counterpart of their own small and inconspicuous organ, and from that time forward fall a victim to envy for the penis.

A little girl behaves differently. She makes her judgement and her decision in a flash. She has seen it and knows that she is without it and wants to have it.¹

¹ This is an opportunity for correcting a statement which I made many years ago. I believed that the sexual interest of children, unlike that of pubescents, was aroused, not by the difference between the sexes, but by the problem of where babies come from. We now see that, at all events with girls, this is certainly not the case. With boys it may no doubt happen sometimes one way and sometimes the other; or with both sexes chance experiences may determine the event.

Here what has been named the masculinity complex of women branches off. It may put great difficulties in the way of their regular development towards femininity, if it cannot be got over soon enough. The hope of some day obtaining a penis in spite of everything and so of becoming like a man may persist to an incredibly late age and may become a motive for strange and otherwise unaccountable actions. Or again, a process may set in which I should like to call a 'disavowal', a process which in the mental life of children seems neither uncommon nor very dangerous but which in an adult would mean the beginning of a psychosis. Thus a girl may refuse to accept the fact of being castrated, may harden herself in the conviction that she does possess a penis, and may subsequently be compelled to behave as though she were a man.
The psychical consequences of envy for the penis, in so far as it does not become absorbed in the reaction-formation of the masculinity complex, are various and far-reaching. After a woman has become aware of the wound to her narcissism, she develops, like a scar, a sense of inferiority. When she has passed beyond her first attempt at explaining her lack of a penis as being a punishment personal to herself and has realized that that sexual character is a universal one, she begins to share the contempt felt by men for a sex which is the lesser in so important a respect, and, at least in holding that opinion, insists on being like a man.¹
[1925], 4151

A third consequence of penis-envy seems to be a loosening of the girl's relation with her mother as a love-object. The situation as a whole is not very clear, but it can be seen that in the end the girl's mother, who sent her into the world so insufficiently equipped, is almost always held responsible for her lack of a penis. The way in which this comes about historically is often that soon after the girl has discovered that her genitals are unsatisfactory she begins to show jealousy of another child on the ground that her mother is fonder of it than of her, which serves as a reason for her giving up her affectionate relation to her mother. It will fit in with this if the child which has been preferred by her mother is made into the first object of the beating-phantasy which ends in masturbation.
[1925], 4152

I cannot explain the opposition which is raised in this way by little girls to phallic masturbation except by supposing that there is some concurrent factor which turns her violently against that pleasurable activity. Such a factor lies close at hand. It cannot be anything else than her narcissistic sense of humiliation which is bound up with penis-envy, the reminder that after all this is a point on which she cannot compete with boys and that it would therefore be best for her to give up the idea of doing so. Thus the little girl's recognition of the anatomical distinction between the sexes forces her away from masculinity and masculine masturbation on to new lines which lead to the development of femininity.
[1925], 4153

So far there has been no question of the Oedipus complex, nor has it up to this point played any part. But now the girl's libido slips into a new position along the line - there is no other way of putting it - of the equation 'penis-child'. She gives up her wish for a penis and puts in place of it a wish for a child: and with that purpose in view she takes her father as a love object. Her mother becomes the object of her jealousy. The girl has turned into a little woman. If I am to credit a single analytic instance, this new situation can give rise to physical sensations which would have to be regarded as a premature awakening of the female genital apparatus. When the girl's attachment to her father comes to grief later on and has to be abandoned, it may give place to an identification with him and the girl may thus return to her masculinity complex and perhaps remain fixated in it.
[1925], 4154
I have now said the essence of what I had to say: I will stop, therefore, and cast an eye over our findings. We have gained some insight into the prehistory of the Oedipus complex in girls. The corresponding period in boys is more or less unknown. In girls the Oedipus complex is a secondary formation. The operations of the castration complex precede it and prepare for it. As regards the relation between the Oedipus and castration complexes there is a fundamental contrast between the two sexes. Whereas in boys the Oedipus complex is destroyed by the castration complex, in girls it is made possible and led up to by the castration complex. This contradiction is cleared up if we reflect that the castration complex always operates in the sense implied in its subject-matter: it inhibits and limits masculinity and encourages femininity. The difference between the sexual development of males and females at the stage we have been considering is an intelligible consequence of the anatomical distinction between their genitals and of the psychical situation involved in it; it corresponds to the difference between a castration that has been carried out and one that has merely been threatened. In their essentials, therefore, our findings are self-evident and it should have been possible to foresee them.

[1925j, 4154]

In girls the motive for the demolition of the Oedipus complex is lacking. Castration has already had its effect, which was to force the child into the situation of the Oedipus complex. Thus the Oedipus complex escapes the fate which it meets with in boys: it may be slowly abandoned or dealt with by repression, or its effects may persist far into women's normal mental life. I cannot evade the notion (though I hesitate to give it expression) that for women the level of what is ethically normal is different from what it is in men. Their super-ego is never so inexorable, so impersonal, so independent of its emotional origins as we require it to be in men. Character-traits which critics of every epoch have brought up against women - that they show less sense of justice than men, that they are less ready to submit to the great exigencies of life, that they are more often influenced in their judgements by feelings of affection or hostility - all these would be amply accounted for by the modification in the formation of their super-ego which we have inferred above. We must not allow ourselves to be deflected from such conclusions by the denials of the feminists, who are anxious to force us to regard the two sexes as completely equal in position and worth; but we shall, of course, willingly agree that the majority of men are also far behind the masculine ideal and that all human individuals, as a result of their bisexual disposition and of cross-inheritance, combine in themselves both masculine and feminine characteristics, so that pure masculinity and femininity remain theoretical constructions of uncertain content.

[1925j, 4155]

This is as far as our investigations into the formation of symptoms take us. It is hardly worth while summing them up, for the results they have yielded are scanty and incomplete and tell us scarcely anything that we do not already know. It would be fruitless to turn our attention to symptom-formation in other disorders besides phobias, conversion hysteria and obsessional neurosis, for too little is known about them. But in reviewing those three neuroses together we are brought up against a very serious problem the consideration of which can no longer be put off. All three have as their outcome the destruction of the Oedipus complex; and in all three the motive force of the ego's opposition is, we believe, the fear of castration. Yet it is only in the phobias that this fear comes to the surface and is acknowledged. What has become of it in the other two neuroses? How has the ego spared itself this fear? The problem becomes accentuated when we recall the possibility, already referred to, that anxiety arises directly, by a kind of fermentation, from a libidinal cathexis whose processes have been disturbed. Furthermore, is it absolutely certain that fear of castration is the only motive force of repression (or defence)? If we think of neuroses in women we are bound to doubt it. For though we can with certainty establish in them the presence of a castration complex, we can hardly speak with propriety of castration anxiety where castration has already taken place.

[1926d, 4281]
Another characteristic of early infantile sexuality is that the female sexual organ proper as yet plays no part in it: the child has not yet discovered it. Stress falls entirely on the male organ, all the child's interest is directed towards the question of whether it is present or not. We know less about the sexual life of little girls than of boys. But we need not feel ashamed of this distinction; after all, the sexual life of adult women is a 'dark continent' for psychology. But we have learnt that girls feel deeply their lack of a sexual organ that is equal in value to the male one; they regard themselves on that account as inferior, and this 'envy for the penis' is the origin of a whole number of characteristic feminine reactions.

Quite different are the effects of the castration complex in the female. She acknowledges the fact of her castration, and with it, too, the superiority of the male and her own inferiority; but she rebels against this unwelcome state of affairs. From this divided attitude three lines of development open up. The first leads to a general revulsion from sexuality. The little girl, frightened by the comparison with boys, grows dissatisfied with her clitoris, and gives up her phallic activity and with it her sexuality in general as well as a good part of her masculinity in other fields. The second line leads her to cling with defiant self-assertiveness to her threatened masculinity. To an incredibly late age she clings to the hope of getting a penis some time. That hope becomes her life's aim; and the phantasy of being a man in spite of everything often persists as a formative factor over long periods. This 'masculinity complex' in women can also result in a manifest homosexual choice of object. Only if her development follows the third, very circuitous, path does she reach the final normal female attitude, in which she takes her father as her object and so finds her way to the feminine form of the Oedipus complex. Thus in women the Oedipus complex is the end-result of a fairly lengthy development. It is not destroyed, but created, by the influence of castration; it escapes the strongly hostile influences which, in the male, have a destructive effect on it, and indeed it is all too often not surmounted by the female at all. For this reason, too, the cultural consequences of its break-up are smaller and of less importance in her. We should probably not be wrong in saying that it is this difference in the reciprocal relation between the Oedipus and the castration complex which gives its special stamp to the character of females as social beings.¹

Another, much more specific motive for turning away from the mother arises from the effect of the castration complex on the creature who is without a penis. At some time or other the little girl makes the discovery of her organic inferiority - earlier and more easily, of course, if there are brothers or other boys about. We have already taken note of the three paths which diverge from this point: (a) the one which leads to a cessation of her whole sexual life, (b) the one which leads to a defiant over-emphasis of her masculinity, and (c) the first steps towards definitive femininity. It is not easy to determine the exact timing here or the typical course of events. Even the point of time when the discovery of castration is made varies, and a number of other factors seem to be inconstant and to depend on chance. The state of the girl's own phallic activity plays a part; and so too does the question whether this activity was found out or not, and how much interference with it she experienced afterwards.

When the little girl discovers her own deficiency, from seeing a male genital, it is only with hesitation and reluctance that she accepts the unwelcome knowledge. As we have seen, she clings obstinately to the expectation of one day having a genital of the same kind too, and her wish for it survives long after her hope has expired. The child invariably regards castration in the first instance as a misfortune peculiar to herself; only later does she realize that it extends to certain other children and lastly to certain grown-ups. When she comes to understand the general nature of this characteristic, it follows that femaleness - and with it, of course, her mother - suffers a great depreciation in her eyes.
This account of how girls respond to the impression of castration and the prohibition against masturbation will very probably strike the reader as confused and contradictory. This is not entirely the author's fault. In truth, it is hardly possible to give a description which has general validity. We find the most different reactions in different individuals, and in the same individual the contrary attitudes exist side by side. With the first intervention of the prohibition, the conflict is there, and from now on it will accompany the development of the sexual function. Insight into what takes place is made particularly difficult by the fact of its being so hard to distinguish the mental processes of this first phase from later ones by which they are overlaid and are distorted in memory. Thus, for instance, a girl may later construe the fact of castration as a punishment for her masturbatory activity, and she will attribute the carrying out of this punishment to her father, but neither of these ideas can have been a primary one. Similarly, boys regularly fear castration from their father, although in their case, too, the threat most usually comes from their mother.

However this may be, at the end of this first phase of attachment to the mother, there emerges, as the girl's strongest motive for turning away from her, the reproach that her mother did not give her a proper penis - that is to say, brought her into the world as a female. A second reproach, which does not reach quite so far back, is rather a surprising one. It is that her mother did not give her enough milk, did not suckle her long enough. Under the conditions of modern civilization this may be true often enough, but certainly not so often as is asserted in analyses. It would seem rather that this accusation gives expression to the general dissatisfaction of children, who, in our monogamous civilization, are weaned from the breast after six or nine months, whereas the primitive mother devotes herself exclusively to her child for two or three years. It is as though our children had remained for ever unsated, as though they had never sucked long enough at their mother's breast. But I am not sure whether, if one analysed children who had been suckled as long as the children of primitive peoples, one would not come upon the same complaint. Such is the greed of a child's libido!

Abraham's (1921) description of the manifestations of the castration complex in the female is still unsurpassed; but one would be glad if it had included the factor of the girl's original exclusive attachment to her mother. I am in agreement with the principal points in Jeanne Lampl-de Groot's¹ (1927) important paper. In this the complete identity of the pre-Oedipus phase in boys and girls is recognized, and the girl's sexual (phallic) activity towards her mother is affirmed and substantiated by observations. The turning-away from the mother is traced to the influence of the girl's recognition of castration, which obliges her to give up her sexual object, and often masturbation along with it. The whole development is summed up in the formula that the girl goes through a phase of the 'negative' Oedipus complex before she can enter the positive one. A point on which I find the writer's account inadequate is that it represents the turning-away from the mother as being merely a change of object and does not discuss the fact that it is accompanied by the plainest manifestations of hostility. To this hostility full justice is done in Helene Deutsch's latest paper, on feminine masochism and its relation to frigidity (1930), in which she also recognizes the girl's phallic activity and the intensity of her attachment to her mother. Helene Deutsch states further that the girl's turning towards her father takes place via her passive trends (which have already been awakened in relation to her mother). In her earlier book (1925) the author had not yet set herself free from the endeavour to apply the Oedipus pattern to the pre-Oedipus phase, and she therefore interpreted the little girl's phallic activity as an identification with her father.

[1931b, 4597]

[1931b, 4598]

[1931b, 4605]
Fear of castration is not, of course, the only motive for repression: indeed, it finds no place in women, for though they have a castration complex they cannot have a fear of being castrated. Its place is taken in their sex by a fear of loss of love, which is evidently a later prolongation of the infant's anxiety if it finds its mother absent. You will realize how real a situation of danger is indicated by this anxiety. If a mother is absent or has withdrawn her love from her child, it is no longer sure of the satisfaction of its needs and is perhaps exposed to the most distressing feelings of tension. Do not reject the idea that these determinants of anxiety may at bottom repeat the situation of the original anxiety at birth, which, to be sure, also represented a separation from the mother. Indeed, if you follow a train of thought suggested by Ferenczi, you may add the fear of castration to this series, for a loss of the male organ results in an inability to unite once more with the mother (or a substitute for her) in the sexual act. I may mention to you incidentally that the very frequent phantasy of returning into the mother's womb is a substitute for this wish to copulate. There would be many interesting things and surprising connections to tell you at this point, but I cannot go outside the framework of an introduction to psycho-analysis. I will only draw your attention to the fact that here psychological researches trench upon the facts of biology. [1933a, 4694]

I believe we have found this specific factor, and indeed where we expected to find it, even though in a surprising form. Where we expected to find it, I say, for it lies in the castration complex. After all, the anatomical distinction must express itself in psychical consequences. It was, however, a surprise to learn from analyses that girls hold their mother responsible for their lack of a penis and do not forgive her for their being thus put at a disadvantage. [1933a, 4726]

As you hear, then, we ascribe a castration complex to women as well. And for good reasons, though its content cannot be the same as with boys. In the latter the castration complex arises after they have learnt from the sight of the female genitals that the organ which they value so highly need not necessarily accompany the body. At this the boy recalls to mind the threats he brought on himself by his doings with that organ, he begins to give credence to them and falls under the influence of fear of castration, which will be the most powerful motive force in his subsequent development. The castration complex of girls is also started by the sight of the genitals of the other sex. They at once notice the difference and, it must be admitted, its significance too. They feel seriously wronged, often declare that they want to 'have something like it too', and fall a victim to 'envy for the penis', which will leave ineradicable traces on their development and the formation of their character and which will not be surmounted in even the most favourable cases without a severe expenditure of psychical energy. The girl's recognition of the fact of her being without a penis does not by any means imply that she submits to the fact easily. On the contrary, she continues to hold on for a long time to the wish to get something like it herself and she believes in that possibility for improbably long years; and analysis can show that, at a period when knowledge of reality has long since rejected the fulfilment of the wish as unattainable, it persists in the unconscious and retains a considerable cathexis of energy. The wish to get the longed-for penis eventually in spite of everything may contribute to the motives that drive a mature woman to analysis, and what she may reasonably expect from analysis - a capacity, for instance, to carry on an intellectual profession - may often be recognized as a sublimated modification of this repressed wish. [1933a, 4727]
One cannot very well doubt the importance of envy for the penis. You may take it as an instance of male injustice if I assert that envy and jealousy play an even greater part in the mental life of women than of men. It is not that I think these characteristics are absent in men or that I think they have no other roots in women than envy for the penis; but I am inclined to attribute their greater amount in women to this latter influence. Some analysts, however, have shown an inclination to depreciate the importance of this first instalment of penis-envy in the phallic phase. They are of opinion that what we find of this attitude in women is in the main a secondary structure which has come about on the occasion of later conflicts by regression to this early infantile impulse. This, however, is a general problem of depth psychology. In many pathological - or even unusual - instinctual attitudes (for instance, in all sexual perversions) the question arises of how much of their strength is to be attributed to early infantile fixations and how much to the influence of later experiences and developments. In such cases it is almost always a matter of complementary series such as we put forward in our discussion of the aetiology of the neuroses. Both factors play a part in varying amounts in the causation; a less on the one side is balanced by a more on the other. The infantile factor sets the pattern in all cases but does not always determine the issue, though it often does. Precisely in the case of penis-envy I should argue decidedly in favour of the preponderance of the infantile factor.

[1933a, 4727]

The discovery that she is castrated is a turning-point in a girl's growth. Three possible lines of development start from it: one leads to sexual inhibition or to neurosis, the second to change of character in the sense of a masculinity complex, the third, finally, to normal femininity. We have learnt a fair amount, though not everything, about all three.

[1933a, 4728]

The essential content of the first is as follows: the little girl has hitherto lived in a masculine way, has been able to get pleasure by the excitation of her clitoris and has brought this activity into relation with her sexual wishes directed towards her mother, which are often active ones; now, owing to the influence of her penis-envy, she loses her enjoyment in her phallic sexuality. Her self-love is mortified by the comparison with the boy's far superior equipment and in consequence she renounces her masturbatory satisfaction from her clitoris, repudiates her love for her mother and at the same time not infrequently represses a good part of her sexual trends in general. No doubt her turning away from her mother does not occur all at once, for to begin with the girl regards her castration as an individual misfortune, and only gradually extends it to other females and finally to her mother as well. Her love was directed to her phallic mother; with the discovery that her mother is castrated it becomes possible to drop her as an object, so that the motives for hostility, which have long been accumulating, gain the upper hand. This means, therefore, that as a result of the discovery of women's lack of a penis they are debased in value for girls just as they are for boys and later perhaps for men.

[1933a, 4728]
With the transference of the wish for a penis-baby on to her father, the girl has entered the situation of the Oedipus complex. Her hostility to her mother, which did not need to be freshly created, is now greatly intensified, for she becomes the girl's rival, who receives from her father everything that she desires from him. For a long time the girl's Oedipus complex concealed her pre-Oedipus attachment to her mother from our view, though it is nevertheless so important and leaves such lasting fixations behind it. For girls the Oedipus situation is the outcome of a long and difficult development; it is a kind of preliminary solution, a position of rest which is not soon abandoned, especially as the beginning of the latency period is not far distant. And we are now struck by a difference between the two sexes, which is probably momentous, in regard to the relation of the Oedipus complex to the castration complex. In a boy the Oedipus complex, in which he desires his mother and would like to get rid of his father as being a rival, develops naturally from the phase of his phallic sexuality. The threat of castration compels him, however, to give up that attitude. Under the impression of the danger of losing his penis, the Oedipus complex is abandoned, repressed and, in the most normal cases, entirely destroyed, and a severe superego is set up as its heir. What happens with a girl is almost the opposite. The castration complex prepares for the Oedipus complex instead of destroying it; the girl is driven out of her attachment to her mother through the influence of her envy for the penis and she enters the Oedipus situation as though into a haven of refuge. In the absence of fear of castration the chief motive is lacking which leads boys to surmount the Oedipus complex. Girls remain in it for an indeterminate length of time; they demolish it late and, even so, incompletely. In these circumstances the formation of the superego must suffer; it cannot attain the strength and independence which give it its cultural significance, and feminists are not pleased when we point out to them the effects of this factor upon the average feminine character.

[1933a, 4731]

To go back a little. We mentioned as the second possible reaction to the discovery of female castration the development of a powerful masculinity complex. By this we mean that the girl refuses, as it were, to recognize the unwelcome fact and, defiantly rebellious, even exaggerates her previous masculinity, clings to her clitoral activity and takes refuge in an identification with her phallic mother or her father. What can it be that decides in favour of this outcome? We can only suppose that it is a constitutional factor, a greater amount of activity, such as is ordinarily characteristic of a male. However that may be, the essence of this process is that at this point in development the wave of passivity is avoided which opens the way to the turn towards femininity. The extreme achievement of such a masculinity complex would appear to be the influencing of the choice of an object in the sense of manifest homosexuality. Analytic experience teaches us, to be sure, that female homosexuality is seldom or never a direct continuation of infantile masculinity. Even for a girl of this kind it seems necessary that she should take her father as an object for some time and enter the Oedipus situation. But afterwards, as a result of her inevitable disappointments from her father, she is driven to regress into her early masculinity complex. The significance of these disappointments must not be exaggerated; a girl who is destined to become feminine is not spared them, though they do not have the same effect. The predominance of the constitutional factor seems indisputable; but the two phases in the development of female homosexuality are well mirrored in the practices of homosexuals, who play the parts of mother and baby with each other as often and as clearly as those of husband and wife.

[1933a, 4732]
With the phallic phase and in the course of it the sexuality of early childhood reaches its height and approaches its dissolution. Thereafter boys and girls have different histories. Both have begun to put their intellectual activity at the service of sexual researches; both start off from the premiss of the universal presence of the penis. But now the paths of the sexes diverge. The boy enters the Oedipus phase; he begins to manipulate his penis and simultaneously has phantasies of carrying out some sort of activity with it in relation to his mother, till, owing to the combined effect of a threat of castration and the sight of the absence of a penis in females, he experiences the greatest trauma of his life and this introduces the period of latency with all its consequences. The girl, after vainly attempting to do the same as the boy, comes to recognize her lack of a penis or rather the inferiority of her clitoris, with permanent effects on the development of her character; as a result of this first disappointment in rivalry, she often begins by turning away altogether from sexual life.

[1940a [1938], 4965]

The effects of the castration complex in little girls are more uniform and no less profound. A female child has, of course, no need to fear the loss of a penis; she must, however, react to the fact of not having received one. From the very first she envies boys its possession; her whole development may be said to take place under the colours of envy for the penis. She begins by making vain attempts to do the same as boys and later, with greater success, makes efforts to compensate for her defect - efforts which may lead in the end to a normal feminine attitude. If during the phallic phase she tries to get pleasure like a boy by the manual stimulation of her genitals, it often happens that she fails to obtain sufficient satisfaction and extends her judgement of inferiority from her stunted penis to her whole self. As a rule she soon gives up masturbating, since she has no wish to be reminded of the superiority of her brother or playmate, and turns away from sexuality altogether.

[1940a [1938], 5000]

If a little girl persists in her first wish - to grow into a boy - in extreme cases she will end as a manifest homosexual, and otherwise she will exhibit markedly masculine traits in the conduct of her later life, will choose a masculine vocation, and so on. The other path leads by way of abandoning the mother she has loved: the daughter, under the influence of her envy for the penis, cannot forgive her mother for having sent her into the world so insufficiently equipped. In her resentment over this she gives up her mother and puts someone else in her place as the object of her love - her father. If one has lost a love-object, the most obvious reaction is to identify oneself with it, to replace it from within, as it were, by identification. This mechanism now comes to the little girl's help. Identification with her mother can take the place of attachment to her mother. The little daughter puts herself in her mother's place, as she has always done in her games; she tries to take her mother's place with her father, and begins to hate the mother she used to love, and from two motives: from jealousy as well as from mortification over the penis she has been denied. Her new relation to her father may start by having as its content a wish to have his penis at her disposal, but it culminates in another wish - to have a baby from him as a gift. The wish for a baby has thus taken the place of the wish for a penis, or has at all events split off from it.

[1940a [1938], 5000]
It is an interesting thing that the relation between the Oedipus complex and the castration complex should take such a different shape - an opposite one, in fact - in the case of females as compared to that of males. In males, as we have seen, the threat of castration brings the Oedipus complex to an end; in females we find that, on the contrary, it is their lack of a penis that forces them into their Oedipus complex. It does little harm to a woman if she remains in her feminine Oedipus attitude. (The term 'Electra complex' has been proposed for it.) She will in that case choose her husband for his paternal characteristics and be ready to recognize his authority. Her longing to possess a penis, which is in fact unappeasable, may find satisfaction if she can succeed in completing her love for the organ by extending it to the bearer of the organ, just as happened earlier when she progressed from her mother's breast to her mother as a whole person. 
[1940a [1938], 5001]

In trying to introduce this factor into the structure of our theory, we must not overlook the fact that it cannot, by its very nature, occupy the same position in both sexes. In males the striving to be masculine is completely ego-syntonic from the first; the passive attitude, since it presupposes an acceptance of castration, is energetically repressed, and often its presence is only indicated by excessive overcompensations. In females, too, the striving to be masculine is ego-syntonic at a certain period - namely in the phallic phase, before the development to femininity has set in. But it then succumbs to the momentous process of repression whose outcome, as has so often been shown, determines the fortunes of a woman's femininity. A great deal depends on whether a sufficient amount of her masculinity complex escapes repression and exercises a permanent influence on her character. Normally, large portions of the complex are transformed and contribute to the construction of her femininity: the appeased wish for a penis is destined to be converted into a wish for a baby and for a husband, who possesses a penis. It is strange, however, how often we find that the wish for masculinity has been retained in the unconscious and, from out of its state of repression, exercises a disturbing influence. 
[1937c, 5044]
Analytic observation enables us to recognize or guess these connections between the phallic organization, the Oedipus complex, the threat of castration, the formation of the super-ego and the latency period. These connections justify the statement that the destruction of the Oedipus complex is brought about by the threat of castration. But this does not dispose of the problem; there is room for a theoretical speculation which may upset the results we have come to or put them in a new light. Before we start along this new path, however, we must turn to a question which has arisen in the course of this discussion and has so far been left on one side. The process which has been described refers, as has been expressly said, to male children only. How does the corresponding development take place in little girls? [1924d, 4089]

At this point our material - for some incomprehensible reason - becomes far more obscure and full of gaps. The female sex, too, develops an Oedipus complex, a super-ego and a latency period. May we also attribute a phallic organization and a castration complex to it? The answer is in the affirmative; but these things cannot be the same as they are in boys. Here the feminist demand for equal rights for the sexes does not take us far, for the morphological distinction is bound to find expression in differences of psychical development. 'Anatomy is Destiny', to vary a saying of Napoleon's. The little girl's clitoris behaves just like a penis to begin with; but, when she makes a comparison with a playfellow of the other sex, she perceives that she has 'come off badly' and she feels this as a wrong done to her and as a ground for inferiority. For a while still she consoles herself with the expectation that later on, when she grows older, she will acquire just as big an appendage as the boy's. Here the masculinity complex of women branches off. A female child, however, does not understand her lack of a penis as being a sex character; she explains it by assuming that at some earlier date she had possessed an equally large organ and had then lost it by castration. She seems not to extend this inference from herself to other, adult females, but, entirely on the lines of the phallic phase, to regard them as possessing large and complete - that is to say, male - genitals. The essential difference thus comes about that the girl accepts castration as an accomplished fact, whereas the boy fears the possibility of its occurrence. [1924d, 4090]

The fear of castration being thus excluded in the little girl, a powerful motive also drops out for the setting-up of a super-ego and for the breaking-off of the infantile genital organization. In her, far more than in the boy, these changes seem to be the result of upbringing and of intimidation from outside which threatens her with a loss of love. The girl's Oedipus complex is much simpler than that of the small bearer of the penis; in my experience, it seldom goes beyond the taking of her mother's place and the adopting of a feminine attitude towards her father. Renunciation of the penis is not tolerated by the girl without some attempt at compensation. She slips - along the line of a symbolic equation, one might say - from the penis to a baby. Her Oedipus complex culminates in a desire, which is long retained, to receive a baby from her father as a gift - to bear him a child. One has an impression that the Oedipus complex is then gradually given up because this wish is never fulfilled. The two wishes - to possess a penis and a child - remain strongly cathexed in the unconscious and help to prepare the female creature for her later sexual role. The comparatively lesser strength of the sadistic contribution to her sexual instinct, which we may no doubt connect with the stunted growth of her penis, makes it easier in her case for the direct sexual trends to be transformed into aim-inhibited trends of an affectionate kind. It must be admitted, however, that in general our insight into these developmental processes in girls is unsatisfactory, incomplete and vague. [1924d, 4090]
In examining the earliest mental shapes assumed by the sexual life of children we have been in the habit of taking as the subject of our investigations the male child, the little boy. With little girls, so we have supposed, things must be similar, though in some way or other they must nevertheless be different. The point in development at which this difference lay could not be clearly determined.
[1925j, 4147]

There is an interesting contrast between the behaviour of the two sexes. In the analogous situation, when a little boy first catches sight of a girl's genital region, he begins by showing irresolution and lack of interest; he sees nothing or disavows what he has seen, he softens it down or looks about for expedients for bringing it into line with his expectations. It is not until later, when some threat of castration has obtained a hold upon him, that the observation becomes important to him: if he then recollects or repeats it, it arouses a terrible storm of emotion in him and forces him to believe in the reality of the threat which he has hitherto laughed at. This combination of circumstances leads to two reactions, which may become fixed and will in that case, whether separately or together or in conjunction with other factors, permanently determine the boy's relations to women: horror of the mutilated creature or triumph and contempt for her. These developments, however, belong to the future, though not to a very remote one.
[1925j, 4150]

A little girl behaves differently. She makes her judgement and her decision in a flash. She has seen it and knows that she is without it and wants to have it.¹
[1925j, 4150]

A third consequence of penis-envy seems to be a loosening of the girl's relation with her mother as a love-object. The situation as a whole is not very clear, but it can be seen that in the end the girl's mother, who sent her into the world so insufficiently equipped, is almost always held responsible for her lack of a penis. The way in which this comes about historically is often that soon after the girl has discovered that her genitals are unsatisfactory she begins to show jealousy of another child on the ground that her mother is fonder of it than of her, which serves as a reason for her giving up her affectionate relation to her mother. It will fit in with this if the child which has been preferred by her mother is made into the first object of the beating-phantasy which ends in masturbation.
[1925j, 4152]

So far there has been no question of the Oedipus complex, nor has it up to this point played any part. But now the girl's libido slips into a new position along the line - there is no other way of putting it - of the equation 'penis-child'. She gives up her wish for a penis and puts in place of it a wish for a child: and with that purpose in view she takes her father as a love object. Her mother becomes the object of her jealousy. The girl has turned into a little woman. If I am to credit a single analytic instance, this new situation can give rise to physical sensations which would have to be regarded as a premature awakening of the female genital apparatus. When the girl's attachment to her father comes to grief later on and has to be abandoned, it may give place to an identification with him and the girl may thus return to her masculinity complex and perhaps remain fixated in it.
[1925j, 4154]
I have now said the essence of what I had to say: I will stop, therefore, and cast an eye over our findings. We have gained some insight into the prehistory of the Oedipus complex in girls. The corresponding period in boys is more or less unknown. In girls the Oedipus complex is a secondary formation. The operations of the castration complex precede it and prepare for it. As regards the relation between the Oedipus and castration complexes there is a fundamental contrast between the two sexes. Whereas in boys the Oedipus complex is destroyed by the castration complex, in girls it is made possible and led up to by the castration complex. This contradiction is cleared up if we reflect that the castration complex always operates in the sense implied in its subject-matter: it inhibits and limits masculinity and encourages femininity. The difference between the sexual development of males and females at the stage we have been considering is an intelligible consequence of the anatomical distinction between their genitals and of the psychical situation involved in it; it corresponds to the difference between a castration that has been carried out and one that has merely been threatened. In their essentials, therefore, our findings are self-evident and it should have been possible to foresee them.

The Oedipus complex, however, is such an important thing that the manner in which one enters and leaves it cannot be without its effects. In boys (as I have shown at length in the paper to which I have just referred and to which all of my present remarks are closely related) the complex is not simply repressed, it is literally smashed to pieces by the shock of threatened castration. Its libidinal cathexes are abandoned, desexualized and in part sublimated; its objects are incorporated into the ego, where they form the nucleus of the super-ego and give that new structure its characteristic qualities. In normal, or, it is better to say, in ideal cases, the Oedipus complex exists no longer, even in the unconscious; the super-ego has become its heir. Since the penis (to follow Ferenczi) owes its extraordinarily high narcissistic cathexis to its organic significance for the propagation of the species, the catastrophe to the Oedipus complex (the abandonment of incest and the institution of conscience and morality) may be regarded as a victory of the race over the individual. This is an interesting point of view when one considers that neurosis is based upon a struggle of the ego against the demands of the sexual function. But to leave the standpoint of individual psychology is not of any immediate help in clarifying this complicated situation.

In girls the motive for the demolition of the Oedipus complex is lacking. Castration has already had its effect, which was to force the child into the situation of the Oedipus complex. Thus the Oedipus complex escapes the fate which it meets with in boys: it may be slowly abandoned or dealt with by repression, or its effects may persist far into women's normal mental life. I cannot evade the notion (though I hesitate to give it expression) that for women the level of what is ethically normal is different from what it is in men. Their super-ego is never so inexorable, so impersonal, so independent of its emotional origins as we require it to be in men. Character-trait which critics of every epoch have brought up against women - that they show less sense of justice than men, that they are less ready to submit to the great exigencies of life, that they are more often influenced in their judgements by feelings of affection or hostility - all these would be amply accounted for by the modification in the formation of their super-ego which we have inferred above. We must not allow ourselves to be deflected from such conclusions by the denials of the feminists, who are anxious to force us to regard the two sexes as completely equal in position and worth; but we shall, of course, willingly agree that the majority of men are also far behind the masculine ideal and that all human individuals, as a result of their bisexual disposition and of cross-inheritance, combine in themselves both masculine and feminine characteristics, so that pure masculinity and femininity remain theoretical constructions of uncertain content.
When, in an earlier part of this discussion, we found that the danger of castration was of importance in more than one neurotic illness, we put ourselves on guard against overestimating that factor, since it could not be a decisive one for the female sex, who are undoubtedly more subject to neuroses than men. We now see that there is no danger of our regarding castration anxiety as the sole motive force of the defensive processes which lead to neurosis. I have shown elsewhere how little girls, in the course of their development, are led into making a tender object-cathexis by their castration complex. It is precisely in women that the danger situation of loss of object seems to have remained the most effective. All we need to do is to make a slight modification in our description of their determinant of anxiety, in the sense that it is no longer a matter of feeling the want of, or actually losing the object itself, but of losing the object's love. Since there is no doubt that hysteria has a strong affinity with femininity, just as obsessional neurosis has with masculinity, it appears probable that, as a determinant of anxiety, loss of love plays much the same part in hysteria as the threat of castration does in phobias and fear of the super-ego in obsessional neurosis.

Quite different are the effects of the castration complex in the female. She acknowledges the fact of her castration, and with it, too, the superiority of the male and her own inferiority; but she rebels against this unwelcome state of affairs. From this divided attitude three lines of development open up. The first leads to a general revulsion from sexuality. The little girl, frightened by the comparison with boys, grows dissatisfied with her clitoris, and gives up her phallic activity and with it her sexuality in general as well as a good part of her masculinity in other fields. The second line leads her to cling with defiant self-assertiveness to her threatened masculinity. To an incredibly late age she clings to the hope of getting a penis some time. That hope becomes her life's aim; and the phantasy of being a man in spite of everything often persists as a formative factor over long periods. This 'masculinity complex' in women can also result in a manifest homosexual choice of object. Only if her development follows the third, very circuitous, path does she reach the final normal female attitude, in which she takes her father as her object and so finds her way to the feminine form of the Oedipus complex. Thus in women the Oedipus complex is the end-result of a fairly lengthy development. It is not destroyed, but created, by the influence of castration; it escapes the strongly hostile influences which, in the male, have a destructive effect on it, and indeed it is all too often not surmounted by the female at all. For this reason, too, the cultural consequences of its break-up are smaller and of less importance in her. We should probably not be wrong in saying that it is this difference in the reciprocal relation between the Oedipus and the castration complex which gives its special stamp to the character of females as social beings.

Another, much more specific motive for turning away from the mother arises from the effect of the castration complex on the creature who is without a penis. At some time or other the little girl makes the discovery of her organic inferiority - earlier and more easily, of course, if there are brothers or other boys about. We have already taken note of the three paths which diverge from this point: (a) the one which leads to a cessation of her whole sexual life, (b) the one which leads to a defiant over-emphasis of her masculinity, and (c) the first steps towards definitive femininity. It is not easy to determine the exact timing here or the typical course of events. Even the point of time when the discovery of castration is made varies, and a number of other factors seem to be inconstant and to depend on chance. The state of the girl's own phallic activity plays a part; and so too does the question whether this activity was found out or not, and how much interference with it she experienced afterwards.
Abraham's (1921) description of the manifestations of the castration complex in the female is still unsurpassed; but one would be glad if it had included the factor of the girl's original exclusive attachment to her mother. I am in agreement with the principal points in Jeanne Lampl-de Groot's¹ (1927) important paper. In this the complete identity of the pre-Oedipus phase in boys and girls is recognized, and the girl's sexual (phallic) activity towards her mother is affirmed and substantiated by observations. The turning-away from the mother is traced to the influence of the girl's recognition of castration, which obliges her to give up her sexual object, and often masturbation along with it. The whole development is summed up in the formula that the girl goes through a phase of the 'negative' Oedipus complex before she can enter the positive one. A point on which I find the writer's account inadequate is that it represents the turning-away from the mother as being merely a change of object and does not discuss the fact that it is accompanied by the plainest manifestations of hostility. To this hostility full justice is done in Helene Deutsch's latest paper, on feminine masochism and its relation to frigidity (1930), in which she also recognizes the girl's phallic activity and the intensity of her attachment to her mother. Helene Deutsch states further that the girl's turning towards her father takes place viâ her passive trends (which have already been awakened in relation to her mother). In her earlier book (1925) the author had not yet set herself free from the endeavour to apply the Oedipus pattern to the pre-Oedipus phase, and she therefore interpreted the little girl's phallic activity as an identification with her father.

[1931b, 4605]

Fear of castration is not, of course, the only motive for repression: indeed, it finds no place in women, for though they have a castration complex they cannot have a fear of being castrated. Its place is taken in their sex by a fear of loss of love, which is evidently a later prolongation of the infant's anxiety if it finds its mother absent. You will realize how real a situation of danger is indicated by this anxiety. If a mother is absent or has withdrawn her love from her child, it is no longer sure of the satisfaction of its needs and is perhaps exposed to the most distressing feelings of tension. Do not reject the idea that these determinants of anxiety may at bottom repeat the situation of the original anxiety at birth, which, to be sure, also represented a separation from the mother. Indeed, if you follow a train of thought suggested by Ferenczi, you may add the fear of castration to this series, for a loss of the male organ results in an inability to unite once more with the mother (or a substitute for her) in the sexual act. I may mention to you incidentally that the very frequent phantasy of returning into the mother's womb is a substitute for this wish to copulate. There would be many interesting things and surprising connections to tell you at this point, but I cannot go outside the framework of an introduction to psychoanalysis. I will only draw your attention to the fact that here psychological researches trench upon the facts of biology.

[1933a, 4694]

I believe we have found this specific factor, and indeed where we expected to find it, even though in a surprising form. Where we expected to find it, I say, for it lies in the castration complex. After all, the anatomical distinction must express itself in psychical consequences. It was, however, a surprise to learn from analyses that girls hold their mother responsible for their lack of a penis and do not forgive her for their being thus put at a disadvantage.

[1933a, 4726]
As you hear, then, we ascribe a castration complex to women as well. And for good reasons, though its content cannot be the same as with boys. In the latter the castration complex arises after they have learnt from the sight of the female genitals that the organ which they value so highly need not necessarily accompany the body. At this the boy recalls to mind the threats he brought on himself by his doings with that organ, he begins to give credence to them and falls under the influence of fear of castration, which will be the most powerful motive force in his subsequent development. The castration complex of girls is also started by the sight of the genitals of the other sex. They at once notice the difference and, it must be admitted, its significance too. They feel seriously wronged, often declare that they want to 'have something like it too', and fall a victim to 'envy for the penis', which will leave ineradicable traces on their development and the formation of their character and which will not be surmounted in even the most favourable cases without a severe expenditure of psychical energy. The girl's recognition of the fact of her being without a penis does not by any means imply that she submits to the fact easily. On the contrary, she continues to hold on for a long time to the wish to get something like it herself and she believes in that possibility for impossibly long years; and analysis can show that, at a period when knowledge of reality has long since rejected the fulfilment of the wish as unattainable, it persists in the unconscious and retains a considerable cathexis of energy. The wish to get the longed-for penis eventually in spite of everything may contribute to the motives that drive a mature woman to analysis, and what she may reasonably expect from analysis - a capacity, for instance, to carry on an intellectual profession - may often be recognized as a sublimated modification of this repressed wish.

The discovery that she is castrated is a turning-point in a girl's growth. Three possible lines of development start from it: one leads to sexual inhibition or to neurosis, the second to change of character in the sense of a masculinity complex, the third, finally, to normal femininity. We have learnt a fair amount, though not everything, about all three.

The essential content of the first is as follows: the little girl has hitherto lived in a masculine way, has been able to get pleasure by the excitation of her clitoris and has brought this activity into relation with her sexual wishes directed towards her mother, which are often active ones; now, owing to the influence of her penis-envy, she loses her enjoyment in her phallic sexuality. Her self-love is mortified by the comparison with the boy's far superior equipment and in consequence she renounces her masturbatory satisfaction from her clitoris, repudiates her love for her mother and at the same time not infrequently represses a good part of her sexual trends in general. No doubt her turning away from her mother does not occur all at once, for to begin with the girl regards her castration as an individual misfortune, and only gradually extends it to other females and finally to her mother as well. Her love was directed to her phallic mother; with the discovery that her mother is castrated it becomes possible to drop her as an object, so that the motives for hostility, which have long been accumulating, gain the upper hand. This means, therefore, that as a result of the discovery of women's lack of a penis they are debased in value for girls just as they are for boys and later perhaps for men.
With the transference of the wish for a penis-baby on to her father, the girl has entered the situation of the Oedipus complex. Her hostility to her mother, which did not need to be freshly created, is now greatly intensified, for she becomes the girl's rival, who receives from her father everything that she desires from him. For a long time the girl's Oedipus complex concealed her pre-Oedipus attachment to her mother from our view, though it is nevertheless so important and leaves such lasting fixations behind it. For girls the Oedipus situation is the outcome of a long and difficult development; it is a kind of preliminary solution, a position of rest which is not soon abandoned, especially as the beginning of the latency period is not far distant. And we are now struck by a difference between the two sexes, which is probably momentous, in regard to the relation of the Oedipus complex to the castration complex. In a boy the Oedipus complex, in which he desires his mother and would like to get rid of his father as being a rival, develops naturally from the phase of his phallic sexuality. The threat of castration compels him, however, to give up that attitude. Under the impression of the danger of losing his penis, the Oedipus complex is abandoned, repressed and, in the most normal cases, entirely destroyed, and a severe super-ego is set up as its heir. What happens with a girl is almost the opposite. The castration complex prepares for the Oedipus complex instead of destroying it; the girl is driven out of her attachment to her mother through the influence of her envy for the penis and she enters the Oedipus situation as though into a haven of refuge. In the absence of fear of castration the chief motive is lacking which leads boys to surmount the Oedipus complex. Girls remain in it for an indeterminate length of time; they demolish it late and, even so, incompletely. In these circumstances the formation of the super-ego must suffer; it cannot attain the strength and independence which give it its cultural significance, and feminists are not pleased when we point out to them the effects of this factor upon the average feminine character.

[1933a, 4731]

With the phallic phase and in the course of it the sexuality of early childhood reaches its height and approaches its dissolution. Thereafter boys and girls have different histories. Both have begun to put their intellectual activity at the service of sexual researches; both start off from the premiss of the universal presence of the penis. But now the paths of the sexes diverge. The boy enters the Oedipus phase; he begins to manipulate his penis and simultaneously has phantasies of carrying out some sort of activity with it in relation to his mother, till, owing to the combined effect of a threat of castration and the sight of the absence of a penis in females, he experiences the greatest trauma of his life and this introduces the period of latency with all its consequences. The girl, after vainly attempting to do the same as the boy, comes to recognize her lack of a penis or rather the inferiority of her clitoris, with permanent effects on the development of her character; as a result of this first disappointment in rivalry, she often begins by turning away altogether from sexual life.

[1940a [1938], 4965]

The effects of the castration complex in little girls are more uniform and no less profound. A female child has, of course, no need to fear the loss of a penis; she must, however, react to the fact of not having received one. From the very first she envies boys its possession; her whole development may be said to take place under the colours of envy for the penis. She begins by making vain attempts to do the same as boys and later, with greater success, makes efforts to compensate for her defect - efforts which may lead in the end to a normal feminine attitude. If during the phallic phase she tries to get pleasure like a boy by the manual stimulation of her genitals, it often happens that she fails to obtain sufficient satisfaction and extends her judgement of inferiority from her stunted penis to her whole self. As a rule she soon gives up masturbating, since she has no wish to be reminded of the superiority of her brother or playmate, and turns away from sexuality altogether.

[1940a [1938], 5000]
It is an interesting thing that the relation between the Oedipus complex and the castration complex should take such a different shape - an opposite one, in fact - in the case of females as compared to that of males. In males, as we have seen, the threat of castration brings the Oedipus complex to an end; in females we find that, on the contrary, it is their lack of a penis that forces them into their Oedipus complex. It does little harm to a woman if she remains in her feminine Oedipus attitude. (The term 'Electra complex' has been proposed for it.) She will in that case choose her husband for his paternal characteristics and be ready to recognize his authority. Her longing to possess a penis, which is in fact unappeasable, may find satisfaction if she can succeed in completing her love for the organ by extending it to the bearer of the organ, just as happened earlier when she progressed from her mother's breast to her mother as a whole person.

[1940a [1938], 5001]
We have lately been made more clearly aware than before that a child's sexual development advances to a certain phase at which the genital organ has already taken over the leading role. But this genital is the male one only, or, more correctly, the penis; the female genital has remained undiscovered. This phallic phase, which is contemporaneous with the Oedipus complex, does not develop further to the definitive genital organization, but is succeeded by the latency period. Its termination, however, takes place in a typical manner and in conjunction with events that are of regular recurrence.

Now it is my view that what brings about the destruction of the child's phallic genital organization is this threat of castration. Not immediately, it is true, and not without other influences being brought to bear as well. For to begin with the boy does not believe in the threat or obey it in the least. Psycho-analysis has recently attached importance to two experiences which all children go through and which, it is suggested, prepare them for the loss of highly valued parts of the body. These experiences are the withdrawal of the mother's breast - at first intermittently and later for good - and the daily demand on them to give up the contents of the bowel. But there is no evidence to show that, when the threat of castration takes place, those experiences have any effect. It is not until a fresh experience comes his way that the child begins to reckon with the possibility of being castrated, and then only hesitatingly and unwillingly, and not without making efforts to depreciate the significance of something he has himself observed.

I have described elsewhere how this turning away takes place. The object-cathexes are given up and replaced by identifications. The authority of the father or the parents is introjected into the ego, and there it forms the nucleus of the super-ego, which takes over the severity of the father and perpetuates his prohibition against incest, and so secures the ego from the return of the libidinal object-cathexis. The libidinal trends belonging to the Oedipus complex are in part desexualized and sublimated (a thing which probably happens with every transformation into an identification) and in part inhibited in their aim and changed into impulses of affection. The whole process has, on the one hand, preserved the genital organ - has averted the danger of its loss - and, on the other, has paralysed it - has removed its function. This process ushers in the latency period, which now interrupts the child's sexual development.

Analytic observation enables us to recognize or guess these connections between the phallic organization, the Oedipus complex, the threat of castration, the formation of the super-ego and the latency period. These connections justify the statement that the destruction of the Oedipus complex is brought about by the threat of castration. But this does not dispose of the problem; there is room for a theoretical speculation which may upset the results we have come to or put them in a new light. Before we start along this new path, however, we must turn to a question which has arisen in the course of this discussion and has so far been left on one side. The process which has been described refers, as has been expressly said, to male children only. How does the corresponding development take place in little girls?
At this point our material - for some incomprehensible reason - becomes far more obscure and full of gaps. The female sex, too, develops an Oedipus complex, a super-ego and a latency period. May we also attribute a phallic organization and a castration complex to it? The answer is in the affirmative; but these things cannot be the same as they are in boys. Here the feminist demand for equal rights for the sexes does not take us far, for the morphological distinction is bound to find expression in differences of psychical development. 'Anatomy is Destiny', to vary a saying of Napoleon's. The little girl's clitoris behaves just like a penis to begin with; but, when she makes a comparison with a playfellow of the other sex, she perceives that she has 'come off badly' and she feels this as a wrong done to her and as a ground for inferiority. For a while still she consoles herself with the expectation that later on, when she grows older, she will acquire just as big an appendage as the boy's. Here the masculinity complex of women branches off. A female child, however, does not understand her lack of a penis as being a sex character; she explains it by assuming that at some earlier date she had possessed an equally large organ and had then lost it by castration. She seems not to extend this inference from herself to other, adult females, but, entirely on the lines of the phallic phase, to regard them as possessing large and complete - that is to say, male - genitals. The essential difference thus comes about that the girl accepts castration as an accomplished fact, whereas the boy fears the possibility of its occurrence.

[1924d, 4090]

I have no doubt that the chronological and causal relations described here between the Oedipus complex, sexual intimidation (the threat of castration), the formation of the super-ego and the beginning of the latency period are of a typical kind; but I do not wish to assert that this type is the only possible one. Variations in the chronological order and in the linking-up of these events are bound to have a very important bearing on the development of the individual.

[1924d, 4091]

Various sorts. In the first place, impressions capable of permanently influencing the child's budding sexual life - such as observations of sexual activities between adults, or sexual experiences of his own with an adult or another child (no rare events); or, again, overhearing conversations, understood either at the time or retrospectively, from which the child thought it could draw conclusions about mysterious or uncanny matters; or again, remarks or actions by the child himself which give evidence of significant attitudes of affection or enmity towards other people. It is of special importance in an analysis to induce a memory of the patient's own forgotten sexual activity as a child and also of the intervention by the adults which brought it to an end.

[1926e, 4358]

We have already learned, too, that there is yet another difference between the sexes, which relates to the Oedipus complex. We have an impression here that what we have said about the Oedipus complex applies with complete strictness to the male child only and that we are right in rejecting the term 'Electra complex' which seeks to emphasize the analogy between the attitude of the two sexes. It is only in the male child that we find the fateful combination of love for the one parent and simultaneous hatred for the other as a rival. In his case it is the discovery of the possibility of castration, as proved by the sight of the female genitals, which forces on him the transformation of his Oedipus complex, and which leads to the creation of his super-ego and thus initiates all the processes that are designed to make the individual find a place in the cultural community. After the paternal agency has been internalized and become a super-ego, the next task is to detach the latter from the figures of whom it was originally the psychical representative. In this remarkable course of development it is precisely the boy's narcissistic interest in his genitals - his interest in preserving his penis - which is turned round into a curtailing of his infantile sexuality.

[1931b, 4593]
With the phallic phase and in the course of it the sexuality of early childhood reaches its height and approaches its dissolution. Thereafter boys and girls have different histories. Both have begun to put their intellectual activity at the service of sexual researches; both start off from the premiss of the universal presence of the penis. But now the paths of the sexes diverge. The boy enters the Oedipus phase; he begins to manipulate his penis and simultaneously has phantasies of carrying out some sort of activity with it in relation to his mother, till, owing to the combined effect of a threat of castration and the sight of the absence of a penis in females, he experiences the greatest trauma of his life and this introduces the period of latency with all its consequences. The girl, after vainly attempting to do the same as the boy, comes to recognize her lack of a penis or rather the inferiority of her clitoris, with permanent effects on the development of her character; as a result of this first disappointment in rivalry, she often begins by turning away altogether from sexual life.

[1940a [1938], 4965]
On the other hand, these forces which act like dams upon sexual development - disgust, shame and morality - must also be regarded as historical precipitates of the external inhibitions to which the sexual instinct has been subjected during the psychogenesis of the human race. We can observe the way in which, in the development of individuals, they arise at the appropriate moment, as though spontaneously, when upbringing and external influence give the signal.

The barrier against incest is probably among the historical acquisitions of mankind, and, like other moral taboos, has no doubt already become established in many persons by organic inheritance. (Cf. my *Totem and Taboo*, 1912-13.) Psycho-analytic investigation shows, however, how intensely the individual struggles with the temptation to incest during his period of growth and how frequently the barrier is transgressed in phantasies and even in reality.

The phantasies of the pubertal period have as their starting-point the infantile sexual researches that were abandoned in childhood. No doubt, too, they are also present before the end of the latency period. They may persist wholly, or to a great extent, unconsciously and for that reason it is often impossible to date them accurately. They are of great importance in the origin of many symptoms, since they precisely constitute preliminary stages of these symptoms and thus lay down the forms in which the repressed libidinal components find satisfaction. In the same way, they are the prototypes of the nocturnal phantasies which become conscious as dreams. Dreams are often nothing more than revivals of pubertal phantasies of this kind under the influence of, and in relation to, some stimulus left over from the waking life of the previous day (the 'day's residues'). Some among the sexual phantasies of the pubertal period are especially prominent, and are distinguished by their very general occurrence and by being to a great extent independent of individual experience. Such are the adolescent's phantasies of overhearing his parents in sexual intercourse, of having been seduced at an early age by someone he loves and of having been threatened with castration; such, too, are his phantasies of being in the womb, and even of experiences there, and the so-called 'Family Romance', in which he reacts to the difference between his attitude towards his parents now and in his childhood. The close relations existing between these phantasies and myths has been demonstrated in the case of the last instance by Otto Rank (1909).

Other factors which, along with precocity, may be classed as temporal also deserve attention. The order in which the various instinctual impulses come into activity seems to be phylogenetically determined; so, too, does the length of time during which they are able to manifest themselves before they succumb to the effects of some freshly emerging instinctual impulse or to some typical repression. Variations, however, seem to occur both in temporal sequence and in duration, and these variations must exercise a determining influence upon the final result. It cannot be a matter of indifference whether a given current makes its appearance earlier or later than a current flowing in the opposite direction, for the effect of a repression cannot be undone. Divergences in the temporal sequence in which the components come together invariably produce a difference in the outcome. On the other hand, instinctual impulses which emerge with special intensity often run a surprisingly short course - as, for instance, the heterosexual attachment of persons who later become manifest homosexuals. There is no justification for the fear that trends which set in with the greatest violence in childhood will permanently dominate the adult character; it is just as likely that they will disappear and make way for an opposite tendency. ('Gestrenge Herren regieren nicht Lange.')
Among these forbidden wishes special emphasis deserves to be further laid on the incestuous ones - that is, on those aiming at sexual intercourse with parents and brothers and sisters. You know what horror is felt, or at least professed, in human society at such intercourse, and what stress is laid on the prohibitions directed against it. Tremendous efforts have been made to explain this horror of incest. Some people have supposed that breeding considerations on the part of Nature have found psychical representation in this prohibition, since inbreeding would impair racial characters. Others have maintained that, as a result of living together from early childhood onwards, sexual desire has been diverted from the people in question. In both these cases, it may be remarked, an avoidance of incest would be secured automatically, and it would not be clear why such severe prohibitions were called for, which would point rather to the presence of a strong desire for it. Psycho-analytic researches have shown unmistakably that the choice of an incestuous love-object is, on the contrary, the first and invariable one, and that it is not until later that resistance to it sets in; it is no doubt impossible to trace back this resistance to individual psychology.

[1916-1917, 3298]

There is no doubt whatever that at this time his father was turning into the terrifying figure that threatened him with castration. The cruel God with whom he was then struggling - who made men sinful, only to punish them afterwards, who sacrificed his own son and the sons of men - this God threw back his character on to the patient's father, though, on the other hand, the boy was at the same time trying to defend his father against the God. At this point the boy had to fit into a phylogenetic pattern, and he did so, although his personal experiences may not have agreed with it. Although the threats or hints of castration which had come his way had emanated from women,¹ this could not hold up the final result for long. In spite of everything it was his father from whom in the end he came to fear castration. In this respect heredity triumphed over accidental experience; in man's prehistory it was unquestionably the father who practised castration as a punishment and who later softened it down into circumcision. The further the patient went in repressing sensuality during the course of the development of the obsessional neurosis,² the more natural it must have become to him to attribute these evil intentions to his father, who was the true representative of sensual activity.

[1918b, 3568]

This study of the determinants of anxiety has, as it were, shown the defensive behaviour of the ego transfigured in a rational light. Each situation of danger corresponds to a particular period of life or a particular developmental phase of the mental apparatus and appears to be justifiable for it. In early infancy the individual is really not equipped to master psychically the large sums of excitation that reach him whether from without or from within. Again, at a certain period of life his most important interest really is that the people he is dependent on should not withdraw their loving care of him. Later on in his boyhood, when he feels that his father is a powerful rival in regard to his mother and becomes aware of his own aggressive inclinations towards him and of his sexual intentions towards his mother, he really is justified in being afraid of his father; and his fear of being punished by him can find expression through phylogenetic reinforcement in the fear of being castrated. Finally, as he enters into social relationships, it really is necessary for him to be afraid of his super-ego, to have a conscience; and the absence of that factor would give rise to severe conflicts, dangers and so on.

[1926d, 4301]
You will be no less surprised to hear that male children suffer from a fear of being robbed of their sexual organ by their father, so that this fear of being castrated has a most powerful influence on the development of their character and in deciding the direction to be followed by their sexuality. And here again mythology may give you the courage to believe psycho-analysis. The same Kronos who swallowed his children also emasculated his father Uranus, and was afterwards himself emasculated in revenge by his son Zeus, who had been rescued though his mother's cunning. If you have felt inclined to suppose that all that psycho-analysis reports about the early sexuality of children is derived from the disordered imagination of the analysts, you must at least admit that their imagination has created the same product as the imaginative activities of primitive man, of which myths and fairy tales are the precipitate. The alternative friendlier, and probably also the more pertinent view would be that in the mental life of children to-day we can still detect the same archaic factors which were once dominant generally in the primaeval days of human civilization. In his mental development the child would be repeating the history of his race in an abbreviated form, just as embryology long since recognized was the case with somatic development.

[1926e, 4354]

But we have not made any mention at all so far of what the real danger is that the child is afraid of as a result of being in love with his mother. The danger is the punishment of being castrated, of losing his genital organ. You will of course object that after all that is not a real danger. Our boys are not castrated because they are in love with their mothers during the phase of the Oedipus complex. But the matter cannot be dismissed so simply. Above all, it is not a question of whether castration is really carried out; what is decisive is that the danger is one that threatens from outside and that the child believes in it. He has some ground for this, for people threaten him often enough with cutting off his penis during the phallic phase, at the time of his early masturbation, and hints at that punishment must regularly find a phylogenetic reinforcement in him. It is our suspicion that during the human family's primaeval period castration used actually to be carried out by a jealous and cruel father upon growing boys, and that circumcision, which so frequently plays a part in puberty rites among primitive peoples, is a clearly recognizable relic of it. We are aware that here we are diverging widely from the general opinion; but we must hold fast to the view that fear of castration is one of the commonest and strongest motives for repression and thus for the formation of neuroses. The analysis of cases in which circumcision, though not, it is true, castration, has been carried out on boys as a cure or punishment for masturbation (a far from rare occurrence in Anglo-American society) has given our conviction a last degree of certainty. It is very tempting at this point to go more deeply into the castration complex, but I will stick to our subject.

[1933a, 4693]

The work of analysis has, however, brought something else to light which exceeds in its importance what we have so far considered. When we study the reactions to early traumas, we are quite often surprised to find that they are not strictly limited to what the subject himself has really experienced but diverge from it in a way which fits in much better with the model of a phylogenetic event and, in general, can only be explained by such an influence. The behaviour of neurotic children towards their parents in the Oedipus and castration complex abounds in such reactions, which seem unjustified in the individual case and only become intelligible phylogenetically - by their connection with the experience of earlier generations. It would be well worth while to place this material, which I am able to appeal to here, before the public in a collected form. Its evidential value seems to me strong enough for me to venture on a further step and to posit the assertion that the archaic heritage of human beings comprises not only dispositions but also subject-matter - memory-traces of the experience of earlier generations. In this way the compass as well as the importance of the archaic heritage would be significantly extended.

[1939a, 4921]
Castration has a place too in the Oedipus legend, for the blinding with which Oedipus punishes himself after the discovery of his crime is, by the evidence of dreams, a symbolic substitute for castration. The possibility cannot be excluded that a phylogenetic memory-trace may contribute to the extraordinarily terrifying effect of the threat - a memory-trace from the prehistory of the primal family, where the jealous father actually robbed his son of his genitals if the latter became troublesome to him as a rival with a woman. The primal custom of circumcision, another symbolic substitute for castration, can only be understood as an expression of submission to the father's will. (Cf. the puberty rites of primitive peoples.) No investigation has yet been made of the form taken by the events described above among peoples and in civilizations which do not suppress masturbation in children.

We have heard how the weak and immature ego of the first period of childhood is permanently damaged by the stresses put upon it in its efforts to fend off the dangers that are peculiar to that period of life. Children are protected against the dangers that threaten them from the external world by the solicitude of their parents; they pay for this security by a fear of loss of love which would deliver them over helpless to the dangers of the external world. This factor exerts a decisive influence on the outcome of the conflict when a boy finds himself in the situation of the Oedipus complex, in which the threat to his narcissism by the danger of castration, reinforced from primal sources, takes possession of him. Driven by the combined operation of these two influences, the contemporary real danger and the remembered one with its phylogenetic basis, the child embarks on his attempts at defence - repressions - which are effective for the moment but nevertheless turn out to be psychologically inadequate when the later re-animation of sexual life brings a reinforcement to the instinctual demands which have been repudiated in the past. If this is so, it would have to be said from a biological standpoint that the ego comes to grief over the task of mastering the excitations of the early sexual period, at a time when its immaturity makes it incompetent to do so. It is in this lagging of ego development behind libidinal development that we see the essential precondition of neurosis; and we cannot escape the conclusion that neuroses could be avoided if the childish ego were spared this task - if, that is to say, the child's sexual life were allowed free play, as happens among many primitive peoples. It may be that the aetiology of neurotic illnesses is more complicated than we have here described it; if so, we have at least brought out one essential part of the aetiological complex. Nor should we forget the phylogenetic influences, which are represented in some way in the id in forms that we are not yet able to grasp, and which must certainly act upon the ego more powerfully in that early period than later. On the other hand, the realization dawns on us that such an early attempt at damming up the sexual instinct, so decided a partisanship by the young ego in favour of the external as opposed to the internal world, brought about by the prohibition of infantile sexuality, cannot be without its effect on the individual's later readiness for culture. The instinctual demands forced away from direct satisfaction are compelled to enter on new paths leading to substitutive satisfaction, and in the course of these détours they may become desexualized and their connection with their original instinctual aims may become looser. And at this point we may anticipate the thesis that many of the highly valued assets of our civilization were acquired at the cost of sexuality and by the restriction of sexual motive forces.
He made this reply without having any sense of guilt as yet. But this was the occasion of his acquiring the 'castration complex', the presence of which we are so often obliged to infer in analysing neurotics, though they one and all struggle violently against recognizing it. There is much of importance to be said upon the significance of this element in the life of a child. The 'castration complex' has left marked traces behind it in myths (and not only in Greek myths); in a passage in my Interpretation of Dreams, and elsewhere, I have touched upon the part it plays.¹

¹ I cannot interrupt the discussion so far as to demonstrate the typical character of the unconscious train of thought which I think there is here reason for attributing to little Hans. The castration complex is the deepest unconscious root of anti-semitism; for even in the nursery little boys hear that a Jew has something cut off his penis - a piece of his penis, they think - and this gives them a right to despise Jews. And there is no stronger unconscious root for the sense of superiority over women. Weininger (the young philosopher who, highly gifted but sexually deranged, committed suicide after producing his remarkable book, Geschlecht und Charakter), in a chapter that attracted much attention, treated Jews and women with equal hostility and overwhelmed them with the same insults. Being a neurotic, Weininger was completely under the sway of his infantile complexes; and from that standpoint what is common to Jews and women is their relation to the castration complex.

² [Footnote added 1919:] The conclusion strikes me as inescapable that here we may also trace one of the roots of the anti-semitism which appears with such elemental force and finds such irrational expression among the nations of the West. Circumcision is unconsciously equated with castration. If we venture to carry our conjectures back to the primateval days of the human race we can surmise that originally circumcision must have been a milder substitute, designed to take the place of castration.

Crawley, in language which differs only slightly from the current terminology of psycho-analysis, declares that each individual is separated from the others by a 'taboo of personal isolation', and that it is precisely the minor differences in people who are otherwise alike that form the basis of feelings of strangeness and hostility between them. It would be tempting to pursue this idea and to derive from this 'narcissism of minor differences' the hostility which in every human relation we see fighting successfully against feelings of fellowship and overpowering the commandment that all men should love one another. Psycho-analysis believes that it has discovered a large part of what underlies the narcissistic rejection of women by men, which is so much mixed up with despising them, in drawing attention to the castration complex and its influence on the opinion in which women are held.

I shall discuss on another occasion the explanation of these animal phobias and the significance attaching to them. I will only remark in anticipation that this explanation is in complete harmony with the principal characteristic shown by the neurosis from which the present dreamer suffered later in his life. His fear of his father was the strongest motive for his falling ill, and his ambivalent attitude towards every father-surrogate was the dominating feature of his life as well as of his behaviour during the treatment.
If in my patient's case the wolf was merely a first father-surrogate, the question arises whether the hidden content in the fairy tales of the wolf that ate up the little goats and of 'Little Red Riding-Hood' may not simply be infantile fear of the father.¹ Moreover, my patient's father had the characteristic, shown by so many people in relation to their children, of indulging in 'affectionate abuse'; and it is possible that during the patient's earlier years his father (though he grew severe later on) may more than once, as he caressed the little boy or played with him, have threatened in fun to 'gobble him up'. One of my patients told me that her two children could never get to be fond of their grandfather, because in the course of his affectionate romping with them he used to frighten them by saying he would cut open their tummies.

We know from psycho-analytic experience, however, that the fear of damaging or losing one's eyes is a terrible one in children. Many adults retain their apprehensiveness in this respect, and no physical injury is so much dreaded by them as an injury to the eye. We are accustomed to say, too, that we will treasure a thing as the apple of our eye. A study of dreams, phantasies and myths has taught us that anxiety about one's eyes, the fear of going blind, is often enough a substitute for the dread of being castrated. The self-blinding of the mythical criminal, Oedipus, was simply a mitigated form of the punishment of castration - the only punishment that was adequate for him by the lex talionis. We may try on rationalistic grounds to deny that fears about the eye are derived from the fear of castration, and may argue that it is very natural that so precious an organ as the eye should be guarded by a proportionate dread. Indeed, we might go further and say that the fear of castration itself contains no other significance and no deeper secret than a justifiable dread of this rational kind. But this view does not account adequately for the substitutive relation between the eye and the male organ which is seen to exist in dreams and myths and phantasies; nor can it dispel the impression that the threat of being castrated in especial excites a peculiarly violent and obscure emotion, and that this emotion is what first gives the idea of losing other organs its intense colouring. All further doubts are removed when we learn the details of their 'castration complex' from the analysis of neurotic patients, and realize its immense importance in their mental life.

This revolt against castration or a feminine attitude has been torn out of its organic context by Alfred Adler. He has linked it superficially or falsely with the longing for power, and has postulated it as an independent 'masculine protest'. Since a neurosis can only arise from a conflict between two trends, it is as justifiable to see the cause of 'every' neurosis in the masculine protest as it is to see it in the feminine attitude against which the protest is being made. It is quite true that this masculine protest plays a regular part in the formation of character - in some types of people a very large part - and that we meet it in the analysis of neurotic men as a vigorous resistance. Psycho-analysis has attached due importance to the masculine protest in connection with the castration complex, without being able to accept its omnipotence or its omnipresence in neuroses. The most marked case of a masculine protest with all its manifest reactions and character-traits that I have met with in analysis was that of a patient who came to me for treatment on account of an obsessional neurosis in whose symptoms the unresolved conflict between a masculine and a feminine attitude (fear of castration and desire for castration) found clear expression. In addition, the patient had developed masochistic phantasies which were wholly derived from a wish to accept castration; and he had even gone beyond these phantasies to real satisfaction in perverse situations. The whole of his state rested - like Adler's theory itself - on the repression and denial of early infantile fixations of love.
We know, too, to what a degree depreciation of women, horror of women, and a disposition to homosexuality are derived from the final conviction that women have no penis. Ferenczi (1923) has recently, with complete justice, traced back the mythological symbol of horror - Medusa's head - to the impression of the female genitals devoid of a penis.¹

We have sufficient acquaintance with this kind of masochism in men (to whom, owing to the material at my command, I shall restrict my remarks), derived from masochistic - and therefore often impotent - subjects whose phantasies either terminate in an act of masturbation or represent a sexual satisfaction in themselves. The real-life performances of masochistic perverts tally completely with these phantasies, whether the performances are carried out as an end in themselves or serve to induce potency and to lead to the sexual act. In both cases - for the performances are, after all, only a carrying-out of the phantasies in play - the manifest content is of being gagged, bound, painfully beaten, whipped, in some way maltreated, forced into unconditional obedience, dirtied and debased. It is far more rare for mutilations to be included in the content, and then only subject to strict limitations. The obvious interpretation, and one easily arrived at, is that the masochist wants to be treated like a small and helpless child, but, particularly, like a naughty child. It is unnecessary to quote cases to illustrate this; for the material is very uniform and is accessible to any observer, even to non-analysts. But if one has an opportunity of studying cases in which the masochistic phantasies have been especially richly elaborated, one quickly discovers that they place the subject in a characteristically female situation; they signify, that is, being castrated, or copulated with, or giving birth to a baby. For this reason I have called this form of masochism, a potiori as it were, the feminine form, although so many of its features point to infantile life. This superimposed stratification of the infantile and the feminine will find a simple explanation later on. Being castrated - or being blinded, which stands for it - often leaves a negative trace of itself in phantasies, in the condition that no injury is to occur precisely to the genitals or the eyes. (Masochistic tortures, incidentally, rarely make such a serious impression as the cruelties of sadism, whether imagined or performed.) A sense of guilt, too, finds expression in the manifest content of masochistic phantasies; the subject assumes that he has committed some crime (the nature of which is left indefinite) which is to be expiated by all these painful and tormenting procedures. This looks like a superficial rationalization of the masochistic subject-matter, but behind it there lies a connection with infantile masturbation. On the other hand, this factor of guilt provides a transition to the third, moral, form of masochism.

[1924c, 4074]
The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-erotism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother's organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors' own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child's first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child's life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child's early years become re-animated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of 'male' or 'female' but of 'possessing a penis' or 'castrated'. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses.⁶

There is much to be told, for which our expectations have not prepared us, about the contents, manifestations and achievements of this early period of sexuality. For instance, you will no doubt be surprised to hear how often little boys are afraid of being eaten up by their father. (And you may also be surprised at my including this fear among the phenomena of sexual life.) But I may remind you of the mythological tale which you may still recall from your schooldays of how the god Kronos swallowed his children. How strange this must have sounded to you when you first heard it! But I suppose none of us thought about it at the time. To-day we can also call to mind a number of fairy tales in which some ravenous animal like a wolf appears, and we shall recognize it as a disguise of the father. And this is an opportunity of assuring you that it was only through the knowledge of infantile sexuality that it became possible to understand mythology and the world of fairy tales. Here then something has been gained as a by-product of analytic studies.
You will be no less surprised to hear that male children suffer from a fear of being robbed of their sexual organ by their father, so that this fear of being castrated has a most powerful influence on the development of their character and in deciding the direction to be followed by their sexuality. And here again mythology may give you the courage to believe psycho-analysis. The same Kronos who swallowed his children also emasculated his father Uranus, and was afterwards himself emasculated in revenge by his son Zeus, who had been rescued though his mother's cunning. If you have felt inclined to suppose that all that psycho-analysis reports about the early sexuality of children is derived from the disordered imagination of the analysts, you must at least admit that their imagination has created the same product as the imaginative activities of primitive man, of which myths and fairy tales are the precipitate. The alternative friendlier, and probably also the more pertinent view would be that in the mental life of children to-day we can still detect the same archaic factors which were once dominant generally in the primaeval days of human civilization. In his mental development the child would be repeating the history of his race in an abbreviated form, just as embryology long since recognized was the case with somatic development.

[1926e, 4354]

What happened, therefore, was that the boy refused to take cognizance of the fact of his having perceived that a woman does not possess a penis. No, that could not be true: for if a woman had been castrated, then his own possession of a penis was in danger; and against that there rose in rebellion the portion of his narcissism which Nature has, as a precaution, attached to that particular organ. In later life a grown man may perhaps experience a similar panic when the cry goes up that Throne and Altar are in danger, and similar illogical consequences will ensue. If I am not mistaken, Laforgue would say in this case that the boy 'scotomizes' his perception of the woman's lack of a penis.¹ A new technical term is justified when it describes a new fact or emphasizes it. This is not so here. The oldest word in our psycho-analytic terminology, 'repression', already relates to this pathological process. If we wanted to differentiate more sharply between the vicissitude of the idea as distinct from that of the affect, and reserve the word 'Verdrängung' ['repression'] for the affect, then the correct German word for the vicissitude of the idea would be 'Verleugnung' ['disavowal']. 'Scotomization' seems to me particularly unsuitable, for it suggests that the perception is entirely wiped out, so that the result is the same as when a visual impression falls on the blind spot in the retina. In the situation we are considering, on the contrary, we see that the perception has persisted, and that a very energetic action has been undertaken to maintain the disavowal. It is not true that, after the child has made his observation of the woman, he has preserved unaltered his belief that women have a phallus. He has retained that belief, but he has also given it up. In the conflict between the weight of the unwelcome perception and the force of his counter-wish, a compromise has been reached, as is only possible under the dominance of the unconscious laws of thought - the primary processes. Yes, in his mind the woman has got a penis, in spite of everything; but this penis is no longer the same as it was before. Something else has taken its place, has been appointed its substitute, as it were, and now inherits the interest which was formerly directed to its predecessor. But this interest suffers an extraordinary increase as well, because the horror of castration has set up a memorial to itself in the creation of this substitute. Furthermore, an aversion, which is never absent in any fetishist, to the real female genitals remains a stigma indelebile of the repression that has taken place. We can now see what the fetish achieves and what it is that maintains it. It remains a token of triumph over the threat of castration and a protection against it. It also saves the fetishist from becoming a homosexual, by endowing women with the characteristic which makes them tolerable as sexual objects. In later life, the fetishist feels that he enjoys yet another advantage from his substitute for a genital. The meaning of the fetish is not known to other people, so the fetish is not withheld from him: it is easily accessible and he can readily obtain the sexual satisfaction attached to it. What other men have to woo and make exertions for can be had by the fetishist with no trouble at all.

[1927e, 4536]
Returning to my description of fetishism, I may say that there are many and weighty additional proofs of the divided attitude of fetishists to the question of the castration of women. In very subtle instances both the disavowal and the affirmation of the castration have found their way into the construction of the fetish itself. This was so in the case of a man whose fetish was an athletic support-belt which could also be worn as bathing drawers. This piece of clothing covered up the genitals entirely and concealed the distinction between them. Analysis showed that it signified that women were castrated and that they were not castrated; and it also allowed of the hypothesis that men were castrated, for all these possibilities could equally well be concealed under the belt - the earliest rudiment of which in his childhood had been the fig-leaf on a statue. A fetish of this sort, doubly derived from contrary ideas, is of course especially durable. In other instances the divided attitude shows itself in what the fetishist does with his fetish, whether in reality or in his imagination. To point out that he reveres his fetish is not the whole story; in many cases he treats it in a way which is obviously equivalent to a representation of castration. This happens particularly if he has developed a strong identification with his father and plays the part of the latter; for it is to him that as a child he ascribed the woman's castration. Affection and hostility in the treatment of the fetish - which run parallel with the disavowal and the acknowledgement of castration - are mixed in unequal proportions in different cases, so that the one or the other is more clearly recognizable. We seem here to approach an understanding, even if a distant one, of the behaviour of the 'coupeur de nattes'. In him the need to carry out the castration which he disavows has come to the front. His action contains in itself the two mutually incompatible assertions: 'the woman has still got a penis' and 'my father has castrated the woman'. Another variant, which is also a parallel to fetishism in social psychology, might be seen in the Chinese custom of mutilating the female foot and then revering it like a fetish after it has been mutilated. It seems as though the Chinese male wants to thank the woman for having submitted to being castrated.

[1927e, 4538]

But what has been said so far does not exhaust the consequences of the repression of the hatred of the father in the Oedipus complex. There is something fresh to be added: namely that in spite of everything the identification with the father finally makes a permanent place for itself in the ego. It is received into the ego, but establishes itself there as a separate agency in contrast to the rest of the content of the ego. We then give it the name of super-ego and ascribe to it, the inheritor of the parental influence, the most important functions. If the father was hard, violent and cruel, the super-ego takes over those attributes from him and, in the relations between the ego and it, the passivity which was supposed to have been repressed is re-established. The super-ego has become sadistic, and the ego becomes masochistic - that is to say, at bottom passive in a feminine way. A great need for punishment develops in the ego, which in part offers itself as a victim to Fate, and in part finds satisfaction in ill-treatment by the super-ego (that is, in the sense of guilt). For every punishment is ultimately castration and, as such, a fulfilment of the old passive attitude towards the father. Even Fate is, in the last resort, only a later projection of the father.

[1928b, 4561]

One thing that is left over in men from the influence of the Oedipus complex is a certain amount of disparagement in their attitude towards women, whom they regard as being castrated. In extreme cases this gives rise to an inhibition in their choice of object, and, if it is supported by organic factors, to exclusive homosexuality.

[1931b, 4593]
The essential content of the first is as follows: the little girl has hitherto lived in a masculine way, has been able to get pleasure by the excitation of her clitoris and has brought this activity into relation with her sexual wishes directed towards her mother, which are often active ones; now, owing to the influence of her penis-envy, she loses her enjoyment in her phallic sexuality. Her self-love is mortified by the comparison with the boy's far superior equipment and in consequence she renounces her masturbatory satisfaction from her clitoris, repudiates her love for her mother and at the same time not infrequently represses a good part of her sexual trends in general. No doubt her turning away from her mother does not occur all at once, for to begin with the girl regards her castration as an individual misfortune, and only gradually extends it to other females and finally to her mother as well. Her love was directed to her phallic mother; with the discovery that her mother is castrated it becomes possible to drop her as an object, so that the motives for hostility, which have long been accumulating, gain the upper hand. This means, therefore, that as a result of the discovery of women's lack of a penis they are debased in value for girls just as they are for boys and later perhaps for men.

[1933a, 4728]

The deeper motives for hatred of the Jews are rooted in the remotest past ages; they operate from the unconscious of the peoples, and I am prepared to find that at first they will not seem credible. I venture to assert that jealousy of the people which declared itself the first-born, favourite child of God the Father, has not yet been surmounted among other peoples even today: it is as though they had thought there was truth in the claim. Further, among the customs by which the Jews made themselves separate, that of circumcision has made a disagreeable, uncanny impression, which is to be explained, no doubt, by its recalling the dreaded castration and along with it a portion of the primaeval past which is gladly forgotten. And finally, as the latest motive in this series, we must not forget that all those peoples who excel to-day in their hatred of Jews became Christians only in late historic times, often driven to it by bloody coercion. It might be said that they are all 'mis-baptized'. They have been left, under a thin veneer of Christianity, what their ancestors were, who worshipped a barbarous polytheism. They have not got over a grudge against the new religion which was imposed on them; but they have displaced the grudge on to the source from which Christianity reached them. The fact that the Gospels tell a story which is set among Jews, and in fact deals only with Jews, has made this displacement easy for them. Their hatred of Jews is at bottom a hatred of Christians, and we need not be surprised that in the German National-Socialist revolution this intimate relation between the two monotheist religions finds such a clear expression in the hostile treatment of both of them.

[1939a, 4914]
The conclusion strikes me as inescapable that here we may also trace one of the roots of the anti-semitism which appears with such elemental force and finds such irrational expression among the nations of the West. Circumcision is unconsciously equated with castration. If we venture to carry our conjectures back to the primaeval days of the human race we can surmise that originally circumcision must have been a milder substitute, designed to take the place of castration.

Fear of castration plays an extremely large part, in the case of the youthful neurotics whom we come across, as an interference in their relations with their father. The illuminating instance reported by Ferenczi (1913a) has shown us how a little boy took as his totem the beast that had pecked at his little penis. When our children come to hear of ritual circumcision, they equate it with castration. The parallel in social psychology to this reaction by children has not yet been worked out, so far as I am aware. In primaeval times and in primitive races, where circumcision is so frequent, it is performed at the age of initiation into manhood and it is at that age that its significance is to be found; it was only as a secondary development that it was shifted back to the early years of life. It is of very great interest to find that among primitive peoples circumcision is combined with cutting the hair and knocking out teeth or is replaced by them, and that our children, who cannot possibly have any knowledge of this, in fact treat these two operations, in the anxiety with which they react to them, as equivalents of castration.

'Pulling off a branch' as a symbolic representation of masturbation is not merely in harmony with vulgar descriptions of the act but has far-reaching mythological parallels. But that masturbation, or rather the punishment for it - castration -, should be represented by the falling out or pulling out of teeth is especially remarkable, since there is a counterpart to it in anthropology which can be known to only a very small number of dreamers. There seems to me no doubt that the circumcision practised by so many peoples is an equivalent and substitute for castration. And we now learn that certain primitive tribes in Australia carry out circumcision as a puberty rite (at the festival to celebrate a boy's attaining sexual maturity), while other tribes, their near neighbours, have replaced this act by the knocking out of a tooth.

His hallucination of the severed finger was instigated, as he reported later on, by the story that a female relation of his had been born with six toes and that the extra one had immediately afterwards been chopped off with an axe. Women, then, had no penis because it was taken away from them at birth. In this manner he came, at the period of the obsessional neurosis, to accept what he had already learned during the dream but had at the time rejected by repression. He must also have become acquainted, during the readings and discussions of the sacred story, with the ritual circumcision of Christ and of the Jews in general.
But we have not made any mention at all so far of what the real danger is that the child is afraid of as a result of being in love with his mother. The danger is the punishment of being castrated, of losing his genital organ. You will of course object that after all that is not a real danger. Our boys are not castrated because they are in love with their mothers during the phase of the Oedipus complex. But the matter cannot be dismissed so simply. Above all, it is not a question of whether castration is really carried out; what is decisive is that the danger is one that threatens from outside and that the child believes in it. He has some ground for this, for people threaten him often enough with cutting off his penis during the phallic phase, at the time of his early masturbation, and hints at that punishment must regularly find a phylogenetic reinforcement in him. It is our suspicion that during the human family's primaenal period castration used actually to be carried out by a jealous and cruel father upon growing boys, and that circumcision, which so frequently plays a part in puberty rites among primitive peoples, is a clearly recognizable relic of it. We are aware that here we are diverging widely from the general opinion; but we must hold fast to the view that fear of castration is one of the commonest and strongest motives for repression and thus for the formation of neuroses. The analysis of cases in which circumcision, though not, it is true, castration, has been carried out on boys as a cure or punishment for masturbation (a far from rare occurrence in Anglo-American society) has given our conviction a last degree of certainty. It is very tempting at this point to go more deeply into the castration complex, but I will stick to our subject.

[1933a, 4693]

The deeper motives for hatred of the Jews are rooted in the remotest past ages; they operate from the unconscious of the peoples, and I am prepared to find that at first they will not seem credible. I venture to assert that jealousy of the people which declared itself the first-born, favourite child of God the Father, has not yet been surmounted among other peoples even today: it is as though they had thought there was truth in the claim. Further, among the customs by which the Jews made themselves separate, that of circumcision has made a disagreeable, uncanny impression, which is to be explained, no doubt, by its recalling the dreaded castration and along with it a portion of the primaenal past which is gladly forgotten. And finally, as the latest motive in this series, we must not forget that all those peoples who excel to-day in their hatred of Jews became Christians only in late historic times, often driven to it by bloody coercion. It might be said that they are all 'mis-baptized'. They have been left, under a thin veneer of Christianity, what their ancestors were, who worshipped a barbarous polytheism. They have not got over a grudge against the new religion which was imposed on them; but they have displaced the grudge on to the source from which Christianity reached them. The fact that the Gospels tell a story which is set among Jews, and in fact deals only with Jews, has made this displacement easy for them. Their hatred of Jews is at bottom a hatred of Christians, and we need not be surprised that in the German National-Socialist revolution this intimate relation between the two monotheist religions finds such a clear expression in the hostile treatment of both of them.

[1939a, 4914]
Our construction of prehistory forces us to another explanation. The command in favour of exogamy, of which the horror of incest is the negative expression, was a product of the will of the father and carried this will on after he had been removed. Hence comes the strength of its emotional tone and the impossibility of finding a rational basis for it - that is, its sacredness. We confidently expect that an investigation of all the other cases of a sacred prohibition would lead to the same conclusion as in that of the horror of incest: that what is sacred was originally nothing other than the prolongation of the will of the primal father. This would also throw light on the hitherto incomprehensible ambivalence of the words which express the concept of sacredness. It is the ambivalence which in general dominates the relation to the father. [The Latin] 'sacer' means not only 'sacred', 'consecrated', but also something that we can only translate as 'infamous', 'detestable' (e.g. 'auri sacra fames'). But the father's will was not only something which one might not touch, which one had to hold in high respect, but also something one trembled before, because it demanded a painful instinctual renunciation. When we hear that Moses made his people holy by introducing the custom of circumcision we now understand the deep meaning of that assertion. Circumcision is the symbolic substitute for the castration which the primal father once inflicted upon his sons in the plenitude of his absolute power, and whoever accepted that symbol was showing by it that he was prepared to submit to the father's will, even if it imposed the most painful sacrifice on him.

[1939a, 4940]

1 Castration has a place too in the Oedipus legend, for the blinding with which Oedipus punishes himself after the discovery of his crime is, by the evidence of dreams, a symbolic substitute for castration. The possibility cannot be excluded that a phylogenetic memory-trace may contribute to the extraordinarily terrifying effect of the threat - a memory-trace from the prehistory of the primal family, where the jealous father actually robbed his son of his genitals if the latter became troublesome to him as a rival with a woman. The primaeval custom of circumcision, another symbolic substitute for castration, can only be understood as an expression of submission to the father's will. (Cf. the puberty rites of primitive peoples.) No investigation has yet been made of the form taken by the events described above among peoples and in civilizations which do not suppress masturbation in children.

[1940a [1938], 4997]
The taboo of virginity and something of its motivation has been depicted most powerfully of all in a well-known dramatic character, that of Judith in Hebbel's tragedy *Judith und Holofernes*. Judith is one of those women whose virginity is protected by a taboo. Her first husband was paralysed on the bridal night by a mysterious anxiety, and never again dared to touch her, 'My beauty is like belladonna,' she says. 'Enjoyment of it brings madness and death.' When the Assyrian general is besieging her city, she conceives the plan of seducing him by her beauty and of destroying him, thus employing a patriotic motive to conceal a sexual one. After she has been deflowered by this powerful man, who boasts of his strength and ruthlessness, she finds the strength in her fury to strike off his head, and thus becomes the liberator of her people. Beheading is well known to us as a symbolic substitute for castrating; Judith is accordingly the woman who castrates the man who has deflowered her, which was just the wish of the newly-married woman expressed in the dream I reported. It is clear that Hebbel has intentionally sexualized the patriotic narrative from the Apocrypha of the Old Testament, for there Judith is able to boast after her return that she has not been defiled, nor is there in the Biblical text any mention of her uncanny wedding night. But probably, with the fine perception of a poet, he sensed the ancient motive, which had been lost in the tendentious narrative, and has merely restored its earlier content to the material.

It may fairly be said that in these children's phobias some of the features of totemism reappear, but reversed into their negative. We are, however, indebted to Ferenczi (1913a) for an interesting history of a single case which can only be described as an instance of positive totemism in a child. It is true that in the case of little Árpád (the subject of Ferenczi's report) his totemic interests did not arise in direct relation with his Oedipus complex but on the basis of its narcissistic precondition, the fear of castration. But any attentive reader of the story of little Hans will find abundant evidence that he, too, admired his father as possessing a big penis and feared him as threatening his own. The same part is played by the father alike in the Oedipus and the castration complexes - the part of a dreaded enemy to the sexual interests of childhood. The punishment which he threatens is castration, or its substitute, blinding.¹

¹ For the substitution of blinding for castration - a substitution that occurs, too, in the myth of Oedipus - see Reitler (1913), Ferenczi (1913b), Rank (1913) and Eder (1913).

¹ Fear of castration plays an extremely large part, in the case of the youthful neurotics whom we come across, as an interference in their relations with their father. The illuminating instance reported by Ferenczi (1913a) has shown us how a little boy took as his totem the beast that had pecked at his little penis. When our children come to hear of ritual circumcision, they equate it with castration. The parallel in social psychology to this reaction by children has not yet been worked out, so far as I am aware. In primaeval times and in primitive races, where circumcision is so frequent, it is performed at the age of initiation into manhood and it is at that age that its significance is to be found; it was only as a secondary development that it was shifted back to the early years of life. It is of very great interest to find that among primitive peoples circumcision is combined with cutting the hair and knocking out teeth or is replaced by them, and that our children, who cannot possibly have any knowledge of this, in fact treat these two operations, in the anxiety with which they react to them, as equivalents of castration.
Experience in the analysis of dreams has sufficiently well established the hat as a symbol of the genital organ, most frequently of the male organ. It cannot be said, however, that the symbol is an intelligible one. In phantasies and in numerous symptoms the head too appears as a symbol of the male genitals, or, if one prefers to put it so, as something standing for them. It will sometimes have been noticed that patients suffering from obsessions express an amount of abhorrence of and indignation against punishment by beheading far greater than they do in the case of any other form of death; and in such cases the analyst may be led to explain to them that they are treating being beheaded as a substitute for being castrated. Instances have often been analysed and published of dreams dreamt by young people or reported as having occurred in youth, which concerned the subject of castration, and in which a round ball was mentioned which could only be interpreted as the head of the dreamer's father. I was recently able to solve a ceremonial performed by a woman patient before going to sleep, in which she had to lay her small top pillow diamond-wise on the other ones and to rest her head exactly in the long diameter of the diamond-shape. The diamond had the meaning that is familiar to us from drawings on walls [graffiti]; the head was supposed to represent a male organ.

[1916c, 3122]

Another symbol of the female genitals which deserves mention is a jewel-case. Jewel and treasure are used in dreams as well as in waking life to describe someone who is loved. Sweets frequently represent sexual enjoyment. Satisfaction obtained from a person's own genitals is indicated by all kinds of playing, including piano-playing. Symbolic representations par excellence of masturbation are gliding or sliding and pulling off a branch. The falling out of a tooth or the pulling out of a tooth is a particularly notable dream-symbol. Its first meaning is undoubtedly castration as a punishment for masturbating. We come across special representations of sexual intercourse less often than might be expected from what has been said so far. Rhythmic activities such as dancing, riding and climbing must be mentioned here, as well as violent experiences such as being run over; so, too, certain manual crafts, and, of course, threatening with weapons.

[1916-1917, 3250]

'Pulling off a branch' as a symbolic representation of masturbation is not merely in harmony with vulgar descriptions of the act but has far-reaching mythological parallels. But that masturbation, or rather the punishment for it - castration -, should be represented by the falling out or pulling out of teeth is especially remarkable, since there is a counterpart to it in anthropology which can be known to only a very small number of dreamers. There seems to me no doubt that the circumcision practised by so many peoples is an equivalent and substitute for castration. And we now learn that certain primitive tribes in Australia carry out circumcision as a puberty rite (at the festival to celebrate a boy's attaining sexual maturity), while other tribes, their near neighbours, have replaced this act by the knocking out of a tooth.

[1916-1917, 3258]

(b) She saw a deep pit in the vineyard, which she knew had been caused by a tree being torn out. She added a remark that the tree was missing. She meant that she had not seen the tree in her dream; but the same wording served to express another thought which made the symbolic interpretation quite certain. The dream referred to another piece of infantile sexual theory - to the belief that girls originally had the same genitals as boys and that their later shape was the result of castration (the tearing out of a tree).

[1916-1917, 3282]
If a pillow was a woman, then the shaking of the eiderdown till all the feathers were at the bottom and caused a swelling there had a sense as well. It meant making a woman pregnant; but she never failed to smooth away the pregnancy again, for she had for years been afraid that her parents' intercourse would result in another child and so present her with a competitor. On the other hand, if the big pillow was a woman, the mother, then the small top-pillow could only stand for the daughter. Why did this pillow have to be placed diamond-wise and her head precisely along its centre line? It was easy to recall to her that this diamond shape is the inscription scribbled on every wall to represent the open female genitals. If so, she herself was playing the man and replacing the male organ by her head. (Cf. the symbolism of beheading for castrating.)

[1916-1917, 3347]
Among the occurrences which recur again and again in the youthful history of neurotics - which are scarcely ever absent - there are a few of particular importance, which also deserve, on that account, I think, to be brought into greater prominence than the rest. As specimens of this class I will enumerate these: observation of parental intercourse, seduction by an adult and threat of being castrated. It would be a mistake to suppose that they are never characterized by material reality; on the contrary, this is often established incontestably through enquiries from older members of the patient's family. It is by no means a rare thing, for instance, for a little boy, who is beginning to play with his penis in a naughty way and is not yet aware that one must conceal such activities, to be threatened by a parent or nurse with having his penis or his sinful hand cut off. Parents will often admit this when they are asked, since they think they have done something useful in making such a threat; a number of people have a correct conscious memory of such a threat, especially if it was made at a somewhat later period. If the threat is delivered by the mother or some other female she usually shifts its performance on to the father or the doctor. In Struwwelpeter, the famous work of the Frankfurt paediatrician Hoffmann (which owes its popularity precisely to an understanding of the sexual and other complexes of childhood), you will find castration softened into a cutting-off of the thumbs as a punishment for obstinate sucking. But it is highly improbable that children are threatened with castration as often as it appears in the analyses of neurotics. We shall be satisfied by realizing that the child puts a threat of this kind together in his imagination on the basis of hints, helped out by a knowledge that auto-erotic satisfaction is forbidden and under the impression of his discovery of the female genitals. Nor is it only in proletarian families that it is perfectly possible for a child, while he is not yet credited with possessing an understanding or a memory, to be a witness of the sexual act between his parents or other grown-up people; and the possibility cannot be rejected that he will be able to understand and react to the impression in retrospect. If, however, the intercourse is described with the most minute details, which would be difficult to observe, or if, as happens most frequently, it turns out to have been intercourse from behind more ferarum [in the manner of animals], there can be no remaining doubt that the phantasy is based on an observation of intercourse between animals (such as dogs) and that its motive was the child's unsatisfied scopophilia during puberty. The extreme achievement on these lines is a phantasy of observing parental intercourse while one is still an unborn baby in the womb. Phantasies of being seduced are of particular interest, because so often they are not phantasies but real memories. Fortunately, however, they are nevertheless not real as often as seemed at first to be shown by the findings of analysis. Seduction by an older child or by one of the same age is even more frequent than by an adult; and if in the case of girls who produce such an event in the story of their childhood their father figures fairly regularly as the seducer, there can be no doubt either of the imaginary nature of the accusation or of the motive that has led to it. A phantasy of being seduced when no seduction has occurred is usually employed by a child to screen the auto-erotic period of his sexual activity. He spares himself shame about masturbation by retrospectively phantasying a desired object into these earliest times. You must not suppose, however, that sexual abuse of a child by its nearest male relatives belongs entirely to the realm of phantasy. Most analysts will have treated cases in which such events were real and could be unimpeachably established; but even so they related to the later years of childhood and had been transposed into earlier times. [1916-1917, 3426]
'If in my patient's case the wolf was merely a first father surrogate, the question arises whether the hidden content in the fairy tales of the wolf that ate up the little goats and of "Little Red Riding-Hood" may not simply be infantile fear of the father.¹ Moreover, my patient's father had the characteristic, shown by so many people in relation to their children, of indulging in "affectionate abuse"; and it is possible that during the patient's earlier years his father (though he grew severe later on) may more than once, as he caressed the little boy or played with him, have threatened in fun to "gobble him up". One of my patients told me that her two children could never get to be fond of their grandfather, because in the course of his affectionate romping with them he used to frighten them by saying he would cut open their tummies.'
[1918b, 3523]

We know from psycho-analytic experience, however, that the fear of damaging or losing one's eyes is a terrible one in children. Many adults retain their apprehensiveness in this respect, and no physical injury is so much dreaded by them as an injury to the eye. We are accustomed to say, too, that we will treasure a thing as the apple of our eye. A study of dreams, phantasies and myths has taught us that anxiety about one's eyes, the fear of going blind, is often enough a substitute for the dread of being castrated. The self-blinding of the mythical criminal, Oedipus, was simply a mitigated form of the punishment of castration - the only punishment that was adequate for him by the lex talionis. We may try on rationalistic grounds to deny that fears about the eye are derived from the fear of castration, and may argue that it is very natural that so precious an organ as the eye should be guarded by a proportionate dread. Indeed, we might go further and say that the fear of castration itself contains no other significance and no deeper secret than a justifiable dread of this rational kind. But this view does not account adequately for the substitutive relation between the eye and the male organ which is seen to exist in dreams and myths and phantasies; nor can it dispel the impression that the threat of being castrated in especial excites a peculiarly violent and obscure emotion, and that this emotion is what first gives the idea of losing other organs its intense colouring. All further doubts are removed when we learn the details of their 'castration complex' from the analysis of neurotic patients, and realize its immense importance in their mental life
[1919h, 3684]

Moreover, I would not recommend any opponent of the psycho-analytic view to select this particular story of the Sand-Man with which to support his argument that anxiety about the eyes has nothing to do with the castration complex. For why does Hoffmann bring the anxiety about eyes into such intimate connection with the father's death? And why does the Sand-Man always appear as a disturber of love? He separates the unfortunate Nathaniel from his betrothed and from her brother, his best friend; he destroys the second object of his love, Olympia, the lovely doll; and he drives him into suicide at the moment when he has won back his Clara and is about to be happily united to her. Elements in the story like these, and many others, seem arbitrary and meaningless so long as we deny all connection between fears about the eye and castration; but they become intelligible as soon as we replace the Sand-Man by the dreaded father at whose hands castration is expected.¹
[1919h, 3684]
The theme of the 'double' has been very thoroughly treated by Otto Rank (1914). He has gone into the connections which the 'double' has with reflections in mirrors, with shadows, with guardian spirits, with the belief in the soul and with the fear of death; but he also lets in a flood of light on the surprising evolution of the idea. For the 'double' was originally an insurance against the destruction of the ego, an 'energetic denial of the power of death', as Rank says; and probably the 'immortal' soul was the first 'double' of the body. This invention of doubling as a preservation against extinction has its counterpart in the language of dreams, which is fond of representing castration by a doubling or multiplication of a genital symbol. The same desire led the Ancient Egyptians to develop the art of making images of the dead in lasting materials. Such ideas, however, have sprung from the soil of unbounded self-love, from the primary narcissism which dominates the mind of the child and of primitive man. But when this stage has been surmounted, the 'double' reverses its aspect. From having been an assurance of immortality, it becomes the uncanny harbinger of death.

[1919h, 3687]

Dismembered limbs, a severed head, a hand cut off at the wrist, as in a fairy tale of Hauff's, feet which dance by themselves, as in the book by Schaeffer which I mentioned above - all these have something peculiarly uncanny about them, especially when, as in the last instance, they prove capable of independent activity in addition. As we already know, this kind of uncanniness springs from its proximity to the castration complex. To some people the idea of being buried alive by mistake is the most uncanny thing of all. And yet psycho-analysis has taught us that this terrifying phantasy is only a transformation of another phantasy which had originally nothing terrifying about it at all, but was qualified by a certain lasciviousness - the phantasy, I mean, of intra-uterine existence.

[1919h, 3694]

Nor shall we conceal the fact that for almost every example adduced in support of our hypothesis one may be found which rebuts it. The story of the severed hand in Hauff's fairy tale certainly has an uncanny effect, and we have traced that effect back to the castration complex; but most readers will probably agree with me in judging that no trace of uncanniness is provoked by Herodotus's story of the treasure of Rhampsinitus, in which the master-thief, whom the princess tries to hold fast by the hand, leaves his brother's severed hand behind with her instead. Again, the prompt fulfilment of the wishes of Polycrates undoubtedly affects us in the same uncanny way as it did the king of Egypt; yet our own fairy stories are crammed with instantaneous wish-fulfilments which produce no uncanny effect whatever. In the story of 'The Three Wishes', the woman is tempted by the savoury smell of a sausage to wish that she might have one too, and in an instant it lies on a plate before her. In her annoyance at her hastiness her husband wishes it may hang on her nose. And there it is, dangling from her nose. All this is very striking but not in the least uncanny. Fairy tales quite frankly adopt the animistic standpoint of the omnipotence of thoughts and wishes, and yet I cannot think of any genuine fairy story which has anything uncanny about it. We have heard that it is in the highest degree uncanny when an inanimate object - a picture or a doll - comes to life; nevertheless in Hans Andersen's stories the household utensils, furniture and tin soldiers are alive, yet nothing could well be more remote from the uncanny. And we should hardly call it uncanny when Pygmalion's beautiful statue comes to life.

[1919h, 3695]

To decapitate = to castrate. The terror of Medusa is thus a terror of castration that is linked to the sight of something. Numerous analyses have made us familiar with the occasion for this: it occurs when a boy, who has hitherto been unwilling to believe the threat of castration, catches sight of the female genitals, probably those of an adult, surrounded by hair, and essentially those of his mother.

[1940c [1922], 3943]
The hair upon Medusa's head is frequently represented in works of art in the form of snakes, and these once again are derived from the castration complex. It is a remarkable fact that, however frightening they may be in themselves, they nevertheless serve actually as a mitigation of the horror, for they replace the penis, the absence of which is the cause of the horror. This is a confirmation of the technical rule according to which a multiplication of penis symbols signifies castration.

[1940c [1922], 3943]

We have sufficient acquaintance with this kind of masochism in men (to whom, owing to the material at my command, I shall restrict my remarks), derived from masochistic - and therefore often impotent - subjects whose phantasies either terminate in an act of masturbation or represent a sexual satisfaction in themselves. The real-life performances of masochistic perversors tally completely with these phantasies, whether the performances are carried out as an end in themselves or serve to induce potency and to lead to the sexual act. In both cases - for the performances are, after all, only a carrying-out of the phantasies in play - the manifest content is of being gagged, bound, painfully beaten, whipped, in some way maltreated, forced into unconditional obedience, dirtied and debased. It is far more rare for mutilations to be included in the content, and then only subject to strict limitations. The obvious interpretation, and one easily arrived at, is that the masochist wants to be treated like a small and helpless child, but, particularly, like a naughty child. It is unnecessary to quote cases to illustrate this; for the material is very uniform and is accessible to any observer, even to non-analysts. But if one has an opportunity of studying cases in which the masochistic phantasies have been especially richly elaborated, one quickly discovers that they place the subject in a characteristically female situation; they signify, that is, being castrated, or copulated with, or giving birth to a baby. For this reason I have called this form of masochism, a potiori as it were, the feminine form, although so many of its features point to infantile life. This superimposed stratification of the infantile and the feminine will find a simple explanation later on. Being castrated - or being blinded, which stands for it - often leaves a negative trace of itself in phantasies, in the condition that no injury is to occur precisely to the genitals or the eyes. (Masochistic tortures, incidentally, rarely make such a serious impression as the cruelties of sadism, whether imagined or performed.) A sense of guilt, too, finds expression in the manifest content of masochistic phantasies; the subject assumes that he has committed some crime (the nature of which is left indefinite) which is to be expiated by all these painful and tormenting procedures. This looks like a superficial rationalization of the masochistic subject-matter, but behind it there lies a connection with infantile masturbation. On the other hand, this factor of guilt provides a transition to the third, moral, form of masochism.

[1924c, 4074]
Returning to my description of fetishism, I may say that there are many and weighty additional proofs of the divided attitude of fetishists to the question of the castration of women. In very subtle instances both the disavowal and the affirmation of the castration have found their way into the construction of the fetish itself. This was so in the case of a man whose fetish was an athletic support-belt which could also be worn as bathing drawers. This piece of clothing covered up the genitals entirely and concealed the distinction between them. Analysis showed that it signified that women were castrated and that they were not castrated; and it also allowed of the hypothesis that men were castrated, for all these possibilities could equally well be concealed under the belt - the earliest rudiment of which in his childhood had been the fig-leaf on a statue. A fetish of this sort, doubly derived from contrary ideas, is of course especially durable. In other instances the divided attitude shows itself in what the fetishist does with his fetish, whether in reality or in his imagination. To point out that he reveres his fetish is not the whole story; in many cases he treats it in a way which is obviously equivalent to a representation of castration. This happens particularly if he has developed a strong identification with his father and plays the part of the latter; for it is to him that as a child he ascribed the woman's castration. Affection and hostility in the treatment of the fetish - which run parallel with the disavowal and the acknowledgement of castration - are mixed in unequal proportions in different cases, so that the one or the other is more clearly recognizable. We seem here to approach an understanding, even if a distant one, of the behaviour of the 'coupeur de nattes'. In him the need to carry out the castration which he disavows has come to the front. His action contains in itself the two mutually incompatible assertions: 'the woman has still got a penis' and 'my father has castrated the woman'. Another variant, which is also a parallel to fetishism in social psychology, might be seen in the Chinese custom of mutilating the female foot and then revering it like a fetish after it has been mutilated. It seems as though the Chinese male wants to thank the woman for having submitted to being castrated.

We have not yet finished with symbols. There are some which we believed we recognized but which nevertheless worried us because we could not explain how this particular symbol had come to have that particular meaning. In such cases confirmations from elsewhere - from philology, folklore, mythology or ritual - were bound to be especially welcome. An instance of this sort is the symbol of an overcoat or cloak. We have said that in a woman's dreams this stands for a man. I hope it will impress you when you hear that Theodor Reik (1920) gives us this information: 'During the extremely ancient bridal ceremonial of the Bedouins, the bridegroom covers the bride with a special cloak known as "Aba" and speaks the following ritual words: "Henceforth none save I shall cover thee!" (Quoted from Robert Eisler). We have also found several fresh symbols, at least two of which I will tell you of. According to Abraham (1922) a spider in dreams is a symbol of the mother, but of the phallic mother, of whom we are afraid; so that the fear of spiders expresses dread of mother-incest and horror of the female genitals. You know, perhaps, that the mythological creation, Medusa's head, can be traced back to the same motif of fright at castration. The other symbol I want to talk to you about is that of the bridge, which has been explained by Ferenczi (1921 and 1922). First it means the male organ, which unites the two parents in sexual intercourse; but afterwards it develops further meanings which are derived from this first one. In so far as it is thanks to the male organ that we are able to come into the world at all, out of the amniotic fluid, a bridge becomes the crossing from the other world (the unborn state, the womb) to this world (life); and, since men also picture death as a return to the womb (to the water), a bridge also acquires the meaning of something that leads to death, and finally, at a further remove from its original sense, it stands for transitions or changes in condition generally. It tallies with this, accordingly, if a woman who has not overcome her wish to be a man has frequent dreams of bridges that are too short to reach the further shore.
A reversal into the opposite is unexpectedly found in another myth which in appearance has very little to do with the fire myth. The Lernaean hydra with its countless flickering serpent's heads - one of which was immortal - was, as its name tells us, a water-dragon. Heracles, the culture-hero, fought it by cutting off its heads; but they always grew again, and it was only after he had burnt up the immortal head with fire that he overcame the monster. A water-dragon subdued by fire - that surely makes no sense. But, as in so many dreams, sense emerges if we reverse the manifest content. In that case the hydra is a brand of fire and the flickering serpent's heads are the flames; and these, in proof of their libidinal nature, once more display, like Prometheus's liver, the phenomenon of re-growth, of renewal after attempted destruction. Heracles, then, extinguishes this brand of fire with - water. (The immortal head is no doubt the phallus itself, and its destruction signifies castration.) But Heracles was also the deliverer of Prometheus and slew the bird which devoured his liver. Should we not suspect a deeper connection between the two myths? It is as though the deed of the one hero was made up for by the other. Prometheus (like the Mongolian law) had forbidden the quenching of fire; Heracles permitted it in the case in which the brand of fire threatened disaster. The second myth seems to correspond to the reaction of a later epoch of civilization to the events of the acquisition of power over fire. It looks as though this line of approach might take us quite a distance into the secrets of the myth; but admittedly we should carry a feeling of certainty with us only a short way.

[1932a, 4785]

¹ Castration has a place too in the Oedipus legend, for the blinding with which Oedipus punishes himself after the discovery of his crime is, by the evidence of dreams, a symbolic substitute for castration. The possibility cannot be excluded that a phylogenetic memory-trace may contribute to the extraordinarily terrifying effect of the threat - a memory-trace from the prehistory of the primal family, where the jealous father actually robbed his son of his genitals if the latter became troublesome to him as a rival with a woman. The primaeval custom of circumcision, another symbolic substitute for castration, can only be understood as an expression of submission to the father's will. (Cf. the puberty rites of primitive peoples.) No investigation has yet been made of the form taken by the events described above among peoples and in civilizations which do not suppress masturbation in children.

[1940a [1938], 4997]
There is a possible anatomical analogy to what I believe to be the course of development of the infantile sexual function in Bayer's discovery (1902) that the internal sexual organs (i.e. the uterus) are as a rule larger in new-born children than in older ones. It is not certain, however, what view we should take of this involution that occurs after birth (which has been shown by Halban to apply also to other portions of the genital apparatus). According to Halban (1904) the process of involution comes to an end after a few weeks of extra-uterine life. [Added 1920:]
Those authorities who regard the interstitial portion of the sex-gland as the organ that determines sex have on their side been led by anatomical researches to speak of infantile sexuality and a period of sexual latency. I quote a passage from Lipschütz's book (1919, 168), which I mentioned on p. 1473:

"We shall be doing more justice to the facts if we say that the maturation of the sexual characters which is accomplished at puberty is only due to a great acceleration which occurs at that time of processes which began much earlier - in my view as early as during intra-uterine life.' What has hitherto been described in a summary way as puberty is probably only a second major phase of puberty which sets in about the middle of the second decade of life . . . Childhood, from birth until the beginning of this second major phase, might be described as "the intermediate phase of puberty" (ibid., 170). Attention was drawn to this coincidence between anatomical findings and psychological observation in a review by Ferenczi (1920). The agreement is marred only by the fact that the 'first peak' in the development of the sexual organ occurs during the early intra-uterine period, whereas the early efflorescence of infantile sexual life must be ascribed to the third and fourth years of life. There is, of course, no need to expect that anatomical growth and psychical development must be exactly simultaneous. The researches in question were made on the sex-glands of human beings. Since a period of latency in the psychological sense does not occur in animals, it would be very interesting to know whether the anatomical findings which have led these writers to assume the occurrence of two peaks in sexual development are also demonstrable in the higher animals.

SEXUAL INHIBITIONS
It is during this period of total or only partial latency that are built up the mental forces which are later to impede the course of the sexual instinct and, like dams, restrict its flow - disgust, feelings of shame and the claims of aesthetic and moral ideals. One gets an impression from civilized children that the construction of these dams is a product of education, and no doubt education has much to do with it. But in reality this development is organically determined and fixed by heredity, and it can occasionally occur without any help at all from education. Education will not be trespassing beyond its appropriate domain if it limits itself to following the lines which have already been laid down organically and to impressing them somewhat more clearly and deeply.

REACTION-FORMATION AND SUBLIMATION
What is it that goes to the making of these constructions which are so important for the growth of a civilized and normal individual? They probably emerge at the cost of the infantile sexual impulses themselves. Thus the activity of those impulses does not cease even during this period of latency, though their energy is diverted, wholly or in great part, from their sexual use and directed to other ends. Historians of civilization appear to be at one in assuming that powerful components are acquired for every kind of cultural achievement by this diversion of sexual instinctual forces from sexual aims and their direction to new ones - a process which deserves the name of 'sublimation'. To this we would add, accordingly, that the same process plays a part in the development of the individual and we would place its beginning in the period of sexual latency of childhood.
It is possible further to form some idea of the mechanism of this process of sublimation. On the one hand, it would seem, the sexual impulses cannot be utilized during these years of childhood, since the reproductive functions have been deferred - a fact which constitutes the main feature of the period of latency. On the other hand, these impulses would seem in themselves to be perverse - that is, to arise from erotogenic zones and to derive their activity from instincts which, in view of the direction of the subject's development, can only arouse unpleasurable feelings. They consequently evoke opposing mental forces (reacting impulses) which, in order to suppress this unpleasure effectively, build up the mental dams that have already mentioned - disgust, shame and morality.²

[1905d, 1500]

INTERRUPTIONS OF THE LATENCY PERIOD We must not deceive ourselves as to the hypothetical nature and insufficient clarity of our knowledge concerning the processes of the infantile period of latency or deferment; but we shall be on firmer ground in pointing out that such an application of infantile sexuality represents an educational ideal from which individual development usually diverges at some point and often to a considerable degree. From time to time a fragmentary manifestation of sexuality which has evaded sublimation may break through; or some sexual activity may persist through the whole duration of the latency period until the sexual instinct emerges with greater intensity at puberty. In so far as educators pay any attention at all to infantile sexuality, they behave exactly as though they shared our views as to the construction of the moral defensive forces at the cost of sexuality, and as though they knew that sexual activity makes a child ineducable: for they stigmatize every sexual manifestation by children as a 'vice', without being able to do much against it. We, on the other hand, have every reason for turning our attention to these phenomena which are so much dreaded by education, for we may expect them to help us to discover the original configuration of the sexual instincts.

[1905d, 1501]

The most striking of the processes at puberty has been picked upon as constituting its essence: the manifest growth of the external genitalia. (The latency period of childhood is, on the other hand, characterized by a relative cessation of their growth.) In the meantime the development of the internal genitalia has advanced far enough for them to be able to discharge the sexual products or, as the case may be, to bring about the formation of a new living organism. Thus a highly complicated apparatus has been made ready and awaits the moment of being put into operation.

[1905d, 1525]

This failure of the function of the sexual mechanism owing to fore-pleasure is best avoided if the primacy of the genitals too is adumbrated in childhood; and indeed things seem actually arranged to bring this about in the second half of childhood (from the age of eight to puberty). During these years the genital zones already behave in much the same way as in maturity; they become the seat of sensations of excitation and of preparatory changes whenever any pleasure is felt from the satisfaction of other erotogenic zones, though this result is still without a purpose - that is to say, contributes nothing to a continuation of the sexual process. Already in childhood, therefore, alongside of the pleasure of satisfaction there is a certain amount of sexual tension, although it is less constant and less in quantity. We can now understand why, in discussing the sources of sexuality, we were equally justified in saying of a given process that it was sexually satisfying or sexually exciting. It will be noticed that in the course of our enquiry we began by exaggerating the distinction between infantile and mature sexual life, and that we are now setting this right. Not only the deviations from normal sexual life but its normal form as well are determined by the infantile manifestations of sexuality.

[1905d, 1528]
THE SEXUAL OBJECT DURING EARLY INFANCY  But even after sexual activity has become detached from the taking of nourishment, an important part of this first and most significant of all sexual relations is left over, which helps to prepare for the choice of an object and thus to restore the happiness that has been lost. All through the period of latency children learn to feel for other people who help them in their helplessness and satisfy their needs a love which is on the model of, and a continuation of, their relation as sucklings to their nursing mother. There may perhaps be an inclination to dispute the possibility of identifying a child's affection and esteem for those who look after him with sexual love. I think, however, that a closer psychological examination may make it possible to establish this identity beyond any doubt. A child's intercourse with anyone responsible for his care affords him an unending source of sexual excitation and satisfaction from his erotic zones. This is especially so since the person in charge of him, who, after all, is as a rule his mother, herself regards him with feelings that are derived from her own sexual life: she strokes him, kisses him, rocks him and quite clearly treats him as a substitute for a complete sexual object.¹ A mother would probably be horrified if she were made aware that all her marks of affection were rousing her child's sexual instinct and preparing for its later intensity. She regards what she does as asexual, 'pure' love, since, after all, she carefully avoids applying more excitations to the child's genitals than are unavoidable in nursery care. As we know, however, the sexual instinct is not aroused only by direct excitation of the genital zone. What we call affection will unfailingly show its effects one day on the genital zones as well. Moreover, if the mother understood more of the high importance of the part played by instincts in mental life as a whole - in all its ethical and psychical achievements - she would spare herself any self-reproaches even after her enlightenment. She is only fulfilling her task in teaching the child to love. After all, he is meant to grow up into a strong and capable person with vigorous sexual needs and to accomplish during his life all the things that human beings are urged to do by their instincts. It is true that an excess of parental affection does harm by causing precocious sexual maturity and also because, by spoiling the child, it makes him incapable in later life of temporarily doing without love or of being content with a smaller amount of it. One of the clearest indications that a child will later become neurotic is to be seen in an insatiable demand for his parents' affection. And on the other hand neuropathic parents, who are inclined as a rule to display excessive affection, are precisely those who are most likely by their caresses to arouse the child's disposition to neurotic illness. Incidentally, this example shows that there are ways more direct than inheritance by which neurotic parents can hand their disorder on to their children.

[1905d, 1536]

THE BARRIER AGAINST INCEST  We see, therefore, that the parents' affection for their child may awaken his sexual instinct prematurely (i.e. before the somatic conditions of puberty are present) to such a degree that the mental excitation breaks through in an unmistakable fashion to the genital system. If, on the other hand, they are fortunate enough to avoid this, then their affection can perform its task of directing the child in his choice of a sexual object when he reaches maturity. No doubt the simplest course for the child would be to choose as his sexual objects the same persons whom, since his childhood, he has loved with what may be described as damped-down libido.¹ But, by the postponing of sexual maturation, time has been gained in which the child can erect, among other restraints on sexuality, the barrier against incest, and can thus take up into himself the moral precepts which expressly exclude from his object-choice, as being blood relations, the persons whom he has loved in his childhood. Respect for this barrier is essentially a cultural demand made by society. Society must defend itself against the danger that the interests which it needs for the establishment of higher social units may be swallowed up by the family; and for this reason, in the case of every individual, but in particular of adolescent boys, it seeks by all possible means to loosen their connection with their family - a connection which, in their childhood, is the only important one.² [1905d, 1538]
¹ [Footnote added 1920:] The phantasies of the pubertal period have as their starting-point the infantile sexual researches that were abandoned in childhood. No doubt, too, they are also present before the end of the latency period. They may persist wholly, or to a great extent, unconsciously and for that reason it is often impossible to date them accurately. They are of great importance in the origin of many symptoms, since they precisely constitute preliminary stages of these symptoms and thus lay down the forms in which the repressed libidinal components find satisfaction. In the same way, they are the prototypes of the nocturnal phantasies which become conscious as dreams. Dreams are often nothing more than revivals of pubertal phantasies of this kind under the influence of, and in relation to, some stimulus left over from the waking life of the previous day (the 'day's residues'). Some among the sexual phantasies of the pubertal period are especially prominent, and are distinguished by their very general occurrence and by being to a great extent independent of individual experience. Such are the adolescent's phantasies of overhearing his parents in sexual intercourse, of having been seduced at an early age by someone he loves and of having been threatened with castration; such, too, are his phantasies of being in the womb, and even of experiences there, and the so-called 'Family Romance', in which he reacts to the difference between his attitude towards his parents now and in his childhood. The close relations existing between these phantasies and myths has been demonstrated in the case of the last instance by Otto Rank (1909).

[1905d, 1539]

After having explained the preponderance of perverse tendencies in psychoneurotics by recognizing it as a collateral filling of subsidiary channels when the main current of the instinctual stream has been blocked by 'repression',¹ we proceeded to a consideration of sexual life in childhood. We found it a regrettable thing that the existence of the sexual instinct in childhood has been denied and that the sexual manifestations not infrequently to be observed in children have been described as irregularities. It seemed to us on the contrary that children bring germs of sexual activity with them into the world, that they already enjoy sexual satisfaction when they begin to take nourishment and that they persistently seek to repeat the experience in the familiar activity of 'thumb-sucking'. The sexual activity of children, however, does not, it appeared, develop pari passu with their other functions, but, after a short period of efflorescence from the ages of two to five, enters upon the so-called period of latency. During that period the production of sexual excitation is not by any means stopped but continues and produces a store of energy which is employed to a great extent for purposes other than sexual - namely, on the one hand in contributing the sexual components to social feelings and on the other hand (through repression and reaction-forming) in building up the subsequently developed barriers against sexuality. On this view, the forces destined to retain the sexual instinct upon certain lines are built up in childhood chiefly at the cost of perverse sexual impulses and with the assistance of education. A certain portion of the infantile sexual impulses would seem to evade these uses and succeed in expressing itself as sexual activity. We next found that sexual excitation in children springs from a multiplicity of forces. Satisfaction arises first and foremost from the appropriate sensory excitation of what we have described as erotogenic zones. It seems probable that any part of the skin and any sense-organ - probably, indeed, any organ - can function as an erotogenic zone, though there are some particularly marked erotogenic zones whose excitation would seem to be secured from the very first by certain organic contrivances. It further appears that sexual excitation arises as a by-product, as it were, of a large number of processes that occur in the organism, as soon as they reach a certain degree of intensity, and most especially of any relatively powerful emotion, even though it is of a distressing nature. The excitations from all these sources are not yet combined; but each follows its own separate aim, which is merely the attainment of a certain sort of pleasure. In childhood, therefore, the sexual instinct is not unified and is at first without an object, that is, auto-erotic.

[1905d, 1543]
The fact that the onset of sexual development in human beings occurs in two phases, i.e. that the development is interrupted by the period of latency, seemed to call for particular notice. This appears to be one of the necessary conditions of the aptitude of men for developing a higher civilization, but also of their tendency to neurosis. So far as we know, nothing analogous is to be found in man’s animal relatives. It would seem that the origin of this peculiarity of man must be looked for in the prehistory of the human species.

[1905d, 1545]

I know that no one is prepared to believe in a state of things so long as it appears to be unintelligible and to offer no angle from which an explanation can be attempted. But we can at least bring the underlying factors nearer to our understanding by the help of the postulates I laid down in my *Three Essays on the Theory of Sexuality* in 1905. I there attempted to show that the sexual instinct of man is highly complex and is put together from contributions made by numerous constituents and component instincts. Important contributions to 'sexual excitation' are furnished by the peripheral excitations of certain specially designated parts of the body (the genitals, mouth, anus, urethra), which therefore deserve to be described as 'erotogenic zones'. But the amounts of excitation coming in from these parts of the body do not all undergo the same vicissitudes, nor is the fate of all of them the same at every period of life. Generally speaking, only a part of them is made use of in sexual life; another part is deflected from sexual aims and directed towards others - a process which deserves the name of 'sublimation'. During the period of life which may be called the period of 'sexual latency' - i.e. from the completion of the fifth year to the first manifestations of puberty (round about the eleventh year) - reactions, or counter-forces, such as shame, disgust and morality, are created in the mind. They are actually formed at the expense of the excitations proceeding from the erotogenic zones, and they rise like dams to oppose the later activity of the sexual instincts. Now anal erotism is one of the components of the instinct which, in the course of development and in accordance with the education demanded by our present civilization, have become unserviceable for sexual aims. It is therefore plausible to suppose that these character-traits of orderliness, parsimony and obstinacy, which are so often prominent in people who were formerly anal erotics, are to be regarded as the first and most constant results of the sublimation of anal erotism.

[1908b, 1943]

(3) The supersession of the pleasure principle by the reality principle, with all the psychical consequences involved, which is here schematically condensed into a single sentence, is not in fact accomplished all at once; nor does it take place simultaneously all along the line. For while this development is going on in the ego-instincts, the sexual instincts become detached from them in a very significant way. The sexual instincts behave auto-erotically at first; they obtain their satisfaction in the subject's own body and therefore do not find themselves in the situation of frustration which was what necessitated the institution of the reality principle; and when, later on, the process of finding an object begins, it is soon interrupted by the long period of latency, which delays sexual development until puberty. These two factors - auto-erotism and the latency period - have as their result that the sexual instinct is held up in its psychical development and remains far longer under the dominance of the pleasure principle, from which in many people it is never able to withdraw.

[1911b, 2555]
At this point a portion of our case history fits in, which I have so far kept back. The patient's sexual life began in her earliest childhood with beating-phantasies. After they were suppressed, an unusually long period of latency set in, during which the girl passed through a period of exalted moral growth, without any awakening of female sexual feelings. Her marriage, which took place at an early age, opened a time of normal sexual activity. This period, during which she was a happy wife, continued for a number of years, until her first great frustration brought on the hysterical neurosis. When this was followed by her genital life losing all its value, her sexual life, as I have said, returned to the infantile stage of sadism.

[1913i, 2627]

From about the sixth to the eighth year of life onwards, we can observe a halt and retrogression in sexual development, which, in cases where it is most propitious culturally, deserves to be called a period of latency. The latency period may also be absent: it need not bring with it any interruption of sexual activity and sexual interests along the whole line. The majority of experiences and mental impulses before the start of the latency period now fall victim to infantile amnesia - the forgetting (already discussed by us) which veils our earliest youth from us and makes us strangers to it. The task is set us in every psycho-analysis of bringing this forgotten period back into memory. It is impossible to avoid a suspicion that the beginnings of sexual life which are included in that period have provided the motive for its being forgotten - that this forgetting, in fact, is an outcome of repression.

[1916-1917, 3394]

We shall naturally not be surprised to hear that the sexual impulsons that are inhibited in their aims arise out of the directly sexual ones when internal or external obstacles make the sexual aims unattainable. The repression during the period of latency is an internal obstacle of this kind - or rather one which has become internal. We have assumed that the father of the primal horde owing to his sexual intolerance compelled all his sons to be abstinent, and thus forced them into ties that were inhibited in their aims, while he reserved for himself freedom of sexual enjoyment and in this way remained without ties. All the ties upon which a group depends are of the character of instincts that are inhibited in their aims. But here we have approached the discussion of a new subject, which deals with the relation between directly sexual instincts and the formation of groups.

[1921c, 3830]

The Diphasic Onset of Sexual Development. - Towards the end of the fifth year this early period of sexual life normally comes to an end. It is succeeded by a period of more or less complete latency, during which ethical restraints are built up, to act as defences against the desires of the Oedipus complex. In the subsequent period of puberty, the Oedipus complex is revivified in the unconscious and embarks upon further modifications. It is only at puberty that the sexual instincts develop to their full intensity; but the direction of that development, as well as all the predispositions for it, have already been determined by the early efflorescence of sexuality during childhood which preceded it. This diphasic development of the sexual function - in two stages, interrupted by the latency period - appears to be a biological peculiarity of the human species and to contain the determining factor for the origin of neuroses.

[1923a, 3923]
If we consider once more the origin of the super-ego as we have described it, we shall recognize that it is the outcome of two highly important factors, one of a biological and the other of a historical nature: namely, the lengthy duration in man of his childhood helplessness and dependence, and the fact of his Oedipus complex, the repression of which we have shown to be connected with the interruption of libidinal development by the latency period and so with the diphasic onset of man's sexual life. According to one psycho-analytic hypothesis, the last-mentioned phenomenon, which seems to be peculiar to man, is a heritage of the cultural development necessitated by the glacial epoch. We see, then, that the differentiation of the super-ego from the ego is no matter of chance; it represents the most important characteristics of the development both of the individual and of the species; indeed, by giving permanent expression to the influence of the parents it perpetuates the existence of the factors to which it owes its origin.

[1923b, 3969]

To an ever-increasing extent the Oedipus complex reveals its importance as the central phenomenon of the sexual period of early childhood. After that, its dissolution takes place; it succumbs to repression, as we say, and is followed by the latency period. It has not yet become clear, however, what it is that brings about its destruction. Analyses seem to show that it is the experience of painful disappointments. The little girl likes to regard herself as what her father loves above all else; but the time comes when she has to endure a harsh punishment from him and she is cast out of her fool's paradise. The boy regards his mother as his own property; but he finds one day that she has transferred her love and solicitude to a new arrival. Reflection must deepen our sense of the importance of those influences, for it will emphasize the fact that distressing experiences of this sort, which act in opposition to the content of the complex, are inevitable. Even when no special events occur, like those we have mentioned as examples, the absence of the satisfaction hoped for, the continued denial of the desired baby, must in the end lead the small lover to turn away from his hopeless longing. In this way the Oedipus complex would go to its destruction from its lack of success, from the effects of its internal impossibility.

[1924d, 4085]

We have lately been made more clearly aware than before that a child's sexual development advances to a certain phase at which the genital organ has already taken over the leading role. But this genital is the male one only, or, more correctly, the penis; the female genital has remained undiscovered. This phallic phase, which is contemporaneous with the Oedipus complex, does not develop further to the definitive genital organization, but is submerged, and is succeeded by the latency period. Its termination, however, takes place in a typical manner and in conjunction with events that are of regular recurrence.

[1924d, 4086]

I have described elsewhere how this turning away takes place. The object-cathexes are given up and replaced by identifications. The authority of the father or the parents is introjected into the ego, and there it forms the nucleus of the super-ego, which takes over the severity of the father and perpetuates his prohibition against incest, and so secures the ego from the return of the libidinal object-cathexis. The libidinal trends belonging to the Oedipus complex are in part desexualized and sublimated (a thing which probably happens with every transformation into an identification) and in part inhibited in their aim and changed into impulses of affection. The whole process has, on the one hand, preserved the genital organ - has averted the danger of its loss - and, on the other, has paralysed it - has removed its function. This process ushers in the latency period, which now interrupts the child's sexual development.

[1924d, 4088]
And now, as a third point, psycho-analysis has shown us, to our growing astonishment, the enormously important part played by what is known as the 'Oedipus complex' - that is, the emotional relation of a child to its two parents - in the mental life of human beings. Our astonishment diminishes when we realize that the Oedipus complex is the psychical correlate of two fundamental biological facts: the long period of the human child's dependence, and the remarkable way in which its sexual life reaches a first climax in the third to fifth years of life, and then, after a period of inhibition, sets in again at puberty. And here, the discovery was made that a third and extremely serious part of human intellectual activity, the part which has created the great institutions of religion, law, ethics, and all forms of civic life, has as its fundamental aim the enabling of the individual to master his Oedipus complex and to divert his libido from its infantile attachments into the social ones that are ultimately desired. The applications of psycho-analysis to the science of religion and sociology (e.g. by the present writer, Theodor Reik and Oskar Pfister), which have led to these findings, are still young and insufficiently appreciated; but it cannot be doubted that further studies will only confirm the certainty of these important conclusions.

[1924f, 4117]

By its theory of the instincts psycho-analysis offended the feelings of individuals in so far as they regarded themselves as members of the social community; another branch of its theory was calculated to hurt every single person at the tenderest point of his own psychical development. Psycho-analysis disposed once and for all of the fairy tale of an asexual childhood. It demonstrated the fact that sexual interests and activities occur in small children from the beginning of their lives. It showed what transformations those activities pass through, how at about the age of five they succumb to inhibition and how from puberty onwards they enter the service of the reproductive function. It recognized that early infantile sexual life reaches its peak in what is known as the Oedipus complex (an emotional attachment of the child to the parent of the opposite sex accompanied by an attitude of rivalry to the parent of the same sex) and that at that period of life this impulsion extends uninhibited into a straightforward sexual desire. This can be confirmed so easily that only the greatest efforts could make it possible to overlook it. Every individual has in fact gone through this phase but has afterwards energetically repressed its purport and succeeded in forgetting it. A horror of incest and an enormous sense of guilt are left over from this prehistoric epoch of the individual's existence. It may be that something quite similar occurred in the prehistoric epoch of the human species as a whole and that the beginnings of morality, religion and social order were intimately connected with the surmounting of that primaeval era. To adults their prehistory seems so inglorious that they refuse to allow themselves to be reminded of it: they were infuriated when psycho-analysis tried to lift the veil of amnesia from their years of childhood. There was only one way out: what psycho-analysis asserted must be false and what posed as a new science must be a tissue of fancies and distortions.

[1925e, 4128]
The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-erotism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother's organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors' own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child's first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child's life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child's early years become reanimated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of 'male' or 'female' but of 'possessing a penis' or 'castrated'. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses.

² (Footnote added 1935:) The period of latency is a physiological phenomenon. It can, however, only give rise to a complete interruption of sexual life in cultural organizations which have made the suppression of infantile sexuality a part of their system. This is not the case with the majority of primitive peoples.

Another possibility has to be considered. Perhaps regression is the result not of a constitutional factor but of a time-factor. It may be that regression is rendered possible not because the genital organization of the libido is too feeble but because the opposition of the ego begins too early, while the sadistic phase is at its height. I am not prepared to express a definite opinion on this point, but I may say that analytic observation does not speak in favour of such an assumption. It shows rather that, by the time an obsessional neurosis is entered upon, the phallic stage has already been reached. Moreover, the onset of this neurosis belongs to a later time of life than that of hysteria - to the second period of childhood, after the latency period has set in. In a woman patient whose case I was able to study and who was overtaken by this disorder at a very late date, it became clear that the determining cause of her regression and of the emergence of her obsessional neurosis was a real occurrence through which her genital life, which had up till then been intact, lost all its value.¹

[1925d, 4212]

[1926d, 4272]
In enforcing regression, the ego scores its first success in its defensive struggle against the
demands of the libido. (In this connection it is of advantage to distinguish the more general
notion of 'defence' from 'repression'. Repression is only one of the mechanisms which defence
makes use of.) It is perhaps in obsessional cases more than in normal or hysterical ones that
we can most clearly recognize that the motive force of defence is the castration complex and
that what is being fended off are the trends of the Oedipus complex. We are at present dealing
with the beginning of the latency period, a period which is characterized by the dissolution of the
Oedipus complex, the creation or consolidation of the super-ego and the erection of ethical and
aesthetic barriers in the ego. In obsessional neuroses these processes are carried further than
is normal. In addition to the destruction of the Oedipus complex a regressive degradation of the
libido takes place, the super-ego becomes exceptionally severe and unkind, and the ego, in
obedience to the super-ego, produces strong reaction-formations in the shape of
conscientiousness, pity and cleanliness. Implacable, though not always on that account
successful, severity is shown in condemning the temptation to continue early infantile
masturbation, which now attaches itself to regressive (sadistic-anal) ideas but which
nevertheless represents the unsubjugated part of the phallic organization. There is an inherent
contradiction about this state of affairs, in which, precisely in the interests of masculinity (that is
to say, from fear of castration), every activity belonging to masculinity is stopped. But here, too,
obsessional neurosis is only overdoing the normal method of getting rid of the Oedipus
complex. We once more find here an illustration of the truth that every exaggeration contains
the seed of its own undoing. For, under the guise of obsessional acts, the masturbation that has
been suppressed approaches ever more closely to satisfaction.

The chief task during the latency period seems to be the fending-off of the temptation to
masturbate. This struggle produces a series of symptoms which appear in a typical fashion in
the most different individuals and which in general have the character of a ceremonial. It is a
great pity that no one has as yet collected them and systematically analysed them. Being the
earliest products of the neurosis they should best be able to shed light on the mechanisms
employed in its symptom-formation. They already exhibit the features which will emerge so
disastrously if a serious illness follows. They tend to become attached to activities (which would
later be carried out almost automatically) such as going to sleep, washing, dressing and walking
about; and they tend also to repetition and waste of time. Why this should be so is at present
not at all clear; but the sublimation of anal-erotic components plays an unmistakable part in it.

In describing the evolution of the various danger-situations from their prototype, the act of
birth, I have had no intention of asserting that every later determinant of anxiety completely
invalidates the preceding one. It is true that, as the development of the ego goes on, the earlier
danger-situations tend to lose their force and to be set aside, so that we might say that each
period of the individual's life has its appropriate determinant of anxiety. Thus the danger of
psychical helplessness is appropriate to the period of life when his ego is immature; the danger
of loss of object, to early childhood when he is still dependent on others; the danger of
castration, to the phallic phase; and the fear of his super-ego, to the latency period.
Nevertheless, all these danger-situations and determinants of anxiety can persist side by side
and cause the ego to react to them with anxiety at a period later than the appropriate one; or,
again, several of them can come into operation at the same time. It is possible, moreover, that
there is a fairly close relationship between the danger-situation that is operative and the form
taken by the ensuing neurosis.'
Why this should be so calls for a rather long reply. First of all, we must sift the facts. In a great number of cases the old determinants of anxiety do really lapse, after having produced neurotic reactions. The phobias of very young children, fears of being alone or in the dark or with strangers - phobias which can almost be called normal - usually pass off later on; the child 'grows out of them', as we say about some other disturbances of childhood. Animal phobias, which are of such frequent occurrence, undergo the same fate and many conversion hysterias of early years find no continuation in later life. Ceremonial actions appear extremely often in the latency period, but only a very small percentage of them develop later into a full obsessional neurosis. In general, so far as we can tell from our observations of town children belonging to the white races and living according to fairly high cultural standards, the neuroses of childhood are in the nature of regular episodes in a child's development, although too little attention is still being paid to them. Signs of childhood neuroses can be detected in all adult neurotics without exception; but by no means all children who show those signs become neurotic in later life. It must be, therefore, that certain determinants of anxiety are relinquished and certain danger-situations lose their significance as the individual becomes more mature. Moreover, some of these danger-situations manage to survive into later times by modifying their determinants of anxiety so as to bring them up to date. Thus, for instance, a man may retain his fear of castration in the guise of a syphilidophobia, after he has come to know that it is no longer customary to castrate people for indulging their sexual lusts, but that, on the other hand, severe diseases may overtake anyone who thus gives way to his instincts. Other determinants of anxiety, such as fear of the super-ego, are destined not to disappear at all but to accompany people throughout their lives. In that case the neurotic will differ from the normal person in that his reactions to the dangers in question will be unduly strong. Finally, being grown-up affords no absolute protection against a return of the original traumatic anxiety-situation. Each individual has in all probability a limit beyond which his mental apparatus fails in its function of mastering the quantities of excitation which require to be disposed of.

[1926d, 4302]
An important element in the theory of repression is the view that repression is not an event that occurs once but that it requires a permanent expenditure. If this expenditure were to cease, the repressed impulse, which is being fed all the time from its sources, would on the next occasion flow along the channels from which it had been forced away, and the repression would either fail in its purpose or would have to be repeated an indefinite number of times. Thus it is because instincts are continuous in their nature that the ego has to make its defensive action secure by a permanent expenditure. This action undertaken to protect repression is observable in analytic treatment as resistance. Resistance presupposes the existence of what I have called anticathexis. An anticathexis of this kind is clearly seen in obsessional neurosis. It appears there in the form of an alteration of the ego, as a reaction-formation in the ego, and is effected by the reinforcement of the attitude which is the opposite of the instinctual trend that has to be repressed - as, for instance, in pity, conscientiousness and cleanliness. These reaction-formations of obsessional neurosis are essentially exaggerations of the normal traits of character which develop during the latency period. The presence of an anticathexis in hysteria is much more difficult to detect, though theoretically it is equally indispensable. In hysteria, too, a certain amount of alteration of the ego through reaction-formation is unmistakable and in some circumstances becomes so marked that it forces itself on our attention as the principal symptom. The conflict due to ambivalence, for instance, is resolved in hysteria by this means. The subject's hatred of a person whom he loves is kept down by an exaggerated amount of tenderness for him and apprehensiveness about him. But the difference between reaction-formations in obsessional neurosis and in hysteria is that in the latter they do not have the universality of a character-trait but are confined to particular relationships. A hysterical woman, for instance, may be specially affectionate with her own children whom at bottom she hates; but she will not on that account be more loving in general than other women or even more affectionate to other children. The reaction-formation of hysteria clings tenaciously to a particular object and never spreads over into a general disposition of the ego, whereas what is characteristic of obsessional neurosis is precisely a spreading-over of this kind - a loosening of relations to the object and a facilitation of displacement in the choice of object.

Then I will pursue the subject further; in any case it is not easy for me to get away from it. I will tell you, then, that the most remarkable thing about the sexual life of children seems to me that it passes through the whole of its very far-reaching development in the first five years of life. From then onwards until puberty there stretches what is known as the period of latency. During it sexuality normally advances no further; on the contrary, the sexual urges diminish in strength and many things are given up and forgotten which the child did and knew. During that period of life, after the early efflorescence of sexuality has withered, such attitudes of the ego as shame, disgust and morality arise, which are destined to stand up against the later tempest of puberty and to lay down the path of the freshly awakening sexual desires. This 'diphasic onset', as it is named, of sexual life has a great deal to do with the genesis of neurotic illnesses. It seems to occur only in human beings, and it is perhaps one of the determinants of the human privilege of becoming neurotic. The prehistory of sexual life was just as much overlooked before psycho-analysis as, in another department, the background to conscious mental life. You will rightly suspect that the two are intimately connected.
It can be done very well. It is hardly to be believed what goes on in a child of four or five years old. Children are very active-minded at that age; their early sexual period is also a period of intellectual flowering. I have an impression that with the onset of the latency period they become mentally inhibited as well, stupider. From that time on, too, many children lose their physical charm. And, as regards the damage done by early analysis, I may inform you that the first child on whom the experiment was ventured, nearly twenty years ago, has since then grown into a healthy and capable young man, who has passed through his puberty irreproachably, in spite of some severe psychical traumas. It may be hoped that things will turn out no worse for the other 'victims' of early analysis. Much that is of interest attaches to these child analyses; it is possible that in the future they will become still more important. From the point of view of theory, their value is beyond question. They give unambiguous information on problems which remain unsolved in the analyses of adults; and they thus protect the analyst from errors that might have momentous consequences for him. One surprises the factors that lead to the formation of a neurosis while they are actually at work and one cannot then mistake them. In the child's interest, it is true, analytic influence must be combined with educational measures. The technique has still to receive its shaping. But practical interest is aroused by the observation that a very large number of our children pass through a plainly neurotic phase in the course of their development. Since we have learnt how to look more sharply, we are tempted to say that neurosis in children is not the exception but the rule, as though it could scarcely be avoided on the path from the innate disposition of infancy to civilized society. In most cases this neurotic phase in childhood is overcome spontaneously. But may it not also regularly leave its traces in the average healthy adult? On the other hand in those who are neurotics in later life we never fail to find links with the illness in childhood, though at the time it need not have been very noticeable. In a precisely analogous way physicians to-day, I believe, hold the view that each one of us has gone through an attack of tuberculosis in his childhood. It is true that in the case of the neuroses the factor of immunization does not operate, but only the factor of predisposition.

[1926e, 4357]

(2) For cultural reasons the most intense repression falls upon the sexual instincts; but it is precisely in connection with them that repression most easily miscarries, so that neurotic symptoms are found to be substitutive satisfactions of repressed sexuality. The belief that in man sexual life begins only at puberty is incorrect. On the contrary, signs of it can be detected from the beginning of extra-uterine existence; it reaches a first culminating point at or before the fifth year ('early period'), after which it is inhibited or interrupted ('latency period') until the age of puberty, which is the second climax of its development. This diphasic onset of sexual development seems to be distinctive of the genus Homo. All experiences during the first period of childhood are of the greatest importance to the individual, and in combination with his inherited sexual constitution form the dispositions for the subsequent development of character and disease. It is wrong to make sexuality coincide with 'genitality'. The sexual instincts pass through a complicated course of development, and it is only at the end of it that the 'primacy of the genital zones' is attained. Before this there are a number of 'pregenital' organizations of the libido - points at which it may become 'fixated' and to which, in the event of subsequent repression, it will return ('regression'). The infantile fixations of the libido are what determine the form of any later neurosis. Thus the neuroses are to be regarded as inhibitions in the development of the libido. There are no specific causes of nervous disorders; the question whether a conflict finds a healthy solution or leads to a neurotic inhibition of function depends upon quantitative considerations.

[1926f, 4405]
These three points - the very early appearance of these experiences (during the first five years of life), the fact of their being forgotten and their sexual-aggressive content - are closely interconnected. The traumas are either experiences on the subject's own body or sense perceptions, mostly of something seen and heard - that is, experiences or impressions. The interconnection of these three points is established by a theory, a product of the work of analysis which alone can bring about a knowledge of the forgotten experiences, or, to put it more vividly but also more incorrectly, bring them back to memory. The theory is that, in contrast to popular opinion, the sexual life of human beings (or what corresponds to it later on) exhibits an early efflorescence which comes to an end at about the fifth year and is followed by what is known as the period of latency (till puberty) in which there is no further development of sexuality and indeed what has been attained undergoes a retrogression. This theory is confirmed by the anatomical investigation of the growth of the internal genitalia; it leads us to suppose that the human race is descended from a species of animal which reached sexual maturity in five years and rouses a suspicion that the postponement of sexual life and its diphasic onset are intimately connected with the history of hominization. Human beings appear to be the only animal organisms with a latency period and sexual retardation of this kind. Investigations on the primates (which, so far as I know, are not available) would be indispensable for testing this theory. It cannot be a matter of indifference psychologically that the period of infantile amnesia coincides with this early period of sexuality. It may be that this state of things provides the true determinant for the possibility of neurosis, which is in a sense a human prerogative and from this point of view appears as a vestige - a 'survival' - of primaeval times like certain portions of our bodily anatomy.

[1939a, 4900]

The chief interest is naturally focused on the first of these assertions, the most unexpected of all. It has been found that in early childhood there are signs of bodily activity to which only an ancient prejudice could deny the name of sexual and which are linked to psychical phenomena that we come across later in adult erotic life - such as fixation to particular objects, jealousy, and so on. It is further found, however, that these phenomena which emerge in early childhood form part of an ordered course of development, that they pass through a regular process of increase, reaching a climax towards the end of the fifth year, after which there follows a lull. During this lull progress is at a standstill and much is unlearnt and there is much recession. After the end of this period of latency, as it is called, sexual life advances once more with puberty; we might say that it has a second efflorescence. And here we come upon the fact that the onset of sexual life is diphasic, that it occurs in two waves - something that is unknown except in man and evidently has an important bearing on hominization.¹ It is not a matter of indifference that the events of this early period, except for a few residues, fall a victim to infantile amnesia. Our views on the aetiology of the neuroses and our technique of analytic therapy are derived from these conceptions; and our tracing of the developmental processes in this early period has also provided evidence for yet other conclusions.

[1940a [1938], 4964]
As regards the other point - the specific instinctual factor - we come upon an interesting discrepancy between theory and experience. Theoretically there is no objection to supposing that any sort of instinctual demand might occasion the same repressions and their consequences; but our observation shows us invariably, so far as we can judge, that the excitations that play this pathogenic part arise from the component instincts of sexual life. The symptoms of neuroses are, it might be said, without exception either a substitutive satisfaction of some sexual urge or measures to prevent such a satisfaction; and as a rule they are compromises between the two, of the kind that come about in accordance with the laws operating between contraries in the unconscious. The gap in our theory cannot at present be filled; our decision is made more difficult by the fact that most of the urges of sexual life are not of a purely erotic nature but have arisen from alloys of the erotic instinct with portions of the destructive instinct. But it cannot be doubted that the instincts which manifest themselves physiologically as sexuality play a prominent, unexpectedly large part in the causation of the neuroses - whether it is an exclusive one remains to be decided. It must also be borne in mind that in the course of cultural development no other function has been so energetically and extensively repudiated as precisely the sexual one. Theory must rest satisfied with a few hints that betray a deeper connection: the fact that the first period of childhood, during which the ego begins to be differentiated from the id, is also the period of the early sexual efflorescence which is brought to an end by the period of latency; that it can hardly be a matter of chance that this momentous early period subsequently falls a victim to infantile amnesia; and lastly, that biological changes in sexual life (such as the function's diphasic onset which we have already mentioned, the disappearance of the periodic character of sexual excitation and the transformation in the relation between female menstruation and male excitation) - that these innovations in sexuality must have been of high importance in the evolution of animals into man. It is left for the science of the future to bring these still isolated data together into a new understanding. It is not in psychology but in biology that there is a gap here. We shall not be wrong, perhaps, in saying that the weak point in the ego's organization seems to lie in its attitude to the sexual function, as though the biological antithesis between self-preservation and the preservation of the species had found a psychological expression at that point.

[1940a [1938], 4994]
REACTION-FORMATION AND SUBLIMATION

What is it that goes to the making of these constructions which are so important for the growth of a civilized and normal individual? They probably emerge at the cost of the infantile sexual impulses themselves. Thus the activity of those impulses does not cease even during this period of latency, though their energy is diverted, wholly or in great part, from their sexual use and directed to other ends. Historians of civilization appear to be at one in assuming that powerful components are acquired for every kind of cultural achievement by this diversion of sexual instinctual forces from sexual aims and their direction to new ones - a process which deserves the name of 'sublimation'. To this we would add, accordingly, that the same process plays a part in the development of the individual and we would place its beginning in the period of sexual latency of childhood.¹

[1905d, 1500]

It is possible further to form some idea of the mechanism of this process of sublimation. On the one hand, it would seem, the sexual impulses cannot be utilized during these years of childhood, since the reproductive functions have been deferred - a fact which constitutes the main feature of the period of latency. On the other hand, these impulses would seem in themselves to be perverse - that is, to arise from erotogenic zones and to derive their activity from instincts which, in view of the direction of the subject's development, can only arouse unpleasurable feelings. They consequently evoke opposing mental forces (reacting impulses) which, in order to suppress this unpleasure effectively, build up the mental dams that have already mentioned - disgust, shame and morality.²

[1905d, 1500]
After having explained the preponderance of perverse tendencies in psychoneurotics by recognizing it as a collateral filling of subsidiary channels when the main current of the instinctual stream has been blocked by 'repression',¹ we proceeded to a consideration of sexual life in childhood. We found it a regrettable thing that the existence of the sexual instinct in childhood has been denied and that the sexual manifestations not infrequently to be observed in children have been described as irregularities. It seemed to us on the contrary that children bring germs of sexual activity with them into the world, that they already enjoy sexual satisfaction when they begin to take nourishment and that they persistently seek to repeat the experience in the familiar activity of 'thumb-sucking'. The sexual activity of children, however, does not, it appeared, develop pari passu with their other functions, but, after a short period of efflorescence from the ages of two to five, enters upon the so-called period of latency. During that period the production of sexual excitation is not by any means stopped but continues and produces a store of energy which is employed to a great extent for purposes other than sexual - namely, on the one hand in contributing the sexual components to social feelings and on the other hand (through repression and reaction-forming) in building up the subsequently developed barriers against sexuality. On this view, the forces destined to retain the sexual instinct upon certain lines are built up in childhood chiefly at the cost of perverse sexual impulses and with the assistance of education. A certain portion of the infantile sexual impulses would seem to evade these uses and succeed in expressing itself as sexual activity. We next found that sexual excitation in children springs from a multiplicity of forces. Satisfaction arises first and foremost from the appropriate sensory excitation of what we have described as erotogenic zones. It seems probable that any part of the skin and any sense-organ - probably, indeed, any organ - can function as an erotogenic zone, though there are some particularly marked erotogenic zones whose excitation would seem to be secured from the very first by certain organic contrivances. It further appears that sexual excitation arises as a by-product, as it were, of a large number of processes that occur in the organism, as soon as they reach a certain degree of intensity, and most especially of any relatively powerful emotion, even though it is of a distressing nature. The excitations from all these sources are not yet combined; but each follows its own separate aim, which is merely the attainment of a certain sort of pleasure. In childhood, therefore, the sexual instinct is not unified and is at first without an object, that is, auto-erotic.

SUBLIMATION The third alternative result of an abnormal constitutional disposition is made possible by the process of sublimation. This enables excessively strong excitations arising from particular sources of sexuality to find an outlet and use in other fields, so that a not inconsiderable increase in psychical efficiency results from a disposition which is itself perilous. Here we have one of the origins of artistic activity; and, according to the completeness or incompleteness of the sublimation, a characterological analysis of a highly gifted individual, and in particular of one with an artistic disposition, may reveal a mixture, in every proportion, of efficiency, perversion and neurosis. A sub-species of sublimation is to be found in suppression by reaction-formation, which, as we have seen, begins during a child's period of latency and continues in favourable cases throughout his whole life. What we describe as a person's 'character' is built up to a considerable extent from the material of sexual excitations and is composed of instincts that have been fixed since childhood, of constructions achieved by means of sublimation, and of other constructions, employed for effectively holding in check perverse impulses which have been recognized as being unutilizable.¹ The multifariously perverse sexual disposition of childhood can accordingly be regarded as the source of a number of our virtues, in so far as through reaction-formation it stimulates their development.²

[1905d, 1543]

[1905d, 1549]
I could not further elucidate this part of my theory without a detailed discussion of my views on repression. It will be enough here to refer to my Three Essays (1905d), in which I have attempted to throw some light - if only a feeble one - on the somatic processes in which the essential nature of sexuality is to be looked for. I have there shown that the constitutional sexual disposition of children is incomparably more variegated than might have been expected, that it deserves to be described as 'polymorphously perverse' and that what is spoken of as the normal behaviour of the sexual function emerges from this disposition after certain of its components have been repressed. By pointing out the infantile elements in sexuality I was able to establish a simple correlation between health, perversion and neurosis. I showed that normality is a result of the repression of certain component instincts and constituents of the infantile disposition and of the subordination of the remaining constituents under the primacy of the genital zones in the service of the reproductive function. I showed that perversions correspond to disturbances of this coalescence owing to the overpowering and compulsive development of certain of the component instincts, while neuroses can be traced back to an excessive repression of the libidinal trends. Since almost all the perverse instincts of the infantile disposition can be recognized as the forces concerned in the formation of symptoms in neuroses, though in a state of repression, I was able to describe neurosis as being the 'negative' of perversion.

[1906a, 1581]

I know that no one is prepared to believe in a state of things so long as it appears to be unintelligible and to offer no angle from which an explanation can be attempted. But we can at least bring the underlying factors nearer to our understanding by the help of the postulates I laid down in my Three Essays on the Theory of Sexuality in 1905. I there attempted to show that the sexual instinct of man is highly complex and is put together from contributions made by numerous constituents and component instincts. Important contributions to 'sexual excitation' are furnished by the peripheral excitations of certain specially designated parts of the body (the genitals, mouth, anus, urethra), which therefore deserve to be described as 'erogenic zones'. But the amounts of excitation coming in from these parts of the body do not all undergo the same vicissitudes, nor is the fate of all of them the same at every period of life. Generally speaking, only a part of them is made use of in sexual life; another part is deflected from sexual aims and directed towards others - a process which deserves the name of 'sublimation'. During the period of life which may be called the period of 'sexual latency' - i.e. from the completion of the fifth year to the first manifestations of puberty (round about the eleventh year) - reaction-formations, or counter-forces, such as shame, disgust and morality, are created in the mind. They are actually formed at the expense of the excitations proceeding from the erogenic zones, and they rise like dams to oppose the later activity of the sexual instincts. Now anal erotism is one of the components of the instinct which, in the course of development and in accordance with the education demanded by our present civilization, have become unserviceable for sexual aims. It is therefore plausible to suppose that these character-traits of orderliness, parsimony and obstinacy, which are so often prominent in people who were formerly anal erotics, are to be regarded as the first and most constant results of the sublimation of anal erotism.²

[1908b, 1943]

Yet another circumstance facilitates this equation in neurotic thought. The original erotic interest in defaecation is, as we know, destined to be extinguished in later years. In those years the interest in money makes its appearance as a new interest which had been absent in childhood. This makes it easier for the earlier impulsion, which is in process of losing its aim, to be carried over to the newly emerging aim.

[1908b, 1945]
Further prospects are opened up when we take into consideration the fact that in man the sexual instinct does not originally serve the purposes of reproduction at all, but has as its aim the gaining of particular kinds of pleasure.¹ It manifests itself in this way in human infancy, during which it attains its aim of gaining pleasure not only from the genitals but from other parts of the body (the erotogenic zones), and can therefore disregard any objects other than these convenient ones. We call this stage the stage of auto-erotism, and the child’s upbringing has, in our view, the task of restricting it, because to linger in it would make the sexual instinct uncontrollable and unserviceable later on. The development of the sexual instinct then proceeds from auto-erotism to object-love and from the autonomy of the erotogenic zones to their subordination under the primacy of the genitals, which are put at the service of reproduction. During this development a part of the sexual excitation which is provided by the subject’s own body is inhibited as being unserviceable for the reproductive function and in favourable cases is brought to sublimation. The forces that can be employed for cultural activities are thus to a great extent obtained through the suppression of what are known as the perverse elements of sexual excitation.

[1908d, 1953]

These considerations have been based so far on the requirement laid down by the second of the stages of civilization which we have postulated, the requirement that every sexual activity of the kind described as perverse is prohibited, while what is called normal sexual intercourse is freely permitted. We have found that even when the line between sexual freedom and restriction is drawn at this point, a number of individuals are ruled out as perverts, and a number of others, who make efforts not to be perverts whilst constitutionally they should be so, are forced into nervous illness. It is easy to predict the result that will follow if sexual freedom is still further circumscribed and the requirements of civilization are raised to the level of the third stage, which bans all sexual activity outside legal marriage. The number of strong natures who openly oppose the demands of civilization will increase enormously, and so will the number of weaker ones who, faced with the conflict between the pressure of cultural influences and the resistance of their constitution, take flight into neurotic illness.

[1908d, 1955]

Before I can regard this synthesis as completed I must turn to yet another aspect of the case, which will take us into the very heart of the difficulties that lie in the way of our understanding of neurotic states. We have seen how our little patient was overtaken by a great wave of repression and that it caught precisely those of his sexual components that were dominant.¹ He gave up masturbation, and turned away in disgust from everything that reminded him of excrement and of looking on at other people performing their natural functions. But these were not the components which were stirred up by the precipitating cause of the illness (his seeing the horse fall down) or which provided the material for the symptoms, that is, the content of the phobia.

[1909b, 2117]
Furthermore, let me say in Hans's favour (and I frankly admit my partisan attitude) that he is not the only child who has been overtaken by a phobia at some time or other in his childhood. Troubles of that kind are well known to be quite extraordinarily frequent, even in children the strictness of whose upbringing has left nothing to be desired. In later life these children either become neurotic or remain healthy. Their phobias are shouted down in the nursery because they are inaccessible to treatment and are decidedly inconvenient. In the course of months or years they diminish, and the child seems to recover; but no one can tell what psychological changes are necessitated by such a recovery, or what alterations in character are involved in it. When, however, an adult neurotic patient comes to us for psycho-analytic treatment (and let us assume that his illness has only become manifest after he has reached maturity), we find regularly that his neurosis has as its point of departure an infantile anxiety such as we have been discussing, and is in fact a continuation of it; so that, as it were, a continuous and undisturbed thread of psychical activity, taking its start from the conflicts of his childhood, has been spun through his life - irrespective of whether the first symptom of those conflicts has persisted or has retreated under the pressure of circumstances. I think, therefore, that Hans's illness may perhaps have been no more serious than that of many other children who are not branded as 'degenerates'; but since he was brought up without being intimidated, and with as much consideration and as little coercion as possible, his anxiety dared to show itself more boldly. With him there was no place for such motives as a bad conscience or a fear of punishment, which with other children must no doubt contribute to making the anxiety less. It seems to me that we concentrate too much upon symptoms and concern ourselves too little with their causes. In bringing up children we aim only at being left in peace and having no difficulties, in short, at training up a model child, and we pay very little attention to whether such a course of development is for the child's good as well. I can therefore quite imagine that it may have been to Hans's advantage to have produced this phobia. For it directed his parents' attention to the unavoidable difficulties by which a child is confronted when in the course of his cultural training he is called upon to overcome the innate instinctual components of his mind; and his trouble brought his father to his assistance. It may be that Hans now enjoys an advantage over other children, in that he no longer carries within him that seed in the shape of repressed complexes which must always be of some significance for a child's later life, and which undoubtedly brings with it a certain degree of deformity of character if not a predisposition to a subsequent neurosis. I am inclined to think that this is so, but I do not know if many others will share my opinion; nor do I know whether experience will prove me right.

[1909b, 2120]

It is inevitable and perfectly normal that a child should take his parents as the first objects of his love. But his libido should not remain fixated to these first objects; later on, it should merely take them as a model, and should make a gradual transition from them on to extraneous people when the time for the final choice of an object arrives. The detachment of the child from his parents is thus a task that cannot be evaded if the young individual's social fitness is not to be endangered. During the time at which repression is making its selection among the component instincts, and later, when there should be a slackening of the parents' influence, which is essentially responsible for the expenditure of energy on these repressions, the task of education meets with great problems, which at the present time are certainly not always dealt with in an understanding and unobjectionable manner.

[1910a, 2233]
We must expressly insist that we have never reckoned Leonardo as a neurotic or a 'nerve case', as the awkward phrase goes. Anyone who protests at our so much as daring to examine him in the light of discoveries gained in the field of pathology is still clinging to prejudices which we have to-day rightly abandoned. We no longer think that health and illness, normal and neurotic people, are to be sharply distinguished from each other, and that neurotic traits must necessarily be taken as proofs of a general inferiority. To-day we know that neurotic symptoms are structures which are substitutes for certain achievements of repression that we have to carry out in the course of our development from a child to a civilized human being. We know too that we all produce such substitutive structures, and that it is only their number, intensity and distribution which justify us in using the practical concept of illness and in inferring the presence of constitutional inferiority. From the slight indications we have about Leonardo's personality we should be inclined to place him close to the type of neurotic that we describe as 'obsessional'; and we may compare his researches to the 'obsessive brooding' of neurotics, and his inhibitions to what are known as their 'abullas'.

A powerful wave of repression brought this childhood excess to an end, and established the dispositions which were to become manifest in the years of puberty. The most obvious result of the transformation was the avoidance of every crudely sensual activity; Leonardo was enabled to live in abstinence and to give the impression of being an asexual human being. When the excitations of puberty came in their flood upon the boy they did not, however, make him ill by forcing him to develop substitutive structures of a costly and harmful kind. Owing to his very early inclination towards sexual curiosity the greater portion of the needs of his sexual instinct could be sublimated into a general urge to know, and thus evaded repression. A much smaller portion of his libido continued to be devoted to sexual aims and represented a stunted adult sexual life. Because his love for his mother had been repressed, this portion was driven to take up a homosexual attitude and manifested itself in ideal love for boys. The fixation on his mother and on the blissful memories of his relations with her continued to be preserved in the unconscious, but for the time being it remained in an inactive state. In this way repression, fixation and sublimation all played their part in disposing of the contributions which the sexual instinct made to Leonardo's mental life.

Secondly, we know that the sexual instinct is originally divided into a great number of components - or rather, it develops out of them - some of which cannot be taken up into the instinct in its later form, but have at an earlier stage to be suppressed or put to other uses. These are above all the coprophilic instinctual components, which have proved incompatible with our aesthetic standards of culture, probably since, as a result of our adopting an erect gait, we raised our organ of smell from the ground. The same is true of a large portion of the sadistic urges which are a part of erotic life. But all such developmental processes affect only the upper layers of the complex structure. The fundamental processes which produce erotic excitation remain unaltered. The excremental is all too intimately and inseparably bound up with the sexual; the position of the genitals - \textit{inter unrinas et faeces} - remains the decisive and unchangeable factor. One might say here, varying a well-known saying of the great Napoleon: 'Anatomy is destiny.' The genitals themselves have not taken part in the development of the human body in the direction of beauty: they have remained animal, and thus love, too, has remained in essence just as animal as it ever was. The instincts of love are hard to educate; education of them achieves now too much, now too little. What civilization aims at making out of them seems unattainable except at the price of a sensible loss of pleasure; the persistence of the impulses that could not be made use of can be detected in sexual activity in the form of non-satisfaction.
If, then, as we have learnt, psychogenic disturbances of vision depend on certain ideas connected with seeing being cut off from consciousness, we must, on the psycho-analytic view, assume that these ideas have come into opposition to other, more powerful ones, for which we use the collective concept of the 'ego'- a compound which is made up variously at different times - and have for that reason come under repression. But what can be the origin of this opposition, which makes for repression, between the ego and various groups of ideas? You will no doubt notice that it was not possible to frame such a question before the advent of psycho-analysis, for nothing was known earlier of psychical conflict and repression. Our researches, however, have put us in a position to give us the desired answer. Our attention has been drawn to the importance of the instincts in ideational life. We have discovered that every instinct tries to make itself effective by activating ideas that are in keeping with its aims. These instincts are not always compatible with one another; their interests often come into conflict. Opposition between ideas is only an expression of struggles between the various instincts. From the point of view of our attempted explanation, a quite specially important part is played by the undeniable opposition between the instincts which subserve sexuality, the attainment of sexual pleasure, and those other instincts, which have as their aim the self-preservation of the individual - the ego-instincts. As the poet has said, all the organic instincts that operate in our mind may be classified as 'hunger' or 'love'. We have traced the 'sexual instinct' from its first manifestations in children to its final form, which is described as 'normal'. We have found that it is put together from numerous 'component instincts' which are attached to excitations of regions of the body; and we have come to see that these separate instincts have to pass through a complicated development before they can be brought effectively to serve the aims of reproduction. The light thrown by psychology on the evolution of our civilization has shown us that it originates mainly at the cost of the sexual component instincts, and that these must be suppressed, restricted, transformed and directed to higher aims, in order that the mental constructions of civilization may be established. We have been able to recognize as a valuable outcome of these researches something that our colleagues have not yet been willing to believe, namely that the human ailments known as 'neuroses' are derived from the many different ways in which these processes of transformation in the sexual component instincts may miscarry. The 'ego' feels threatened by the claims of the sexual instincts and fends them off by repressions; these, however, do not always have the desired result, but lead to the formation of dangerous substitutes for the repressed and to burdensome reactions on the part of the ego. From these two classes of phenomena taken together there emerge what we call the symptoms of neuroses.

[1910i, 2368]
Nevertheless, psycho-analysis and folklore have not allowed themselves to be deterred from transgressing these prohibitions and have been able as a result to teach us all kinds of things that are indispensable for an understanding of human nature. If we limit ourselves here to what has been learnt about the excretory functions, it may be said that the chief finding from psycho-analytic research has been the fact that the human infant is obliged to recapitulate during the early part of his development the changes in the attitude of the human race towards excremental matters which probably had their start when *homo sapiens* first raised himself off Mother Earth. In the earliest years of infancy there is as yet no trace of shame about the excretory functions or of disgust at excreta. Small children show great interest in these, just as they do in others of their bodily secretions; they like occupying themselves with them and can derive many kinds of pleasure from doing so. Excreta, regarded as parts of a child's own body and as products of his own organism, have a share in the esteem - the narcissistic esteem, as we should call it - with which he regards everything relating to his self. Children are, indeed, proud of their own excretions and make use of them to help in asserting themselves against adults. Under the influence of its upbringing, the child's coprophilic instincts and inclinations gradually succumb to repression; it learns to keep them secret, to be ashamed of them and to feel disgust at their objects. Strictly speaking, however, the disgust never goes so far as to apply to a child's own excretions, but is content with repudiating them when they are the products of other people. The interest which has hitherto been attached to excrement is carried over on to other objects - for instance, from faeces on to money, which is, of course, late in acquiring significance for children. Important constituents in the formation of character are developed, or strengthened, from the repression of coprophilic inclinations.

If we examine sexuality in the adult with the help of psycho-analysis, and consider the life of children in the light of the knowledge thus gained, we perceive that sexuality is not merely a function serving the purposes of reproduction, on a par with digestion, respiration, etc. It is something far more independent, which stands in contrast to all the individual's other activities and is only forced into an alliance with the individual's economy after a complicated course of development involving the imposition of numerous restrictions. Cases, theoretically quite conceivable, in which the interests of these sexual impulses fail to coincide with the self-preservation of the individual seem actually to be presented by the group of neurotic illnesses. For the final formula which psycho-analysis has arrived at on the nature of the neuroses runs thus: The primal conflict which leads to neuroses is one between the sexual instincts and those which maintain the ego. The neuroses represent a more or less partial overpowering of the ego by sexuality after the ego's attempts at suppressing sexuality have failed.
When educators have become familiar with the findings of psycho-analysis, it will be easier for them to reconcile themselves to certain phases of infantile development and they will, among other things, not be in danger of over-estimating the importance of the socially unserviceable or perverse instinctual impulses which emerge in children. On the contrary they will refrain from any attempt at forcibly suppressing such impulses, when they learn that efforts of this kind often produce no less undesirable results than the alternative, which is so much dreaded by educators, of giving free play to children's naughtiness. The forcible suppression of strong instincts by external means never has the effect in a child of these instincts being extinguished or brought under control; it leads to repression, which establishes a predisposition to later nervous illness. Psycho-analysis has frequent opportunities of observing the part played by inopportune and undiscerning severity of upbringing in the production of neuroses, or the price, in loss of efficiency and of capacity for enjoyment, which has to be paid for the normality upon which the educator insists. And psycho-analysis can also show what precious contributions to the formation of character are made by these asocial and perverse instincts in the child, if they are not subjected to repression but are diverted from their original aims to more valuable ones by the process known as 'sublimation'. Our highest virtues have grown up, as reaction formations and sublimations, out of our worst dispositions. Education should scrupulously refrain from burying these precious springs of action and should restrict itself to encouraging the processes by which these energies are led along safe paths. Whatever we can expect in the way of prophylaxis against neurosis in the individual lies in the hands of a psycho-analytically enlightened education.¹

[1913j, 2825]

The revolutionary discoveries of psycho-analysis in regard to the mental life of children - the part played in it by sexual impulses (von Hug-Hellmuth), and the fate of those components of sexuality which become unserviceable in the function of reproduction - were bound early to direct attention to education and to stimulate an attempt to bring analytic points of view into the foreground in that field of work. Recognition is due to Dr. Pfister for having, with sincere enthusiasm, initiated the application of psycho-analysis in this direction and brought it to the notice of ministers of religion and those concerned with education. (Cf. The Psycho-Analytic Method, 1913.) He has succeeded in gaining the sympathy and participation of a number of Swiss teachers in this. Other members of his profession are said to share his views but to have preferred nevertheless to remain cautiously in the background. In their retreat from psycho-analysis, a section of Vienna analysts seem to have arrived at a kind of combination of medicine and education.¹

[1914d, 2903]

The content of the Ucs. may be compared with an aboriginal population in the mind. If inherited mental formations exist in the human being - something analogous to instinct¹ in animals - these constitute the nucleus of the Ucs. Later there is added to them what is discarded during childhood development as unserviceable; and this need not differ in its nature from what is inherited. A sharp and final division between the content of the two systems does not, as a rule, take place till puberty.

[1915e, 3017]
In forming this opinion of sensual sucking we have already become acquainted with two
decisive characteristics of infantile sexuality. It makes its appearance attached to the satisfaction
of the major organic needs, and it behaves auto-erotically - that is, it seeks and finds its objects in
the infant's own body. What has been shown most clearly in connection with the intake of
nourishment is repeated in part with the excretions. We conclude that infants have feelings of
pleasure in the process of evacuating urine and faeces and that they soon contrive to arrange
those actions in such a way as to bring them the greatest possible yield of pleasure through the
corresponding excitations of the erotogenic zones of the mucous membrane. It is here for the first
time (as Lou Andreas-Salomé has subtly perceived) that they encounter the external world as an
inhibiting power, hostile to their desire for pleasure, and have a glimpse of later conflicts both
external and internal. An infant must not produce his excreta at whatever moment he chooses,
but when other people decide that he shall. In order to induce him to forgo these sources of
pleasure, he is told that everything that has to do with these functions is improper and must be
kept secret. This is where he is first obliged to exchange pleasure for social respectability. To
begin with, his attitude to his excreta themselves is quite different. He feels no disgust at his
faeces, values them as a portion of his own body with which he will not readily part, and makes
use of them as his first 'gift', to distinguish people whom he values especially highly. Even after
education has succeeded in its aim of making these inclinations alien to him, he carries on his
high valuation of faeces in his estimate of 'gifts' and 'money'. On the other hand he seems to
regard his achievements in urinating with peculiar pride.

[1916-1917, 3385]

There is something else that I must add in order to complete our view of sexual perversions.
However infamous they may be, however sharply they may be contrasted with normal sexual
activity, quiet consideration will show that some perverse trait or other is seldom absent from the
sexual life of normal people. Even a kiss can claim to be described as a perverse act, since it
consists in the bringing together of two oral erotogenic zones instead of the two genitals. Yet no
one rejects it as perverse; on the contrary, it is permitted in theatrical performances as a softened
hint at the sexual act. But precisely kissing can easily turn into a complete perversion - if, that is
to say, it becomes so intense that a genital discharge and orgasm follow upon it directly, an event
that is far from rare. We can learn, too, that for one person feeling and looking at the object are
indispensable preconditions of sexual enjoyment, that another person will pinch or bite at the
climax of sexual excitation, that the highest pitch of excitement in lovers is not always provoked
by the genitals but by some other region of the object's body, and any number of similar things
besides. There is no sense in excluding people with individual traits of this kind from the class of
the normal and putting them among the perverts. On the contrary, we shall recognize more and
more clearly that the essence of the perversions lies not in the extension of the sexual aim, not in
the replacement of the genitals, not even always in the variant choice of the object, but solely in
the exclusiveness with which these deviations are carried out and as a result of which the sexual
act serving the purpose of reproduction is put on one side. In so far as the perverse actions are
inserted in the performance of the normal sexual act as preparatory or intensifying contributions,
they are in reality not perversions at all. The gulf between normal and perverse sexuality is of
course very much narrowed by facts of this kind. It is an easy conclusion that normal sexuality
has emerged out of something that was in existence before it, by weeding out certain features of
that material as unserviceable and collecting together the rest in order to subordinate them to a
new aim, that of reproduction.

[1916-1917, 3391]
To-day we will follow yet another side of this development namely the relation of the component sexual instincts to their object. Or rather, we will make a hasty survey of this development and dwell somewhat longer on one of its rather late consequences. A few of the components of the sexual instinct, there, have an object from the first and hold fast to it - for instance, the instinct for mastery (sadism) and the scopophilic and epistemophilic instincts. Others, more definitely linked to particular erotogenic zones of the body, have one to begin with only so long as they are still attached to the non-sexual functions, and give it up when they become separated from them. Thus the first object of the oral component of the sexual instinct is the mother's breast which satisfies the infant's need for nourishment. The erotic component, which is satisfied simultaneously during the sucking, makes itself independent with the act of sensual sucking \[\text{lutschen}\]; it gives up the outside object and replaces it by an area of the subject's own body. The oral instinct becomes auto-erotic, as are the anal and other erotogenic instincts from the first. Further development, to put the matter as concisely as possible, has two aims: firstly, the abandonment of auto-erotism, the replacement of the subject's own body once more by an outside object, and secondly, the unification of the various objects of the separate instincts and their replacement by a single object. This can, of course, only be achieved if the object is again a whole body, similar to the subject's own. Nor can it be effected unless a number of the auto-erotic instinctual impulses are left behind as being unserviceable.

[1916-1917, 3396]

The things I have just been discussing, Gentlemen, compel me to enter more closely into the origin and significance of the mental activity which is described as 'phantasy'. As you are aware, it enjoys a universally high reputation, without its position in mental life having become clear. I have the following remarks to make about it. The human ego is, as you know, slowly educated by the pressure of external necessity to appreciate reality and obey the reality principle; in the course of this process it is obliged to renounce, temporarily or permanently, a variety of the objects and aims at which its striving for pleasure, and not only for sexual pleasure, is directed. But men have always found it hard to renounce pleasure; they cannot bring themselves to do it without some kind of compensation. They have therefore retained a mental activity in which all these abandoned sources of pleasure and methods of achieving pleasure are granted a further existence - a form of existence in which they are left free from the claims of reality and of what we call 'reality-testing'. Every desire takes before long the form of picturing its own fulfilment; there is no doubt that dwelling upon imaginary wish-fulfilments brings satisfaction with it, although it does not interfere with a knowledge that what is concerned is not real. Thus in the activity of phantasy human beings continue to enjoy the freedom from external compulsion which they have long since renounced in reality. They have contrived to alternate between remaining an animal of pleasure and being once more a creature of reason. Indeed, they cannot subsist on the scanty satisfaction which they can extort from reality. 'We cannot do without auxiliary constructions', as Theodor Fontane once said. The creation of the mental realm of phantasy finds a perfect parallel in the establishment of 'reservations' or 'nature reserves' in places where the requirements of agriculture, communications and industry threaten to bring about changes in the original face of the earth which will quickly make it unrecognizable. A nature reserve preserves its original state which everywhere else has to our regret been sacrificed to necessity. Everything, including what is useless and even what is noxious, can grow and proliferate there as it pleases. The mental realm of phantasy is just such a reservation withdrawn from the reality principle.

[1916-1917, 3427]
For a time psycho-analysis seemed fated to merge into psychology without being able to show why the psychology of the sick differed from that of the normal. In the course of its advance, however, it came up against the problem of dreams, which are abnormal products of the mind created by normal men under regularly recurrent physiological conditions. When psycho-analysis had solved the problem of dreams, it had discovered in unconscious psychical processes the common ground in which the highest and the lowest of mental impulses have their roots and from which spring the most normal as well as the most morbid and erratic of mental productions. The new picture of the workings of the mind began to grow ever clearer and more complete. It was a picture of obscure instinctual forces organic in origin, striving towards inborn aims, and, above them, of an agency comprising more highly organized mental structures - acquisitions of human evolution made under the impact of human history -, an agency which has taken over portions of the instinctual impulses, has developed them further or has even directed them towards higher aims, but which in any case binds them firmly and manipulates their energy to suit its own purposes. This higher organization, however, which is known to us as the ego, has rejected another portion of these same elementary instinctual impulses as being unserviceable because they cannot be fitted into the organic unity of the individual or because they rebel against the individual's cultural aims. The ego is not in a position to exterminate these unsubdued mental powers, but it turns its back on them, lets them remain at the lowest psychological level, defends itself from their demands by the energetic erection of protective and antithetical barriers or seeks to come to terms with them by means of substitutive satisfactions. These instincts which have fallen victim to repression - untamed and indestructible, yet inhibited from any kind of activity - together with their primitive mental representatives, constitute the mental underworld, the nucleus of the true unconscious, and are at every moment ready to assert their demands and, by hook or by crook, to force their way forward to satisfaction. To this is due the instability of the proud superstructure of the mind, the emergence at night of the proscribed and repressed material in the form of dreams, and the tendency to fall ill with neuroses and psychoses as soon as the balance of power between the ego and the repressed shifts to the disadvantage of the ego.

In 1913 Otto Rank and Hanns Sachs, in an extremely interesting work, brought together the results which had been achieved up to that time in the application of psycho-analysis to the mental sciences. The most easily accessible branches of those sciences seem to be mythology and the history of literature and religion. No final formula has yet been found enabling us to give an appropriate place to myths in this connection. Otto Rank, in a large volume on the incest complex (1912), has produced evidence of the surprising fact that the choice of subject matter, especially for dramatic works, is principally determined by the ambit of what psycho-analysis has termed the 'Oedipus complex'. By working it over with the greatest variety of modifications, distortions and disguises, the dramatist seeks to deal with his own most personal relations to this emotional theme. It is in attempting to master the Oedipus complex - that is to say, a person's emotional attitude towards his family, or in a narrower sense towards his father and mother - that individual neurotics come to grief, and for this reason that complex habitually forms the nucleus of their neuroses. It does not owe its importance to any unintelligible conjunction; the emphasis laid upon the relation of children to their parents is an expression of the biological facts that the young of the human race pass through a long period of dependence and are slow in reaching maturity, as well as that their capacity for love undergoes a complicated course of development. Consequently, the overcoming of the Oedipus complex coincides with the most efficient way of mastering the archaic, animal heritage of humanity. It is true that that heritage comprises all the forces that are required for the subsequent cultural development of the individual, but they must first be sorted out and worked over. This archaic heirloom is not fit to be used for the purposes of civilized social life in the form in which it is inherited by the individual.
There can be no doubt, however, that the replacement of the pleasure principle by the reality principle can only be made responsible for a small number, and by no means the most intense, of unpleasurable experiences. Another occasion of the release of unpleasure, which occurs with no less regularity, is to be found in the conflicts and dissensions that take place in the mental apparatus while the ego is passing through its development into more highly composite organizations. Almost all the energy with which the apparatus is filled arises from its innate instinctual impulses. But these are not all allowed to reach the same phases of development. In the course of things it happens again and again that individual instincts or parts of instincts turn out to be incompatible in their aims or demands with the remaining ones, which are able to combine into the inclusive unity of the ego. The former are then split off from this unity by the process of repression, held back at lower levels of psychical development and cut off, to begin with, from the possibility of satisfaction. If they succeed subsequently, as can so easily happen with repressed sexual instincts, in struggling through, by roundabout paths, to a direct or to a substitutive satisfaction, that event, which would in other cases have been an opportunity for pleasure, is felt by the ego as unpleasure. As a consequence of the old conflict which ended in repression, a new breach has occurred in the pleasure principle at the very time when certain instincts were endeavouring, in accordance with the principle, to obtain fresh pleasure. The details of the process by which repression turns a possibility of pleasure into a source of unpleasure are not yet clearly understood or cannot be clearly represented; but there is no doubt that all neurotic unpleasure is of that kind - pleasure that cannot be felt as such.¹

[1920g, 3717]

The Process of Finding an Object, and the Oedipus Complex. - In the first instance the oral component instinct finds satisfaction by attaching itself to the sating of the desire for nourishment; and its object is the mother's breast. It then detaches itself, becomes independent and at the same time auto-erotic, that is, it finds an object in the child's own body. Others of the component instincts also start by being auto-erotic and are not until later diverted on to an external object. It is a particularly important fact that the component instincts belonging to the genital zone habitually pass through a period of intense auto-erotic satisfaction. The component instincts are not all equally serviceable in the final genital organization of libido; some of them (for instance, the anal components) are consequently left aside and suppressed, or undergo complicated transformations.

[1923a, 3922]
The sexual function, as I found, is in existence from the very beginning of the individual's life, though at first it is attached to the other vital functions and does not become independent of them until later; it has to pass through a long and complicated process of development before it becomes what we are familiar with as the normal sexual life of the adult. It begins by manifesting itself in the activity of a whole number of component instincts. These are dependent upon erotogenic zones in the body; some of them make their appearance in pairs of opposite impulses (such as sadism and masochism or the impulses to look and to be looked at); they operate independently of one another in a search for pleasure, and they find their object for the most part in the subject's own body. Thus at first the sexual function is non-centralized and predominantly auto-erotic. Later, syntheses begin to appear in it; a first stage of organization is reached under the dominance of the oral components, an anal-sadistic stage follows, and it is only after the third stage has at last been reached that the primacy of the genitals is established and that the sexual function begins to serve the ends of reproduction. In the course of this process of development a number of elements of the various component instincts turn out to be unserviceable for this last end and are therefore left on one side or turned to other uses, while others are diverted from their aims and carried over into the genital organization. I gave the name of libido to the energy of the sexual instincts and to that form of energy alone. I was next driven to suppose that the libido does not always pass through its prescribed course of development smoothly. As a result either of the excessive strength of certain of the components or of experiences involving premature satisfaction, fixations of the libido may occur at various points in the course of its development. If subsequently a repression takes place, the libido flows back to these points (a process described as regression), and it is from them that the energy breaks through in the form of a symptom. Later on it further became clear that the localization of the point of fixation is what determines the choice of neurosis, that is, the form in which the subsequent illness makes its appearance.

[1925d, 4211]

The sexual life of children is of course different from that of adults. The sexual function, from its beginnings to the definitive form in which it is so familiar to us, undergoes a complicated process of development. It grows together from numerous component instincts with different aims and passes through several phases of organization till at last it comes into the service of reproduction. Not all the component instincts are equally serviceable for the final outcome; they must be diverted, remodelled and in part suppressed. Such a far-reaching course of development is not always passed through without a flaw; inhibitions in development take place, partial fixations at early stages of development. If obstacles arise later on to the exercise of the sexual function, the sexual urge - the libido, as we call it - is apt to hark back to these earlier points of fixation. The study of the sexuality of children and its transformations up to maturity has also given us the key to an understanding of what are known as the sexual perversions, which people used always to describe with all the requisite indications of disgust but whose origin they were never able to explain. The whole topic is of uncommon interest, but for the purposes of our conversation there is not much sense in telling you more about it. To find one's way about in it one of course needs anatomical and physiological knowledge, all of which is unfortunately not to be acquired in medical schools. But a familiarity with the history of civilization and with mythology is equally indispensable.

[1926e, 4353]
Then I will pursue the subject further; in any case it is not easy for me to get away from it. I will
tell you, then, that the most remarkable thing about the sexual life of children seems to me that it
passes through the whole of its very far-reaching development in the first five years of life. From
then onwards until puberty there stretches what is known as the period of latency. During it
sexuality normally advances no further; on the contrary, the sexual urges diminish in strength and
many things are given up and forgotten which the child did and knew. During that period of life,
after the early efflorescence of sexuality has withered, such attitudes of the ego as shame,
disgust and morality arise, which are destined to stand up against the later tempest of puberty
and to lay down the path of the freshly awakening sexual desires. This 'diphasic onset', as it is
named, of sexual life has a great deal to do with the genesis of neurotic illnesses. It seems to
occur only in human beings, and it is perhaps one of the determinants of the human privilege of
becoming neurotic. The prehistory of sexual life was just as much overlooked before psycho-
analysis as, in another department, the background to conscious mental life. You will rightly
suspect that the two are intimately connected.

We now observe that the store of religious ideas includes not only wish-fulfilments but important
historical recollections. This concurrent influence of past and present must give religion a truly
incomparable wealth of power. But perhaps with the help of an analogy yet another discovery
may begin to dawn on us. Though it is not a good plan to transplant ideas far from the soil in
which they grew up, yet here is a conformity which we cannot avoid pointing out. We know that a
human child cannot successfully complete its development to the civilized stage without passing
through a phase of neurosis sometimes of greater and sometimes of less distinctness. This is
because so many instinctual demands which will later be unserviceable cannot be suppressed by
the rational operation of the child's intellect but have to be tamed by acts of repression, behind
which, as a rule, lies the motive of anxiety. Most of these infantile neuroses are overcome
spontaneously in the course of growing up, and this is especially true of the obsessional neuroses
of childhood. The remainder can be cleared up later still by psycho-analytic treatment. In just the
same way, one might assume, humanity as a whole, in its development through the ages, fell into
states analogous to the neuroses, and for the same reasons - namely because in the times of its
ignorance and intellectual weakness the instinctual renunciations indispensable for man's
communal existence had only been achieved by it by means of purely affective forces. The
precipitates of these processes resembling repression which took place in prehistoric times still
remained attached to civilization for long periods. Religion would thus be the universal
obsessional neurosis of humanity; like the obsessional neurosis of children, it arose out of the
Oedipus complex, out of the relation to the father. If this view is right, it is to be supposed that a
turning-away from religion is bound to occur with the fatal inevitability of a process of growth, and
that we find ourselves at this very juncture in the middle of that phase of development. Our
behaviour should therefore be modelled on that of a sensible teacher who does not oppose an
impending new development but seeks to ease its path and mitigate the violence of its irruption.
Our analogy does not, to be sure, exhaust the essential nature of religion. If, on the one hand,
religion brings with it obsessional restrictions, exactly as an individual obsessional neurosis does,
on the other hand it comprises a system of wishful illusions together with a disavowal of reality,
such as we find in an isolated form nowhere else but in amentia, in a state of blissful hallucinatory
confusion. But these are only analogies, by the help of which we endeavour to understand a
social phenomenon; the pathology of the individual does not supply us with a fully valid
counterpart.

[1926e, 4353]

[1927c, 4452]
By allowing common feeling to be our guide in deciding what features of human life are to be regarded as civilized, we have obtained a clear impression of the general picture of civilization; but it is true that so far we have discovered nothing that is not universally known. At the same time we have been careful not to fall in with the prejudice that civilization is synonymous with perfecting, that it is the road to perfection pre-ordained for men. But now a point of view presents itself which may lead in a different direction. The development of civilization appears to us as a peculiar process which mankind undergoes, and in which several things strike us as familiar. We may characterize this process with reference to the changes which it brings about in the familiar instinctual dispositions of human beings, to satisfy which is, after all, the economic task of our lives. A few of these instincts are not used up in such a manner that something appears in their place which, in an individual, we describe as a character-trait. The most remarkable example of such a process is found in the anal erotism of young human beings. Their original interest in the excretory function, its organs and products, is changed in the course of their growth into a group of traits which are familiar to us as parsimony, a sense of order and cleanliness - qualities which, though valuable and welcome in themselves, may be intensified till they become markedly dominant and produce what is called the anal character. How this happens we do not know, but there is no doubt about the correctness of the finding.¹ Now we have seen that order and cleanliness are important requirements of civilization, although their vital necessity is not very apparent, any more than their suitability as sources of enjoyment. At this point we cannot fail to be struck by the similarity between the process of civilization and the libidinal development of the individual. Other instincts are induced to displace the conditions for their satisfaction, to lead them into other paths. In most cases this process coincides with that of the sublimation (of instinctual aims) with which we are familiar, but in some it can be differentiated from it. Sublimation of instinct is an especially conspicuous feature of cultural development; it is what makes it possible for higher psychical activities, scientific, artistic or ideological, to play such an important part in civilized life. If one were to yield to a first impression, one would say that sublimation is a vicissitude which has been forced upon the instincts entirely by civilization. But it would be wiser to reflect upon this a little longer. In the third place, finally, and this seems the most important of all, it is impossible to overlook the extent to which civilization is built up upon a renunciation of instinct, how much it presupposes precisely the non-satisfaction (by suppression, repression or some other means?) of powerful instincts. This 'cultural frustration' dominates the large field of social relationships between human beings. As we already know, it is the cause of the hostility against which all civilizations have to struggle. It will also make severe demands on our scientific work, and we shall have much to explain here. It is not easy to understand how it can become possible to deprive an instinct of satisfaction. Nor is doing so without danger. If the loss is not compensated for economically, one can be certain that serious disorders will ensue.

[1930a, 4494]
We find ourselves on firmer ground when we investigate the manner in which the life of the instincts serves the sexual function. Here we have acquired quite definite knowledge, with which you too are already familiar. It is not the case, then, that we recognize a sexual instinct which is from the first the vehicle of an urge towards the aim of the sexual function - the union of the two sex-cells. What we see is a great number of component instincts arising from different areas and regions of the body, which strive for satisfaction fairly independently of one another and find that satisfaction in something that we may call 'organ-pleasure'. The genitals are the latest of these 'erotogenic zones' and the name of 'sexual' pleasure cannot be withheld from their organ-pleasure. These impulses which strive for pleasure are not all taken up into the final organization of the sexual function. A number of them are set aside as unserviceable, by repression or some other means; a few of them are diverted from their aim in the remarkable manner I have mentioned and used to strengthen other impulses; yet others persist in minor roles, and serve for the performance of introductory acts, for the production of fore-pleasure. You have heard how in the course of this long-drawn-out development several phases of preliminary organization can be recognized and also how this history of the sexual function explains its aberrations and atrophies. The first of these 'pregenital' phases is known to us as the oral one because, in conformity with the way in which an infant in arms is nourished, the erotogenic zone of the mouth dominates what may be called the sexual activity of that period of life. At a second level the sadistic and anal impulses come to the fore, undoubtedly in connection with the appearance of the teeth, the strengthening of the muscular apparatus and the control of the sphincter functions. We have learnt a number of interesting details about this remarkable stage of development in particular. Thirdly comes the phallic phase in which in both sexes the male organ (and what corresponds to it in girls) attains an importance which can no longer be overlooked. We have reserved the name of genital phase for the definitive sexual organization which is established after puberty and in which the female genital organ for the first time meets with the recognition which the male one acquired long before.

[1933a, 4703]
Among these wishful impulses derived from infancy, which can neither be destroyed nor inhibited, there are some whose fulfilment would be a contradiction of the purposive ideas of secondary thinking. The fulfilment of these wishes would no longer generate an affect of pleasure but of unpleasure; and it is precisely this transformation of affect which constitutes the essence of what we term 'repression'. The problem of repression lies in the question of how it is and owing to what motive forces that this transformation occurs; but it is a problem that we need only touch upon here. It is enough for us to be clear that a transformation of this kind does occur in the course of development - we have only to recall the way in which disgust emerges in childhood after having been absent to begin with - and that it is related to the activity of the secondary system. The memories on the basis of which the unconscious wish brings about the release of affect were never accessible to the $\text{Pcs.}$, and consequently the release of the affect attaching to those memories cannot be inhibited either. It is for the very reason of this generation of affect that these ideas are now inaccessible even by way of the preconscious thoughts on to which they have transferred their wishful force. On the contrary, the unpleasure principle takes control and causes the $\text{Pcs.}$ to turn away from the transference thoughts. They are left to themselves - 'repressed' - and thus it is that the presence of a store of infantile memories, which has from the first been held back from the $\text{Pcs.}$, becomes a *sine qua non* for repression.

[1900a, 1031]

**SEXUAL INHIBITIONS** It is during this period of total or only partial latency that are built up the mental forces which are later to impede the course of the sexual instinct and, like dams, restrict its flow - disgust, feelings of shame and the claims of aesthetic and moral ideals. One gets an impression from civilized children that the construction of these dams is a product of education, and no doubt education has much to do with it. But in reality this development is organically determined and fixed by heredity, and it can occasionally occur without any help at all from education. Education will not be trespassing beyond its appropriate domain if it limits itself to following the lines which have already been laid down organically and to impressing them somewhat more clearly and deeply.

[1905d, 1500]

**REACTION-FORMATION AND SUBLIMATION** What is it that goes to the making of these constructions which are so important for the growth of a civilized and normal individual? They probably emerge at the cost of the infantile sexual impulses themselves. Thus the activity of those impulses does not cease even during this period of latency, though their energy is diverted, wholly or in great part, from their sexual use and directed to other ends. Historians of civilization appear to be at one in assuming that powerful components are acquired for every kind of cultural achievement by this diversion of sexual instinctual forces from sexual aims and their direction to new ones - a process which deserves the name of 'sublimation'. To this we would add, accordingly, that the same process plays a part in the development of the individual and we would place its beginning in the period of sexual latency of childhood.¹

[1905d, 1500]

It is possible further to form some idea of the mechanism of this process of sublimation. On the one hand, it would seem, the sexual impulses cannot be utilized during these years of childhood, since the reproductive functions have been deferred - a fact which constitutes the main feature of the period of latency. On the other hand, these impulses would seem in themselves to be perverse - that is, to arise from erotogenic zones and to derive their activity from instincts which, in view of the direction of the subject's development, can only arouse unpleasurable feelings. They consequently evoke opposing mental forces (reacting impulses) which, in order to suppress this unpleasure effectively, build up the mental dams that have already mentioned - disgust, shame and morality.²

[1905d, 1500]
INTERRUPTIONS OF THE LATENCY PERIOD  We must not deceive ourselves as to the hypothetical nature and insufficient clarity of our knowledge concerning the processes of the infantile period of latency or deferment; but we shall be on firmer ground in pointing out that such an application of infantile sexuality represents an educational ideal from which individual development usually diverges at some point and often to a considerable degree. From time to time a fragmentary manifestation of sexuality which has evaded sublimation may break through; or some sexual activity may persist through the whole duration of the latency period until the sexual instinct emerges with greater intensity at puberty. In so far as educators pay any attention at all to infantile sexuality, they behave exactly as though they shared our views as to the construction of the moral defensive forces at the cost of sexuality, and as though they knew that sexual activity makes a child ineducable: for they stigmatize every sexual manifestation by children as a 'vice', without being able to do much against it. We, on the other hand, have every reason for turning our attention to these phenomena which are so much dreaded by education, for we may expect them to help us to discover the original configuration of the sexual instincts.

[1905d, 1501]

POLYMORPHOUSLY PERVERSE DISPOSITION  It is an instructive fact that under the influence of seduction children can become polymorphously perverse, and can be led into all possible kinds of sexual irregularities. This shows that an aptitude for them is innately present in their disposition. There is consequently little resistance towards carrying them out, since the mental dams against sexual excesses - shame, disgust and morality - have either not yet been constructed at all or are only in course of construction, according to the age of the child. In this respect children behave in the same kind of way as an average uncultivated woman in whom the same polymorphously perverse disposition persists. Under ordinary conditions she may remain normal sexually, but if she is led on by a clever seducer she will find every sort of perversion to her taste, and will retain them as part of her own sexual activities. Prostitutes exploit the same polymorphous, that is, infantile, disposition for the purposes of their profession; and, considering the immense number of women who are prostitutes or who must be supposed to have an aptitude for prostitution without becoming engaged in it, it becomes impossible not to recognize that this same disposition to perversions of every kind is a general and fundamental human characteristic.

[1905d, 1510]
COMPONENT INSTINCTS Moreover, the effects of seduction do not help to reveal the early history of the sexual instinct; they rather confuse our view of it by presenting children prematurely with a sexual object for which the infantile sexual instinct at first shows no need. It must, however, be admitted that infantile sexual life, in spite of the preponderating dominance of erotogenic zones, exhibits components which from the very first involve other people as sexual objects. Such are the instincts of scopophilia, exhibitionism and cruelty, which appear in a sense independently of erotogenic zones; these instincts do not enter into intimate relations with genital life until later, but are already to be observed in childhood as independent impulses, distinct in the first instance from erotogenic sexual activity. Small children are essentially without shame, and at some periods of their earliest years show an unmistakable satisfaction in exposing their bodies, with especial emphasis on the sexual parts. The counterpart of this supposedly perverse inclination, curiosity to see other people’s genitals, probably, does not become manifest until somewhat later in childhood, when the obstacle set up by a sense of shame has already reached a certain degree of development. Under the influence of seduction the scopophilic perversion can attain great importance in the sexual life of a child. But my researches into the early years of normal people, as well as of neurotic patients, force me to the conclusion that scopophilia can also appear in children as a spontaneous manifestation. Small children whose attention has once been drawn - as a rule by masturbation - to their own genitals usually take the further step without help from outside and develop a lively interest in the genitals of their playmates. Since opportunities for satisfying curiosity of this kind usually occur only in the course of satisfying the two kinds of need for excretion, children of this kind turn into voyeurs, eager spectators of the processes of micturition and defaecation. When repression of these inclinations sets in, the desire to see other people's genitals (whether of their own or the opposite sex) persists as a tormenting compulsion, which in some cases of neurosis later affords the strongest motive force for the formation of symptoms. [1905d, 1511]

MECHANICAL EXCITATIONS At this point we must also mention the production of sexual excitation by rhythmic mechanical agitation of the body. Stimuli of this kind operate in three different ways: on the sensory apparatus of the vestibular nerves, on the skin, and on the deeper parts (e.g. the muscles and articular structures). The existence of these pleasurable sensations - and it is worth emphasizing the fact that in this connection the concepts of 'sexual excitation' and 'satisfaction' can to a great extent be used without distinction, a circumstance which we must later endeavour to explain - the existence, then, of these pleasurable sensations, caused by forms of mechanical agitation of the body, is confirmed by the fact that children are so fond of games of passive movement, such as swinging and being thrown up into the air, and insist on such games being incessantly repeated.¹ It is well known that rocking is habitually used to induce sleep in restless children. The shaking produced by driving in carriages and later by railway-travel exercises such a fascinating effect upon older children that every boy, at any rate, has at one time or other in his life wanted to be an engine driver or a coachman. It is a puzzling fact that boys take such an extraordinarily intense interest in things connected with railways, and, at the age at which the production of phantasies is most active (shortly before puberty), use those things as the nucleus of a symbolism that is peculiarly sexual. A compulsive link of this kind between railway-travel and sexuality is clearly derived from the pleasurable character of the sensations of movement. In the event of repression, which turns so many childish preferences into their opposite, these same individuals, when they are adolescents or adults, will react to rocking or swinging with a feeling of nausea, will be terribly exhausted by a railway journey, or will be subject to attacks of anxiety on the journey and will protect themselves against a repetition of the painful experience by a dread of railway-travel. [1905d, 1520]
As we all know, it is not until puberty that the sharp distinction is established between the masculine and feminine characters. From that time on, this contrast has a more decisive influence than any other upon the shaping of human life. It is true that the masculine and feminine dispositions are already easily recognizable in childhood. The development of the inhibitions of sexuality (shame, disgust, pity, etc.) takes place in little girls earlier and in the face of less resistance than in boys; the tendency to sexual repression seems in general to be greater; and, where the component instincts of sexuality appear, they prefer the passive form. The auto-erotic activity of the erogenous zones is, however, the same in both sexes, and owing to this uniformity there is no possibility of a distinction between the two sexes such as arises after puberty. So far as the auto-erotic and masturbatory manifestations of sexuality are concerned, we might lay it down that the sexuality of little girls is of a wholly masculine character. Indeed, if we were able to give a more definite connotation to the concepts of 'masculine' and 'feminine', it would even be possible to maintain that libido is invariably and necessarily of a masculine nature, whether it occurs in men or in women and irrespective of whether its object is a man or a woman.¹

[1905d, 1533]

THE BARRIER AGAINST INCEST We see, therefore, that the parents' affection for their child may awaken his sexual instinct prematurely (i.e. before the somatic conditions of puberty are present) to such a degree that the mental excitation breaks through in an unmistakable fashion to the genital system. If, on the other hand, they are fortunate enough to avoid this, then their affection can perform its task of directing the child in his choice of a sexual object when he reaches maturity. No doubt the simplest course for the child would be to choose as his sexual objects the same persons whom, since his childhood, he has loved with what may be described as damped-down libido.¹ But, by the postponing of sexual maturation, time has been gained in which the child can erect, among other restraints on sexuality, the barrier against incest, and can thus take up into himself the moral precepts which expressly exclude from his object-choice, as being blood relations, the persons whom he has loved in his childhood. Respect for this barrier is essentially a cultural demand made by society. Society must defend itself against the danger that the interests which it needs for the establishment of higher social units may be swallowed up by the family; and for this reason, in the case of every individual, but in particular of adolescent boys, it seeks by all possible means to loosen their connection with their family - a connection which, in their childhood, is the only important one.²

[1905d, 1538]
The time has arrived for me to attempt to summarize what I have said. We started out from the aberrations of the sexual instinct in respect of its object and of its aim and we were faced by the question of whether these arise from an innate disposition or are acquired as a result of experiences in life. We arrived at an answer to this question from an understanding, derived from psycho-analytic investigation, of the workings of the sexual instinct in psychoneurotics, a numerous class of people and one not far removed from the healthy. We found that in them tendencies to every kind of perversion can be shown to exist as unconscious forces and betray their presence as factors leading to the formation of symptoms. It was thus possible to say that neurosis is, as it were, the negative of perversion. In view of what was now seen to be the wide dissemination of tendencies to perversion we were driven to the conclusion that a disposition to perversions is an original and universal disposition of the human sexual instinct and that normal sexual behaviour is developed out of it as a result of organic changes and psychical inhibitions occurring in the course of maturation; we hoped to be able to show the presence of this original disposition in childhood. Among the forces restricting the direction taken by the sexual instinct we laid emphasis upon shame, disgust, pity and the structures of morality and authority erected by society. We were thus led to regard any established aberration from normal sexuality as an instance of developmental inhibition and infantilism. Though it was necessary to place in the foreground the importance of the variations in the original disposition, a co-operative and not an opposing relation was to be assumed as existing between them and the influences of actual life. It appeared, on the other hand, that since the original disposition is necessarily a complex one, the sexual instinct itself must be something put together from various factors, and that in the perversions it falls apart, as it were, into its components. The perversions were thus seen to be on the one hand inhibitions, and on the other hand dissociations, of normal development. Both these aspects were brought together in the supposition that the sexual instinct of adults arises from a combination of a number of impulses of childhood into a unity, an impulsion with a single aim.
[1905d, 1542]
After having explained the preponderance of perverse tendencies in psychoneurotics by recognizing it as a collateral filling of subsidiary channels when the main current of the instinctual stream has been blocked by 'repression',¹ we proceeded to a consideration of sexual life in childhood. We found it a regrettable thing that the existence of the sexual instinct in childhood has been denied and that the sexual manifestations not infrequently to be observed in children have been described as irregularities. It seemed to us on the contrary that children bring germs of sexual activity with them into the world, that they already enjoy sexual satisfaction when they begin to take nourishment and that they persistently seek to repeat the experience in the familiar activity of 'thumb-sucking'. The sexual activity of children, however, does not, it appeared, develop pari passu with their other functions, but, after a short period of efflorescence from the ages of two to five, enters upon the so-called period of latency. During that period the production of sexual excitation is not by any means stopped but continues and produces a store of energy which is employed to a great extent for purposes other than sexual - namely, on the one hand in contributing the sexual components to social feelings and on the other hand (through repression and reaction-forming) in building up the subsequently developed barriers against sexuality. On this view, the forces destined to retain the sexual instinct upon certain lines are built up in childhood chiefly at the cost of perverse sexual impulses and with the assistance of education. A certain portion of the infantile sexual impulses would seem to evade these uses and succeed in expressing itself as sexual activity. We next found that sexual excitation in children springs from a multiplicity of forces. Satisfaction arises first and foremost from the appropriate sensory excitation of what we have described as erotogenic zones. It seems probable that any part of the skin and any sense-organ - probably, indeed, any organ - can function as an erotogenic zone, though there are some particularly marked erotogenic zones whose excitation would seem to be secured from the very first by certain organic contrivances. It further appears that sexual excitation arises as a by-product, as it were, of a large number of processes that occur in the organism, as soon as they reach a certain degree of intensity, and most especially of any relatively powerful emotion, even though it is of a distressing nature. The excitations from all these sources are not yet combined; but each follows its own separate aim, which is merely the attainment of a certain sort of pleasure. In childhood, therefore, the sexual instinct is not unified and is at first without an object, that is, auto-erotic.

1905d, 1543

The third alternative result of an abnormal constitutional disposition is made possible by the process of sublimation. This enables excessively strong excitations arising from particular sources of sexuality to find an outlet and use in other fields, so that a not inconsiderable increase in psychical efficiency results from a disposition which is itself perilous. Here we have one of the origins of artistic activity; and, according to the completeness or incompleteness of the sublimation, a characterological analysis of a highly gifted individual, and in particular of one with an artistic disposition, may reveal a mixture, in every proportion, of efficiency, perversion and neurosis. A sub-species of sublimation is to be found in suppression by reaction-formation, which, as we have seen, begins during a child's period of latency and continues in favourable cases throughout his whole life. What we describe as a person's ‘character’ is built up to a considerable extent from the material of sexual excitations and is composed of instincts that have been fixed since childhood, of constructions achieved by means of sublimation, and of other constructions, employed for effectively holding in check perverse impulses which have been recognized as being unutilizable.¹ The multifariously perverse sexual disposition of childhood can accordingly be regarded as the source of a number of our virtues, in so far as through reaction-formation it stimulates their development.²

1905d, 1549
PRECOCITY One such factor is spontaneous sexual precocity, whose presence at least can be demonstrated with certainty in the aetiology of the neuroses though, like other factors, it is not in itself a sufficient cause. It is manifested in the interruption, abbreviation or bringing to an end of the infantile period of latency; and it is a cause of disturbances by occasioning sexual manifestations which, owing on the one hand to the sexual inhibitions being incomplete and on the other hand to the genital system being undeveloped, are bound to be in the nature of perversions. These tendencies to perversion may thereafter either persist as such or, after repressions have set in, become the motive forces of neurotic symptoms. In any case sexual precocity makes more difficult the later control of the sexual instinct by the higher mental agencies which is so desirable, and it increases the impulsive quality which, quite apart from this, characterizes the psychical representations of the instinct. Sexual precocity often runs parallel with premature intellectual development and, linked in this way, is to be found in the childhood history of persons of the greatest eminence and capacity; under such conditions its effects do not seem to be so pathogenic as when it appears in isolation.
[1905d, 1551]

It can only help to clarify things if at this point we go back to fundamental facts. A desire to see the organs peculiar to each sex exposed is one of the original components of our libido. It may itself be a substitute for something earlier and go back to a hypothetical primary desire to touch the sexual parts. As so often, looking has replaced touching.¹ The libido for looking and touching is present in everyone in two forms, active and passive, male and female; and, according to the preponderance of the sexual character, one form or the other predominates. It is easy to observe the inclination to self-exposure in young children. In cases in which the germ of this inclination escapes its usual fate of being buried and suppressed, it develops in men into the familiar perversion known as exhibitionism. In women the inclination to passive exhibitionism is almost invariably buried under the imposing reactive function of sexual modesty, but not without a loophole being left for it in relation to clothes. I need only hint at the elasticity and variability in the amount of exhibitionism that women are permitted to retain in accordance with differing convention and circumstances.
[1905c, 1695]
I know that no one is prepared to believe in a state of things so long as it appears to be unintelligible and to offer no angle from which an explanation can be attempted. But we can at least bring the underlying factors nearer to our understanding by the help of the postulates I laid down in my *Three Essays on the Theory of Sexuality* in 1905. I there attempted to show that the sexual instinct of man is highly complex and is put together from contributions made by numerous constituents and component instincts. Important contributions to 'sexual excitation' are furnished by the peripheral excitations of certain specially designated parts of the body (the genitals, mouth, anus, urethra), which therefore deserve to be described as 'erotogenic zones'. But the amounts of excitation coming in from these parts of the body do not all undergo the same vicissitudes, nor is the fate of all of them the same at every period of life. Generally speaking, only a part of them is made use of in sexual life; another part is deflected from sexual aims and directed towards others - a process which deserves the name of 'sublimation'. During the period of life which may be called the period of 'sexual latency' - i.e. from the completion of the fifth year to the first manifestations of puberty (round about the eleventh year) - reaction-formations, or counter-forces, such as shame, disgust and morality, are created in the mind. They are actually formed at the expense of the excitations proceeding from the erotogenic zones, and they rise like dams to oppose the later activity of the sexual instincts. Now anal erotism is one of the components of the instinct which, in the course of development and in accordance with the education demanded by our present civilization, have become unserviceable for sexual aims. It is therefore plausible to suppose that these character-traits of orderliness, parsimony and obstinacy, which are so often prominent in people who were formerly anal erotics, are to be regarded as the first and most constant results of the sublimation of anal erotism.² [1908b, 1943]

Further prospects are opened up when we take into consideration the fact that in man the sexual instinct does not originally serve the purposes of reproduction at all, but has as its aim the gaining of particular kinds of pleasure.¹ It manifests itself in this way in human infancy, during which it attains its aim of gaining pleasure not only from the genitals but from other parts of the body (the erotogenic zones), and can therefore disregard any objects other than these convenient ones. We call this stage the stage of *auto-erotism*, and the child's upbringing has, in our view, the task of restricting it, because to linger in it would make the sexual instinct uncontrollable and unserviceable later on. The development of the sexual instinct then proceeds from auto-erotism to object-love and from the autonomy of the erotogenic zones to their subordination under the primacy of the genitals, which are put at the service of reproduction. During this development a part of the sexual excitation which is provided by the subject's own body is inhibited as being unserviceable for the reproductive function and in favourable cases is brought to sublimation. The forces that can be employed for cultural activities are thus to a great extent obtained through the suppression of what are known as the *perverse* elements of sexual excitation. [1908d, 1953]
Their ignorance of the vagina also makes it possible for children to believe in the second of their sexual theories. If the baby grows in the mother's body and is then removed from it, this can only happen along the one possible pathway - the anal aperture. The baby must be evacuated like a piece of excrement, like a stool. When, in later childhood, the same question is the subject of solitary reflection or of a discussion between two children, the explanations probably arrived at are that the baby emerges from the navel, which comes open, or that the abdomen is slit up and the baby taken out - which was what happened to the wolf in the story of Little Red Riding-Hood. These theories are expressed aloud and also consciously remembered later on; they no longer contain anything objectionable. These same children have by then completely forgotten that in earlier years they believed in another theory of birth, which is now obstructed by the repression of the anal sexual components that has meanwhile occurred. At that time a motion was something which could be talked about in the nursery without shame. The child was still not so distant from his constitutional coprophilic inclinations. There was nothing degraded about coming into the world like a heap of faeces, which had not yet been condemned by feelings of disgust. The cloacal theory, which, after all, is valid for so many animals, was the most natural theory, and it alone could obtrude upon the child as being a probable one. [1908c, 1973]

But Hans was not by any means a bad character; he was not even one of those children who at his age still give free play to the propensity towards cruelty and violence which is a constituent of human nature. On the contrary, he had an unusually kind-hearted and affectionate disposition; his father reported that the transformation of aggressive tendencies into feelings of pity took place in him at a very early age. Long before the phobia he had become uneasy when he saw the horses in a merry-go-round being beaten; and he was never unmoved if any one wept in his presence. At one stage in the analysis a piece of suppressed sadism made its appearance in a particular context;¹ but it was suppressed sadism, and we shall presently have to discover from the content what it stood for and what it was meant to replace. And Hans deeply loved the father against whom he cherished these death-wishes; and while his intellect demurred to such a contradiction,² he could not help demonstrating the fact of its existence, by hitting his father and immediately afterwards kissing the place he had hit. We ourselves, too, must guard against making a difficulty of such a contradiction. The emotional life of man is in general made up of pairs of contraries such as these.³ Indeed, if it were not so, repressions and neuroses would perhaps never come about. In the adult these pairs of contrary emotions do not as a rule become simultaneously conscious except at the climaxes of passionate love; at other times they usually go on suppressing each other until one of them succeeds in keeping the other altogether out of sight. But in children they can exist peaceably side by side for quite a considerable time. [1909b, 2097]

Before I can regard this synthesis as completed I must turn to yet another aspect of the case, which will take us into the very heart of the difficulties that lie in the way of our understanding of neurotic states. We have seen how our little patient was overtaken by a great wave of repression and that it caught precisely those of his sexual components that were dominant.⁴ He gave up masturbation, and turned away in disgust from everything that reminded him of excrement and of looking on at other people performing their natural functions. But these were not the components which were stirred up by the precipitating cause of the illness (his seeing the horse fall down) or which provided the material for the symptoms, that is, the content of the phobia. [1909b, 2117]
¹ Hans's father even observed that simultaneously with this repression a certain amount of sublimation set in. From the time of the beginning of his anxiety Hans began to show an increased interest in music and to develop his inherited musical gift.
[1909b, 2117]

We have no information about the circumstances of his heredity; on the other hand we have seen that the accidental conditions of his childhood had a profound and disturbing effect on him. His illegitimate birth deprived him of his father's influence until perhaps his fifth year, and left him open to the tender seductions of a mother whose only solace he was. After being kissed by her into precocious sexual maturity, he must no doubt have embarked on a phase of infantile sexual activity of which only one single manifestation is definitely attested - the intensity of his infantile sexual researches. The instinct to look and the instinct to know were those most strongly excited by the impressions of his early childhood; the erotogenic zone of the mouth was given an emphasis which it never afterwards surrendered. From his later behaviour in the contrary direction, such as his exaggerated sympathy for animals, we can conclude that there was no lack of strong sadistic traits in this period of his childhood.
[1910c, 2300]

If, then, as we have learnt, psychogenic disturbances of vision depend on certain ideas connected with seeing being cut off from consciousness, we must, on the psycho-analytic view, assume that these ideas have come into opposition to other, more powerful ones, for which we use the collective concept of the 'ego'- a compound which is made up variously at different times - and have for that reason come under repression. But what can be the origin of this opposition, which makes for repression, between the ego and various groups of ideas? You will no doubt notice that it was not possible to frame such a question before the advent of psycho-analysis, for nothing was known earlier of psychical conflict and repression. Our researches, however, have put us in a position to give us the desired answer. Our attention has been drawn to the importance of the instincts in ideational life. We have discovered that every instinct tries to make itself effective by activating ideas that are in keeping with its aims. These instincts are not always compatible with one another; their interests often come into conflict. Opposition between ideas is only an expression of struggles between the various instincts. From the point of view of our attempted explanation, a quite specially important part is played by the undeniable opposition between the instincts which subserve sexuality, the attainment of sexual pleasure, and those other instincts, which have as their aim the self-preservation of the individual - the ego-instincts. As the poet has said, all the organic instincts that operate in our mind may be classified as 'hunger' or 'love'. We have traced the 'sexual instinct' from its first manifestations in children to its final form, which is described as 'normal'. We have found that it is put together from numerous 'component instincts' which are attached to excitations of regions of the body; and we have come to see that these separate instincts have to pass through a complicated development before they can be brought effectively to serve the aims of reproduction. The light thrown by psychology on the evolution of our civilization has shown us that it originates mainly at the cost of the sexual component instincts, and that these must be suppressed, restricted, transformed and directed to higher aims, in order that the mental constructions of civilization may be established. We have been able to recognize as a valuable outcome of these researches something that our colleagues have not yet been willing to believe, namely that the human ailments known as 'neuroses' are derived from the many different ways in which these processes of transformation in the sexual component instincts may miscarry. The 'ego' feels threatened by the claims of the sexual instincts and fends them off by repressions; these, however, do not always have the desired result, but lead to the formation of dangerous substitutes for the repressed and to burdensome reactions on the part of the ego. From these two classes of phenomena taken together there emerge what we call the symptoms of neuroses.
[1910i, 2368]
Psycho-analysis has taught us that in the very earliest period of childhood faeces is a highly prized substance, in relation to which coprophilic instincts find satisfaction. With the repression of these instincts, which is accelerated as much as possible by up-bringing, this substance falls into contempt and then serves conscious purposes as a means of expressing disdain and scorn. Certain forms of mental activity such as joking are still able to make the obstructed source of pleasure accessible for a brief moment, and thus show how much of the esteem in which human beings once held their faeces still remains preserved in the unconscious. The most important residue of this former esteem is, however, that all the interest which the child has had in faeces is transferred in the adult on to another material which he learns in life to set above almost everything else - gold.¹ How old this connection between excrement and gold is can be seen from an observation by Jeremias:² gold, according to ancient oriental mythology, is the excrement of hell.³

At this point a portion of our case history fits in, which I have so far kept back. The patient's sexual life began in her earliest childhood with beating-phantasies. After they were suppressed, an unusually long period of latency set in, during which the girl passed through a period of exalted moral growth, without any awakening of female sexual feelings. Her marriage, which took place at an early age, opened a time of normal sexual activity. This period, during which she was a happy wife, continued for a number of years, until her first great frustration brought on the hysterical neurosis. When this was followed by her genital life losing all its value, her sexual life, as I have said, returned to the infantile stage of sadism.

When educators have become familiar with the findings of psycho-analysis, it will be easier for them to reconcile themselves to certain phases of infantile development and they will, among other things, not be in danger of over-estimating the importance of the socially unserviceable or perverse instinctual impulses which emerge in children. On the contrary they will refrain from any attempt at forcibly suppressing such impulses, when they learn that efforts of this kind often produce no less undesirable results than the alternative, which is so much dreaded by educators, of giving free play to children's naughtiness. The forcible suppression of strong instincts by external means never has the effect in a child of these instincts being extinguished or brought under control; it leads to repression, which establishes a predisposition to later nervous illness. Psycho-analysis has frequent opportunities of observing the part played by inopportune and undiscerning severity of upbringing in the production of neuroses, or the price, in loss of efficiency and of capacity for enjoyment, which has to be paid for the normality upon which the educator insists. And psycho-analysis can also show what precious contributions to the formation of character are made by these asocial and perverse instincts in the child, if they are not subjected to repression but are diverted from their original aims to more valuable ones by the process known as 'sublimation'. Our highest virtues have grown up, as reaction formations and sublimations, out of our worst dispositions. Education should scrupulously refrain from burying these precious springs of action and should restrict itself to encouraging the processes by which these energies are led along safe paths. Whatever we can expect in the way of prophylaxis against neurosis in the individual lies in the hands of a psycho-analytically enlightened education.¹

For the sake of completeness I may add that feelings of pity cannot be described as a result of a transformation of instinct occurring in sadism, but necessitate the notion of a reaction-formation against that instinct. (For the difference, see later.)
The Diphasic Onset of Sexual Development. - Towards the end of the fifth year this early period of sexual life normally comes to an end. It is succeeded by a period of more or less complete latency, during which ethical restraints are built up, to act as defences against the desires of the Oedipus complex. In the subsequent period of puberty, the Oedipus complex is revivified in the unconscious and embarks upon further modifications. It is only at puberty that the sexual instincts develop to their full intensity; but the direction of that development, as well as all the predispositions for it, have already been determined by the early efflorescence of sexuality during childhood which preceded it. This diphasic development of the sexual function - in two stages, interrupted by the latency period - appears to be a biological peculiarity of the human species and to contain the determining factor for the origin of neuroses. [1923a, 3923]

I have described elsewhere how this turning away takes place. The object-cathexes are given up and replaced by identifications. The authority of the father or the parents is introjected into the ego, and there it forms the nucleus of the super-ego, which takes over the severity of the father and perpetuates his prohibition against incest, and so secures the ego from the return of the libidinal object-cathexis. The libidinal trends belonging to the Oedipus complex are in part desexualized and sublimated (a thing which probably happens with every transformation into an identification) and in part inhibited in their aim and changed into impulses of affection. The whole process has, on the one hand, preserved the genital organ - has averted the danger of its loss - and, on the other, has paralysed it - has removed its function. This process ushers in the latency period, which now interrupts the child's sexual development. [1924d, 4088]
The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-erotism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother's organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors' own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child's first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child's life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child's early years become re-animated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of 'male' or 'female' but of 'possessing a penis' or 'castrated'. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses.

[1925d, 4212]
In enforcing regression, the ego scores its first success in its defensive struggle against the demands of the libido. (In this connection it is of advantage to distinguish the more general notion of 'defence' from 'repression'. Repression is only one of the mechanisms which defence makes use of.) It is perhaps in obsessional cases more than in normal or hysterical ones that we can most clearly recognize that the motive force of defence is the castration complex and that what is being fended off are the trends of the Oedipus complex. We are at present dealing with the beginning of the latency period, a period which is characterized by the dissolution of the Oedipus complex, the creation or consolidation of the super-ego and the erection of ethical and aesthetic barriers in the ego. In obsessional neuroses these processes are carried further than is normal. In addition to the destruction of the Oedipus complex a regressive degradation of the libido takes place, the super-ego becomes exceptionally severe and unkind, and the ego, in obedience to the super-ego, produces strong reaction-formations in the shape of conscientiousness, pity and cleanliness. Implacable, though not always on that account successful, severity is shown in condemning the temptation to continue early infantile masturbation, which now attaches itself to regressive (sadistic-anal) ideas but which nevertheless represents the unsubjugated part of the phallic organization. There is an inherent contradiction about this state of affairs, in which, precisely in the interests of masculinity (that is to say, from fear of castration), every activity belonging to masculinity is stopped. But here, too, obsessional neurosis is only overdoing the normal method of getting rid of the Oedipus complex. We once more find here an illustration of the truth that every exaggeration contains the seed of its own undoing. For, under the guise of obsessional acts, the masturbation that has been suppressed approaches ever more closely to satisfaction.

An important element in the theory of repression is the view that repression is not an event that occurs once but that it requires a permanent expenditure. If this expenditure were to cease, the repressed impulse, which is being fed all the time from its sources, would on the next occasion flow along the channels from which it had been forced away, and the repression would either fail in its purpose or would have to be repeated an indefinite number of times. Thus it is because instincts are continuous in their nature that the ego has to make its defensive action secure by a permanent expenditure. This action undertaken to protect repression is observable in analytic treatment as resistance. Resistance presupposes the existence of what I have called anticathexis. An anticathexis of this kind is clearly seen in obsessional neurosis. It appears there in the form of an alteration of the ego, as a reaction-formation in the ego, and is effected by the reinforcement of the attitude which is the opposite of the instinctual trend that has to be repressed - as, for instance, in pity, conscientiousness and cleanliness. These reaction-formations of obsessional neurosis are essentially exaggerations of the normal traits of character which develop during the latency period. The presence of an anticathexis in hysteria is much more difficult to detect, though theoretically it is equally indispensable. In hysteria, too, a certain amount of alteration of the ego through reaction-formation is unmistakable and in some circumstances becomes so marked that it forces itself on our attention as the principal symptom. The conflict due to ambivalence, for instance, is resolved in hysteria by this means. The subject's hatred of a person whom he loves is kept down by an exaggerated amount of tenderness for him and apprehensiveness about him. But the difference between reaction-formations in obsessional neurosis and in hysteria is that in the latter they do not have the universality of a character-trait but are confined to particular relationships. A hysterical woman, for instance, may be specially affectionate with her own children whom at bottom she hates; but she will not on that account be more loving in general than other women or even more affectionate to other children. The reaction-formation of hysteria clings tenaciously to a particular object and never spreads over into a general disposition of the ego, whereas what is characteristic of obsessional neurosis is precisely a spreading-over of this kind - a loosening of relations to the object and a facilitation of displacement in the choice of object.
Then I will pursue the subject further; in any case it is not easy for me to get away from it. I will
tell you, then, that the most remarkable thing about the sexual life of children seems to me that
it passes through the whole of its very far-reaching development in the first five years of life.
From then onwards until puberty there stretches what is known as the period of latency. During
it sexuality normally advances no further; on the contrary, the sexual urges diminish in strength
and many things are given up and forgotten which the child did and knew. During that period of
life, after the early efflorescence of sexuality has withered, such attitudes of the ego as shame,
disgust and morality arise, which are destined to stand up against the later tempest of puberty
and to lay down the path of the freshly awakening sexual desires. This 'diphasic onset', as it is
named, of sexual life has a great deal to do with the genesis of neurotic illnesses. It seems to
occur only in human beings, and it is perhaps one of the determinants of the human privilege of
becoming neurotic. The prehistory of sexual life was just as much overlooked before psycho-
analysis as, in another department, the background to conscious mental life. You will rightly
suspect that the two are intimately connected.
[1926e, 4353]
THE BARRIER AGAINST INCEST  We see, therefore, that the parents' affection for their child may awaken his sexual instinct prematurely (i.e. before the somatic conditions of puberty are present) to such a degree that the mental excitation breaks through in an unmistakable fashion to the genital system. If, on the other hand, they are fortunate enough to avoid this, then their affection can perform its task of directing the child in his choice of a sexual object when he reaches maturity. No doubt the simplest course for the child would be to choose as his sexual objects the same persons whom, since his childhood, he has loved with what may be described as damped-down libido.¹ But, by the postponing of sexual maturation, time has been gained in which the child can erect, among other restraints on sexuality, the barrier against incest, and can thus take up into himself the moral precepts which expressly exclude from his object-choice, as being blood relations, the persons whom he has loved in his childhood. Respect for this barrier is essentially a cultural demand made by society. Society must defend itself against the danger that the interests which it needs for the establishment of higher social units may be swallowed up by the family; and for this reason, in the case of every individual, but in particular of adolescent boys, it seeks by all possible means to loosen their connection with their family - a connection which, in their childhood, is the only important one.²

² [Footnote added 1915:] The barrier against incest is probably among the historical acquisitions of mankind, and, like other moral taboos, has no doubt already become established in many persons by organic inheritance. (Cf. my Totem and Taboo, 1912-13.) Psycho-analytic investigation shows, however, how intensely the individual struggles with the temptation to incest during his period of growth and how frequently the barrier is transgressed in phantasies and even in reality.

In spite of the gaps in our knowledge of infantile sexual life, we had to proceed to an attempt at examining the alterations brought about in it by the arrival of puberty. We selected two of these as being the decisive ones: the subordination of all the other sources of sexual excitation under the primacy of the genital zones and the process of finding an object. Both of these are already adumbrated in childhood. The first is accomplished by the mechanism of exploiting fore-pleasure: what were formerly self-contained sexual acts, attended by pleasure and excitation, become acts preparatory to the new sexual aim (the discharge of the sexual products), the attainment of which, enormously pleasurable, brings the sexual excitation to an end. In this connection we had to take into account the differentiation of sexuality into masculine and feminine; and we found that in order to become a woman a further stage of repression is necessary, which discards a portion of infantile masculinity and prepares the woman for changing her leading genital zone. As regards object-choice, we found that it is given its direction by the childhood hints (revived at puberty) of the child's sexual inclination towards his parents and others in charge of him, but that it is diverted away from them, on to other people who resemble them, owing to the barrier against incest which has meanwhile been erected. Finally it must be added that during the transition period of puberty the processes of somatic and of psychical development continue for a time side by side independently, until the irruption of an intense mental erotic impulse, leading to the innervation of the genitals, brings about the unity of the erotic function which is necessary for normality.

A most suitable continuation of the giraffe phantasy. He had a suspicion that to take possession of his mother was forbidden; he had come up against the barrier against incest. But he regarded it as forbidden in itself. His father was with him each time in the forbidden exploits which he carried out in his imagination, and was locked up with him. His father, he thought, also did that enigmatic forbidden something with his mother which he replaced by an act of violence such as smashing a window-pane or forcing a way into an enclosed space.
Let us return to the sexual development of children. We have some arrears to make up owing to our having paid more attention to the somatic than to the mental phenomena of sexual life. The child's first choice of an object, which derives from its need for help, claims our further interest. Its choice is directed in the first instance to all those who look after it, but these soon give place to its parents. Children's relations to their parents, as we learn alike from direct observations of children and from later analytic examination of adults, are by no means free from elements of accompanying sexual excitation. The child takes both of its parents, and more particularly one of them, as the object of its erotic wishes. In so doing, it usually follows some indication from its parents, whose affection bears the clearest characteristics of a sexual activity, even though of one that is inhibited in its aims. As a rule a father prefers his daughter and a mother her son; the child reacts to this by wishing, if he is a son, to take his father's place, and, if she is a daughter, her mother's. The feelings which are aroused in these relations between parents and children and in the resulting ones between brothers and sisters are not only of a positive or affectionate kind but also of a negative or hostile one. The complex which is thus formed is doomed to early repression; but it continues to exercise a great and lasting influence from the unconscious. It is to be suspected that, together with its extensions, it constitutes the nuclear complex of every neurosis, and we may expect to find it no less actively at work in other regions of mental life. The myth of King Oedipus, who killed his father and took his mother to wife, reveals, with little modification, the infantile wish, which is later opposed and repudiated by the barrier against incest. Shakespeare's Hamlet is equally rooted in the soil of the incest-complex, but under a better disguise.

These affectionate fixations of the child persist throughout childhood, and continually carry along with them erotism, which is consequently diverted from its sexual aims. Then at the age of puberty they are joined by the powerful 'sensual' current which no longer mistakes its aims. It never fails, apparently, to follow the earlier paths and to cathect the objects of the primary infantile choice with quotas of libido that are now far stronger. Here, however, it runs up against the obstacles that have been erected in the meantime by the barrier against incest; consequently it will make efforts to pass on from these objects which are unsuitable in reality, and find a way as soon as possible to other, extraneous objects with which a real sexual life may be carried on. These new objects will still be chosen on the model (imago) of the infantile ones, but in the course of time they will attract to themselves the affection that was tied to the earlier ones. A man shall leave his father and his mother - according to the biblical command - and shall cleave unto his wife; affection and sensuality are then united. The greatest intensity of sensual passion will bring with it the highest psychical valuation of the object - this being the normal overvaluation of the sexual object on the part of a man.

We have reduced psychical impotence to the failure of the affectionate and the sensual currents in love to combine, and this developmental inhibition has in turn been explained as being due to the influences of strong childhood fixations and of later frustration in reality through the intervention of the barrier against incest. There is one principal objection to the theory we advance; it does too much. It explains why certain people suffer from psychical impotence, but it leaves us with the apparent mystery of how others have been able to escape this disorder. Since we must recognize that all the relevant factors known to us - the strong childhood fixation, the incest-barrier and the frustration in the years of development after puberty - are to be found in practically all civilized human beings, we should be justified in expecting psychical impotence to be a universal affliction under civilization and not a disorder confined to some individuals.
I do not hesitate to make the two factors at work in psychical impotence in the strict sense - the factors of intense incestuous fixation in childhood and the frustration by reality in adolescence - responsible, too, for this extremely common characteristic of the love of civilized men. It sounds not only disagreeable but also paradoxical, yet it must nevertheless be said that anyone who is to be really free and happy in love must have surmounted his respect for women and have come to terms with the idea of incest with his mother or sister. Anyone who subjects himself to a serious self-examination on the subject of this requirement will be sure to find that he regards the sexual act basically as something degrading, which defiles and pollutes not only the body. The origin of this low opinion, which he will certainly not willingly acknowledge, must be looked for in the period of his youth in which the sensual current in him was already strongly developed but its satisfaction with an object outside the family was almost as completely prohibited as it was with an incestuous one.
[1912d, 2343]

It is my belief that, however strange it may sound, we must reckon with the possibility that something in the nature of the sexual instinct itself is unfavourable to the realization of complete satisfaction. If we consider the long and difficult developmental history of the instinct, two factors immediately spring to mind which might be made responsible for this difficulty. Firstly, as a result of the diphasic onset of object-choice, and the interposition of the barrier against incest, the final object of the sexual instinct is never any longer the original object but only a surrogate for it. Psycho-analysis has shown us that when the original object of a wishful impulse has been lost as a result of repression, it is frequently represented by an endless series of substitutive objects none of which, however, brings full satisfaction. This may explain the inconstancy in object-choice, the 'craving for stimulation' which is so often a feature of the love of adults.
[1912d, 2345]

A man's relation to his mother-in-law is complicated by similar impulses, though they have another source. It is regularly found that he chose his mother as the object of his love, and perhaps his sister as well, before passing on to his final choice. Because of the barrier that exists against incest, his love is deflected from the two figures on whom his affection was centred in his childhood on to an outside object that is modelled upon them. The place of his own and his sister's mother is taken by his mother-in-law. He has an impulse to fall back upon his original choice, though everything in him fights against it. His horror of incest insists that the genealogical history of his choice of an object for his love shall not be recalled. His repudiation of this impulse is also facilitated by the fact that his mother-in-law is only a contemporary figure; he has not known her all his life, so that there is no unchangeable picture of her preserved in his unconscious. A streak of irritability and malevolence that is apt to be present in the medley of his feelings leads us to suspect that she does in fact offer him a temptation to incest; and this is confirmed by the not uncommon event of a man openly falling in love with the woman who is later to be his mother-in-law before transferring his love to her daughter.
[1912-1913, 2664]

But the fact that exogamous sexual restrictions were imposed intentionally throws no light on the motive which led to their imposition. What is the ultimate source of the horror of incest which must be recognized as the root of exogamy? To explain it by the existence of an instinctive dislike of sexual intercourse with blood relatives - that is to say, by an appeal to the fact that there is a horror of incest - is clearly unsatisfactory; for social experience shows that, in spite of this supposed instinct, incest is no uncommon event even in our present-day society, and history tells us of cases in which incestuous marriage between privileged persons was actually the rule.
[1912-1913, 2763]
It seems to me very remarkable that Westermarck should consider that this innate aversion to sexual intercourse with those with whom one has been intimate in childhood is also the equivalent in psychical terms of the biological fact that inbreeding is detrimental to the species. A biological instinct of the kind suggested would scarcely have gone so far astray in its psychological expression that, instead of applying to blood relatives (intercourse with whom might be injurious to reproduction), it affected persons who were totally innocuous in this respect, merely because they shared a common home. I cannot resist referring, too, to Frazer's admirable criticism of Westermarck's theory. Frazer finds it inexplicable that to-day there should be scarcely any sexual aversion to intercourse with house-mates, whereas the horror of incest, which on Westermarck's theory is only a derivative of that aversion, should have increased so enormously. But some further comments of Frazer's go deeper, and these I shall reproduce in full, since they are in essential agreement with the arguments which I put forward in my essay on taboo:

[1912-1913, 2764]

I may add to these excellent arguments of Frazer's that the findings of psycho-analysis make the hypothesis of an innate aversion to incestuous intercourse totally untenable. They have shown, on the contrary, that the earliest sexual excitations of youthful human beings are invariably of an incestuous character and that such impulses when repressed play a part that can scarcely be over-estimated as motive forces of neuroses in later life.

[1912-1913, 2764]

Thus the view which explains the horror of incest as an innate instinct must be abandoned. Nor can anything more favourable be said of another, widely held explanation of the law against incest, according to which primitive peoples noticed at an early date the dangers with which their race was threatened by inbreeding and for that reason deliberately adopted the prohibition. There are a host of objections to this theory. (Cf. Durkheim, 1898.) Not only must the prohibition against incest be older than any domestication of animals which might have enabled men to observe the effects of inbreeding upon racial characters, but even to-day the detrimental results of inbreeding are not established with certainty and cannot easily be demonstrated in man. Moreover, everything that we know of contemporary savages makes it highly improbable that their most remote ancestors were already concerned with the question of preserving their later progeny from injury. Indeed it is almost absurd to attribute to such improvident creatures motives of hygiene and eugenics to which consideration is scarcely paid in our own present-day civilization.¹

[1912-1913, 2765]

The two taboos of totemism with which human morality has its beginning are not on a par psychologically. The first of them, the law protecting the totem animal, is founded wholly on emotional motives: the father had actually been eliminated, and in no real sense could the deed be undone. But the second rule, the prohibition of incest, has a powerful practical basis as well. Sexual desires do not unite men but divide them. Though the brothers had banded together in order to overcome their father, they were all one another's rivals in regard to the women. Each of them would have wished, like his father, to have all the women to himself. The new organization would have collapsed in a struggle of all against all, for none of them was of such over-mastering strength as to be able to take on his father's part with success. Thus the brothers had no alternative, if they were to live together, but - not, perhaps, until they had passed through many dangerous crises - to institute the law against incest, by which they all alike renounced the women whom they desired and who had been their chief motive for despatching their father. In this way they rescued the organization which had made them strong - and which may have been based on homosexual feelings and acts, originating perhaps during the period of their expulsion from the horde. Here, too, may perhaps have been the germ of the institution of matriarchy, described by Bachofen, which was in turn replaced by the patriarchal organization of the family.

[1912-1913, 2784]
The Diphasic Onset of Sexual Development. - Towards the end of the fifth year this early period of sexual life normally comes to an end. It is succeeded by a period of more or less complete latency, during which ethical restraints are built up, to act as defences against the desires of the Oedipus complex. In the subsequent period of puberty, the Oedipus complex is revivified in the unconscious and embarks upon further modifications. It is only at puberty that the sexual instincts develop to their full intensity; but the direction of that development, as well as all the predispositions for it, have already been determined by the early efflorescence of sexuality during childhood which preceded it. This diphasic development of the sexual function - in two stages, interrupted by the latency period - appears to be a biological peculiarity of the human species and to contain the determining factor for the origin of neuroses.

[1923a, 3923]

By its theory of the instincts psycho-analysis offended the feelings of individuals in so far as they regarded themselves as members of the social community; another branch of its theory was calculated to hurt every single person at the tenderest point of his own psychical development. Psycho-analysis disposed once and for all of the fairy tale of an asexual childhood. It demonstrated the fact that sexual interests and activities occur in small children from the beginning of their lives. It showed what transformations those activities pass through, how at about the age of five they succumb to inhibition and how from puberty onwards they enter the service of the reproductive function. It recognized that early infantile sexual life reaches its peak in what is known as the Oedipus complex (an emotional attachment of the child to the parent of the opposite sex accompanied by an attitude of rivalry to the parent of the same sex) and that at that period of life this impulsion extends uninhibited into a straightforward sexual desire. This can be confirmed so easily that only the greatest efforts could make it possible to overlook it. Every individual has in fact gone through this phase but has afterwards energetically repressed its purport and succeeded in forgetting it. A horror of incest and an enormous sense of guilt are left over from this prehistoric epoch of the individual's existence. It may be that something quite similar occurred in the prehistoric epoch of the human species as a whole and that the beginnings of morality, religion and social order were intimately connected with the surmounting of that primaeval era. To adults their prehistory seems so inglorious that they refuse to allow themselves to be reminded of it: they were infuriated when psycho-analysis tried to lift the veil of amnesia from their years of childhood. There was only one way out: what psycho-analysis asserted must be false and what posed as a new science must be a tissue of fancies and distortions.

[1925e, 4128]

The Oedipus complex, however, is such an important thing that the manner in which one enters and leaves it cannot be without its effects. In boys (as I have shown at length in the paper to which I have just referred and to which all of my present remarks are closely related) the complex is not simply repressed, it is literally smashed to pieces by the shock of threatened castration. Its libidinal cathexes are abandoned, desexualized and in part sublimated; its objects are incorporated into the ego, where they form the nucleus of the super-ego and give that new structure its characteristic qualities. In normal, or, it is better to say, in ideal cases, the Oedipus complex exists no longer, even in the unconscious; the super-ego has become its heir. Since the penis (to follow Ferenczi) owes its extraordinarily high narcissistic cathexis to its organic significance for the propagation of the species, the catastrophe to the Oedipus complex (the abandonment of incest and the institution of conscience and morality) may be regarded as a victory of the race over the individual. This is an interesting point of view when one considers that neurosis is based upon a struggle of the ego against the demands of the sexual function. But to leave the standpoint of individual psychology is not of any immediate help in clarifying this complicated situation.

[1925j, 4155]
INTERRUPTIONS OF THE LATENCY PERIOD  We must not deceive ourselves as to the hypothetical nature and insufficient clarity of our knowledge concerning the processes of the infantile period of latency or deferment; but we shall be on firmer ground in pointing out that such an application of infantile sexuality represents an educational ideal from which individual development usually diverges at some point and often to a considerable degree. From time to time a fragmentary manifestation of sexuality which has evaded sublimation may break through; or some sexual activity may persist through the whole duration of the latency period until the sexual instinct emerges with greater intensity at puberty. In so far as educators pay any attention at all to infantile sexuality, they behave exactly as though they shared our views as to the construction of the moral defensive forces at the cost of sexuality, and as though they knew that sexual activity makes a child ineducable: for they stigmatize every sexual manifestation by children as a 'vice', without being able to do much against it. We, on the other hand, have every reason for turning our attention to these phenomena which are so much dreaded by education, for we may expect them to help us to discover the original configuration of the sexual instincts. [1905d, 1501]

This failure of the function of the sexual mechanism owing to fore-pleasure is best avoided if the primacy of the genitals too is adumbrated in childhood; and indeed things seem actually arranged to bring this about in the second half of childhood (from the age of eight to puberty). During these years the genital zones already behave in much the same way as in maturity; they become the seat of sensations of excitation and of preparatory changes whenever any pleasure is felt from the satisfaction of other erotogenic zones, though this result is still without a purpose - that is to say, contributes nothing to a continuation of the sexual process. Already in childhood, therefore, alongside of the pleasure of satisfaction there is a certain amount of sexual tension, although it is less constant and less in quantity. We can now understand why, in discussing the sources of sexuality, we were equally justified in saying of a given process that it was sexually satisfying or sexually exciting. It will be noticed that in the course of our enquiry we began by exaggerating the distinction between infantile and mature sexual life, and that we are now setting this right. Not only the deviations from normal sexual life but its normal form as well are determined by the infantile manifestations of sexuality. [1905d, 1528]
After having explained the preponderance of perverse tendencies in psychoneurotics by recognizing it as a collateral filling of subsidiary channels when the main current of the instinctual stream has been blocked by 'repression',¹ we proceeded to a consideration of sexual life in childhood. We found it a regrettable thing that the existence of the sexual instinct in childhood has been denied and that the sexual manifestations not infrequently to be observed in children have been described as irregularities. It seemed to us on the contrary that children bring germs of sexual activity with them into the world, that they already enjoy sexual satisfaction when they begin to take nourishment and that they persistently seek to repeat the experience in the familiar activity of 'thumb-sucking'. The sexual activity of children, however, does not, it appeared, develop pari passu with their other functions, but, after a short period of efflorescence from the ages of two to five, enters upon the so-called period of latency. During that period the production of sexual excitation is not by any means stopped but continues and produces a store of energy which is employed to a great extent for purposes other than sexual - namely, on the one hand in contributing the sexual components to social feelings and on the other hand (through repression and reaction-forming) in building up the subsequently developed barriers against sexuality. On this view, the forces destined to retain the sexual instinct upon certain lines are built up in childhood chiefly at the cost of perverse sexual impulses and with the assistance of education. A certain portion of the infantile sexual impulses would seem to evade these uses and succeed in expressing itself as sexual activity. We next found that sexual excitation in children springs from a multiplicity of forces. Satisfaction arises first and foremost from the appropriate sensory excitation of what we have described as erotogenic zones. It seems probable that any part of the skin and any sense-organ - probably, indeed, any organ - can function as an erotogenic zone, though there are some particularly marked erotogenic zones whose excitation would seem to be secured from the very first by certain organic contrivances. It further appears that sexual excitation arises as a by-product, as it were, of a large number of processes that occur in the organism, as soon as they reach a certain degree of intensity, and most especially of any relatively powerful emotion, even though it is of a distressing nature. The excitations from all these sources are not yet combined; but each follows its own separate aim, which is merely the attainment of a certain sort of pleasure. In childhood, therefore, the sexual instinct is not unified and is at first without an object, that is, auto-erotic.

[1905d, 1543]

It was not possible to say what amount of sexual activity can occur in childhood without being described as abnormal or detrimental to further development. The nature of these sexual manifestations was found to be predominantly masturbatory. Experience further showed that the external influences of seduction are capable of provoking interruptions of the latency period or even its cessation, and that in this connection the sexual instinct of children proves in fact to be polymorphously perverse; it seems, moreover, that any such premature sexual activity diminishes a child's educability.

[1905d, 1545]
PREOCITY  One such factor is spontaneous sexual precocity, whose presence at least can be
demonstrated with certainty in the aetiology of the neuroses though, like other
factors, it is not in itself a sufficient cause. It is manifested in the interruption, abbreviation or
bringing to an end of the infantile period of latency; and it is a cause of disturbances by
occasioning sexual manifestations which, owing on the one hand to the sexual inhibitions being
incomplete and on the other hand to the genital system being undeveloped, are bound to be in
the nature of perversions. These tendencies to perversion may thereafter either persist as such
or, after repressions have set in, become the motive forces of neurotic symptoms. In any case
sexual precocity makes more difficult the later control of the sexual instinct by the higher mental
agencies which is so desirable, and it increases the impulsive quality which, quite apart from this,
characterizes the psychical representations of the instinct. Sexual precocity often runs parallel
with premature intellectual development and, linked in this way, is to be found in the childhood
history of persons of the greatest eminence and capacity; under such conditions its effects do not
seem to be so pathogenic as when it appears in isolation.
[1905d, 1551]

In one important respect Norbert Hanold behaved quite differently from an ordinary human
being. He took no interest in living women; the science of which he was the servant had taken
that interest away from him and displaced it on to women of marble or bronze. This is not to be
regarded as a trivial peculiarity; on the contrary, it was the basic precondition of the events to be
described. For one day it came about that one particular sculpture of that kind laid claim to the
whole of the interest which is ordinarily directed only to a living woman, and with that his delusion
was there. We then see unrolled before our eyes the manner in which his delusion is cured
through a happy turn of events, and his interest displaced back from the marble to a living
woman. The author does not let us follow the influences which led our hero to turn away from
women; he only informs us that his attitude was not explained by his innate disposition, which, on
the contrary, included some amount of imaginative (and, we might add, erotic) needs. And, as we
learn later in the story, he did not avoid other children in his childhood: he had a friendship at that
age with a little girl, was her inseparable companion, shared his little meals with her, used to
thump her too and let her rumple his hair. It is in attachments such as this, in combinations like
this of affection and aggressiveness, that the immature erotism of childhood finds its expression;
its consequences only emerge later, but then they are irresistible, and during childhood itself it is
as a rule recognized as erotism only by doctors and creative writers. Our own writer shows us
clearly that he too is of the same opinion; for he makes his hero suddenly develop a lively interest
in women's feet and their way of placing them. This interest was bound to bring him a bad
reputation both among scientists and among the women of the town he lived in, a reputation of
being a foot-fetishist; but we cannot avoid tracing the interest back to the memory of his childhood
playmate. For there can be no doubt that even in her childhood the girl showed the same
peculiarity of a graceful gait, with her toes almost perpendicularly raised as she stepped along;
and it was because it represented that same gait that an ancient marble relief acquired such great
importance for Norbert Hanold. Incidentally we may add that in his derivation of the remarkable
phenomenon of fetishism the author is in complete agreement with science. Ever since Binet we
have in fact tried to trace fetishism back to erotic impressions in childhood.
[1907a, 1845]
The first of these theories starts out from the neglect of the differences between the sexes on which I laid stress at the beginning of this paper as being characteristic of children. It consists in attributing to everyone, including females, the possession of a penis, such as the boy knows from his own body. It is precisely in what we must regard as the 'normal' sexual constitution that already in childhood the penis is the leading erotogenic zone and the chief auto-erotic sexual object; and the boy's estimate of its value is logically reflected in his inability to imagine a person like himself who is without this essential constituent. When a small boy sees his little sister's genitals, what he says shows that his prejudice is already strong enough to falsify his perception. He does not comment on the absence of a penis, but invariably says, as though by way of consolation and to put things right: 'Her ---'s still quite small. But when she gets bigger it'll grow all right.' The idea of a woman with a penis returns in later life, in the dreams of adults: the dreamer, in a state of nocturnal sexual excitation, will throw a woman down, strip her and prepare for intercourse - and then, in place of the female genitals, he beholds a well-developed penis and breaks off the dream and the excitation. The numerous hermaphrodites of classical antiquity faithfully reproduce this idea, universally held in childhood; one may observe that to most normal people they cause no offence, while the real hermaphroditic formations of the genitals which are permitted to occur by Nature nearly always excite the greatest abhorrence.

[1908c, 1971]

If this idea of a woman with a penis becomes 'fixated' in an individual when he is a child, resisting all the influences of later life and making him as a man unable to do without a penis in his sexual object, then, although in other respects he may lead a normal sexual life, he is bound to become a homosexual, and will seek his sexual object among men who, owing to some other physical and mental characteristics, remind him of women. Real women, when he comes to know them later, remain impossible as sexual objects for him, because they lack the essential sexual attraction; indeed, in connection with another impression of his childhood life, they may even become abhorrent to him. The child, having been mainly dominated by excitations in the penis, will usually have obtained pleasure by stimulating it with his hand; he will have been detected in this by his parents or nurse and terrorized by the threat of having his penis cut off. The effect of this 'threat of castration' is proportionate to the value set upon that organ and is quite extraordinarily deep and persistent. Legends and myths testify to the upheaval in the child's emotional life and to the horror which is linked with the castration complex - a complex which is subsequently remembered by consciousness with corresponding reluctance. The woman's genitalia, when seen later on, are regarded as a mutilated organ and recall this threat, and they therefore arouse horror instead of pleasure in the homosexual. This reaction cannot be altered in any way when the homosexual comes to learn from science that his childish assumption that women had a penis too was not so far wrong after all. Anatomy has recognized the clitoris within the female pudenda as being an organ that is homologous to the penis; and the physiology of the sexual processes has been able to add that this small penis which does not grow any bigger behaves in fact during childhood like a real and genuine penis - that it becomes the seat of excitations which lead to its being touched, that its excitability gives the little girl's sexual activity a masculine character and that a wave of repression in the years of puberty is needed in order for this masculine sexuality to be discarded and the woman to emerge. Since the sexual function of many women is crippled, whether by their obstinate clinging on to this excitability of the clitoris so that they remain anaesthetic in intercourse, or by such excessive repression occurring that its operation is partly replaced by hysterical compensatory formations - all this seems to show that there is some truth in the infantile sexual theory that women, like men, possess a penis.

[1908c, 1971]
Before the child comes under the dominance of the castration-complex - at a time when he still holds women at full value - he begins to display an intense desire to look, as an erotic instinctual activity. He wants to see other people's genitals, at first in all probability to compare them with his own. The erotic attraction that comes from his mother soon culminates in a longing for her genital organ, which he takes to be a penis. With the discovery, which is not made till later, that women do not have a penis, this longing often turns into its opposite and gives place to a feeling of disgust which in the years of puberty can become the cause of psychical impotence, misogyny and permanent homosexuality. But the fixation on the object that was once strongly desired, the woman's penis, leaves indelible traces on the mental life of the child, who has pursued that portion of his infantile sexual researches with particular thoroughness. Fetishistic reverence for a woman's foot and shoe appears to take the foot merely as a substitutive symbol for the woman's penis which was once revered and later missed; without knowing it, 'coupeurs de nattes'¹ play the part of people who carry out an act of castration on the female genital organ. [1910c, 2271]
There is a possible anatomical analogy to what I believe to be the course of development of the infantile sexual function in Bayer's discovery (1902) that the internal sexual organs (i.e. the uterus) are as a rule larger in new-born children than in older ones. It is not certain, however, what view we should take of this involution that occurs after birth (which has been shown by Halban to apply also to other portions of the genital apparatus). According to Halban (1904) the process of involution comes to an end after a few weeks of extra-uterine life. [Added 1920:]
Those authorities who regard the interstitial portion of the sex-gland as the organ that determines sex have on their side been led by anatomical researches to speak of infantile sexuality and a period of sexual latency. I quote a passage from Lipschütz’s book (1919, 168), which I mentioned on p. 1473 n: 'We shall be doing more justice to the facts if we say that the maturation of the sexual characters which is accomplished at puberty is only due to a great acceleration which occurs at that time of processes which began much earlier - in my view as early as during intra-uterine life.' 'What has hitherto been described in a summary way as puberty is probably only a second major phase of puberty which sets in about the middle of the second decade of life . . . Childhood, from birth until the beginning of this second major phase, might be described as "the intermediate phase of puberty"' (ibid., 170). Attention was drawn to this coincidence between anatomical findings and psychological observation in a review by Ferenczi (1920). The agreement is marred only by the fact that the 'first peak' in the development of the sexual organ occurs during the early intra-uterine period, whereas the early efflorescence of infantile sexual life must be ascribed to the third and fourth years of life. There is, of course, no need to expect that anatomical growth and psychical development must be exactly simultaneous. The researches in question were made on the sex-glands of human beings. Since a period of latency in the psychological sense does not occur in animals, it would be very interesting to know whether the anatomical findings which have led these writers to assume the occurrence of two peaks in sexual development are also demonstrable in the higher animals. [1905d, 1499]

It is possible further to form some idea of the mechanism of this process of sublimation. On the one hand, it would seem, the sexual impulses cannot be utilized during these years of childhood, since the reproductive functions have been deferred - a fact which constitutes the main feature of the period of latency. On the other hand, these impulses would seem in themselves to be perverse - that is, to arise from erotogenic zones and to derive their activity from instincts which, in view of the direction of the subject's development, can only arouse unpleasurable feelings. They consequently evoke opposing mental forces (reacting impulses) which, in order to suppress this unpleasure effectively, build up the mental dams that have already mentioned - disgust, shame and morality.²
[1905d, 1500]

The fact that the onset of sexual development in human beings occurs in two phases, i.e. that the development is interrupted by the period of latency, seemed to call for particular notice. This appears to be one of the necessary conditions of the aptitude of men for developing a higher civilization, but also of their tendency to neurosis. So far as we know, nothing analogous is to be found in man's animal relatives. It would seem that the origin of this peculiarity of man must be looked for in the prehistory of the human species.
[1905d, 1545]
If, however, the derivation of perversions from the Oedipus complex can be generally established, our estimate of its importance will have gained added strength. For in our opinion the Oedipus complex is the actual nucleus of neuroses, and the infantile sexuality which culminates in this complex is the true determinant of neuroses. What remains of the complex in the unconscious represents the disposition to the later development of neuroses in the adult. In this way the beating-phantasy and other analogous perverse fixations would also only be precipitates of the Oedipus complex, scars, so to say, left behind after the process has ended, just as the notorious 'sense of inferiority' corresponds to a narcissistic scar of the same sort. In taking this view of the matter I must express my unreserved agreement with Marcinowski (1918), who has recently put it forward most happily. As is well known, this neurotic delusion of inferiority is only a partial one, and is completely compatible with the existence of a self-overvaluation derived from other sources. The origin of the Oedipus complex itself, and the destiny which compels man, probably alone among all animals, to begin his sexual life twice over, first like all other creatures in his early childhood, and then after a long interruption once more at the age of puberty - all the problems that are connected with man's 'archaic heritage' - have been discussed by me elsewhere, and I have no intention of going into them in this place. [1919e, 3654]

Neurosis stands outside this series. It also is based upon a peculiarity in the development of the human libido - the twice repeated start made by the directly sexual function, with an intervening period of latency.¹ To this extent it resembles hypnosis and group formation in having the character of a regression, which is absent from being in love. It makes its appearance wherever the advance from directly sexual instincts to those that are inhibited in their aims has not been wholly successful; and it represents a conflict between those portions of the instincts which have been received into the ego after having passed through this development and those portions of them which, springing from the repressed unconscious, strive - as do other, completely repressed, instinctual impulses - to attain direct satisfaction. Neuroses are extraordinarily rich in content, for they embrace all possible relations between the ego and the object - both those in which the object is retained and others in which it is abandoned or erected inside the ego itself - and also the conflicting relations between the ego and its ego ideal. [1921c, 3834]

The Diphasic Onset of Sexual Development. - Towards the end of the fifth year this early period of sexual life normally comes to an end. It is succeeded by a period of more or less complete latency, during which ethical restraints are built up, to act as defences against the desires of the Oedipus complex. In the subsequent period of puberty, the Oedipus complex is revivified in the unconscious and embarks upon further modifications. It is only at puberty that the sexual instincts develop to their full intensity; but the direction of that development, as well as all the predispositions for it, have already been determined by the early efflorescence of sexuality during childhood which preceded it. This diphasic development of the sexual function - in two stages, interrupted by the latency period - appears to be a biological peculiarity of the human species and to contain the determining factor for the origin of neuroses. [1923a, 3923]
If we consider once more the origin of the super-ego as we have described it, we shall recognize that it is the outcome of two highly important factors, one of a biological and the other of a historical nature: namely, the lengthy duration in man of his childhood helplessness and dependence, and the fact of his Oedipus complex, the repression of which we have shown to be connected with the interruption of libidinal development by the latency period and so with the diphasic onset of man's sexual life. According to one psycho-analytic hypothesis, the last-mentioned phenomenon, which seems to be peculiar to man, is a heritage of the cultural development necessitated by the glacial epoch. We see, then, that the differentiation of the super-ego from the ego is no matter of chance; it represents the most important characteristics of the development both of the individual and of the species; indeed, by giving permanent expression to the influence of the parents it perpetuates the existence of the factors to which it owes its origin.

Readers of my *Three Essays on the Theory of Sexuality* (1905) will be aware that I have never undertaken any thorough remodelling of that work in its later editions, but have retained the original arrangement and have kept abreast of the advances made in our knowledge by means of interpolations and alterations in the text. In doing this, it may often have happened that what was old and what was more recent did not admit of being merged into an entirely uncontradictory whole. Originally, as we know, the accent was on a portrayal of the fundamental difference between the sexual life of children and of adults; later, the *pregenital organizations* of the libido made their way into the foreground, and also the remarkable and momentous fact of the *diphasic onset* of sexual development. Finally, our interest was engaged by the *sexual researches* of children; and from this we were able to recognize the far-reaching *approximation of the final outcome of sexuality in childhood* (in about the fifth year) to the definitive form taken by it in the adult. This is the point at which I left things in the last (1922) edition of my *Three Essays*.

I have described elsewhere how this turning away takes place. The object-cathexes are given up and replaced by identifications. The authority of the father or the parents is introjected into the ego, and there it forms the nucleus of the super-ego, which takes over the severity of the father and perpetuates his prohibition against incest, and so secures the ego from the return of the libidinal object-cathexis. The libidinal trends belonging to the Oedipus complex are in part desexualized and sublimated (a thing which probably happens with every transformation into an identification) and in part inhibited in their aim and changed into impulses of affection. The whole process has, on the one hand, preserved the genital organ - has averted the danger of its loss - and, on the other, has paralysed it - has removed its function. This process ushers in the latency period, which now interrupts the child's sexual development.

[1923b, 3969]

[1923e, 4058]

[1924d, 4088]
And now, as a third point, psycho-analysis has shown us, to our growing astonishment, the enormously important part played by what is known as the 'Oedipus complex' - that is, the emotional relation of a child to its two parents - in the mental life of human beings. Our astonishment diminishes when we realize that the Oedipus complex is the psychical correlate of two fundamental biological facts: the long period of the human child's dependence, and the remarkable way in which its sexual life reaches a first climax in the third to fifth years of life, and then, after a period of inhibition, sets in again at puberty. And here, the discovery was made that a third and extremely serious part of human intellectual activity, the part which has created the great institutions of religion, law, ethics, and all forms of civic life, has as its fundamental aim the enabling of the individual to master his Oedipus complex and to divert his libido from its infantile attachments into the social ones that are ultimately desired. The applications of psycho-analysis to the science of religion and sociology (e.g. by the present writer, Theodor Reik and Oskar Pfister), which have led to these findings, are still young and insufficiently appreciated; but it cannot be doubted that further studies will only confirm the certainty of these important conclusions.

[1924f, 4117]

The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-erotism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother's organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors' own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child's first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child's life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child's early years become re-animated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of 'male' or 'female' but of 'possessing a penis' or 'castrated'. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses.

[1925d, 4212]
The advent of puberty opens a decisive chapter in the history of an obsessional neurosis. The genital organization which has been broken off in childhood starts again with great vigour. But, as we know, the sexual development in childhood determines what direction this new start at puberty will take. Not only will the early aggressive impulses be re-awakened; but a greater or lesser proportion of the new libidinal impulses - in bad cases the whole of them - will have to follow the course prescribed for them by regression and will emerge as aggressive and destructive tendencies. In consequence of the erotic trends being disguised in this way and owing to the powerful reaction-formations in the ego, the struggle against sexuality will henceforward be carried on under the banner of ethical principles. The ego will recoil with astonishment from promptings to cruelty and violence which enter consciousness from the id, and it has no notion that in them it is combating erotic wishes, including some to which it would not otherwise have taken exception. The overstrict super-ego insists all the more strongly on the suppression of sexuality, since this has assumed such repellent forms. Thus in obsessional neurosis the conflict is aggravated in two directions: the defensive forces become more intolerant and the forces that are to be fended off become more intolerable. Both effects are due to a single factor, namely, regression of the libido.

[1926d, 4275]

The existence of the second, phylogenetic, factor, is based only upon inference. We have been led to assume its existence by a remarkable feature in the development of the libido. We have found that the sexual life of man, unlike that of most of the animals nearly related to him, does not make a steady advance from birth to maturity, but that, after an early efflorescence up till the fifth year, it undergoes a very decided interruption; and that it then starts on its course once more at puberty, taking up again the beginnings broken off in early childhood. This has led us to suppose that something momentous must have occurred in the vicissitudes of the human species which has left behind this interruption in the sexual development of the individual as a historical precipitate. This factor owes its pathogenic significance to the fact that the majority of the instinctual demands of this infantile sexuality are treated by the ego as dangers and fended off as such, so that the later sexual impulses of puberty, which in the natural course of things would be ego-syntonic, run the risk of succumbing to the attraction of their infantile prototypes and following them into repression. It is here that we come upon the most direct aetiology of the neuroses. It is a curious thing that early contact with the demands of sexuality should have a similar effect on the ego to that produced by premature contact with the external world.

[1926d, 4309]

Then I will pursue the subject further; in any case it is not easy for me to get away from it. I will tell you, then, that the most remarkable thing about the sexual life of children seems to me that it passes through the whole of its very far-reaching development in the first five years of life. From then onwards until puberty there stretches what is known as the period of latency. During it sexuality normally advances no further; on the contrary, the sexual urges diminish in strength and many things are given up and forgotten which the child did and knew. During that period of life, after the early efflorescence of sexuality has withered, such attitudes of the ego as shame, disgust and morality arise, which are destined to stand up against the later tempest of puberty and to lay down the path of the freshly awakening sexual desires. This 'diphasic onset', as it is named, of sexual life has a great deal to do with the genesis of neurotic illnesses. It seems to occur only in human beings, and it is perhaps one of the determinants of the human privilege of becoming neurotic. The prehistory of sexual life was just as much overlooked before psycho-analysis as, in another department, the background to conscious mental life. You will rightly suspect that the two are intimately connected.

[1926e, 4353]
(2) For cultural reasons the most intense repression falls upon the sexual instincts; but it is precisely in connection with them that repression most easily miscarries, so that neurotic symptoms are found to be substitutive satisfactions of repressed sexuality. The belief that in man sexual life begins only at puberty is incorrect. On the contrary, signs of it can be detected from the beginning of extra-uterine existence; it reaches a first culminating point at or before the fifth year (‘early period’), after which it is inhibited or interrupted (‘latency period’) until the age of puberty, which is the second climax of its development. This diphasic onset of sexual development seems to be distinctive of the genus Homo. All experiences during the first period of childhood are of the greatest importance to the individual, and in combination with his inherited sexual constitution form the dispositions for the subsequent development of character and disease. It is wrong to make sexuality coincide with ‘genitality’. The sexual instincts pass through a complicated course of development, and it is only at the end of it that the ‘primacy of the genital zones’ is attained. Before this there are a number of ‘pregenital’ organizations of the libido - points at which it may become ‘fixated’ and to which, in the event of subsequent repression, it will return (‘regression’). The infantile fixations of the libido are what determine the form of any later neurosis. Thus the neuroses are to be regarded as inhibitions in the development of the libido. There are no specific causes of nervous disorders; the question whether a conflict finds a healthy solution or leads to a neurotic inhibition of function depends upon quantitative considerations.

[1926f, 4405]

These three points - the very early appearance of these experiences (during the first five years of life), the fact of their being forgotten and their sexual-aggressive content - are closely inter connected. The traumas are either experiences on the subject's own body or sense perceptions, mostly of something seen and heard - that is, experiences or impressions. The interconnection of these three points is established by a theory, a product of the work of analysis which alone can bring about a knowledge of the forgotten experiences, or, to put it more vividly but also more incorrectly, bring them back to memory. The theory is that, in contrast to popular opinion, the sexual life of human beings (or what corresponds to it later on) exhibits an early efflorescence which comes to an end at about the fifth year and is followed by what is known as the period of latency (till puberty) in which there is no further development of sexuality and indeed what has been attained undergoes a retrogression. This theory is confirmed by the anatomical investigation of the growth of the internal genitalia; it leads us to suppose that the human race is descended from a species of animal which reached sexual maturity in five years and rouses a suspicion that the postponement of sexual life and its diphasic onset are intimately connected with the history of hominization. Human beings appear to be the only animal organisms with a latency period and sexual retardation of this kind. Investigations on the primates (which, so far as I know, are not available) would be indispensable for testing this theory. It cannot be a matter of indifference psychologically that the period of infantile amnesia coincides with this early period of sexuality. It may be that this state of things provides the true determinant for the possibility of neurosis, which is in a sense a human prerogative and from this point of view appears as a vestige - a 'survival' - of primaeval times like certain portions of our bodily anatomy.

[1939a, 4900]
The chief interest is naturally focused on the first of these assertions, the most unexpected of all. It has been found that in early childhood there are signs of bodily activity to which only an ancient prejudice could deny the name of sexual and which are linked to psychical phenomena that we come across later in adult erotic life - such as fixation to particular objects, jealousy, and so on. It is further found, however, that these phenomena which emerge in early childhood form part of an ordered course of development, that they pass through a regular process of increase, reaching a climax towards the end of the fifth year, after which there follows a lull. During this lull progress is at a standstill and much is unlearnt and there is much recession. After the end of this period of latency, as it is called, sexual life advances once more with puberty; we might say that it has a second efflorescence. And here we come upon the fact that the onset of sexual life is *diphasic*, that it occurs in two waves - something that is unknown except in man and evidently has an important bearing on hominization.¹ It is not a matter of indifference that the events of this early period, except for a few residues, fall a victim to *infantile amnesia*. Our views on the aetiology of the neuroses and our technique of analytic therapy are derived from these conceptions; and our tracing of the developmental processes in this early period has also provided evidence for yet other conclusions.

[1940a [1938], 4964]

As regards the other point - the specific instinctual factor - we come upon an interesting discrepancy between theory and experience. Theoretically there is no objection to supposing that any sort of instinctual demand might occasion the same repressions and their consequences; but our observation shows us invariably, so far as we can judge, that the excitations that play this pathogenic part arise from the component instincts of sexual life. The symptoms of neuroses are, it might be said, without exception either a substitutive satisfaction of some sexual urge or measures to prevent such a satisfaction; and as a rule they are compromises between the two, of the kind that come about in accordance with the laws operating between contraries in the unconscious. The gap in our theory cannot at present be filled; our decision is made more difficult by the fact that most of the urges of sexual life are not of a purely erotic nature but have arisen from alloys of the erotic instinct with portions of the destructive instinct. But it cannot be doubted that the instincts which manifest themselves physiologically as sexuality play a prominent, unexpectedly large part in the causation of the neuroses - whether it is an exclusive one remains to be decided. It must also be borne in mind that in the course of cultural development no other function has been so energetically and extensively repudiated as precisely the sexual one. Theory must rest satisfied with a few hints that betray a deeper connection: the fact that the first period of childhood, during which the ego begins to be differentiated from the id, is also the period of the early sexual efflorescence which is brought to an end by the period of latency; that it can hardly be a matter of chance that this momentous early period subsequently falls a victim to infantile amnesia; and lastly, that biological changes in sexual life (such as the function's diphasic onset which we have already mentioned, the disappearance of the periodic character of sexual excitation and the transformation in the relation between female menstruation and male excitation) - that these innovations in sexuality must have been of high importance in the evolution of animals into man. It is left for the science of the future to bring these still isolated data together into a new understanding. It is not in psychology but in biology that there is a gap here. We shall not be wrong, perhaps, in saying that the weak point in the ego's organization seems to lie in its attitude to the sexual function, as though the biological antithesis between self-preservation and the preservation of the species had found a psychological expression at that point.

[1940a [1938], 4994]
We have heard how the weak and immature ego of the first period of childhood is permanently damaged by the stresses put upon it in its efforts to fend off the dangers that are peculiar to that period of life. Children are protected against the dangers that threaten them from the external world by the solicitude of their parents; they pay for this security by a fear of loss of love which would deliver them over helpless to the dangers of the external world. This factor exerts a decisive influence on the outcome of the conflict when a boy finds himself in the situation of the Oedipus complex, in which the threat to his narcissism by the danger of castration, reinforced from primaeval sources, takes possession of him. Driven by the combined operation of these two influences, the contemporary real danger and the remembered one with its phylogenetic basis, the child embarks on his attempts at defence - repressions - which are effective for the moment but nevertheless turn out to be psychologically inadequate when the later re-animation of sexual life brings a reinforcement to the instinctual demands which have been repudiated in the past. If this is so, it would have to be said from a biological standpoint that the ego comes to grief over the task of mastering the excitations of the early sexual period, at a time when its immaturity makes it incompetent to do so. It is in this lagging of ego development behind libidinal development that we see the essential precondition of neurosis; and we cannot escape the conclusion that neuroses could be avoided if the childish ego were spared this task - if, that is to say, the child's sexual life were allowed free play, as happens among many primitive peoples. It may be that the aetiology of neurotic illnesses is more complicated than we have here described it; if so, we have at least brought out one essential part of the aetiological complex. Nor should we forget the phylogenetic influences, which are represented in some way in the id in forms that we are not yet able to grasp, and which must certainly act upon the ego more powerfully in that early period than later. On the other hand, the realization dawns on us that such an early attempt at damming up the sexual instinct, so decided a partisanship by the young ego in favour of the external as opposed to the internal world, brought about by the prohibition of infantile sexuality, cannot be without its effect on the individual's later readiness for culture. The instinctual demands forced away from direct satisfaction are compelled to enter on new paths leading to substitutive satisfaction, and in the course of these détours they may become desexualized and their connection with their original instinctual aims may become looser. And at this point we may anticipate the thesis that many of the highly valued assets of our civilization were acquired at the cost of sexuality and by the restriction of sexual motive forces.

[1940a [1938], 5006]
With the arrival of puberty, changes set in which are destined to give infantile sexual life its final, normal shape. The sexual instinct has hitherto been predominantly auto-erotic; it now finds a sexual object. Its activity has hitherto been derived from a number of separate instincts and erotogenic zones, which, independently of one another, have pursued a certain sort of pleasure as their sole sexual aim. Now, however, a new sexual aim appears, and all the component instincts combine to attain it, while the erotogenic zones become subordinated to the primacy of the genital zone.¹ Since the new sexual aim assigns very different functions to the two sexes, their sexual development now diverges greatly. That of males is the more straightforward and the more understandable, while that of females actually enters upon a kind of involution. A normal sexual life is only assured by an exact convergence of the two currents directed towards the sexual object and sexual aim, the affectionate current and the sensual one. (The former, the affectionate current, comprises what remains over of the infantile efflorescence of sexuality.) It is like the completion of a tunnel which has been driven through a hill from both directions.

¹[1905d, 1524]

The most striking of the processes at puberty has been picked upon as constituting its essence: the manifest growth of the external genitalia. (The latency period of childhood is, on the other hand, characterized by a relative cessation of their growth.) In the meantime the development of the internal genitalia has advanced far enough for them to be able to discharge the sexual products or, as the case may be, to bring about the formation of a new living organism. Thus a highly complicated apparatus has been made ready and awaits the moment of being put into operation.

¹[1905d, 1525]

This apparatus is to be set in motion by stimuli, and observation shows us that stimuli can impinge on it from three directions: from the external world by means of the excitation of the erotogenic zones with which we are already familiar, from the organic interior by ways which we have still to explore, and from mental life, which is itself a storehouse for external impressions and a receiving-post for internal excitations. All three kinds of stimuli produce the same effect, namely a condition described as 'sexual excitement', which shows itself by two sorts of indication, mental and somatic. The mental indications consist in a peculiar feeling of tension of an extremely compelling character; and among the numerous somatic ones are first and foremost a number of changes in the genitals, which have the obvious sense of being preparations for the sexual act - the erection of the male organ and the lubrication of the vagina.

¹[1905d, 1525]

As we all know, it is not until puberty that the sharp distinction is established between the masculine and feminine characters. From that time on, this contrast has a more decisive influence than any other upon the shaping of human life. It is true that the masculine and feminine dispositions are already easily recognizable in childhood. The development of the inhibitions of sexuality (shame, disgust, pity, etc.) takes place in little girls earlier and in the face of less resistance than in boys; the tendency to sexual repression seems in general to be greater; and, where the component instincts of sexuality appear, they prefer the passive form. The auto-erotic activity of the erotogenic zones is, however, the same in both sexes, and owing to this uniformity there is no possibility of a distinction between the two sexes such as arises after puberty. So far as the auto-erotic and masturbatory manifestations of sexuality are concerned, we might lay it down that the sexuality of little girls is of a wholly masculine character. Indeed, if we were able to give a more definite connotation to the concepts of 'masculine' and 'feminine', it would even be possible to maintain that libido is invariably and necessarily of a masculine nature, whether it occurs in men or in women and irrespective of whether its object is a man or a woman.

¹[1905d, 1533]
If we are to understand how a little girl turns into a woman, we must follow the further vicissitudes of this excitability of the clitoris. Puberty, which brings about so great an accession of libido in boys, is marked in girls by a fresh wave of repression, in which it is precisely clitoridal sexuality that is affected. What is thus overtaken by repression is a piece of masculine sexuality. The intensification of the brake upon sexuality brought about by pubertal repression in women serves as a stimulus to the libido in men and causes an increase of its activity. Along with this heightening of libido there is also an increase of sexual overvaluation which only emerges in full force in relation to a woman who holds herself back and who denies her sexuality. When at last the sexual act is permitted and the clitoris itself becomes excited, it still retains a function: the task, namely, of transmitting the excitation to the adjacent female sexual parts, just as - to use a simile - pine shavings can be kindled in order to set a log of harder wood on fire. Before this transference can be effected, a certain interval of time must often elapse, during which the young woman is anaesthetic. This anaesthesia may become permanent if the clitoridal zone refuses to abandon its excitability, an event for which the way is prepared precisely by an extensive activity of that zone in childhood. Anaesthesia in women, as is well known, is often only apparent and local. They are anaesthetic at the vaginal orifice but are by no means incapable of excitement originating in the clitoris or even in other zones. Alongside these erotogenic determinants of anaesthesia must also be set the psychical determinants, which equally arise from repression.

When erotogenic susceptibility to stimulation has been successfully transferred by a woman from the clitoris to the vaginal orifice, it implies that she has adopted a new leading zone for the purposes of her later sexual activity. A man, on the other hand, retains his leading zone unchanged from childhood. The fact that women change their leading erotogenic zone in this way, together with the wave of repression at puberty, which, as it were, puts aside their childish masculinity, are the chief determinants of the greater proneness of woman to neurosis and especially to hysteria. These determinants, therefore, are intimately related to the essence of femininity.

The processes at puberty thus establish the primacy of the genital zones; and, in a man, the penis, which has now become capable of erection, presses forward insistently towards the new sexual aim - penetration into a cavity in the body which excites his genital zone. Simultaneously on the psychical side the process of finding an object, for which preparations have been made from earliest childhood, is completed. At a time at which the first beginnings of sexual satisfaction are still linked with the taking of nourishment, the sexual instinct has a sexual object outside the infant's own body in the shape of his mother's breast. It is only later that the instinct loses that object, just at the time, perhaps, when the child is able to form a total idea of the person to whom the organ that is giving him satisfaction belongs. As a rule the sexual instinct then becomes auto-erotic, and not until the period of latency has been passed through is the original relation restored. There are thus good reasons why a child sucking at his mother's breast has become the prototype of every relation of love. The finding of an object is in fact a refunding of it.¹

¹[1905d, 1535]
In spite of the gaps in our knowledge of infantile sexual life, we had to proceed to an attempt at examining the alterations brought about in it by the arrival of puberty. We selected two of these as being the decisive ones: the subordination of all the other sources of sexual excitation under the primacy of the genital zones and the process of finding an object. Both of these are already adumbrated in childhood. The first is accomplished by the mechanism of exploiting fore-pleasure: what were formerly self-contained sexual acts, attended by pleasure and excitation, become acts preparatory to the new sexual aim (the discharge of the sexual products), the attainment of which, enormously pleasurable, brings the sexual excitation to an end. In this connection we had to take into account the differentiation of sexuality into masculine and feminine; and we found that in order to become a woman a further stage of repression is necessary, which discards a portion of infantile masculinity and prepares the woman for changing her leading genital zone. As regards object-choice, we found that it is given its direction by the childhood hints (revived at puberty) of the child's sexual inclination towards his parents and others in charge of him, but that it is diverted away from them, on to other people who resemble them, owing to the barrier against incest which has meanwhile been erected. Finally it must be added that during the transition period of puberty the processes of somatic and of psychical development continue for a time side by side independently, until the irruption of an intense mental erotic impulse, leading to the innervation of the genitals, brings about the unity of the erotic function which is necessary for normality.

I do not know how the case could be better stated, but perhaps I may add a few remarks. It is undoubtedly nothing else but the customary prudishness and their own bad conscience over sexual matters that causes adults to adopt this attitude of 'mystery-making' in front of children; but possibly a part is also played by a piece of theoretical ignorance on their part, which we can counteract by giving the adults some enlightenment. It is commonly believed that the sexual instinct is absent in children and only begins to emerge in them at puberty when the sexual organs mature. This is a gross error, equally serious in its effects both on knowledge and on practice; and it is so easily corrected by observation that one wonders how it could ever have been made. As a matter of fact, the new-born baby brings sexuality with it into the world, certain sexual sensations accompany its development as a suckling and during early childhood, and only very few children would seem to escape sexual activities and sensations before puberty. Anyone who would like to find a detailed exposition of these statements can do so in my *Three Essays on the Theory of Sexuality*, to which I have referred above. There he will learn that the organs of reproduction proper are not the only parts of the body which provide sexual sensations of pleasure, and that nature has even so ordered matters that actual stimulations of the genitals are unavoidable during early childhood. This period of life, during which a certain quota of what is undoubtedly sexual pleasure is produced by the excitation of various parts of the skin (erogogenic zones), by the activity of certain biological instincts and as an accompanying excitation in many affective states, is called the period of *auto-erotism*, to use a term introduced by Havelock Ellis. All that puberty does is to give the genitals primacy among all the other zones and sources which produce pleasure, and thus to force erotism into the service of the function of reproduction. This process can naturally undergo certain inhibitions, and in many people (those who later become perverts and neurotics) it is only incompletely accomplished. On the other hand, the child is capable long before puberty of most of the psychical manifestations of love-tenderness, for example, devotion and jealousy. Often enough, too, an irruption of these mental states is associated with the physical sensations of sexual excitation, so that the child cannot remain in doubt as to the connection between the two. In short, except for his reproductive power, a child has a fully-developed capacity for love long before puberty; and it may be asserted that the ‘mystery-making’ merely prevents him from being able to gain an intellectual grasp of activities for which he is psychically prepared and physically adjusted.
A powerful wave of repression brought this childhood excess to an end, and established the dispositions which were to become manifest in the years of puberty. The most obvious result of the transformation was the avoidance of every crudely sensual activity; Leonardo was enabled to live in abstinence and to give the impression of being an asexual human being. When the excitations of puberty came in their flood upon the boy they did not, however, make him ill by forcing him to develop substitutive structures of a costly and harmful kind. Owing to his very early inclination towards sexual curiosity the greater portion of the needs of his sexual instinct could be sublimated into a general urge to know, and thus evaded repression. A much smaller portion of his libido continued to be devoted to sexual aims and represented a stunted adult sexual life. Because his love for his mother had been repressed, this portion was driven to take up a homosexual attitude and manifested itself in ideal love for boys. The fixation on his mother and on the blissful memories of his relations with her continued to be preserved in the unconscious, but for the time being it remained in an inactive state. In this way repression, fixation and sublimation all played their part in disposing of the contributions which the sexual instinct made to Leonardo’s mental life. [1910c, 2301]

These affectionate fixations of the child persist throughout childhood, and continually carry along with them erotism, which is consequently diverted from its sexual aims. Then at the age of puberty they are joined by the powerful 'sensual' current which no longer mistakes its aims. It never fails, apparently, to follow the earlier paths and to cathet the objects of the primary infantile choice with quotas of libido that are now far stronger. Here, however, it runs up against the obstacles that have been erected in the meantime by the barrier against incest; consequently it will make efforts to pass on from these objects which are unsuitable in reality, and find a way as soon as possible to other, extraneous objects with which a real sexual life may be carried on. These new objects will still be chosen on the model (imago) of the infantile ones, but in the course of time they will attract to themselves the affection that was tied to the earlier ones. A man shall leave his father and his mother - according to the biblical command - and shall cleave unto his wife; affection and sensuality are then united. The greatest intensity of sensual passion will bring with it the highest psychical valuation of the object - this being the normal overvaluation of the sexual object on the part of a man. [1912d, 2339]
Two factors will decide whether this advance in the developmental path of the libido is to fail. First, there is the amount of frustration in reality, which opposes the new object-choice and reduces its value for the person concerned. There is after all no point in embarking upon an object-choice if no choice is to be allowed at all or if there is no prospect of being able to choose anything suitable. Secondly, there is the amount of attraction which the infantile objects that have to be relinquished are able to exercise, and which is in proportion to the erotic cathexis attaching to them in childhood. If these two factors are sufficiently strong, the general mechanism by which the neuroses are formed comes into operation. The libido turns away from reality, is taken over by imaginative activity (the process of introversion), strengthens the images of the first sexual objects and becomes fixated to them. The obstacle raised against incest, however, compels the libido that has turned to these objects to remain in the unconscious. The masturbatory activity carried out by the sensual current, which is now part of the unconscious, makes its own contribution in strengthening this fixation. Nothing is altered in this state of affairs if the advance which has miscarried in reality is now completed in phantasy, and if in the phantasy-situations that lead to masturbatory satisfaction the original sexual objects are replaced by different ones. As a result of this substitution the phantasies become admissible to consciousness, but no progress is made in the allocation of the libido in reality. In this way it can happen that the whole of a young man's sensuality becomes tied to incestuous objects in the unconscious, or to put it another way, becomes fixated to unconscious incestuous phantasies. The result is then total impotence, which is perhaps further ensured by the simultaneous onset of an actual weakening of the organs that perform the sexual act.

I do not hesitate to make the two factors at work in psychical impotence in the strict sense - the factors of intense incestuous fixation in childhood and the frustration by reality in adolescence - responsible, too, for this extremely common characteristic of the love of civilized men. It sounds not only disagreeable but also paradoxical, yet it must nevertheless be said that anyone who is to be really free and happy in love must have surmounted his respect for women and have come to terms with the idea of incest with his mother or sister. Anyone who subjects himself to a serious self-examination on the subject of this requirement will be sure to find that he regards the sexual act basically as something degrading, which defiles and pollutes not only the body. The origin of this low opinion, which he will certainly not willingly acknowledge, must be looked for in the period of his youth in which the sensual current in him was already strongly developed but its satisfaction with an object outside the family was almost as completely prohibited as it was with an incestuous one.

At puberty, as we know, there set in new and very strong impulsions towards directly sexual aims. In unfavourable cases they remain separate, in the form of a sensual current, from the 'affectionate' trends of feeling which persist. We then have before us a picture whose two aspects are typified with such delight by certain schools of literature. A man will show a sentimental enthusiasm for women whom he deeply respects but who do not excite him to sexual activities, and he will only be potent with other women whom he does not 'love' and thinks little of or even despises. More often, however, the adolescent succeeds in bringing about a certain degree of synthesis between the unsensual, heavenly love and the sensual, earthly love, and his relation to his sexual object is characterized by the interaction of uninhibited instincts and of instincts inhibited in their aim. The depth to which anyone is in love, as contrasted with his purely sensual desire, may be measured by the size of the share taken by the aim-inhibited instincts of affection.
And now, as a third point, psycho-analysis has shown us, to our growing astonishment, the enormously important part played by what is known as the 'Oedipus complex' - that is, the emotional relation of a child to its two parents - in the mental life of human beings. Our astonishment diminishes when we realize that the Oedipus complex is the psychical correlate of two fundamental biological facts: the long period of the human child's dependence, and the remarkable way in which its sexual life reaches a first climax in the third to fifth years of life, and then, after a period of inhibition, sets in again at puberty. And here, the discovery was made that a third and extremely serious part of human intellectual activity, the part which has created the great institutions of religion, law, ethics, and all forms of civic life, has as its fundamental aim the enabling of the individual to master his Oedipus complex and to divert his libido from its infantile attachments into the social ones that are ultimately desired. The applications of psycho-analysis to the science of religion and sociology (e.g. by the present writer, Theodor Reik and Oskar Pfister), which have led to these findings, are still young and insufficiently appreciated; but it cannot be doubted that further studies will only confirm the certainty of these important conclusions. [1924f, 4117]

By its theory of the instincts psycho-analysis offended the feelings of individuals in so far as they regarded themselves as members of the social community; another branch of its theory was calculated to hurt every single person at the tenderest point of his own psychical development. Psycho-analysis disposed once and for all of the fairy tale of an asexual childhood. It demonstrated the fact that sexual interests and activities occur in small children from the beginning of their lives. It showed what transformations those activities pass through, how at about the age of five they succumb to inhibition and how from puberty onwards they enter the service of the reproductive function. It recognized that early infantile sexual life reaches its peak in what is known as the Oedipus complex (an emotional attachment of the child to the parent of the opposite sex accompanied by an attitude of rivalry to the parent of the same sex) and that at that period of life this impulsion extends uninhibited into a straightforward sexual desire. This can be confirmed so easily that only the greatest efforts could make it possible to overlook it. Every individual has in fact gone through this phase but has afterwards energetically repressed its purport and succeeded in forgetting it. A horror of incest and an enormous sense of guilt are left over from this prehistoric epoch of the individual's existence. It may be that something quite similar occurred in the prehistoric epoch of the human species as a whole and that the beginnings of morality, religion and social order were intimately connected with the surmounting of that primaeval era. To adults their prehistory seems so inglorious that they refuse to allow themselves to be reminded of it: they were infuriated when psycho-analysis tried to lift the veil of amnesia from their years of childhood. There was only one way out: what psycho-analysis asserted must be false and what posed as a new science must be a tissue of fancies and distortions. [1925e, 4128]

¹ This is an opportunity for correcting a statement which I made many years ago. I believed that the sexual interest of children, unlike that of pubescents, was aroused, not by the difference between the sexes, but by the problem of where babies come from. We now see that, at all events with girls, this is certainly not the case. With boys it may no doubt happen sometimes one way and sometimes the other; or with both sexes chance experiences may determine the event. [1925j, 4150]
The most striking of the processes at puberty has been picked upon as constituting its essence: the manifest growth of the external genitalia. (The latency period of childhood is, on the other hand, characterized by a relative cessation of their growth.) In the meantime the development of the internal genitalia has advanced far enough for them to be able to discharge the sexual products or, as the case may be, to bring about the formation of a new living organism. Thus a highly complicated apparatus has been made ready and awaits the moment of being put into operation.

[1905d, 1525]

As we all know, it is not until puberty that the sharp distinction is established between the masculine and feminine characters. From that time on, this contrast has a more decisive influence than any other upon the shaping of human life. It is true that the masculine and feminine dispositions are already easily recognizable in childhood. The development of the inhibitions of sexuality (shame, disgust, pity, etc.) takes place in little girls earlier and in the face of less resistance than in boys; the tendency to sexual repression seems in general to be greater; and, where the component instincts of sexuality appear, they prefer the passive form. The auto-erotic activity of the erotogenic zones is, however, the same in both sexes, and owing to this uniformity there is no possibility of a distinction between the two sexes such as arises after puberty. So far as the auto-erotic and masturbatory manifestations of sexuality are concerned, we might lay it down that the sexuality of little girls is of a wholly masculine character. Indeed, if we were able to give a more definite connotation to the concepts of 'masculine' and 'feminine', it would even be possible to maintain that libido is invariably and necessarily of a masculine nature, whether it occurs in men or in women and irrespective of whether its object is a man or a woman.

[1905d, 1533]

The results of the threat of castration are multifarious and incalculable; they affect the whole of a boy's relations with his father and mother and subsequently with men and women in general. As a rule the child's masculinity is unable to stand up to this first shock. In order to preserve his sexual organ he renounces the possession of his mother more or less completely; his sexual life often remains permanently encumbered by the prohibition. If a strong feminine component, as we call it, is present in him, its strength is increased by this intimidation of his masculinity. He falls into a passive attitude to his father, such as he attributes to his mother. It is true that as a result of the threat he has given up masturbation, but not the activities of his imagination accompanying it. On the contrary, since these are now the only form of sexual satisfaction remaining to him, he indulges in them more than before and in these phantasies, though he still continues to identify himself with his father, he also does so, simultaneously and perhaps predominantly, with his mother. Derivatives and modified products of these early masturbatory phantasies usually make their way into his later ego and play a part in the formation of his character. Apart from this encouragement of his femininity, fear and hatred of his father gain greatly in intensity. The boy's masculinity withdraws, as it were, into a defiant attitude towards his father, which will dominate his later behaviour in human society in a compulsive fashion. A residue of his erotic fixation to his mother is often left in the form of an excessive dependence on her, and this persists as a kind of bondage to women. He no longer ventures to love his mother, but he cannot risk not being loved by her, for in that case he would be in danger of being betrayed by her to his father and handed over to castration. The whole experience, with all its antecedents and consequences, of which my account has only been able to give a selection, is subjected to a highly energetic repression, and, as is made possible by the laws operating in the unconscious id, all the mutually contending emotional impulses and reactions which are set going at that time are preserved in the unconscious and ready to disturb the later development of the ego after puberty. When the somatic process of sexual maturation puts fresh life into the old libidinal fixations which had apparently been surmounted, sexual life will turn out to be inhibited, without homogeneity and fallen apart into mutually conflicting urges.

[1940a [1938], 4998]
INTERRUPTIONS OF THE LATENCY PERIOD   We must not deceive ourselves as to the hypothetical nature and insufficient clarity of our knowledge concerning the processes of the infantile period of latency or deferment; but we shall be on firmer ground in pointing out that such an application of infantile sexuality represents an educational ideal from which individual development usually diverges at some point and often to a considerable degree. From time to time a fragmentary manifestation of sexuality which has evaded sublimation may break through; or some sexual activity may persist through the whole duration of the latency period until the sexual instinct emerges with greater intensity at puberty. In so far as educators pay any attention at all to infantile sexuality, they behave exactly as though they shared our views as to the construction of the moral defensive forces at the cost of sexuality, and as though they knew that sexual activity makes a child ineducable: for they stigmatize every sexual manifestation by children as a ‘vice’, without being able to do much against it. We, on the other hand, have every reason for turning our attention to these phenomena which are so much dreaded by education, for we may expect them to help us to discover the original configuration of the sexual instincts.

[1905d, 1501]

It is in the world of ideas, however, that the choice of an object is accomplished at first; and the sexual life of maturing youth is almost entirely restricted to indulging in phantasies, that is, in ideas that are not destined to be carried into effect.¹ In these phantasies the infantile tendencies invariably emerge once more, but this time with intensified pressure from somatic sources. Among these tendencies the first place is taken with uniform frequency by the child’s sexual impulses towards his parents, which are as a rule already differentiated owing to the attraction of the opposite sex - the son being drawn towards his mother and the daughter towards her father.² At the same time as these plainly incestuous phantasies are overcome and repudiated, one of the most significant, but also one of the most painful, psychical achievements of the pubertal period is completed: detachment from parental authority, a process that alone makes possible the opposition, which is so important for the progress of civilization, between the new generation and the old. At every stage in the course of development through which all human beings ought by rights to pass, a certain number are held back; so there are some who have never got over their parents’ authority and have withdrawn their affection from them either very incompletely or not at all. They are mostly girls, who, to the delight of their parents, have persisted in all their childish love far beyond puberty. It is most instructive to find that it is precisely these girls who in their later marriage lack the capacity to give their husbands what is due to them; they make cold wives and remain sexually anaesthetic. We learn from this that sexual love and what appears to be non-sexual love for parents are fed from the same sources; the latter, that is to say, merely corresponds to an infantile fixation of the libido.

[1905d, 1539]

These affectionate fixations of the child persist throughout childhood, and continually carry along with them erotism, which is consequently diverted from its sexual aims. Then at the age of puberty they are joined by the powerful ‘sensual’ current which no longer mistakes its aims. It never fails, apparently, to follow the earlier paths and to cathect the objects of the primary infantile choice with quotas of libido that are now far stronger. Here, however, it runs up against the obstacles that have been erected in the meantime by the barrier against incest; consequently it will make efforts to pass on from these objects which are unsuitable in reality, and find a way as soon as possible to other, extraneous objects with which a real sexual life may be carried on. These new objects will still be chosen on the model (imago) of the infantile ones, but in the course of time they will attract to themselves the affection that was tied to the earlier ones. A man shall leave his father and his mother - according to the biblical command - and shall cleave unto his wife; affection and sensuality are then united. The greatest intensity of sensual passion will bring with it the highest psychical valuation of the object - this being the normal overvaluation of the sexual object on the part of a man.

[1912d, 2339]
I do not hesitate to make the two factors at work in psychical impotence in the strict sense - the factors of intense incestuous fixation in childhood and the frustration by reality in adolescence - responsible, too, for this extremely common characteristic of the love of civilized men. It sounds not only disagreeable but also paradoxical, yet it must nevertheless be said that anyone who is to be really free and happy in love must have surmounted his respect for women and have come to terms with the idea of incest with his mother or sister. Anyone who subjects himself to a serious self-examination on the subject of this requirement will be sure to find that he regards the sexual act basically as something degrading, which defiles and pollutes not only the body. The origin of this low opinion, which he will certainly not willingly acknowledge, must be looked for in the period of his youth in which the sensual current in him was already strongly developed but its satisfaction with an object outside the family was almost as completely prohibited as it was with an incestuous one.

[1912d, 2343]

The clinical fact which meets us behind the form of the Oedipus complex as it is established by analysis is of the highest practical significance. We learn that at puberty, when the sexual instinct first makes its demands in full strength, the old familiar incestuous objects are taken up again and freshly cathexed with libido. The infantile object-choice was only a feeble one, but it was a prelude, pointing the direction for the object-choice at puberty. At this point, then, very intense emotional processes come into play, following the direction of the Oedipus complex or reacting against it, processes which, however, since their premisses have become intolerable, must to a large extent remain apart from consciousness. From this time onwards, the human individual has to devote himself to the great task of detaching himself from his parents, and not until that task is achieved can he cease to be a child and become a member of the social community. For the son this task consists in detaching his libidinal wishes from his mother and employing them for the choice of a real outside love-object, and in reconciling himself with his father if he has remained in opposition to him, or in freeing himself from his pressure if, as a reaction to his infantile rebelliousness, he has become subservient to him. These tasks are set to everyone; and it is remarkable how seldom they are dealt with in an ideal manner - that is, in one which is correct both psychologically and socially. By neurotics, however, no solution at all is arrived at: the son remains all his life bowed beneath his father's authority and he is unable to transfer his libido to an outside sexual object. With the relationship changed round, the same fate can await the daughter. In this sense the Oedipus complex may justly be regarded as the nucleus of the neuroses.

[1916-1917, 3402]

The Diphasic Onset of Sexual Development. - Towards the end of the fifth year this early period of sexual life normally comes to an end. It is succeeded by a period of more or less complete latency, during which ethical restraints are built up, to act as defences against the desires of the Oedipus complex. In the subsequent period of puberty, the Oedipus complex is revivified in the unconscious and embarks upon further modifications. It is only at puberty that the sexual instincts develop to their full intensity; but the direction of that development, as well as all the predispositions for it, have already been determined by the early efflorescence of sexuality during childhood which preceded it. This diphasic development of the sexual function - in two stages, interrupted by the latency period - appears to be a biological peculiarity of the human species and to contain the determining factor for the origin of neuroses.

[1923a, 3923]
The advent of puberty opens a decisive chapter in the history of an obsessional neurosis. The genital organization which has been broken off in childhood starts again with great vigour. But, as we know, the sexual development in childhood determines what direction this new start at puberty will take. Not only will the early aggressive impulses be re-awakened; but a greater or lesser proportion of the new libidinal impulses - in bad cases the whole of them - will have to follow the course prescribed for them by regression and will emerge as aggressive and destructive tendencies. In consequence of the erotic trends being disguised in this way and owing to the powerful reaction-formations in the ego, the struggle against sexuality will henceforward be carried on under the banner of ethical principles. The ego will recoil with astonishment from promptings to cruelty and violence which enter consciousness from the id, and it has no notion that in them it is combating erotic wishes, including some to which it would not otherwise have taken exception. The overstrict super-ego insists all the more strongly on the suppression of sexuality, since this has assumed such repellent forms. Thus in obsessional neurosis the conflict is aggravated in two directions: the defensive forces become more intolerant and the forces that are to be fended off become more intolerable. Both effects are due to a single factor, namely, regression of the libido.
[1926d, 4275]
The characteristics of infantile sexual life which we have hitherto emphasized are the facts that it is essentially auto-erotic (i.e. that it finds its object in the infant's own body) and that its individual component instincts are upon the whole disconnected and independent of one another in their search for pleasure. The final outcome of sexual development lies in what is known as the normal sexual life of the adult, in which the pursuit of pleasure comes under the sway of the reproductive function and in which the component instincts, under the primacy of a single erotogenic zone, form a firm organization directed towards a sexual aim attached to some extraneous sexual object.

[1905d, 1516]

With the arrival of puberty, changes set in which are destined to give infantile sexual life its final, normal shape. The sexual instinct has hitherto been predominantly auto-erotic; it now finds a sexual object. Its activity has hitherto been derived from a number of separate instincts and erotogenic zones, which, independently of one another, have pursued a certain sort of pleasure as their sole sexual aim. Now, however, a new sexual aim appears, and all the component instincts combine to attain it, while the erotogenic zones become subordinated to the primacy of the genital zone.¹ Since the new sexual aim assigns very different functions to the two sexes, their sexual development now diverges greatly. That of males is the more straightforward and the more understandable, while that of females actually enters upon a kind of involution. A normal sexual life is only assured by an exact convergence of the two currents directed towards the sexual object and sexual aim, the affectionate current and the sensual one. (The former, the affectionate current, comprises what remains over of the infantile efflorescence of sexuality.) It is like the completion of a tunnel which has been driven through a hill from both directions.

[1905d, 1524]

The new sexual aim in men consists in the discharge of the sexual products. The earlier one, the attainment of pleasure, is by no means alien to it; on the contrary, the highest degree of pleasure is attached to this final act of the sexual process. The sexual instinct is now subordinated to the reproductive function; it becomes, so to say, altruistic. If this transformation is to succeed, the original dispositions and all the other characteristics of the instincts must be taken into account in the process. Just as on any other occasion on which the organism should by rights make new combinations and adjustments leading to complicated mechanisms, here too there are possibilities of pathological disorders if these new arrangements are not carried out. Every pathological disorder of sexual life is rightly to be regarded as an inhibition in development.

[1905d, 1524]

The processes at puberty thus establish the primacy of the genital zones; and, in a man, the penis, which has now become capable of erection, presses forward insistently towards the new sexual aim - penetration into a cavity in the body which excites his genital zone. Simultaneously on the psychical side the process of finding an object, for which preparations have been made from earliest childhood, is completed. At a time at which the first beginnings of sexual satisfaction are still linked with the taking of nourishment, the sexual instinct has a sexual object outside the infant's own body in the shape of his mother's breast. It is only later that the instinct loses that object, just at the time, perhaps, when the child is able to form a total idea of the person to whom the organ that is giving him satisfaction belongs. As a rule the sexual instinct then becomes auto-erotic, and not until the period of latency has been passed through is the original relation restored. There are thus good reasons why a child sucking at his mother's breast has become the prototype of every relation of love. The finding of an object is in fact a refunding of it.¹

[1905d, 1535]
In spite of the gaps in our knowledge of infantile sexual life, we had to proceed to an attempt at examining the alterations brought about in it by the arrival of puberty. We selected two of these as being the decisive ones: the subordination of all the other sources of sexual excitation under the primacy of the genital zones and the process of finding an object. Both of these are already adumbrated in childhood. The first is accomplished by the mechanism of exploiting fore-pleasure: what were formerly self-contained sexual acts, attended by pleasure and excitation, become acts preparatory to the new sexual aim (the discharge of the sexual products), the attainment of which, enormously pleasurable, brings the sexual excitation to an end. In this connection we had to take into account the differentiation of sexuality into masculine and feminine; and we found that in order to become a woman a further stage of repression is necessary, which discards a portion of infantile masculinity and prepares the woman for changing her leading genital zone. As regards object-choice, we found that it is given its direction by the childhood hints (revived at puberty) of the child's sexual inclination towards his parents and others in charge of him, but that it is diverted away from them, on to other people who resemble them, owing to the barrier against incest which has meanwhile been erected. Finally it must be added that during the transition period of puberty the processes of somatic and of psychical development continue for a time side by side independently, until the irruption of an intense mental erotic impulse, leading to the innervation of the genitals, brings about the unity of the erotic function which is necessary for normality.

If the relation between all the different dispositions - a relation which we will assume to be abnormal - persists and grows stronger at maturity, the result can only be a perverse sexual life. The analysis of abnormal constitutional dispositions of this kind has not yet been properly taken in hand. But we already know cases which can easily be explained on such a basis as this. Writers on the subject, for instance, have asserted that the necessary precondition of a whole number of perverse fixations lies in an innate weakness of the sexual instinct. In this form the view seems to me untenable. It makes sense, however, if what is meant is a constitutional weakness of one particular factor in the sexual instinct, namely the genital zone - a zone which takes over the function of combining the separate sexual activities for the purposes of reproduction. For if the genital zone is weak, this combination, which is required to take place at puberty, is bound to fail, and the strongest of the other components of sexuality will continue its activity as a perversion.¹

I could not further elucidate this part of my theory without a detailed discussion of my views on repression. It will be enough here to refer to my Three Essays (1905d), in which I have attempted to throw some light - if only a feeble one - on the somatic processes in which the essential nature of sexuality is to be looked for. I have there shown that the constitutional sexual disposition of children is incomparably more variegated than might have been expected, that it deserves to be described as 'polymorphously perverse' and that what is spoken of as the normal behaviour of the sexual function emerges from this disposition after certain of its components have been repressed. By pointing out the infantile elements in sexuality I was able to establish a simple correlation between health, perversion and neurosis. I showed that normality is a result of the repression of certain component instincts and constituents of the infantile disposition and of the subordination of the remaining constituents under the primacy of the genital zones in the service of the reproductive function. I showed that perversions correspond to disturbances of this coalescence owing to the overpowering and compulsory development of certain of the component instincts, while neuroses can be traced back to an excessive repression of the libidinal trends. Since almost all the perverse instincts of the infantile disposition can be recognized as the forces concerned in the formation of symptoms in neuroses, though in a state of repression, I was able to describe neurosis as being the 'negative' of perversion.
I do not know how the case could be better stated, but perhaps I may add a few remarks. It is undoubtedly nothing else but the customary prudishness and their own bad conscience over sexual matters that causes adults to adopt this attitude of 'mystery-making' in front of children; but possibly a part is also played by a piece of theoretical ignorance on their part, which we can counteract by giving the adults some enlightenment. It is commonly believed that the sexual instinct is absent in children and only begins to emerge in them at puberty when the sexual organs mature. This is a gross error, equally serious in its effects both on knowledge and on practice; and it is so easily corrected by observation that one wonders how it could ever have been made. As a matter of fact, the new-born baby brings sexuality with it into the world, certain sexual sensations accompany its development as a suckling and during early childhood, and only very few children would seem to escape sexual activities and sensations before puberty. Anyone who would like to find a detailed exposition of these statements can do so in my *Three Essays on the Theory of Sexuality*, to which I have referred above. There he will learn that the organs of reproduction proper are not the only parts of the body which provide sexual sensations of pleasure, and that nature has even so ordered matters that actual stimulations of the genitals are unavoidable during early childhood. This period of life, during which a certain quota of what is undoubtedly sexual pleasure is produced by the excitation of various parts of the skin (erotic zones), by the activity of certain biological instincts and as an accompanying excitation in many affective states, is called the period of auto-erotism, to use a term introduced by Havelock Ellis. All that puberty does is to give the genitals primacy among all the other zones and sources which produce pleasure, and thus to force erotism into the service of the function of reproduction. This process can naturally undergo certain inhibitions, and in many people (those who later become perverts and neurasthenics) it is only incompletely accomplished. On the other hand, the child is capable long before puberty of most of the psychical manifestations of love-tenderness, for example, devotion and jealousy. Often enough, too, an irruption of these mental states is associated with the physical sensations of sexual excitation, so that the child cannot remain in doubt as to the connection between the two. In short, except for his reproductive power, a child has a fully-developed capacity for love long before puberty; and it may be asserted that the 'mystery-making' merely prevents him from being able to gain an intellectual grasp of activities for which he is psychically prepared and physically adjusted.

[1907c, 1914]

Further prospects are opened up when we take into consideration the fact that in man the sexual instinct does not originally serve the purposes of reproduction at all, but has as its aim the gaining of particular kinds of pleasure.¹ It manifests itself in this way in human infancy, during which it attains its aim of gaining pleasure not only from the genitals but from other parts of the body (the erotic zones), and can therefore disregard any objects other than these convenient ones. We call this stage the stage of auto-erotism, and the child's upbringing has, in our view, the task of restricting it, because to linger in it would make the sexual instinct uncontrollable and unserviceable later on. The development of the sexual instinct then proceeds from auto-erotism to object-love and from the autonomy of the erotic zones to their subordination under the primacy of the genitals, which are put at the service of reproduction. During this development a part of the sexual excitation which is provided by the subject's own body is inhibited as being unserviceable for the reproductive function and in favourable cases is brought to sublimation. The forces that can be employed for cultural activities are thus to a great extent obtained through the suppression of what are known as the perverse elements of sexual excitation.

[1908d, 1953]
Thus the word 'to love' moves further and further into the sphere of the pure pleasure-relation of the ego to the object and finally becomes fixed to sexual objects in the narrower sense and to those which satisfy the needs of sublimated sexual instincts. The distinction between the ego-instincts and the sexual instincts which we have imposed upon our psychology is thus seen to be in conformity with the spirit of our language. The fact that we are not in the habit of saying of a single sexual instinct that it loves its object, but regard the relation of the ego to its sexual object as the most appropriate case in which to employ the word 'love' - this fact teaches us that the word can only begin to be applied in this relation after there has been a synthesis of all the component instincts of sexuality under the primacy of the genitals and in the service of the reproductive function.

[1915c, 2972]

It now remains for us to put together what we know of the genesis of love and hate. Love is derived from the capacity of the ego to satisfy some of its instinctual impulses auto-erotically by obtaining organ-pleasure. It is originally narcissistic, then passes over on to objects, which have been incorporated into the extended ego, and expresses the motor efforts of the ego towards these objects as sources of pleasure. It becomes intimately linked with the activity of the later sexual instincts and, when these have been completely synthesized, coincides with the sexual impulsion as a whole. Preliminary stages of love emerge as provisional sexual aims while the sexual instincts are passing through their complicated development. As the first of these aims we recognize the phase of incorporating or devouring - a type of love which is consistent with abolishing the object's separate existence and which may therefore be described as ambivalent. At the higher stage of the pregenital sadistic-anal organization, the striving for the object appears in the form of an urge for mastery, to which injury or annihilation of the object is a matter of indifference. Love in this form and at this preliminary stage is hardly to be distinguished from hate in its attitude towards the object. Not until the genital organization is established does love become the opposite of hate.

[1915c, 2973]

Accordingly, I can now describe to you the form taken by a child's sexual life before the establishment of the primacy of the genitals, preparations for which are made in the first period of infancy preceding the latency period and which is permanently organized from puberty onwards. A kind of loose organization which may be called 'pregenital' exists during this early period. During this phase what stand in the forefront are not the genital component instincts but the sadistic and anal ones. The contrast between 'masculine' and 'feminine' plays no part here as yet. Its place is taken by the contrast between 'active' and 'passive', which may be described as a precursor of the sexual polarity and which later on is soldered to that polarity. What appears to us as masculine in the activities of this phase, when we look at it from the point of view of the genital phase, turns out to be an expression of an instinct for mastery which easily passes over into cruelty. Trends with a passive aim are attached to the erotogenic zone of the anal orifice, which is very important at this period. The instincts for looking and for gaining knowledge are powerfully at work; the genitals actually play a part in sexual life only as organs for the excretion of urine. The component instincts of this phase are not without objects, but those objects do not necessarily converge into a single object. The sadistic-anal organization is the immediate forerunner of the phase of genital primacy. Detailed study shows how much of it is retained in the later definitive shape of things and shows too the way in which its component instincts are compelled to take their place in the new genital organization. Behind the sadistic-anal phase of libidinal development we get a glimpse of a still earlier and more primitive stage of organization, in which the erotogenic zone of the mouth plays the chief part. As you will guess, the sexual activity of sensual sucking belongs to it. We must admire the understanding of the Ancient Egyptians who, in their art, represented children, including the God Horus, with a finger in their mouth. Only recently Abraham has given examples of the traces which this primitive oral phase leaves behind it in later sexual life.

[1916-1917, 3395]
I can well suppose, Gentlemen, that this last account of the sexual organizations has obstructed rather than instructed you, and it may be that I have once more entered too much into details. But you must have patience. What you have just heard will derive increased value for you from its later application. For the present you should keep firmly in mind that sexual life (or, as we put it, the libidinal function) does not emerge as something ready-made and does not even develop further in its own likeness, but passes through a series of successive phases which do not resemble one another; its development is thus several times repeated - like that of a caterpillar into a butterfly. The turning-point of this development is the subordination of all the component sexual instincts under the primacy of the genitals and along with this the subjection of sexuality to the reproductive function. This is preceded by a sexual life that might be described as distracted - the independent activity of the different component instincts striving for organ-pleasure. This anarchy is mitigated by abortive beginnings of 'pregenital' organizations - a sadistic-anal phase preceded by an oral one, which is perhaps the most primitive. In addition, there are the various, still incompletely known, processes which lead one stage of organization over to the subsequent and next higher one. We shall learn later what an important light is thrown on the neuroses by the fact that the libido passes through such a long course of development and one which has so many breaks in it.

[1916-1917, 3396]

From that moment we had to face the problem of the later history of the anal-erotic instinctual impulses. What becomes of them when, owing to the establishment of a definitive genital organization, they have lost their importance in sexual life? Do they preserve their original nature, but in a state of repression? Are they sublimated or assimilated by transformation into character-traits? Or do they find a place within the new organization of sexuality characterized by genital primacy? Or, since none of these vicissitudes of anal erotism is likely to be the only one, to what extent and in what way does each of them share in deciding its fate? For the organic sources of anal erotism cannot of course be buried as a result of the emergence of the genital organization.

[1917c, 3599]

In the obscurity that reigns at present in the theory of the instincts, it would be unwise to reject any idea that promises to throw light on it. We started out from the great opposition between the life and death instincts. Now object-love itself presents us with a second example of a similar polarity - that between love (or other affection) and hate (or aggressiveness). If only we could succeed in relating these two polarities to each other and in deriving one from the other! From the very first we recognized the presence of a sadistic component in the sexual instinct.¹ As we know, it can make itself independent and can, in the form of a perversion, dominate an individual's entire sexual activity. It also emerges as a predominant component instinct in one of the 'pregenital organizations', as I have named them. But how can the sadistic instinct, whose aim it is to injure the object, be derived from Eros, the preserver of life? Is it not plausible to suppose that this sadism is in fact a death instinct which, under the influence of the narcissistic libido, has been forced away from the ego and has consequently only emerged in relation to the object? It now enters the service of the sexual function. During the oral stage of organization of the libido, the act of obtaining erotic mastery over an object coincides with that object's destruction; later, the sadistic instinct separates off, and finally, at the stage of genital primacy, it takes on, for the purposes of reproduction, the function of overpowering the sexual object to the extent necessary for carrying out the sexual act. It might indeed be said that the sadism which has been forced out of the ego has pointed the way for the libidinal components of the sexual instinct, and that these follow after it to the object. Wherever the original sadism has undergone no mitigation or intermixture, we find the familiar ambivalence of love and hate in erotic life.

[1920g, 3755]
In young children, for instance, ambivalent emotional attitudes towards those who are nearest to them exist side by side for a long time, without either of them interfering with the expression of the other and opposite one. If eventually a conflict breaks out between the two, it is often settled by the child making a change of object and displacing one of the ambivalent emotions on to a substitute. The history of the development of a neurosis in an adult will also show that a suppressed emotion may frequently persist for a long time in unconscious or even in conscious phantasies, the content of which naturally runs directly counter to some predominant tendency, and yet that this opposition does not result in any proceedings on the part of the ego against what it has repudiated. The phantasy is tolerated for quite a long time, until suddenly one day, usually as a result of an increase in the affective cathexis of the phantasy, a conflict breaks out between it and the ego with all the usual consequences. In the process of a child's development into a mature adult there is a more and more extensive integration of his personality, a co-ordination of the separate instinctual impulses and purposive trends which have grown up in him independently of one another. The analogous process in the domain of sexual life has long been known to us as the co-ordination of all the sexual instincts into a definitive genital organization. (Three Essays on the Theory of Sexuality, 1905d.) Moreover, that the unification of the ego is liable to the same interferences as that of the libido is shown by numerous familiar instances, such as that of men of science who have preserved their faith in the Bible, and other similar cases. - The various possible ways in which the ego can later disintegrate form a special chapter in psychopathology.

The Development of the Libido. - The sexual instinct, the dynamic manifestation of which in mental life we shall call 'libido', is made up of component instincts into which it may once more break up and which are only gradually united into well-defined organizations. The sources of these component instincts are the organs of the body and in particular certain specially marked erotogenic zones; but contributions are made to libido from every important functional process in the body. At first the individual component instincts strive for satisfaction independently of one another, but in the course of development they become more and more convergent and concentrated. The first (pregenital) stage of organization to be discerned is the oral one, in which - in conformity with the suckling's predominant interest - the oral zone plays the leading part. This is followed by the sadistic-anal organization, in which the anal zone and the component instinct of sadism are particularly prominent; at this stage the difference between the sexes is represented by the contrast between active and passive. The third and final stage of organization is that in which the majority of the component instincts converge under the primacy of the genital zones. As a rule this development is passed through swiftly and unobtrusively; but some individual portions of the instincts remain behind at the prodromal stages of the process and thus give rise to fixations of libido, which are important as constituting predispositions for subsequent irruptions of repressed impulses and which stand in a definite relation to the later development of neuroses and perversions. (See the article on 'The Libido Theory').

The Process of Finding an Object, and the Oedipus Complex. - In the first instance the oral component instinct finds satisfaction by attaching itself to the satiating of the desire for nourishment; and its object is the mother's breast. It then detaches itself, becomes independent and at the same time auto-erotic, that is, it finds an object in the child's own body. Others of the component instincts also start by being auto-erotic and are not until later diverted on to an external object. It is a particularly important fact that the component instincts belonging to the genital zone habitually pass through a period of intense auto-erotic satisfaction. The component instincts are not all equally serviceable in the final genital organization of libido; some of them (for instance, the anal components) are consequently left aside and suppressed, or undergo complicated transformations.
To-day I should no longer be satisfied with the statement that in the early period of childhood the primacy of the genitals has been effected only very incompletely or not at all. The approximation of the child's sexual life to that of the adult goes much further and is not limited solely to the coming into being of the choice of an object. Even if a proper combination of the component instincts under the primacy of the genitals is not effected, nevertheless, at the height of the course of development of infantile sexuality, interest in the genitals and in their activity acquires a dominating significance which falls little short of that reached in maturity. At the same time, the main characteristic of this 'infantile genital organization' is its difference from the final genital organization of the adult. This consists in the fact that, for both sexes, only one genital, namely the male one, comes into account. What is present, therefore, is not a primacy of the genitals, but a primacy of the phallus.

It is not unimportant to bear in mind what transformations are undergone, during the sexual development of childhood, by the polarity of sex with which we are familiar. A first antithesis is introduced with the choice of object, which, of course, presupposes a subject and an object. At the stage of the pregenital sadistic-anal organization, there is as yet no question of male and female; the antithesis between active and passive is the dominant one.¹ At the following stage of infantile genital organization, which we now know about, maleness exists, but not femaleness. The antithesis here is between having a male genital and being castrated. It is not until development has reached its completion at puberty that the sexual polarity coincides with male and female. Maleness combines subject, activity and possession of the penis; femaleness takes over object and passivity. The vagina is now valued as a place of shelter for the penis; it enters into the heritage of the womb.

Erotogenic masochism accompanies the libido through all its developmental phases and derives from them its changing psychical coatings. The fear of being eaten up by the totem animal (the father) originates from the primitive oral organization; the wish to be beaten by the father comes from the sadistic-anal phase which follows it; castration, although it is later disavowed, enters into the content of masochistic phantasies as a precipitate of the phallic stage or organization;¹ and from the final genital organization there arise, of course, the situations of being copulated with and of giving birth, which are characteristic of femaleness. The part played in masochism by the nates, too, is easily understandable, apart from its obvious basis in reality. The nates are the part of the body which is given erotogenic preference in the sadistic-anal phase, like the breast in the oral phase and the penis in the genital phase.
By its theory of the instincts psycho-analysis offended the feelings of individuals in so far as they regarded themselves as members of the social community; another branch of its theory was calculated to hurt every single person at the tenderest point of his own psychical development. Psycho-analysis disposed once and for all of the fairy tale of an asexual childhood. It demonstrated the fact that sexual interests and activities occur in small children from the beginning of their lives. It showed what transformations those activities pass through, how at about the age of five they succumb to inhibition and how from puberty onwards they enter the service of the reproductive function. It recognized that early infantile sexual life reaches its peak in what is known as the Oedipus complex (an emotional attachment of the child to the parent of the opposite sex accompanied by an attitude of rivalry to the parent of the same sex) and that at that period of life this impulse extends uninhibited into a straightforward sexual desire. This can be confirmed so easily that only the greatest efforts could make it possible to overlook it. Every individual has in fact gone through this phase but has afterwards energetically repressed its purport and succeeded in forgetting it. A horror of incest and an enormous sense of guilt are left over from this prehistoric epoch of the individual's existence. It may be that something quite similar occurred in the prehistoric epoch of the human species as a whole and that the beginnings of morality, religion and social order were intimately connected with the surmounting of that primaeval era. To adults their prehistory seems so inglorious that they refuse to allow themselves to be reminded of it: they were infuriated when psycho-analysis tried to lift the veil of amnesia from their years of childhood. There was only one way out: what psycho-analysis asserted must be false and what posed as a new science must be a tissue of fancies and distortions.

The sexual function, as I found, is in existence from the very beginning of the individual's life, though at first it is attached to the other vital functions and does not become independent of them until later; it has to pass through a long and complicated process of development before it becomes what we are familiar with as the normal sexual life of the adult. It begins by manifesting itself in the activity of a whole number of component instincts. These are dependent upon erotogenic zones in the body; some of them make their appearance in pairs of opposite impulses (such as sadism and masochism or the impulses to look and to be looked at); they operate independently of one another in a search for pleasure, and they find their object for the most part in the subject's own body. Thus at first the sexual function is non-centralized and predominantly auto-erotic. Later, syntheses begin to appear in it; a first stage of organization is reached under the dominance of the oral components, an anal-sadistic stage follows, and it is only after the third stage has at last been reached that the primacy of the genitals is established and that the sexual function begins to serve the ends of reproduction. In the course of this process of development a number of elements of the various component instincts turn out to be unserviceable for this last end and are therefore left on one side or turned to other uses, while others are diverted from their aims and carried over into the genital organization. I gave the name of libido to the energy of the sexual instincts and to that form of energy alone. I was next driven to suppose that the libido does not always pass through its prescribed course of development smoothly. As a result either of the excessive strength of certain of the components or of experiences involving premature satisfaction, fixations of the libido may occur at various points in the course of its development. If subsequently a repression takes place, the libido flows back to these points (a process described as regression), and it is from them that the energy breaks through in the form of a symptom. Later on it further became clear that the localization of the point of fixation is what determines the choice of neurosis, that is, the form in which the subsequent illness makes its appearance.

As regards the metapsychological explanation of regression, I am inclined to find it in a 'defusion of instinct', in a detachment of the erotic components which, with the onset of the genital stage, had joined the destructive cathexes belonging to the sadistic phase.
The advent of puberty opens a decisive chapter in the history of an obsessional neurosis. The genital organization which has been broken off in childhood starts again with great vigour. But, as we know, the sexual development in childhood determines what direction this new start at puberty will take. Not only will the early aggressive impulses be re-awakened; but a greater or lesser proportion of the new libidinal impulses - in bad cases the whole of them - will have to follow the course prescribed for them by regression and will emerge as aggressive and destructive tendencies. In consequence of the erotic trends being disguised in this way and owing to the powerful reaction-formations in the ego, the struggle against sexuality will henceforward be carried on under the banner of ethical principles. The ego will recoil with astonishment from promptings to cruelty and violence which enter consciousness from the id, and it has no notion that in them it is combating erotic wishes, including some to which it would not otherwise have taken exception. The overstrict super-ego insists all the more strongly on the suppression of sexuality, since this has assumed such repellent forms. Thus in obsessional neurosis the conflict is aggravated in two directions: the defensive forces become more intolerant and the forces that are to be fended off become more intolerable. Both effects are due to a single factor, namely, regression of the libido.

[1926d, 4275]

It is almost humiliating that, after working so long, we should still be having difficulty in understanding the most fundamental facts. But we have made up our minds to simplify nothing and to hide nothing. If we cannot see things clearly we will at least see clearly what the obscurities are. What is hampering us here is evidently some hitch in the development of our theory of the instincts. We began by tracing the organization of the libido through its successive stages - from the oral through the sadistic-anal to the genital - and in doing so placed all the components of the sexual instinct on the same footing. Later it appeared that sadism was the representative of another instinct, which was opposed to Eros. This new view, that the instincts fall into two groups, seems to explode the earlier construction of the successive stages of libidinal organization. But we do not have to break fresh ground in order to find a way out of the difficulty. The solution has been at hand for a long time and lies in the fact that what we are concerned with are scarcely ever pure instinctual impulses but mixtures in various proportions of the two groups of instincts. If this is so, there is no need to revise our view of the organizations of the libido. A sadistic cathexis of an object may also legitimately claim to be treated as a libidinal one; and an aggressive impulse against the father can just as well be subjected to repression as a tender impulse towards the mother. Nevertheless we shall bear in mind for future consideration the possibility that repression is a process which has a special relation to the genital organization of the libido and that the ego resorts to other methods of defence when it has to secure itself against the libido on other levels of organization. To continue: a case like 'Little Hans's' does not enable us to come to any clear conclusion. It is true that in him an aggressive impulse was disposed of by repression, but this happened after the genital organization had been reached.

[1926d, 4282]
(2) For cultural reasons the most intense repression falls upon the sexual instincts; but it is precisely in connection with them that repression most easily miscarries, so that neurotic symptoms are found to be substitutive satisfactions of repressed sexuality. The belief that in man sexual life begins only at puberty is incorrect. On the contrary, signs of it can be detected from the beginning of extra-uterine existence; it reaches a first culminating point at or before the fifth year ('early period'), after which it is inhibited or interrupted ('latency period') until the age of puberty, which is the second climax of its development. This diphasic onset of sexual development seems to be distinctive of the genus Homo. All experiences during the first period of childhood are of the greatest importance to the individual, and in combination with his inherited sexual constitution form the dispositions for the subsequent development of character and disease. It is wrong to make sexuality coincide with 'genitality'. The sexual instincts pass through a complicated course of development, and it is only at the end of it that the 'primacy of the genital zones' is attained. Before this there are a number of 'pregenital' organizations of the libido - points at which it may become 'fixated' and to which, in the event of subsequent repression, it will return ('regression'). The infantile fixations of the libido are what determine the form of any later neurosis. Thus the neuroses are to be regarded as inhibitions in the development of the libido. There are no specific causes of nervous disorders; the question whether a conflict finds a healthy solution or leads to a neurotic inhibition of function depends upon quantitative considerations.

[1926f, 4405]

We find ourselves on firmer ground when we investigate the manner in which the life of the instincts serves the sexual function. Here we have acquired quite definite knowledge, with which you too are already familiar. It is not the case, then, that we recognize a sexual instinct which is from the first the vehicle of an urge towards the aim of the sexual function - the union of the two sex-cells. What we see is a great number of component instincts arising from different areas and regions of the body, which strive for satisfaction fairly independently of one another and find that satisfaction in something that we may call 'organ-pleasure'. The genitals are the latest of these 'erotogenic zones' and the name of 'sexual' pleasure cannot be withheld from their organ-pleasure. These impulses which strive for pleasure are not all taken up into the final organization of the sexual function. A number of them are set aside as unserviceable, by repression or some other means; a few of them are diverted from their aim in the remarkable manner I have mentioned and used to strengthen other impulses; yet others persist in minor roles, and serve for the performance of introductory acts, for the production of fore-pleasure. You have heard how in the course of this long-drawn-out development several phases of preliminary organization can be recognized and also how this history of the sexual function explains its aberrations and atrophies. The first of these 'pregenital' phases is known to us as the oral one because, in conformity with the way in which an infant in arms is nourished, the erotogenic zone of the mouth dominates what may be called the sexual activity of that period of life. At a second level the sadistic and anal impulses come to the fore, undoubtedly in connection with the appearance of the teeth, the strengthening of the muscular apparatus and the control of the sphincter functions. We have learnt a number of interesting details about this remarkable stage of development in particular. Thirdly comes the phallic phase in which in both sexes the male organ (and what corresponds to it in girls) attains an importance which can no longer be overlooked. We have reserved the name of genital phase for the definitive sexual organization which is established after puberty and in which the female genital organ for the first time meets with the recognition which the male one acquired long before.

[1933a, 4703]
It would be a mistake to suppose that these three phases succeed one another in a clear-cut fashion. One may appear in addition to another; they may overlap one another, may be present alongside of one another. In the early phases the different component instincts set about their pursuit of pleasure independently of one another; in the phallic phase there are the beginnings of an organization which subordinates the other urges to the primacy of the genitals and signifies the start of a co-ordination of the general urge towards pleasure into the sexual function. The complete organization is only achieved at puberty, in a fourth, genital phase. A state of things is then established in which (1) some earlier libidinal cathexes are retained, (2) others are taken into the sexual function as preparatory, auxiliary acts, the satisfaction of which produces what is known as fore-pleasure, and (3) other urges are excluded from the organization, and are either suppressed altogether (repressed) or are employed in the ego in another way, forming character-traits or undergoing sublimation with a displacement of their aims.

[1940a [1938], 4966]
LEADING ZONES IN MEN AND WOMEN

Apart from this I have only the following to add. The leading erotogenic zone in female children is located at the clitoris, and is thus homologous to the masculine genital zone of the glans penis. All my experience concerning masturbation in little girls has related to the clitoris and not to the regions of the external genitalia that are important in later sexual functioning. I am even doubtful whether a female child can be led by the influence of seduction to anything other than clitoridal masturbation. If such a thing occurs, it is quite exceptional. The spontaneous discharges of sexual excitement which occur so often precisely in little girls are expressed in spasms of the clitoris. Frequent erections of that organ make it possible for girls to form a correct judgement, even without any instruction, of the sexual manifestations of the other sex: they merely transfer on to boys the sensations derived from their own sexual processes.

[1905d, 1534]

If we are to understand how a little girl turns into a woman, we must follow the further vicissitudes of this excitability of the clitoris. Puberty, which brings about so great an accession of libido in boys, is marked in girls by a fresh wave of repression, in which it is precisely clitoridal sexuality that is affected. What is thus overtaken by repression is a piece of masculine sexuality. The intensification of the brake upon sexuality brought about by pubertal repression in women serves as a stimulus to the libido in men and causes an increase of its activity. Along with this heightening of libido there is also an increase of sexual overvaluation which only emerges in full force in relation to a woman who holds herself back and who denies her sexuality. When at last the sexual act is permitted and the clitoris itself becomes excited, it still retains a function: the task, namely, of transmitting the excitation to the adjacent female sexual parts, just as, to use a simile, pine shavings can be kindled in order to set a log of harder wood on fire. Before this transference can be effected, a certain interval of time must often elapse, during which the young woman is anaesthetic. This anaesthesia may become permanent if the clitoridal zone refuses to abandon its excitability, an event for which the way is prepared precisely by an extensive activity of that zone in childhood. Anaesthesia in women, as is well known, is often only apparent and local. They are anaesthetic at the vaginal orifice but are by no means incapable of excitement originating in the clitoris or even in other zones. Alongside these erotogenic determinants of anaesthesia must also be set the psychical determinants, which equally, arise from repression.

[1905d, 1534]

When erotogenic susceptibility to stimulation has been successfully transferred by a woman from the clitoris to the vaginal orifice, it implies that she has adopted a new leading zone for the purposes of her later sexual activity. A man, on the other hand, retains his leading zone unchanged from childhood. The fact that women change their leading erotogenic zone in this way, together with the wave of repression at puberty, which, as it were, puts aside their childish masculinity, are the chief determinants of the greater proneness of woman to neurosis and especially to hysteria. These determinants, therefore, are intimately related to the essence of femininity.

[1905d, 1534]
The processes at puberty thus establish the primacy of the genital zones; and, in a man, the penis, which has now become capable of erection, presses forward insistently towards the new sexual aim - penetration into a cavity in the body which excites his genital zone. Simultaneously on the psychical side the process of finding an object, for which preparations have been made from earliest childhood, is completed. At a time at which the first beginnings of sexual satisfaction are still linked with the taking of nourishment, the sexual instinct has a sexual object outside the infant's own body in the shape of his mother's breast. It is only later that the instinct loses that object, just at the time, perhaps, when the child is able to form a total idea of the person to whom the organ that is giving him satisfaction belongs. As a rule the sexual instinct then becomes auto-erotic, and not until the period of latency has been passed through is the original relation restored. There are thus good reasons why a child sucking at his mother's breast has become the prototype of every relation of love. The finding of an object is in fact a refinding of it.¹

[1905d, 1535]

In spite of the gaps in our knowledge of infantile sexual life, we had to proceed to an attempt at examining the alterations brought about in it by the arrival of puberty. We selected two of these as being the decisive ones: the subordination of all the other sources of sexual excitation under the primacy of the genital zones and the process of finding an object. Both of these are already adumbrated in childhood. The first is accomplished by the mechanism of exploiting fore-pleasure: what were formerly self-contained sexual acts, attended by pleasure and excitation, become acts preparatory to the new sexual aim (the discharge of the sexual products), the attainment of which, enormously pleasurable, brings the sexual excitation to an end. In this connection we had to take into account the differentiation of sexuality into masculine and feminine; and we found that in order to become a woman a further stage of repression is necessary, which discards a portion of infantile masculinity and prepares the woman for changing her leading genital zone. As regards object-choice, we found that it is given its direction by the childhood hints (revived at puberty) of the child's sexual inclination towards his parents and others in charge of him, but that it is diverted away from them, on to other people who resemble them, owing to the barrier against incest which has meanwhile been erected. Finally it must be added that during the transition period of puberty the processes of somatic and of psychical development continue for a time side by side independently, until the irruption of an intense mental erotic impulse, leading to the innervation of the genitals, brings about the unity of the erotic function which is necessary for normality.

[1905d, 1545]
If this idea of a woman with a penis becomes 'fixated' in an individual when he is a child, resisting all the influences of later life and making him as a man unable to do without a penis in his sexual object, then, although in other respects he may lead a normal sexual life, he is bound to become a homosexual, and will seek his sexual object among men who, owing to some other physical and mental characteristics, remind him of women. Real women, when he comes to know them later, remain impossible as sexual objects for him, because they lack the essential sexual attraction; indeed, in connection with another impression of his childhood life, they may even become abhorrent to him. The child, having been mainly dominated by excitations in the penis, will usually have obtained pleasure by stimulating it with his hand; he will have been detected in this by his parents or nurse and terrorized by the threat of having his penis cut off. The effect of this 'threat of castration' is proportionate to the value set upon that organ and is quite extraordinarily deep and persistent. Legends and myths testify to the upheaval in the child's emotional life and to the horror which is linked with the castration complex - a complex which is subsequently remembered by consciousness with corresponding reluctance. The woman's genitalia, when seen later on, are regarded as a mutilated organ and recall this threat, and they therefore arouse horror instead of pleasure in the homosexual. This reaction cannot be altered in any way when the homosexual comes to learn from science that his childish assumption that women had a penis too was not so far wrong after all. Anatomy has recognized the clitoris within the female pudenda as being an organ that is homologous to the penis; and the physiology of the sexual processes has been able to add that this small penis which does not grow any bigger behaves in fact during childhood like a real and genuine penis - that it becomes the seat of excitations which lead to its being touched, that its excitability gives the little girl's sexual activity a masculine character and that a wave of repression in the years of puberty is needed in order for this masculine sexuality to be discarded and the woman to emerge. Since the sexual function of many women is crippled, whether by their obstinate clinging on to this excitability of the clitoris so that they remain anaesthetic in intercourse, or by such excessive repression occurring that its operation is partly replaced by hysterical compensatory formations - all this seems to show that there is some truth in the infantile sexual theory that women, like men, possess a penis.

[1908c, 1971]

Speaking as a whole, hysterical attacks, like hysteria in general, revive a piece of sexual activity in women which existed during their childhood and at that time revealed an essentially masculine character. It can often be observed that girls who have shown a boyish nature and inclinations up to the years before puberty are precisely those who become hysterical from puberty onwards. In a whole number of cases the hysterical neurosis merely represents an excessive accentuation of the typical wave of repression which, by doing away with her masculine sexuality, allows the woman to emerge.

[1909a, 1984]
Though I am anxious to cut short this discussion still further, I must nevertheless tell you a little about the sexual researches of children: they are too characteristic of infantile sexuality and of too great significance for the symptomatology of the neuroses to be passed over. Infantile sexual researches begin very early, sometimes before the third year of life. They do not relate to the distinction between the sexes, for this means nothing to children, since they (or at any rate boys) attribute the same male genital to both sexes. If, afterwards, a boy makes the discovery of the vagina from seeing his little sister or a girl playmate, he tries, to begin with, to disavow the evidence of his senses, for he cannot imagine a human creature like himself who is without such a precious portion. Later on, he takes fright at the possibility thus presented to him; and any threats that may have been made to him earlier, because he took too intense an interest in his little organ, now produce a deferred effect. He comes under the sway of the castration complex, the form taken by which plays a great part in the construction of his character if he remains normal, in his neurosis if he falls ill, and in his resistances if he comes into analytic treatment. As regards little girls, we can say of them that they feel greatly at a disadvantage owing to their lack of a big, visible penis, that they envy boys for possessing one and that, in the main for this reason, they develop a wish to be a man - a wish that re-emerges later on, in any neurosis that may arise if they meet with a mishap in playing a feminine part. In her childhood, moreover, a girl's clitoris takes on the role of a penis entirely: it is characterized by special excitability and is the area in which auto-erotic satisfaction is obtained. The process of a girl's becoming a woman depends very much on the clitoris passing on this sensitivity to the vaginal orifice in good time and completely. In cases of what is known as sexual anaesthesia in women the clitoris has obstinately retained its sensitivity.

[1916-1917, 3387]

There is yet another surprising effect of penis-envy, or of the discovery of the inferiority of the clitoris, which is undoubtedly the most important of all. In the past I had often formed an impression that in general women tolerate masturbation worse than men, that they more frequently fight against it and that they are unable to make use of it in circumstances in which a man would seize upon it as a way of escape without any hesitation. Experience would no doubt elicit innumerable exceptions to this statement, if we attempted to turn it into a rule. The reactions of human individuals of both sexes are of course made up of masculine and feminine traits. But it appeared to me nevertheless as though masturbation were further removed from the nature of women than of men, and the solution of the problem could be assisted by the reflection that masturbation, at all events of the clitoris, is a masculine activity and that the elimination of clitoridal sexuality is a necessary precondition for the development of femininity. Analyses of the remote phallic period have now taught me that in girls, soon after the first signs of penis-envy, an intense current of feeling against masturbation makes its appearance, which cannot be attributed exclusively to the educational influence of those in charge of the child. This impulse is clearly a forerunner of the wave of repression which at puberty will do away with a large amount of the girl's masculine sexuality in order to make room for the development of her femininity. It may happen that this first opposition to auto-erotic activity fails to attain its end. And this was in fact the case in the instances which I analysed. The conflict continued, and both then and later the girl did everything she could to free herself from the compulsion to masturbate. Many of the later manifestations of sexual life in women remain unintelligible unless this powerful motive is recognized.

[1925j, 4153]
¹ (Footnote added 1935:) The information about infantile sexuality was obtained from the study of men and the theory deduced from it was concerned with male children. It was natural enough to expect to find a complete parallel between the two sexes; but this turned out not to hold. Further investigations and reflections revealed profound differences between the sexual development of men and women. The first sexual object of a baby girl (just as of a baby boy) is her mother; and before a woman can reach the end of her normal development she has to change not only her sexual object but also her leading genital zone. From this circumstance difficulties arise and possibilities of inhibition which are not present in the case of men.

[1925d, 4212]

During the phase of the normal Oedipus complex we find the child tenderly attached to the parent of the opposite sex, while its relation to the parent of its own sex is predominantly hostile. In the case of a boy there is no difficulty in explaining this. His first love-object was his mother. She remains so; and, with the strengthening of his erotic desires and his deeper insight into the relations between his father and mother, the former is bound to become his rival. With the small girl it is different. Her first object, too, was her mother. How does she find her way to her father? How, when and why does she detach herself from her mother? We have long understood that the development of female sexuality is complicated by the fact that the girl has the task of giving up what was originally her leading genital zone the clitoris - in favour of a new zone - the vagina. But it now seems to us that there is a second change of the same sort which is no less characteristic and important for the development of the female: the exchange of her original object - her mother - for her father. The way in which the two tasks are connected with each other is not yet clear to us.

[1931b, 4590]

First of all, there can be no doubt that the bisexuality, which is present, as we believe, in the innate disposition of human beings, comes to the fore much more clearly in women than in men. A man, after all, has only one leading sexual zone, one sexual organ, whereas a woman has two: the vagina - the female organ proper - and the clitoris, which is analogous to the male organ. We believe we are justified in assuming that for many years the vagina is virtually non-existent and possibly does not produce sensations until puberty. It is true that recently an increasing number of observers report that vaginal impulses are present even in these early years. In women, therefore, the main genital occurrences of childhood must take place in relation to the clitoris. Their sexual life is regularly divided into two phases, of which the first has a masculine character, while only the second is specifically feminine. Thus in female development there is a process of transition from the one phase to the other, to which there is nothing analogous in the male. A further complication arises from the fact that the clitoris, with its virile character, continues to function in later female sexual life in a manner which is very variable and which is certainly not yet satisfactorily understood. We do not, of course, know the biological basis of these peculiarities in women; and still less are we able to assign them any teleological purpose.

[1931b, 4592]
Both sexes seem to pass through the early phases of libidinal development in the same manner. It might have been expected that in girls there would already have been some lag in aggressiveness in the sadistic-anal phase, but such is not the case. Analysis of children's play has shown our women analysts that the aggressive impulses of little girls leave nothing to be desired in the way of abundance and violence. With their entry into the phallic phase the differences between the sexes are completely eclipsed by their agreements. We are now obliged to recognize that the little girl is a little man. In boys, as we know, this phase is marked by the fact that they have learnt how to derive pleasurable sensations from their small penis and connect its excited state with their ideas of sexual intercourse. Little girls do the same thing with their still smaller clitoris. It seems that with them all their masturbatory acts are carried out on this penis-equivalent, and that the truly feminine vagina is still undiscovered by both sexes. It is true that there are a few isolated reports of early vaginal sensations as well, but it could not be easy to distinguish these from sensations in the anus or vestibulum; in any case they cannot play a great part. We are entitled to keep to our view that in the phallic phase of girls the clitoris is the leading erotogenic zone. But it is not, of course, going to remain so. With the change to femininity the clitoris should wholly or in part hand over its sensitivity, and at the same time its importance, to the vagina. This would be one of the two tasks which a woman has to perform in the course of her development, whereas the more fortunate man has only to continue at the time of his sexual maturity the activity that he has previously carried out at the period of the early efflorescence of his sexuality.
[1933a, 4720]
With the arrival of puberty, changes set in which are destined to give infantile sexual life its final, normal shape. The sexual instinct has hitherto been predominantly auto-erotic; it now finds a sexual object. Its activity has hitherto been derived from a number of separate instincts and erotogenic zones, which, independently of one another, have pursued a certain sort of pleasure as their sole sexual aim. Now, however, a new sexual aim appears, and all the component instincts combine to attain it, while the erotogenic zones become subordinated to the primacy of the genital zone.¹ Since the new sexual aim assigns very different functions to the two sexes, their sexual development now diverges greatly. That of males is the more straightforward and the more understandable, while that of females actually enters upon a kind of involution. A normal sexual life is only assured by an exact convergence of the two currents directed towards the sexual object and sexual aim, the affectionate current and the sensual one. (The former, the affectionate current, comprises what remains over of the infantile efflorescence of sexuality.) It is like the completion of a tunnel which has been driven through a hill from both directions. [1905d, 1524]

The new sexual aim in men consists in the discharge of the sexual products. The earlier one, the attainment of pleasure, is by no means alien to it; on the contrary, the highest degree of pleasure is attached to this final act of the sexual process. The sexual instinct is now subordinated to the reproductive function; it becomes, so to say, altruistic. If this transformation is to succeed, the original dispositions and all the other characteristics of the instincts must be taken into account in the process. Just as on any other occasion on which the organism should by rights make new combinations and adjustments leading to complicated mechanisms, here too there are possibilities of pathological disorders if these new arrangements are not carried out. Every pathological disorder of sexual life is rightly to be regarded as an inhibition in development. [1905d, 1524]

The processes at puberty thus establish the primacy of the genital zones; and, in a man, the penis, which has now become capable of erection, presses forward insistently towards the new sexual aim - penetration into a cavity in the body which excites his genital zone. Simultaneously on the psychical side the process of finding an object, for which preparations have been made from earliest childhood, is completed. At a time at which the first beginnings of sexual satisfaction are still linked with the taking of nourishment, the sexual instinct has a sexual object outside the infant's own body in the shape of his mother's breast. It is only later that the instinct loses that object, just at the time, perhaps, when the child is able to form a total idea of the person to whom the organ that is giving him satisfaction belongs. As a rule the sexual instinct then becomes auto-erotic, and not until the period of latency has been passed through is the original relation restored. There are thus good reasons why a child sucking at his mother's breast has become the prototype of every relation of love. The finding of an object is in fact a refinding of it.¹ [1905d, 1535]
In spite of the gaps in our knowledge of infantile sexual life, we had to proceed to an attempt at examining the alterations brought about in it by the arrival of puberty. We selected two of these as being the decisive ones: the subordination of all the other sources of sexual excitation under the primacy of the genital zones and the process of finding an object. Both of these are already adumbrated in childhood. (The former, the affectionate current, comprises what remains over of the infantile efflorescence of sexuality.) It is like the completion of a tunnel which has been driven through a hill from both directions.

Where are we to look for the source of these dispositions? We have become aware that the psychical functions concerned - above all, the sexual function, but various important ego-functions too - have to undergo a long and complicated development before reaching the state characteristic of the normal adult. We can assume that these developments are not always so smoothly carried out that the total function passes through this regular progressive modification. Wherever a portion of it clings to a previous stage, what is known as a 'point of fixation' results, to which the function may regress if the subject falls ill through some external disturbance.
With the arrival of puberty, changes set in which are destined to give infantile sexual life its final, normal shape. The sexual instinct has hitherto been predominantly auto-erotic; it now finds a sexual object. Its activity has hitherto been derived from a number of separate instincts and erotogenic zones, which, independently of one another, have pursued a certain sort of pleasure as their sole sexual aim. [1905d, 1524]

[1905d, 1545]
It is in the world of ideas, however, that the choice of an object is accomplished at first; and the sexual life of maturing youth is almost entirely restricted to indulging in phantasies, that is, in ideas that are not destined to be carried into effect.¹ In these phantasies the infantile tendencies invariably emerge once more, but this time with intensified pressure from somatic sources. Among these tendencies the first place is taken with uniform frequency by the child's sexual impulses towards his parents, which are as a rule already differentiated owing to the attraction of the opposite sex - the son being drawn towards his mother and the daughter towards her father.² At the same time as these plainly incestuous phantasies are overcome and repudiated, one of the most significant, but also one of the most painful, psychical achievements of the pubertal period is completed: detachment from parental authority, a process that alone makes possible the opposition, which is so important for the progress of civilization, between the new generation and the old. At every stage in the course of development through which all human beings ought by rights to pass, a certain number are held back; so there are some who have never got over their parents' authority and have withdrawn their affection from them either very incompletely or not at all. They are mostly girls, who, to the delight of their parents, have persisted in all their childish love far beyond puberty. It is most instructive to find that it is precisely these girls who in their later marriage lack the capacity to give their husbands what is due to them; they make cold wives and remain sexually anaesthetic. We learn from this that sexual love and what appears to be non-sexual love for parents are fed from the same sources; the latter, that is to say, merely corresponds to an infantile fixation of the libido.

A child’s affection for his parents is no doubt the most important infantile trace which, after being revived at puberty, points the way to his choice of an object; but it is not the only one. Other starting-points with the same early origin enable a man to develop more than one sexual line, based no less upon his childhood, and to lay down very various conditions for his object-choice.²

These affectionate fixations of the child persist throughout childhood, and continually carry along with them erotism, which is consequently diverted from its sexual aims. Then at the age of puberty they are joined by the powerful 'sensual' current which no longer mistakes its aims. It never fails, apparently, to follow the earlier paths and to cathect the objects of the primary infantile choice with quotas of libido that are now far stronger. Here, however, it runs up against the obstacles that have been erected in the meantime by the barrier against incest; consequently it will make efforts to pass on from these objects which are unsuitable in reality, and find a way as soon as possible to other, extraneous objects with which a real sexual life may be carried on. These new objects will still be chosen on the model (imago) of the infantile ones, but in the course of time they will attract to themselves the affection that was tied to the earlier ones. A man shall leave his father and his mother - according to the biblical command - and shall cleave unto his wife; affection and sensuality are then united. The greatest intensity of sensual passion will bring with it the highest psychical valuation of the object - this being the normal overvaluation of the sexual object on the part of a man.
The clinical fact which meets us behind the form of the Oedipus complex as it is established by analysis is of the highest practical significance. We learn that at puberty, when the sexual instinct first makes its demands in full strength, the old familiar incestuous objects are taken up again and freshly cathected with libido. The infantile object-choice was only a feeble one, but it was a prelude, pointing the direction for the object-choice at puberty. At this point, then, very intense emotional processes come into play, following the direction of the Oedipus complex or reacting against it, processes which, however, since their premisses have become intolerable, must to a large extent remain apart from consciousness. From this time onwards, the human individual has to devote himself to the great task of detaching himself from his parents, and not until that task is achieved can he cease to be a child and become a member of the social community. For the son this task consists in detaching his libidinal wishes from his mother and employing them for the choice of a real outside love-object, and in reconciling himself with his father if he has remained in opposition to him, or in freeing himself from his pressure if, as a reaction to his infantile rebelliousness, he has become subservient to him. These tasks are set to everyone; and it is remarkable how seldom they are dealt with in an ideal manner - that is, in one which is correct both psychologically and socially. By neurotics, however, no solution at all is arrived at: the son remains all his life bowed beneath his father's authority and he is unable to transfer his libido to an outside sexual object. With the relationship changed round, the same fate can await the daughter. In this sense the Oedipus complex may justly be regarded as the nucleus of the neuroses.

[1916-1917, 3402]

The Diphasic Onset of Sexual Development. - Towards the end of the fifth year this early period of sexual life normally comes to an end. It is succeeded by a period of more or less complete latency, during which ethical restraints are built up, to act as defences against the desires of the Oedipus complex. In the subsequent period of puberty, the Oedipus complex is revivified in the unconscious and embarks upon further modifications. It is only at puberty that the sexual instincts develop to their full intensity; but the direction of that development, as well as all the predispositions for it, have already been determined by the early efflorescence of sexuality during childhood which preceded it. This diphasic development of the sexual function - in two stages, interrupted by the latency period - appears to be a biological peculiarity of the human species and to contain the determining factor for the origin of neuroses.

[1923a, 3923]
The process of arriving at an object, which plays such an important part in mental life, takes place alongside of the organization of the libido. After the stage of auto-erotism, the first love-object in the case of both sexes is the mother; and it seems probable that to begin with a child does not distinguish its mother's organ of nutrition from its own body. Later, but still in the first years of infancy, the relation known as the Oedipus complex becomes established: boys concentrate their sexual wishes upon their mother and develop hostile impulses against their father as being a rival, while girls adopt an analogous attitude.¹ All of the different variations and consequences of the Oedipus complex are important; and the innately bisexual constitution of human beings makes itself felt and increases the number of simultaneously active tendencies. Children do not become clear for quite a long time about the differences between the sexes; and during this period of sexual researches they produce typical sexual theories which, being circumscribed by the incompleteness of their authors' own physical development, are a mixture of truth and error and fail to solve the problems of sexual life (the riddle of the Sphinx - that is, the question of where babies come from). We see, then, that a child's first object-choice is an incestuous one. The whole course of development that I have described is run through rapidly. For the most remarkable feature of the sexual life of man is its diphasic onset, its onset in two waves, with an interval between them. It reaches a first climax in the fourth or fifth year of a child's life. But thereafter this early efflorescence of sexuality passes off; the sexual impulses which have shown such liveliness are overcome by repression, and a period of latency follows, which lasts until puberty and during which the reaction-formations of morality, shame, and disgust are built up.² Of all living creatures man alone seems to show this diphasic onset of sexual growth, and it may perhaps be the biological determinant of his predisposition to neuroses. At puberty the impulses and object-relations of a child's early years become re-animated, and amongst them the emotional ties of its Oedipus complex. In the sexual life of puberty there is a struggle between the urges of early years and the inhibitions of the latency period. Before this, and while the child is at the highest point of its infantile sexual development, a genital organization of a sort is established; but only the male genitals play a part in it, and the female ones remain undiscovered. (I have described this as the period of phallic primacy.) At this stage the contrast between the sexes is not stated in terms of 'male' or 'female' but of 'possessing a penis' or 'castrated'. The castration complex which arises in this connection is of the profoundest importance in the formation alike of character and of neuroses.

[1925d, 4212]
The results of the threat of castration are multifarious and incalculable; they affect the whole of a boy’s relations with his father and mother and subsequently with men and women in general. As a rule the child’s masculinity is unable to stand up to this first shock. In order to preserve his sexual organ he renounces the possession of his mother more or less completely; his sexual life often remains permanently encumbered by the prohibition. If a strong feminine component, as we call it, is present in him, its strength is increased by this intimidation of his masculinity. He falls into a passive attitude to his father, such as he attributes to his mother. It is true that as a result of the threat he has given up masturbation, but not the activities of his imagination accompanying it. On the contrary, since these are now the only form of sexual satisfaction remaining to him, he indulges in them more than before and in these phantasies, though he still continues to identify himself with his father, he also does so, simultaneously and perhaps predominantly, with his mother. Derivatives and modified products of these early masturbatory phantasies usually make their way into his later ego and play a part in the formation of his character. Apart from this encouragement of his femininity, fear and hatred of his father gain greatly in intensity. The boy's masculinity withdraws, as it were, into a defiant attitude towards his father, which will dominate his later behaviour in human society in a compulsive fashion. A residue of his erotic fixation to his mother is often left in the form of an excessive dependence on her, and this persists as a kind of bondage to women. He no longer ventures to love his mother, but he cannot risk not being loved by her, for in that case he would be in danger of being betrayed by her to his father and handed over to castration. The whole experience, with all its antecedents and consequences, of which my account has only been able to give a selection, is subjected to a highly energetic repression, and, as is made possible by the laws operating in the unconscious id, all the mutually contending emotional impulses and reactions which are set going at that time are preserved in the unconscious and ready to disturb the later development of the ego after puberty. When the somatic process of sexual maturation puts fresh life into the old libidinal fixations which had apparently been surmounted, sexual life will turn out to be inhibited, without homogeneity and fallen apart into mutually conflicting urges. [1940a [1938], 4998]
DIPHASIC CHOICE OF OBJECT  It may be regarded as typical of the choice of an object that the process is diphasic, that is, that it occurs in two waves. The first of these begins between the ages of two and five, and is brought to a halt or to a retreat by the latency period; it is characterized by the infantile nature of the sexual aims. The second wave sets in with puberty and determines the final outcome of sexual life.

[1905d, 1518]

Although the diphasic nature of object-choice comes down in essentials to no more than the operation of the latency period, it is of the highest importance in regard to disturbances of that final outcome. The resultants of infantile object-choice are carried over into the later period. They either persist as such or are revived at the actual time of puberty. But as a consequence of the repression which has developed between the two phases they prove unutilizable. Their sexual aims have become mitigated and they now represent what may be described as the 'affectionate current' of sexual life. Only psycho-analytic investigation can show that behind this affection, admiration and respect there lie concealed the old sexual longings of the infantile component instincts which have now become unserviceable. The object-choice of the pubertal period is obliged to dispense with the objects of childhood and to start afresh as a 'sensual current'. Should these two currents fail to converge, the result is often that one of the ideals of sexual life, the focusing of all desires upon a single object, will be unattainable.

[1905d, 1518]

THE BARRIER AGAINST INCEST  We see, therefore, that the parents' affection for their child may awaken his sexual instinct prematurely (i.e. before the somatic conditions of puberty are present) to such a degree that the mental excitation breaks through in an unmistakable fashion to the genital system. If, on the other hand, they are fortunate enough to avoid this, then their affection can perform its task of directing the child in his choice of a sexual object when he reaches maturity. No doubt the simplest course for the child would be to choose as his sexual objects the same persons whom, since his childhood, he has loved with what may be described as damped-down libido.¹ But, by the postponing of sexual maturation, time has been gained in which the child can erect, among other restraints on sexuality, the barrier against incest, and can thus take up into himself the moral precepts which expressly exclude from his object-choice, as being blood relations, the persons whom he has loved in his childhood. Respect for this barrier is essentially a cultural demand made by society. Society must defend itself against the danger that the interests which it needs for the establishment of higher social units may be swallowed up by the family; and for this reason, in the case of every individual, but in particular of adolescent boys, it seeks by all possible means to loosen their connection with their family - a connection which, in their childhood, is the only important one.²

[1905d, 1538]
In spite of the gaps in our knowledge of infantile sexual life, we had to proceed to an attempt at examining the alterations brought about in it by the arrival of puberty. We selected two of these as being the decisive ones: the subordination of all the other sources of sexual excitation under the primacy of the genital zones and the process of finding an object. Both of these are already adumbrated in childhood. The first is accomplished by the mechanism of exploiting fore-pleasure: what were formerly self-contained sexual acts, attended by pleasure and excitation, become acts preparatory to the new sexual aim (the discharge of the sexual products), the attainment of which, enormously pleasurable, brings the sexual excitation to an end. In this connection we had to take into account the differentiation of sexuality into masculine and feminine; and we found that in order to become a woman a further stage of repression is necessary, which discards a portion of infantile masculinity and prepares the woman for changing her leading genital zone. As regards object-choice, we found that it is given its direction by the childhood hints (revived at puberty) of the child's sexual inclination towards his parents and others in charge of him, but that it is diverted away from them, on to other people who resemble them, owing to the barrier against incest which has meanwhile been erected. Finally it must be added that during the transition period of puberty the processes of somatic and of psychical development continue for a time side by side independently, until the irruption of an intense mental erotic impulse, leading to the innervation of the genitals, brings about the unity of the erotic function which is necessary for normality.

[1905d, 1545]

It is inevitable and perfectly normal that a child should take his parents as the first objects of his love. But his libido should not remain fixated to these first objects; later on, it should merely take them as a model, and should make a gradual transition from them on to extraneous people when the time for the final choice of an object arrives. The detachment of the child from his parents is thus a task that cannot be evaded if the young individual's social fitness is not to be endangered. During the time at which repression is making its selection among the component instincts, and later, when there should be a slackening of the parents' influence, which is essentially responsible for the expenditure of energy on these repressions, the task of education meets with great problems, which at the present time are certainly not always dealt with in an understanding and unobjectionable manner.

[1910a, 2233]

These affective fixations of the child persist throughout childhood, and continually carry along with them erotism, which is consequently diverted from its sexual aims. Then at the age of puberty they are joined by the powerful 'sensual' current which no longer mistakes its aims. It never fails, apparently, to follow the earlier paths and to cathect the objects of the primary infantile choice with quotas of libido that are now far stronger. Here, however, it runs up against the obstacles that have been erected in the meantime by the barrier against incest; consequently it will make efforts to pass on from these objects which are unsuitable in reality, and find a way as soon as possible to other, extraneous objects with which a real sexual life may be carried on. These new objects will still be chosen on the model (imago) of the infantile ones, but in the course of time they will attract to themselves the affection that was tied to the earlier ones. A man shall leave his father and his mother - according to the biblical command - and shall cleave unto his wife; affection and sensuality are then united. The greatest intensity of sensual passion will bring with it the highest psychical valuation of the object - this being the normal overvaluation of the sexual object on the part of a man.

[1912d, 2339]
Two factors will decide whether this advance in the developmental path of the libido is to fail. First, there is the amount of frustration in reality, which opposes the new object-choice and reduces its value for the person concerned. There is after all no point in embarking upon an object-choice if no choice is to be allowed at all or if there is no prospect of being able to choose anything suitable. Secondly, there is the amount of attraction which the infantile objects that have to be relinquished are able to exercise, and which is in proportion to the erotic cathexis attaching to them in childhood. If these two factors are sufficiently strong, the general mechanism by which the neuroses are formed comes into operation. The libido turns away from reality, is taken over by imaginative activity (the process of introversion), strengthens the images of the first sexual objects and becomes fixed to them. The obstacle raised against incest, however, compels the libido that has turned to these objects to remain in the unconscious. The masturbatory activity carried out by the sensual current, which is now part of the unconscious, makes its own contribution in strengthening this fixation. Nothing is altered in this state of affairs if the advance which has miscarried in reality is now completed in phantasy, and if in the phantasy-situations that lead to masturbatory satisfaction the original sexual objects are replaced by different ones. As a result of this substitution the phantasies become admissible to consciousness, but no progress is made in the allocation of the libido in reality. In this way it can happen that the whole of a young man's sensuality becomes tied to incestuous objects in the unconscious, or to put it another way, becomes fixed to unconscious incestuous phantasies. The result is then total impotence, which is perhaps further ensured by the simultaneous onset of an actual weakening of the organs that perform the sexual act.

I do not hesitate to make the two factors at work in psychical impotence in the strict sense - the factors of intense incestuous fixation in childhood and the frustration by reality in adolescence - responsible, too, for this extremely common characteristic of the love of civilized men. It sounds not only disagreeable but also paradoxical, yet it must nevertheless be said that anyone who is to be really free and happy in love must have surmounted his respect for women and have come to terms with the idea of incest with his mother or sister. Anyone who subjects himself to a serious self-examination on the subject of this requirement will be sure to find that he regards the sexual act basically as something degrading, which defiles and pollutes not only the body. The origin of this low opinion, which he will certainly not willingly acknowledge, must be looked for in the period of his youth in which the sensual current in him was already strongly developed but its satisfaction with an object outside the family was almost as completely prohibited as it was with an incestuous one.

It is my belief that, however strange it may sound, we must reckon with the possibility that something in the nature of the sexual instinct itself is unfavourable to the realization of complete satisfaction. If we consider the long and difficult developmental history of the instinct, two factors immediately spring to mind which might be made responsible for this difficulty Firstly, as a result of the diphasic onset of object-choice, and the interposition of the barrier against incest, the final object of the sexual instinct is never any longer the original object but only a surrogate for it. Psycho-analysis has shown us that when the original object of a wishful impulse has been lost as a result of repression, it is frequently represented by an endless series of substitutive objects none of which, however, brings full satisfaction. This may explain the inconstancy in object-choice, the 'craving for stimulation' which is so often a feature of the love of adults.
However, this motive does not go deep enough either; besides, being bound up with civilized conditions, it fails to provide a satisfactory connection with the state of affairs among primitive people. All the more important, therefore, is the next factor, which is based on the evolution of the libido. We have learnt from analytic researches how universal and how powerful the earliest allocations of libido are. In these we are concerned with infantile sexual wishes which are clung to (in women usually a fixation of the libido on the father or a brother who takes his place) - wishes which frequently enough were directed towards other things than intercourse, or included it only as a dimly perceived goal. The husband is almost always so to speak only a substitute, never the right man; it is another man - in typical cases the father - who has first claim to a woman's love, the husband at most takes second place. It depends on how intense this fixation is and on how obstinately it is maintained whether the substitute is rejected as unsatisfying. Frigidity is thus among the genetic determinants of neuroses. The more powerful the psychical element in a woman's sexual life is, the greater will be the capacity for resistance shown by her distribution of libido to the upheaval of the first sexual act, and the less overpowering will be the effect which bodily possession of her can produce. Frigidity may then become established as a neurotic inhibition or provide the foundation for the development of other neuroses and even a moderate diminution of potency in the man will greatly contribute to help this process.

The clinical fact which meets us behind the form of the Oedipus complex as it is established by analysis is of the highest practical significance. We learn that at puberty, when the sexual instinct first makes its demands in full strength, the old familiar incestuous objects are taken up again and freshly cathected with libido. The infantile object-choice was only a feeble one, but it was a prelude, pointing the direction for the object-choice at puberty. At this point, then, very intense emotional processes come into play, following the direction of the Oedipus complex or reacting against it, processes which, however, since their premisses have become intolerable, must to a large extent remain apart from consciousness. From this time onwards, the human individual has to devote himself to the great task of detaching himself from his parents, and not until that task is achieved can he cease to be a child and become a member of the social community. For the son this task consists in detaching his libidinal wishes from his mother and employing them for the choice of a real outside love-object, and in reconciling himself with his father if he has remained in opposition to him, or in freeing himself from his pressure if, as a reaction to his infantile rebelliousness, he has become subservient to him. These tasks are set to everyone; and it is remarkable how seldom they are dealt with in an ideal manner - that is, in one which is correct both psychologically and socially. By neurotics, however, no solution at all is arrived at: the son remains all his life bowed beneath his father's authority and he is unable to transfer his libido to an outside sexual object. With the relationship changed round, the same fate can await the daughter. In this sense the Oedipus complex may justly be regarded as the nucleus of the neuroses.

There are abundant indications that being in love only made its appearance late on in the sexual relations between men and women; so that the opposition between sexual love and group ties is also a late development. Now it may seem as though this assumption were incompatible with our myth of the primal family. For it was after all by their love for their mothers and sisters that the mob of brothers was, as we have supposed, driven to parricide; and it is difficult to imagine this love as being anything but undivided and primitive - that is, as an intimate union of the affectionate and sensual. But further consideration resolves this objection to our theory into a confirmation of it. One of the reactions to the parricide was after all the institution of totemic exogamy, the prohibition of any sexual relation with those women of the family who had been tenderly loved since childhood. In this way a wedge was driven in between a man's affectionate and sensual feelings, one still firmly fixed in his erotic life to-day. As a result of this exogamy the sensual needs of men had to be satisfied with strange and unloved women.
The Process of Finding an Object, and the Oedipus Complex. - In the first instance the oral component instinct finds satisfaction by attaching itself to the sating of the desire for nourishment; and its object is the mother's breast. It then detaches itself, becomes independent and at the same time auto-erotic, that is, it finds an object in the child's own body. Others of the component instincts also start by being auto-erotic and are not until later diverted on to an external object. It is a particularly important fact that the component instincts belonging to the genital zone habitually pass through a period of intense auto-erotic satisfaction. The component instincts are not all equally serviceable in the final genital organization of libido; some of them (for instance, the anal components) are consequently left aside and suppressed, or undergo complicated transformations.

[1923a, 3922]

¹ (Footnote added 1935:) The information about infantile sexuality was obtained from the study of men and the theory deduced from it was concerned with male children. It was natural enough to expect to find a complete parallel between the two sexes; but this turned out not to hold. Further investigations and reflections revealed profound differences between the sexual development of men and women. The first sexual object of a baby girl (just as of a baby boy) is her mother; and before a woman can reach the end of her normal development she has to change not only her sexual object but also her leading genital zone. From this circumstance difficulties arise and possibilities of inhibition which are not present in the case of men.

[1925d, 4212]

Parallel with this first great difference there is the other, concerned with the finding of the object. In the case of a male, his mother becomes his first love-object as a result of her feeding him and looking after him, and she remains so until she is replaced by someone who resembles her or is derived from her. A female's first object, too, must be her mother: the primary conditions for a choice of object are, of course, the same for all children. But at the end of her development, her father - a man - should have become her new love-object. In other words, to the change in her own sex there must correspond a change in the sex of her object. The new problems that now require investigating are in what way this change takes place, how radically or how incompletely it is carried out, and what the different possibilities are which present themselves in the course of this development.

[1931b, 4592]
The processes at puberty thus establish the primacy of the genital zones; and, in a man, the penis, which has now become capable of erection, presses forward insistently towards the new sexual aim - penetration into a cavity in the body which excites his genital zone. Simultaneously on the psychical side the process of finding an object, for which preparations have been made from earliest childhood, is completed. At a time at which the first beginnings of sexual satisfaction are still linked with the taking of nourishment, the sexual instinct has a sexual object outside the infant's own body in the shape of his mother's breast. It is only later that the instinct loses that object, just at the time, perhaps, when the child is able to form a total idea of the person to whom the organ that is giving him satisfaction belongs. As a rule the sexual instinct then becomes auto-erotic, and not until the period of latency has been passed through is the original relation restored. There are thus good reasons why a child sucking at his mother's breast has become the prototype of every relation of love. The finding of an object is in fact a refining of it.¹

In spite of the gaps in our knowledge of infantile sexual life, we had to proceed to an attempt at examining the alterations brought about in it by the arrival of puberty. We selected two of these as being the decisive ones: the subordination of all the other sources of sexual excitation under the primacy of the genital zones and the process of finding an object. Both of these are already adumbrated in childhood. The first is accomplished by the mechanism of exploiting fore-pleasure: what were formerly self-contained sexual acts, attended by pleasure and excitation, become acts preparatory to the new sexual aim (the discharge of the sexual products), the attainment of which, enormously pleasurable, brings the sexual excitation to an end. In this connection we had to take into account the differentiation of sexuality into masculine and feminine; and we found that in order to become a woman a further stage of repression is necessary, which discards a portion of infantile masculinity and prepares the woman for changing her leading genital zone. As regards object-choice, we found that it is given its direction by the childhood hints (revived at puberty) of the child's sexual inclination towards his parents and others in charge of him, but that it is diverted away from them, on to other people who resemble them, owing to the barrier against incest which has meanwhile been erected. Finally it must be added that during the transition period of puberty the processes of somatic and of psychical development continue for a time side by side independently, until the irruption of an intense mental erotic impulse, leading to the innervation of the genitals, brings about the unity of the erotic function which is necessary for normality.

In spite of the gaps in our knowledge of infantile sexual life, we had to proceed to an attempt at examining the alterations brought about in it by the arrival of puberty. We selected two of these as being the decisive ones: the subordination of all the other sources of sexual excitation under the primacy of the genital zones and the process of finding an object. Both of these are already adumbrated in childhood. The first is accomplished by the mechanism of exploiting fore-pleasure: what were formerly self-contained sexual acts, attended by pleasure and excitation, become acts preparatory to the new sexual aim (the discharge of the sexual products), the attainment of which, enormously pleasurable, brings the sexual excitation to an end. In this connection we had to take into account the differentiation of sexuality into masculine and feminine; and we found that in order to become a woman a further stage of repression is necessary, which discards a portion of infantile masculinity and prepares the woman for changing her leading genital zone. Finally it must be added that during the transition period of puberty the processes of somatic and of psychical development continue for a time side by side independently, until the irruption of an intense mental erotic impulse, leading to the innervation of the genitals, brings about the unity of the erotic function which is necessary for normality.

These affectionate fixations of the child persist throughout childhood, and continually carry along with them erotism, which is consequently diverted from its sexual aims. Then at the age of puberty they are joined by the powerful 'sensual' current which no longer mistakes its aims. It never fails, apparently, to follow the earlier paths and to cathect the objects of the primary infantile choice with quotas of libido that are now far stronger. Here, however, it runs up against the obstacles that have been erected in the meantime by the barrier against incest; consequently it will make efforts to pass on from these objects which are unsuitable in reality, and find a way as soon as possible to other, extraneous objects with which a real sexual life may be carried on. These new objects will still be chosen on the model (imago) of the infantile ones, but in the course of time they will attract to themselves the affection that was tied to the earlier ones. A man shall leave his father and his mother - according to the biblical command - and shall cleave unto his wife; affection and sensuality are then united. The greatest intensity of sensual passion will bring with it the highest psychical valuation of the object - this being the normal overvaluation of the sexual object on the part of a man.

¹[1905d, 1535]
Two factors will decide whether this advance in the developmental path of the libido is to fail. First, there is the amount of frustration in reality, which opposes the new object-choice and reduces its value for the person concerned. There is after all no point in embarking upon an object-choice if no choice is to be allowed at all or if there is no prospect of being able to choose anything suitable. Secondly, there is the amount of attraction which the infantile objects that have to be relinquished are able to exercise, and which is in proportion to the erotic cathexis attaching to them in childhood. If these two factors are sufficiently strong, the general mechanism by which the neuroses are formed comes into operation. The libido turns away from reality, is taken over by imaginative activity (the process of introversion), strengthens the images of the first sexual objects and becomes fixated to them. The obstacle raised against incest, however, compels the libido that has turned to these objects to remain in the unconscious. The masturbatory activity carried out by the sensual current, which is now part of the unconscious, makes its own contribution in strengthening this fixation. Nothing is altered in this state of affairs if the advance which has miscarried in reality is now completed in phantasy, and if in the phantasy-situations that lead to masturbatory satisfaction the original sexual objects are replaced by different ones. As a result of this substitution the phantasies become admissible to consciousness, but no progress is made in the allocation of the libido in reality. In this way it can happen that the whole of a young man's sensuality becomes tied to incestuous objects in the unconscious, or to put it another way, becomes fixated to unconscious incestuous phantasies. The result is then total impotence, which is perhaps further ensured by the simultaneous onset of an actual weakening of the organs that perform the sexual act. [1912d, 2339]
The processes at puberty thus establish the primacy of the genital zones; and, in a man, the penis, which has now become capable of erection, presses forward insistently towards the new sexual aim - penetration into a cavity in the body which excites his genital zone. Simultaneously on the psychical side the process of finding an object, for which preparations have been made from earliest childhood, is completed. At a time at which the first beginnings of sexual satisfaction are still linked with the taking of nourishment, the sexual instinct has a sexual object outside the infant's own body in the shape of his mother's breast. It is only later that the instinct loses that object, just at the time, perhaps, when the child is able to form a total idea of the person to whom the organ that is giving him satisfaction belongs. As a rule the sexual instinct then becomes auto-erotic, and not until the period of latency has been passed through is the original relation restored. There are thus good reasons why a child sucking at his mother's breast has become the prototype of every relation of love. The finding of an object is in fact a refinding of it.¹

[1905d, 1535]

In spite of the gaps in our knowledge of infantile sexual life, we had to proceed to an attempt at examining the alterations brought about in it by the arrival of puberty. We selected two of these as being the decisive ones: the subordination of all the other sources of sexual excitation under the primacy of the genital zones and the process of finding an object. Both of these are already adumbrated in childhood. The first is accomplished by the mechanism of exploiting fore-pleasure: what were formerly self-contained sexual acts, attended by pleasure and excitation, become acts preparatory to the new sexual aim (the discharge of the sexual products), the attainment of which, enormously pleasurable, brings the sexual excitation to an end. In this connection we had to take into account the differentiation of sexuality into masculine and feminine; and we found that in order to become a woman a further stage of repression is necessary, which discards a portion of infantile masculinity and prepares the woman for changing her leading genital zone. As regards object-choice, we found that it is given its direction by the childhood hints (revived at puberty) of the child's sexual inclination towards his parents and others in charge of him, but that it is diverted away from them, on to other people who resemble them, owing to the barrier against incest which has meanwhile been erected. Finally it must be added that during the transition period of puberty the processes of somatic and of psychical development continue for a time side by side independently, until the irruption of an intense mental erotic impulse, leading to the innervation of the genitals, brings about the unity of the erotic function which is necessary for normality.

[1905d, 1545]
It is in the world of ideas, however, that the choice of an object is accomplished at first; and the sexual life of maturing youth is almost entirely restricted to indulging in phantasies, that is, in ideas that are not destined to be carried into effect.¹ In these phantasies the infantile tendencies invariably emerge once more, but this time with intensified pressure from somatic sources. Among these tendencies the first place is taken with uniform frequency by the child's sexual impulses towards his parents, which are as a rule already differentiated owing to the attraction of the opposite sex - the son being drawn towards his mother and the daughter towards her father.² At the same time as these plainly incestuous phantasies are overcome and repudiated, one of the most significant, but also one of the most painful, psychical achievements of the pubertal period is completed: detachment from parental authority, a process that alone makes possible the opposition, which is so important for the progress of civilization, between the new generation and the old. At every stage in the course of development through which all human beings ought by rights to pass, a certain number are held back; so there are some who have never got over their parents' authority and have withdrawn their affection from them either very incompletely or not at all. They are mostly girls, who, to the delight of their parents, have persisted in all their childish love far beyond puberty. It is most instructive to find that it is precisely these girls who in their later marriage lack the capacity to give their husbands what is due to them; they make cold wives and remain sexually anaesthetic. We learn from this that sexual love and what appears to be non-sexual love for parents are fed from the same sources; the latter, that is to say, merely corresponds to an infantile fixation of the libido.

¹ [Footnote added 1920:] The phantasies of the pubertal period have as their starting-point the infantile sexual researches that were abandoned in childhood. No doubt, too, they are also present before the end of the latency period. They may persist wholly, or to a great extent, unconsciously and for that reason it is often impossible to date them accurately. They are of great importance in the origin of many symptoms, since they precisely constitute preliminary stages of these symptoms and thus lay down the forms in which the repressed libidinal components find satisfaction. In the same way, they are the prototypes of the nocturnal phantasies which become conscious as dreams. Dreams are often nothing more than revivals of pubertal phantasies of this kind under the influence of, and in relation to, some stimulus left over from the waking life of the previous day (the 'day's residues'). Some among the sexual phantasies of the pubertal period are especially prominent, and are distinguished by their very general occurrence and by being to a great extent independent of individual experience. Such are the adolescent's phantasies of overhearing his parents in sexual intercourse, of having been seduced at an early age by someone he loves and of having been threatened with castration; such, too, are his phantasies of being in the womb, and even of experiences there, and the so-called 'Family Romance', in which he reacts to the difference between his attitude towards his parents now and in his childhood. The close relations existing between these phantasies and myths has been demonstrated in the case of the last instance by Otto Rank (1909).

² [1905d, 1539]
Though even to-day I do not consider these assertions incorrect, it is not to be wondered at that, in the course of ten years of continuous effort at reaching an understanding of these phenomena, I have made a considerable step forward from the views I then held, and now believe that I am in a position, on the basis of deeper experience, to correct the insufficiencies, the displacements and the misunderstandings under which my theory then laboured. At that time my material was still scanty, and it happened by chance to include a disproportionately large number of cases in which sexual seduction by an adult or by older children played the chief part in the history of the patient's childhood. I thus over-estimated the frequency of such events (though in other respects they were not open to doubt). Moreover, I was at that period unable to distinguish with certainty between falsifications made by hysterics in their memories of childhood and traces of real events. Since then I have learned to explain a number of phantasies of seduction as attempts at fending off memories of the subject's own sexual activity (infantile masturbation). When this point had been clarified, the 'traumatic' element in the sexual experiences of childhood lost its importance and what was left was the realization that infantile sexual activity (whether spontaneous or provoked) prescribes the direction that will be taken by later sexual life after maturity. The same clarification (which corrected the most important of my early mistakes) also made it necessary to modify my view of the mechanism of hysterical symptoms. They were now no longer to be regarded as direct derivatives of the repressed memories of childhood experiences; but between the symptoms and the childish impressions there were inserted the patient's phantasies (or imaginary memories), mostly produced during the years of puberty, which on the one side were built up out of and over the childhood memories and on the other side were transformed directly into the symptoms. It was only after the introduction of this element of hysterical phantasies that the texture of the neurosis and its relation to the patient's life became intelligible; a surprising analogy came to light, too, between these unconscious phantasies of hysterics and the imaginary creations of paranoics which become conscious as delusions.

[1906a, 1578]

A common source and normal prototype of all these creations of phantasy is to be found in what are called the day-dreams of youth. These have already received some, though as yet insufficient, notice in the literature of the subject.¹ They occur with perhaps equal frequency in both sexes, though it seems that while in girls and women they are invariably of an erotic nature, in men they may be either erotic or ambitious. Nevertheless the importance of the erotic factor in men, too, should not be given a secondary rating; a closer investigation of a man's day-dreams generally shows that all his heroic exploits are carried out and all his successes achieved only in order to please a woman and to be preferred by her to other men.² These phantasies are satisfactions of wishes proceeding from deprivation and longing. They are justly called 'day-dreams', for they give us the key to an understanding of night-dreams - in which the nucleus of the dream-formation consists of nothing else than complicated day-time phantasies of this kind that have been distorted and are misunderstood by the conscious psychical agency.³

[1908a, 1932]
In considering the question of abstinence, the distinction is not nearly strictly enough made between two forms of it - namely abstention from any sexual activity whatever and abstention from sexual intercourse with the opposite sex. Many people who boast of succeeding in being abstinent have only been able to do so with the help of masturbation and similar satisfactions which are linked with the auto-erotic sexual activities of early childhood. But precisely because of this connection such substitutive means of sexual satisfaction are by no means harmless; they predispose to the numerous varieties of neuroses and psychoses which are conditional on an involution of sexual life to its infantile forms. Masturbation, moreover, is far from meeting the ideal demands of civilized sexual morality, and consequently drives young people into the same conflicts with the ideals of education which they hoped to escape by abstinence. Furthermore, it vitiates the character through indulgence, and this in more than one way. In the first place, it teaches people to achieve important aims without taking trouble and by easy paths instead of through an energetic exertion of force - that is, it follows the principle that sexuality lays down the pattern of behaviour; secondly, in the phantasies that accompany satisfaction the sexual object is raised to a degree of excellence which is not easily found again in reality. A witty writer (Karl Kraus in the Vienna paper Die Fackel) once expressed this truth in reverse by cynically remarking: 'Copulation is no more than an unsatisfying substitute for masturbation.'

[1908d, 1960]

Now that we have gained an insight into this piece of mental development we can no longer regard it as contradictory and incomprehensible that the precondition of the loved one's being like a prostitute should derive directly from the mother complex. The type of male love which we have described bears the traces of this evolution and is simple to understand as a fixation on the phantasies formed by the boy in puberty - phantasies which have later after all found a way out into real life. There is no difficulty in assuming that the masturbation assiduously practised in the years of puberty has played its part in the fixation of the phantasies.

[1910h, 2333]
The brilliantly told, faultlessly motivated story is of course complete in itself and is certain to make a deep effect upon the reader. But analysis shows us that its invention is based fundamentally upon a wishful phantasy belonging to the period of puberty, which a number of people actually remember consciously. The phantasy embodies a boy's wish that his mother should herself initiate him into sexual life in order to save him from the dreaded injuries caused by masturbation. (The numerous creative works that deal with the theme of redemption have the same origin.) The 'vice' of masturbation is replaced by the addiction to gambling; and the emphasis laid upon the passionate activity of the hands betrays this derivation. Indeed, the passion for play is an equivalent of the old compulsion to masturbate; 'playing' is the actual word used in the nursery to describe the activity of the hands upon the genitals. The irresistible nature of the temptation, the solemn resolutions, which are nevertheless invariably broken, never to do it again, the stupefying pleasure and the bad conscience which tells the subject that he is ruining himself (committing suicide) - all these elements remain unaltered in the process of substitution. It is true that Zweig's story is told by the mother, not by the son. It must flatter the son to think: 'If my mother only knew what dangers masturbation involves me in, she would certainly save me from them by allowing me to lavish all my tenderness on her own body'. The equation of the mother with a prostitute, which is made by the young man in the story, is linked up with the same phantasy. It brings the unattainable woman within easy reach. The bad conscience which accompanies the phantasy brings about the unhappy ending of the story. It is also interesting to notice how the \textit{façade} given to the story by its author seeks to disguise its analytic meaning. For it is extremely questionable whether the erotic life of women is dominated by sudden and mysterious impulses. On the contrary, analysis reveals an adequate motivation for the surprising behaviour of this woman who had hitherto turned away from love. Faithful to the memory of her dead husband, she had armed herself against all similar attractions; but - and here the son's phantasy is right - she did not, as a mother, escape her quite unconscious transference of love on to her son, and Fate was able to catch her at this undefended spot. [1928b, 4568]
It is in the world of ideas, however, that the choice of an object is accomplished at first; and
the sexual life of maturing youth is almost entirely restricted to indulging in phantasies, that is, in
ideas that are not destined to be carried into effect.¹ In these phantasies the infantile tendencies
invariably emerge once more, but this time with intensified pressure from somatic sources.
Among these tendencies the first place is taken with uniform frequency by the child's sexual
impulses towards his parents, which are as a rule already differentiated owing to the attraction
of the opposite sex - the son being drawn towards his mother and the daughter towards her
father.² At the same time as these plainly incestuous phantasies are overcome and repudiated,
one of the most significant, but also one of the most painful, psychical achievements of the
pubertal period is completed: detachment from parental authority, a process that alone makes
possible the opposition, which is so important for the progress of civilization, between the new
generation and the old. At every stage in the course of development through which all human
beings ought by rights to pass, a certain number are held back; so there are some who have
never got over their parents' authority and have withdrawn their affection from them either very
incompletely or not at all. They are mostly girls, who, to the delight of their parents, have
persisted in all their childish love far beyond puberty. It is most instructive to find that it is
precisely these girls who in their later marriage lack the capacity to give their husbands what is
due to them; they make cold wives and remain sexually anaesthetic. We learn from this that
sexual love and what appears to be non-sexual love for parents are fed from the same sources;
the latter, that is to say, merely corresponds to an infantile fixation of the libido.
[1905d, 1539]

Now that we have gained an insight into this piece of mental development we can no longer
regard it as contradictory and incomprehensible that the precondition of the loved one's being
like a prostitute should derive directly from the mother complex. The type of male love which we
have described bears the traces of this evolution and is simple to understand as a fixation on
the phantasies formed by the boy in puberty - phantasies which have later after all found a way
out into real life. There is no difficulty in assuming that the masturbation assiduously practised in
the years of puberty has played its part in the fixation of the phantasies.
[1910h, 2333]

If an infant could speak, he would no doubt pronounce the act of sucking at his mother's
breast by far the most important in his life. He is not far wrong in this, for in this single act he is
satisfying at once the two great vital needs. We are therefore not surprised to learn from
psycho-analysis how such psychical importance the act retains all through life. Sucking at the
mother's breast is the starting-point of the whole of sexual life, the unmatched prototype of
every later sexual satisfaction, to which phantasy often enough recurs in times of need. This
sucking involves making the mother's breast the first object of the sexual instinct. I can give you
no idea of the important bearing of this first object upon the choice of every later object, of the
profound effects it has in its transformations and substitutions in even the remotest regions of
our sexual life. But at first the infant, in his sucking activity, gives up this object and replaces it
by a part of his own body. He begins to suck his thumbs or his own tongue. In this way he
makes himself independent of the consent of the external world as regards gaining pleasure,
and besides this he increases it by adding the excitation of a second area of his body. The
erotogenic zones are not all equally generous in yielding pleasure; it is therefore an important
experience when the infant, as Lindner reports, discovers, in the course of feeling around, the
specially excitable regions afforded by his genitals and so finds his way from sucking to
masturbation.
[1916-1917, 3385]
Allow me, therefore, to proceed with my brief account of infantile sexuality. What I have already reported of two systems of organs might be confirmed in reference to the others. A child's sexual life is indeed made up entirely of the activities of a number of component instincts which seek, independently of one another, to obtain pleasure, in part from the subject's own body and in part already from an external object. Among these organs the genitals come into prominence very soon. There are people in whom obtaining pleasure from their own genitals, without the assistance of any other genitals or of an object, continues uninterruptedly from infantile masturbation to the unavoidable masturbation of puberty and persists for an indefinite length of time afterwards. Incidentally, the topic of masturbation is not one that can be so easily disposed of: it is something that calls for examination from many angles.

We should not be as short-sighted as the person in charge of the child who threatens him with castration, and we must not overlook the fact that at this time masturbation by no means represents the whole of his sexual life. As can be clearly shown, he stands in the Oedipus attitude to his parents; his masturbation is only a genital discharge of the sexual excitation belonging to the complex, and throughout his later years will owe its importance to that relationship. The Oedipus complex offered the child two possibilities of satisfaction, an active and a passive one. He could put himself in his father's place in a masculine fashion and have intercourse with his mother as his father did, in which case he would soon have felt the latter as a hindrance; or he might want to take the place of his mother and be loved by his father, in which case his mother would become superfluous. The child may have had only very vague notions as to what constitutes a satisfying erotic intercourse; but certainly the penis must play a part in it, for the sensations in his own organ were evidence of that. So far he had had no occasion to doubt that women possessed a penis. But now his acceptance of the possibility of castration, his recognition that women were castrated, made an end of both possible ways of obtaining satisfaction from the Oedipus complex. For both of them entailed the loss of his penis - the masculine one as a resulting punishment and the feminine one as a precondition. If the satisfaction of love in the field of the Oedipus complex is to cost the child his penis, a conflict is bound to arise between his narcissistic interest in that part of his body and the libidinal cathexis of his parental objects. In this conflict the first of these forces normally triumphs: the child's ego turns away from the Oedipus complex.

[1916-1917, 3386]

[1924d, 4088]
The brilliantly told, faultlessly motivated story is of course complete in itself and is certain to make a deep effect upon the reader. But analysis shows us that its invention is based fundamentally upon a wishful phantasy belonging to the period of puberty, which a number of people actually remember consciously. The phantasy embodies a boy's wish that his mother should herself initiate him into sexual life in order to save him from the dreaded injuries caused by masturbation. (The numerous creative works that deal with the theme of redemption have the same origin.) The 'vice' of masturbation is replaced by the addiction to gambling; and the emphasis laid upon the passionate activity of the hands betrays this derivation. Indeed, the passion for play is an equivalent of the old compulsion to masturbate; 'playing' is the actual word used in the nursery to describe the activity of the hands upon the genitals. The irresistible nature of the temptation, the solemn resolutions, which are nevertheless invariably broken, never to do it again, the stupefying pleasure and the bad conscience which tells the subject that he is ruining himself (committing suicide) - all these elements remain unaltered in the process of substitution. It is true that Zweig's story is told by the mother, not by the son. It must flatter the son to think: 'if my mother only knew what dangers masturbation involves me in, she would certainly save me from them by allowing me to lavish all my tenderness on her own body'. The equation of the mother with a prostitute, which is made by the young man in the story, is linked up with the same phantasy. It brings the unattainable woman within easy reach. The bad conscience which accompanies the phantasy brings about the unhappy ending of the story. It is also interesting to notice how the façade given to the story by its author seeks to disguise its analytic meaning. For it is extremely questionable whether the erotic life of women is dominated by sudden and mysterious impulses. On the contrary, analysis reveals an adequate motivation for the surprising behaviour of this woman who had hitherto turned away from love. Faithful to the memory of her dead husband, she had armed herself against all similar attractions; but - and here the son's phantasy is right - she did not, as a mother, escape her quite unconscious transference of love on to her son, and Fate was able to catch her at this undefended spot.

If the addiction to gambling, with the unsuccessful struggles to break the habit and the opportunities it affords for self-punishment, is a repetition of the compulsion to masturbate, we shall not be surprised to find that it occupied such a large space in Dostoevsky's life. After all, we find no cases of severe neurosis in which the auto-erotic satisfaction of early childhood and of puberty has not played a part; and the relation between efforts to suppress it and fear of the father are too well known to need more than a mention.¹

[1928b, 4568]
You all know the immense aetiological importance attributed by our neurotic patients to their masturbation. They make it responsible for all their troubles and we have the greatest difficulty in persuading them that they are mistaken. In fact, however, we ought to admit to them that they are right, for masturbation is the executive agent of infantile sexuality, from the faulty development of which they are indeed suffering. But what neurotics mostly blame is the masturbation of the period of puberty; they have mostly forgotten that of early infancy, which is what is really in question. I wish I might have an opportunity some time of explaining to you at length how important all the factual details of early masturbation become for the individual’s subsequent neurosis or character: whether or not it was discovered, how the parents struggled against it or permitted it, or whether he succeeded in suppressing it himself. All of this leaves permanent traces on his development. But I am on the whole glad that I need not do this. It would be a hard and tedious task and at the end of it you would put me in an embarrassing situation by quite certainly asking me to give you some practical advice as to how a parent or educator should deal with the masturbation of small children. From the development of girls, which is what my present lecture is concerned with, I can give you the example of a child herself trying to get free from masturbating. She does not always succeed in this. If envy for the penis has provoked a powerful impulse against clitoral masturbation but this nevertheless refuses to give way, a violent struggle for liberation ensues in which the girl, as it were, herself takes over the role of her deposed mother and gives expression to her entire dissatisfaction with her inferior clitoris in her efforts against obtaining satisfaction from it. Many years later, when her masturbatory activity has long since been suppressed, an interest still persists which we must interpret as a defence against a temptation that is still dreaded. It manifests itself in the emergence of sympathy for those to whom similar difficulties are attributed, it plays a part as a motive in contracting a marriage and, indeed, it may determine the choice of a husband or lover. Disposing of early infantile masturbation is truly no easy or indifferent business.

[1933a, 4729]
With the arrival of puberty, changes set in which are destined to give infantile sexual life its final, normal shape. The sexual instinct has hitherto been predominantly auto-erotic; it now finds a sexual object. Its activity has hitherto been derived from a number of separate instincts and erotogenic zones, which, independently of one another, have pursued a certain sort of pleasure as their sole sexual aim. Now, however, a new sexual aim appears, and all the component instincts combine to attain it, while the erotogenic zones become subordinated to the primacy of the genital zone.¹ Since the new sexual aim assigns very different functions to the two sexes, their sexual development now diverges greatly. That of males is the more straightforward and the more understandable, while that of females actually enters upon a kind of involution. A normal sexual life is only assured by an exact convergence of the two currents directed towards the sexual object and sexual aim, the affectionate current and the sensual one. (The former, the affectionate current, comprises what remains over of the infantile efflorescence of sexuality.) It is like the completion of a tunnel which has been driven through a hill from both directions.

It is not unimportant to bear in mind what transformations are undergone, during the sexual development of childhood, by the polarity of sex with which we are familiar. A first antithesis is introduced with the choice of object, which, of course, presupposes a subject and an object. At the stage of the pregenital sadistic-anal organization, there is as yet no question of male and female; the antithesis between active and passive is the dominant one.¹ At the following stage of infantile genital organization, which we now know about, maleness exists, but not femaleness. The antithesis here is between having a male genital and being castrated. It is not until development has reached its completion at puberty that the sexual polarity coincides with male and female. Maleness combines subject, activity and possession of the penis; femaleness takes over object and passivity. The vagina is now valued as a place of shelter for the penis; it enters into the heritage of the womb.

[1905d, 1524]

[1923e, 4062]
It has justly been said that the Oedipus complex is the nuclear complex of the neuroses, and constitutes the essential part of their content. It represents the peak of infantile sexuality, which, through its after-effects, exercises a decisive influence on the sexuality of adults. Every new arrival on this planet is faced by the task of mastering the Oedipus complex; anyone who fails to do so falls a victim to neurosis. With the progress of psycho-analytic studies the importance of the Oedipus complex has become more and more clearly evident; its recognition has become the shibboleth that distinguishes the adherents of psycho-analysis from its opponents. [1905d, 1539]

PERTINACITY OF EARLY IMPRESSIONS The importance of all early sexual manifestations is increased by a psychical factor of unknown origin, which at the moment, it must be admitted, can only be brought forward as a provisional psychological concept. I have in mind the fact that, in order to account for the situation, it is necessary to assume that these early impressions of sexual life are characterized by an increased pertinacity or susceptibility to fixation in persons who are later to become neurotics or perverts. For the same premature sexual manifestations, when they occur in other persons, fail to make so deep an impression; they do not tend in a compulsive manner towards repetition nor do they lay down the path to be taken by the sexual instinct for a whole lifetime. Part of the explanation of this pertinacity of early impressions may perhaps lie in another psychical factor which we must not overlook in the causation of the neuroses, namely the preponderance attaching in mental life to memory-traces in comparison with recent impressions. This factor is clearly dependent on intellectual education and increases in proportion to the degree of individual culture. The savage has been described in contrast as ‘das unglückselige Kind des Augenblickes’ ['The hapless child of the moment.'].¹ In consequence of the inverse relation holding between civilization and the free development of sexuality, of which the consequences can be followed far into the structure of our existences, the course taken by the sexual life of a child is just as unimportant for later life where the cultural or social level is relatively low as it is important where that level is relatively high. [1905d, 1552]
Though even to-day I do not consider these assertions incorrect, it is not to be wondered at that, in the course of ten years of continuous effort at reaching an understanding of these phenomena, I have made a considerable step forward from the views I then held, and now believe that I am in a position, on the basis of deeper experience, to correct the insufficiencies, the displacements and the misunderstandings under which my theory then laboured. At that time my material was still scanty, and it happened by chance to include a disproportionately large number of cases in which sexual seduction by an adult or by older children played the chief part in the history of the patient's childhood. I thus over-estimated the frequency of such events (though in other respects they were not open to doubt). Moreover, I was at that period unable to distinguish with certainty between falsifications made by hysterics in their memories of childhood and traces of real events. Since then I have learned to explain a number of phantasies of seduction as attempts at fending off memories of the subject's own sexual activity (infantile masturbation). When this point had been clarified, the 'traumatic' element in the sexual experiences of childhood lost its importance and what was left was the realization that infantile sexual activity (whether spontaneous or provoked) prescribes the direction that will be taken by later sexual life after maturity. The same clarification (which corrected the most important of my early mistakes) also made it necessary to modify my view of the mechanism of hysterical symptoms. They were now no longer to be regarded as direct derivatives of the repressed memories of childhood experiences; but between the symptoms and the childish impressions there were inserted the patient's phantasies (or imaginary memories), mostly produced during the years of puberty, which on the one side were built up out of and over the childhood memories and on the other side were transformed directly into the symptoms. It was only after the introduction of this element of hysterical phantasies that the texture of the neurosis and its relation to the patient's life became intelligible; a surprising analogy came to light, too, between these unconscious phantasies of hysterics and the imaginary creations of paranoics which become conscious as delusions.

[1906a, 1578]

When striking cases of psychical impotence are exhaustively investigated by means of psycho-analysis, the following information is obtained about the psychosexual processes at work in them. Here again - as very probably in all neurotic disturbances - the foundation of the disorder is provided by an inhibition in the developmental history of the libido before it assumes the form which we take to be its normal termination. Two currents whose union is necessary to ensure a completely normal attitude in love have, in the cases we are considering, failed to combine. These two may be distinguished as the affectionate and the sensual current.

[1912d, 2338]

These affectionate fixations of the child persist throughout childhood, and continually carry along with them erotism, which is consequently diverted from its sexual aims. Then at the age of puberty they are joined by the powerful 'sensual' current which no longer mistakes its aims. It never fails, apparently, to follow the earlier paths and to cathet the objects of the primary infantile choice with quotas of libido that are now far stronger. Here, however, it runs up against the obstacles that have been erected in the meantime by the barrier against incest; consequently it will make efforts to pass on from these objects which are unsuitable in reality, and find a way as soon as possible to other, extraneous objects with which a real sexual life may be carried on. These new objects will still be chosen on the model (imago) of the infantile ones, but in the course of time they will attract to themselves the affection that was tied to the earlier ones. A man shall leave his father and his mother - according to the biblical command - and shall cleave unto his wife; affection and sensualty are then united. The greatest intensity of sensual passion will bring with it the highest psychical valuation of the object - this being the normal overvaluation of the sexual object on the part of a man.

[1912d, 2339]
Two factors will decide whether this advance in the developmental path of the libido is to fail. First, there is the amount of frustration in reality, which opposes the new object-choice and reduces its value for the person concerned. There is after all no point in embarking upon an object-choice if no choice is to be allowed at all or if there is no prospect of being able to choose anything suitable. Secondly, there is the amount of attraction which the infantile objects that have to be relinquished are able to exercise, and which is in proportion to the erotic cathexis attaching to them in childhood. If these two factors are sufficiently strong, the general mechanism by which the neuroses are formed comes into operation. The libido turns away from reality, is taken over by imaginative activity (the process of introversion), strengthens the images of the first sexual objects and becomes fixated to them. The obstacle raised against incest, however, compels the libido that has turned to these objects to remain in the unconscious. The masturbatory activity carried out by the sensual current, which is now part of the unconscious, makes its own contribution in strengthening this fixation. Nothing is altered in this state of affairs if the advance which has miscarried in reality is now completed in phantasy, and if in the phantasy-situations that lead to masturbatory satisfaction the original sexual objects are replaced by different ones. As a result of this substitution the phantasies become admissible to consciousness, but no progress is made in the allocation of the libido in reality. In this way it can happen that the whole of a young man's sensuality becomes tied to incestuous objects in the unconscious, or to put it another way, becomes fixated to unconscious incestuous phantasies. The result is then total impotence, which is perhaps further ensured by the simultaneous onset of an actual weakening of the organs that perform the sexual act.
[1912d, 2339]

It must be understood that each individual, through the combined operation of his innate disposition and the influences brought to bear on him during his early years, has acquired a specific method of his own in his conduct of his erotic life - that is, in the preconditions to falling in love which he lays down, in the instincts he satisfies and the aims he sets himself in the course of it.¹ This produces what might be described as a stereotype plate (or several such), which is constantly repeated - constantly reprinted afresh - in the course of the person's life, so far as external circumstances and the nature of the love objects accessible to him permit, and which is certainly not entirely insusceptible to change in the face of recent experiences. Now, our observations have shown that only a portion of these impulses which determine the course of erotic life have passed through the full process of psychical development. That portion is directed towards reality, is at the disposal of the conscious personality, and forms a part of it. Another portion of the libidinal impulses has been held up in the course of development; it has been kept away from the conscious personality and from reality, and has either been prevented from further expansion except in phantasy or has remained wholly in the unconscious so that it is unknown to the personality's consciousness. If someone's need for love is not entirely satisfied by reality, he is bound to approach every new person whom he meets with libidinal anticipatory ideas; and it is highly probable that both portions of his libido, the portion that is capable of becoming conscious as well as the unconscious one, have a share in forming that attitude.
[1912b, 2457]
The Diphasic Onset of Sexual Development. - Towards the end of the fifth year this early period of sexual life normally comes to an end. It is succeeded by a period of more or less complete latency, during which ethical restraints are built up, to act as defences against the desires of the Oedipus complex. In the subsequent period of puberty, the Oedipus complex is revivified in the unconscious and embarks upon further modifications. It is only at puberty that the sexual instincts develop to their full intensity; but the direction of that development, as well as all the predispositions for it, have already been determined by the early efflorescence of sexuality during childhood which preceded it. This diphasic development of the sexual function - in two stages, interrupted by the latency period - appears to be a biological peculiarity of the human species and to contain the determining factor for the origin of neuroses.

[1923a, 3923]

The advent of puberty opens a decisive chapter in the history of an obsessional neurosis. The genital organization which has been broken off in childhood starts again with great vigour. But, as we know, the sexual development in childhood determines what direction this new start at puberty will take. Not only will the early aggressive impulses be re-awakened; but a greater or lesser proportion of the new libidinal impulses - in bad cases the whole of them - will have to follow the course prescribed for them by regression and will emerge as aggressive and destructive tendencies. In consequence of the erotic trends being disguised in this way and owing to the powerful reaction- formations in the ego, the struggle against sexuality will henceforward be carried on under the banner of ethical principles. The ego will recoil with astonishment from promptings to cruelty and violence which enter consciousness from the id, and it has no notion that in them it is combating erotic wishes, including some to which it would not otherwise have taken exception. The overstrict super-ego insists all the more strongly on the suppression of sexuality, since this has assumed such repellent forms. Thus in obsessional neurosis the conflict is aggravated in two directions: the defensive forces become more intolerant and the forces that are to be fended off become more intolerable. Both effects are due to a single factor, namely, regression of the libido.

[1926d, 4275]

A prohibition of masturbation, as we have seen, becomes an incentive for giving it up; but it also becomes a motive for rebelling against the person who prohibits it - that is to say, the mother, or the mother-substitute who later regularly merges with her. A defiant persistence in masturbation appears to open the way to masculinity. Even where the girl has not succeeded in suppressing her masturbation, the effect of the apparently vain prohibition is seen in her later efforts to free herself at all costs from a satisfaction which has been spoilt for her. When she reaches maturity her object-choice may still be influenced by this persisting purpose. Her resentment at being prevented from free sexual activity plays a big part in her detachment from her mother. The same motive comes into operation again after puberty, when her mother takes up her duty of guarding her daughter's chastity. We shall, of course, not forget that the mother is similarly opposed to a boy's masturbating and thus provides him, too, with a strong motive for rebellion.

[1931b, 4596]
This account of how girls respond to the impression of castration and the prohibition against masturbation will very probably strike the reader as confused and contradictory. This is not entirely the author's fault. In truth, it is hardly possible to give a description which has general validity. We find the most different reactions in different individuals, and in the same individual the contrary attitudes exist side by side. With the first intervention of the prohibition, the conflict is there, and from now on it will accompany the development of the sexual function. Insight into what takes place is made particularly difficult by the fact of its being so hard to distinguish the mental processes of this first phase from later ones by which they are overlaid and are distorted in memory. Thus, for instance, a girl may later construe the fact of castration as a punishment for her masturbatory activity, and she will attribute the carrying out of this punishment to her father, but neither of these ideas can have been a primary one. Similarly, boys regularly fear castration from their father, although in their case, too, the threat most usually comes from their mother.

[1931b, 4597]

The road that led to this application is easily traced. When in the treatment of an adult neurotic we followed up the determinants of his symptoms, we were regularly led back to his early childhood. A knowledge of the later aetiological factors was not sufficient either for understanding the case or for producing a therapeutic effect. We were therefore compelled to make ourselves acquainted with the psychical peculiarities of childhood; we learnt a quantity of things which could not have been learnt except through analysis, and we were able to put right many opinions that were generally held about childhood. We recognized that particular importance attached to the first years of childhood - up to the age of five, perhaps - for several reasons. Firstly, because those years include the early efflorescence of sexuality which leaves behind it decisive instigating factors for the sexual life of maturity. Secondly, because the impressions of this period impinge upon an immature and feeble ego, and act upon it like traumas. The ego cannot fend off the emotional storms which they provoke in any way except by repression and in this manner acquires in childhood all its dispositions to later illnesses and functional disturbances. We realized that the difficulty of childhood lies in the fact that in a short span of time a child has to appropriate the results of a cultural evolution which stretches over thousands of years, including the acquisition of control over his instincts and adaptation to society - or at least the first beginnings of these two. He can only achieve a part of this modification through his own development; much must be imposed on him by education. We are not surprised that children often carry out this task very imperfectly. During these early times many of them pass through states that may be put on a par with neuroses - and this is certainly so in the case of all those who produce manifest illnesses later on. In some children the neurotic illness does not wait till maturity but breaks out already in childhood and gives parents and doctors plenty of trouble.

[1933a, 4747]
It has long since become common knowledge that the experiences of a person's first five years exercise a determining effect on his life, which nothing later can withstand. Much that deserves knowing might be said about the way in which these early impressions maintain themselves against any influences in more mature periods of life - but it would not be relevant here. It may, however, be less well known that the strongest compulsive influence arises from impressions which impinge upon a child at a time when we would have to regard his psychical apparatus as not yet completely receptive. The fact itself cannot be doubted; but it is so puzzling that we may make it more comprehensible by comparing it with a photographic exposure which can be developed after any interval of time and transformed into a picture. I am nevertheless glad to point out that this uncomfortable discovery of ours has been anticipated by an imaginative writer, with the boldness that is permitted to poets. E. T. A. Hoffmann used to trace back the wealth of figures that put themselves at his disposal for his creative writings to the changing images and impressions which he had experienced during a journey of some weeks in a post-chaise while he was still an infant at his mother's breast. What children have experienced at the age of two and have not understood, need never be remembered by them except in dreams; they may only come to know of it through psycho-analytic treatment. But at some later time it will break into their life with obsessional impulses, it will govern their actions, it will decide their sympathies and antipathies and will quite often determine their choice of a love-object, for which it is so frequently impossible to find a rational basis. The two points at which these facts touch upon our problem cannot be mistaken.

[1939a, 4944]
It is essential to understand clearly that the concepts of 'masculine' and 'feminine', whose meaning seems so unambiguous to ordinary people, are among the most confused that occur in science. It is possible to distinguish at least three uses. 'Masculine' and 'feminine' are used sometimes in the sense of activity and passivity, sometimes in a biological, and sometimes, again, in a sociological sense. The first of these three meanings is the essential one and the most serviceable in psycho-analysis. When, for instance, libido was described in the text above as being 'masculine', the word was being used in this sense, for an instinct is always active even when it has a passive aim in view. The second, or biological, meaning of 'masculine' and 'feminine' is the one whose applicability can be determined most easily. Here 'masculine' and 'feminine' are characterized by the presence of spermatozoa or ova respectively and by the functions proceeding from them. Activity and its concomitant phenomena (more powerful muscular development, aggressiveness, greater intensity of libido) are as a rule linked with biological masculinity; but they are not necessarily so, for there are animal species in which these qualities are on the contrary assigned to the female. The third, or sociological, meaning receives its connotation from the observation of actually existing masculine and feminine individuals. Such observation shows that in human beings pure masculinity or femininity is not to be found either in a psychological or a biological sense. Every individual on the contrary displays a mixture of the character-traits belonging to his own and to the opposite sex; and he shows a combination of activity and passivity whether or not these last character-traits tally with his biological ones.

In spite of the gaps in our knowledge of infantile sexual life, we had to proceed to an attempt at examining the alterations brought about in it by the arrival of puberty. We selected two of these as being the decisive ones: the subordination of all the other sources of sexual excitation under the primacy of the genital zones and the process of finding an object. Both of these are already adumbrated in childhood. The first is accomplished by the mechanism of exploiting fore-pleasure: what were formerly self-contained sexual acts, attended by pleasure and excitation, become acts preparatory to the new sexual aim (the discharge of the sexual products), the attainment of which, enormously pleasurable, brings the sexual excitation to an end. In this connection we had to take into account the differentiation of sexuality into masculine and feminine; and we found that in order to become a woman a further stage of repression is necessary, which discards a portion of infantile masculinity and prepares the woman for changing her leading genital zone. As regards object-choice, we found that it is given its direction by the childhood hints (revived at puberty) of the child's sexual inclination towards his parents and others in charge of him, but that it is diverted away from them, on to other people who resemble them, owing to the barrier against incest which has meanwhile been erected. Finally it must be added that during the transition period of puberty the processes of somatic and of psychical development continue for a time side by side independently, until the irruption of an intense mental erotic impulse, leading to the innervation of the genitals, brings about the unity of the erotic function which is necessary for normality.
It is not unimportant to bear in mind what transformations are undergone, during the sexual development of childhood, by the polarity of sex with which we are familiar. A first antithesis is introduced with the choice of object, which, of course, presupposes a subject and an object. At the stage of the pregenital sadistic-anal organization, there is as yet no question of male and female; the antithesis between active and passive is the dominant one.¹ At the following stage of infantile genital organization, which we now know about, maleness exists, but not femaleness. The antithesis here is between having a male genital and being castrated. It is not until development has reached its completion at puberty that the sexual polarity coincides with male and female. Maleness combines subject, activity and possession of the penis; femaleness takes over object and passivity. The vagina is now valued as a place of shelter for the penis; it enters into the heritage of the womb.

¹ (Footnote added 1935:) The information about infantile sexuality was obtained from the study of men and the theory deduced from it was concerned with male children. It was natural enough to expect to find a complete parallel between the two sexes; but this turned out not to hold. Further investigations and reflections revealed profound differences between the sexual development of men and women. The first sexual object of a baby girl (just as of a baby boy) is her mother; and before a woman can reach the end of her normal development she has to change not only her sexual object but also her leading genital zone. From this circumstance difficulties arise and possibilities of inhibition which are not present in the case of men.

[1923e, 4062] [1925d, 4212]
Although the diphasic nature of object-choice comes down in essentials to no more than the operation of the latency period, it is of the highest importance in regard to disturbances of that final outcome. The resultants of infantile object-choice are carried over into the later period. They either persist as such or are revived at the actual time of puberty. But as a consequence of the repression which has developed between the two phases they prove unutilizable. Their sexual aims have become mitigated and they now represent what may be described as the 'affectionate current' of sexual life. Only psycho-analytic investigation can show that behind this affection, admiration and respect there lie concealed the old sexual longings of the infantile component instincts which have now become unserviceable. The object-choice of the pubertal period is obliged to dispense with the objects of childhood and to start afresh as a 'sensual current'. Should these two currents fail to converge, the result is often that one of the ideals of sexual life, the focusing of all desires upon a single object, will be unattainable.

With the arrival of puberty, changes set in which are destined to give infantile sexual life its final, normal shape. The sexual instinct has hitherto been predominantly auto-erotic; it now finds a sexual object. Its activity has hitherto been derived from a number of separate instincts and erotogenic zones, which, independently of one another, have pursued a certain sort of pleasure as their sole sexual aim. Now, however, a new sexual aim appears, and all the component instincts combine to attain it, while the erotogenic zones become subordinated to the primacy of the genital zone.¹ Since the new sexual aim assigns very different functions to the two sexes, their sexual development now diverges greatly. That of males is the more straightforward and the more understandable, while that of females actually enters upon a kind of involution. A normal sexual life is only assured by an exact convergence of the two currents directed towards the sexual object and sexual aim, the affectionate current and the sensual one. (The former, the affectionate current, comprises what remains over of the infantile efflorescence of sexuality.) It is like the completion of a tunnel which has been driven through a hill from both directions.

¹ [Footnote added 1915:] Cf. what has been said on p. 1518 about children's object-choice and the 'affectionate current'.

In spite of the gaps in our knowledge of infantile sexual life, we had to proceed to an attempt at examining the alterations brought about in it by the arrival of puberty. We selected two of these as being the decisive ones: the subordination of all the other sources of sexual excitation under the primacy of the genital zones and the process of finding an object. Both of these are already adumbrated in childhood. The first is accomplished by the mechanism of exploiting fore-pleasure: what were formerly self-contained sexual acts, attended by pleasure and excitation, become acts preparatory to the new sexual aim (the discharge of the sexual products), the attainment of which, enormously pleasurable, brings the sexual excitation to an end. In this connection we had to take into account the differentiation of sexuality into masculine and feminine; and we found that in order to become a woman a further stage of repression is necessary, which discards a portion of infantile masculinity and prepares the woman for changing her leading genital zone. As regards object-choice, we found that it is given its direction by the childhood hints (revived at puberty) of the child's sexual inclination towards his parents and others in charge of him, but that it is diverted away from them, on to other people who resemble them, owing to the barrier against incest which has meanwhile been erected. Finally it must be added that during the transition period of puberty the processes of somatic and of psychical development continue for a time side by side independently, until the irruption of an intense mental erotic impulse, leading to the innervation of the genitals, brings about the unity of the erotic function which is necessary for normality.
When striking cases of psychical impotence are exhaustively investigated by means of psycho-analysis, the following information is obtained about the psychosexual processes at work in them. Here again - as very probably in all neurotic disturbances - the foundation of the disorder is provided by an inhibition in the developmental history of the libido before it assumes the form which we take to be its normal termination. Two currents whose union is necessary to ensure a completely normal attitude in love have, in the cases we are considering, failed to combine. These two may be distinguished as the affectionate and the sensual current.

The affectionate current is the older of the two. It springs from the earliest years of childhood; it is formed on the basis of the interests of the self-preservative instinct and is directed to the members of the family and those who look after the child. From the very beginning it carries along with it contributions from the sexual instincts - components of erotic interest - which can already be seen more or less clearly even in childhood and in any event are uncovered in neurotics by psycho-analysis later on. It corresponds to the child's primary object-choice. We learn in this way that the sexual instincts find their first objects by attaching themselves to the valuations made by the ego-instincts, precisely in the way in which the first sexual satisfactions are experienced in attachment to the bodily functions necessary for the preservation of life. The 'affection' shown by the child's parents and those who look after him, which seldom fails to betray its erotic nature ('the child is an erotic plaything'), does a very great deal to raise the contributions made by erotism to the cathexes of his ego-instincts, and to increase them to an amount which is bound to play a part in his later development, especially when certain other circumstances lend their support.

These affectionate fixations of the child persist throughout childhood, and continually carry along with them erotism, which is consequently diverted from its sexual aims. Then at the age of puberty they are joined by the powerful 'sensual' current which no longer mistakes its aims. It never fails, apparently, to follow the earlier paths and to cathect the objects of the primary infantile choice with quotas of libido that are now far stronger. Here, however, it runs up against the obstacles that have been erected in the meantime by the barrier against incest; consequently it will make efforts to pass on from these objects which are unsuitable in reality, and find a way as soon as possible to other, extraneous objects with which a real sexual life may be carried on. These new objects will still be chosen on the model (imago) of the infantile ones, but in the course of time they will attract to themselves the affection that was tied to the earlier ones. A man shall leave his father and his mother - according to the biblical command - and shall cleave unto his wife; affection and sensuality are then united. The greatest intensity of sensual passion will bring with it the highest psychical valuation of the object - this being the normal overvaluation of the sexual object on the part of a man.
Two factors will decide whether this advance in the developmental path of the libido is to fail. First, there is the amount of frustration in reality, which opposes the new object-choice and reduces its value for the person concerned. There is after all no point in embarking upon an object-choice if no choice is to be allowed at all or if there is no prospect of being able to choose anything suitable. Secondly, there is the amount of attraction which the infantile objects that have to be relinquished are able to exercise, and which is in proportion to the erotic cathexis attaching to them in childhood. If these two factors are sufficiently strong, the general mechanism by which the neuroses are formed comes into operation. The libido turns away from reality, is taken over by imaginative activity (the process of introversion), strengthens the images of the first sexual objects and becomes fixated to them. The obstacle raised against incest, however, compels the libido that has turned to these objects to remain in the unconscious. The masturbatory activity carried out by the sensual current, which is now part of the unconscious, makes its own contribution in strengthening this fixation. Nothing is altered in this state of affairs if the advance which has miscarried in reality is now completed in phantasy, and if in the phantasy-situations that lead to masturbatory satisfaction the original sexual objects are replaced by different ones. As a result of this substitution the phantasies become admissible to consciousness, but no progress is made in the allocation of the libido in reality. In this way it can happen that the whole of a young man's sensuality becomes tied to incestuous objects in the unconscious, or to put it another way, becomes fixated to unconscious incestuous phantasies. The result is then total impotence, which is perhaps further ensured by the simultaneous onset of an actual weakening of the organs that perform the sexual act. [1912d, 2339]

Less severe conditions are required to bring about the state known specifically as psychical impotence. Here the fate of the sensual current must not be that its whole charge has to conceal itself behind the affectationate current; it must have remained sufficiently strong or uninhibited to secure a partial outlet into reality. The sexual activity of such people shows the clearest signs, however, that it has not the whole psychical driving force of the instinct behind it. It is capricious, easily disturbed, often not properly carried out, and not accompanied by much pleasure. But above all it is forced to avoid the affectationate current. A restriction has thus been placed on object-choice. The sensual current that has remained active seeks only objects which do not recall the incestuous figures forbidden to it; if someone makes an impression that might lead to a high psychical estimation of her, this impression does not find an issue in any sensual excitation but in affection which has no erotic effect. The whole sphere of love in such people remains divided in the two directions personified in art as sacred and profane (or animal) love. Where they love they do not desire and where they desire they cannot love. They seek objects which they do not need to love, in order to keep their sensuality away from the objects they love; and, in accordance with the laws of 'complexive sensitiveness' and of the return of the repressed, the strange failure shown in psychical impotence makes its appearance whenever an object which has been chosen with the aim of avoiding incest recalls the prohibited object through some feature, often an inconspicuous one. [1912d, 2340]

The main protective measure against such a disturbance which men have recourse to in this split in their love consists in a psychical debasement of the sexual object, the overvaluation that normally attaches to the sexual object being reserved for the incestuous object and its representatives. As soon as the condition of debasement is fulfilled, sensuality can be freely expressed, and important sexual capacities and a high degree of pleasure can develop. There is a further factor which contributes to this result. People in whom there has not been a proper confluence of the affectationate and the sensual currents do not usually show much refinement in their modes of behaviour in love; they have retained perverse sexual aims whose non-fulfilment is felt as a serious loss of pleasure, and whose fulfilment on the other hand seems possible only with a debased and despised sexual object. [1912d, 2340]
We can now understand the motives behind the boy's phantasies mentioned in the first of these 'Contributions' (above, p. 2331), which degrade the mother to the level of a prostitute. They are efforts to bridge the gulf between the two currents in love, at any rate in phantasy, and by debasing the mother to acquire her as an object of sensuality.

We have reduced psychical impotence to the failure of the affectionate and the sensual currents in love to combine, and this developmental inhibition has in turn been explained as being due to the influences of strong childhood fixations and of later frustration in reality through the intervention of the barrier against incest. There is one principal objection to the theory we advance; it does too much. It explains why certain people suffer from psychical impotence, but it leaves us with the apparent mystery of how others have been able to escape this disorder. Since we must recognize that all the relevant factors known to us - the strong childhood fixation, the incest-barrier and the frustration in the years of development after puberty - are to be found in practically all civilized human beings, we should be justified in expecting psychical impotence to be a universal affliction under civilization and not a disorder confined to some individuals.

The condition of forbiddenness in the erotic life of women is, I think, comparable to the need on the part of men to debase their sexual object. Both are consequences of the long period of delay, which is demanded by education for cultural reasons, between sexual maturity and sexual activity. Both aim at abolishing the psychical impotence that results from the failure of affectionate and sensual impulses to coalesce. That the effect of the same causes should be so different in men and in women may perhaps be traced to another difference in the behaviour of the two sexes. Civilized women do not usually transgress the prohibition on sexual activity in the period during which they have to wait, and thus they acquire the intimate connection between prohibition and sexuality. Men usually break through this prohibition if they can satisfy the condition of debasing the object, and so they carry on this condition into their love in later life.

At puberty, as we know, there set in new and very strong impulsions towards directly sexual aims. In unfavourable cases they remain separate, in the form of a sensual current, from the 'affectionate' trends of feeling which persist. We then have before us a picture whose two aspects are typified with such delight by certain schools of literature. A man will show a sentimental enthusiasm for women whom he deeply respects but who do not excite him to sexual activities, and he will only be potent with other women whom he does not 'love' and thinks little of or even despises. More often, however, the adolescent succeeds in bringing about a certain degree of synthesis between the unsensual, heavenly love and the sensual, earthly love, and his relation to his sexual object is characterized by the interaction of uninhibited instincts and of instincts inhibited in their aim. The depth to which anyone is in love, as contrasted with his purely sensual desire, may be measured by the size of the share taken by the aim-inhibited instincts of affection.
There are abundant indications that being in love only made its appearance late on in the sexual relations between men and women; so that the opposition between sexual love and group ties is also a late development. Now it may seem as though this assumption were incompatible with our myth of the primal family. For it was after all by their love for their mothers and sisters that the mob of brothers was, as we have supposed, driven to parricide; and it is difficult to imagine this love as being anything but undivided and primitive - that is, as an intimate union of the affectionate and sensual. But further consideration resolves this objection to our theory into a confirmation of it. One of the reactions to the parricide was after all the institution of totemic exogamy, the prohibition of any sexual relation with those women of the family who had been tenderly loved since childhood. In this way a wedge was driven in between a man's affectionate and sensual feelings, one still firmly fixed in his erotic life to-day.¹ As a result of this exogamy the sensual needs of men had to be satisfied with strange and unloved women.

[1921c, 3831]
At puberty, as we know, there set in new and very strong impulsions towards directly sexual aims. In unfavourable cases they remain separate, in the form of a sensuous current, from the 'affectionate' trends of feeling which persist. We then have before us a picture whose two aspects are typified with such delight by certain schools of literature. A man will show a sentimental enthusiasm for women whom he deeply respects but who do not excite him to sexual activities, and he will only be potent with other women whom he does not 'love' and thinks little of or even despises.¹ More often, however, the adolescent succeeds in bringing about a certain degree of synthesis between the unsensual, heavenly love and the sensuous, earthly love, and his relation to his sexual object is characterized by the interaction of uninhibited instincts and of instincts inhibited in their aim. The depth to which anyone is in love, as contrasted with his purely sensual desire, may be measured by the size of the share taken by the aim-inhibited instincts of affection.

[1921c, 3804]

I mentioned the fact that in her behaviour to her adored lady the girl had adopted the characteristic masculine type of love. Her humility and her tender lack of pretensions, 'che poco spera e nulla chiede', her bliss when she was allowed to accompany the lady a little way and to kiss her hand on parting, her joy when she heard her praised as beautiful (while any recognition of her own beauty by another person meant nothing at all to her), her pilgrimages to places once visited by the loved one, the silence of all more sensual wishes - all these little traits in her resembled the first passionate adoration of a youth for a celebrated actress whom he regards as far above him, to whom he scarcely dares lift his bashful eyes. The correspondence with 'a special type of choice of object made by men' that I have described elsewhere (1910h), whose special features I traced to attachment to the mother, held good even to the smallest details. It may seem remarkable that she was not in the least repelled by the bad reputation of her beloved, although her own observations sufficiently confirmed the truth of such rumours. She was after all a well-brought-up and modest girl, who had avoided sexual adventures for herself, and who regarded coarsely sensual satisfactions as unaesthetic. But already her first passions had been for women who were not celebrated for specially strict propriety. The first protest her father made against her love-choice had been evoked by the pertinacity with which she sought the company of a film actress at a summer resort. Moreover, in all these affairs it had never been a question of women who had any reputation for homosexuality, and who might, therefore, have offered her some prospect of homosexual satisfaction; on the contrary, she illogically courted women who were coquettes in the ordinary sense of the word, and she rejected without hesitation the willing advances made by a homosexual friend of her own age. For her, the bad reputation of her 'lady', however, was positively a 'necessary condition for love'. All that is enigmatic in this attitude vanishes when we remember that in the case too of the *masculine* type of object-choice derived from the mother it is a necessary condition that the loved object should be in some way or other 'of bad repute' sexually - someone who really may be called a *cocotte*. When the girl learnt later how far her adored lady deserved this description and that she lived simply by giving her bodily favours, her reaction took the form of great compassion and of phantasies and plans for 'rescuing' her beloved from these ignoble circumstances. We were struck by the same urge to 'rescue' in the men of the type referred to above, and in my description of it I have tried to give the analytic derivation of this urge.

[1920a, 3850]
Other patients, again, suffer from disturbances in a particular field in which emotional life converges with demands of a bodily sort. If they are men, they find they are incapable of giving physical expression to their tenderest feelings towards the opposite sex, while towards less loved objects they may perhaps have every reaction at their command. Or their sensual feelings attach them to people whom they despise and from whom they would like to get free; or those same feelings impose requirements on them whose fulfilment they themselves find repulsive. If they are women, they feel prevented by anxiety or disgust or by unknown obstructions from meeting the demands of sexual life; or, if they have surrendered to love, they find themselves cheated of the enjoyment which nature has provided as a reward for such compliance. [1926e, 4329]
SEXUAL INHIBITIONS    It is during this period of total or only partial latency that are built up the mental forces which are later to impede the course of the sexual instinct and, like dams, restrict its flow - disgust, feelings of shame and the claims of aesthetic and moral ideals. One gets an impression from civilized children that the construction of these dams is a product of education, and no doubt education has much to do with it. But in reality this development is organically determined and fixed by heredity, and it can occasionally occur without any help at all from education. Education will not be trespassing beyond its appropriate domain if it limits itself to following the lines which have already been laid down organically and to impressing them somewhat more clearly and deeply.

[1905d, 1500]

² [Footnote added 1915:] The barrier against incest is probably among the historical acquisitions of mankind, and, like other moral taboos, has no doubt already become established in many persons by organic inheritance. (Cf. my Totem and Taboo, 1912-13.) Psycho-analytic investigation shows, however, how intensely the individual struggles with the temptation to incest during his period of growth and how frequently the barrier is transgressed in phantasies and even in reality.

[1905d, 1538]

I will dwell for a little to-day on yet another point in ego development, partly because I have some remoter aims in view, but also because what follows is precisely calculated to justify the sharp separation between the ego-instincts and the sexual instincts which we favour but which is not self-evident. In forming our judgement of the two courses of development both of the ego and of the libido - we must lay emphasis on a consideration which has not often hitherto been taken into account. For both of them are at bottom heritages, abbreviated recapitulations of the development which all mankind has passed through from its primaeval days over long periods of time. In the case of the development of the libido, this phylogenetic origin is, I venture to think, immediately obvious. Consider how in one class of animals the genital apparatus is brought into the closest relation to the mouth, while in another it cannot be distinguished from the excretory apparatus, and in yet others it is linked to the motor organs - all of which you will find attractively set out in W. Bölsche’s valuable book. Among animals one can find, so to speak in petrified form, every species of perversion of the sexual organization. In the case of human beings, however, this phylogenetic point of view is partly veiled by the fact that what is at bottom inherited is nevertheless freshly acquired in the development of the individual, probably because the same conditions which originally necessitated its acquisition persist and continue to operate upon each individual. I should like to add that originally the operation of these conditions was creative but that it is now evocative. Besides this, there is no doubt that the prescribed course of development can be disturbed and altered in each individual by recent external influences. But we know the power which forced a development of this kind upon humanity and maintains its pressure in the same direction to-day. It is, once again, frustration by reality, or, if we are to give it its true, grand name, the pressure of vital needs - Necessity (Άνάγκη). She has been a strict educator and has made much out of us. The neurotics are among those of her children to whom her strictness has brought evil results; but that is a risk with all education. This appreciation of the necessities of life need not, incidentally, weigh against the importance, of `internal developmental trends', if such can be shown to be present.

[1916-1917, 3414]
The only impression we gain is that these events of childhood are somehow demanded as a necessity, that they are among the essential elements of a neurosis. If they have occurred in reality, so much to the good; but if they have been withheld by reality, they are put together from hints and supplemented by phantasy. The outcome is the same, and up to the present we have not succeeded in pointing to any difference in the consequences, whether phantasy or reality has had the greater share in these events of childhood. Here we simply have once again one of the complemental relations that I have so often mentioned; moreover it is the strangest of all we have met with. Whence comes the need for these phantasies and the material for them? There can be no doubt that their sources lie in the instincts; but it has still to be explained why the same phantasies with the same content are created on every occasion. I am prepared with an answer which I know will seem daring to you. I believe these primal phantasies, as I should like to call them, and no doubt a few others as well, are a phylogenetic endowment. In them the individual reaches beyond his own experience into primaeval experience at points where his own experience as been too rudimentary. It seems to me quite possible that all the things that are told to us to-day in analysis as phantasy - the seduction of children, the inflaming of sexual excitement by observing parental intercourse, the threat of castration (or rather castration itself) - were once real occurrences in the primaeval times of the human family, and that children in their phantasies are simply filling in the gaps in individual truth with prehistoric truth. I have repeatedly been led to suspect that the psychology of the neuroses has stored up in it more of the antiquities of human development than any other source.

I have now come to the end of what I had to say about this case. There remain two problems, of the many that it raises, which seem to me to deserve special emphasis. The first relates to the phylogenetically inherited schemata, which, like the categories of philosophy, are concerned with the business of ‘placing’ the impressions derived from actual experience. I am inclined to take the view that they are precipitates from the history of human civilization. The Oedipus complex, which comprises a child’s relation to his parents, is one of them - is, in fact, the best known member of the class. Wherever experiences fail to fit in with the hereditary schema, they become remodelled in the imagination - a process which might very profitably be followed out in detail. It is precisely such cases that are calculated to convince us of the independent existence of the schema. We are often able to see the schema triumphing over the experience of the individual; as when in our present case the boy's father became the castrator and the menace of his infantile sexuality in spite of what was in other respects an inverted Oedipus complex. A similar process is at work where a nurse comes to play the mother's part or where the two become fused together. The contradictions between experience and the schema seem to supply the conflicts of childhood with an abundance of material.
As regards the prehistory of the Oedipus complex in boys we are far from complete clarity. We know that that period includes an identification of an affectionate sort with the boy's father, an identification which is still free from any sense of rivalry in regard to his mother. Another element of that stage is invariably, I believe, a masturbatory activity in connection with the genitals, the masturbation of early childhood, the more or less violent suppression of which by those in charge of the child sets the castration complex in action. It is to be assumed that this masturbation is attached to the Oedipus complex and serves as a discharge for the sexual excitation belonging to it. It is, however, uncertain whether the masturbation has this character from the first, or whether on the contrary it makes its first appearance spontaneously as an activity of a bodily organ and is only brought into relation with the Oedipus complex at some later date; this second possibility is by far the more probable. Another doubtful question is the part played by bed-wetting and by the breaking of that habit through the intervention of training measures. We are inclined to make the simple connection that continued bed-wetting is a result of masturbation and that its suppression is regarded by boys as an inhibition of their genital activity - that is, as having the meaning of a threat of castration; but whether we are always right in supposing this remains to be seen. Finally, analysis shows us in a shadowy way how the fact of a child at a very early age listening to his parents copulating may set up his first sexual excitation, and how that event may, owing to its after-effects, act as a starting-point for the child's whole sexual development. Masturbation, as well as the two attitudes in the Oedipus complex, later on become attached to this early experience, the child having subsequently interpreted its meaning. It is impossible, however, to suppose that these observations of coitus are of universal occurrence, so that at this point we are faced with the problem of 'primal phantasies'. Thus the prehistory of the Oedipus complex, even in boys, raises all of these questions for sifting and explanation; and there is the further problem of whether we are to suppose that the process invariably follows the same course, or whether a great variety of different preliminary stages may not converge upon the same terminal situation. [1925j, 4148]

You will be no less surprised to hear that male children suffer from a fear of being robbed of their sexual organ by their father, so that this fear of being castrated has a most powerful influence on the development of their character and in deciding the direction to be followed by their sexuality. And here again mythology may give you the courage to believe psycho-analysis. The same Kronos who swallowed his children also emasculated his father Uranus, and was afterwards himself emasculated in revenge by his son Zeus, who had been rescued though his mother's cunning. If you have felt inclined to suppose that all that psycho-analysis reports about the early sexuality of children is derived from the disordered imagination of the analysts, you must at least admit that their imagination has created the same product as the imaginative activities of primitive man, of which myths and fairy tales are the precipitate. The alternative friendlier, and probably also the more pertinent view would be that in the mental life of children to-day we can still detect the same archaic factors which were once dominant generally in the primaeval days of human civilization. In his mental development the child would be repeating the history of his race in an abbreviated form, just as embryology long since recognized was the case with somatic development. [1926e, 4354]
The work of analysis has, however, brought something else to light which exceeds in its importance what we have so far considered. When we study the reactions to early traumas, we are quite often surprised to find that they are not strictly limited to what the subject himself has really experienced but diverge from it in a way which fits in much better with the model of a phylogenetic event and, in general, can only be explained by such an influence. The behaviour of neurotic children towards their parents in the Oedipus and castration complex abounds in such reactions, which seem unjustified in the individual case and only become intelligible phylogenetically - by their connection with the experience of earlier generations. It would be well worth while to place this material, which I am able to appeal to here, before the public in a collected form. Its evidential value seems to me strong enough for me to venture on a further step and to posit the assertion that the archaic heritage of human beings comprises not only dispositions but also subject-matter - memory-traces of the experience of earlier generations. In this way the compass as well as the importance of the archaic heritage would be significantly extended.

[1939a, 4921]

A child's first erotic object is the mother's breast that nourishes it; love has its origin in attachment to the satisfied need for nourishment. There is no doubt that, to begin with, the child does not distinguish between the breast and its own body; when the breast has to be separated from the body and shifted to the 'outside' because the child so often finds it absent, it carries with it as an 'object' a part of the original narcissistic libidinal cathexis. This first object is later completed into the person of the child's mother, who not only nourishes it but also looks after it and thus arouses in it a number of other physical sensations, pleasurable and unpleasurable. By her care of the child's body she becomes its first seducer. In these two relations lies the root of a mother's importance, unique, without parallel, established unalterably for a whole lifetime as the first and strongest love-object and as the prototype of all later love-relations - for both sexes. In all this the phylogenetic foundation has so much the upper hand over personal accidental experience that it makes no difference whether a child has really sucked at the breast or has been brought up on the bottle and never enjoyed the tenderness of a mother's care. In both cases the child's development takes the same path; it may be that in the second case its later longing grows all the greater. And for however long it is fed at its mother's breast, it will always be left with a conviction after it has been weaned that its feeding was too short and too little.

[1940a [1938], 4996]
The affectionate current is the older of the two. It springs from the earliest years of childhood; it is formed on the basis of the interests of the self-preservation instinct and is directed to the members of the family and those who look after the child. From the very beginning it carries along with it contributions from the sexual instincts - components of erotic interest - which can already be seen more or less clearly even in childhood and in any event are uncovered in neurotics by psycho-analysis later on. It corresponds to the child’s primary object-choice. We learn in this way that the sexual instincts find their first objects by attaching themselves to the valuations made by the ego-instincts, precisely in the way in which the first sexual satisfactions are experienced in attachment to the bodily functions necessary for the preservation of life. The 'affection' shown by the child’s parents and those who look after him, which seldom fails to betray its erotic nature ('the child is an erotic plaything'), does a very great deal to raise the contributions made by erotism to the cathexes of his ego-instincts, and to increase them to an amount which is bound to play a part in his later development, especially when certain other circumstances lend their support.

[1912d, 2338]

However, this motive does not go deep enough either; besides, being bound up with civilized conditions, it fails to provide a satisfactory connection with the state of affairs among primitive people. All the more important, therefore, is the next factor, which is based on the evolution of the libido. We have learnt from analytic researches how universal and how powerful the earliest allocations of libido are. In these we are concerned with infantile sexual wishes which are clung to (in women usually a fixation of the libido on the father or a brother who takes his place) - wishes which frequently enough were directed towards other things than intercourse, or included it only as a dimly perceived goal. The husband is almost always so to speak only a substitute, never the right man; it is another man - in typical cases the father - who has first claim to a woman's love, the husband at most takes second place. It depends on how intense this fixation is and on how obstinately it is maintained whether the substitute is rejected as unsatisfying. Frigidity is thus among the genetic determinants of neuroses. The more powerful the psychical element in a woman's sexual life is, the greater will be the capacity for resistance shown by her distribution of libido to the upheaval of the first sexual act, and the less overpowering will be the effect which bodily possession of her can produce. Frigidity may then become established as a neurotic inhibition or provide the foundation for the development of other neuroses and even a moderate diminution of potency in the man will greatly contribute to help this process.

[1918a, 2358]

Some notable discoveries have been made in the course of this investigation of the infantile mind. Thus it has been possible to confirm, what has often already been suspected, the extraordinarily important influence exerted by the impressions of childhood (and particularly by its earliest years) on the whole course of later development. This brings us up against a psychological paradox - which for psycho-analysts alone is no paradox - that it is precisely these most important of all impressions that are not remembered in later years. Psycho-analysis has been able to establish the decisive and indestructible character of these earliest experiences in the clearest possible way in the case of sexual life. ‘On revient toujours à ses premiers amours’ is sober truth. The many riddles in the sexual life of adults can only be solved if stress is laid on the infantile factors in love. Theoretical light is thrown on their influence by the consideration that an individual's first experiences in childhood do not occur only by chance but also correspond to the first activities of his innate or constitutional instinctual dispositions.

[1913], 2819]
Where, then, does the libido find the fixations which it requires in order to break through the repressions? In the activities and experiences of infantile sexuality, in the abandoned component trends, in the objects of childhood which have been given up. It is to them, accordingly, that the libido returns. The significance of this period of childhood is twofold: on the one hand, during it the instinctual trends which the child has inherited with his innate disposition first become manifest, and secondly, others of his instincts are for the first time awakened and made active by external impressions and accidental experiences. There is no doubt, I think, that we are justified in making this twofold division. The manifestation of the innate disposition is indeed not open to any critical doubts, but analytic experience actually compels us to assume that purely chance experiences in childhood are able to leave fixations of the libido behind them. Nor do I see any theoretical difficulty in this. Constitutional dispositions are also undoubtedly after-effects of experiences by ancestors in the past; they too were once acquired. Without such acquisition there would be no heredity. And is it conceivable that acquisition such as this, leading to inheritance, would come to an end precisely with the generation we are considering? The significance of infantile experiences should not be totally neglected, as people like doing, in comparison with the experiences of the subject's ancestors and of his own maturity; on the contrary, they call for particular consideration. They are all the more momentous because they occur in times of incomplete development and are for that very reason liable to have traumatic effects. The studies on developmental mechanics by Roux and others have shown that the prick of a needle into an embryonic germinal layer in the act of cell-division results in a severe disturbance of development. The same injury inflicted on a larval or fully grown animal would do no damage.

The theory of psycho-analysis (a theory based on observation) holds firmly to the view that the motive forces of repression must not be sexualized. Man's archaic heritage forms the nucleus of the unconscious mind; and whatever part of that heritage has to be left behind in the advance to later phases of development, because it is unserviceable or incompatible with what is new and harmful to it, falls a victim to the process of repression. This selection is made more successfully with one group of instincts than with the other. In virtue of special circumstances which have often been pointed out already, the latter group, that of the sexual instincts, are able to defeat the intentions of repression, and to enforce their representation by substitutive formations of a disturbing kind. For this reason infantile sexuality, which is held under repression, acts as the chief motive force in the formation of symptoms; and the essential part of its content, the Oedipus complex, is the nuclear complex of neuroses. I hope that in this paper I have raised an expectation that the sexual aberrations of childhood, as well as those of mature life, are ramifications of the same complex.
The Development of the Libido. - The sexual instinct, the dynamic manifestation of which in mental life we shall call 'libido', is made up of component instincts into which it may once more break up and which are only gradually united into well-defined organizations. The sources of these component instincts are the organs of the body and in particular certain specially marked erogenous zones; but contributions are made to libido from every important functional process in the body. At first the individual component instincts strive for satisfaction independently of one another, but in the course of development they become more and more convergent and concentrated. The first (pregenital) stage of organization to be discerned is the oral one, in which - in conformity with the suckling's predominant interest - the oral zone plays the leading part. This is followed by the sadistic-anal organization, in which the anal zone and the component instinct of sadism are particularly prominent; at this stage the difference between the sexes is represented by the contrast between active and passive. The third and final stage of organization is that in which the majority of the component instincts converge under the primacy of the genital zones. As a rule this development is passed through swiftly and unobtrusively; but some individual portions of the instincts remain behind at the prodromal stages of the process and thus give rise to fixations of libido, which are important as constituting predispositions for subsequent irruptions of repressed impulses and which stand in a definite relation to the later development of neuroses and perversions. (See the article on 'The Libido Theory'.) [1923a, 3921]

Advance in knowledge made ever clearer the enormous part played in mental life by sexual wishful impulses, and led to a detailed study of the nature and development of the sexual instinct.¹ But we also came upon another purely empirical finding, in the discovery that the experiences and conflicts of the first years of childhood play an unsuspectedly important part in the individual's development and leave behind them ineffaceable dispositions bearing upon the period of maturity. This led to the revelation of something that had hitherto been fundamentally overlooked by science - infantile sexuality, which, from the tenderest age onwards, is manifested both in physical reactions and in mental attitudes. In order to bring together this sexuality of children with what is described as the normal sexuality of adults and the abnormal sexual life of perverts, the concept of what was sexual had itself to be corrected and widened in a manner which could be justified by the evolution of the sexual instinct. [1924f, 4107]

In my own writings and in those of my followers more and more stress is laid on the necessity that the analyses of neurotics shall deal thoroughly with the remotest period of their childhood, the time of the early efflorescence of sexual life. It is only by examining the first manifestations of the patient's innate instinctual constitution and the effects of his earliest experiences that we can accurately gauge the motive forces that have led to his neurosis and can be secure against the errors into which we might be tempted by the degree to which things have become remodelled and overlaid in adult life. This requirement is not only of theoretical but also of practical importance, for it distinguishes our efforts from the work of those physicians whose interests are focused exclusively on therapeutic results and who employ analytic methods, but only up to a certain point. An analysis of early childhood such as we are considering is tedious and laborious and makes demands both upon the physician and upon the patient which cannot always be met. Moreover, it leads us into dark regions where there are as yet no sign posts. Indeed, analysts may feel reassured, I think, that there is no risk of their work becoming mechanical, and so of losing its interest, during the next few decades. [1925j, 4146]
(2) For cultural reasons the most intense repression falls upon the sexual instincts; but it is precisely in connection with them that repression most easily miscarries, so that neurotic symptoms are found to be substitutive satisfactions of repressed sexuality. The belief that in man sexual life begins only at puberty is incorrect. On the contrary, signs of it can be detected from the beginning of extra-uterine existence; it reaches a first culminating point at or before the fifth year ('early period'), after which it is inhibited or interrupted ('latency period') until the age of puberty, which is the second climax of its development. This diphasic onset of sexual development seems to be distinctive of the genus Homo. All experiences during the first period of childhood are of the greatest importance to the individual, and in combination with his inherited sexual constitution form the dispositions for the subsequent development of character and disease. It is wrong to make sexuality coincide with 'genitality'. The sexual instincts pass through a complicated course of development, and it is only at the end of it that the 'primacy of the genital zones' is attained. Before this there are a number of 'pregenital' organizations of the libido - points at which it may become 'fixated' and to which, in the event of subsequent repression, it will return ('regression'). The infantile fixations of the libido are what determine the form of any later neurosis. Thus the neuroses are to be regarded as inhibitions in the development of the libido. There are no specific causes of nervous disorders; the question whether a conflict finds a healthy solution or leads to a neurotic inhibition of function depends upon quantitative considerations.

[1926f, 4405]

The results of the threat of castration are multifarious and incalculable; they affect the whole of a boy's relations with his father and mother and subsequently with men and women in general. As a rule the child's masculinity is unable to stand up to this first shock. In order to preserve his sexual organ he renounces the possession of his mother more or less completely; his sexual life often remains permanently encumbered by the prohibition. If a strong feminine component, as we call it, is present in him, its strength is increased by this intimidation of his masculinity. He falls into a passive attitude to his father, such as he attributes to his mother. It is true that as a result of the threat he has given up masturbation, but not the activities of his imagination accompanying it. On the contrary, since these are now the only form of sexual satisfaction remaining to him, he indulges in them more than before and in these phantasies, though he still continues to identify himself with his father, he also does so, simultaneously and perhaps predominantly, with his mother. Derivatives and modified products of these early masturbatory phantasies usually make their way into his later ego and play a part in the formation of his character. Apart from this encouragement of his femininity, fear and hatred of his father gain greatly in intensity. The boy's masculinity withdraws, as it were, into a defiant attitude towards his father, which will dominate his later behaviour in human society in a compulsive fashion. A residue of his erotic fixation to his mother is often left in the form of an excessive dependence on her, and this persists as a kind of bondage to women. He no longer ventures to love his mother, but he cannot risk not being loved by her, for in that case he would be in danger of being betrayed by her to his father and handed over to castration. The whole experience, with all its antecedents and consequences, of which my account has only been able to give a selection, is subjected to a highly energetic repression, and, as is made possible by the laws operating in the unconscious id, all the mutually contending emotional impulses and reactions which are set going at that time are preserved in the unconscious and ready to disturb the later development of the ego after puberty. When the somatic process of sexual maturation puts fresh life into the old libidinal fixations which had apparently been surmounted, sexual life will turn out to be inhibited, without homogeneity and fallen apart into mutually conflicting urges.

[1940a [1938], 4998]
I cannot offer any proof here that the truth is nevertheless otherwise; but I may say that I am strongly inclined to suppose that dream-wishes are more strictly determined. It is true that children's dreams prove beyond a doubt that a wish that has not been dealt with during the day can act as a dream-instigator. But it must not be forgotten that it is a child's wish, a wishful impulse of the strength proper to children. I think it is highly doubtful whether in the case of an adult a wish that has not been fulfilled during the day would be strong enough to produce a dream. It seems to me, on the contrary, that, with the progressive control exercised upon our instinctual life by our thought-activity, we are more and more inclined to renounce as unprofitable the formation or retention of such intense wishes as children know. It is possible that there are individual differences in this respect, and that some people retain an infantile type of mental process longer than others, just as there are similar differences in regard to the diminution of visual imagery, which is so vivid in early years. But in general, I think, a wish that has been left over unfulfilled from the previous day is insufficient to produce a dream in the case of an adult. I readily admit that a wishful impulse originating in the conscious will contribute to the instigation of a dream, but it will probably not do more than that. The dream would not materialize if the preconscious wish did not succeed in finding reinforcement from elsewhere. 

[1900a, 984]

It is possible further to form some idea of the mechanism of this process of sublimation. On the one hand, it would seem, the sexual impulses cannot be utilized during these years of childhood, since the reproductive functions have been deferred - a fact which constitutes the main feature of the period of latency. On the other hand, these impulses would seem in themselves to be perverse - that is, to arise from erotogenic zones and to derive their activity from instincts which, in view of the direction of the subject's development, can only arouse unpleasurable feelings. They consequently evoke opposing mental forces (reacting impulses) which, in order to suppress this unpleasure effectively, build up the mental dams that have already mentioned - disgust, shame and morality.²

[1905d, 1500]
After having explained the preponderance of perverse tendencies in psychoneurotics by recognizing it as a collateral filling of subsidiary channels when the main current of the instinctual stream has been blocked by 'repression',¹ we proceeded to a consideration of sexual life in childhood. We found it a regrettable thing that the existence of the sexual instinct in childhood has been denied and that the sexual manifestations not infrequently to be observed in children have been described as irregularities. It seemed to us on the contrary that children bring germs of sexual activity with them into the world, that they already enjoy sexual satisfaction when they begin to take nourishment and that they persistently seek to repeat the experience in the familiar activity of 'thumb-sucking'. The sexual activity of children, however, does not, it appeared, develop pari passu with their other functions, but, after a short period of efflorescence from the ages of two to five, enters upon the so-called period of latency. During that period the production of sexual excitation is not by any means stopped but continues and produces a store of energy which is employed to a great extent for purposes other than sexual - namely, on the one hand in contributing the sexual components to social feelings and on the other hand (through repression and reaction-forming) in building up the subsequently developed barriers against sexuality. On this view, the forces destined to retain the sexual instinct upon certain lines are built up in childhood chiefly at the cost of perverse sexual impulses and with the assistance of education. A certain portion of the infantile sexual impulses would seem to evade these uses and succeed in expressing itself as sexual activity. We next found that sexual excitation in children springs from a multiplicity of forces. Satisfaction arises first and foremost from the appropriate sensory excitation of what we have described as erotogenic zones. It seems probable that any part of the skin and any sense-organ - probably, indeed, any organ - can function as an erotogenic zone, though there are some particularly marked erotogenic zones whose excitation would seem to be secured from the very first by certain organic contrivances. It further appears that sexual excitation arises as a by-product, as it were, of a large number of processes that occur in the organism, as soon as they reach a certain degree of intensity, and most especially of any relatively powerful emotion, even though it is of a distressing nature. The excitations from all these sources are not yet combined; but each follows its own separate aim, which is merely the attainment of a certain sort of pleasure. In childhood, therefore, the sexual instinct is not unified and is at first without an object, that is, auto-erotic.

I could not further elucidate this part of my theory without a detailed discussion of my views on repression. It will be enough here to refer to my Three Essays (1905d), in which I have attempted to throw some light - if only a feeble one - on the somatic processes in which the essential nature of sexuality is to be looked for. I have there shown that the constitutional sexual disposition of children is incomparably more variegated than might have been expected, that it deserves to be described as 'polymorphously perverse' and that what is spoken of as the normal behaviour of the sexual function emerges from this disposition after certain of its components have been repressed. By pointing out the infantile elements in sexuality I was able to establish a simple correlation between health, perversion and neurosis. I showed that normality is a result of the repression of certain component instincts and constituents of the infantile disposition and of the subordination of the remaining constituents under the primacy of the genital zones in the service of the reproductive function. I showed that perversions correspond to disturbances of this coalescence owing to the overpowering and compulsive development of certain of the component instincts, while neuroses can be traced back to an excessive repression of the libidinal trends. Since almost all the perverse instincts of the infantile disposition can be recognized as the forces concerned in the formation of symptoms in neuroses, though in a state of repression, I was able to describe neurosis as being the 'negative' of perversion.

[1905d, 1543]

[1906a, 1581]
I know that no one is prepared to believe in a state of things so long as it appears to be unintelligible and to offer no angle from which an explanation can be attempted. But we can at least bring the underlying factors nearer to our understanding by the help of the postulates I laid down in my *Three Essays on the Theory of Sexuality* in 1905. I there attempted to show that the sexual instinct of man is highly complex and is put together from contributions made by numerous constituents and component instincts. Important contributions to 'sexual excitation' are furnished by the peripheral excitations of certain specially designated parts of the body (the genitals, mouth, anus, urethra), which therefore deserve to be described as 'erotogenic zones'. But the amounts of excitation coming in from these parts of the body do not all undergo the same vicissitudes, nor is the fate of all of them the same at every period of life. Generally speaking, only a part of them is made use of in sexual life; another part is deflected from sexual aims and directed towards others - a process which deserves the name of 'sublimation'. During the period of life which may be called the period of 'sexual latency' - i.e. from the completion of the fifth year to the first manifestations of puberty (round about the eleventh year) - reaction-formations, or counter-forces, such as shame, disgust and morality, are created in the mind. They are actually formed at the expense of the excitations proceeding from the erotogenic zones, and they rise like dams to oppose the later activity of the sexual instincts. Now anal erotism is one of the components of the instinct which, in the course of development and in accordance with the education demanded by our present civilization, have become unserviceable for sexual aims. It is therefore plausible to suppose that these character-traits of orderliness, parsimony and obstinacy, which are so often prominent in people who were formerly anal erotics, are to be regarded as the first and most constant results of the sublimation of anal erotism.²

[1908b, 1943]

Yet another circumstance facilitates this equation in neurotic thought. The original erotic interest in defaecation is, as we know, destined to be extinguished in later years. In those years the interest in money makes its appearance as a new interest which had been absent in childhood. This makes it easier for the earlier impulsion, which is in process of losing its aim, to be carried over to the newly emerging aim.

[1908b, 1945]

Further prospects are opened up when we take into consideration the fact that in man the sexual instinct does not originally serve the purposes of reproduction at all, but has as its aim the gaining of particular kinds of pleasure.¹ It manifests itself in this way in human infancy, during which it attains its aim of gaining pleasure not only from the genitals but from other parts of the body (the erotogenic zones), and can therefore disregard any objects other than these convenient ones. We call this stage the stage of *auto-erotism*, and the child's upbringing has, in our view, the task of restricting it, because to linger in it would make the sexual instinct uncontrollable and unserviceable later on. The development of the sexual instinct then proceeds from auto-erotism to object-love and from the autonomy of the erotogenic zones to their subordination under the primacy of the genitals, which are put at the service of reproduction. During this development a part of the sexual excitation which is provided by the subject's own body is inhibited as being unserviceable for the reproductive function and in favourable cases is brought to sublimation. The forces that can be employed for cultural activities are thus to a great extent obtained through the suppression of what are known as the *perverse* elements of sexual excitation.

[1908d, 1953]
These considerations have been based so far on the requirement laid down by the second of the stages of civilization which we have postulated, the requirement that every sexual activity of the kind described as perverse is prohibited, while what is called normal sexual intercourse is freely permitted. We have found that even when the line between sexual freedom and restriction is drawn at this point, a number of individuals are ruled out as perverts, and a number of others, who make efforts not to be perverts whilst constitutionally they should be so, are forced into nervous illness. It is easy to predict the result that will follow if sexual freedom is still further circumscribed and the requirements of civilization are raised to the level of the third stage, which bans all sexual activity outside legal marriage. The number of strong natures who openly oppose the demands of civilization will increase enormously, and so will the number of weaker ones who, faced with the conflict between the pressure of cultural influences and the resistance of their constitution, take flight into neurotic illness.
[1908d, 1955]

Before I can regard this synthesis as completed I must turn to yet another aspect of the case, which will take us into the very heart of the difficulties that lie in the way of our understanding of neurotic states. We have seen how our little patient was overtaken by a great wave of repression and that it caught precisely those of his sexual components that were dominant.¹ He gave up masturbation, and turned away in disgust from everything that reminded him of excrement and of looking on at other people performing their natural functions. But these were not the components which were stirred up by the precipitating cause of the illness (his seeing the horse fall down) or which provided the material for the symptoms, that is, the content of the phobia.
[1909b, 2117]
Furthermore, let me say in Hans's favour (and I frankly admit my partisan attitude) that he is not the only child who has been overtaken by a phobia at some time or other in his childhood. Troubles of that kind are well known to be quite extraordinarily frequent, even in children the strictness of whose upbringing has left nothing to be desired. In later life these children either become neurotic or remain healthy. Their phobias are shouted down in the nursery because they are inaccessible to treatment and are decidedly inconvenient. In the course of months or years they diminish, and the child seems to recover; but no one can tell what psychological changes are necessitated by such a recovery, or what alterations in character are involved in it. When, however, an adult neurotic patient comes to us for psycho-analytic treatment (and let us assume that his illness has only become manifest after he has reached maturity), we find regularly that his neurosis has as its point of departure an infantile anxiety such as we have been discussing, and is in fact a continuation of it; so that, as it were, a continuous and undisturbed thread of psychological activity, taking its start from the conflicts of his childhood, has been spun through his life - irrespective of whether the first symptom of those conflicts has persisted or has retreated under the pressure of circumstances. I think, therefore, that Hans's illness may perhaps have been no more serious than that of many other children who are not branded as 'degenerates'; but since he was brought up without being intimidated, and with as much consideration and as little coercion as possible, his anxiety dared to show itself more boldly. With him there was no place for such motives as a bad conscience or a fear of punishment, which with other children must no doubt contribute to making the anxiety less. It seems to me that we concentrate too much upon symptoms and concern ourselves too little with their causes. In bringing up children we aim only at being left in peace and having no difficulties, in short, at training up a model child, and we pay very little attention to whether such a course of development is for the child's good as well. I can therefore quite imagine that it may have been to Hans's advantage to have produced this phobia. For it directed his parents' attention to the unavoidable difficulties by which a child is confronted when in the course of his cultural training he is called upon to overcome the innate instinctual components of his mind; and his trouble brought his father to his assistance. It may be that Hans now enjoys an advantage over other children, in that he no longer carries within him that seed in the shape of repressed complexes which must always be of some significance for a child's later life, and which undoubtedly brings with it a certain degree of deformity of character if not a predisposition to a subsequent neurosis. I am inclined to think that this is so, but I do not know if many others will share my opinion; nor do I know whether experience will prove me right.

[1909b, 2120]

It is inevitable and perfectly normal that a child should take his parents as the first objects of his love. But his libido should not remain fixated to these first objects; later on, it should merely take them as a model, and should make a gradual transition from them on to extraneous people when the time for the final choice of an object arrives. The detachment of the child from his parents is thus a task that cannot be evaded if the young individual's social fitness is not to be endangered. During the time at which repression is making its selection among the component instincts, and later, when there should be a slackening of the parents' influence, which is essentially responsible for the expenditure of energy on these repressions, the task of education meets with great problems, which at the present time are certainly not always dealt with in an understanding and unobjectionable manner.

[1910a, 2233]
We must expressly insist that we have never reckoned Leonardo as a neurotic or a 'nerve case', as the awkward phrase goes. Anyone who protests at our so much as daring to examine him in the light of discoveries gained in the field of pathology is still clinging to prejudices which we have to-day rightly abandoned. We no longer think that health and illness, normal and neurotic people, are to be sharply distinguished from each other, and that neurotic traits must necessarily be taken as proofs of a general inferiority. To-day we know that neurotic symptoms are structures which are substitutes for certain achievements of repression that we have to carry out in the course of our development from a child to a civilized human being. We know too that we all produce such substitutive structures, and that it is only their number, intensity and distribution which justify us in using the practical concept of illness and in inferring the presence of constitutional inferiority. From the slight indications we have about Leonardo's personality we should be inclined to place him close to the type of neurotic that we describe as 'obsessional'; and we may compare his researches to the 'obsessive brooding' of neurotics, and his inhibitions to what are known as their 'abulia'.
[1910c, 2300]

A powerful wave of repression brought this childhood excess to an end, and established the dispositions which were to become manifest in the years of puberty. The most obvious result of the transformation was the avoidance of every crudely sensual activity; Leonardo was enabled to live in abstinence and to give the impression of being an asexual human being. When the excitations of puberty came in their flood upon the boy they did not, however, make him ill by forcing him to develop substitutive structures of a costly and harmful kind. Owing to his very early inclination towards sexual curiosity the greater portion of the needs of his sexual instinct could be sublimated into a general urge to know, and thus evaded repression. A much smaller portion of his libido continued to be devoted to sexual aims and represented a stunted adult sexual life. Because his love for his mother had been repressed, this portion was driven to take up a homosexual attitude and manifested itself in ideal love for boys. The fixation on his mother and on the blissful memories of his relations with her continued to be preserved in the unconscious, but for the time being it remained in an inactive state. In this way repression, fixation and sublimation all played their part in disposing of the contributions which the sexual instinct made to Leonardo's mental life.
[1910c, 2301]

Secondly, we know that the sexual instinct is originally divided into a great number of components - or rather, it develops out of them - some of which cannot be taken up into the instinct in its later form, but have at an earlier stage to be suppressed or put to other uses. These are above all the coprophilic instinctual components, which have proved incompatible with our aesthetic standards of culture, probably since, as a result of our adopting an erect gait, we raised our organ of smell from the ground. The same is true of a large portion of the sadistic urges which are a part of erotic life. But all such developmental processes affect only the upper layers of the complex structure. The fundamental processes which produce erotic excitation remain unaltered. The excremental is all too intimately and inseparably bound up with the sexual; the position of the genitals - inter uninas et faeces - remains the decisive and unchangeable factor. One might say here, varying a well-known saying of the great Napoleon: 'Anatomy is destiny.' The genitals themselves have not taken part in the development of the human body in the direction of beauty: they have remained animal, and thus love, too, has remained in essence just as animal as it ever was. The instincts of love are hard to educate; education of them achieves now too much, now too little. What civilization aims at making out of them seems unattainable except at the price of a sensible loss of pleasure; the persistence of the impulses that could not be made use of can be detected in sexual activity in the form of non-satisfaction.
[1912d, 2346]
If, then, as we have learnt, psychogenic disturbances of vision depend on certain ideas connected with seeing being cut off from consciousness, we must, on the psycho-analytic view, assume that these ideas have come into opposition to other, more powerful ones, for which we use the collective concept of the 'ego'- a compound which is made up variously at different times - and have for that reason come under repression. But what can be the origin of this opposition, which makes for repression, between the ego and various groups of ideas? You will no doubt notice that it was not possible to frame such a question before the advent of psycho-analysis, for nothing was known earlier of psychical conflict and repression. Our researches, however, have put us in a position to give us the desired answer. Our attention has been drawn to the importance of the instincts in ideational life. We have discovered that every instinct tries to make itself effective by activating ideas that are in keeping with its aims. These instincts are not always compatible with one another; their interests often come into conflict. Opposition between ideas is only an expression of struggles between the various instincts. From the point of view of our attempted explanation, a quite specially important part is played by the undeniable opposition between the instincts which subserve sexuality, the attainment of sexual pleasure, and those other instincts, which have as their aim the self-preservation of the individual - the ego-instincts. As the poet has said, all the organic instincts that operate in our mind may be classified as 'hunger' or 'love'. We have traced the 'sexual instinct' from its first manifestations in children to its final form, which is described as 'normal'. We have found that it is put together from numerous 'component instincts' which are attached to excitations of regions of the body; and we have come to see that these separate instincts have to pass through a complicated development before they can be brought effectively to serve the aims of reproduction. The light thrown by psychology on the evolution of our civilization has shown us that it originates mainly at the cost of the sexual component instincts, and that these must be suppressed, restricted, transformed and directed to higher aims, in order that the mental constructions of civilization may be established. We have been able to recognize as a valuable outcome of these researches something that our colleagues have not yet been willing to believe, namely that the human ailments known as 'neuroses' are derived from the many different ways in which these processes of transformation in the sexual component instincts may miscarry. The 'ego' feels threatened by the claims of the sexual instincts and fends them off by repressions; these, however, do not always have the desired result, but lead to the formation of dangerous substitutes for the repressed and to burdensome reactions on the part of the ego. From these two classes of phenomena taken together there emerge what we call the symptoms of neuroses.

[1910i, 2368]
Nevertheless, psycho-analysis and folklore have not allowed themselves to be deterred from transgressing these prohibitions and have been able as a result to teach us all kinds of things that are indispensable for an understanding of human nature. If we limit ourselves here to what has been learnt about the excretory functions, it may be said that the chief finding from psycho-analytic research has been the fact that the human infant is obliged to recapitulate during the early part of his development the changes in the attitude of the human race towards excremental matters which probably had their start when *homo sapiens* first raised himself off Mother Earth. In the earliest years of infancy there is as yet no trace of shame about the excretory functions or of disgust at excreta. Small children show great interest in these, just as they do in others of their bodily secretions; they like occupying themselves with them and can derive many kinds of pleasure from doing so. Excreta, regarded as parts of a child's own body and as products of his own organism, have a share in the esteem - the narcissistic esteem, as we should call it - with which he regards everything relating to his self. Children are, indeed, proud of their own excretions and make use of them to help in asserting themselves against adults. Under the influence of its upbringing, the child's coprophilic instincts and inclinations gradually succumb to repression; it learns to keep them secret, to be ashamed of them and to feel disgust at their objects. Strictly speaking, however, the disgust never goes so far as to apply to a child's own excretions, but is content with repudiating them when they are the products of other people. The interest which has hitherto been attached to excrement is carried over on to other objects - for instance, from faeces on to money, which is, of course, late in acquiring significance for children. Important constituents in the formation of character are developed, or strengthened, from the repression of coprophilic inclinations.

If we examine sexuality in the adult with the help of psycho-analysis, and consider the life of children in the light of the knowledge thus gained, we perceive that sexuality is not merely a function serving the purposes of reproduction, on a par with digestion, respiration, etc. It is something far more independent, which stands in contrast to all the individual's other activities and is only forced into an alliance with the individual's economy after a complicated course of development involving the imposition of numerous restrictions. Cases, theoretically quite conceivable, in which the interests of these sexual impulses fail to coincide with the self-preservation of the individual seem actually to be presented by the group of neurotic illnesses. For the final formula which psycho-analysis has arrived at on the nature of the neuroses runs thus: The primal conflict which leads to neuroses is one between the sexual instincts and those which maintain the ego. The neuroses represent a more or less partial overpowering of the ego by sexuality after the ego's attempts at suppressing sexuality have failed.

[1913k, 2640]

If we examine sexuality in the adult with the help of psycho-analysis, and consider the life of children in the light of the knowledge thus gained, we perceive that sexuality is not merely a function serving the purposes of reproduction, on a par with digestion, respiration, etc. It is something far more independent, which stands in contrast to all the individual's other activities and is only forced into an alliance with the individual's economy after a complicated course of development involving the imposition of numerous restrictions. Cases, theoretically quite conceivable, in which the interests of these sexual impulses fail to coincide with the self-preservation of the individual seem actually to be presented by the group of neurotic illnesses. For the final formula which psycho-analysis has arrived at on the nature of the neuroses runs thus: The primal conflict which leads to neuroses is one between the sexual instincts and those which maintain the ego. The neuroses represent a more or less partial overpowering of the ego by sexuality after the ego's attempts at suppressing sexuality have failed.

[1913j, 2817]
When educators have become familiar with the findings of psycho-analysis, it will be easier for them to reconcile themselves to certain phases of infantile development and they will, among other things, not be in danger of over-estimating the importance of the socially unserviceable or perverse instincual impulses which emerge in children. On the contrary they will refrain from any attempt at forcibly suppressing such impulses, when they learn that efforts of this kind often produce no less undesirable results than the alternative, which is so much dreaded by educators, of giving free play to children's naughtiness. The forcible suppression of strong instincts by external means never has the effect in a child of these instincts being extinguished or brought under control; it leads to repression, which establishes a predisposition to later nervous illness. Psycho-analysis has frequent opportunities of observing the part played by inopportune and undiscerning severity of upbringing in the production of neuroses, or the price, in loss of efficiency and of capacity for enjoyment, which has to be paid for the normality upon which the educator insists. And psycho-analysis can also show what precious contributions to the formation of character are made by these asocial and perverse instincts in the child, if they are not subjected to repression but are diverted from their original aims to more valuable ones by the process known as 'sublimation'. Our highest virtues have grown up, as reaction formations and sublimations, out of our worst dispositions. Education should scrupulously refrain from burying these precious springs of action and should restrict itself to encouraging the processes by which these energies are led along safe paths. Whatever we can expect in the way of prophylaxis against neurosis in the individual lies in the hands of a psycho-analytically enlightened education.¹

The revolutionary discoveries of psycho-analysis in regard to the mental life of children - the part played in it by sexual impulses (von Hug-Hellmuth), and the fate of those components of sexuality which become unserviceable in the function of reproduction - were bound early to direct attention to education and to stimulate an attempt to bring analytic points of view into the foreground in that field of work. Recognition is due to Dr. Pfister for having, with sincere enthusiasm, initiated the application of psycho-analysis in this direction and brought it to the notice of ministers of religion and those concerned with education. (Cf. The Psycho-Analytic Method, 1913.) He has succeeded in gaining the sympathy and participation of a number of Swiss teachers in this. Other members of his profession are said to share his views but to have preferred nevertheless to remain cautiously in the background. In their retreat from psycho-analysis, a section of Vienna analysts seem to have arrived at a kind of combination of medicine and education.¹

The content of the Ucs. may be compared with an aboriginal population in the mind. If inherited mental formations exist in the human being - something analogous to instinct¹ in animals - these constitute the nucleus of the Ucs. Later there is added to them what is discarded during childhood development as unserviceable; and this need not differ in its nature from what is inherited. A sharp and final division between the content of the two systems does not, as a rule, take place till puberty.

¹ [1913], 2825

¹ [1914d, 2903]

¹ [1915e, 3017]
The transformation of 'bad' instincts is brought about by two factors working in the same direction, an internal and an external one. The internal factor consists in the influence exercised on the bad (let us say, the egoistic) instincts by erotism - that is, by the human need for love, taken in its widest sense. By the admixture of erotic components the egoistic instincts are transformed into social ones. We learn to value being loved as an advantage for which we are willing to sacrifice other advantages. The external factor is the force exercised by upbringing, which represents the claims of our cultural environment, and this is continued later by the direct pressure of that environment. Civilization has been attained through the renunciation of instinctual satisfaction, and it demands the same renunciation from each newcomer in turn. Throughout an individual's life there is a constant replacement of external by internal compulsion. The influences of civilization cause an ever-increasing transformation of egoistic trends into altruistic and social ones by an admixture of erotic elements. In the last resort it may be assumed that every internal compulsion which makes itself felt in the development of human beings was originally - that is, in the history of mankind - only an external one. Those who are born to-day bring with them as an inherited organization some degree of tendency (disposition) towards the transformation of egoistic into social instincts, and this disposition is easily stimulated into bringing about that result. A further portion of this instinctual transformation has to be accomplished during the life of the individual himself. So the human being is subject not only to the pressure of his immediate cultural environment, but also to the influence of the cultural history of his ancestors.

[1915b, 3074]

To-day we will follow yet another side of this development namely the relation of the component sexual instincts to their object. Or rather, we will make a hasty survey of this development and dwell somewhat longer on one of its rather late consequences. A few of the components of the sexual instinct, there, have an object from the first and hold fast to it - for instance, the instinct for mastery (sadism) and the scopophilic and epistemophilic instincts. Others, more definitely linked to particular erotogenic zones of the body, have one to begin with only so long as they are still attached to the non-sexual functions, and give it up when they become separated from them. Thus the first object of the oral component of the sexual instinct is the mother's breast which satisfies the infant's need for nourishment. The erotic component, which is satisfied simultaneously during the sucking, makes itself independent with the act of sensual sucking [lutschen]; it gives up the outside object and replaces it by an area of the subject's own body. The oral instinct becomes auto-erotic, as are the anal and other erotogenic instincts from the first. Further development, to put the matter as concisely as possible, has two aims: firstly, the abandonment of auto-erotism, the replacement of the subject's own body once more by an outside object, and secondly, the unification of the various objects of the separate instincts and their replacement by a single object. This can, of course, only be achieved if the object is again a whole body, similar to the subject's own. Nor can it be effected unless a number of the auto-erotic instinctual impulses are left behind as being unserviceable.

[1916-1917, 3396]
The things I have just been discussing, Gentlemen, compel me to enter more closely into the origin and significance of the mental activity which is described as ‘phantasy’. As you are aware, it enjoys a universally high reputation, without its position in mental life having become clear. I have the following remarks to make about it. The human ego is, as you know, slowly educated by the pressure of external necessity to appreciate reality and obey the reality principle; in the course of this process it is obliged to renounce, temporarily or permanently, a variety of the objects and aims at which its striving for pleasure, and not only for sexual pleasure, is directed. But men have always found it hard to renounce pleasure; they cannot bring themselves to do it without some kind of compensation. They have therefore retained a mental activity in which all these abandoned sources of pleasure and methods of achieving pleasure are granted a further existence - a form of existence in which they are left free from the claims of reality and of what we call ‘reality-testing’. Every desire takes before long the form of picturing its own fulfilment; there is no doubt that dwelling upon imaginary wish-fulfilments brings satisfaction with it, although it does not interfere with a knowledge that what is concerned is not real. Thus in the activity of phantasy human beings continue to enjoy the freedom from external compulsion which they have long since renounced in reality. They have contrived to alternate between remaining an animal of pleasure and being once more a creature of reason. Indeed, they cannot subsist on the scanty satisfaction which they can extort from reality. ‘We cannot do without auxiliary constructions’, as Theodor Fontane once said. The creation of the mental realm of phantasy finds a perfect parallel in the establishment of ‘reservations’ or ‘nature reserves’ in places where the requirements of agriculture, communications and industry threaten to bring about changes in the original face of the earth which will quickly make it unrecognizable. A nature reserve preserves its original state which everywhere else has to our regret been sacrificed to necessity. Everything, including what is useless and even what is noxious, can grow and proliferate there as it pleases. The mental realm of phantasy is just such a reservation withdrawn from the reality principle.

[1916-1917, 3427]
For a time psycho-analysis seemed fated to merge into psychology without being able to show why the psychology of the sick differed from that of the normal. In the course of its advance, however, it came up against the problem of dreams, which are abnormal products of the mind created by normal men under regularly recurrent physiological conditions. When psycho-analysis had solved the problem of dreams, it had discovered in *unconscious* psychical processes the common ground in which the highest and the lowest of mental impulses have their roots and from which spring the most normal as well as the most morbid and erratic of mental productions. The new picture of the workings of the mind began to grow ever clearer and more complete. It was a picture of obscure instinctual forces organic in origin, striving towards inborn aims, and, above them, of an agency comprising more highly organized mental structures - acquisitions of human evolution made under the impact of human history -, an agency which has taken over portions of the instinctual impulses, has developed them further or has even directed them towards higher aims, but which in any case binds them firmly and manipulates their energy to suit its own purposes. This higher organization, however, which is known to us as the ego, has rejected another portion of these same elementary instinctual impulses as being unserviceable because they cannot be fitted into the organic unity of the individual or because they rebel against the individual's cultural aims. The ego is not in a position to exterminate these unsubdued mental powers, but it turns its back on them, lets them remain at the lowest psychological level, defends itself from their demands by the energetic erection of protective and antithetical barriers or seeks to come to terms with them by means of substitutive satisfactions. These instincts which have fallen victim to repression - untamed and indestructible, yet inhibited from any kind of activity - together with their primitive mental representatives, constitute the mental underworld, the nucleus of the true unconscious, and are at every moment ready to assert their demands and, by hook or by crook, to force their way forward to satisfaction. To this is due the instability of the proud superstructure of the mind, the emergence at night of the proscribed and repressed material in the form of dreams, and the tendency to fall ill with neuroses and psychoses as soon as the balance of power between the ego and the repressed shifts to the disadvantage of the ego.

[1919g, 3703]

There can be no doubt, however, that the replacement of the pleasure principle by the reality principle can only be made responsible for a small number, and by no means the most intense, of unpleasurable experiences. Another occasion of the release of unpleasure, which occurs with no less regularity, is to be found in the conflicts and dissensions that take place in the mental apparatus while the ego is passing through its development into more highly composite organizations. Almost all the energy with which the apparatus is filled arises from its innate instinctual impulses. But these are not all allowed to reach the same phases of development. In the course of things it happens again and again that individual instincts or parts of instincts turn out to be incompatible in their aims or demands with the remaining ones, which are able to combine into the inclusive unity of the ego. The former are then split off from this unity by the process of repression, held back at lower levels of psychical development and cut off, to begin with, from the possibility of satisfaction. If they succeed subsequently, as can so easily happen with repressed sexual instincts, in struggling through, by roundabout paths, to a direct or to a substitutive satisfaction, that event, which would in other cases have been an opportunity for pleasure, is felt by the ego as unpleasure. As a consequence of the old conflict which ended in repression, a new breach has occurred in the pleasure principle at the very time when certain instincts were endeavouring, in accordance with the principle, to obtain fresh pleasure. The details of the process by which repression turns a possibility of pleasure into a source of unpleasure are not yet clearly understood or cannot be clearly represented; but there is no doubt that all neurotic unpleasure is of that kind - pleasure that cannot be felt as such.¹

[1920g, 3717]
The Process of Finding an Object, and the Oedipus Complex. - In the first instance the oral component instinct finds satisfaction by attaching itself to the satiating of the desire for nourishment; and its object is the mother's breast. It then detaches itself, becomes independent and at the same time auto-erotic, that is, it finds an object in the child's own body. Others of the component instincts also start by being auto-erotic and are not until later diverted on to an external object. It is a particularly important fact that the component instincts belonging to the genital zone habitually pass through a period of intense auto-erotic satisfaction. The component instincts are not all equally serviceable in the final genital organization of libido; some of them (for instance, the anal components) are consequently left aside and suppressed, or undergo complicated transformations.

[1923a, 3922]

The sexual function, as I found, is in existence from the very beginning of the individual's life, though at first it is attached to the other vital functions and does not become independent of them until later; it has to pass through a long and complicated process of development before it becomes what we are familiar with as the normal sexual life of the adult. It begins by manifesting itself in the activity of a whole number of component instincts. These are dependent upon erotogenic zones in the body; some of them make their appearance in pairs of opposite impulses (such as sadism and masochism or the impulses to look and to be looked at); they operate independently of one another in a search for pleasure, and they find their object for the most part in the subject's own body. Thus at first the sexual function is non-centralized and predominantly auto-erotic. Later, syntheses begin to appear in it; a first stage of organization is reached under the dominance of the oral components, an anal-sadistic stage follows, and it is only after the third stage has at last been reached that the primacy of the genitals is established and that the sexual function begins to serve the ends of reproduction. In the course of this process of development a number of elements of the various component instincts turn out to be unserviceable for this last end and are therefore left on one side or turned to other uses, while others are diverted from their aims and carried over into the genital organization. I gave the name of libido to the energy of the sexual instincts and to that form of energy alone. I was next driven to suppose that the libido does not always pass through its prescribed course of development smoothly. As a result either of the excessive strength of certain of the components or of experiences involving premature satisfaction, fixations of the libido may occur at various points in the course of its development. If subsequently a repression takes place, the libido flows back to these points (a process described as regression), and it is from them that the energy breaks through in the form of a symptom. Later on it further became clear that the localization of the point of fixation is what determines the choice of neurosis, that is, the form in which the subsequent illness makes its appearance.

[1925d, 4211]
The sexual life of children is of course different from that of adults. The sexual function, from its beginnings to the definitive form in which it is so familiar to us, undergoes a complicated process of development. It grows together from numerous component instincts with different aims and passes through several phases of organization till at last it comes into the service of reproduction. Not all the component instincts are equally serviceable for the final outcome; they must be diverted, remodelled and in part suppressed. Such a far-reaching course of development is not always passed through without a flaw; inhibitions in development take place, partial fixations at early stages of development. If obstacles arise later on to the exercise of the sexual function, the sexual urge - the libido, as we call it - is apt to hark back to these earlier points of fixation. The study of the sexuality of children and its transformations up to maturity has also given us the key to an understanding of what are known as the sexual perversions, which people used always to describe with all the requisite indications of disgust but whose origin they were never able to explain. The whole topic is of uncommon interest, but for the purposes of our conversation there is not much sense in telling you more about it. To find one's way about in it one of course needs anatomical and physiological knowledge, all of which is Unfortunately not to be acquired in medical schools. But a familiarity with the history of civilization and with mythology is equally indispensable.

We now observe that the store of religious ideas includes not only wish-fulfillments but important historical recollections. This concurrent influence of past and present must give religion a truly incomparable wealth of power. But perhaps with the help of an analogy yet another discovery may begin to dawn on us. Though it is not a good plan to transplant ideas far from the soil in which they grew up, yet here is a conformity which we cannot avoid pointing out. We know that a human child cannot successfully complete its development to the civilized stage without passing through a phase of neurosis sometimes of greater and sometimes of less distinctness. This is because so many instinctual demands which will later be unserviceable cannot be suppressed by the rational operation of the child's intellect but have to be tamed by acts of repression, behind which, as a rule, lies the motive of anxiety. Most of these infantile neuroses are overcome spontaneously in the course of growing up, and this is especially true of the obsessional neuroses of childhood. The remainder can be cleared up later still by psychoanalytic treatment. In just the same way, one might assume, humanity as a whole, in its development through the ages, fell into states analogous to the neuroses, and for the same reasons - namely because in the times of its ignorance and intellectual weakness the instinctual renunciations indispensable for man's communal existence had only been achieved by it by means of purely affective forces. The precipitates of these processes resembling repression which took place in prehistoric times still remained attached to civilization for long periods. Religion would thus be the universal obsessional neurosis of humanity; like the obsessional neurosis of children, it arose out of the Oedipus complex, out of the relation to the father. If this view is right, it is to be supposed that a turning-away from religion is bound to occur with the fatal inevitability of a process of growth, and that we find ourselves at this very juncture in the middle of that phase of development. Our behaviour should therefore be modelled on that of a sensible teacher who does not oppose an impending new development but seeks to ease its path and mitigate the violence of its irruption. Our analogy does not, to be sure, exhaust the essential nature of religion. If, on the one hand, religion brings with it obsessional restrictions, exactly as an individual obsessional neurosis does, on the other hand it comprises a system of wishful illusions together with a disavowal of reality, such as we find in an isolated form nowhere else but in amnesia, in a state of blissful hallucinatory confusion. But these are only analogies, by the help of which we endeavour to understand a social phenomenon; the pathology of the individual does not supply us with a fully valid counterpart.

[1926e, 4353]

[1927c, 4452]
By allowing common feeling to be our guide in deciding what features of human life are to be regarded as civilized, we have obtained a clear impression of the general picture of civilization; but it is true that so far we have discovered nothing that is not universally known. At the same time we have been careful not to fall in with the prejudice that civilization is synonymous with perfecting, that it is the road to perfection pre-ordained for men. But now a point of view presents itself which may lead in a different direction. The development of civilization appears to us as a peculiar process which mankind undergoes, and in which several things strike us as familiar. We may characterize this process with reference to the changes which it brings about in the familiar instinctual dispositions of human beings, to satisfy which is, after all, the economic task of our lives. A few of these instincts are used up in such a manner that something appears in their place which, in an individual, we describe as a character-trait. The most remarkable example of such a process is found in the anal erotism of young human beings. Their original interest in the excretory function, its organs and products, is changed in the course of their growth into a group of traits which are familiar to us as parsimony, a sense of order and cleanliness - qualities which, though valuable and welcome in themselves, may be intensified till they become markedly dominant and produce what is called the anal character. How this happens we do not know, but there is no doubt about the correctness of the finding.¹ Now we have seen that order and cleanliness are important requirements of civilization, although their vital necessity is not very apparent, any more than their suitability as sources of enjoyment. At this point we cannot fail to be struck by the similarity between the process of civilization and the libidinal development of the individual. Other instincts are induced to displace the conditions for their satisfaction, to lead them into other paths. In most cases this process coincides with that of the sublimation (of instinctual aims) with which we are familiar, but in some it can be differentiated from it. Sublimation of instinct is an especially conspicuous feature of cultural development; it is what makes it possible for higher psychical activities, scientific, artistic or ideological, to play such an important part in civilized life. If one were to yield to a first impression, one would say that sublimation is a vicissitude which has been forced upon the instincts entirely by civilization. But it would be wiser to reflect upon this a little longer. In the third place, finally, and this seems the most important of all, it is impossible to overlook the extent to which civilization is built up upon a renunciation of instinct, how much it presupposes precisely the non-satisfaction (by suppression, repression or some other means?) of powerful instincts. This 'cultural frustration' dominates the large field of social relationships between human beings. As we already know, it is the cause of the hostility against which all civilizations have to struggle. It will also make severe demands on our scientific work, and we shall have much to explain here. It is not easy to understand how it can become possible to deprive an instinct of satisfaction. Nor is doing so without danger. If the loss is not compensated for economically, one can be certain that serious disorders will ensue.

¹[1930a, 4494]
We find ourselves on firmer ground when we investigate the manner in which the life of the instincts serves the sexual function. Here we have acquired quite definite knowledge, with which you too are already familiar. It is not the case, then, that we recognize a sexual instinct which is from the first the vehicle of an urge towards the aim of the sexual function - the union of the two sex-cells. What we see is a great number of component instincts arising from different areas and regions of the body, which strive for satisfaction fairly independently of one another and find that satisfaction in something that we may call 'organ-pleasure'. The genitals are the latest of these 'erotogenic zones' and the name of 'sexual' pleasure cannot be withheld from their organ-pleasure. These impulses which strive for pleasure are not all taken up into the final organization of the sexual function. A number of them are set aside as unserviceable, by repression or some other means; a few of them are diverted from their aim in the remarkable manner I have mentioned and used to strengthen other impulses; yet others persist in minor roles, and serve for the performance of introductory acts, for the production of fore-pleasure. You have heard how in the course of this long-drawn-out development several phases of preliminary organization can be recognized and also how this history of the sexual function explains its aberrations and atrophies. The first of these 'pregenital' phases is known to us as the oral one because, in conformity with the way in which an infant in arms is nourished, the erotogenic zone of the mouth dominates what may be called the sexual activity of that period of life. At a second level the sadistic and anal impulses come to the fore, undoubtedly in connection with the appearance of the teeth, the strengthening of the muscular apparatus and the control of the sphincter functions. We have learnt a number of interesting details about this remarkable stage of development in particular. Thirdly comes the phallic phase in which in both sexes the male organ (and what corresponds to it in girls) attains an importance which can no longer be overlooked. We have reserved the name of genital phase for the definitive sexual organization which is established after puberty and in which the female genital organ for the first time meets with the recognition which the male one acquired long before.

It would be a mistake to suppose that these three phases succeed one another in a clear-cut fashion. One may appear in addition to another; they may overlap one another, may be present alongside of one another. In the early phases the different component instincts set about their pursuit of pleasure independently of one another; in the phallic phase there are the beginnings of an organization which subordinates the other urges to the primacy of the genitals and signifies the start of a co-ordination of the general urge towards pleasure into the sexual function. The complete organization is only achieved at puberty, in a fourth, genital phase. A state of things is then established in which (1) some earlier libidinal catexes are retained, (2) others are taken into the sexual function as preparatory, auxiliary acts, the satisfaction of which produces what is known as fore-pleasure, and (3) other urges are excluded from the organization, and are either suppressed altogether (repressed) or are employed in the ego in another way, forming character-traits or undergoing sublimation with a displacement of their aims.

[1940a [1938], 4966]
As regards the second kind of emotional reaction, which is not directed against me this time, but against my patient - supposing that my view of her is correct - and which regards the perverse nature of her phantasies as horrible, I should like to say emphatically that a medical man has no business to indulge in such passionate condemnation. I may also remark in passing that it seems to me superfluous for a physician who is writing upon the aberrations of the sexual instincts to seize every opportunity of inserting into the text expressions of his personal repugnance at such revolting things. We are faced by a fact; and it is to be hoped that we shall grow accustomed to it, when we have put our own tastes on one side. We must learn to speak without indignation of what we call the sexual perversions - instances in which the sexual function has extended its limits in respect either to the part of the body concerned or to the sexual object chosen. The uncertainty in regard to the boundaries of what is to be called normal sexual life, when we take different races and different epochs into account, should in itself be enough to cool the zealot's ardour. We surely ought not to forget that the perversion which is the most repellent to us, the sensual love of a man for a man, was not only tolerated by a people so far our superiors in cultivation as were the Greeks, but was actually entrusted by them with important social functions. The sexual life of each one of us extends to a slight degree - now in this direction, now in that - beyond the narrow lines imposed as the standard of normality. The perversions are neither bestial nor degenerate in the emotional sense of the word. They are a development of germs all of which are contained in the undifferentiated sexual disposition of the child, and which, by being suppressed or by being diverted to higher, asexual aims - by being 'sublimated' - are destined to provide the energy for a great number of our cultural achievements. When, therefore, any one has become a gross and manifest pervert, it would be more correct to say that he has remained one, for he exhibits a certain stage of inhibited development. All psychoneurotics are persons with strongly marked perverse tendencies, which have been repressed in the course of their development and have become unconscious. Consequently their unconscious phantasies show precisely the same content as the documentarily recorded actions of perverts - even though they have not read Krafft-Ebing's _Psychopathia Sexualis_, to which simple-minded people attribute such a large share of the responsibility for the production of perverse tendencies. Psychoneuroses are, so to speak, the negative of perversions. In neurotics their sexual constitution, under which the effects of heredity are included, operates in combination with any accidental influences in their life which may disturb the development of normal sexuality. A stream of water which meets with an obstacle in the river-bed is dammed up and flows back into old channels which had formerly seemed fated to run dry. The motive forces leading to the formation of hysterical symptoms draw their strength not only from repressed normal sexuality but also from unconscious perverse activities.¹

[1905e, 1387]

The revolutionary discoveries of psycho-analysis in regard to the mental life of children - the part played in it by sexual impulses (von Hug-Hellmuth), and the fate of those components of sexuality which become unserviceable in the function of reproduction - were bound early to direct attention to education and to stimulate an attempt to bring analytic points of view into the foreground in that field of work. Recognition is due to Dr. Pfister for having, with sincere enthusiasm, initiated the application of psycho-analysis in this direction and brought it to the notice of ministers of religion and those concerned with education. (Cf. _The Psycho-Analytic Method_, 1913.) He has succeeded in gaining the sympathy and participation of a number of Swiss teachers in this. Other members of his profession are said to share his views but to have preferred nevertheless to remain cautiously in the background. In their retreat from psycho-analysis, a section of Vienna analysts seem to have arrived at a kind of combination of medicine and education.¹

[1914d, 2903]
As regards the second kind of emotional reaction, which is not directed against me this time, but against my patient - supposing that my view of her is correct - and which regards the perverse nature of her phantasies as horrible, I should like to say emphatically that a medical man has no business to indulge in such passionate condemnation. I may also remark in passing that it seems to me superfluous for a physician who is writing upon the aberrations of the sexual instincts to seize every opportunity of inserting into the text expressions of his personal repugnance at such revolting things. We are faced by a fact; and it is to be hoped that we shall grow accustomed to it, when we have put our own tastes on one side. We must learn to speak without indignation of what we call the sexual perversions - instances in which the sexual function has extended its limits in respect either to the part of the body concerned or to the sexual object chosen. The uncertainty in regard to the boundaries of what is to be called normal sexual life, when we take different races and different epochs into account, should in itself be enough to cool the zealot's ardour. We surely ought not to forget that the perversion which is the most repellent to us, the sensual love of a man for a man, was not only tolerated by a people so far our superiors in cultivation as were the Greeks, but was actually entrusted by them with important social functions. The sexual life of each one of us extends to a slight degree - now in this direction, now in that - beyond the narrow lines imposed as the standard of normality. The perversions are neither bestial nor degenerate in the emotional sense of the word. They are a development of germs all of which are contained in the undifferentiated sexual disposition of the child, and which, by being suppressed or by being diverted to higher, asexual aims - by being 'sublimated' - are destined to provide the energy for a great number of our cultural achievements. When, therefore, any one has become a gross and manifest pervert, it would be more correct to say that he has remained one, for he exhibits a certain stage of inhibited development. All psychoneurotics are persons with strongly marked perverse tendencies, which have been repressed in the course of their development and have become unconscious. Consequently their unconscious phantasies show precisely the same content as the documentarily recorded actions of perverts - even though they have not read Krafft-Ebing's Psychopathia Sexualis, to which simple-minded people attribute such a large share of the responsibility for the production of perverse tendencies. Psychoneuroses are, so to speak, the negative of perversions. In neurotics their sexual constitution, under which the effects of heredity are included, operates in combination with any accidental influences in their life which may disturb the development of normal sexuality. A stream of water which meets with an obstacle in the river-bed is dammed up and flows back into old channels which had formerly seemed fated to run dry. The motive forces leading to the formation of hysterical symptoms draw their strength not only from repressed normal sexuality but also from unconscious perverse activities.¹

[1905e, 1387]
The same holds true of seeing - an activity that is ultimately derived from touching. Visual impressions remain the most frequent pathway along which libidinal excitation is aroused; indeed, natural selection counts upon the accessibility of this pathway - if such a teleological form of statement is permissible - when it encourages the development of beauty in the sexual object. The progressive concealment of the body which goes along with civilization keeps sexual curiosity awake. This curiosity seeks to complete the sexual object by revealing its hidden parts. It can, however, be diverted ('sublimated') in the direction of art, if its interest can be shifted away from the genitals on to the shape of the body as a whole.¹ It is usual for most normal people to linger to some extent over the intermediate sexual aim of a looking that has a sexual tinge to it; indeed, this offers them a possibility of directing some proportion of their libido on to higher artistic aims. On the other hand, this pleasure in looking becomes a perversion (a) if it is restricted exclusively to the genitals, or (b) if it is connected with the overriding of disgust (as in the case of *voyeurs* or people who look on at excretory functions), or (c) if, instead of being preparatory to the normal sexual aim, it supplants it. This last is markedly true of exhibitionists, who, if I may trust the findings of several analyses, exhibit their own genitals in order to obtain a reciprocal view of the genitals of the other person.²

[1905d, 1483]

**REACTION-FORMATION AND SUBLIMATION** What is it that goes to the making of these constructions which are so important for the growth of a civilized and normal individual? They probably emerge at the cost of the infantile sexual impulses themselves. Thus the activity of those impulses does not cease even during this period of latency, though their energy is diverted, wholly or in great part, from their sexual use and directed to other ends. Historians of civilization appear to be at one in assuming that powerful components are acquired for every kind of cultural achievement by this diversion of sexual instinctual forces from sexual aims and their direction to new ones - a process which deserves the name of 'sublimation'. To this we would add, accordingly, that the same process plays a part in the development of the individual and we would place its beginning in the period of sexual latency of childhood.¹

[1905d, 1500]

The same pathways, however, along which sexual disturbances trench upon the other somatic functions must also perform another important function in normal health. They must serve as paths for the attraction of sexual instinctual forces to aims that are other than sexual, that is to say, for the sublimation of sexuality. But we must end with a confession that very little is as yet known with certainty of these pathways, though they certainly exist and can probably be traversed in both directions.

[1905d, 1523]
The time has arrived for me to attempt to summarize what I have said. We started out from the aberrations of the sexual instinct in respect of its object and of its aim and we were faced by the question of whether these arise from an innate disposition or are acquired as a result of experiences in life. We arrived at an answer to this question from an understanding, derived from psycho-analytic investigation, of the workings of the sexual instinct in psychoneurotics, a numerous class of people and one not far removed from the healthy. We found that in them tendencies to every kind of perversion can be shown to exist as unconscious forces and betray their presence as factors leading to the formation of symptoms. It was thus possible to say that neurosis is, as it were, the negative of perversion. In view of what was now seen to be the wide dissemination of tendencies to perversion we were driven to the conclusion that a disposition to perversions is an original and universal disposition of the human sexual instinct and that normal sexual behaviour is developed out of it as a result of organic changes and psychical inhibitions occurring in the course of maturation; we hoped to be able to show the presence of this original disposition in childhood. Among the forces restricting the direction taken by the sexual instinct we laid emphasis upon shame, disgust, pity and the structures of morality and authority erected by society. We were thus led to regard any established aberration from normal sexuality as an instance of developmental inhibition and infantilism. Though it was necessary to place in the foreground the importance of the variations in the original disposition, a co-operative and not an opposing relation was to be assumed as existing between them and the influences of actual life. It appeared, on the other hand, that since the original disposition is necessarily a complex one, the sexual instinct itself must be something put together from various factors, and that in the perversions it falls apart, as it were, into its components. The perversions were thus seen to be on the one hand inhibitions, and on the other hand dissociations, of normal development. Both these aspects were brought together in the supposition that the sexual instinct of adults arises from a combination of a number of impulses of childhood into a unity, an impulsion with a single aim.

[1905d, 1542]

FURTHER MODIFICATION On the other hand, it is not possible to adopt the view that the form to be taken by sexual life is unambiguously decided, once and for all, with the inception of the different components of the sexual constitution. On the contrary, the determining process continues, and further possibilities arise according to the vicissitudes of the tributary streams of sexuality springing from their separate sources. This further modification is clearly what brings the decisive outcome, and constitutions which might be described as the same can lead to three different final results :-

[1905d, 1547]
REPRESSION  A different result is brought about if in the course of development some of the components which are of excessive strength in the disposition are submitted to the process of repression (which, it must be insisted, is not equivalent to their being abolished). If this happens, the excitations concerned continue to be generated as before; but they are prevented by psychical obstruction from attaining their aim and are diverted into numerous other channels till they find their way to expression as symptoms. The outcome may be an approximately normal sexual life - though usually a restricted one - but there is in addition psychoneurotic illness. These particular cases have become familiar to us from the psychoanalytic investigation of neurotics. Their sexual life begins like that of perverts, and a considerable part of their childhood is occupied with perverse sexual activity which occasionally extends far into maturity. A reversal due to repression then occurs, owing to internal causes (usually before puberty, but now and then even long afterwards), and from that time onwards neurosis takes the place of perversion, without the old impulses being extinguished. We are reminded of the proverb ‘Junge Hure, alte Betschwester’, only that here youth has lasted all too short a time. The fact that perversion can be replaced by neurosis in the life of the same person, like the fact which we have already mentioned that perversion and neurosis can be distributed among different members of the same family, tallies with the view that neurosis is the negative of perversion.

[1905d, 1548]

SUBLIMATION  The third alternative result of an abnormal constitutional disposition is made possible by the process of sublimation. This enables excessively strong excitations arising from particular sources of sexuality to find an outlet and use in other fields, so that a not inconsiderable increase in psychical efficiency results from a disposition which is itself perilous. Here we have one of the origins of artistic activity; and, according to the completeness or incompleteness of the sublimation, a characterological analysis of a highly gifted individual, and in particular of one with an artistic disposition, may reveal a mixture, in every proportion, of efficiency, perversion and neurosis. A sub-species of sublimation is to be found in supression by reaction-formation, which, as we have seen, begins during a child's period of latency and continues in favourable cases throughout his whole life. What we describe as a person's 'character' is built up to a considerable extent from the material of sexual excitations and is composed of instincts that have been fixed since childhood, of constructions achieved by means of sublimation, and of other constructions, employed for effectively holding in check perverse impulses which have been recognized as being unutilizable.¹ The multifariously perverse sexual disposition of childhood can accordingly be regarded as the source of a number of our virtues, in so far as through reaction-formation it stimulates their development.²

[1905d, 1549]
I could not further elucidate this part of my theory without a detailed discussion of my views on repression. It will be enough here to refer to my *Three Essays* (1905d), in which I have attempted to throw some light - if only a feeble one - on the somatic processes in which the essential nature of sexuality is to be looked for. I have there shown that the constitutional sexual disposition of children is incomparably more variegated than might have been expected, that it deserves to be described as 'polymorphously perverse' and that what is spoken of as the normal behaviour of the sexual function emerges from this disposition after certain of its components have been repressed. By pointing out the infantile elements in sexuality I was able to establish a simple correlation between health, perversion and neurosis. I showed that normality is a result of the repression of certain component instincts and constituents of the infantile disposition and of the subordination of the remaining constituents under the primacy of the genital zones in the service of the reproductive function. I showed that perversions correspond to disturbances of this coalescence owing to the overpowering and compulsive development of certain of the component instincts, while neuroses can be traced back to an excessive repression of the libidinal trends. Since almost all the perverse instincts of the infantile disposition can be recognized as the forces concerned in the formation of symptoms in neuroses, though in a state of repression, I was able to describe neurosis as being the 'negative' of perversion.

[1906a, 1581]

Unconscious phantasies have either been unconscious all along and have been formed in the unconscious; or - as is more often the case - they were once conscious phantasies, day-dreams, and have since been purposely forgotten and have become unconscious through 'repression'. Their content may afterwards either have remained the same or have undergone alterations, so that the present unconscious phantasies are derivatives of the once conscious ones. Now an unconscious phantasy has a very important connection with the subject's sexual life; for it is identical with the phantasy which served to give him sexual satisfaction during a period of masturbation. At that time the masturbatory act (in the widest sense of the term) was compounded of two parts. One was the evocation of a phantasy and the other some active behaviour for obtaining self-gratification at the height of the phantasy. This compound, as we know, was itself merely soldered together.¹ Originally the action was a purely auto-erotic procedure for the purpose of obtaining pleasure from some particular part of the body, which could be described as erotogenic. Later, this action became merged with a wishful idea from the sphere of object-love and served as a partial realization of the situation in which the phantasy culminated. When, subsequently, the subject renounces this type of satisfaction, composed of masturbation and phantasy, the action is given up, while the phantasy, from being conscious, becomes unconscious. If no other mode of sexual satisfaction supervenes, the subject remains abstinent; and if he does not succeed in sublimating his libido - that is, in deflecting his sexual excitation to higher aims -, the condition is now fulfilled for his unconscious phantasy to be revived and to proliferate, and, at least as regards some part of its content, to put itself into effect, with the whole force of his need for love, in the form of a pathological symptom.

[1908a, 1934]
I know that no one is prepared to believe in a state of things so long as it appears to be unintelligible and to offer no angle from which an explanation can be attempted. But we can at least bring the underlying factors nearer to our understanding by the help of the postulates I laid down in my *Three Essays on the Theory of Sexuality* in 1905. I there attempted to show that the sexual instinct of man is highly complex and is put together from contributions made by numerous constituents and component instincts. Important contributions to 'sexual excitation' are furnished by the peripheral excitations of certain specially designated parts of the body (the genitals, mouth, anus, urethra), which therefore deserve to be described as 'erotogenic zones'. But the amounts of excitation coming in from these parts of the body do not all undergo the same vicissitudes, nor is the fate of all of them the same at every period of life. Generally speaking, only a part of them is made use of in sexual life; another part is deflected from sexual aims and directed towards others - a process which deserves the name of 'sublimation'. During the period of life which may be called the period of 'sexual latency' - i.e. from the completion of the fifth year to the first manifestations of puberty (round about the eleventh year) - reaction-formations, or counter-forces, such as shame, disgust and morality, are created in the mind. They are actually formed at the expense of the excitations proceeding from the erotogenic zones, and they rise like dams to oppose the later activity of the sexual instincts. Now anal erotism is one of the components of the instinct which, in the course of development and in accordance with the education demanded by our present civilization, have become unserviceable for sexual aims. It is therefore plausible to suppose that these character-traits of orderliness, parsimony and obstinacy, which are so often prominent in people who were formerly anal erotics, are to be regarded as the first and most constant results of the sublimation of anal erotism.

If we take the second of these stages as an average, we must point out that a number of people are, on account of their organization, not equal to meeting its demands. In whole classes of individuals the development of the sexual instinct, as we have described it above, from auto-erotism to object-love with its aim of uniting the genitals, has not been carried out correctly and sufficiently fully. As a result of these disturbances of development two kinds of harmful deviation from normal sexuality - that is, sexuality which is serviceable to civilization - come about; and the relation between these two is almost that of positive and negative.

These considerations have been based so far on the requirement laid down by the second of the stages of civilization which we have postulated, the requirement that every sexual activity of the kind described as perverse is prohibited, while what is called normal sexual intercourse is freely permitted. We have found that even when the line between sexual freedom and restriction is drawn at this point, a number of individuals are ruled out as perverts, and a number of others, who make efforts not to be perverts whilst constitutionally they should be so, are forced into nervous illness. It is easy to predict the result that will follow if sexual freedom is still further circumscribed and the requirements of civilization are raised to the level of the third stage, which bans all sexual activity outside legal marriage. The number of strong natures who openly oppose the demands of civilization will increase enormously, and so will the number of weaker ones who, faced with the conflict between the pressure of cultural influences and the resistance of their constitution, take flight into neurotic illness.
To this unimpeachable body of evidence we shall be able to add fresh material, if we turn to
the history of the masturbatory side of our patient's sexual activities. There is a conflict between
the opinions of doctors and patients on this subject which has not hitherto been properly
appreciated. The patients are unanimous in their belief that masturbation, by which they mean
masturbation during puberty, is the root and origin of all their troubles. The doctors are, upon
the whole, unable to decide what line to take; but, influenced by the knowledge that not only
neurotics but most normal people pass through a period of masturbation during their puberty,
the majority of them are inclined to dismiss the patients' assertions as gross exaggerations. In
my opinion the patients are once again nearer to a correct view than the doctors; for the
patients have some glimmering notion of the truth, while the doctors are in danger of
overlooking an essential point. The thesis propounded by the patients certainly does not
 correspond to the facts in the sense in which they themselves construe it, namely, that
masturbation during puberty (which may almost be described as a typical occurrence) is
responsible for all neurotic disturbances. Their thesis requires interpretation. The masturbation
of puberty is in fact no more than a revival of the masturbation of infancy, a subject which has
hitherto invariably been neglected. Infantile masturbation reaches a kind of climax, as a rule,
between the ages of three and four or five; and it is the clearest expression of a child's sexual
constitution, in which the aetiology of subsequent neuroses must be sought. In this disguised
way, therefore, the patients are putting the blame for their illnesses upon their infantile sexuality;
and they are perfectly right in doing so. On the other hand, the problem of masturbation
becomes insoluble if we attempt to treat it as a clinical unit, and forget that it can represent the
discharge of every variety of sexual component and of every sort of phantasy to which such
components can give rise. The injurious effects of masturbation are only in a very small degree
autonomous - that is to say, determined by its own nature. They are in substance merely part
and parcel of the pathogenic significance of the subject's sexual life as a whole. The fact that so
many people can tolerate masturbation - that is, a certain amount of it - without injury merely
shows that their sexual constitution and the course of development of their sexual life have
been such as to allow them to exercise the sexual function within the limits of what is culturally
permissible; whereas other people, because their sexual constitution has been less favourable
or their development has been disturbed, fall ill as a result of their sexuality - they cannot, that
is, achieve the necessary suppression or sublimation of their sexual components without having
recourse to inhibitions or substitutes.¹
[1909d, 2159]

A second outcome of the work of psycho-analysis is that it then becomes possible for the
unconscious instincts revealed by it to be employed for the useful purposes which they would
have found earlier if development had not been interrupted. For the extirpation of the infantile
wishful impulses is by no means the ideal aim of development. Owing to their repressions,
neurotics have sacrificed many sources of mental energy whose contributions would have been
of great value in the formation of their character and in their activity in life. We know of a far
more expedient process of development, called 'sublimation', in which the energy of the infantile
wishful impulses is not cut off but remains ready for use - the unserviceable aim of the various
impulses being replaced by one that is higher, and perhaps no longer sexual. It happens to be
precisely the components of the sexual instinct that are specially marked by a capacity of this
kind for sublimation, for exchanging their sexual aim for another one which is comparatively
remote and socially valuable. It is probable that we owe our highest cultural successes to the
contributions of energy made in this way to our mental functions. Premature repression makes
the sublimation of the repressed instinct impossible; when the repression is lifted, the path to
sublimation becomes free once more.
[1910a, 2238]
Observation of men's daily lives shows us that most people succeed in directing very considerable portions of their sexual instinctual forces to their professional activity. The sexual instinct is particularly well fitted to make contributions of this kind since it is endowed with a capacity for sublimation: that is, it has the power to replace its immediate aim by other aims which may be valued more highly and which are not sexual. We accept this process as proved whenever the history of a person's childhood - that is, the history of his mental development - shows that in childhood this over-powerful instinct was in the service of sexual interests. We find further confirmation if a striking atrophy occurs in the sexual life of maturity, as though a portion of sexual activity had now been replaced by the activity of the over-powerful instinct.

In virtue of a special disposition, the third type, which is the rarest and most perfect, escapes both inhibition of thought and neurotic compulsive thinking. It is true that here too sexual repression comes about, but it does not succeed in relegating a component instinct of sexual desire to the unconscious. Instead, the libido evades the fate of repression by being sublimated from the very beginning into curiosity and by becoming attached to the powerful instinct for research as a reinforcement. Here, too, the research becomes to some extent compulsive and a substitute for sexual activity; but owing to the complete difference in the underlying psychical processes (sublimation instead of an irruption from the unconscious ) the quality of neurosis is absent; there is no attachment to the original complexes of infantile sexual research, and the instinct can operate freely in the service of intellectual interest. Sexual repression, which has made the instinct so strong through the addition to it of sublimated libido, is still taken into account by the instinct, in that it avoids any concern with sexual themes.

A powerful wave of repression brought this childhood excess to an end, and established the dispositions which were to become manifest in the years of puberty. The most obvious result of the transformation was the avoidance of every crudely sensual activity; Leonardo was enabled to live in abstinence and to give the impression of being an asexual human being. When the excitations of puberty came in their flood upon the boy they did not, however, make him ill by forcing him to develop substitutive structures of a costly and harmful kind. Owing to his very early inclination towards sexual curiosity the greater portion of the needs of his sexual instinct could be sublimated into a general urge to know, and thus evaded repression. A much smaller portion of his libido continued to be devoted to sexual aims and represented a stunted adult sexual life. Because his love for his mother had been repressed, this portion was driven to take up a homosexual attitude and manifested itself in ideal love for boys. The fixation on his mother and on the blissful memories of his relations with her continued to be preserved in the unconscious, but for the time being it remained in an inactive state. In this way repression, fixation and sublimation all played their part in disposing of the contributions which the sexual instinct made to Leonardo's mental life.
But even if the historical material at our disposal were very abundant, and if the psychical mechanisms could be dealt with with the greatest assurance, there are two important points at which a psycho-analytic enquiry would not be able to make us understand how inevitable it was that the person concerned should have turned out in the way he did and in no other way. In Leonardo's case we have had to maintain the view that the accident of his illegitimate birth and the excessive tenderness of his mother had the most decisive influence on the formation of his character and on his later fortune, since the sexual repression which set in after this phase of childhood caused him to sublimate his libido into the urge to know, and established his sexual inactivity for the whole of his later life. But this repression after the first erotic satisfactions of childhood need not necessarily have taken place; in someone else it might perhaps not have taken place or might have assumed much less extensive proportions. We must recognize here a degree of freedom which cannot be resolved any further by psycho-analytic means. Equally, one has no right to claim that the consequence of this wave of repression was the only possible one. It is probable that another person would not have succeeded in withdrawing the major portion of his libido from repression by sublimating it into a craving for knowledge; under the same influences he would have sustained a permanent injury to his intellectual activity or have acquired an insurmountable disposition to obsessional neurosis. We are left, then, with these two characteristics of Leonardo which are inexplicable by the efforts of psycho-analysis: his quite special tendency towards instinctual repressions, and his extraordinary capacity for sublimating the primitive instincts.
[1910c, 2303]
If, then, as we have learnt, psychogenic disturbances of vision depend on certain ideas connected with seeing being cut off from consciousness, we must, on the psycho-analytic view, assume that these ideas have come into opposition to other, more powerful ones, for which we use the collective concept of the 'ego'- a compound which is made up variously at different times - and have for that reason come under repression. But what can be the origin of this opposition, which makes for repression, between the ego and various groups of ideas? You will no doubt notice that it was not possible to frame such a question before the advent of psycho-analysis, for nothing was known earlier of psychical conflict and repression. Our researches, however, have put us in a position to give us the desired answer. Our attention has been drawn to the importance of the instincts in ideational life. We have discovered that every instinct tries to make itself effective by activating ideas that are in keeping with its aims. These instincts are not always compatible with one another; their interests often come into conflict. Opposition between ideas is only an expression of struggles between the various instincts. From the point of view of our attempted explanation, a quite specially important part is played by the undeniable opposition between the instincts which subserve sexuality, the attainment of sexual pleasure, and those other instincts, which have as their aim the self-preservation of the individual - the ego-instincts. As the poet has said, all the organic instincts that operate in our mind may be classified as 'hunger' or 'love'. We have traced the 'sexual instinct' from its first manifestations in children to its final form, which is described as 'normal'. We have found that it is put together from numerous 'component instincts' which are attached to excitations of regions of the body; and we have come to see that these separate instincts have to pass through a complicated development before they can be brought effectively to serve the aims of reproduction. The light thrown by psychology on the evolution of our civilization has shown us that it originates mainly at the cost of the sexual component instincts, and that these must be suppressed, restricted, transformed and directed to higher aims, in order that the mental constructions of civilization may be established. We have been able to recognize as a valuable outcome of these researches something that our colleagues have not yet been willing to believe, namely that the human ailments known as 'neuroses' are derived from the many different ways in which these processes of transformation in the sexual component instincts may miscarry. The 'ego' feels threatened by the claims of the sexual instincts and fends them off by repressions; these, however, do not always have the desired result, but lead to the formation of dangerous substitutes for the repressed and to burdensome reactions on the part of the ego. From these two classes of phenomena taken together there emerge what we call the symptoms of neuroses.

[1910i, 2368]

Researches into the sexual activity of children have led to a further conception of the sexual instinct, based not on its purposes but on its sources. The sexual instinct possesses in a high degree the capacity for being diverted from direct sexual aims and for being directed towards higher aims which are no longer sexual ('sublimation'). The instinct is thus enabled to make most important contributions to the social and artistic achievements of humanity.

[1913m, 2547]
(d) Just as the third type has brought the dispositional determinant before us almost in isolation, so the fourth type, which now follows, draws our attention to another factor, which comes into consideration in every single case and might easily for that very reason be overlooked in a theoretical discussion. We see people fall ill who have hitherto been healthy, who have met with no fresh experience and whose relation to the external world has undergone no change, so that the onset of their illness inevitably gives an impression of spontaneity. A closer consideration of such cases, however, shows us that none the less a change has taken place in them whose importance we must rate very highly as a cause of illness. As a result of their having reached a particular period of life, and in conformity with regular biological processes, the quantity of libido in their mental economy has experienced an increase which is in itself enough to upset the equilibrium of their health and to set up the necessary conditions for a neurosis. It is well known that more or less sudden increases of libido of this kind are habitually associated with puberty and the menopause - with the attainment of a certain age in women; in some people they may in addition be manifested in periodicities that are still unknown. Here the damming-up of libido is the primary factor; it becomes pathogenic as a consequence of a relative frustration on the part of the external world, which would still have granted satisfaction to a smaller claim by the libido. The unsatisfied and dammed-up libido can once again open up paths to regression and kindle the same conflicts which we have demonstrated in the case of absolute external frustration. We are reminded in this way that the quantitative factor should not be left out of account in any consideration of the precipitating causes of illness. All the other factors - frustration, fixation, developmental inhibition - remain ineffective unless they affect a certain amount of libido and bring about a damming-up of libido of a certain height. It is true that we are unable to measure this amount of libido which seems to us indispensable for a pathogenic effect; we can only postulate it after the resulting illness has started. There is only one direction in which we can determine it more precisely. We may assume that it is not a question of an absolute quantity, but of the relation between the quota of libido in operation and the quantity of libido which the individual ego is able to deal with - that is, to hold under tension, to sublimate or to employ directly. For this reason a relative increase in the quantity of libido may have the same effects as an absolute one. An enfeeblement of the ego owing to organic illness or owing to some special demand upon its energy will be able to cause the emergence of neuroses which would otherwise have remained latent in spite of any disposition that might be present.

[1912c, 2563]
We are justified in saying that they have been diverted from these sexual aims, even though there is some difficulty in giving a description of such a diversion of aim which will conform to the requirements of metapsychology. Moreover, those instincts which are inhibited in their aims always preserve some few of their original sexual aims; even an affectionate devotee, even a friend or an admirer, desires the physical proximity and the sight of the person who is now loved only in the 'Pauline' sense. If we choose, we may recognize in this diversion of aim a beginning of the sublimation of the sexual instincts, or on the other hand we may fix the limits of sublimation at some more distant point. Those sexual instincts which are inhibited in their aims have a great functional advantage over those which are uninhibited. Since they are not capable of really complete satisfaction, they are especially adapted to create permanent ties; while those instincts which are directly sexual incur a loss of energy each time they are satisfied, and must wait to be renewed by a fresh accumulation of sexual libido, so that meanwhile the object may have been changed. The inhibited instincts are capable of any degree of admixture with the uninhibited; they can be transformed back into them, just as they arose out of them. It is well known how easily erotic wishes develop out of emotional relations of a friendly character, based upon appreciation and admiration (compare Molière's 'Kiss me for the love of Greek'), between a master and a pupil, between a performer and a delighted listener, and especially in the case of women. In fact the growth of emotional ties of this kind, with their purposeless beginnings, provides a much frequented pathway to sexual object-choice. Pfister, in his Frömmigkeit des Grafen von Zinzendorf (1910), has given an extremely clear and certainly not an isolated example of how easily even an intense religious tie can revert to ardent sexual excitement. On the other hand it is also very usual for directly sexual impulsions, short-lived in themselves, to be transformed into a lasting and purely affectionate tie; and the consolidation of a passionate love marriage rests to a large extent upon this process.

Sublimation. - An attentive examination of the sexual trends, which alone were accessible to psycho-analysis, had meanwhile led to some remarkable detailed findings. What is described as the sexual instinct turns out to be of a highly composite nature and is liable to disintegrate once more into its component instincts. Each component instinct is unalterably characterized by its source, that is, by the region or zone of the body from which its excitation is derived. Each has furthermore as distinguishable features an object and an aim. The aim is always discharge accompanied by satisfaction, but it is capable of being changed from activity to passivity. The object is less closely attached to the instinct than was at first supposed; it is easily exchanged for another one, and, moreover, an instinct which had an external object can be turned round upon the subject's own self. The separate instincts can either remain independent of one another or - in what is still an inexplicable manner - can be combined and merged into one another to perform work in common. They are also able to replace one another and to transfer their libidinal cathexis to one another, so that the satisfaction of one instinct can take the place of the satisfaction of others. The most important vicissitude which an instinct can undergo seems to be sublimation; here both object and aim are changed, so that what was originally a sexual instinct finds satisfaction in some achievement which is no longer sexual but has a higher social or ethical valuation. These different features do not as yet combine to form an integral picture.
The transformation of object-libido into narcissistic libido which thus takes place obviously implies an abandonment of sexual aims, a desexualization - a kind of sublimation, therefore. Indeed, the question arises, and deserves careful consideration, whether this is not the universal road to sublimation, whether all sublimation does not take place though the mediation of the ego, which begins by changing sexual object-libido into narcissistic libido and then, perhaps, goes on to give it another aim.¹ We shall later on have to consider whether other instinctual vicissitudes may not also result from this transformation, whether, for instance, it may not bring about a defusion of the various instincts that are fused together.

[1923b, 3964]

I have lately developed a view of the instincts¹ which I shall here hold to and take as the basis of my further discussions. According to this view we have to distinguish two classes of instincts, one of which, the sexual instincts or Eros, is by far the more conspicuous and accessible to study. It comprises not merely the uninhibited sexual instinct proper and the instinctual impulses of an aim-inhibited or sublimated nature derived from it, but also the self-preservation instinct, which must be assigned to the ego and which at the beginning of our analytic work we had good reason for contrasting with the sexual object-instincts. The second class of instincts was not so easy to point to; in the end we came to recognize sadism as its representative. On the basis of theoretical considerations, supported by biology, we put forward the hypothesis of a death instinct, the task of which is to lead organic life back into the inanimate state; on the other hand, we supposed that Eros, by bringing about a more and more far-reaching combination of the particles into which living substance is dispersed, aims at complicating life and at the same time, of course, at preserving it. Acting in this way, both the instincts would be conservative in the strictest sense of the word, since both would be endeavouring to re-establish a state of things that was disturbed by the emergence of life. The emergence of life would thus be the cause of the continuance of life and also at the same time of the striving towards death; and life itself would be a conflict and compromise between these two trends. The problem of the origin of life would remain a cosmological one; and the problem of the goal and purpose of life would be answered dualistically.

[1923b, 3974]

If this displaceable energy is desexualized libido, it may also be described as sublimated energy; for it would still retain the main purpose of Eros - that of uniting and binding - in so far as it helps towards establishing the unity, or tendency to unity, which is particularly characteristic of the ego. If thought processes in the wider sense are to be included among these displacements, then the activity of thinking is also supplied from the sublimation of erotic motive forces.

[1923b, 3979]

Here we arrive again at the possibility which has already been discussed that sublimation may take place regularly, through the mediation of the ego. The other case will be recollected, in which the ego deals with the first object-cathexes of the id (and certainly with later ones too) by taking over the libido from them into itself and binding it to the alteration of the ego produced by means of identification. The transformation into ego-libido of course involves an abandonment of sexual aims, a desexualization. In any case this throws light upon an important function of the ego in its relation to Eros. By thus getting hold of the libido from the object-cathexes, setting itself up as sole love-object, and desexualizing or sublimating the libido of the id, the ego is working in opposition to the purposes of Eros and placing itself at the service of the opposing instinctual impulses. It has to acquiesce in some of the other object-cathexes of the id; it has, so to speak, to participate in them. We shall come back later to another possible consequence of this activity of the ego.

[1923b, 3979]
And from the struggle against Eros! It can hardly be doubted that the pleasure principle serves the id as a compass in its struggle against the libido - the force that introduces disturbances into the process of life. If it is true that Fechner's principle of constancy governs life, which thus consists of a continuous descent towards death, it is the claims of Eros, of the sexual instincts, which, in the form of instinctual needs, hold up the falling level and introduce fresh tensions. The id, guided by the pleasure principle - that is, by the perception of unpleasure - fends off these tensions in various ways. It does so in the first place by complying as swiftly as possible with the demands of the non-desexualized libido - by striving for the satisfaction of the directly sexual trends. But it does so in a far more comprehensive fashion in relation to one particular form of satisfaction in which all component demands converge - by discharge of the sexual substances, which are saturated vehicles, so to speak, of the erotic tensions. The ejection of the sexual substances in the sexual act corresponds in a sense to the separation of soma and germ-plasm. This accounts for the likeness of the condition that follows complete sexual satisfaction to dying, and for the fact that death coincides with the act of copulation in some of the lower animals. These creatures die in the act of reproduction because, after Eros has been eliminated through the process of satisfaction, the death instinct has a free hand for accomplishing its purposes. Finally, as we have seen, the ego, by sublimating some of the libido for itself and its purposes, assists the id in its work of mastering the tensions.

Towards the two classes of instincts the ego's attitude is not impartial. Through its work of identification and sublimation it gives the death instincts in the id assistance in gaining control over the libido, but in so doing it runs the risk of becoming the object of the death instincts and of itself perishing. In order to be able to help in this way it has had itself to become filled with libido; it thus itself becomes the representative of Eros and henceforward desires to live and to be loved.

The second of my alleged extensions of the concept of sexuality finds its justification in the fact revealed by psycho-analytic investigation that all of these affectionate impulses were originally of a completely sexual nature but have become inhibited in their aim or sublimated. The manner in which the sexual instincts can thus be influenced and diverted enables them to be employed for cultural activities of every kind, to which indeed they bring the most important contributions.
In the Oedipus complex the libido was seen to be attached to the image of the parental figures. But earlier there was a period in which there were no such objects. There followed from this fact the concept (of fundamental importance for the libido theory) of a state in which the subject's libido filled his own ego and had that for its object. This state could be called narcissism or self-love. A moment's reflection showed that this state never completely ceases. All through the subject's life his ego remains the great reservoir of his libido, from which object-cathexes are sent out and into which the libido can stream back again from the objects. Thus narcissistic libido is constantly being transformed into object-libido, and vice versa. An excellent instance of the length to which this transformation can go is afforded by the state of being in love, whether in a sexual or sublimated manner, which goes so far as involving a sacrifice of the self. Whereas hitherto in considering the process of repression attention had only been paid to what was repressed, these ideas made it possible to form a correct estimate of the repressing forces too. It had been said that repression was set in action by the instincts of self-preservation operating in the ego (the 'ego-instincts') and that it was brought to bear upon the libidinal instincts. But since the instincts of self-preservation were now recognized as also being of a libidinal nature, as being narcissistic libido, the process of repression was seen to be a process occurring within the libido itself; narcissistic libido was opposed to object-libido, the interest of self-preservation was defending itself against the demands of object-love, and therefore against the demands of sexuality in the narrower sense as well.

[1925d, 4231]

This is not very illuminating. We can only note that disturbances of the sexual function are brought about by a great variety of means. (1) The libido may simply be turned away (this seems most readily to produce what we regard as an inhibition pure and simple); (2) the function may be less well carried out; (3) it may be hampered by having conditions attached to it, or modified by being diverted to other aims; (4) it may be prevented by security measures; (5) if it cannot be prevented from starting, it may be immediately interrupted by the appearance of anxiety; and (6), if it is nevertheless carried out, there may be a subsequent reaction of protest against it and an attempt to undo what has been done.

[1926d, 4249]

Within this narrow compass it has been impossible to mention many matters of the greatest interest, such as the 'sublimation' of instincts, the part played by symbolism, the problem of 'ambivalence', etc. Nor has there been space to allude to the applications of psycho-analysis, which originated, as we have seen, in the sphere of medicine, to other departments of knowledge (such as Social Anthropology, the Study of Religion, Literary History and Education) where its influence is constantly increasing. It is enough to say that psycho-analysis, in its character of the psychology of the deepest, unconscious mental acts, promises to become the link between psychiatry and all of these other branches of mental science.

[1926f, 4406]
Another technique for fending off suffering is the employment of the displacements of libido which our mental apparatus permits of and through which its function gains so much in flexibility. The task here is that of shifting the instinctual aims in such a way that they cannot come up against frustration from the external world. In this, sublimation of the instincts lends its assistance. One gains the most if one can sufficiently heighten the yield of pleasure from the sources of psychical and intellectual work. When that is so, fate can do little against one. A satisfaction of this kind, such as an artist's joy in creating, in giving his phantasies body, or a scientist's in solving problems or discovering truths, has a special quality which we shall certainly one day be able to characterize in metapsychological terms. At present we can only say figuratively that such satisfactions seem 'finer and higher'. But their intensity is mild as compared with that derived from the sating of crude and primary instinctual impulses; it does not convulse our physical being. And the weak point of this method is that it is not applicable generally: it is accessible to only a few people. It presupposes the possession of special dispositions and gifts which are far from being common to any practical degree. And even to the few who do possess them, this method cannot give complete protection from suffering. It creates no impenetrable armour against the arrows of fortune, and it habitually fails when the source of suffering is a person's own body.¹

¹ When there is no special disposition in a person which imperatively prescribes what direction his interests in life shall take, the ordinary professional work that is open to everyone can play the part assigned to it by Voltaire's wise advice. It is not possible, within the limits of a short survey, to discuss adequately the significance of work for the economics of the libido. No other technique for the conduct of life attaches the individual so firmly to reality as laying emphasis on work; for his work at least gives him a secure place in a portion of reality, in the human community. The possibility it offers of displacing a large amount of libidinal components, whether narcissistic, aggressive or even erotic, on to professional work and on to the human relations connected with it lends it a value by no means second to what it enjoys as something indispensable to the preservation and justification of existence in society. Professional activity is a source of special satisfaction if it is a freely chosen one - if, that is to say, by means of sublimation, it makes possible the use of existing inclinations, of persisting or constitutionally reinforced instinctual impulses. And yet, as a path to happiness, work is not highly prized by men. They do not strive after it as they do after other possibilities of satisfaction. The great majority of people only work under the stress of necessity, and this natural human aversion to work raises most difficult social problems.

While this procedure already clearly shows an intention of making oneself independent of the external world by seeking satisfaction in internal, psychical processes, the next procedure brings out those features yet more strongly. In it, the connection with reality is still further loosened; satisfaction is obtained from illusions, which are recognized as such without the discrepancy between them and reality being allowed to interfere with enjoyment. The region from which these illusions arise is the life of the imagination; at the time when the development of the sense of reality took place, this region was expressly exempted from the demands of reality-testing and was set apart for the purpose of fulfilling wishes which were difficult to carry out. At the head of these satisfactions through phantasy stands the enjoyment of works of art - an enjoyment which, by the agency of the artist, is made accessible even to those who are not themselves creative.¹ People who are receptive to the influence of art cannot set too high a value on it as a source of pleasure and consolation in life. Nevertheless the mild narcosis induced in us by art can do no more than bring about a transient withdrawal from the pressure of vital needs, and it is not strong enough to make us forget real misery.
In spite of the incompleteness, I will venture on a few remarks as a conclusion to our enquiry. The programme of becoming happy, which the pleasure principle imposes on us, cannot be fulfilled; yet we must not - indeed, we cannot - give up our efforts to bring it nearer to fulfilment by some means or other. Very different paths may be taken in that direction, and we may give priority either to the positive aspect of the aim, that of gaining pleasure, or to its negative one, that of avoiding unpleasure. By none of these paths can we attain all that we desire. Happiness, in the reduced sense in which we recognize it as possible, is a problem of the economics of the individual's libido. There is no golden rule which applies to everyone: every man must find out for himself in what particular fashion he can be saved. All kinds of different factors will operate to direct his choice. It is a question of how much real satisfaction he can expect to get from the external world, how far he is led to make himself independent of it, and, finally, how much strength he feels he has for altering the world to suit his wishes. In this, his psychical constitution will play a decisive part, irrespectively of the external circumstances. The man who is predominantly erotic will give first preference to his emotional relationships to other people; the narcissistic man, who inclines to be self-sufficient, will seek his main satisfactions in his internal mental processes; the man of action will never give up the external world on which he can try out his strength. As regards the second of these types, the nature of his talents and the amount of instinctual sublimation open to him will decide where he shall locate his interests. Any choice that is pushed to an extreme will be penalized by exposing the individual to the dangers which arise if a technique of living that has been chosen as an exclusive one should prove inadequate. Just as a cautious business-man avoids tying up all his capital in one concern, so, perhaps, worldly wisdom will advise us not to look for the whole of our satisfaction from a single aspiration. Its success is never certain, for that depends on the convergence of many factors, perhaps on none more than on the capacity of the psychical constitution to adapt its function to the environment and then to exploit that environment for a yield of pleasure. A person who is born with a specially unfavourable instinctual constitution, and who has not properly undergone the transformation and rearrangement of his libidinal components which is indispensable for later achievements, will find it hard to obtain happiness from his external situation, especially if he is faced with tasks of some difficulty. As a last technique of living, which will at least bring him substitutive satisfactions, he is offered that of a flight into neurotic illness - a flight which he usually accomplishes when he is still young. The man who sees his pursuit of happiness come to nothing in later years can still find consolation in the yield of pleasure of chronic intoxication; or he can embark on the desperate attempt at rebellion seen in a psychosis.¹

[1930a, 4482]
By allowing common feeling to be our guide in deciding what features of human life are to be regarded as civilized, we have obtained a clear impression of the general picture of civilization; but it is true that so far we have discovered nothing that is not universally known. At the same time we have been careful not to fall in with the prejudice that civilization is synonymous with perfecting, that it is the road to perfection pre-ordained for men. But now a point of view presents itself which may lead in a different direction. The development of civilization appears to us as a peculiar process which mankind undergoes, and in which several things strike us as familiar. We may characterize this process with reference to the changes which it brings about in the familiar instinctual dispositions of human beings, to satisfy which is, after all, the economic task of our lives. A few of these instincts are used up in such a manner that something appears in their place which, in an individual, we describe as a character-trait. The most remarkable example of such a process is found in the anal erotism of young human beings. Their original interest in the excretory function, its organs and products, is changed in the course of their growth into a group of traits which are familiar to us as parsimony, a sense of order and cleanliness - qualities which, though valuable and welcome in themselves, may be intensified till they become markedly dominant and produce what is called the anal character. How this happens we do not know, but there is no doubt about the correctness of the finding.¹ Now we have seen that order and cleanliness are important requirements of civilization, although their vital necessity is not very apparent, any more than their suitability as sources of enjoyment. At this point we cannot fail to be struck by the similarity between the process of civilization and the libidinal development of the individual. Other instincts are induced to displace the conditions for their satisfaction, to lead them into other paths. In most cases this process coincides with that of the sublimation (of instinctual aims) with which we are familiar, but in some it can be differentiated from it. Sublimation of instinct is an especially conspicuous feature of cultural development; it is what makes it possible for higher psychical activities, scientific, artistic or ideological, to play such an important part in civilized life. If one were to yield to a first impression, one would say that sublimation is a vicissitude which has been forced upon the instincts entirely by civilization. But it would be wiser to reflect upon this a little longer. In the third place, finally, and this seems the most important of all, it is impossible to overlook the extent to which civilization is built up upon a renunciation of instinct, how much it presupposes precisely the non-satisfaction (by suppression, repression or some other means?) of powerful instincts. This 'cultural frustration' dominates the large field of social relationships between human beings. As we already know, it is the cause of the hostility against which all civilizations have to struggle. It will also make severe demands on our scientific work, and we shall have much to explain here. It is not easy to understand how it can become possible to deprive an instinct of satisfaction. Nor is doing so without danger. If the loss is not compensated for economically, one can be certain that serious disorders will ensue.

[1930a, 4494]
The conjecture which goes deepest, however, is the one which takes its start from what I have said above (p. 4495) in my footnote. It is to the effect that, with the assumption of an erect posture by man and with the depreciation of his sense of smell, it was not only his anal erotism which threatened to fall a victim to organic repression, but the whole of his sexuality; so that since this, the sexual function has been accompanied by a repugnance which cannot further be accounted for, and which prevents its complete satisfaction and forces it away from the sexual aim into sublimations and libidinal displacements. I know that Bleuler (1913) once pointed to the existence of a primary repelling attitude like this towards sexual life. All neurotics, and many others besides, take exception to the fact that ‘inter urinas et faeces nascimur’.

The genitals, too, give rise to strong sensations of smell which many people cannot tolerate and which spoil sexual intercourse for them. Thus we should find that the deepest root of the sexual repression which advances along with civilization is the organic defence of the new form of life achieved with man's erect gait against his earlier animal existence. This result of scientific research coincides in a remarkable way with commonplace prejudices that have often made themselves heard. Nevertheless, these things are at present no more than unconfirmed possibilities which have not been substantiated by science. Nor should we forget that, in spite of the undeniable depreciation of olfactory stimuli, there exist even in Europe people among whom the strong genital odours which are so repellent to us are highly prized as sexual stimulants and who refuse to give them up. (Cf. the collections of folklore obtained from Iwan Bloch's questionnaire on the sense of smell in sexual life published in different volumes of Friedrich S. Krauss's Anthropophyteia.)

[1930a, 4499]

An instinct, then, is distinguished from a stimulus by the fact that it arises from sources of stimulation within the body, that it operates as a constant force and that the subject cannot avoid it by flight, as is possible with an external stimulus. We can distinguish an instinct's source, object and aim. Its source is a state of excitation in the body, its aim is the removal of that excitation; on its path from its source to its aim the instinct becomes operative psychically. We picture it as a certain quota of energy which presses in a particular direction. It is from this pressing that it derives its name of 'Trieb'. People speak of 'active' and 'passive' instincts, but it would be more correct to speak of instincts with active and passive aims: for an expenditure of activity is needed to achieve a passive aim as well. The aim can be achieved in the subject's own body; as a rule an external object is brought in, in regard to which the instinct achieves its external aim; its internal aim invariably remains the bodily change which is felt as satisfaction. It has not become clear to us whether the relation of the instinct to its somatic source gives it a specific quality and if so what. The evidence of analytic experience shows that it is an undoubted fact that instinctual impulses from one source attach themselves to those from other sources and share their further vicissitudes and that in general one instinctual satisfaction can be replaced by another. But it must be admitted that we do not understand this very well. The relations of an instinct to its aim and object are also open to alterations; both can be exchanged for other ones, though its relation to its object is nevertheless the more easily loosened. A certain kind of modification of the aim and change of the object, in which our social valuation is taken into account, is described by us as 'sublimation'. Besides this, we have grounds for distinguishing instincts which are 'inhibited in their aim' - instinctual impulses from sources well known to us with an unambiguous aim, but which come to a stop on their way to satisfaction, so that a lasting object-cathexis comes about and a permanent trend. Such, for instance, is the relation of tenderness, which undoubtedly originates from the sources of sexual need and invariably renounces its satisfaction.

[1933a, 4702]
It would be a mistake to suppose that these three phases succeed one another in a clear-cut fashion. One may appear in addition to another; they may overlap one another, may be present alongside of one another. In the early phases the different component instincts set about their pursuit of pleasure independently of one another; in the phallic phase there are the beginnings of an organization which subordinates the other urges to the primacy of the genitals and signifies the start of a co-ordination of the general urge towards pleasure into the sexual function. The complete organization is only achieved at puberty, in a fourth, genital phase. A state of things is then established in which (1) some earlier libidinal cathexes are retained, (2) others are taken into the sexual function as preparatory, auxiliary acts, the satisfaction of which produces what is known as fore-pleasure, and (3) other urges are excluded from the organization, and are either suppressed altogether (repressed) or are employed in the ego in another way, forming character-traits or undergoing sublimation with a displacement of their aims.

[1940a [1938], 4966]
From the third year of life a child's sexual life shows much agreement with an adult's. It differs from the latter, as we already know, in lacking a firm organization under the primacy of the genitals, in its inevitable traits of perversion and also, of course, in the far lesser intensity of the whole trend. But from the point of view of theory the most interesting phases of sexual, or, as we will say, of libidinal, development lie earlier than this point of time. This course of development takes place so rapidly that we should probably never have succeeded in getting a firm hold of its fleeting pictures by direct observation. It was only with the help of the psycho-analytic investigation of the neuroses that it became possible to discern the still earlier phases of the development of the libido. These are nothing but constructions, to be sure, but, if you carry out psycho-analyses in practice, you will find that they are necessary and useful constructions. You will soon learn how it comes about that pathology can here put us in possession of conditions which we should inevitably overlook in a normal subject.

[1916-1917, 3394]

The analytic researches carried out by the writer fell, to begin with, into the error of greatly overestimating the importance of seduction as a source of sexual manifestations in children and as a root for the formation of neurotic symptoms. This misapprehension was corrected when it became possible to appreciate the extraordinarily large part played in the mental life of neurotics by the activities of phantasy, which clearly carried more weight in neurosis than did external reality. Behind these phantasies there came to light the material which allows us to draw the picture which follows of the development of the sexual function.

[1923a, 3921]

My surprising discoveries as to the sexuality of children were made in the first instance through the analysis of adults. But later (from about 1908 onwards) it became possible to confirm them fully and in every detail by direct observations upon children. Indeed, it is so easy to convince oneself of the regular sexual activities of children that one cannot help asking in astonishment how the human race can have succeeded in overlooking the facts and in maintaining for so long the wishful legend of the asexuality of childhood. This surprising circumstance must be connected with the amnesia which, with the majority of adults, hides their own infancy.

[1925d, 4214]

Oh, by no means. It is based on direct observation. What happened was this. We had begun by inferring the content of sexual childhood from the analysis of adults - that is to say, some twenty to forty years later. Afterwards, we undertook analyses on children themselves, and it was no small triumph when we were thus able to confirm in them everything that we had been able to divine, in spite of the amount to which it had been overlaid and distorted in the interval.

[1926e, 4356]
The Development of the Libido. - The sexual instinct, the dynamic manifestation of which in mental life we shall call 'libido', is made up of component instincts into which it may once more break up and which are only gradually united into well-defined organizations. The sources of these component instincts are the organs of the body and in particular certain specially marked erotogenic zones; but contributions are made to libido from every important functional process in the body. At first the individual component instincts strive for satisfaction independently of one another, but in the course of development they become more and more convergent and concentrated. The first (pregenital) stage of organization to be discerned is the oral one, in which - in conformity with the suckling's predominant interest - the oral zone plays the leading part. This is followed by the sadistic-anal organization, in which the anal zone and the component instinct of sadism are particularly prominent; at this stage the difference between the sexes is represented by the contrast between active and passive. The third and final stage of organization is that in which the majority of the component instincts converge under the primacy of the genital zones. As a rule this development is passed through swiftly and unobtrusively; but some individual portions of the instincts remain behind at the prodromal stages of the process and thus give rise to fixations of libido, which are important as constituting predispositions for subsequent irruptions of repressed impulses and which stand in a definite relation to the later development of neuroses and perversions. (See the article on 'The Libido Theory'.) [1923a, 3921]
TEMPORAL FACTORS  Other factors which, along with precocity, may be classed as temporal also deserve attention. The order in which the various instinctual impulses come into activity seems to be phylogenetically determined; so, too, does the length of time during which they are able to manifest themselves before they succumb to the effects of some freshly emerging instinctual impulse or to some typical repression. Variations, however, seem to occur both in temporal sequence and in duration, and these variations must exercise a determining influence upon the final result. It cannot be a matter of indifference whether a given current makes its appearance earlier or later than a current flowing in the opposite direction, for the effect of a repression cannot be undone. Divergences in the temporal sequence in which the components come together invariably produce a difference in the outcome. On the other hand, instinctual impulses which emerge with special intensity often run a surprisingly short course - as, for instance, the heterosexual attachment of persons who later become manifest homosexuals. There is no justification for the fear that trends which set in with the greatest violence in childhood will permanently dominate the adult character; it is just as likely that they will disappear and make way for an opposite tendency. ('Gestrenge Herren regieren nicht Lange.')¹

Our attitude to the phases of the organization of the libido has in general shifted a little. Whereas earlier we chiefly emphasized the way in which each of them passed away before the next, our attention now is directed to the facts that show us how much of each earlier phase persists alongside of and behind the later configurations and obtains a permanent representation in the libidinal economy and character of the subject. Still more significant have studies become which have taught us how frequently under pathological conditions regressions to earlier phases occur and that particular regressions are characteristic of particular forms of illness. But I cannot go into that here, it forms part of the specialized psychology of the neuroses.

It would be a mistake to suppose that these three phases succeed one another in a clear-cut fashion. One may appear in addition to another; they may overlap one another, may be present alongside of one another. In the early phases the different component instincts set about their pursuit of pleasure independently of one another; in the phallic phase there are the beginnings of an organization which subordinates the other urges to the primacy of the genitals and signifies the start of a co-ordination of the general urge towards pleasure into the sexual function. The complete organization is only achieved at puberty, in a fourth, genital phase. A state of things is then established in which (1) some earlier libidinal cathexes are retained, (2) others are taken into the sexual function as preparatory, auxiliary acts, the satisfaction of which produces what is known as fore-pleasure, and (3) other urges are excluded from the organization, and are either suppressed altogether (repressed) or are employed in the ego in another way, forming character-traits or undergoing sublimation with a displacement of their aims.

¹[1905d, 1551]

[1933a, 4705]

[1940a [1938], 4966]
PREGENITAL ORGANIZATIONS  The study, with the help of psycho-analysis, of the inhibitions and disturbances of this process of development enables us to recognize abortive beginnings and preliminary stages of a firm organization of the component instincts such as this - preliminary stages which themselves constitute a sexual regime of a sort. These phases of sexual organization are normally passed through smoothly, without giving more than a hint of their existence. It is only in pathological cases that they become active and recognizable to superficial observation. [1905d, 1516]

AFTER-EFFECTS OF INFANTILE OBJECT-CHOICE  Even a person who has been fortunate enough to avoid an incestuous fixation of his libido does not entirely escape its influence. It often happens that a young man falls in love seriously for the first time with a mature woman, or a girl with an elderly man in a position of authority; this is clearly an echo of the phase of development that we have been discussing, since these figures are able to re-animate pictures of their mother or father.¹ There can be no doubt that every object-choice whatever is based, though less closely, on these prototypes. A man, especially, looks for someone who can represent his picture of his mother, as it has dominated his mind from his earliest childhood; and accordingly, if his mother is still alive, she may well resent this new version of herself and meet her with hostility. In view of the importance of a child's relations to his parents in determining his later choice of a sexual object, it can easily be understood that any disturbance of those relations will produce the gravest effects upon his adult sexual life. Jealousy in a lover is never without an infantile root or at least an infantile reinforcement. If there are quarrels between the parents or if their marriage is unhappy, the ground will be prepared in their children for the severest predisposition to a disturbance of sexual development or to a neurotic illness. [1905d, 1540]

FACTORS INTERFERING WITH DEVELOPMENT  Every step on this long path of development can become a point of fixation, every juncture in this involved combination can be an occasion for a dissociation of the sexual instinct, as we have already shown from numerous instances. It remains for us to enumerate the various factors, internal and external, that interfere with development, and to indicate the place in the mechanism on which the disturbance arising from each of them impinges. The factors that we shall enumerate can evidently not be of equal importance, and we must be prepared for difficulties in assigning an appropriate value to each. [1905d, 1546]

We shall be in even closer harmony with psycho-analytic research if we give a place of preference among the accidental factors to the experiences of early childhood. The single aetiological series then falls into two, which may be called the dispositional and the definitive. In the first the constitution and the accidental experiences of childhood interact in the same manner as do the disposition and later traumatic experiences in the second. All the factors that impair sexual development show their effects by bringing about a regression, a return to an earlier phase of development. [1905d, 1550]
Further information now became available relating to people who had remained normal; and this led to the unexpected finding that the sexual history of their childhood did not necessarily differ in essentials from that of neurotics, and, in particular, that the part played by seduction was the same in both cases. As a consequence, accidental influences receded still further into the background as compared with 'repression' (as I now began to say instead of 'defence'). Thus it was no longer a question of what sexual experiences a particular individual had had in his childhood, but rather of his reaction to those experiences - of whether he had reacted to them by 'repression' or not. It could be shown how in the course of development a spontaneous infantile sexual activity was often broken off by an act of repression. Thus a mature neurotic individual was invariably pursued by a certain amount of 'sexual repression' from his childhood; this found expression when he was faced by the demands of real life, and the psycho-analyses of hysterics showed that they fell ill as a result of the conflict between their libido and their sexual repression and that their symptoms were in the nature of compromises between the two mental currents. [1906a, 1580]

When you ask me for an expression of opinion on 'the sexual enlightenment of children', I assume that what you want is not a regular, formal treatise on the subject which shall take into account the excessive mass of literature that has grown up around it, but the independent judgement of an individual doctor whose professional activities have offered him special opportunities for concerning himself with sexual problems. I know that you have followed my scientific efforts with interest and that, unlike many of our colleagues, you do not dismiss my ideas without examining them because I regard the psychosexual constitution and certain noxae of sexual life as the most important causes of the neurotic disorders that are so common. My *Three Essays on the Theory of Sexuality*, too, where I have described the way in which the sexual instinct is compounded and the disturbances which may occur in its development into the function of sexuality, have recently had a friendly reception in your journal. [1907c, 1912]
I do not know how the case could be better stated, but perhaps I may add a few remarks. It is undoubtedly nothing else but the customary prudishness and their own bad conscience over sexual matters that causes adults to adopt this attitude of 'mystery-making' in front of children; but possibly a part is also played by a piece of theoretical ignorance on their part, which we can counteract by giving the adults some enlightenment. It is commonly believed that the sexual instinct is absent in children and only begins to emerge in them at puberty when the sexual organs mature. This is a gross error, equally serious in its effects both on knowledge and on practice; and it is so easily corrected by observation that one wonders how it could ever have been made. As a matter of fact, the new-born baby brings sexuality with it into the world, certain sexual sensations accompany its development as a suckling and during early childhood, and only very few children would seem to escape sexual activities and sensations before puberty. Anyone who would like to find a detailed exposition of these statements can do so in my *Three Essays on the Theory of Sexuality*, to which I have referred above. There he will learn that the organs of reproduction proper are not the only parts of the body which provide sexual sensations of pleasure, and that nature has even so ordered matters that actual stimulations of the genitals are unavoidable during early childhood. This period of life, during which a certain quota of what is undoubtedly sexual pleasure is produced by the excitation of various parts of the skin (erogogenic zones), by the activity of certain biological instincts and as an accompanying excitation in many affective states, is called the period of *auto-erotism*, to use a term introduced by Havelock Ellis. All that puberty does is to give the genitals primacy among all the other zones and sources which produce pleasure, and thus to force erotism into the service of the function of reproduction. This process can naturally undergo certain inhibitions, and in many people (those who later become perverts and neurotics) it is only incompletely accomplished. On the other hand, the child is capable long before puberty of most of the psychical manifestations of love-tenderness, for example, devotion and jealousy. Often enough, too, an irruption of these mental states is associated with the physical sensations of sexual excitation, so that the child cannot remain in doubt as to the connection between the two. In short, except for his reproductive power, a child has a fully-developed capacity for love long before puberty; and it may be asserted that the 'mystery-making' merely prevents him from being able to gain an intellectual grasp of activities for which he is psychically prepared and physically adjusted.

[1907c, 1914]
The sexual instinct - or, more correctly, the sexual instincts, for analytic investigation teaches us that the sexual instinct is made up of many separate constituents or component instincts - is probably more strongly developed in man than in most of the higher animals; it is certainly more constant, since it has almost entirely overcome the periodicity to which it is tied in animals. It places extraordinarily large amounts of force at the disposal of civilized activity, and it does this in virtue of its especially marked characteristic of being able to displace its aim without materially diminishing in intensity. This capacity to exchange its originally sexual aim for another one, which is no longer sexual but which is psychically related to the first aim, is called the capacity for sublimation. In contrast to this displaceability, in which its value for civilization lies, the sexual instinct may also exhibit a particularly obstinate fixation which renders it unserviceable and which sometimes causes it to degenerate into what are described as abnormalities. The original strength of the sexual instinct probably varies in each individual; certainly the proportion of it which is suitable for sublimation varies. It seems to us that it is the innate constitution of each individual which decides in the first instance how large a part of his sexual instinct it will be possible to sublimate and make use of. In addition to this, the effects of experience and the intellectual influences upon his mental apparatus succeed in bringing about the sublimation of a further portion of it. To extend this process of displacement indefinitely is, however, certainly not possible, any more than is the case with the transformation of heat into mechanical energy in our machines. A certain amount of direct sexual satisfaction seems to be indispensable for most organizations, and a deficiency in this amount, which varies from individual to individual, is visited by phenomena which, on account of their detrimental effects on functioning and their subjective quality of unpleasure, must be regarded as an illness.

If we take the second of these stages as an average, we must point out that a number of people are, on account of their organization, not equal to meeting its demands. In whole classes of individuals the development of the sexual instinct, as we have described it above, from auto-erotism to object-love with its aim of uniting the genitals, has not been carried out correctly and sufficiently fully. As a result of these disturbances of development two kinds of harmful deviation from normal sexuality - that is, sexuality which is serviceable to civilization - come about; and the relation between these two is almost that of positive and negative.¹

In the first place (disregarding people whose sexual instinct is altogether excessive and uninhibitable) there are the different varieties perverts, in whom an infantile fixation to a preliminary sexual aim has prevented the primacy of the reproductive function from being established, and the homosexuals or inverters, in whom, in a manner that is not yet quite understood, the sexual aim has been deflected away from the opposite sex. If the injurious effects of these two kinds of developmental disturbance are less than might be expected, this mitigation can be ascribed precisely to the complex way in which the sexual instinct is put together, which makes it possible for a person's sexual life to reach a serviceable final form even if one or more components of the instinct have been shut off from development. The constitution of people suffering from inversion - the homosexuals - is, indeed, often distinguished by their sexual instinct's possessing a special aptitude for cultural sublimation.

[1908d, 1952]

[1908d, 1953]
The answer to the first question touches on a problem which has often been discussed and cannot be exhaustively treated here - that of sexual abstinence. Our third stage of civilization demands of individuals of both sexes that they shall practise abstinence until they are married and that all who do not contract a legal marriage shall remain abstinent throughout their lives. The position, agreeable to all the authorities, that sexual abstinence is not harmful and not difficult to maintain, has also been widely supported by the medical profession. It may be asserted, however, that the task of mastering such a powerful impulse as that of the sexual instinct by any other means than satisfying it is one which can call for the whole of a man's forces. Mastering it by sublimation, by deflecting the sexual instinctual forces away from their sexual aim to higher cultural aims, can be achieved by a minority and then only intermittently, and least easily during the period of ardent and vigorous youth. Most of the rest become neurotic or are harmed in one way or another. Experience shows that the majority of the people who make up our society are constitutionally unfit to face the task of abstinence. Those who would have fallen ill under milder sexual restrictions fall ill all the more readily and more severely before the demands of our cultural sexual morality of to-day; for we know no better safe-guard against the threat to normal sexual life offered by defective innate dispositions or disturbances of development than sexual satisfaction itself. The more a person is disposed to neurosis, the less can he tolerate abstinence; instincts which have been withdrawn from normal development, in the sense in which it has been described above, become at the same time all the more uninhibitable. But even those people who would have retained their health under the requirements of the second stage of civilization will now succumb to neurosis in great numbers. For the psychical value of sexual satisfaction increases with its frustration. The dammed-up libido is now put in a position to detect one or other of the weaker spots which are seldom absent in the structure of sexual life, and there to break through and obtain substitutive satisfaction of a neurotic kind in the form of pathological symptoms. Anyone who is able to penetrate the determinants of nervous illness will soon become convinced that its increase in our society arises from the intensification of sexual restrictions.

[1908d, 1956]

There is a dictum in general pathology, Gentlemen, which asserts that every developmental process carries with it the seed of a pathological disposition, in so far as that process may be inhibited, delayed, or may run its course incompletely. The same thing is true of the highly complicated development of the sexual function. It does not occur smoothly in every individual; and, if not, it leaves behind it either abnormalities or a predisposition to fall ill later, along the path of involution (i.e. regression). It may happen that not all the component instincts submit to the dominance of the genital zone. An instinct which remains in this way independent leads to what we describe as a perversion, and may substitute its own sexual aim for the normal one. It very often happens, as I have already said, that auto-erotism is not completely conquered, and evidence of this is given by a great variety of subsequent disturbances. The originally equal value attached to the two sexes as sexual objects may persist, and this will lead to a tendency in adult life to homosexual activity, which can in certain circumstances be intensified into exclusive homosexuality. These classes of disturbance represent direct inhibitions in the development of the sexual function; they comprise the perversions and, what is by no means rare, general infantilism in sexual life.

[1910a, 2231]

When striking cases of psychical impotence are exhaustively investigated by means of psychoanalysis, the following information is obtained about the psychosexual processes at work in them. Here again - as very probably in all neurotic disturbances - the foundation of the disorder is provided by an inhibition in the developmental history of the libido before it assumes the form which we take to be its normal termination. Two currents whose union is necessary to ensure a completely normal attitude in love have, in the cases we are considering, failed to combine. These two may be distinguished as the affectionate and the sensual current.

[1912d, 2338]
We have reduced psychical impotence to the failure of the affectionate and the sensual currents in love to combine, and this developmental inhibition has in turn been explained as being due to the influences of strong childhood fixations and of later frustration in reality through the intervention of the barrier against incest. There is one principal objection to the theory we advance; it does too much. It explains why certain people suffer from psychical impotence, but it leaves us with the apparent mystery of how others have been able to escape this disorder. Since we must recognize that all the relevant factors known to us - the strong childhood fixation, the incest-barrier and the frustration in the years of development after puberty - are to be found in practically all civilized human beings, we should be justified in expecting psychical impotence to be a universal affliction under civilization and not a disorder confined to some individuals.

[1912d, 2341]

If, then, as we have learnt, psychogenic disturbances of vision depend on certain ideas connected with seeing being cut off from consciousness, we must, on the psycho-analytic view, assume that these ideas have come into opposition to other, more powerful ones, for which we use the collective concept of the 'ego'- a compound which is made up variously at different times - and have for that reason come under repression. But what can be the origin of this opposition, which makes for repression, between the ego and various groups of ideas? You will no doubt notice that it was not possible to frame such a question before the advent of psycho-analysis, for nothing was known earlier of psychical conflict and repression. Our researches, however, have put us in a position to give us the desired answer. Our attention has been drawn to the importance of the instincts in ideational life. We have discovered that every instinct tries to make itself effective by activating ideas that are in keeping with its aims. These instincts are not always compatible with one another; their interests often come into conflict. Opposition between ideas is only an expression of struggles between the various instincts. From the point of view of our attempted explanation, a quite specially important part is played by the undeniable opposition between the instincts which subserve sexuality, the attainment of sexual pleasure, and those other instincts, which have as their aim the self-preservation of the individual - the ego-instincts. As the poet has said, all the organic instincts that operate in our mind may be classified as 'hunger' or 'love'. We have traced the 'sexual instinct' from its first manifestations in children to its final form, which is described as 'normal'. We have found that it is put together from numerous 'component instincts' which are attached to excitations of regions of the body; and we have come to see that these separate instincts have to pass through a complicated development before they can be brought effectively to serve the aims of reproduction. The light thrown by psychology on the evolution of our civilization has shown us that it originates mainly at the cost of the sexual component instincts, and that these must be suppressed, restricted, transformed and directed to higher aims, in order that the mental constructions of civilization may be established. We have been able to recognize as a valuable outcome of these researches something that our colleagues have not yet been willing to believe, namely that the human ailments known as 'neuroses' are derived from the many different ways in which these processes of transformation in the sexual component instincts may miscarry. The 'ego' feels threatened by the claims of the sexual instincts and fends them off by repressions; these, however, do not always have the desired result, but lead to the formation of dangerous substitutes for the repressed and to burdensome reactions on the part of the ego. From these two classes of phenomena taken together there emerge what we call the symptoms of neuroses.

[1910i, 2368]
I shall now endeavour (and I think the attempt is neither unnecessary nor unjustifiable) to show that the knowledge of psychological processes, which, thanks to psycho-analysis, we now possess, already enables us to understand the part played by a homosexual wish in the development of paranoia. Recent investigations¹ have directed our attention to a stage in the development of the libido which it passes through on the way from auto-eroticism to object-love.² This stage has been given the name of narcissism. What happens is this. There comes a time in the development of the individual at which he unifies his sexual instincts (which have hitherto been engaged in auto-erotic activities) in order to obtain a love-object; and he begins by taking himself, his own body, as his love-object, and only subsequently proceeds from this to the choice of some person other than himself as his object. This half-way phase between auto-eroticism and object-love may perhaps be indispensable normally; but it appears that many people linger unusually long in this condition, and that many of its features are carried over by them into the later stages of their development. What is of chief importance in the subject's self thus chosen as a love object may already be the genitals. The line of development then leads on to the choice of an external object with similar genitals - that is, to homosexual object-choice - and thence to heterosexuality. People who are manifest homosexuals in later life have, it may be presumed, never emancipated themselves from the binding condition that the object of their choice must possess genitals like their own; and in this connection the infantile sexual theories which attribute the same kind of genitals to both sexes exert much influence.

¹[1911c, 2430]

In my Three Essays on the Theory of Sexuality I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics endevour to protect themselves against any such sexualization of their social instinctual cathexes, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-eroticism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) schizophrenia; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.

²[1911c, 2431]
It must be understood that each individual, through the combined operation of his innate disposition and the influences brought to bear on him during his early years, has acquired a specific method of his own in his conduct of his erotic life - that is, in the preconditions to falling in love which he lays down, in the instincts he satisfies and the aims he sets himself in the course of it.¹ This produces what might be described as a stereotype plate (or several such), which is constantly repeated - constantly reprinted afresh - in the course of the person's life, so far as external circumstances and the nature of the love objects accessible to him permit, and which is certainly not entirely insusceptible to change in the face of recent experiences. Now, our observations have shown that only a portion of these impulses which determine the course of erotic life have passed through the full process of psychical development. That portion is directed towards reality, is at the disposal of the conscious personality, and forms a part of it. Another portion of the libidinal impulses has been held up in the course of development; it has been kept away from the conscious personality and from reality, and has either been prevented from further expansion except in phantasy or has remained wholly in the unconscious so that it is unknown to the personality's consciousness. If someone's need for love is not entirely satisfied by reality, he is bound to approach every new person whom he meets with libidinal anticipatory ideas; and it is highly probable that both portions of his libido, the portion that is capable of becoming conscious as well as the unconscious one, have a share in forming that attitude.

1912b, 2457

The cultural development imposed on mankind is the factor which necessitates the restrictions and repressions of the sexual instinct, greater or lesser sacrifices being demanded according to the individual constitution. Development is hardly ever achieved smoothly, and disturbances may occur (whether on account of the individual constitution or of premature sexual incidents) leaving behind a disposition to future neuroses. Such dispositions may remain harmless if the adult's life proceeds satisfactorily and quietly; but they become pathogenic if the conditions of mature life forbid satisfaction of the libido or make too high demands on its suppression.

1913m, 2547

(7) While the ego goes through its transformation from a pleasure-ego into a reality-ego, the sexual instincts undergo the changes that lead them from their original auto-erotism through various intermediate phases to object-love in the service of procreation. If we are right in thinking that each step in these two courses of development may become the site of a disposition to later neurotic illness, it is plausible to suppose that the form taken by the subsequent illness (the choice of neurosis) will depend on the particular phase of the development of the ego and of the libido in which the dispositional inhibition of development has occurred. Thus unexpected significance attaches to the chronological features of the two developments (which have not yet been studied), and to possible variations in their synchronization.

1911b, 2556

(c) The next type, which I shall describe as falling ill from an inhibition in development, looks like an exaggeration of the second one - falling ill from the demands of reality. There is no theoretical reason for distinguishing it, but only a practical one; for those we are here concerned with are people who fall ill as soon as they get beyond the irresponsible age of childhood, and who have thus never reached a phase of health - a phase, that is, of capacity for achievement and enjoyment which is on the whole unrestricted. The essential feature of the dispositional process is in these cases quite plain. Their libido has never left its infantile fixations; the demands of reality are not suddenly made upon a wholly or partly mature person, but arise from the very fact of growing older, since it is obvious that they constantly alter with the subject's increasing age. Thus conflict falls into the background in comparison with insufficiency. But here, too, all our other experience leads us to postulate an effort at overcoming the fixations of childhood; for otherwise the outcome of the process could never be neurosis but only a stationary infantilism.

1912c, 2563
Where are we to look for the source of these dispositions? We have become aware that the psychical functions concerned - above all, the sexual function, but various important ego-functions too - have to undergo a long and complicated development before reaching the state characteristic of the normal adult. We can assume that these developments are not always so smoothly carried out that the total function passes through this regular progressive modification. Wherever a portion of it clings to a previous stage, what is known as a 'point of fixation' results, to which the function may regress if the subject falls ill through some external disturbance.

I shall now take my footing once more on the clinical observation of an individual case. Over a long period I studied a woman patient whose neurosis underwent an unusual change. It began, after a traumatic experience, as a straightforward anxiety hysteria and retained that character for a few years. One day, however, it suddenly changed into an obsessional neurosis of the severest type. A case of this kind could not fail to become significant in more than one direction. On the one hand, it might perhaps claim to be looked upon like a bilingual document and to show how an identical content could be expressed by the two neuroses in different languages. On the other hand, it threatened to contradict completely our theory that disposition arises from developmental inhibition, unless we were prepared to accept the supposition that a person could innately possess more than one weak spot in his libidinal development. I told myself that we had no right to dismiss this latter possibility; but I was greatly interested to arrive at an understanding of the case.

Psycho-analysis has done justice to the sexual function in man by making a detailed examination of its importance in mental and practical life - an importance which has been emphasized by many creative writers and by some philosophers, but which has never been recognized by science. But in the first place it was necessary to enlarge the unduly restricted concept of sexuality, an enlargement that was justified by reference to the extensions of sexuality occurring in the so called perversions and to the behaviour of children. It turned out to be impossible to maintain any longer that childhood was asexual and was invaded for the first time by a sudden inrush of sexual impulses at the age of puberty. On the contrary, when once the blinkers of partiality and prejudice had been removed, observation had no difficulty in revealing that sexual interests and activities are present in the human child at almost every age and from the very first. The importance of this infantile sexuality is not impaired by the fact that we cannot everywhere draw a clear line between it and a child's asexual activity. It differs, however, from what is described as the 'normal' sexuality of adults. It includes the germs of all those sexual activities which in later life are sharply contrasted with normal sexual life as being perversions, and as such bound to seem incomprehensible and vicious. The normal sexuality of adults emerges from infantile sexuality by a series of developments, combinations, divisions and suppressions, which are scarcely ever achieved with ideal perfection and consequently leave behind predispositions to a retrogression of the function in the form of illness.
Another and far more surprising discovery has been that, in spite of all the later development that occurs in the adult, none of the infantile mental formations perish. All the wishes, instinctual impulses, modes of reaction and attitudes of childhood are still demonstrably present in maturity and in appropriate circumstances can emerge once more. They are not destroyed but merely overlaid - to use the spatial mode of description which psycho-analytic psychology has been obliged to adopt. Thus it is part of the nature of the mental past that, unlike the historic past, it is not absorbed by its derivatives; it persists (whether actually or only potentially) alongside what has proceeded from it. The proof of this assertion lies in the fact that the dreams of normal people revive their childhood characters every night and reduce their whole mental life to an infantile level. This same return to psychical infantilism ('regression') appears in the neuroses and psychoses, whose peculiarities may to a great extent be described as psychical archaisms. The strength in which the residues of infancy are still present in the mind shows us the amount of disposition to illness; that disposition may accordingly be regarded as an expression of an inhibition in development. The part of a person's psychical material which has remained infantile and has been repressed as being unserviceable constitutes the core of his unconscious. And we believe we can follow in our patients' life-histories the way in which this unconscious, held back as it is by the forces of repression, lies in wait for a chance to become active and makes use of its opportunities if the later and higher psychical structures fail to master the difficulties of real life. [1913j, 2820]

With this sexual activity of the first years of childhood the inherited constitution of the individual also came into its own. Disposition and experience are here linked up in an indissoluble aetiologial unity. For disposition exaggerates impressions which would otherwise have been completely commonplace and have had no effect, so that they become traumas giving rise to stimulations and fixations; while experiences awaken factors in the disposition which, without them, might have long remained dormant and perhaps never have developed. The last word on the subject of traumatic aetiology was spoken later by Abraham, when he pointed out that the sexual constitution which is peculiar to children is precisely calculated to provoke sexual experiences of a particular kind - namely traumas. [1914d, 2887]

The object [Objekt] of an instinct is the thing in regard to which or through which the instinct is able to achieve its aim. It is what is most variable about an instinct and is not originally connected with it, but becomes assigned to it only in consequence of being peculiarly fitted to make satisfaction possible. The object is not necessarily something extraneous: it may equally well be a part of the subject's own body. It may be changed any number of times in the course of the vicissitudes which the instinct undergoes during its existence; and highly important parts are played by this displacement of instinct. It may happen that the same object serves for the satisfaction of several instincts simultaneously, a phenomenon which Adler has called a 'confluence' of instincts [Triebverschränkung]. A particularly close attachment of the instinct to its object is distinguished by the term 'fixation'. This frequently occurs at very early periods of the development of an instinct and puts an end to its mobility through its intense opposition to detachment. [1915c, 2960]
The clinical fact which meets us behind the form of the Oedipus complex as it is established by
analysis is of the highest practical significance. We learn that at puberty, when the sexual instinct
first makes its demands in full strength, the old familiar incestuous objects are taken up again and
freshly cathexed with libido. The infantile object-choice was only a feeble one, but it was a
prelude, pointing the direction for the object-choice at puberty. At this point, then, very intense
emotional processes come into play, following the direction of the Oedipus complex or reacting
against it, processes which, however, since their premisses have become intolerable, must to a
large extent remain apart from consciousness. From this time onwards, the human individual has
to devote himself to the great task of detaching himself from his parents, and not until that task is
achieved can he cease to be a child and become a member of the social community. For the son
this task consists in detaching his libidinal wishes from his mother and employing them for the
choice of a real outside love-object, and in reconciling himself with his father if he has remained in
opposition to him, or in freeing himself from his pressure if, as a reaction to his infantile
rebelliousness, he has become subservient to him. These tasks are set to everyone; and it is
remarkable how seldom they are dealt with in an ideal manner - that is, in one which is correct
both psychologically and socially. By neurotics, however, no solution at all is arrived at: the son
remains all his life bowed beneath his father's authority and he is unable to transfer his libido to
an outside sexual object. With the relationship changed round, the same fate can await the
daughter. In this sense the Oedipus complex may justly be regarded as the nucleus of the
neuroses.

[1916-1917, 3402]

We are, I think, in agreement with the theories of general pathology in assuming that a
development of this kind involves two dangers - first, of inhibition, and secondly, of regression.
That is to say, in view of the general tendency of biological processes to variation, it is bound to
be the case that not every preparatory phase will be passed through with equal success and
completely superseded: portions of the function will be permanently held back at these early
stages, and the total picture of development will be qualified by some amount of developmental
inhibition.

[1916-1917, 3403]

If you go into the matter more closely, you will have no difficulty in detecting the weak points in
these comparisons. I will therefore declare without more ado that I regard it as possible in the
case of every particular sexual trend that some portions of it have stayed behind at earlier stages
of its development, even though other portions may have reached their final goal. You will
recognize here that we are picturing every such trend as a current which has been continuous
since the beginning of life but which we have divided up, to some extent artificially, into separate
successive advances. Your impression that these ideas stand in need of greater clarification is
justified; but to attempt it would take us too far afield. Let me further make it clear that we propose
to describe the lagging behind of a part trend at an earlier stage as a fixation - a fixation, that is,
of the instinct.

[1916-1917, 3404]
You may now have an impression that deprivation has been reduced to insignificance owing to all these methods of tolerating it. But no, it retains its pathogenic power. The counter-measures are on the whole insufficient. There is a limit to the amount of unsatisfied libido that human beings on the average can put up with. The plasticity or free mobility of the libido is by no means fully preserved in everyone, and sublimation is never able to deal with more than a certain fraction of libido, quite apart from the fact that many people are gifted with only a small amount of capacity to sublimate. The most important of these limitations is evidently that upon the mobility of the libido, since it makes a person's satisfaction depend on the attainment of only a very small number of aims and objects. You have only to recall that an imperfect development of the libido leaves behind it very fertile and perhaps, too, very numerous libidinal fixations to early phases of the organization and of the finding of objects, which are for the most part incapable of real satisfaction, and you will recognize in libidinal fixation the second powerful factor which combines with frustration as the cause of illness. You can declare, as a schematic abbreviation, that libidinal fixation represents the predisposing, internal factor in the aetiology of the neuroses, while frustration represents the accidental, external one.

The tenacity with which the libido adheres to particular trends and objects - what may be described as the 'adhesiveness' of the libido - makes its appearance as an independent factor, varying from individual to individual, whose determinants are quite unknown to us, but whose significance for the aetiology of the neuroses we shall certainly no longer underestimate. We should not, on the other hand, over-estimate the intimacy of this connection. For a similar 'adhesiveness' of the libido occurs (for unknown reasons) under numerous conditions in normal people, and it is found as a determining factor in people who are in one sense the contrary of neurotics - in perverts. It was known even before the days of psycho-analysis (cf. Binet) that in the anamnesis of perverts a very early impression of an abnormal instinctual trend or choice of object was quite often found, to which the subject's libido remained attached all through his life. It is often impossible to say what it is that enabled this impression to exercise such an intense attraction on the libido. I will describe a case of this sort which I myself observed.

Where, then, does the libido find the fixations which it requires in order to break through the repressions? In the activities and experiences of infantile sexuality, in the abandoned component trends, in the objects of childhood which have been given up. It is to them, accordingly, that the libido returns. The significance of this period of childhood is twofold: on the one hand, during it the instinctual trends which the child has inherited with his innate disposition first become manifest, and secondly, others of his instincts are for the first time awakened and made active by external impressions and accidental experiences. There is no doubt, I think, that we are justified in making this twofold division. The manifestation of the innate disposition is indeed not open to any critical doubts, but analytic experience actually compels us to assume that purely chance experiences in childhood are able to leave fixations of the libido behind them. Nor do I see any theoretical difficulty in this. Constitutional dispositions are also undoubtedly after-effects of experiences by ancestors in the past; they too were once acquired. Without such acquisition there would be no heredity. And is it conceivable that acquisition such as this, leading to inheritance, would come to an end precisely with the generation we are considering? The significance of infantile experiences should not be totally neglected, as people like doing, in comparison with the experiences of the subject's ancestors and of his own maturity; on the contrary, they call for particular consideration. They are all the more momentous because they occur in times of incomplete development and are for that very reason liable to have traumatic effects. The studies on developmental mechanics by Roux and others have shown that the prick of a needle into an embryonic germinial layer in the act of cell-division results in a severe disturbance of development. The same injury inflicted on a larval or fully grown animal would do no damage.
In the second place, we must reflect that it would be inconceivable for the libido to regress so regularly to the period of childhood unless there were something there to exercise an attraction on it. The fixation which we have supposed to be present at particular points in the course of development can only have a meaning if we regard it as consisting in the retention of a certain quota of libidinal energy. And finally I may point out to you that between the intensity and pathogenic importance of infantile and of later experiences a complemental relationship exists similar to the series we have already discussed. There are cases in which the whole weight of causation falls on the sexual experiences of childhood, cases in which those impressions exert a definitely traumatic effect and call for no other support than can be afforded them by an average sexual constitution and the fact of its incomplete development. Alongside of these cases there are others in which the whole accent lies on the later conflicts and the emphasis we find in the analysis laid on the impressions of childhood appears entirely as the work of regression. Thus we have extremes of ‘developmental inhibition’ and ‘regression’ and between them every degree of co-operation between the two factors.

[1916-1917, 3422]

Your second observation, too, raises a justifiable question, but it is aimed in the wrong direction. It is true that a withdrawal of the object-libido into the ego is not directly pathogenic; it takes place, indeed, as we know, every time before we go to sleep, only to be reversed when we wake up. The amoeba withdraws its protrusions only to send them out again at the first opportunity. But it is quite a different thing when a particular, very energetic process forces a withdrawal of libido from objects. Here the libido that has become narcissistic cannot find its way back to objects, and this interference with the libido’s mobility certainly becomes pathogenic. It seems that an accumulation of narcissistic libido beyond a certain amount is not tolerated. We may even imagine that it was for that very reason that object-cathexes originally came about, that the ego was obliged to send out its libido so as not to fall ill as a result of its being dammed up. If it lay within our plan to go more deeply into dementia praecox, I would show you that the process which detaches the libido from objects and cuts off its return to them is closely related to the process of repression and is to be looked at as its counterpart. But you would, first and foremost, find yourselves on familiar ground when you learnt that the determinants of this process are almost identical - so far as we know at present - with those of repression. The conflict seems to be the same and to be carried on between the same forces. If the outcome is so different from, for instance, that in hysteria, the reason can only depend on a difference in innate disposition. The weak spot in the libidinal development of these patients lies in a different phase; the determining fixation, which, as you will recollect, permits the irruption that leads to the formation of symptoms, lies elsewhere, probably in the stage of primitive narcissism to which dementia praecox returns in its final outcome. It is very remarkable that in the case of all the narcissistic neuroses we have to assume fixation points for the libido going back to far earlier phases of development than in hysteria or obsessional neurosis. As you heard, however, the concepts which we arrived at during our study of the transference neuroses are adequate in helping us to find our way about in the narcissistic neuroses which are so much more severe in practice. The conformities go very far; at bottom the field of phenomena is the same. And you can imagine how small a prospect anyone has of explaining these disorders (which belong within the sphere of psychiatry) who is not forearmed for his task with an analytic knowledge of the transference neuroses.

[1916-1917, 3466]
The opposition which he at first offered to religion had three different points of origin. To begin
with, there was, in general, his characteristic (which we have seen exemplified already) of fending
off all novelties. Any position of the libido which he had once taken up was obstinately defended
by him from fear of what he would lose by giving it up and from distrust of the probability of a
complete substitute being afforded by the new position that was in view. This is an important and
fundamental psychological peculiarity, which I described in my *Three Essays on the Theory of
Sexuality* (1905) as a susceptibility to 'fixation'. Under the name of psychical 'inertia' Jung has
attempted to erect it into the principal cause of all the failures of neurotics. I think he is wrong in
this; for this factor has a far more general application and plays an important part in the lives of
the non-neurotic as well. Great mobility or sluggishness of libidinal cathexes (as well as of other
kinds of energetic cathexes) are special characteristics which attach to many normal people and by
no means to all neurotics, and which have hitherto not been brought into relation with other
qualities. They are, as it were, like prime numbers, not further divisible. We only know one thing
about them, and that is that mobility of the mental cathexes is a quality which shows striking
diminution with the advance of age. This has given us one of the indications of the limits within
which psycho-analytic treatment is effective. There are some people, however, who retain this
mental plasticity far beyond the usual age-limit, and others who lose it very prematurely. If the
latter are neurotics, we make the unwelcome discovery that it is impossible to undo developments
in them which, in apparently similar circumstances, have been easily dealt with in other people.
So that in considering the conversion of psychical energy no less than of physical, we must make
use of the concept of an *entropy*, which opposes the undoing of what has already occurred.

[1918b, 3591]

With this as a starting-point we go on to make our first important discovery. We learn that, when
we try to understand neurotic disorders, by far the greater significance attaches to the sexual
instincts; that in fact neuroses are the specific disorders, so to speak, of the sexual function; that
in general whether or not a person develops a neurosis depends on the quantity of his libido, and
on the possibility of satisfying it and of discharging it through satisfaction; that the form taken by
the disease is determined by the way in which the individual passes through the course of
development of his sexual function, or, as we put it, by the fixations his libido has undergone in
the course of its development; and, further, that by a special, not very simple technique for
influencing the mind we are able to throw light on the nature of some groups of neuroses and at
the same time to do away with them. Our therapeutic efforts have their greatest success with a
certain class of neuroses which proceed from a conflict between the ego-instincts and the sexual
instincts. For in human beings it may happen that the demands of the sexual instincts, whose
reach of course extends far beyond the individual, seem to the ego to constitute a danger which
threatens its self-preservation or its self-esteem. The ego then assumes the defensive, denies the
sexual instincts the satisfaction they desire and forces them into those by-paths of substitutive
satisfaction which become manifest as nervous symptoms.

[1917a, 3609]
The Development of the Libido. - The sexual instinct, the dynamic manifestation of which in mental life we shall call 'libido', is made up of component instincts into which it may once more break up and which are only gradually united into well-defined organizations. The sources of these component instincts are the organs of the body and in particular certain specially marked erotogenic zones; but contributions are made to libido from every important functional process in the body. At first the individual component instincts strive for satisfaction independently of one another, but in the course of development they become more and more convergent and concentrated. The first (pregenital) stage of organization to be discerned is the oral one, in which - in conformity with the suckling's predominant interest - the oral zone plays the leading part. This is followed by the sadistic-anal organization, in which the anal zone and the component instinct of sadism are particularly prominent; at this stage the difference between the sexes is represented by the contrast between active and passive. The third and final stage of organization is that in which the majority of the component instincts converge under the primacy of the genital zones. As a rule this development is passed through swiftly and unobtrusively; but some individual portions of the instincts remain behind at the prodromal stages of the process and thus give rise to fixations of libido, which are important as constituting predispositions for subsequent irruptions of repressed impulses and which stand in a definite relation to the later development of neuroses and perversions. (See the article on 'The Libido Theory'.)

[1923a, 3921]

This revolt against castration or a feminine attitude has been torn out of its organic context by Alfred Adler. He has linked it superficially or falsely with the longing for power, and has postulated it as an independent 'masculine protest'. Since a neurosis can only arise from a conflict between two trends, it is as justifiable to see the cause of 'every' neurosis in the masculine protest as it is to see it in the feminine attitude against which the protest is being made. It is quite true that this masculine protest plays a regular part in the formation of character - in some types of people a very large part - and that we meet it in the analysis of neurotic men as a vigorous resistance. Psycho-analysis has attached due importance to the masculine protest in connection with the castration complex, without being able to accept its omnipotence or its omnipresence in neuroses. The most marked case of a masculine protest with all its manifest reactions and character-traits that I have met with in analysis was that of a patient who came to me for treatment on account of an obsessional neurosis in whose symptoms the unresolved conflict between a masculine and a feminine attitude (fear of castration and desire for castration) found clear expression. In addition, the patient had developed masochistic phantasies which were wholly derived from a wish to accept castration; and he had even gone beyond these phantasies to real satisfaction in perverse situations. The whole of his state rested - like Adler's theory itself - on the repression and denial of early infantile fixations of love.

[1923d, 4016]
The sexual function, as I found, is in existence from the very beginning of the individual's life, though at first it is attached to the other vital functions and does not become independent of them until later; it has to pass through a long and complicated process of development before it becomes what we are familiar with as the normal sexual life of the adult. It begins by manifesting itself in the activity of a whole number of component instincts. These are dependent upon erotogenic zones in the body; some of them make their appearance in pairs of opposite impulses (such as sadism and masochism or the impulses to look and to be looked at); they operate independently of one another in a search for pleasure, and they find their object for the most part in the subject's own body. Thus at first the sexual function is non-centralized and predominantly auto-erotic. Later, syntheses begin to appear in it; a first stage of organization is reached under the dominance of the oral components, an anal-sadistic stage follows, and it is only after the third stage has at last been reached that the primacy of the genitals is established and that the sexual function begins to serve the ends of reproduction. In the course of this process of development a number of elements of the various component instincts turn out to be unserviceable for this last end and are therefore left on one side or turned to other uses, while others are diverted from their aims and carried over into the genital organization. I gave the name of libido to the energy of the sexual instincts and to that form of energy alone. I was next driven to suppose that the libido does not always pass through its prescribed course of development smoothly. As a result either of the excessive strength of certain of the components or of experiences involving premature satisfaction, fixations of the libido may occur at various points in the course of its development. If subsequently a repression takes place, the libido flows back to these points (a process described as regression), and it is from them that the energy breaks through in the form of a symptom. Later on it further became clear that the localization of the point of fixation is what determines the choice of neurosis, that is, the form in which the subsequent illness makes its appearance.

[1925d, 4211]

The sexual life of children is of course different from that of adults. The sexual function, from its beginnings to the definitive form in which it is so familiar to us, undergoes a complicated process of development. It grows together from numerous component instincts with different aims and passes through several phases of organization till at last it comes into the service of reproduction. Not all the component instincts are equally serviceable for the final outcome; they must be diverted, remodelled and in part suppressed. Such a far-reaching course of development is not always passed through without a flaw; inhibitions in development take place, partial fixations at early stages of development. If obstacles arise later on to the exercise of the sexual function, the sexual urge - the libido, as we call it - is apt to hark back to these earlier points of fixation. The study of the sexuality of children and its transformations up to maturity has also given us the key to an understanding of what are known as the sexual perversions, which people used always to describe with all the requisite indications of disgust but whose origin they were never able to explain. The whole topic is of uncommon interest, but for the purposes of our conversation there is not much sense in telling you more about it. To find one's way about in it one of course needs anatomical and physiological knowledge, all of which is unfortunately not to be acquired in medical schools. But a familiarity with the history of civilization and with mythology is equally indispensable.

[1926e, 4353]
(2) For cultural reasons the most intense repression falls upon the sexual instincts; but it is precisely in connection with them that repression most easily miscarries, so that neurotic symptoms are found to be substitutive satisfactions of repressed sexuality. The belief that in man sexual life begins only at puberty is incorrect. On the contrary, signs of it can be detected from the beginning of extra-uterine existence; it reaches a first culminating point at or before the fifth year ('early period'), after which it is inhibited or interrupted ('latency period') until the age of puberty, which is the second climax of its development. This diphasic onset of sexual development seems to be distinctive of the genus Homo. All experiences during the first period of childhood are of the greatest importance to the individual, and in combination with his inherited sexual constitution form the dispositions for the subsequent development of character and disease. It is wrong to make sexuality coincide with 'genitality'. The sexual instincts pass through a complicated course of development, and it is only at the end of it that the 'primacy of the genital zones' is attained. Before this there are a number of 'pregenital' organizations of the libido - points at which it may become 'fixed' and to which, in the event of subsequent repression, it will return ('regression'). The infantile fixations of the libido are what determine the form of any later neurosis. Thus the neuroses are to be regarded as inhibitions in the development of the libido. There are no specific causes of nervous disorders; the question whether a conflict finds a healthy solution or leads to a neurotic inhibition of function depends upon quantitative considerations.

Since this phase allows room for all the fixations and repressions from which we trace the origin of the neuroses, it would seem as though we must retract the universality of the thesis that the Oedipus complex is the nucleus of the neuroses. But if anyone feels reluctant about making this correction, there is no need for him to do so. On the one hand, we can extend the content of the Oedipus complex to include all the child's relations to both parents; or, on the other, we can take due account of our new findings by saying that the female only reaches the normal positive Oedipus situation after she has surmounted a period before it that is governed by the negative complex. And indeed during that phase a little girl's father is not much else for her than a troublesome rival, although her hostility towards him never reaches the pitch which is characteristic of boys. We have, after all, long given up any expectation of a neat parallelism between male and female sexual development.

It is hard to say anything of the behaviour of the libido in the id and in the super-ego. All that we know about it relates to the ego, in which at first the whole available quota of libido is stored up. We call this state absolute, primary narcissism. It lasts till the ego begins to cathect the ideas of objects with libido, to transform narcissistic libido into object-libido. Throughout the whole of life the ego remains the great reservoir from which libidinal cathexes are sent out to objects and into which they are also once more withdrawn, just as an amoeba behaves with its pseudopodia. It is only when a person is completely in love that the main quota of libido is transferred on to the object and the object to some extent takes the place of the ego. A characteristic of the libido which is important in life is its mobility, the facility with which it passes from one object to another. This must be contrasted with the fixation of the libido to particular objects, which often persists throughout life.
This process is not always performed faultlessly. Inhibitions in its development manifest themselves as the many sorts of disturbance in sexual life. When this is so, we find fixations of the libido to conditions in earlier phases, whose urge, which is independent of the normal sexual aim, is described as *perversion*. One such developmental inhibition, for instance, is homosexuality when it is manifest. Analysis shows that in every case a homosexual object-tie was present and in most cases persisted in a *latent* condition. The situation is complicated by the fact that as a rule the processes necessary for bringing about a normal outcome are not completely present or absent, but *partially* present, so that the final result remains dependent on these *quantitative* relations. In these circumstances the genital organization is, it is true, attained, but it lacks those portions of the libido which have not advanced with the rest and have remained fixated to pregenital objects and aims. This weakening shows itself in a tendency, if there is an absence of genital satisfaction or if there are difficulties in the real external world, for the libido to hark back to its earlier pregenital cathexes (*regression*).

[1940a [1938], 4966]

There is, however, another angle from which we can approach this problem of the variability in the effect of analysis. We know that the first step towards attaining intellectual mastery of our environment is to discover generalizations, rules and laws which bring order into chaos. In doing this we simplify the world of phenomena; but we cannot avoid falsifying it, especially if we are dealing with processes of development and change. What we are concerned with is discerning a *qualitative* alteration, and as a rule in doing so we neglect, at any rate to begin with, a *quantitative* factor. In the real world, transitions and intermediate stages are far more common than sharply differentiated opposite states. In studying developments and changes we direct our attention solely to the outcome; we readily overlook the fact that such processes are usually more or less incomplete - that is to say, that they are in fact only partial alterations. A shrewd satirist of old Austria, Johann Nestroy, once said: 'Every step forward is only half as big as it looks at first.' It is tempting to attribute a quite general validity to this malicious dictum. There are nearly always residual phenomena, a partial hanging-back. When an open-handed Maecenas surprises us by some isolated trait of miserliness, or when a person who is consistently over-kind suddenly indulges in a hostile action, such 'residual phenomena' are invaluable for genetic research. They show us that these praiseworthy and precious qualities are based on compensation and overcompensation which, as was to have been expected, have not been absolutely and fully successful. Our first account of the development of the libido was that an original oral phase gave way to a sadistic-anal phase and that this was in turn succeeded by a phallic-genital one. Later research has not contradicted this view, but it has corrected it by adding that these replacements do not take place all of a sudden but gradually, so that portions of the earlier organization always persist alongside of the more recent one, and even in normal development the transformation is never complete and residues of earlier libidinal fixations may still be retained in the final configuration. The same thing is to be seen in quite other fields. Of all the erroneous and superstitious beliefs of mankind that have supposedly been surmounted there is not one whose residues do not live on among us to-day in the lower strata of civilized peoples or even in the highest strata of cultural society. What has once come to life clings tenaciously to its existence. One feels inclined to doubt sometimes whether the dragons of primaevial days are really extinct. [1937c, 5025]
FACTORS INTERFERING WITH DEVELOPMENT  Every step on this long path of development can become a point of fixation, every juncture in this involved combination can be an occasion for a dissociation of the sexual instinct, as we have already shown from numerous instances. It remains for us to enumerate the various factors, internal and external, that interfere with development, and to indicate the place in the mechanism on which the disturbance arising from each of them impinges. The factors that we shall enumerate can evidently not be of equal importance, and we must be prepared for difficulties in assigning an appropriate value to each.

[1905d, 1546]

CONSTITUTION AND HEREDITY  First and foremost we must name the innate variety of sexual constitutions, upon which it is probable that the principal weight falls, but which can clearly only be inferred from their later manifestations and even then not always with great certainty. We picture this variety as a preponderance of one or another of the many sources of sexual excitation, and it is our view that a difference in disposition of this kind is always bound to find expression in the final result, even though that result may not overstep the limits of what is normal. No doubt it is conceivable that there may also be variations in the original disposition of a kind which must necessarily, and without the concurrence of any other factors, lead to the development of an abnormal sexual life. These might be described as 'degenerative' and be regarded as an expression of inherited degeneracy. In this connection I have a remarkable fact to record. In more than half of the severe cases of hysteria, obsessional neurosis, etc., which I have treated psychotherapeutically, I have been able to prove with certainty that the patient's father suffered from syphilis before marriage, whether there was evidence of tabes or general paralysis, or whether the anamnesis indicated in some other way the presence of syphilitic disease. I should like to make it perfectly plain that the children who later became neurotic bore no physical signs of hereditary syphilis, so that it was their abnormal sexual constitution that was to be regarded as the last echo of their syphilitic heritage. Though I am far from wishing to assert that descent from syphilitic parents is an invariable or indispensable aetiological condition of a neuropathic constitution, I am nevertheless of opinion that the coincidence which I have observed is neither accidental nor unimportant.

[1905d, 1546]

ACCIDENTAL EXPERIENCES  No other influences on the course of sexual development can compare in importance with releases of sexuality, waves of repression and sublimations - the two latter being processes of which the inner causes are quite unknown to us. It might be possible to include repressions and sublimations as a part of the constitutional disposition, by regarding them as manifestations of it in life; and anyone who does so is justified in asserting that the final shape taken by sexual life is principally the outcome of the innate constitution. No one with perception will, however, dispute that an interplay of factors such as this also leaves room for the modifying effects of accidental events experienced in childhood and later. It is not easy to estimate the relative efficacy of the constitutional and accidental factors. In theory one is always inclined to overestimate the former; therapeutic practice emphasizes the importance of the latter. It should, however, of no account be forgotten that the relation between the two is a co-operative and not a mutually exclusive one. The constitutional factor must await experiences before it can make itself felt; the accidental factor must have a constitutional basis in order to come into operation. To cover the majority of cases we can picture what has been described as a 'complemental series', in which the diminishing intensity of one factor is balanced by the increasing intensity of the other; there is, however, no reason to deny the existence of extreme cases at the two ends of the series.

[1905d, 1550]
We shall be in even closer harmony with psycho-analytic research if we give a place of preference among the accidental factors to the experiences of early childhood. The single aetiological series then falls into two, which may be called the dispositional and the definitive. In the first the constitution and the accidental experiences of childhood interact in the same manner as do the disposition and later traumatic experiences in the second. All the factors that impair sexual development show their effects by bringing about a regression, a return to an earlier phase of development.

Let us now resume our task of enumerating the factors which we have found to exercise an influence on sexual development, whether they are themselves operative forces or merely manifestations of such forces.

FIXATION The ground prepared by the psychical factors which have just been enumerated affords a favourable basis for such stimulations of infantile sexuality as are experienced accidentally. The latter (first and foremost, seduction by other children or by adults) provide the material which, with the help of the former, can become fixated as a permanent disorder. A good proportion of the deviations from normal sexual life which are later observed both in neurotics and in perverts are thus established from the very first by the impressions of childhood - a period which is regarded as being devoid of sexuality. The causation is shared between a compliant constitution, precocity, the characteristic of increased pertinacity of early impressions and the chance stimulation of the sexual instinct by extraneous influences.
The hereditary conditions in the case of positive perverts are less well known, for they know how to avoid investigation. Yet there are good reasons to suppose that what is true of the neurones and psychoneuroses occurring in the same family, and distributed between the two sexes in such a way that the male members of the family, or one of them, are positive perverts, while the females, true to the tendency of their sex to repression, are negative perverts, that is, hysterics. This is good evidence of the essential connections which we have shown to exist between the two disorders.

[FURTHER MODIFICATION] On the other hand, it is not possible to adopt the view that the form to be taken by sexual life is unambiguously decided, once and for all, with the inception of the different components of the sexual constitution. On the contrary, the determining process continues, and further possibilities arise according to the vicissitudes of the tributary streams of sexuality springing from their separate sources. This further modification is clearly what brings the decisive outcome, and constitutions which might be described as the same can lead to three different final results: -

If the relation between all the different dispositions - a relation which we will assume to be abnormal - persists and grows stronger at maturity, the result can only be a perverse sexual life. The analysis of abnormal constitutional dispositions of this kind has not yet been properly taken in hand. But we already know cases which can easily be explained on such a basis as this. Writers on the subject, for instance, have asserted that the necessary precondition of a whole number of perverse fixations lies in an innate weakness of the sexual instinct. In this form the view seems to me untenable. It makes sense, however, if what is meant is a constitutional weakness of one particular factor in the sexual instinct, namely the genital zone - a zone which takes over the function of combining the separate sexual activities for the purposes of reproduction. For if the genital zone is weak, this combination, which is required to take place at puberty, is bound to fail, and the strongest of the other components of sexuality will continue its activity as a perversion.¹

[ACCIDENTAL EXPERIENCES] No other influences on the course of sexual development can compare in importance with releases of sexuality, waves of repression and sublimations - the two latter being processes of which the inner causes are quite unknown to us. It might be possible to include repressions and sublimations as a part of the constitutional disposition, by regarding them as manifestations of it in life; and anyone who does so is justified in asserting that the final shape taken by sexual life is principally the outcome of the innate constitution. No one with perception will, however, dispute that an interplay of factors such as this also leaves room for the modifying effects of accidental events experienced in childhood and later. It is not easy to estimate the relative efficacy of the constitutional and accidental factors. In theory one is always inclined to overestimate the former; therapeutic practice emphasizes the importance of the latter. It should, however, of no account be forgotten that the relation between the two is a co-operative and not a mutually exclusive one. The constitutional factor must await experiences before it can make itself felt; the accidental factor must have a constitutional basis in order to come into operation. To cover the majority of cases we can picture what has been described as a 'complemental series', in which the diminishing intensity of one factor is balanced by the increasing intensity of the other; there is, however, no reason to deny the existence of extreme cases at the two ends of the series.

¹[1905d, 1547]
FIXATION   The ground prepared by the psychical factors which have just been enumerated affords a favourable basis for such stimulations of infantile sexuality as are experienced accidentally. The latter (first and foremost, seduction by other children or by adults) provide the material which, with the help of the former, can become fixated as a permanent disorder. A good proportion of the deviations from normal sexual life which are later observed both in neurotics and in perverts are thus established from the very first by the impressions of childhood - a period which is regarded as being devoid of sexuality. The causation is shared between a compliant constitution, precocity, the characteristic of increased pertinacity of early impressions and the chance stimulation of the sexual instinct by extraneous influences.

[1905d, 1552]

After I had made this correction, 'infantile sexual traumas' were in a sense replaced by the 'infantilism of sexuality'. A second modification of the original theory lay not far off. Along with the supposed frequency of seduction in childhood, I ceased also to lay exaggerated stress on the accidental influencing of sexuality on to which I had sought to thrust the main responsibility for the causation of the illness, though I had not on that account denied the constitutional and hereditary factors. I had even hoped to solve the problem of choice of neurosis (the decision to which form of psychoneurosis the patient is to fall a victim) by reference to the details of the sexual experiences of childhood. I believed at that time - though with reservations - that a passive attitude in these scenes produced a predisposition to hysteria and, on the other hand, an active one a predisposition to obsessional neurosis. Later on I was obliged to abandon this view entirely, even though some facts demand that in some way or other the supposed correlation between passivity and hysteria and between activity and obsessional neurosis shall be maintained. Accidental influences derived from experience having thus receded into the background, the factors of constitution and heredity necessarily gained the upper hand once more; but there was this difference between my views and those prevailing in other quarters, that on my theory the 'sexual constitution' took the place of a 'general neuropathic disposition'. In my recently published *Three Essays on the Theory of Sexuality* (1905d) I have tried to give a picture of the variegated nature of this sexual constitution as well as of the composite character of the sexual instinct in general and its derivation from contributory sources from different parts of the organism.

[1906a, 1579]
The sexual instinct - or, more correctly, the sexual instincts, for analytic investigation teaches us that the sexual instinct is made up of many separate constituents or component instincts - is probably more strongly developed in man than in most of the higher animals; it is certainly more constant, since it has almost entirely overcome the periodicity to which it is tied in animals. It places extraordinarily large amounts of force at the disposal of civilized activity, and it does this in virtue of its especially marked characteristic of being able to displace its aim without materially diminishing in intensity. This capacity to exchange its originally sexual aim for another one, which is no longer sexual but which is psychically related to the first aim, is called the capacity for sublimation. In contrast to this displaceability, in which its value for civilization lies, the sexual instinct may also exhibit a particularly obstinate fixation which renders it unserviceable and which sometimes causes it to degenerate into what are described as abnormalities. The original strength of the sexual instinct probably varies in each individual; certainly the proportion of it which is suitable for sublimation varies. It seems to us that it is the innate constitution of each individual which decides in the first instance how large a part of his sexual instinct it will be possible to sublimate and make use of. In addition to this, the effects of experience and the intellectual influences upon his mental apparatus succeed in bringing about the sublimation of a further portion of it. To extend this process of displacement indefinitely is, however, certainly not possible, any more than is the case with the transformation of heat into mechanical energy in our machines. A certain amount of direct sexual satisfaction seems to be indispensable for most organizations, and a deficiency in this amount, which varies from individual to individual, is visited by phenomena which, on account of their detrimental effects on functioning and their subjective quality of unpleasure, must be regarded as an illness.

[1908d, 1952]

The sadistic theory of coitus which, taken in isolation, is misleading where it might have provided confirmatory evidence, is, once again, the expression of one of the innate components of the sexual instinct, any of which may be strongly marked to a greater or lesser degree in each particular child. For this reason the theory is correct up to a certain point; it has in part divined the nature of the sexual act and the 'sex-battle' that precedes it. Not infrequently, too, the child is in a position to support this view by accidental observations which he understands in part correctly, but also in part incorrectly and indeed in a reversed sense. In many marriages the wife does in fact recoil from her husband's embraces, which bring her no pleasure, but the risk of a fresh pregnancy. And so the child who is believed to be asleep (or who is pretending to be asleep) may receive an impression from his mother which he can only interpret as meaning that she is defending herself against an act of violence. At other times the whole marriage offers an observant child the spectacle of an unceasing quarrel, expressed in loud words and unfriendly gestures; so that he need not be surprised if the quarrel is carried on at night as well, and finally settled by the same method which he himself is accustomed to use in his relations with his brothers and sisters or playmates.

[1908c, 1975]
Where, then, does the libido find the fixations which it requires in order to break through the repressions? In the activities and experiences of infantile sexuality, in the abandoned component trends, in the objects of childhood which have been given up. It is to them, accordingly, that the libido returns. The significance of this period of childhood is twofold: on the one hand, during it the instinctual trends which the child has inherited with his innate disposition first become manifest, and secondly, others of his instincts are for the first time awakened and made active by external impressions and accidental experiences. There is no doubt, I think, that we are justified in making this twofold division. The manifestation of the innate disposition is indeed not open to any critical doubts, but analytic experience actually compels us to assume that purely chance experiences in childhood are able to leave fixations of the libido behind them. Nor do I see any theoretical difficulty in this. Constitutional dispositions are also undoubtedly after-effects of experiences by ancestors in the past; they too were once acquired. Without such acquisition there would be no heredity. And is it conceivable that acquisition such as this, leading to inheritance, would come to an end precisely with the generation we are considering? The significance of infantile experiences should not be totally neglected, as people like doing, in comparison with the experiences of the subject's ancestors and of his own maturity; on the contrary, they call for particular consideration. They are all the more momentous because they occur in times of incomplete development and are for that very reason liable to have traumatic effects. The studies on developmental mechanics by Roux and others have shown that the prick of a needle into an embryonic germinal layer in the act of cell-division results in a severe disturbance of development. The same injury inflicted on a larval or fully grown animal would do no damage.

The hereditary sexual constitution presents us with a great variety of dispositions, according as one component instinct or another, alone or in combination with others, is inherited in particular strength. The sexual constitution forms once again, together with the factor of infantile experience, a 'complemental series' exactly similar to the one we first came to know between disposition and the accidental experience of the adult. In both of them we find the same extreme cases and the same relations between the two factors concerned. And here the question suggests itself of whether the most striking kinds of libidinal regressions - those to earlier stages of the sexual organization - may not be predominantly determined by the hereditary constitutional factor. But it is best to postpone answering this question till we have been able to take a wider range of forms of neurotic illness into account.

These facts have a certain interest from the point of view of education, which plans the prevention of neuroses by intervening at an early stage in children's sexual development. So long as one focuses attention principally on infantile sexual experiences, one must suppose that one has done everything for the prophylaxis of nervous illnesses by taking care that the child's development is delayed and that it is spared experiences of the sort. We already know, however, that the preconditions for the causation of neuroses are complex and cannot be influenced in general if we take account of only a single factor. Strict protection of the young loses value because it is powerless against the constitutional factor. Besides, it is more difficult to carry out than educationists imagine and it brings with it two fresh dangers which must not be underestimated: the fact that it may achieve too much - that it may encourage an excess of sexual repression, with damaging results, and the fact that it may send the child out into life without any defence against the onrush of sexual demands that is to be looked for at puberty. Thus it remains extremely doubtful how far prophylaxis in childhood can be carried with advantage and whether an altered attitude to the immediate situation may not offer a better angle of approach for the prevention of neuroses.
You will no doubt have observed that in these last discussions I have introduced a fresh factor into the structure of the aetiological chain - namely the quantity, the magnitude, of the energies concerned. We have still to take this factor into account everywhere. A purely qualitative analysis of the aetiological determinants is not enough. Or, to put it another way, a merely dynamic view of these mental processes is insufficient; an economic line of approach is also needed. We must tell ourselves that the conflict between two trends does not break out till certain intensities of cathexis have been reached, even though the determinants for it have long been present so far as their subject-matter is concerned. In the same way, the pathogenic significance of the constitutional factors must be weighed according to how much more of one component instinct than of another is present in the inherited disposition. It may even be supposed that the disposition of all human beings is qualitatively alike and that they differ only owing to these quantitative conditions. The quantitative factor is no less decisive as regards capacity to resist neurotic illness. It is a matter of what quota of unemployed libido a person is able to hold in suspension and of how large a fraction of his libido he is able to divert from sexual to sublimated aims. The ultimate aim of mental activity, which may be described qualitatively as an endeavour to obtain pleasure and avoid unpleasure, emerges, looked at from the economic point of view, as the task of mastering the amounts of excitation (mass of stimuli) operating in the mental apparatus and of keeping down their accumulation which creates unpleasure.

[1916-1917, 3429]

(2) For cultural reasons the most intense repression falls upon the sexual instincts; but it is precisely in connection with them that repression most easily miscarries, so that neurotic symptoms are found to be substitutive satisfactions of repressed sexuality. The belief that in man sexual life begins only at puberty is incorrect. On the contrary, signs of it can be detected from the beginning of extra-uterine existence; it reaches a first culminating point at or before the fifth year ('early period'), after which it is inhibited or interrupted ('latency period') until the age of puberty, which is the second climax of its development. This diphasic onset of sexual development seems to be distinctive of the genus Homo. All experiences during the first period of childhood are of the greatest importance to the individual, and in combination with his inherited sexual constitution form the dispositions for the subsequent development of character and disease. It is wrong to make sexuality coincide with 'genitality'. The sexual instincts pass through a complicated course of development, and it is only at the end of it that the 'primacy of the genital zones' is attained. Before this there are a number of 'pregenital' organizations of the libido - points at which it may become 'fixated' and to which, in the event of subsequent repression, it will return ('regression'). The infantile fixations of the libido are what determine the form of any later neurosis. Thus the neuroses are to be regarded as inhibitions in the development of the libido. There are no specific causes of nervous disorders; the question whether a conflict finds a healthy solution or leads to a neurotic inhibition of function depends upon quantitative considerations.

[1926f, 4405]
Fenichel (1930) rightly emphasizes the difficulty of recognizing in the material produced in analysis what parts of it represent the unchanged content of the pre-Oedipus phase and what parts have been distorted by regression (or in other ways). He does not accept Jeanne Lampl-de Groot's assertion of the little girl's active attitude in the phallic phase. He also rejects the 'displacement backwards' of the Oedipus complex proposed by Melanie Klein (1928), who places its beginnings as early as the commencement of the second year of life. This dating of it, which would also necessarily imply a modification of our view of all the rest of the child's development, does not in fact correspond to what we learn from the analyses of adults, and it is especially incompatible with my findings as to the long duration of the girl's pre-Oedipus attachment to her mother. A means of softening this contradiction is afforded by the reflection that we are not as yet able to distinguish in this field between what is rigidly fixed by biological laws and what is open to movement and change under the influence of accidental experience. The effect of seduction has long been familiar to us and in just the same way other factors - such as the date at which the child's brothers and sisters are born or the time when it discovers the difference between the sexes, or again its direct observations of sexual intercourse or its parents' behaviour in encouraging or repelling it - may hasten the child's sexual development and bring it to maturity. [1931b, 4606]
ACCIDENTAL EXPERIENCES  No other influences on the course of sexual development can compare in importance with releases of sexuality, waves of repression and sublimations - the two latter being processes of which the inner causes are quite unknown to us. It might be possible to include repressions and sublimations as a part of the constitutional disposition, by regarding them as manifestations of it in life; and anyone who does so is justified in asserting that the final shape taken by sexual life is principally the outcome of the innate constitution. No one with perception will, however, dispute that an interplay of factors such as this also leaves room for the modifying effects of accidental events experienced in childhood and later. It is not easy to estimate the relative efficacy of the constitutional and accidental factors. In theory one is always inclined to overestimate the former; therapeutic practice emphasizes the importance of the latter. It should, however, of no account be forgotten that the relation between the two is a co-operative and not a mutually exclusive one. The constitutional factor must await experiences before it can make itself felt; the accidental factor must have a constitutional basis in order to come into operation. To cover the majority of cases we can picture what has been described as a 'complemental series', in which the diminishing intensity of one factor is balanced by the increasing intensity of the other; there is, however, no reason to deny the existence of extreme cases at the two ends of the series.

[1905d, 1550]

We shall be in even closer harmony with psycho-analytic research if we give a place of preference among the accidental factors to the experiences of early childhood. The single aetiological series then falls into two, which may be called the dispositional and the definitive. In the first the constitution and the accidental experiences of childhood interact in the same manner as do the disposition and later traumatic experiences in the second. All the factors that impair sexual development show their effects by bringing about a regression, a return to an earlier phase of development.

[1905d, 1550]

FIXATION  The ground prepared by the psychical factors which have just been enumerated affords a favourable basis for such stimulations of infantile sexuality as are experienced accidentally. The latter (first and foremost, seduction by other children or by adults) provide the material which, with the help of the former, can become fixated as a permanent disorder. A good proportion of the deviations from normal sexual life which are later observed both in neurotics and in perverts are thus established from the very first by the impressions of childhood - a period which is regarded as being devoid of sexuality. The causation is shared between a compliant constitution, precocity, the characteristic of increased pertinacity of early impressions and the chance stimulation of the sexual instinct by extraneous influences.

[1905d, 1552]
On the other hand, psycho-analysis has fully demonstrated the part played by social conditions and requirements in the causation of neurosis. The forces which, operating from the ego, bring about the restriction and repression of instinct owe their origin essentially to compliance with the demands of civilization. A constitution and a set of childhood experiences which, in other cases, would inevitably lead to a neurosis will produce no such result where this compliance is absent or where these demands are not made by the social circle in which the particular individual is placed. The old assertion that the increase in nervous disorders is a product of civilization is at least a half-truth. Young people are brought into contact with the demands of civilization by upbringing and example; and if instinctual repression occurs independently of these two factors, it is a plausible hypothesis to suppose that a primaeval and prehistoric demand has at last become part of the organized and inherited endowment of mankind. A child who produces instinctual repressions spontaneously is thus merely repeating a part of the history of civilization. What is today an act of internal restraint was once an external one, imposed, perhaps, by the necessities of the moment; and, in the same way, what is now brought to bear upon every growing individual as an external demand of civilization may some day become an internal disposition to repression. [1913j, 2824]

I take the opportunity here of warning you against taking sides in a quite unnecessary dispute. In scientific matters people are very fond of selecting one portion of the truth, putting it in the place of the whole and of then disputing the rest, which is no less true, in favour of this one portion. In just this way a number of schools of opinion have already split off from the psycho-analytic movement, some of which recognize the egoistic instincts while disavowing the sexual ones, and others attribute importance to the influence of the real tasks of life while overlooking the individual's past - and others besides. Now here we have a similar occasion for pointing a contrast and starting a controversy. Are neuroses exogenous or endogenous illnesses? Are they the inevitable result of a particular constitution or the product of certain detrimental (traumatic) experiences in life? More particularly, are they brought about by fixation of the libido (and the other features of the sexual constitution) or by the pressure of frustration? This dilemma seems to me no more sensible on the whole than another that I might put to you: does a baby come about through being begotten by its father or conceived by its mother? Both determinants are equally indispensable, as you will justly reply. In the matter of the causation of the neuroses the relation, if not precisely the same, is very similar. As regards their causation, instances of neurotic illness fall into a series within which the two factors - sexual constitution and experience, or, if you prefer it, fixation of the libido and frustration - are represented in such a manner that if there is more of the one there is less of the other. At one end of the series are the extreme cases of which you could say with conviction: these people, in consequence of the singular development of their libido, would have fallen ill in any case, whatever they had experienced and however carefully their lives had been sheltered. At the other end there are the cases, as to which, on the contrary, you would have had to judge that they would certainly have escaped falling ill if their lives had not brought them into this or that situation. In the cases lying within the series a greater or lesser amount of predisposition in the sexual constitution is combined with a lesser or greater amount of detrimental experience in their lives. Their sexual constitution would not have led them into a neurosis if they had not had these experiences, and these experiences would not have had a traumatic effect on them if their libido had been otherwise disposed. In this series I can perhaps allow a certain preponderance in significance to the predisposing factors; but even that admission depends on how far you choose to extend the frontiers of neurotic illness. [1916-1917, 3409]
Various sorts. In the first place, impressions capable of permanently influencing the child’s budding sexual life - such as observations of sexual activities between adults, or sexual experiences of his own with an adult or another child (no rare events); or, again, overhearing conversations, understood either at the time or retrospectively, from which the child thought it could draw conclusions about mysterious or uncanny matters; or again, remarks or actions by the child himself which give evidence of significant attitudes of affection or enmity towards other people. It is of special importance in an analysis to induce a memory of the patient's own forgotten sexual activity as a child and also of the intervention by the adults which brought it to an end.
[1926e, 4358]

Fenichel (1930) rightly emphasizes the difficulty of recognizing in the material produced in analysis what parts of it represent the unchanged content of the pre-Oedipus phase and what parts have been distorted by regression (or in other ways). He does not accept Jeanne Lampl-de Groot's assertion of the little girl's active attitude in the phallic phase. He also rejects the 'displacement backwards' of the Oedipus complex proposed by Melanie Klein (1928), who places its beginnings as early as the commencement of the second year of life. This dating of it, which would also necessarily imply a modification of our view of all the rest of the child's development, does not in fact correspond to what we learn from the analyses of adults, and it is especially incompatible with my findings as to the long duration of the girl's pre-Oedipus attachment to her mother. A means of softening this contradiction is afforded by the reflection that we are not as yet able to distinguish in this field between what is rigidly fixed by biological laws and what is open to movement and change under the influence of accidental experience. The effect of seduction has long been familiar to us and in just the same way other factors - such as the date at which the child's brothers and sisters are born or the time when it discovers the difference between the sexes, or again its direct observations of sexual intercourse or its parents’ behaviour in encouraging or repelling it - may hasten the child's sexual development and bring it to maturity.
[1931b, 4606]
Among the occurrences which recur again and again in the youthful history of neurotics - which are scarcely ever absent - there are a few of particular importance, which also deserve, on that account, I think, to be brought into greater prominence than the rest. As specimens of this class I will enumerate these: observation of parental intercourse, seduction by an adult and threat of being castrated. It would be a mistake to suppose that they are never characterized by material reality; on the contrary, this is often established incontestably through enquiries from older members of the patient's family. It is by no means a rare thing, for instance, for a little boy, who is beginning to play with his penis in a naughty way and is not yet aware that one must conceal such activities, to be threatened by a parent or nurse with having his penis or his sinful hand cut off. Parents will often admit this when they are asked, since they think they have done something useful in making such a threat; a number of people have a correct conscious memory of such a threat, especially if it was made at a somewhat later period. If the threat is delivered by the mother or some other female she usually shifts its performance on to the father or the doctor. In Struwwelpeter, the famous work of the Frankfurt paediatrician Hoffmann (which owes its popularity precisely to an understanding of the sexual and other complexes of childhood), you will find castration softened into a cutting-off of the thumbs as a punishment for obstinate sucking. But it is highly improbable that children are threatened with castration as often as it appears in the analyses of neurotics. We shall be satisfied by realizing that the child puts a threat of this kind together in his imagination on the basis of hints, helped out by a knowledge that auto-erotic satisfaction is forbidden and under the impression of his discovery of the female genitals. Nor is it only in proletarian families that it is perfectly possible for a child, while he is not yet credited with possessing an understanding or a memory, to be a witness of the sexual act between his parents or other grown-up people; and the possibility cannot be rejected that he will be able to understand and react to the impression in retrospect. If, however, the intercourse is described with the most minute details, which would be difficult to observe, or if, as happens most frequently, it turns out to have been intercourse from behind more ferarum [in the manner of animals], there can be no remaining doubt that the phantasy is based on an observation of intercourse between animals (such as dogs) and that its motive was the child's unsatisfied scopophilia during puberty. The extreme achievement on these lines is a phantasy of observing parental intercourse while one is still an unborn baby in the womb. Fantasies of being seduced are of particular interest, because so often they are not phantasies but real memories. Fortunately, however, they are nevertheless not real as often as seemed at first to be shown by the findings of analysis. Seduction by an older child or by one of the same age is even more frequent than by an adult; and if in the case of girls who produce such an event in the story of their childhood their father figures fairly regularly as the seducer, there can be no doubt either of the imaginary nature of the accusation or of the motive that has led to it. A phantasy of being seduced when no seduction has occurred is usually employed by a child to screen the auto-erotic period of his sexual activity. He spares himself shame about masturbation by retrospectively phantasying a desired object into these earliest times. You must not suppose, however, that sexual abuse of a child by its nearest male relatives belongs entirely to the realm of phantasy. Most analysts will have treated cases in which such events were real and could be unimpeachably established; but even so they related to the later years of childhood and had been transposed into earlier times.

[1916-1917, 3426]
The reappearance of sexual activity is determined by internal causes and external contingencies, both of which can be guessed in cases of neurotic illness from the form taken by their symptoms and can be discovered with certainty by psycho-analytic investigation. I shall have to speak presently of the internal causes; great and lasting importance attaches at this period to the accidental external contingencies. In the foreground we find the effects of seduction, which treats a child as a sexual object prematurely and teaches him, in highly emotional circumstances, how to obtain satisfaction from his genital zones, a satisfaction which he is then usually obliged to repeat again and again by masturbation. An influence of this kind may originate either from adults or from other children. I cannot admit that in my paper on 'The Aetiology of Hysteria' (1896) I exaggerated the frequency or importance of that influence, though I did not then know that persons who remain normal may have had the same experiences in their childhood, and though I consequently overrated the importance of seduction in comparison with the factors of sexual constitution and development.¹ Obviously seduction is not required in order to arouse a child's sexual life; that can also come about spontaneously from internal causes.

[1905d, 1510]

POLYMORPHOUSLY PERVERSE DISPOSITION It is an instructive fact that under the influence of seduction children can become polymorphously perverse, and can be led into all possible kinds of sexual irregularities. This shows that an aptitude for them is innately present in their disposition. There is consequently little resistance towards carrying them out, since the mental dams against sexual excesses - shame, disgust and morality - have either not yet been constructed at all or are only in course of construction, according to the age of the child. In this respect children behave in the same kind of way as an average uncultivated woman in whom the same polymorphously perverse disposition persists. Under ordinary conditions she may remain normal sexually, but if she is led on by a clever seducer she will find every sort of perversion to her taste, and will retain them as part of her own sexual activities. Prostitutes exploit the same polymorphous, that is, infantile, disposition for the purposes of their profession; and, considering the immense number of women who are prostitutes or who must be supposed to have an aptitude for prostitution without becoming engaged in it, it becomes impossible not to recognize that this same disposition to perversions of every kind is a general and fundamental human characteristic.

[1905d, 1510]
COMPONENT INSTINCTS  Moreover, the effects of seduction do not help to reveal the early
history of the sexual instinct; they rather confuse our view of it by
presenting children prematurely with a sexual object for which the infantile sexual instinct at first
shows no need. It must, however, be admitted that infantile sexual life, in spite of the
preponderating dominance of erotogenic zones, exhibits components which from the very first
involve other people as sexual objects. Such are the instincts of scopophilia, exhibitionism and
cruelty, which appear in a sense independently of erotogenic zones; these instincts do not enter
into intimate relations with genital life until later, but are already to be observed in childhood as
independent impulses, distinct in the first instance from erotogenic sexual activity. Small
children are essentially without shame, and at some periods of their earliest years show an
unmistakable satisfaction in exposing their bodies, with especial emphasis on the sexual parts.
The counterpart of this supposedly perverse inclination, curiosity to see other people's genitals,
probably, does not become manifest until somewhat later in childhood, when the obstacle set
up by a sense of shame has already reached a certain degree of development. Under the
influence of seduction the scopophilic perversion can attain great importance in the sexual life of
a child. But my researches into the early years of normal people, as well as of neurotic patients,
force me to the conclusion that scopophilia can also appear in children as a spontaneous
manifestation. Small children whose attention has once been drawn - as a rule by masturbation
- to their own genitals usually take the further step without help from outside and develop a
lively interest in the genitals of their playmates. Since opportunities for satisfying curiosity of this
kind usually occur only in the course of satisfying the two kinds of need for excretion, children of
this kind turn into voyeurs, eager spectators of the processes of micturition and defaecation.
When repression of these inclinations sets in, the desire to see other people's genitals (whether
of their own or the opposite sex) persists as a tormenting compulsion, which in some cases of
neurosis later affords the strongest motive force for the formation of symptoms.
[1905d, 1511]

It was not possible to say what amount of sexual activity can occur in childhood without being
described as abnormal or detrimental to further development. The nature of these sexual
manifestations was found to be predominantly masturbatory. Experience further showed that
the external influences of seduction are capable of provoking interruptions of the latency period
or even its cessation, and that in this connection the sexual instinct of children proves in fact to
be polymorphously perverse; it seems, moreover, that any such premature sexual activity
diminishes a child's educability.
[1905d, 1545]

FIXATION  The ground prepared by the psychical factors which have just been enumerated
affords a favourable basis for such stimulations of infantile sexuality as are
experienced accidentally. The latter (first and foremost, seduction by other children or by adults)
provide the material which, with the help of the former, can become fixated as a permanent
disorder. A good proportion of the deviations from normal sexual life which are later observed
both in neurotics and in perverts are thus established from the very first by the impressions of
childhood - a period which is regarded as being devoid of sexuality. The causation is shared
between a compliant constitution, precocity, the characteristic of increased pertinacity of early
impressions and the chance stimulation of the sexual instinct by extraneous influences.
[1905d, 1552]

¹ Increase in pertinacity may also possibly be the effect of an especially intense somatic manifestation of
sexuality in early years.
[1905d, 1552]
Among the occurrences which recur again and again in the youthful history of neurotics - which are scarcely ever absent - there are a few of particular importance, which also deserve, on that account, I think, to be brought into greater prominence than the rest. As specimens of this class I will enumerate these: observation of parental intercourse, seduction by an adult and threat of being castrated. It would be a mistake to suppose that they are never characterized by material reality; on the contrary, this is often established incontestably through enquiries from older members of the patient's family. It is by no means a rare thing, for instance, for a little boy, who is beginning to play with his penis in a naughty way and is not yet aware that one must conceal such activities, to be threatened by a parent or nurse with having his penis or his sinful hand cut off. Parents will often admit this when they are asked, since they think they have done something useful in making such a threat; a number of people have a correct conscious memory of such a threat, especially if it was made at a somewhat later period. If the threat is delivered by the mother or some other female she usually shifts its performance on to the father or the doctor. In Struwwelpeter, the famous work of the Frankfurt paediatrician Hoffmann (which owes its popularity precisely to an understanding of the sexual and other complexes of childhood), you will find castration softened into a cutting-off of the thumbs as a punishment for obstinate sucking. But it is highly improbable that children are threatened with castration as often as it appears in the analyses of neurotics. We shall be satisfied by realizing that the child puts a threat of this kind together in his imagination on the basis of hints, helped out by a knowledge that auto-erotic satisfaction is forbidden and under the impression of his discovery of the female genitals. Nor is it only in proletarian families that it is perfectly possible for a child, while he is not yet credited with possessing an understanding or a memory, to be a witness of the sexual act between his parents or other grown-up people; and the possibility cannot be rejected that he will be able to understand and react to the impression in retrospect. If, however, the intercourse is described with the most minute details, which would be difficult to observe, or if, as happens most frequently, it turns out to have been intercourse from behind more ferarum [in the manner of animals], there can be no remaining doubt that the phantasy is based on an observation of intercourse between animals (such as dogs) and that its motive was the child's unsatisfied scopophilia during puberty. The extreme achievement on these lines is a phantasy of observing parental intercourse while one is still an unborn baby in the womb. Phantasies of being seduced are of particular interest, because so often they are not phantasies but real memories. Fortunately, however, they are nevertheless not real as often as seemed at first to be shown by the findings of analysis. Seduction by an older child or by one of the same age is even more frequent than by an adult; and if in the case of girls who produce such an event in the story of their childhood their father figures fairly regularly as the seducer, there can be no doubt either of the imaginary nature of the accusation or of the motive that has led to it. A phantasy of being seduced when no seduction has occurred is usually employed by a child to screen the auto-erotic period of his sexual activity. He spares himself shame about masturbation by retrospectively phantasying a desired object into these earliest times. You must not suppose, however, that sexual abuse of a child by its nearest male relatives belongs entirely to the realm of phantasy. Most analysts will have treated cases in which such events were real and could be unimpeachably established; but even so they related to the later years of childhood and had been transposed into earlier times.

[1916-1917, 3426]
Before going further into the question of infantile sexuality I must mention an error into which I fell for a while and which might well have had fatal consequences for the whole of my work. Under the influence of the technical procedure which I used at that time, the majority of my patients reproduced from their childhood scenes in which they were sexually seduced by some grown-up person. With female patients the part of seducer was almost always assigned to their father. I believed these stories, and consequently supposed that I had discovered the roots of the subsequent neurosis in these experiences of sexual seduction in childhood. My confidence was strengthened by a few cases in which relations of this kind with a father, uncle, or elder brother had continued up to an age at which memory was to be trusted. If the reader feels inclined to shake his head at my credulity, I cannot altogether blame him; though I may plead that this was at a time when I was intentionally keeping my critical faculty in abeyance so as to preserve an unprejudiced and receptive attitude towards the many novelties which were coming to my notice every day. When, however, I was at last obliged to recognize that these scenes of seduction had never taken place, and that they were only phantasies which my patients had made up or which I myself had perhaps forced on them, I was for some time completely at a loss. My confidence alike in my technique and in its results suffered a severe blow; it could not be disputed that I had arrived at these scenes by a technical method which I considered correct, and their subject-matter was unquestionably related to the symptoms from which my investigation had started. When I had pulled myself together, I was able to draw the right conclusions from my discovery: namely, that the neurotic symptoms were not related directly to actual events but to wishful phantasies, and that as far as the neurosis was concerned psychical reality was of more importance than material reality. I do not believe even now that I forced the seduction-phantasies on my patients, that I 'suggested' them. I had in fact stumbled for the first time upon the *Oedipus complex*, which was later to assume such an overwhelming importance, but which I did not recognize as yet in its disguise of phantasy. Moreover, seduction during childhood retained a certain share, though a humbler one, in the aetiology of neuroses. But the seducers turned out as a rule to have been older children.

[1925d, 4210]
These are unwelcome complications, considering that we only set out to study simple cases of symptom-formation due to repression, and with that intention selected the earliest and to all appearances, most transparent neuroses of childhood. Instead of a single repression we have found a collection of them and have become involved with regression into the bargain. Perhaps we have added to the confusion by treating the two cases of animal phobia at our disposal - 'Little Hans' and the 'Wolf Man' - as though they were cast in the same mould. As a matter of fact, certain differences between them stand out. It is only with regard to 'Little Hans' that we can say with certainty that what his phobia disposed of were the two main impulses of the Oedipus complex - his aggressiveness towards his father and his over-fondness for his mother. A tender feeling for his father was undoubtedly there too and played a part in repressing the opposite feeling; but we can prove neither that it was strong enough to draw repression upon itself nor that it disappeared afterwards. 'Hans' seems, in fact, to have been a normal boy with what is called a 'positive' Oedipus complex. It is possible that the factors which we do not find were actually at work in him, but we cannot demonstrate their existence. Even the most exhaustive analysis has gaps in its data and is insufficiently documented. In the case of the Russian the deficiency lies elsewhere. His attitude to female objects had been disturbed by an early seduction and his passive, feminine side was strongly developed. The analysis of his wolf-dream revealed very little intentional aggressiveness towards his father, but it brought forward unmistakable proof that what repression overtook was his passive tender attitude to his father. In his case, too, the other factors may have been operative as well; but they were not in evidence. How is it that, in spite of these differences in the two cases, almost amounting to an antithesis, the final outcome - a phobia - was approximately the same? The answer must be sought in another quarter. I think it will be found in the second fact which emerges from our brief comparative examination. It seems to me that in both cases we can detect what the motive force of the repression was and can substantiate our view of its nature from the line of development which the two children subsequently pursued. This motive force was the same in both of them. It was the fear of impending castration. 'Little Hans' gave up his aggressiveness towards his father from fear of being castrated. His fear that a horse would bite him can, without any forcing, be given the full sense of a fear that a horse would bite off his genitals, would castrate him. But it was from fear of being castrated, too, that the little Russian relinquished his wish to be loved by his father, for he thought that a relation of that sort presupposed a sacrifice of his genitals - of the organ which distinguished him from a female. As we see, both forms of the Oedipus complex, the normal, active form and the inverted one, came to grief through the castration complex. The Russian boy's anxiety-idea of being devoured by a wolf contained, it is true, no suggestion of castration, for the oral regression it had undergone had removed it too far from the phallic stage. But the analysis of his dream rendered further proof superfluous. It was a triumph of repression that the form in which his phobia was expressed should no longer have contained any allusion to castration.

[1926d, 4267]

Various sorts. In the first place, impressions capable of permanently influencing the child's budding sexual life - such as observations of sexual activities between adults, or sexual experiences of his own with an adult or another child (no rare events); or, again, overhearing conversations, understood either at the time or retrospectively, from which the child thought it could draw conclusions about mysterious or uncanny matters; or again, remarks or actions by the child himself which give evidence of significant attitudes of affection or enmity towards other people. It is of special importance in an analysis to induce a memory of the patient's own forgotten sexual activity as a child and also of the intervention by the adults which brought it to an end.

[1926e, 4358]
Little girls usually discover for themselves their characteristic phallic activity - masturbation of the clitoris; and to begin with this is no doubt unaccompanied by phantasy. The part played in starting it by nursery hygiene is reflected in the very common phantasy which makes the mother or nurse into a seducer. Whether little girls masturbate less frequently and from the first less energetically than little boys is not certain; quite possibly it is so. Actual seduction, too, is common enough; it is initiated either by other children or by someone in charge of the child who wants to soothe it, or send it to sleep or make it dependent on them. Where seduction intervenes it invariably disturbs the natural course of the developmental processes, and it often leaves behind extensive and lasting consequences.

Fenichel (1930) rightly emphasizes the difficulty of recognizing in the material produced in analysis what parts of it represent the unchanged content of the pre-Oedipus phase and what parts have been distorted by regression (or in other ways). He does not accept Jeanne Lampl-de Groot's assertion of the little girl's active attitude in the phallic phase. He also rejects the 'displacement backwards' of the Oedipus complex proposed by Melanie Klein (1928), who places its beginnings as early as the commencement of the second year of life. This dating of it, which would also necessarily imply a modification of our view of all the rest of the child's development, does not in fact correspond to what we learn from the analyses of adults, and it is especially incompatible with my findings as to the long duration of the girl's pre-Oedipus attachment to her mother. A means of softening this contradiction is afforded by the reflection that we are not as yet able to distinguish in this field between what is rigidly fixed by biological laws and what is open to movement and change under the influence of accidental experience. The effect of seduction has long been familiar to us and in just the same way other factors - such as the date at which the child's brothers and sisters are born or the time when it discovers the difference between the sexes, or again its direct observations of sexual intercourse or its parents' behaviour in encouraging or repelling it - may hasten the child's sexual development and bring it to maturity.

Analytic experience has convinced us of the complete truth of the assertion so often to be heard that the child is psychologically father to the adult and that the events of his first years are of paramount importance for his whole later life. It will thus be of special interest to us if there is something that may be described as the central experience of this period of childhood. Our attention is first attracted by the effects of certain influences which do not apply to all children, though they are common enough - such as the sexual abuse of children by adults, their seduction by other children (brothers or sisters) slightly their seniors, and, what we should not expect, their being deeply stirred by seeing or hearing at first hand sexual behaviour between adults (their parents) mostly at a time at which one would not have thought they could either be interested in or understand any such impressions, or be capable of remembering them later. It is easy to confirm the extent to which such experiences arouse a child's susceptibility and force his own sexual urges into certain channels from which they cannot afterwards depart. Since these impressions are subjected to repression either at once or as soon as they seek to return as memories, they constitute the determinant for the neurotic compulsion which will subsequently make it impossible for the ego to control the sexual function and will probably cause it to turn away from that function permanently. If this latter reaction occurs, the result will be a neurosis; if it is absent, a variety of perversions will develop, or the function, which is of immense importance not only for reproduction but also for the entire shaping of life, will become totally unmanageable.
TEMPORAL FACTORS   Other factors which, along with precocity, may be classed as temporal also deserve attention. The order in which the various instinctual impulses come into activity seems to be phylogenetically determined; so, too, does the length of time during which they are able to manifest themselves before they succumb to the effects of some freshly emerging instinctual impulse or to some typical repression. Variations, however, seem to occur both in temporal sequence and in duration, and these variations must exercise a determining influence upon the final result. It cannot be a matter of indifference whether a given current makes its appearance earlier or later than a current flowing in the opposite direction, for the effect of a repression cannot be undone. Divergences in the temporal sequence in which the components come together invariably produce a difference in the outcome. On the other hand, instinctual impulses which emerge with special intensity often run a surprisingly short course - as, for instance, the heterosexual attachment of persons who later become manifest homosexuals. There is no justification for the fear that trends which set in with the greatest violence in childhood will permanently dominate the adult character; it is just as likely that they will disappear and make way for an opposite tendency. ('Gestrenge Herren regieren nicht Lange.')¹

If we consider a number of analyses of obsessional neurotics we shall find it impossible to escape the impression that a relation between love and hatred such as we have found in our present patient is among the most frequent, the most marked, and probably, therefore, the most important characteristics of obsessional neurosis. But however tempting it may be to bring the problem of the 'choice of neurosis' into connection with instinctual life, there are reasons enough for avoiding such a course. For we must remember that in every neurosis we come upon the same suppressed instincts behind the symptoms. After all, hatred, kept suppressed in the unconscious by love, plays a great part in the pathogenesis of hysteria and paranoia. We know too little of the nature of love to be able to arrive at any definite conclusion here; and, in particular, the relation between the negative factor¹ in love and the sadistic components of the libido remains completely obscure. What follows is therefore to be regarded as no more than a provisional explanation. We may suppose, then, that in the cases of unconscious hatred with which we are concerned the sadistic components of love have, from constitutional causes, been exceptionally strongly developed, and have consequently undergone a premature and all too thorough suppression, and that the neurotic phenomena we have observed arise on the one hand from conscious feelings of affection which have become exaggerated as a reaction, and on the other hand from sadism persisting in the unconscious in the form of hatred.

¹[1905d, 1551]

¹[1909d, 2187]
PRECOCITY  One such factor is spontaneous sexual precocity, whose presence at least can be demonstrated with certainty in the aetiology of the neuroses though, like other factors, it is not in itself a sufficient cause. It is manifested in the interruption, abbreviation or bringing to an end of the infantile period of latency; and it is a cause of disturbances by occasioning sexual manifestations which, owing on the one hand to the sexual inhibitions being incomplete and on the other hand to the genital system being undeveloped, are bound to be in the nature of perversions. These tendencies to perversion may thereafter either persist as such or, after repressions have set in, become the motive forces of neurotic symptoms. In any case sexual precocity makes more difficult the later control of the sexual instinct by the higher mental agencies which is so desirable, and it increases the impulsive quality which, quite apart from this, characterizes the psychical representations of the instinct. Sexual precocity often runs parallel with premature intellectual development and, linked in this way, is to be found in the childhood history of persons of the greatest eminence and capacity; under such conditions its effects do not seem to be so pathogenic as when it appears in isolation.

[1905d, 1551]

FIXATION  The ground prepared by the psychical factors which have just been enumerated affords a favourable basis for such stimulations of infantile sexuality as are experienced accidentally. The latter (first and foremost, seduction by other children or by adults) provide the material which, with the help of the former, can become fixated as a permanent disorder. A good proportion of the deviations from normal sexual life which are later observed both in neurotics and in perverts are thus established from the very first by the impressions of childhood - a period which is regarded as being devoid of sexuality. The causation is shared between a compliant constitution, precocity, the characteristic of increased pertinacity of early impressions and the chance stimulation of the sexual instinct by extraneous influences.

[1905d, 1552]

In the first place Hans was not what one would understand, strictly speaking, by a degenerate child, condemned by his heredity to be a neurotic. On the contrary, he was well formed physically, and was a cheerful, amiable, active-minded young fellow who might give pleasure to more people than his own father. There can be no question, of course, as to his sexual precocity; but on that point there is very little material upon which a fair comparison can be based. I gather, for instance, from a piece of collective research conducted in America, that it is by no means such a rare thing to find object-choice and feelings of love in boys at a similarly early age; and the same may be learnt from studying the records of the childhood of men who have later come to be recognized as 'great'. I should therefore be inclined to believe that sexual precocity is a correlate, which is seldom absent, of intellectual precocity, and that it is therefore to be met with in gifted children more often than might be expected.

[1909b, 2119]

There can be no question that there was something in the sphere of sexuality that stood between the father and son, and that the father had come into some sort of opposition to the son's prematurely developed erotic life. Several years after his father's death, the first time he experienced the pleasurable sensations of copulation, an idea sprang into his mind: 'This is glorious! One might murder one's father for this!' This was at once an echo and an elucidation of the obsessional ideas of his childhood. Moreover, his father, shortly before his death, had directly opposed what later became our patient's dominating passion. He had noticed that his son was always in the lady's company, and had advised him to keep away from her, saying that it was imprudent of him and that he would only make a fool of himself.

[1909d, 2158]
PERTINACITY OF EARLY IMPRESSIONS  The importance of all early sexual manifestations is increased by a psychical factor of unknown origin, which at the moment, it must be admitted, can only be brought forward as a provisional psychological concept. I have in mind the fact that, in order to account for the situation, it is necessary to assume that these early impressions of sexual life are characterized by an increased pertinacity or susceptibility to fixation in persons who are later to become neurotics or perverts. For the same premature sexual manifestations, when they occur in other persons, fail to make so deep an impression; they do not tend in a compulsive manner towards repetition nor do they lay down the path to be taken by the sexual instinct for a whole lifetime. Part of the explanation of this pertinacity of early impressions may perhaps lie in another psychical factor which we must not overlook in the causation of the neuroses, namely the preponderance attaching in mental life to memory-traces in comparison with recent impressions. This factor is clearly dependent on intellectual education and increases in proportion to the degree of individual culture. The savage has been described in contrast as 'das unglückselige Kind des Augenblickes' ['The hapless child of the moment.'].¹ In consequence of the inverse relation holding between civilization and the free development of sexuality, of which the consequences can be followed far into the structure of our existences, the course taken by the sexual life of a child is just as unimportant for later life where the cultural or social level is relatively low as it is important where that level is relatively high.

[F1905d, 1552]

FIXATION  The ground prepared by the psychical factors which have just been enumerated affords a favourable basis for such stimulations of infantile sexuality as are experienced accidentally. The latter (first and foremost, seduction by other children or by adults) provide the material which, with the help of the former, can become fixated as a permanent disorder. A good proportion of the deviations from normal sexual life which are later observed both in neurotics and in perverts are thus established from the very first by the impressions of childhood - a period which is regarded as being devoid of sexuality. The causation is shared between a compliant constitution, precocity, the characteristic of increased pertinacity of early impressions and the chance stimulation of the sexual instinct by extraneous influences.

[F1905d, 1552]
The new sexual aim in men consists in the discharge of the sexual products. The earlier one, the attainment of pleasure, is by no means alien to it; on the contrary, the highest degree of pleasure is attached to this final act of the sexual process. The sexual instinct is now subordinated to the reproductive function; it becomes, so to say, altruistic. If this transformation is to succeed, the original dispositions and all the other characteristics of the instincts must be taken into account in the process. Just as on any other occasion on which the organism should by rights make new combinations and adjustments leading to complicated mechanisms, here too there are possibilities of pathological disorders if these new arrangements are not carried out. Every pathological disorder of sexual life is rightly to be regarded as an inhibition in development.

We shall be in even closer harmony with psycho-analytic research if we give a place of preference among the accidental factors to the experiences of early childhood. The single aetiological series then falls into two, which may be called the dispositional and the definitive. In the first the constitution and the accidental experiences of childhood interact in the same manner as do the disposition and later traumatic experiences in the second. All the factors that impair sexual development show their effects by bringing about a regression, a return to an earlier phase of development.

I do not know how the case could be better stated, but perhaps I may add a few remarks. It is undoubtedly nothing else but the customary prudishness and their own bad conscience over sexual matters that causes adults to adopt this attitude of 'mystery-making' in front of children; but possibly a part is also played by a piece of theoretical ignorance on their part, which we can counteract by giving the adults some enlightenment. It is commonly believed that the sexual instinct is absent in children and only begins to emerge in them at puberty when the sexual organs mature. This is a gross error, equally serious in its effects both on knowledge and on practice; and it is so easily corrected by observation that one wonders how it could ever have been made. As a matter of fact, the new-born baby brings sexuality with it into the world, certain sexual sensations accompany its development as a suckling and during early childhood, and only very few children would seem to escape sexual activities and sensations before puberty. Anyone who would like to find a detailed exposition of these statements can do so in my Three Essays on the Theory of Sexuality, to which I have referred above. There he will learn that the organs of reproduction proper are not the only parts of the body which provide sexual sensations of pleasure, and that nature has even so ordered matters that actual stimulations of the genitals are unavoidable during early childhood. This period of life, during which a certain quota of what is undoubtedly sexual pleasure is produced by the excitation of various parts of the skin (erotogenic zones), by the activity of certain biological instincts and as an accompanying excitation in many affective states, is called the period of auto-erotism, to use a term introduced by Havelock Ellis. All that puberty does is to give the genitals primacy among all the other zones and sources which produce pleasure, and thus to force erotism into the service of the function of reproduction. This process can naturally undergo certain inhibitions, and in many people (those who later become perverts and neurotics) it is only incompletely accomplished. On the other hand, the child is capable long before puberty of most of the psychical manifestations of love-tenderness, for example, devotion and jealousy. Often enough, too, an irruption of these mental states is associated with the physical sensations of sexual excitation, so that the child cannot remain in doubt as to the connection between the two. In short, except for his reproductive power, a child has a fully-developed capacity for love long before puberty; and it may be asserted that the 'mystery-making’ merely prevents him from being able to gain an intellectual grasp of activities for which he is psychically prepared and physically adjusted.

[1907c, 1914]
The sexual instinct - or, more correctly, the sexual instincts, for analytic investigation teaches us that the sexual instinct is made up of many separate constituents or component instincts - is probably more strongly developed in man than in most of the higher animals; it is certainly more constant, since it has almost entirely overcome the periodicity to which it is tied in animals. It places extraordinarily large amounts of force at the disposal of civilized activity, and it does this in virtue of its especially marked characteristic of being able to displace its aim without materially diminishing in intensity. This capacity to exchange its originally sexual aim for another one, which is no longer sexual but which is psychically related to the first aim, is called the capacity for sublimation. In contrast to this displaceability, in which its value for civilization lies, the sexual instinct may also exhibit a particularly obstinate fixation which renders it unserviceable and which sometimes causes it to degenerate into what are described as abnormalities. The original strength of the sexual instinct probably varies in each individual; certainly the proportion of it which is suitable for sublimation varies. It seems to us that it is the innate constitution of each individual which decides in the first instance how large a part of his sexual instinct it will be possible to sublimate and make use of. In addition to this, the effects of experience and the intellectual influences upon his mental apparatus succeed in bringing about the sublimation of a further portion of it. To extend this process of displacement indefinitely is, however, certainly not possible, any more than is the case with the transformation of heat into mechanical energy in our machines. A certain amount of direct sexual satisfaction seems to be indispensable for most organizations, and a deficiency in this amount, which varies from individual to individual, is visited by phenomena which, on account of their detrimental effects on functioning and their subjective quality of unpleasure, must be regarded as an illness.

If we take the second of these stages as an average, we must point out that a number of people are, on account of their organization, not equal to meeting its demands. In whole classes of individuals the development of the sexual instinct, as we have described it above, from auto-erotism to object-love with its aim of uniting the genitals, has not been carried out correctly and sufficiently fully. As a result of these disturbances of development two kinds of harmful deviation from normal sexuality - that is, sexuality which is serviceable to civilization - come about; and the relation between these two is almost that of positive and negative.¹

In the first place (disregarding people whose sexual instinct is altogether excessive and uninhibitable) there are the different varieties perverts, in whom an infantile fixation to a preliminary sexual aim has prevented the primacy of the reproductive function from being established, and the homosexuals or inverts, in whom, in a manner that is not yet quite understood, the sexual aim has been deflected away from the opposite sex. If the injurious effects of these two kinds of developmental disturbance are less than might be expected, this mitigation can be ascribed precisely to the complex way in which the sexual instinct is put together, which makes it possible for a person's sexual life to reach a serviceable final form even if one or more components of the instinct have been shut off from development. The constitution of people suffering from inversion - the homosexuals - is, indeed, often distinguished by their sexual instinct's possessing a special aptitude for cultural sublimation.

[1908d, 1952]

[1908d, 1953]
To this unimpeachable body of evidence we shall be able to add fresh material, if we turn to
the history of the masturbatory side of our patient's sexual activities. There is a conflict between
the opinions of doctors and patients on this subject which has not hitherto been properly
appreciated. The patients are unanimous in their belief that masturbation, by which they mean
masturbation during puberty, is the root and origin of all their troubles. The doctors are, upon
the whole, unable to decide what line to take; but, influenced by the knowledge that not only
neurotics but most normal people pass through a period of masturbation during their puberty,
the majority of them are inclined to dismiss the patients' assertions as gross exaggerations. In
my opinion the patients are once again nearer to a correct view than the doctors; for the
patients have some glimmering notion of the truth, while the doctors are in danger of
overlooking an essential point. The thesis propounded by the patients certainly does not
correspond to the facts in the sense in which they themselves construe it, namely, that
masturbation during puberty (which may almost be described as a typical occurrence) is
responsible for all neurotic disturbances. Their thesis requires interpretation. The masturbation
of puberty is in fact no more than a revival of the masturbation of infancy, a subject which has
hitherto invariably been neglected. Infantile masturbation reaches a kind of climax, as a rule,
between the ages of three and four or five; and it is the clearest expression of a child's sexual
constitution, in which the aetiology of subsequent neuroses must be sought. In this disguised
way, therefore, the patients are putting the blame for their illnesses upon their infantile sexuality;
and they are perfectly right in doing so. On the other hand, the problem of masturbation
becomes insoluble if we attempt to treat it as a clinical unit, and forget that it can represent the
discharge of every variety of sexual component and of every sort of phantasy to which such
components can give rise. The injurious effects of masturbation are only in a very small degree
autonomous - that is to say, determined by its own nature. They are in substance merely part
and parcel of the pathogenic significance of the subject's sexual life as a whole. The fact that so
many people can tolerate masturbation - that is, a certain amount of it - without injury merely
shows that their sexual constitution and the course of development of their sexual life have
been such as to allow them to exercise the sexual function within the limits of what is culturally
permissible; whereas other people, because their sexual constitution has been less favourable
or their development has been disturbed, fall ill as a result of their sexuality - they cannot, that
is, achieve the necessary suppression or sublimation of their sexual components without having
recourse to inhibitions or substitutes.¹

When striking cases of psychical impotence are exhaustively investigated by means of
psycho-analysis, the following information is obtained about the psychosexual processes at
work in them. Here again - as very probably in all neurotic disturbances - the foundation of the
disorder is provided by an inhibition in the developmental history of the libido before it assumes
the form which we take to be its normal termination. Two currents whose union is necessary to
ensure a completely normal attitude in love have, in the cases we are considering, failed to
combine. These two may be distinguished as the affectionate and the sensual current.

We have reduced psychical impotence to the failure of the affectionate and the sensual
currents in love to combine, and this developmental inhibition has in turn been explained as
being due to the influences of strong childhood fixations and of later frustration in reality through
the intervention of the barrier against incest. There is one principal objection to the theory we
advance; it does too much. It explains why certain people suffer from psychical impotence, but it
leaves us with the apparent mystery of how others have been able to escape this disorder.
Since we must recognize that all the relevant factors known to us - the strong childhood fixation,
the incest-barrier and the frustration in the years of development after puberty - are to be found
in practically all civilized human beings, we should be justified in expecting psychical impotence
to be a universal affliction under civilization and not a disorder confined to some individuals.
In my *Three Essays on the Theory of Sexuality* I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics *endeavour to protect themselves against any such sexualization of their social instinctual cathexes*, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) *schizophrenia*; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.

[1911c, 2431]

We are, I think, in agreement with the theories of general pathology in assuming that a development of this kind involves two dangers - first, of *inhibition*, and secondly, of *regression*. That is to say, in view of the general tendency of biological processes to variation, it is bound to be the case that not every preparatory phase will be passed through with equal success and completely superseded: portions of the function will be permanently held back at these early stages, and the total picture of development will be qualified by some amount of developmental inhibition.

[1916-1917, 3403]
Let us look for some analogies to these processes in other fields of knowledge. When, as often happened at early periods of human history, a whole people left their place of domicile and sought a new one, we may be certain that the whole of them did not arrive at the new location. Apart from other losses, it must regularly have happened that small groups or bands of the migrants halted on the way and settled at these stopping places while the main body went further. Or, as you know, to turn to a nearer comparison, in the highest mammals the male sex-glands, which are originally situated deep in the abdominal cavity, start upon a migration at a particular stage of intra-uterine life, which brings them almost directly under the skin of the pelvic extremity. As a consequence of this migration, we find in a number of male individuals that one of these paired organs has remained behind in the pelvic cavity, or that it has become permanently lodged in what is known as the inguinal canal, through which both organs must pass in the course of their migration, or at least that this canal has remained open, though it should normally close up after the sex-glands have completed their change of situation. Or again, when as a young student I was engaged under von Brücke's direction on my first piece of scientific work, I was concerned with the origin of the posterior nerve-roots in the spinal cord of a small fish of very archaic structure; I found that the nerve-fibres of these roots have their origin in large cells in the posterior horn of the grey matter, which is no longer the case in other vertebrates. But I also discovered soon afterwards that nerve-cells of this kind are present outside the grey matter the whole way to what is known as the spinal ganglion of the posterior root; and from this I inferred that the cells of these masses of ganglia had migrated from the spinal cord along the roots of the nerves. This is also shown by their evolutionary history. But in this small fish the whole path of their migration was demonstrated by the cells that had remained behind.

The second danger in a development by stages of this sort lies in the fact that the portions which have proceeded further may also easily return retrogressively to one of these earlier stages - what we describe as a regression. The trend will find itself led into a regression of this kind if the exercise of its function - that is, the attainment of its aim of satisfaction - is met, in its later or more highly developed form, by powerful external obstacles. It is plausible to suppose that fixation and regression are not independent of each other. The stronger the fixations on its path of development, the more readily will the function evade external difficulties by regressing to the fixations - the more incapable, therefore, does the developed function turn out to be of resisting external obstacles in its course. Consider that, if a people which is in movement has left strong detachments behind at the stopping-places on its migration, it is likely that the more advanced parties will be inclined to retreat to these stopping-places if they have been defeated or have come up against a superior enemy. But they will also be in the greater danger of being defeated the more of their number they have left behind on their migration.
The Development of the Libido. - The sexual instinct, the dynamic manifestation of which in mental life we shall call 'libido', is made up of component instincts into which it may once more break up and which are only gradually united into well-defined organizations. The sources of these component instincts are the organs of the body and in particular certain specially marked erogenous zones; but contributions are made to libido from every important functional process in the body. At first the individual component instincts strive for satisfaction independently of one another, but in the course of development they become more and more convergent and concentrated. The first (pregenital) stage of organization to be discerned is the oral one, in which - in conformity with the suckling's predominant interest - the oral zone plays the leading part. This is followed by the sadistic-anal organization, in which the anal zone and the component instinct of sadism are particularly prominent; at this stage the difference between the sexes is represented by the contrast between active and passive. The third and final stage of organization is that in which the majority of the component instincts converge under the primacy of the genital zones. As a rule this development is passed through swiftly and unobtrusively; but some individual portions of the instincts remain behind at the prodromal stages of the process and thus give rise to fixations of libido, which are important as constituting predispositions for subsequent eruptions of repressed impulses and which stand in a definite relation to the later development of neuroses and perversions. (See the article on 'The Libido Theory'.) [1923a, 3921]

The sexual function, as I found, is in existence from the very beginning of the individual's life, though at first it is attached to the other vital functions and does not become independent of them until later; it has to pass through a long and complicated process of development before it becomes what we are familiar with as the normal sexual life of the adult. It begins by manifesting itself in the activity of a whole number of component instincts. These are dependent upon erogenous zones in the body; some of them make their appearance in pairs of opposite impulses (such as sadism and masochism or the impulses to look and to be looked at); they operate independently of one another in a search for pleasure, and they find their object for the most part in the subject's own body. Thus at first the sexual function is non-centralized and predominantly auto-erotic. Later, syntheses begin to appear in it; a first stage of organization is reached under the dominance of the oral components, an anal-sadistic stage follows, and it is only after the third stage has at last been reached that the primacy of the genitals is established and that the sexual function begins to serve the ends of reproduction. In the course of this process of development a number of elements of the various component instincts turn out to be unserviceable for this last end and are therefore left on one side or turned to other uses, while others are diverted from their aims and carried over into the genital organization. I gave the name of libido to the energy of the sexual instincts and to that form of energy alone. I was next driven to suppose that the libido does not always pass through its prescribed course of development smoothly. As a result either of the excessive strength of certain of the components or of experiences involving premature satisfaction, fixations of the libido may occur at various points in the course of its development. If subsequently a repression takes place, the libido flows back to these points (a process described as regression), and it is from them that the energy breaks through in the form of a symptom. Later on it further became clear that the localization of the point of fixation is what determines the choice of neurosis, that is, the form in which the subsequent illness makes its appearance. [1925d, 4211]
(2) For cultural reasons the most intense repression falls upon the sexual instincts; but it is precisely in connection with them that repression most easily miscarries, so that neurotic symptoms are found to be substitutive satisfactions of repressed sexuality. The belief that in man sexual life begins only at puberty is incorrect. On the contrary, signs of it can be detected from the beginning of extra-uterine existence; it reaches a first culminating point at or before the fifth year ('early period'), after which it is inhibited or interrupted ('latency period') until the age of puberty, which is the second climax of its development. This diphasic onset of sexual development seems to be distinctive of the genus Homo. All experiences during the first period of childhood are of the greatest importance to the individual, and in combination with his inherited sexual constitution form the dispositions for the subsequent development of character and disease. It is wrong to make sexuality coincide with 'genitality'. The sexual instincts pass through a complicated course of development, and it is only at the end of it that the 'primacy of the genital zones' is attained. Before this there are a number of 'pregenital' organizations of the libido - points at which it may become 'fixated' and to which, in the event of subsequent repression, it will return ('regression'). The infantile fixations of the libido are what determine the form of any later neurosis. Thus the neuroses are to be regarded as inhibitions in the development of the libido. There are no specific causes of nervous disorders; the question whether a conflict finds a healthy solution or leads to a neurotic inhibition of function depends upon quantitative considerations.

[1926f, 4405]
I do not know how the case could be better stated, but perhaps I may add a few remarks. It is undoubtedly nothing else but the customary prudishness and their own bad conscience over sexual matters that causes adults to adopt this attitude of 'mystery-making' in front of children; but possibly a part is also played by a piece of theoretical ignorance on their part, which we can counteract by giving the adults some enlightenment. It is commonly believed that the sexual instinct is absent in children and only begins to emerge in them at puberty when the sexual organs mature. This is a gross error, equally serious in its effects both on knowledge and on practice; and it is so easily corrected by observation that one wonders how it could ever have been made. As a matter of fact, the new-born baby brings sexuality with it into the world, certain sexual sensations accompany its development as a suckling and during early childhood, and only very few children would seem to escape sexual activities and sensations before puberty. Anyone who would like to find a detailed exposition of these statements can do so in my Three Essays on the Theory of Sexuality, to which I have referred above. There he will learn that the organs of reproduction proper are not the only parts of the body which provide sexual sensations of pleasure, and that nature has even so ordered matters that actual stimulations of the genitals are unavoidable during early childhood. This period of life, during which a certain quota of what is undoubtedly sexual pleasure is produced by the excitation of various parts of the skin (erotogenic zones), by the activity of certain biological instincts and as an accompanying excitation in many affective states, is called the period of auto-erotism, to use a term introduced by Havelock Ellis. All that puberty does is to give the genitals primacy among all the other zones and sources which produce pleasure, and thus to force erotism into the service of the function of reproduction. This process can naturally undergo certain inhibitions, and in many people (those who later become perverts and neurotics) it is only incompletely accomplished. On the other hand, the child is capable long before puberty of most of the psychical manifestations of love-tenderness, for example, devotion and jealousy. Often enough, too, an irruption of these mental states is associated with the physical sensations of sexual excitation, so that the child cannot remain in doubt as to the connection between the two. In short, except for his reproductive power, a child has a fully-developed capacity for love long before puberty; and it may be asserted that the 'mystery-making' merely prevents him from being able to gain an intellectual grasp of activities for which he is psychically prepared and physically adjusted.

[1907c, 1914]

The subject was a man who is to-day quite indifferent to the genitals and other attractions of women, but who can be plunged into irresistible sexual excitement only by a foot of a particular form wearing a shoe. He can recall an event from his sixth year which was decisive for the fixation of his libido. He was sitting on a stool beside the governess who was to give him lessons in English. The governess, who was an elderly, dried-up, plain-looking spinster, with pale-blue eyes and a snub nose, had something wrong with her foot that day, and on that account kept it, wearing a velvet slipper, stretched out on a cushion. Her leg itself was most decently concealed. A thin, scraggy foot, like the one he had then seen belonging to his governess, thereupon became (after a timid attempt at normal sexual activity at puberty) his only sexual object; and the man was irresistibly attracted if a foot of this kind was associated with other features besides which recalled the type of the English governess. This fixation of his libido, however, made him, not into a neurotic, but into a pervert - what we call a foot-fetishist. You see, then, that although an excessive, and moreover premature, fixation of the libido is indispensable for the causation of neuroses, the area of its effects extends far beyond the field of the neuroses. This determinant, too, is as little decisive in itself as is the frustration which we have already talked about.

[1916-1917, 3410]
Nor is it a fact that psycho-analysis has paid no attention whatever to the non-sexual part of the personality. It is precisely the distinction between the ego and sexuality which has enabled us to recognize with special clarity that the ego instincts pass through an important process of development - a development which is neither completely independent of the libido nor without a counter-effect upon it. Nevertheless, we are far less well acquainted with the development of the ego than of the libido, since it is only the study of the narcissistic neuroses that promises to give us an insight into the structure of the ego. We already have before us, however, a notable attempt by Ferenczi to make a theoretical construction of the stages of development of the ego, and there are at least two points at which we have a solid basis for judging that development. It is not our belief that a person's libidinal interests are from the first in opposition to his self-preservation interests; on the contrary, the ego endeavours at every stage to remain in harmony with its sexual organization as it is at the time and to fit itself into it. The succession of the different phases of libidinal development probably follows a prescribed programme. But the possibility cannot be rejected that this course of events can be influenced by the ego, and we may expect equally to find a certain parallelism, a certain correspondence, between the developmental phases of the ego and the libido; indeed a disturbance of that correspondence might provide a pathogenic factor. We are now faced by the important consideration of how the ego behaves if its libido leaves a strong fixation behind at some point in its (the libido's) development. The ego may accept this and consequently become to that extent perverse or, what is the same thing, infantile. It may, however, adopt a non-compliant attitude to the libido's settling down in this position, in which case the ego experiences a repression where the libido has experienced a fixation.

[1916-1917, 3412]

The Development of the Libido. - The sexual instinct, the dynamic manifestation of which in mental life we shall call 'libido', is made up of component instincts into which it may once more break up and which are only gradually united into well-defined organizations. The sources of these component instincts are the organs of the body and in particular certain specially marked erotogenic zones; but contributions are made to libido from every important functional process in the body. At first the individual component instincts strive for satisfaction independently of one another, but in the course of development they become more and more convergent and concentrated. The first (pregenital) stage of organization to be discerned is the oral one, in which - in conformity with the suckling's predominant interest - the oral zone plays the leading part. This is followed by the sadistic-anal organization, in which the anal zone and the component instinct of sadism are particularly prominent; at this stage the difference between the sexes is represented by the contrast between active and passive. The third and final stage of organization is that in which the majority of the component instincts converge under the primacy of the genital zones. As a rule this development is passed through swiftly and unobtrusively; but some individual portions of the instincts remain behind at the prodromal stages of the process and thus give rise to fixations of libido, which are important as constituting predispositions for subsequent irruptions of repressed impulses and which stand in a definite relation to the later development of neuroses and perversions. (See the article on 'The Libido Theory'.)

[1923a, 3921]
Deeper-going psycho-analytic research has raised a just criticism of Binet's assertion. All the observations dealing with this point have recorded a first meeting with the fetish at which it already aroused sexual interest without there being anything in the accompanying circumstances to explain the fact. Moreover, all of these 'early' sexual impressions relate to a time after the age of five or six, whereas psycho-analysis makes it doubtful whether fresh pathological fixations can occur so late as this. The true explanation is that behind the first recollection of the fetish's appearance there lies a submerged and forgotten phase of sexual development. The fetish, like a 'screen memory', represents this phase and is thus a remnant and precipitate of it. The fact that this early infantile phase turns in the direction of fetishism, as well as the choice of the fetish itself, are constitutionally determined.

Since this phase allows room for all the fixations and repressions from which we trace the origin of the neuroses, it would seem as though we must retract the universality of the thesis that the Oedipus complex is the nucleus of the neuroses. But if anyone feels reluctant about making this correction, there is no need for him to do so. On the one hand, we can extend the content of the Oedipus complex to include all the child's relations to both parents; or, on the other, we can take due account of our new findings by saying that the female only reaches the normal positive Oedipus situation after she has surmounted a period before it that is governed by the negative complex. And indeed during that phase a little girl's father is not much else for her than a troublesome rival, although her hostility towards him never reaches the pitch which is characteristic of boys. We have, after all, long given up any expectation of a neat parallelism between male and female sexual development.

[Footnote added 1920:]
The subject was a man who is to-day quite indifferent to the genitals and other attractions of women, but who can be plunged into irresistible sexual excitement only by a foot of a particular form wearing a shoe. He can recall an event from his sixth year which was decisive for the fixation of his libido. He was sitting on a stool beside the governess who was to give him lessons in English. The governess, who was an elderly, dried-up, plain-looking spinster, with pale-blue eyes and a snub nose, had something wrong with her foot that day, and on that account kept it, wearing a velvet slipper, stretched out on a cushion. Her leg itself was most decently concealed. A thin, scraggy foot, like the one he had then seen belonging to his governess, thereupon became (after a timid attempt at normal sexual activity at puberty) his only sexual object; and the man was irresistibly attracted if a foot of this kind was associated with other features besides which recalled the type of the English governess. This fixation of his libido, however, made him, not into a neurotic, but into a pervert - what we call a foot-fetishist. You see, then, that although an excessive, and moreover premature, fixation of the libido is indispensable for the causation of neuroses, the area of its effects extends far beyond the field of the neuroses. This determinant, too, is as little decisive in itself as is the frustration which we have already talked about.

[1916-1917, 3410]

Your second observation, too, raises a justifiable question, but it is aimed in the wrong direction. It is true that a withdrawal of the object-libido into the ego is not directly pathogenic; it takes place, indeed, as we know, every time before we go to sleep, only to be reversed when we wake up. The amoeba withdraws its protrusions only to send them out again at the first opportunity. But it is quite a different thing when a particular, very energetic process forces a withdrawal of libido from objects. Here the libido that has become narcissistic cannot find its way back to objects, and this interference with the libido's mobility certainly becomes pathogenic. It seems that an accumulation of narcissistic libido beyond a certain amount is not tolerated. We may even imagine that it was for that very reason that object-cathexes originally came about, that the ego was obliged to send out its libido so as not to fall ill as a result of its being dammed up. If it lay within our plan to go more deeply into dementia praecox, I would show you that the process which detaches the libido from objects and cuts off its return to them is closely related to the process of repression and is to be looked at as its counterpart. But you would, first and foremost, find yourselves on familiar ground when you learnt that the determinants of this process are almost identical - so far as we know at present - with those of repression. The conflict seems to be the same and to be carried on between the same forces. If the outcome is so different from, for instance, that in hysteria, the reason can only depend on a difference in innate disposition. The weak spot in the libidinal development of these patients lies in a different phase; the determining fixation, which, as you will recollect, permits the irruption that leads to the formation of symptoms, lies elsewhere, probably in the stage of primitive narcissism to which dementia praecox returns in its final outcome. It is very remarkable that in the case of all the narcissistic neuroses we have to assume fixation points for the libido going back to far earlier phases of development than in hysteria or obsessional neurosis. As you heard, however, the concepts which we arrived at during our study of the transference neuroses are adequate in helping us to find our way about in the narcissistic neuroses which are so much more severe in practice. The conformities go very far; at bottom the field of phenomena is the same. And you can imagine how small a prospect anyone has of explaining these disorders (which belong within the sphere of psychiatry) who is not forearmed for his task with an analytic knowledge of the transference neuroses.

[1916-1917, 3466]
Let us look for some analogies to these processes in other fields of knowledge. When, as often happened at early periods of human history, a whole people left their place of domicile and sought a new one, we may be certain that the whole of them did not arrive at the new location. Apart from other losses, it must regularly have happened that small groups or bands of the migrants halted on the way and settled at these stopping places while the main body went further. Or, as you know, to turn to a nearer comparison, in the highest mammals the male sex-glands, which are originally situated deep in the abdominal cavity, start upon a migration at a particular stage of intra-uterine life, which brings them almost directly under the skin of the pelvic extremity. As a consequence of this migration, we find in a number of male individuals that one of these paired organs has remained behind in the pelvic cavity, or that it has become permanently lodged in what is known as the inguinal canal, through which both organs must pass in the course of their migration, or at least that this canal has remained open, though it should normally close up after the sex-glands have completed their change of situation. Or again, when as a young student I was engaged under von Brücke's direction on my first piece of scientific work, I was concerned with the origin of the posterior nerve-roots in the spinal cord of a small fish of very archaic structure; I found that the nerve-fibres of these roots have their origin in large cells in the posterior horn of the grey matter, which is no longer the case in other vertebrates. But I also discovered soon afterwards that nerve-cells of this kind are present outside the grey matter the whole way to what is known as the spinal ganglion of the posterior root; and from this I inferred that the cells of these masses of ganglia had migrated from the spinal cord along the roots of the nerves. This is also shown by their evolutionary history. But in this small fish the whole path of their migration was demonstrated by the cells that had remained behind.
[1916-1917, 3403]
By demonstrating the part played by perverse impulses in the formation of symptoms in the psychoneuroses, we have quite remarkably increased the number of people who might be regarded as perverts. It is not only that neurotics in themselves constitute a very numerous class, but it must also be considered that an unbroken chain bridges the gap between the neuroses in all their manifestations and normality. After all, Moebius could say with justice that we are all to some extent hysterics. Thus the extraordinarily wide dissemination of the perversions forces us to suppose that the disposition to perversions is itself of no great rarity but must form a part of what passes as the normal constitution.

It is, as we have seen, debatable whether the perversions go back to innate determinants or arise, as Binet assumed was the case with fetishism, owing to chance experiences. The conclusion now presents itself to us that there is indeed something innate lying behind the perversions but that it is something innate in everyone, though as a disposition it may vary in its intensity and may be increased by the influences of actual life. What is in question are the innate constitutional roots of the sexual instinct. In one class of cases (the perversions) these roots may grow into the actual vehicles of sexual activity; in others they may be submitted to an insufficient suppression (repression) and thus be able in a roundabout way to attract a considerable proportion of sexual energy to themselves as symptoms; while in the most favourable cases, which lie between these two extremes, they may by means of effective restriction and other kinds of modification bring about what is known as normal sexual life.

We have, however, a further reflection to make. This postulated constitution, containing the germs of all the perversions, will only be demonstrable in children, even though in them it is only with modest degrees of intensity that any of the instincts can emerge. A formula begins to take shape which lays it down that the sexuality of neurotics has remained in, or been brought back to, an infantile state. Thus our interest turns to the sexual life of children, and we will now proceed to trace the play of influences which govern the evolution of infantile sexuality till its outcome in perversion, neurosis or normal sexual life.

The detaching of sexuality from the genitals has the advantage of allowing us to bring the sexual activities of children and of perverts into the same scope as those of normal adults. The sexual activities of children have hitherto been entirely neglected and though those of perverts have been recognized it has been with moral indignation and without understanding. Looked at from the psycho-analytic standpoint, even the most eccentric and repellent perversions are explicable as manifestations of component instincts of sexuality which have freed themselves from the primacy of the genitals and are now in pursuit of pleasure on their own account as they were in the very early days of the libido’s development. The most important of these perversions, homosexuality, scarcely deserves the name. It can be traced back to the constitutional bisexuality of all human beings and to the after-effects of the phallic primacy. Psycho-analysis enables us to point to some trace or other of a homosexual object-choice in everyone. If I have described children as ‘polymorphously perverse’, I was only using a terminology that was generally current; no moral judgement was implied by the phrase. Psycho-analysis has no concern whatever with such judgements of value.
As regards the second kind of emotional reaction, which is not directed against me this time, but against my patient - supposing that my view of her is correct - and which regards the perverse nature of her phantasies as horrible, I should like to say emphatically that a medical man has no business to indulge in such passionate condemnation. I may also remark in passing that it seems to me superfluous for a physician who is writing upon the aberrations of the sexual instincts to seize every opportunity of inserting into the text expressions of his personal repugnance at such revolting things. We are faced by a fact; and it is to be hoped that we shall grow accustomed to it, when we have put our own tastes on one side. We must learn to speak without indignation of what we call the sexual perversions - instances in which the sexual function has extended its limits in respect either to the part of the body concerned or to the sexual object chosen. The uncertainty in regard to the boundaries of what is to be called normal sexual life, when we take different races and different epochs into account, should in itself be enough to cool the zealot's ardour. We surely ought not to forget that the perversion which is the most repellent to us, the sensual love of a man for a man, was not only tolerated by a people so far our superiors in cultivation as were the Greeks, but was actually entrusted by them with important social functions. The sexual life of each one of us extends to a slight degree - now in this direction, now in that - beyond the narrow lines imposed as the standard of normality. The perversions are neither bestial nor degenerate in the emotional sense of the word. They are a development of germs all of which are contained in the undifferentiated sexual disposition of the child, and which, by being suppressed or by being diverted to higher, asexual aims - by being 'sublimated' - are destined to provide the energy for a great number of our cultural achievements. When, therefore, any one has become a gross and manifest pervert, it would be more correct to say that he has remained one, for he exhibits a certain stage of inhibited development. All psychoneurotics are persons with strongly marked perverse tendencies, which have been repressed in the course of their development and have become unconscious. Consequently their unconscious phantasies show precisely the same content as the documentarily recorded actions of perverts - even though they have not read Krafft-Ebing's Psychopathia Sexualis, to which simple-minded people attribute such a large share of the responsibility for the production of perverse tendencies. Psychoneuroses are, so to speak, the negative of perversions. In neurotics their sexual constitution, under which the effects of heredity are included, operates in combination with any accidental influences in their life which may disturb the development of normal sexuality. A stream of water which meets with an obstacle in the river-bed is dammed up and flows back into old channels which had formerly seemed fated to run dry. The motive forces leading to the formation of hysterical symptoms draw their strength not only from repressed normal sexuality but also from unconscious perverse activities.¹

[1905e, 1387]
One of these patients gave me a piece of information which sheds a clear light on the origin of this curious habit. This young woman had never broken herself of the habit of sucking. She retained a memory of her childhood, dating back, according to her, to the first half of her second year, in which she saw herself sucking at her nurse's breast and at the same time pulling rhythmically at the lobe of her nurse's ear. No one will feel inclined to dispute, I think, that the mucous membrane of the lips and mouth is to be regarded as a primary 'erotogenic zone', since it preserves this earlier significance in the act of kissing, which is looked upon as normal. An intense activity of this erotogenic zone at an early age thus determines the subsequent presence of a somatic compliance on the part of the tract of mucous membrane which begins at the lips. Thus, at a time when the sexual object proper, that is, the male organ, has already become known, circumstances may arise which once more increase the excitation of the oral zone, whose erotogenic character has, as we have seen, been retained. It then needs very little creative power to substitute the sexual object of the moment (the penis) for the original object (the nipple) or for the finger which does duty for it, and to place the current sexual object in the situation in which gratification was originally obtained. So we see that this excessively repulsive and perverted phantasy of sucking at a penis has the most innocent origin. It is a new version of what may be described as a prehistoric impression of sucking at the mother's or nurse's breast - an impression which has usually been revived by contact with children who are being nursed. In most instances a cow's udder has aptly played the part of an image intermediate between a nipple and a penis.

[1905e, 1389]

But, once again, in the present paper I have not gone fully into all that might be said to-day about 'somatic compliance', about the infantile germs of perversion, about the erotogenic zones, and about our predisposition towards bisexuality; I have merely drawn attention to the points at which the analysis comes into contact with these organic bases of the symptoms. More than this could not be done with a single case. And I had the same reasons that I have already mentioned for wishing to avoid a cursory discussion of these factors. There is a rich opportunity here for further works, based upon the study of a large number of analyses.

[1905e, 1447]

We have, however, a further reflection to make. This postulated constitution, containing the germs of all the perversions, will only be demonstrable in children, even though in them it is only with modest degrees of intensity that any of the instincts can emerge. A formula begins to take shape which lays it down that the sexuality of neurotics has remained in, or been brought back to, an infantile state. Thus our interest turns to the sexual life of children, and we will now proceed to trace the play of influences which govern the evolution of infantile sexuality till its outcome in perversion, neurosis or normal sexual life.

[1905d, 1495]

It is possible further to form some idea of the mechanism of this process of sublimation. On the one hand, it would seem, the sexual impulses cannot be utilized during these years of childhood, since the reproductive functions have been deferred - a fact which constitutes the main feature of the period of latency. On the other hand, these impulses would seem in themselves to be perverse - that is, to arise from erotogenic zones and to derive their activity from instincts which, in view of the direction of the subject's development, can only arouse unpleasurable feelings. They consequently evoke opposing mental forces (reacting impulses) which, in order to suppress this displeasure effectively, build up the mental dams that have already mentioned - disgust, shame and morality.²

[1905d, 1500]
REPRESSED   A different result is brought about if in the course of development some of the components which are of excessive strength in the disposition are submitted to the process of repression (which, it must be insisted, is not equivalent to their being abolished). If this happens, the excitations concerned continue to be generated as before; but they are prevented by psychical obstruction from attaining their aim and are diverted into numerous other channels till they find their way to expression as symptoms. The outcome may be an approximately normal sexual life - though usually a restricted one - but there is in addition psychoneurotic illness. These particular cases have become familiar to us from the psychoanalytic investigation of neurotics. Their sexual life begins like that of perverts, and a considerable part of their childhood is occupied with perverse sexual activity which occasionally extends far into maturity. A reversal due to repression then occurs, owing to internal causes (usually before puberty, but now and then even long afterwards), and from that time onwards neurosis takes the place of perversion, without the old impulses being extinguished. We are reminded of the proverb ‘Junge Hure, alte Betschwester’, only that here youth has lasted all too short a time. The fact that perversion can be replaced by neurosis in the life of the same person, like the fact which we have already mentioned that perversion and neurosis can be distributed among different members of the same family, tallies with the view that neurosis is the negative of perversion.

[1905d, 1548]

I could not further elucidate this part of my theory without a detailed discussion of my views on repression. It will be enough here to refer to my *Three Essays* (1905d), in which I have attempted to throw some light - if only a feeble one - on the somatic processes in which the essential nature of sexuality is to be looked for. I have there shown that the constitutional sexual disposition of children is incomparably more variegated than might have been expected, that it deserves to be described as ‘polymorphously perverse’ and that what is spoken of as the normal behaviour of the sexual function emerges from this disposition after certain of its components have been repressed. By pointing out the infantile elements in sexuality I was able to establish a simple correlation between health, perversion and neurosis. I showed that normality is a result of the repression of certain component instincts and constituents of the infantile disposition and of the subordination of the remaining constituents under the primacy of the genital zones in the service of the reproductive function. I showed that perversions correspond to disturbances of this coalescence owing to the overpowering and compulsive development of certain of the component instincts, while neuroses can be traced back to an excessive repression of the libidinal trends. Since almost all the perverse instincts of the infantile disposition can be recognized as the forces concerned in the formation of symptoms in neuroses, though in a state of repression, I was able to describe neurosis as being the 'negative' of perversion.

[1906a, 1581]

If we take the second of these stages as an average, we must point out that a number of people are, on account of their organization, not equal to meeting its demands. In whole classes of individuals the development of the sexual instinct, as we have described it above, from autoerotism to object-love with its aim of uniting the genitals, has not been carried out correctly and sufficiently fully. As a result of these disturbances of development two kinds of harmful deviation from normal sexuality - that is, sexuality which is serviceable to civilization - come about; and the relation between these two is almost that of positive and negative.

[1908d, 1953]
First and foremost, it is an untenable error to deny that children have a sexual life and to suppose that sexuality only begins at puberty with the maturation of the genitals. On the contrary, from the very first children have a copious sexual life, which differs at many points from what is later regarded as normal. What in adult life is described as ‘perverse’ differs from the normal in these respects: first, by disregarding the barrier of species (the gulf between men and animals), secondly, by overstepping the barrier against disgust, thirdly that against incest (the prohibition against seeking sexual satisfaction from near blood-relations), fourthly that against members of one's own sex and fifthly the transferring of the part played by the genitals to other organs and areas of the body. None of these barriers existed from the beginning; they were only gradually erected in the course of development and education. Small children are free from them. They recognize no frightful gulf between human beings and animals; the arrogance with which men separate themselves from animals does not emerge until later. To begin with, children exhibit no disgust at excreta but acquire this slowly under the pressure of education; they attach no special importance to the distinction between the sexes, but attribute the same conformation of the genitals to both; they direct their first sexual lusts and their curiosity to those who are nearest and for other reasons dearest to them - parents, brothers and sisters, or nurses; and finally, they show (what later on breaks through once again at the climax of a love-relation) that they expect to derive pleasure not only from their sexual organs, but that many other parts of the body lay claim to the same sensitivity, afford them analogous feelings of pleasure and can accordingly play the part of genitals. Children may thus be described as 'polymorphously perverse', and if these impulses only show traces of activity, that is because on the one hand they are of less intensity compared with those in later life and on the other hand all a child's sexual manifestations are at once energetically suppressed by education. This suppression is, as it were, extended into theory; for adults endeavour to overlook one portion of the sexual manifestations of children and to disguise another portion by misinterpreting its sexual nature, so that they can then disavow the whole of them. It is often the very same people who in the nursery are furious with any sexual naughtinesses of children and afterwards at their writing-tables defend the sexual purity of the same children. When children are left to themselves, or under the influence of seduction, they often bring about quite considerable achievements in the way of perverse sexual activity. Adults are of course right not to take this too seriously and to regard it as 'childishness', or 'playfulness', for children are not to be condemned as fully capable or fully responsible either before the judgement-seat of morals or before the law; but nonetheless these things exist. They have their importance both as indications of a child's innate constitution and as causes and encouragements of later developments in him; they give us information on the sexual life of children and so on human sexual life in general. If, therefore, we once more find all these perverse wishful impulses behind our distorted dreams, that only means that in this field too dreams have taken a step backwards into the state of infancy.

[1916-1917, 3297]

And this brings us to the second novelty that I announced to you. For psycho-analytic research has had to concern itself, too, with the sexual life of children, and this is because the memories and associations arising during the analysis of symptoms regularly led back to the early years of childhood. What we inferred from these analyses was later confirmed point by point by direct observations of children. And it then turned out that all these inclinations to perversion had their roots in childhood, that children have a predisposition to all of them and carry them out to an extent corresponding to their immaturity - in short, that perverse sexuality is nothing else than a magnified infantile sexuality split up into its separate impulses.

[1916-1917, 3381]
At all events you will now see the perversions in a new light and no longer fail to realize their connection with the sexual life of human beings: but at the price of what surprises and of what feelings of distress over these incongruities! No doubt you will feel inclined at first to deny the whole business: the fact that children have anything that can be described as sexual life, the correctness of our observations and the justification for finding any kinship between the behaviour of children and what is later condemned as perversion. So allow me to begin by explaining to you the motives for your opposition, and then to present you with the sum of our observations. To suppose that children have no sexual life - sexual excitations and needs and a kind of satisfaction - but suddenly acquire it between the ages of twelve and fourteen, would (quite apart from any observations) be as improbable, and indeed senseless, biologically as to suppose that they brought no genitals with them into the world and only grew them at the time of puberty. What does awaken in them at this time is the reproductive function, which makes use for its purposes of physical and mental material already present. You are committing the error of confusing sexuality and reproduction and by doing so you are blocking your path to an understanding of sexuality, the perversions and the neuroses. This error is, however, a tendentious one. Strangely enough, it has its source in the fact that you yourselves were once children and, while you were children, came under the influence of education. For society must undertake as one of its most important educative tasks to tame and restrict the sexual instinct when it breaks out as an urge to reproduction, and to subject it to an individual will which is identical with the bidding of society. It is also concerned to postpone the full development of the instinct till the child shall have reached a certain degree of intellectual maturity, for, with the complete irruption of the sexual instinct, educability is for practical purposes at an end. Otherwise, the instinct would break down every dam and wash away the laboriously erected work of civilization. Nor is the task of taming it ever an easy one; its success is sometimes too small, sometimes too great. The motive of human society is in the last resort an economic one; since it does not possess enough provisions to keep its members alive unless they work, it must restrict the number of its members and divert their energies from sexual activity to work. It is faced, in short, by the eternal, primaeval exigencies of life, which are with us to this day. [1916-1917, 3382]
I know you have been wanting for a long time to interrupt me and exclaim: 'Enough of these atrocities! You tell us that defaecating is a source of sexual satisfaction, and already exploited in infancy! that faeces is a valuable substance and that the anus is a kind of genital! We don't believe all that but we do understand why paediatricians and educationists have given a wide berth to psycho-analysis and its findings.' No, Gentlemen. You have merely forgotten that I have been trying to introduce the facts of infantile sexual life to you in connection with the facts of the sexual perversions. Why should you not be aware that for a large number of adults, homosexual and heterosexual alike, the anus does really take over the role of the vagina in sexual intercourse? And that there are many people who retain a voluptuous feeling in defaecating all through their lives and describe it as being far from small? As regards interest in the act of defaecation and enjoyment in watching someone else defaecating, you can get children themselves to confirm the fact when they are a few years older and able to tell you about it. Of course, you must not have systematically intimidated them beforehand, or they will quite understand that they must be silent on the subject. And as to the other things that you are anxious not to believe, I will refer you to the findings of analysis and of the direct observation of children and will add that it calls for real ingenuity not to see all this or to see it differently. Nor do I complain if you find the kinship between infantile sexual activity and sexual perversions something very striking. But it is in fact self-evident: if a child has a sexual life at all it is bound to be of a perverse kind; for, except for a few obscure hints, children are without what makes sexuality into the reproductive function. On the other hand, the abandonment of the reproductive function is the common feature of all perversions. We actually describe a sexual activity as perverse if it has given up the aim of reproduction and pursues the attainment of pleasure as an aim independent of it. So, as you will see, the breach and turning-point in the development of sexual life lies in its becoming subordinate to the purposes of reproduction. Everything that happens before this turn of events and equally everything that disregards it and that aims solely at obtaining pleasure is given the uncomplimentary name of 'perverse' and as such is proscribed.

A perversion in childhood, as is well known, may become the basis for the construction of a perversion having a similar sense and persisting throughout life, one which consumes the subject's whole sexual life. On the other hand the perversion may be broken off and remain in the background of a normal sexual development, from which, however, it continues to withdraw a certain amount of energy. The first of these alternatives was already known before the days of analysis. Analytic investigation, however, of such fully-developed cases almost bridges the gulf between the two. For we find often enough with these perverts that they too made an attempt at developing normal sexual activity, usually at the age of puberty; but their attempt had not enough force in it and was abandoned in the face of the first obstacles which inevitably arise, whereupon they fell back upon their infantile fixation once and for all.

[1916-1917, 3386]

[1919e, 3653]
It would naturally be important to know whether the origin of infantile perversions from the Oedipus complex can be asserted as a general principle. While this cannot be decided without further investigation, it does not seem impossible. When we recall the anamneses which have been obtained in adult cases of perversion we cannot fail to notice that the decisive impression, the 'first experience', of all these perverts, fetishists, etc., is scarcely ever referred back to a time earlier than the sixth year. At this time, however, the dominance of the Oedipus complex is already over; the experience which is recalled, and which has been effective in such a puzzling way, may very well have represented the legacy of that complex. The connections between the experience and the complex which is by this time repressed are bound to remain obscure so long as analysis has not thrown any light on the time before the first 'pathogenic' impression. So it may be imagined how little value is to be attached, for instance, to an assertion that a case of homosexuality is congenital, when the ground given for this belief is that ever since his eighth or sixth year the person in question has felt inclinations only towards his own sex.
[1919e, 3653]

The theory of psycho-analysis (a theory based on observation) holds firmly to the view that the motive forces of repression must not be sexualized. Man's archaic heritage forms the nucleus of the unconscious mind; and whatever part of that heritage has to be left behind in the advance to later phases of development, because it is unserviceable or incompatible with what is new and harmful to it, falls a victim to the process of repression. This selection is made more successfully with one group of instincts than with the other. In virtue of special circumstances which have often been pointed out already, the latter group, that of the sexual instincts, are able to defeat the intentions of repression, and to enforce their representation by substitutive formations of a disturbing kind. For this reason infantile sexuality, which is held under repression, acts as the chief motive force in the formation of symptoms; and the essential part of its content, the Oedipus complex, is the nuclear complex of neuroses. I hope that in this paper I have raised an expectation that the sexual aberrations of childhood, as well as those of mature life, are ramifications of the same complex.
[1919e, 3662]

Sexuality in children showed a different picture in many respects from that in adults, and, surprisingly enough, it exhibited numerous traces of what, in adults, were condemned as 'perversions'. It became necessary to enlarge the concept of what was sexual, till it covered more than the impulsion towards the union of the two sexes in the sexual act or towards provoking particular pleasurable sensations in the genitals. But this enlargement was rewarded by the new possibility of grasping infantile, normal and perverse sexual life as a single whole.
[1923a, 3921]

The detaching of sexuality from the genitals has the advantage of allowing us to bring the sexual activities of children and of perverts into the same scope as those of normal adults. The sexual activities of children have hitherto been entirely neglected and though those of perverts have been recognized it has been with moral indignation and without understanding. Looked at from the psycho-analytic standpoint, even the most eccentric and repellent perversions are explicable as manifestations of component instincts of sexuality which have freed themselves from the primacy of the genitals and are now in pursuit of pleasure on their own account as they were in the very early days of the libido's development. The most important of these perversions, homosexuality, scarcely deserves the name. It can be traced back to the constitutional bisexuality of all human beings and to the after-effects of the phallic primacy. Psycho-analysis enables us to point to some trace or other of a homosexual object-choice in everyone. If I have described children as 'polymorphously perverse', I was only using a terminology that was generally current; no moral judgement was implied by the phrase. Psycho-analysis has no concern whatever with such judgements of value.
[1925d, 4213]
The sexual life of children is of course different from that of adults. The sexual function, from its beginnings to the definitive form in which it is so familiar to us, undergoes a complicated process of development. It grows together from numerous component instincts with different aims and passes through several phases of organization till at last it comes into the service of reproduction. Not all the component instincts are equally serviceable for the final outcome; they must be diverted, remodelled and in part suppressed. Such a far-reaching course of development is not always passed through without a flaw; inhibitions in development take place, partial fixations at early stages of development. If obstacles arise later on to the exercise of the sexual function, the sexual urge - the libido, as we call it - is apt to hark back to these earlier points of fixation. The study of the sexuality of children and its transformations up to maturity has also given us the key to an understanding of what are known as the sexual perversions, which people used always to describe with all the requisite indications of disgust but whose origin they were never able to explain. The whole topic is of uncommon interest, but for the purposes of our conversation there is not much sense in telling you more about it. To find one's way about in it one of course needs anatomical and physiological knowledge, all of which is unfortunately not to be acquired in medical schools. But a familiarity with the history of civilization and with mythology is equally indispensable.

[1926e, 4353]
As regards the second kind of emotional reaction, which is not directed against me this time, but against my patient - supposing that my view of her is correct - and which regards the perverse nature of her phantasies as horrible, I should like to say emphatically that a medical man has no business to indulge in such passionate condemnation. I may also remark in passing that it seems to me superfluous for a physician who is writing upon the aberrations of the sexual instincts to seize every opportunity of inserting into the text expressions of his personal repugnance at such revolting things. We are faced by a fact; and it is to be hoped that we shall grow accustomed to it, when we have put our own tastes on one side. We must learn to speak without indignation of what we call the sexual perversions - instances in which the sexual function has extended its limits in respect either to the part of the body concerned or to the sexual object chosen. The uncertainty in regard to the boundaries of what is to be called normal sexual life, when we take different races and different epochs into account, should in itself be enough to cool the zealot's ardour. We surely ought not to forget that the perversion which is the most repellant to us, the sensual love of a man for a man, was not only tolerated by a people so far our superiors in cultivation as were the Greeks, but was actually entrusted by them with important social functions. The sexual life of each one of us extends to a slight degree - now in this direction, now in that - beyond the narrow lines imposed as the standard of normality. The perversions are neither bestial nor degenerate in the emotional sense of the word. They are a development of germs all of which are contained in the undifferentiated sexual disposition of the child, and which, by being suppressed or by being diverted to higher, asexual aims - by being 'sublimated' - are destined to provide the energy for a great number of our cultural achievements. When, therefore, any one has become a gross and manifest pervert, it would be more correct to say that he has remained one, for he exhibits a certain stage of inhibited development. All psychoneurotics are persons with strongly marked perverse tendencies, which have been repressed in the course of their development and have become unconscious. Consequently their unconscious phantasies show precisely the same content as the documentarily recorded actions of perverts - even though they have not read Krafft-Ebing's *Psychopathia Sexualis*, to which simple-minded people attribute such a large share of the responsibility for the production of perverse tendencies. Psychoneuroses are, so to speak, the negative of perversions. In neurotics their sexual constitution, under which the effects of heredity are included, operates in combination with any accidental influences in their life which may disturb the development of normal sexuality. A stream of water which meets with an obstacle in the river-bed is dammed up and flows back into old channels which had formerly seemed fated to run dry. The motive forces leading to the formation of hysterical symptoms draw their strength not only from repressed normal sexuality but also from unconscious perverse activities.

Any one who has learnt to appreciate the delicacy of the fabric of structures such as dreams will not be surprised to find that Dora's wish that her father might take the place of the man who was her tempter called up in her memory not merely a casual collection of material from her childhood, but precisely such material as was most intimately bound up with the suppression of her temptation. For if Dora felt unable to yield to her love for the man, if in the end she repressed that love instead of surrendering to it, there was no factor upon which her decision depended more directly than upon her premature sexual enjoyment and its consequence - her bed-wetting, her catarrh, and her disgust. An early history of this kind can afford a basis for two kinds of behaviour in response to the demands of love in maturity - which of the two will depend upon the summation of constitutional determinants in the subject. He will either exhibit an abandonment to sexuality which is entirely without resistances and borders upon perversity; or there will be a reaction - he will repudiate sexuality, and will at the same time fall ill of a neurosis. In the case of our present patient, her constitution and the high level of her intellectual and moral upbringing decided in favour of the latter course.
The hereditary conditions in the case of positive perverts are less well known, for they know how to avoid investigation. Yet there are good reasons to suppose that what is true of the neuroses applies also to the perversions. For it is no rare thing to find perversions and psychoneuroses occurring in the same family, and distributed between the two sexes in such a way that the male members of the family, or one of them, are positive perverts, while the females, true to the tendency of their sex to repression, are negative perverts, that is, hysterics. This is good evidence of the essential connections which we have shown to exist between the two disorders.
[1905d, 1546]

I could not further elucidate this part of my theory without a detailed discussion of my views on repression. It will be enough here to refer to my *Three Essays* (1905), in which I have attempted to throw some light - if only a feeble one - on the somatic processes in which the essential nature of sexuality is to be looked for. I have there shown that the constitutional sexual disposition of children is incomparably more variegated than might have been expected, that it deserves to be described as 'polymorphously perverse' and that what is spoken of as the normal behaviour of the sexual function emerges from this disposition after certain of its components have been repressed. By pointing out the infantile elements in sexuality I was able to establish a simple correlation between health, perversion and neurosis. I showed that normality is a result of the repression of certain component instincts and constituents of the infantile disposition and of the subordination of the remaining constituents under the primacy of the genital zones in the service of the reproductive function. I showed that perversions correspond to disturbances of this coalescence owing to the overpowering and compulsive development of certain of the component instincts, while neuroses can be traced back to an excessive repression of the libidinal trends. Since almost all the perverse instincts of the infantile disposition can be recognized as the forces concerned in the formation of symptoms in neuroses, though in a state of repression, I was able to describe neurosis as being the 'negative' of perversion.
[1906a, 1581]

If we take the second of these stages as an average, we must point out that a number of people are, on account of their organization, not equal to meeting its demands. In whole classes of individuals the development of the sexual instinct, as we have described it above, from auto-erotism to object-love with its aim of uniting the genitals, has not been carried out correctly and sufficiently fully. As a result of these disturbances of development two kinds of harmful deviation from normal sexuality - that is, sexuality which is serviceable to civilization - come about; and the relation between these two is almost that of positive and negative.
[1908d, 1953]
Where the sexual instinct is fairly intense, but perverse, there are two possible outcomes. The first, which we shall not discuss further, is that the person affected remains a pervert and has to put up with the consequences of his deviation from the standard of civilization. The second is far more interesting. It is that, under the influence of education and social demands, a suppression of the perverted instincts is indeed achieved, but it is a kind of suppression which is really no suppression at all. It can better be described as a suppression that has failed. The inhibited sexual instincts are, it is true, no longer expressed as such - and this constitutes the success of the process - but they find expression in other ways, which are quite as injurious to the subject and make him quite as useless for society as satisfaction of the suppressed instincts in an unmodified form would have done. This constitutes the failure of the process, which in the long run more than counterbalances its success. The substitutive phenomena which emerge in consequence of the suppression of the instinct amount to what we call nervous illness, or, more precisely, the psychoneuroses.¹ Neurotics are the class of people who, since they possess a recalcitrant organization, only succeed, under the influence of cultural requirements, in achieving a suppression of their instincts which is apparent and which becomes increasingly unsuccessful. They therefore only carry on their collaboration with cultural activities by a great expenditure of force and at the cost of an internal impoverishment, or are obliged at times to interrupt it and fall ill. I have described the neuroses as the ‘negative’ of the perversions because in the neuroses the perverse impulses, after being repressed, manifest themselves from the unconscious part of the mind - because the neuroses contain the same tendencies, though in a state of ‘repression’, as do the positive perversions.

[1908d, 1954]

A sexual constitution like that of little Hans does not appear to carry with it a predisposition to the development either of perversions or of their negative (we will limit ourselves to a consideration of hysteria). As far as my experience goes (and there is still a real need for speaking with caution on this point) the innate constitution of hysterics - that this is also true of perverts is almost self-evident - is marked by the genital zone being relatively less prominent than the other erotogenic zones. But we must expressly except from this rule one particular ‘aberration’ of sexual life. In those who later become homosexuals we meet with the same predominance in infancy of the genital zone (and especially of the penis) as in normal persons.¹ Indeed it is the high esteem felt by the homosexual for the male organ which decides his fate. In his childhood he chooses women as his sexual object, so long as he assumes that they too possess what in his eyes is an indispensable part of the body; when he becomes convinced that women have deceived him in this particular, they cease to be acceptable to him as a sexual object. He cannot forgo a penis in any one who is to attract him to sexual intercourse; and if circumstances are favourable he will fix his libido upon the ‘woman with a penis’, a youth of feminine appearance. Homosexuals, then, are persons who, owing to the erotogenic importance of their own genitals, cannot do without a similar feature in their sexual object. In the course of their development from auto-erotism to object-love, they have remained at a point of fixation between the two.

[1909b, 2093]
The path to perversion branches off sharply from that to neurosis. If these regressions rouse no objection from the ego, no neurosis will come about either; and the libido will arrive at some real, even though no longer normal, satisfaction. But if the ego, which has under its control not only consciousness but also the approaches to motor innervation and accordingly to the realization of mental desires, does not agree with these regressions, conflict will follow. The libido is, as it were, cut off and must try to escape in some direction where, in accordance with the requirements of the pleasure principle, it can find a discharge for its cathexis of energy. It must withdraw from the ego. An escape of this kind is offered it by the fixations on the path of its development which it has now entered on regressively - fixations from which the ego had protected itself in the past by repressions. By cathecting these repressed positions as it flows backward, the libido has withdrawn from the ego and its laws, and has at the same time renounced all the education it has acquired under the ego's influence. It was docile so long as satisfaction beckoned to it; but under the double pressure of external and internal frustration it becomes refractory, and recalls earlier and better times. Such is the libido's fundamentally unchangeable character. The ideas to which it now transfers its energy as a cathexis belong to the system of the unconscious and are subject to the processes which are possible there, particularly to condensation and displacement. In this way conditions are established which completely resemble those in dream-construction. The dream proper, which has been completed in the unconscious and is the fulfilment of an unconscious wishful phantasy, is brought up against a portion of (pre)conscious activity which exercises the office of censorship and which, when it has been indemnified, permits the formation of the manifest dream as a compromise. In the same way, what represents the libido in the unconscious has to reckon with the power of the preconscious ego. The opposition which had been raised against it in the ego pursues it as an 'anticathexis' and compels it to choose a form of expression which can at the same time become an expression of the opposition itself. Thus the symptom emerges as a many-times-distorted derivative of the unconscious libidinal wish-fulfilment, an ingeniously chosen piece of ambiguity with two meanings in complete mutual contradiction. In this last respect, however, there is a distinction between the construction of a dream and of a symptom. For in dream-formation the preconscious purpose is merely concerned to preserve sleep, to allow nothing that would disturb it to make its way into consciousness; it does not insist upon calling out sharply 'No! on the contrary!' to the unconscious wishful impulse. It can afford to be more tolerant because the situation of someone sleeping is less perilous. The state of sleep in itself bars any outlet into reality.

[1916-1917, 3418]

Since the column of faeces stimulates the erotogenic mucous membrane of the bowel, it plays the part of an active organ in regard to it; it behaves just as the penis does to the vaginal mucous membrane, and acts as it were as its forerunner during the cloacal epoch. The handing over of faeces for the sake of (out of love for) some one else becomes a prototype of castration; it is the first occasion upon which an individual parts with a piece of his own body¹ in order to gain the favour of some other person whom he loves. So that a person's love of his own penis, which is in other respects narcissistic, is not without an element of anal erotism. 'Faeces', 'baby' and 'penis' thus form a unity, an unconscious concept (sit venia verbo) - the concept, namely, of 'a little one' that can become separated from one's body. Along these paths of association the libidinal cathexis may become displaced or intensified in ways which are pathologically important and which are revealed by analysis.

[1918b, 3566]
REPRESSION  A different result is brought about if in the course of development some of the components which are of excessive strength in the disposition are submitted to the process of repression (which, it must be insisted, is not equivalent to their being abolished). If this happens, the excitations concerned continue to be generated as before; but they are prevented by psychical obstruction from attaining their aim and are diverted into numerous other channels till they find their way to expression as symptoms. The outcome may be an approximately normal sexual life - though usually a restricted one - but there is in addition psychoneurotic illness. These particular cases have become familiar to us from the psycho-analytic investigation of neurotics. Their sexual life begins like that of perverts, and a considerable part of their childhood is occupied with puerile sexual activity which occasionally extends far into maturity. A reversal due to repression then occurs, owing to internal causes (usually before puberty, but now and then even long afterwards), and from that time onwards neurosis takes the place of perversion, without the old impulses being extinguished. We are reminded of the proverb 'Junge Hure, alte Betschwester', only that here youth has lasted all too short a time. The fact that perversion can be replaced by neurosis in the life of the same person, like the fact which we have already mentioned that perversion and neurosis can be distributed among different members of the same family, tallies with the view that neurosis is the negative of perversion.

In considering the question of abstinence, the distinction is not nearly strictly enough made between two forms of it - namely abstention from any sexual activity whatever and abstention from sexual intercourse with the opposite sex. Many people who boast of succeeding in being abstinent have only been able to do so with the help of masturbation and similar satisfactions which are linked with the auto-erotic sexual activities of early childhood. But precisely because of this connection such substitutive means of sexual satisfaction are by no means harmless; they predispose to the numerous varieties of neuroses and psychoses which are conditional on an involution of sexual life to its infantile forms. Masturbation, moreover, is far from meeting the ideal demands of civilized sexual morality, and consequently drives young people into the same conflicts with the ideals of education which they hoped to escape by abstinence. Furthermore, it vitiates the character through indulgence, and this in more than one way. In the first place, it teaches people to achieve important aims without taking trouble and by easy paths instead of through an energetic exertion of force - that is, it follows the principle that sexuality lays down the pattern of behaviour; secondly, in the phantasies that accompany satisfaction the sexual object is raised to a degree of excellence which is not easily found again in reality. A witty writer (Karl Kraus in the Vienna paper Die Fackel) once expressed this truth in reverse by cynically remarking: 'Copulation is no more than an unsatisfying substitute for masturbation.'

Our work on the question of the disposition to neurotic affections has added the 'infantile' factor to the somatic and hereditary ones hitherto recognized. Psycho-analysis was obliged to trace back patients' mental life to their early infancy, and the conclusion was reached that inhibitions of mental development ('infantilisms') present a disposition to neurosis. In particular, we have learnt from our investigations of sexual life that there really is such a thing as 'infantile sexuality', that the sexual instinct is made up of many components and passes through a complicated course of development, the final outcome of which, after many restrictions and transformations, is the 'normal' sexuality of adults. The puzzling perversions of the sexual instinct which occur in adults appear to be either inhibitions of development, fixations or lop-sided growths. Thus neuroses are the negative of perversions.
The only impression we gain is that these events of childhood are somehow demanded as a necessity, that they are among the essential elements of a neurosis. If they have occurred in reality, so much to the good; but if they have been withheld by reality, they are put together from hints and supplemented by phantasy. The outcome is the same, and up to the present we have not succeeded in pointing to any difference in the consequences, whether phantasy or reality has had the greater share in these events of childhood. Here we simply have once again one of the complementary relations that I have so often mentioned; moreover it is the strangest of all we have met with. Whence comes the need for these phantasies and the material for them? There can be no doubt that their sources lie in the instincts; but it has still to be explained why the same phantasies with the same content are created on every occasion. I am prepared with an answer which I know will seem daring to you. I believe these primal phantasies, as I should like to call them, and no doubt a few others as well, are a phylogenetic endowment. In them the individual reaches beyond his own experience into primaeval experience at points where his own experience as been too rudimentary. It seems to me quite possible that all the things that are told to us to-day in analysis as phantasy - the seduction of children, the inflaming of sexual excitement by observing parental intercourse, the threat of castration (or rather castration itself) - were once real occurrences in the primaeval times of the human family, and that children in their phantasies are simply filling in the gaps in individual truth with prehistoric truth. I have repeatedly been led to suspect that the psychology of the neuroses has stored up in it more of the antiquities of human development than any other source.

The Aetiological Significance of Sexual Life. - The second novelty which emerged after the hypnotic technique had been replaced by free associations was of a clinical nature. It was discovered in the course of the prolonged search for the traumatic experiences from which hysterical symptoms appeared to be derived. The more carefully the search was pursued the more extensive seemed to be the network of aetiologically significant impressions involved, but the further back, too, did they reach into the patient's puberty or childhood. At the same time they assumed a uniform character and eventually it became inevitable to bow before the evidence and recognize that at the root of the formation of every symptom there were to be found traumatic experiences from early sexual life. Thus a sexual trauma stepped into the place of an ordinary trauma and the latter was seen to owe its aetiological significance to an associative or symbolic connection with the former, which had preceded it. An investigation of cases of common nervousness (falling into the two classes of neurasthenia and anxiety neurosis) which was simultaneously undertaken led to the conclusion that these disorders could be traced to contemporary abuses in the patients' sexual life and could be removed if these were brought to an end. It was thus easy to infer that neuroses in general are an expression of disturbances in sexual life, the so-called actual-neuroses being the consequences (by chemical agency) of contemporary injuries and the psycho-neuroses the consequences (by psychical modification) of bygone injuries to a biological function which had hitherto been gravely neglected by science. None of the theses of psycho-analysis has met with such tenacious scepticism or such embittered resistance as this assertion of the preponderating aetiological significance of sexual life in the neuroses. It should, however, be expressly remarked that, in its development up to the present day, psycho-analysis has found no reason to retreat from this opinion.

[1916-1917, 3427]

[1923a, 3920]
I have already mentioned that my investigation of the precipitating and underlying causes of the neuroses led me more and more frequently to conflicts between the subject's sexual impulses and his resistances to sexuality. In my search for the pathogenic situations in which the repressions of sexuality had set in and in which the symptoms, as substitutes for what was repressed, had had their origin, I was carried further and further back into the patient's life and ended by reaching the first years of his childhood. What poets and students of human nature had always asserted turned out to be true: the impressions of that early period of life, though they were for the most part buried in amnesia, left ineradicable traces upon the individual's growth and in particular laid down the disposition to any nervous disorder that was to follow. But since these experiences of childhood were always concerned with sexual excitations and the reaction against them, I found myself faced by the fact of infantile sexuality - once again a novelty and a contradiction of one of the strongest of human prejudices. Childhood was looked upon as 'innocent' and free from the lusts of sex, and the fight with the demon of 'sensuality' was not thought to begin until the troubled age of puberty. Such occasional sexual activities as it had been impossible to overlook in children were put down as signs of degeneracy or premature depravity or as a curious freak of nature. Few of the findings of psycho-analysis have met with such universal contradiction or have aroused such an outburst of indignation as the assertion that the sexual function starts at the beginning of life and reveals its presence by important signs even in childhood. And yet no other finding of analysis can be demonstrated so easily and so completely. [1925d, 4209]

A feebleness of the ego of this sort is to be found in all of us in childhood; and that is why the experiences of the earliest years of childhood are of such great importance for later life. Under the extraordinary burden of this period of childhood we have in a few years to cover the enormous developmental distance between stone-age primitive men and the participants in contemporary civilization, and, at the same time and in particular, we have to fend off the instinctual impulses of the early sexual period - under this burden, then, our ego takes refuge in repression and lays itself open to a childhood neurosis, the precipitate of which it carries with it into maturity as a disposition to a later nervous illness. Everything now depends on how the growing organism is treated by fate. If life becomes too hard, if the gulf between instinctual claims and the demands of reality becomes too great, the ego may fail in its efforts to reconcile the two, and the more readily, the more it is inhibited by the disposition carried over by it from infancy. The process of repression is then repeated, the instincts tear themselves away from the ego's domination, find their substitutive satisfactions along the paths of regression, and the poor ego has become helplessly neurotic. [1926e, 4382]
REPRESSION  A different result is brought about if in the course of development some of the components which are of excessive strength in the disposition are submitted to the process of repression (which, it must be insisted, is not equivalent to their being abolished). If this happens, the excitations concerned continue to be generated as before; but they are prevented by psychical obstruction from attaining their aim and are diverted into numerous other channels till they find their way to expression as symptoms. The outcome may be an approximately normal sexual life - though usually a restricted one - but there is in addition psychoneurotic illness. These particular cases have become familiar to us from the psycho-analytic investigation of neurotics. Their sexual life begins like that of perverts, and a considerable part of their childhood is occupied with perverse sexual activity which occasionally extends far into maturity. A reversal due to repression then occurs, owing to internal causes (usually before puberty, but now and then even long afterwards), and from that time onwards neurosis takes the place of perversion, without the old impulses being extinguished. We are reminded of the proverb 'Junge Hure, alte Betschwester,' only that here youth has lasted all too short a time. The fact that perversion can be replaced by neurosis in the life of the same person, like the fact which we have already mentioned that perversion and neurosis can be distributed among different members of the same family, tallies with the view that neurosis is the negative of perversion.

[1905d, 1548]

I could not further elucidate this part of my theory without a detailed discussion of my views on repression. It will be enough here to refer to my Three Essays (1905d), in which I have attempted to throw some light - if only a feeble one - on the somatic processes in which the essential nature of sexuality is to be looked for. I have there shown that the constitutional sexual disposition of children is incomparably more variegated than might have been expected, that it deserves to be described as 'polymorphously perverse' and that what is spoken of as the normal behaviour of the sexual function emerges from this disposition after certain of its components have been repressed. By pointing out the infantile elements in sexuality I was able to establish a simple correlation between health, perversion and neurosis. I showed that normality is a result of the repression of certain component instincts and constituents of the infantile disposition and of the subordination of the remaining constituents under the primacy of the genital zones in the service of the reproductive function. I showed that perversions correspond to disturbances of this coalescence owing to the overpowering and compulsive development of certain of the component instincts, while neuroses can be traced back to an excessive repression of the libidinal trends. Since almost all the perverse instincts of the infantile disposition can be recognized as the forces concerned in the formation of symptoms in neuroses, though in a state of repression, I was able to describe neurosis as being the 'negative' of perversion.

[1906a, 1581]
In my *Three Essays on the Theory of Sexuality* I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics *endeavour to protect themselves against any such sexualization of their social instinctual cathexes*, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) *schizophrenia*; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations. [1911c, 2431]

Our work on the question of the disposition to neurotic affections has added the 'infantile' factor to the somatic and hereditary ones hitherto recognized. Psycho-analysis was obliged to trace back patients' mental life to their early infancy, and the conclusion was reached that inhibitions of mental development ('infantilisms') present a disposition to neurosis. In particular, we have learnt from our investigations of sexual life that there really is such a thing as 'infantile sexuality', that the sexual instinct is made up of many components and passes through a complicated course of development, the final outcome of which, after many restrictions and transformations, is the 'normal' sexuality of adults. The puzzling perversions of the sexual instinct which occur in adults appear to be either inhibitions of development, fixations or lop-sided growths. Thus neuroses are the negative of perversions. [1913m, 2547]

(7) While the ego goes through its transformation from a pleasure-ego into a reality-ego, the sexual instincts undergo the changes that lead them from their original auto-erotism through various intermediate phases to object-love in the service of procreation. If we are right in thinking that each step in these two courses of development may become the site of a disposition to later neurotic illness, it is plausible to suppose that the form taken by the subsequent illness (the *choice of neurosis*) will depend on the particular phase of the development of the ego and of the libido in which the dispositional inhibition of development has occurred. Thus unexpected significance attaches to the chronological features of the two developments (which have not yet been studied), and to possible variations in their synchronization. [1911b, 2556]
Already a few years back we ventured, with the help of these hypotheses, to approach the problem of choice of neurosis. Our method of work, which aims at discovering normal conditions by studying their disturbances, led us to adopt a very singular and unexpected line of attack. The order in which the main forms of psychoneurosis are usually enumerated - Hysteria, Obsessional Neurosis, Paranoia, Dementia Praecox - corresponds (even though not quite exactly) to the order of the ages at which the onset of these disorders occurs. Hysterical forms of illness can be observed even in earliest childhood; obsessional neurosis usually shows its first symptoms in the second period of childhood (between the ages of six and eight); while the two other psychoneuroses, which I have brought together under the heading of 'paraphrenia', do not appear until after puberty and during adult life. It is these disorders - the last to emerge - which were the first to show themselves accessible to our enquiry into the dispositions that result in the choice of neurosis. The characteristics peculiar to both of them - megalomania, turning away from the world of objects, increased difficulty in transference - have obliged us to conclude that their dispositional fixation is to be looked for in a stage of libidinal development before object-choice has been established - that is in the phase of auto-erotism and of narcissism. Thus these forms of illness, which make their appearance so late, go back to very early inhibitions and fixations.

This would accordingly lead us to suppose that the disposition to hysteria and obsessional neurosis, the two transference neuroses proper, which produce their symptoms at an early age, lies in later phases of libidinal development. But at what point in them should we find a developmental inhibition? and, above all, what would be the difference in phases that would determine a disposition to obsessional neurosis as contrasted with hysteria? For a long time nothing was to be learned about this; and my earlier attempts at discovering these two dispositions - the notion, for instance, that hysteria might be determined by passivity and obsessional neurosis by activity in infantile experience - had soon to be abandoned as incorrect.
Your second observation, too, raises a justifiable question, but it is aimed in the wrong direction. It is true that a withdrawal of the object-libido into the ego is not directly pathogenic; it takes place, indeed, as we know, every time before we go to sleep, only to be reversed when we wake up. The amoeba withdraws its protrusions only to send them out again at the first opportunity. But it is quite a different thing when a particular, very energetic process forces a withdrawal of libido from objects. Here the libido that has become narcissistic cannot find its way back to objects, and this interference with the libido's mobility certainly becomes pathogenic. It seems that an accumulation of narcissistic libido beyond a certain amount is not tolerated. We may even imagine that it was for that very reason that object-cathexes originally came about, that the ego was obliged to send out its libido so as not to fall ill as a result of its being dammed up. If it lay within our plan to go more deeply into dementia praecox, I would show you that the process which detaches the libido from objects and cuts off its return to them is closely related to the process of repression and is to be looked at as its counterpart. But you would, first and foremost, find yourselves on familiar ground when you learnt that the determinants of this process are almost identical - so far as we know at present - with those of repression. The conflict seems to be the same and to be carried on between the same forces. If the outcome is so different from, for instance, that in hysteria, the reason can only depend on a difference in innate disposition. The weak spot in the libidinal development of these patients lies in a different phase; the determining fixation, which, as you will recollect, permits the irruption that leads to the formation of symptoms, lies elsewhere, probably in the stage of primitive narcissism to which dementia praecox returns in its final outcome. It is very remarkable that in the case of all the narcissistic neuroses we have to assume fixation points for the libido going back to far earlier phases of development than in hysteria or obsessional neurosis. As you heard, however, the concepts which we arrived at during our study of the transference neuroses are adequate in helping us to find our way about in the narcissistic neuroses which are so much more severe in practice. The conformities go very far; at bottom the field of phenomena is the same. And you can imagine how small a prospect anyone has of explaining these disorders (which belong within the sphere of psychiatry) who is not forearmed for his task with an analytic knowledge of the transference neuroses.

With this as a starting-point we go on to make our first important discovery. We learn that, when we try to understand neurotic disorders, by far the greater significance attaches to the sexual instincts; that in fact neuroses are the specific disorders, so to speak, of the sexual function; that in general whether or not a person develops a neurosis depends on the quantity of his libido, and on the possibility of satisfying it and of discharging it through satisfaction; that the form taken by the disease is determined by the way in which the individual passes through the course of development of his sexual function, or, as we put it, by the fixations his libido has undergone in the course of its development; and, further, that by a special, not very simple technique for influencing the mind we are able to throw light on the nature of some groups of neuroses and at the same time to do away with them. Our therapeutic efforts have their greatest success with a certain class of neuroses which proceed from a conflict between the ego-instincts and the sexual instincts. For in human beings it may happen that the demands of the sexual instincts, whose reach of course extends far beyond the individual, seem to the ego to constitute a danger which threatens its self-preservation or its self-esteem. The ego then assumes the defensive, denies the sexual instincts the satisfaction they desire and forces them into those by-paths of substitutive satisfaction which become manifest as nervous symptoms.
The Development of the Libido. - The sexual instinct, the dynamic manifestation of which in mental life we shall call 'libido', is made up of component instincts into which it may once more break up and which are only gradually united into well-defined organizations. The sources of these component instincts are the organs of the body and in particular certain specially marked erogenous zones; but contributions are made to libido from every important functional process in the body. At first the individual component instincts strive for satisfaction independently of one another, but in the course of development they become more and more convergent and concentrated. The first (pregenital) stage of organization to be discerned is the oral one, in which - in conformity with the suckling's predominant interest - the oral zone plays the leading part. This is followed by the sadistic-anal organization, in which the anal zone and the component instinct of sadism are particularly prominent; at this stage the difference between the sexes is represented by the contrast between active and passive. The third and final stage of organization is that in which the majority of the component instincts converge under the primacy of the genital zones. As a rule this development is passed through swiftly and unobtrusively; but some individual portions of the instincts remain behind at the prodromal stages of the process and thus give rise to fixations of libido, which are important as constituting predispositions for subsequent irruptions of repressed impulses and which stand in a definite relation to the later development of neuroses and perversions. (See the article on 'The Libido Theory'.)

The sexual function, as I found, is in existence from the very beginning of the individual's life, though at first it is attached to the other vital functions and does not become independent of them until later; it has to pass through a long and complicated process of development before it becomes what we are familiar with as the normal sexual life of the adult. It begins by manifesting itself in the activity of a whole number of component instincts. These are dependent upon erogenous zones in the body; some of them make their appearance in pairs of opposite impulses (such as sadism and masochism or the impulses to look and to be looked at); they operate independently of one another in a search for pleasure, and they find their object for the most part in the subject's own body. Thus at first the sexual function is non-centralized and predominantly auto-erotic. Later, syntheses begin to appear in it; a first stage of organization is reached under the dominance of the oral components, an anal-sadistic stage follows, and it is only after the third stage has at last been reached that the primacy of the genitals is established and that the sexual function begins to serve the ends of reproduction. In the course of this process of development a number of elements of the various component instincts turn out to be unserviceable for this last end and are therefore left on one side or turned to other uses, while others are diverted from their aims and carried over into the genital organization. I gave the name of libido to the energy of the sexual instincts and to that form of energy alone. I was next driven to suppose that the libido does not always pass through its prescribed course of development smoothly. As a result either of the excessive strength of certain of the components or of experiences involving premature satisfaction, fixations of the libido may occur at various points in the course of its development. If subsequently a repression takes place, the libido flows back to these points (a process described as regression), and it is from them that the energy breaks through in the form of a symptom. Later on it further became clear that the localization of the point of fixation is what determines the choice of neurosis, that is, the form in which the subsequent illness makes its appearance.
(2) For cultural reasons the most intense repression falls upon the sexual instincts; but it is precisely in connection with them that repression most easily miscarries, so that neurotic symptoms are found to be substitutive satisfactions of repressed sexuality. The belief that in man sexual life begins only at puberty is incorrect. On the contrary, signs of it can be detected from the beginning of extra-uterine existence; it reaches a first culminating point at or before the fifth year ('early period'), after which it is inhibited or interrupted ('latency period') until the age of puberty, which is the second climax of its development. This diphasic onset of sexual development seems to be distinctive of the genus Homo. All experiences during the first period of childhood are of the greatest importance to the individual, and in combination with his inherited sexual constitution form the dispositions for the subsequent development of character and disease. It is wrong to make sexuality coincide with 'genitality'. The sexual instincts pass through a complicated course of development, and it is only at the end of it that the 'primacy of the genital zones' is attained. Before this there are a number of 'pregenital' organizations of the libido - points at which it may become 'fixated' and to which, in the event of subsequent repression, it will return ('regression'). The infantile fixations of the libido are what determine the form of any later neurosis. Thus the neuroses are to be regarded as inhibitions in the development of the libido. There are no specific causes of nervous disorders; the question whether a conflict finds a healthy solution or leads to a neurotic inhibition of function depends upon quantitative considerations.

[1926f, 4405]

So far all this is trite repetition. And you must not suppose that the many things I have not mentioned this time no longer hold good. This repetition was necessary so that I might use it as the starting-point for a report on the advances in our knowledge. We can boast of having learnt much that is new, particularly about the early organizations of the libido, and of having obtained a clearer grasp of the significance of what is old; and I will give you at least a few examples to demonstrate this. Abraham showed in 1924 that two stages can be distinguished in the sadistic-anal phase. The earlier of these is dominated by the destructive trends of destroying and losing, the later one by trends friendly towards objects - those of keeping and possessing. It is in the middle of this phase, therefore, that consideration for the object makes its first appearance as a precursor of a later erotic cathexis. We are equally justified in making a similar subdivision in the first, oral phase. In the first sub-stage what is in question is only oral incorporation, there is no ambivalence at all in the relation to the object - the mother's breast. The second stage, characterized by the emergence of the biting activity, may be described as the 'oral-sadistic' one; it exhibits for the first time the phenomena of ambivalence, which become so much clearer afterwards, in the following sadistic-anal phase. The value of these new distinctions is to be seen especially if we look for the dispositional points in the development of the libido in the case of particular neuroses, such as obsessional neurosis or melancholia. You must here recall to mind what we have learnt about the connection between fixation of the libido, disposition and regression.

[1933a, 4704]

Our attitude to the phases of the organization of the libido has in general shifted a little. Whereas earlier we chiefly emphasized the way in which each of them passed away before the next, our attention now is directed to the facts that show us how much of each earlier phase persists along of and behind the later configurations and obtains a permanent representation in the libidinal economy and character of the subject. Still more significant have studies become which have taught us how frequently under pathological conditions regressions to earlier phases occur and that particular regressions are characteristic of particular forms of illness. But I cannot go into that here, it forms part of the specialized psychology of the neuroses.

[1933a, 4705]
Your second observation, too, raises a justifiable question, but it is aimed in the wrong direction. It is true that a withdrawal of the object-libido into the ego is not directly pathogenic; it takes place, indeed, as we know, every time before we go to sleep, only to be reversed when we wake up. The amoeba withdraws its protrusions only to send them out again at the first opportunity. But it is quite a different thing when a particular, very energetic process forces a withdrawal of libido from objects. Here the libido that has become narcissistic cannot find its way back to objects, and this interference with the libido's mobility certainly becomes pathogenic. It seems that an accumulation of narcissistic libido beyond a certain amount is not tolerated. We may even imagine that it was for that very reason that object-cathexes originally came about, that the ego was obliged to send out its libido so as not to fall ill as a result of its being dammed up. If it lay within our plan to go more deeply into dementia praecox, I would show you that the process which detaches the libido from objects and cuts off its return to them is closely related to the process of repression and is to be looked at as its counterpart. But you would, first and foremost, find yourselves on familiar ground when you learnt that the determinants of this process are almost identical - so far as we know at present - with those of repression. The conflict seems to be the same and to be carried on between the same forces. If the outcome is so different from, for instance, that in hysteria, the reason can only depend on a difference in innate disposition. The weak spot in the libidinal development of these patients lies in a different phase; the determining fixation, which, as you will recollect, permits the irruption that leads to the formation of symptoms, lies elsewhere, probably in the stage of primitive narcissism to which dementia praecox returns in its final outcome. It is very remarkable that in the case of all the narcissistic neuroses we have to assume fixation points for the libido going back to far earlier phases of development than in hysteria or obsessional neurosis. As you heard, however, the concepts which we arrived at during our study of the transference neuroses are adequate in helping us to find our way about in the narcissistic neuroses which are so much more severe in practice. The conformities go very far; at bottom the field of phenomena is the same. And you can imagine how small a prospect anyone has of explaining these disorders (which belong within the sphere of psychiatry) who is not forearmed for his task with an analytic knowledge of the transference neuroses.

[1916-1917, 3466]
One of these patients gave me a piece of information which sheds a clear light on the origin of this curious habit. This young woman had never broken herself of the habit of sucking. She retained a memory of her childhood, dating back, according to her, to the first half of her second year, in which she saw herself sucking at her nurse's breast and at the same time pulling rhythmically at the lobe of her nurse's ear. No one will feel inclined to dispute, I think, that the mucous membrane of the lips and mouth is to be regarded as a primary 'erotogenic zone', since it preserves this earlier significance in the act of kissing, which is looked upon as normal. An intense activity of this erotogenic zone at an early age thus determines the subsequent presence of a somatic compliance on the part of the tract of mucous membrane which begins at the lips. Thus, at a time when the sexual object proper, that is, the male organ, has already become known, circumstances may arise which once more increase the excitation of the oral zone, whose erotogenic character has, as we have seen, been retained. It then needs very little creative power to substitute the sexual object of the moment (the penis) for the original object (the nipple) or for the finger which does duty for it, and to place the current sexual object in the situation in which gratification was originally obtained. So we see that this excessively repulsive and perverted phantasy of sucking at a penis has the most innocent origin. It is a new version of what may be described as a prehistoric impression of sucking at the mother's or nurse's breast - an impression which has usually been revived by contact with children who are being nursed. In most instances a cow's udder has aptly played the part of an image intermediate between a nipple and a penis.

[1905e, 1389]

It is not every child who sucks in this way. It may be assumed that those children do so in whom there is a constitutional intensification of the erotogenic significance of the labial region. If that significance persists, these same children when they are grown up will become epicures in kissing, will be inclined to perverse kissing, or, if males, will have a powerful motive for drinking and smoking. If, however, repression ensues, they will feel disgust at food and will produce hysterical vomiting. The repression extends to the nutritional instinct owing to the dual purpose served by the labial zone. Many of my women patients who suffer from disturbances of eating, globus hystericus, constriction of the throat and vomiting, have indulged energetically in sucking during their childhood.

[1905d, 1503]
Children who are making use of the susceptibility to erotogenic stimulation of the anal zone betray themselves by holding back their stool till its accumulation brings about violent muscular contractions and, as it passes through the anus, is able to produce powerful stimulation of the mucous membrane. In so doing it must no doubt cause not only painful but also highly pleasurable sensations. One of the clearest signs of subsequent eccentricity or nervousness is to be seen when a baby obstinately refuses to empty his bowels when he is put on the pot - that is, when his nurse wants him to - and holds back that function till he himself chooses to exercise it. He is naturally not concerned with dirtying the bed, he is only anxious not to miss the subsidiary pleasure attached to defaecating. Educators are once more right when they describe children who keep the process back as 'naughty'.

The retention of the faecal mass, which is thus carried out intentionally by the child to begin with, in order to serve, as it were, as a masturbatory stimulus upon the anal zone or to be employed in his relation to the people looking after him, is also one of the roots of the constipation which is so common among neuropaths. Further, the whole significance of the anal zone is reflected in the fact that few neurotics are to be found without their special scatological practices, ceremonies, and so on, which they carefully keep secret.¹

Since the column of faeces stimulates the erotogenic mucous membrane of the bowel, it plays the part of an active organ in regard to it; it behaves just as the penis does to the vaginal mucous membrane, and acts as it were as its forerunner during the cloacal epoch. The handing over of faeces for the sake of (out of love for) some one else becomes a prototype of castration; it is the first occasion upon which an individual parts with a piece of his own body¹ in order to gain the favour of some other person whom he loves. So that a person's love of his own penis, which is in other respects narcissistic, is not without an element of anal erotism. 'Faeces', 'baby' and 'penis' thus form a unity, an unconscious concept (sit venia verbo) - the concept, namely, of 'a little one' that can become separated from one's body. Along these paths of association the libidinal cathexis may become displaced or intensified in ways which are pathologically important and which are revealed by analysis.

¹[1905d, 1507]
²[1918b, 3566]
(2) For cultural reasons the most intense repression falls upon the sexual instincts; but it is precisely in connection with them that repression most easily miscarries, so that neurotic symptoms are found to be substitutive satisfactions of repressed sexuality. The belief that in man sexual life begins only at puberty is incorrect. On the contrary, signs of it can be detected from the beginning of extra-uterine existence; it reaches a first culminating point at or before the fifth year ('early period'), after which it is inhibited or interrupted ('latency period') until the age of puberty, which is the second climax of its development. This diphasic onset of sexual development seems to be distinctive of the genus Homo. All experiences during the first period of childhood are of the greatest importance to the individual, and in combination with his inherited sexual constitution form the dispositions for the subsequent development of character and disease. It is wrong to make sexuality coincide with 'genitality'. The sexual instincts pass through a complicated course of development, and it is only at the end of it that the 'primacy of the genital zones' is attained. Before this there are a number of 'pregenital' organizations of the libido - points at which it may become 'fixated' and to which, in the event of subsequent repression, it will return ('regression'). The infantile fixations of the libido are what determine the form of any later neurosis. Thus the neuroses are to be regarded as inhibitions in the development of the libido. There are no specific causes of nervous disorders; the question whether a conflict finds a healthy solution or leads to a neurotic inhibition of function depends upon quantitative considerations.

This process is not always performed faultlessly. Inhibitions in its development manifest themselves as the many sorts of disturbance in sexual life. When this is so, we find fixations of the libido to conditions in earlier phases, whose urge, which is independent of the normal sexual aim, is described as perversion. One such developmental inhibition, for instance, is homosexuality when it is manifest. Analysis shows that in every case a homosexual object-tie was present and in most cases persisted in a latent condition. The situation is complicated by the fact that as a rule the processes necessary for bringing about a normal outcome are not completely present or absent, but partially present, so that the final result remains dependent on these quantitative relations. In these circumstances the genital organization is, it is true, attained, but it lacks those portions of the libido which have not advanced with the rest and have remained fixated to pregenital objects and aims. This weakening shows itself in a tendency, if there is an absence of genital satisfaction or if there are difficulties in the real external world, for the libido to hark back to its earlier pregenital cathexes (regression).

[1926f, 4405]

[1940a [1938], 4966]
We shall be in even closer harmony with psycho-analytic research if we give a place of preference among the accidental factors to the experiences of early childhood. The single aetiological series then falls into two, which may be called the dispositional and the definitive. In the first the constitution and the accidental experiences of childhood interact in the same manner as do the disposition and later traumatic experiences in the second. All the factors that impair sexual development show their effects by bringing about a regression, a return to an earlier phase of development.
[1905d, 1550]

In my *Three Essays on the Theory of Sexuality* I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paraoides endeavour to protect themselves against any such sexualization of their social instinctual cathexes, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) schizophrenia; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.
[1911c, 2431]

In spite of the very clear differences between the two types of onset of illness that we have described, they nevertheless coincide in essentials and can without difficulty be brought together into a unity. Falling ill from frustration may also be regarded as incapacity for adaptation to reality - in the particular case, that is, in which reality frustrates satisfaction of libido. Falling ill under the conditions of the second type leads directly to a special case of frustration. It is true that reality does not here frustrate every kind of satisfaction; but it frustrates the one kind which the subject declares is the only possible one. Nor does the frustration come immediately from the external world, but primarily from certain trends in the subject's ego. Nevertheless, frustration remains the common factor and the more inclusive one. In consequence of the conflict which immediately sets in in the second type, both kinds of satisfaction - the habitual one as well as the one aimed at - are equally inhibited; a damming-up of libido, with all its consequences, comes about just as it does in the first case. The psychical events leading to the formation of symptoms are if anything easier to follow in the second type than in the first; for in the second type the pathogenic fixations of the libido do not need to be freshly established, but have already been in force while the subject was healthy. A certain amount of introversion of libido is, as a rule, already present; and there is a saving of some part of the subject's regression to the infantile stage, owing to the fact that his forward development has not yet completed its course.
[1912c, 2562]
Your second observation, too, raises a justifiable question, but it is aimed in the wrong direction. It is true that a withdrawal of the object-libido into the ego is not directly pathogenic; it takes place, indeed, as we know, every time before we go to sleep, only to be reversed when we wake up. The amoeba withdraws its protrusions only to send them out again at the first opportunity. But it is quite a different thing when a particular, very energetic process forces a withdrawal of libido from objects. Here the libido that has become narcissistic cannot find its way back to objects, and this interference with the libido's mobility certainly becomes pathogenic. It seems that an accumulation of narcissistic libido beyond a certain amount is not tolerated. We may even imagine that it was for that very reason that object-cathexes originally came about, that the ego was obliged to send out its libido so as not to fall ill as a result of its being dammed up. If it lay within our plan to go more deeply into dementia praecox, I would show you that the process which detaches the libido from objects and cuts off its return to them is closely related to the process of repression and is to be looked at as its counterpart. But you would, first and foremost, find yourselves on familiar ground when you learnt that the determinants of this process are almost identical - so far as we know at present - with those of repression. The conflict seems to be the same and to be carried on between the same forces. If the outcome is so different from, for instance, that in hysteria, the reason can only depend on a difference in innate disposition. The weak spot in the libidinal development of these patients lies in a different phase; the determining fixation, which, as you will recollect, permits the irruption that leads to the formation of symptoms, lies elsewhere, probably in the stage of primitive narcissism to which dementia praecox returns in its final outcome. It is very remarkable that in the case of all the narcissistic neuroses we have to assume fixation points for the libido going back to far earlier phases of development than in hysteria or obsessional neurosis. As you heard, however, the concepts which we arrived at during our study of the transference neuroses are adequate in helping us to find our way about in the narcissistic neuroses which are so much more severe in practice. The conformities go very far; at bottom the field of phenomena is the same. And you can imagine how small a prospect anyone has of explaining these disorders (which belong within the sphere of psychiatry) who is not forearmed for his task with an analytic knowledge of the transference neuroses.

[1916-1917, 3466]
The Theory of Repression. - These theoretical considerations, taken together with the immediate impressions derived from analytic work, lead to a view of the neuroses which may be described in the roughest outline as follows. The neuroses are the expression of conflicts between the ego and such of the sexual impulses as seem to the ego incompatible with its integrity or with its ethical standards. Since these impulses are not ego-syntonic, the ego has repressed them: that is to say, it has withdrawn its interest from them and has shut them off from becoming conscious as well as from obtaining satisfaction by motor discharge. If in the course of analytic work one attempts to make these repressed impulses conscious, one becomes aware of the repressive forces in the form of resistance. But the achievement of repression fails particularly readily in the case of the sexual instincts. Their dammed-up libido finds other ways out from the unconscious: for it regresses to earlier phases of development and earlier attitudes towards objects, and, at weak points in the libidinal development where there are infantile fixations, it breaks through into consciousness and obtains discharge. What results is a symptom and consequently in its essence a substitutive sexual satisfaction. Nevertheless the symptom cannot entirely escape from the repressive forces of the ego and must therefore submit to modifications and displacements exactly as happens with dreams - by means of which its characteristic of being a sexual satisfaction becomes unrecognizable. Consequently symptoms are in the nature of compromises between the repressed sexual instincts and the repressing ego-instincts; they represent a wish-fulfilment for both partners to the conflict simultaneously, but one which is incomplete for each of them. This is quite strictly true of the symptoms of hysteria, while in the symptoms of obsessional neurosis there is often a stronger emphasis upon the side of the repressing function owing to the erection of reaction-formations, which are assurances against sexual satisfaction.

[1923a, 3923]

The sexual function, as I found, is in existence from the very beginning of the individual's life, though at first it is attached to the other vital functions and does not become independent of them until later; it has to pass through a long and complicated process of development before it becomes what we are familiar with as the normal sexual life of the adult. It begins by manifesting itself in the activity of a whole number of component instincts. These are dependent upon erotogenic zones in the body; some of them make their appearance in pairs of opposite impulses (such as sadism and masochism or the impulses to look and to be looked at); they operate independently of one another in a search for pleasure, and they find their object for the most part in the subject's own body. Thus at first the sexual function is non-centralized and predominantly auto-erotic. Later, syntheses begin to appear in it; a first stage of organization is reached under the dominance of the oral components, an anal-sadistic stage follows, and it is only after the third stage has at last been reached that the primacy of the genitals is established and that the sexual function begins to serve the ends of reproduction. In the course of this process of development a number of elements of the various component instincts turn out to be unserviceable for this last end and are therefore left on one side or turned to other uses, while others are diverted from their aims and carried over into the genital organization. I gave the name of libido to the energy of the sexual instincts and to that form of energy alone. I was next driven to suppose that the libido does not always pass through its prescribed course of development smoothly. As a result either of the excessive strength of certain of the components or of experiences involving premature satisfaction, fixations of the libido may occur at various points in the course of its development. If subsequently a repression takes place, the libido flows back to these points (a process described as regression), and it is from them that the energy breaks through in the form of a symptom. Later on it further became clear that the localization of the point of fixation is what determines the choice of neurosis, that is, the form in which the subsequent illness makes its appearance.

[1925d, 4211]
The sexual life of children is of course different from that of adults. The sexual function, from its beginnings to the definitive form in which it is so familiar to us, undergoes a complicated process of development. It grows together from numerous component instincts with different aims and passes through several phases of organization till at last it comes into the service of reproduction. Not all the component instincts are equally serviceable for the final outcome; they must be diverted, remodelled and in part suppressed. Such a far-reaching course of development is not always passed through without a flaw; inhibitions in development take place, partial fixations at early stages of development. If obstacles arise later on to the exercise of the sexual function, the sexual urge - the libido, as we call it - is apt to hark back to these earlier points of fixation. The study of the sexuality of children and its transformations up to maturity has also given us the key to an understanding of what are known as the sexual perversions, which people used always to describe with all the requisite indications of disgust but whose origin they were never able to explain. The whole topic is of uncommon interest, but for the purposes of our conversation there is not much sense in telling you more about it. To find one's way about in it one of course needs anatomical and physiological knowledge, all of which is unfortunately not to be acquired in medical schools. But a familiarity with the history of civilization and with mythology is equally indispensable.

(2) For cultural reasons the most intense repression falls upon the sexual instincts; but it is precisely in connection with them that repression most easily miscarries, so that neurotic symptoms are found to be substitutive satisfactions of repressed sexuality. The belief that in man sexual life begins only at puberty is incorrect. On the contrary, signs of it can be detected from the beginning of extra-uterine existence; it reaches a first culminating point at or before the fifth year ('early period'), after which it is inhibited or interrupted ('latency period') until the age of puberty, which is the second climax of its development. This diphasic onset of sexual development seems to be distinctive of the genus Homo. All experiences during the first period of childhood are of the greatest importance to the individual, and in combination with his inherited sexual constitution form the dispositions for the subsequent development of character and disease. It is wrong to make sexuality coincide with 'genitality'. The sexual instincts pass through a complicated course of development, and it is only at the end of it that the 'primacy of the genital zones' is attained. Before this there are a number of 'pregenital' organizations of the libido - points at which it may become 'fixated' and to which, in the event of subsequent repression, it will return ('regression'). The infantile fixations of the libido are what determine the form of any later neurosis. Thus the neuroses are to be regarded as inhibitions in the development of the libido. There are no specific causes of nervous disorders; the question whether a conflict finds a healthy solution or leads to a neurotic inhibition of function depends upon quantitative considerations.

[1926e, 4353]

[1926f, 4405]
So far all this is trite repetition. And you must not suppose that the many things I have not mentioned this time no longer hold good. This repetition was necessary so that I might use it as the starting-point for a report on the advances in our knowledge. We can boast of having learnt much that is new, particularly about the early organizations of the libido, and of having obtained a clearer grasp of the significance of what is old; and I will give you at least a few examples to demonstrate this. Abraham showed in 1924 that two stages can be distinguished in the sadistic-anal phase. The earlier of these is dominated by the destructive trends of destroying and losing, the later one by trends friendly towards objects - those of keeping and possessing. It is in the middle of this phase, therefore, that consideration for the object makes its first appearance as a precursor of a later erotic cathexis. We are equally justified in making a similar subdivision in the first, oral phase. In the first sub-stage what is in question is only oral incorporation, there is no ambivalence at all in the relation to the object - the mother's breast. The second stage, characterized by the emergence of the biting activity, may be described as the 'oral-sadistic' one; it exhibits for the first time the phenomena of ambivalence, which become so much clearer afterwards, in the following sadistic-anal phase. The value of these new distinctions is to be seen especially if we look for the dispositional points in the development of the libido in the case of particular neuroses, such as obsessional neurosis or melancholia. You must here recall to mind what we have learnt about the connection between fixation of the libido, disposition and regression.

[1933a, 4704]

Our attitude to the phases of the organization of the libido has in general shifted a little. Whereas earlier we chiefly emphasized the way in which each of them passed away before the next, our attention now is directed to the facts that show us how much of each earlier phase persists alongside of and behind the later configurations and obtains a permanent representation in the libidinal economy and character of the subject. Still more significant have studies become which have taught us how frequently under pathological conditions regressions to earlier phases occur and that particular regressions are characteristic of particular forms of illness. But I cannot go into that here, it forms part of the specialized psychology of the neuroses.

[1933a, 4705]

This process is not always performed faultlessly. Inhibitions in its development manifest themselves as the many sorts of disturbance in sexual life. When this is so, we find fixations of the libido to conditions in earlier phases, whose urge, which is independent of the normal sexual aim, is described as perversion. One such developmental inhibition, for instance, is homosexuality when it is manifest. Analysis shows that in every case a homosexual object-tie was present and in most cases persisted in a latent condition. The situation is complicated by the fact that as a rule the processes necessary for bringing about a normal outcome are not completely present or absent, but partially present, so that the final result remains dependent on these quantitative relations. In these circumstances the genital organization is, it is true, attained, but it lacks those portions of the libido which have not advanced with the rest and have remained fixated to pregenital objects and aims. This weakening shows itself in a tendency, if there is an absence of genital satisfaction or if there are difficulties in the real external world, for the libido to hark back to its earlier pregenital cathexes (regression).

[1940a [1938], 4966]
² For example, the phantasies of hysterics concerning sexual and cruel maltreatment correspond, at times even down to details, with the complaints of persecuted paranoics. It is curious, but not unintelligible, that we meet the identical content in the form of reality in the contrivances of perverts for the satisfaction of their desires. [1901b, 1325]

As regards the second kind of emotional reaction, which is not directed against me this time, but against my patient - supposing that my view of her is correct - and which regards the perverse nature of her phantasies as horrible, I should like to say emphatically that a medical man has no business to indulge in such passionate condemnation. I may also remark in passing that it seems to me superfluous for a physician who is writing upon the aberrations of the sexual instincts to seize every opportunity of inserting into the text expressions of his personal repugnance at such revolting things. We are faced by a fact; and it is to be hoped that we shall grow accustomed to it, when we have put our own tastes on one side. We must learn to speak without indignation of what we call the sexual perversions - instances in which the sexual function has extended its limits in respect either to the part of the body concerned or to the sexual object chosen. The uncertainty in regard to the boundaries of what is to be called normal sexual life, when we take different races and different epochs into account, should in itself be enough to cool the zealot's ardour. We surely ought not to forget that the perversion which is the most repellant to us, the sensual love of a man for a man, was not only tolerated by a people so far our superiors in cultivation as were the Greeks, but was actually entrusted by them with important social functions. The sexual life of each one of us extends to a slight degree - now in this direction, now in that - beyond the narrow lines imposed as the standard of normality. The perversions are neither bestial nor degenerate in the emotional sense of the word. They are a development of germs all of which are contained in the undifferentiated sexual disposition of the child, and which, by being suppressed or by being diverted to higher, asexual aims - by being 'sublimated' - are destined to provide the energy for a great number of our cultural achievements. When, therefore, any one has become a gross and manifest pervert, it would be more correct to say that he has remained one, for he exhibits a certain stage of inhibited development. All psychoneurotics are persons with strongly marked perverse tendencies, which have been repressed in the course of their development and have become unconscious. Consequently their unconscious phantasies show precisely the same content as the documentarily recorded actions of perverts - even though they have not read Krafft-Ebing's Psychopathia Sexualis, to which simple-minded people attribute such a large share of the responsibility for the production of perverse tendencies. Psychoneuroses are, so to speak, the negative of perversions. In neurotics their sexual constitution, under which the effects of heredity are included, operates in combination with any accidental influences in their life which may disturb the development of normal sexuality. A stream of water which meets with an obstacle in the river-bed is dammed up and flows back into old channels which had formerly seemed fated to run dry. The motive forces leading to the formation of hysterical symptoms draw their strength not only from repressed normal sexuality but also from unconscious perverse activities.¹ [1905e, 1387]
The less repellent of the so-called sexual perversions are very widely diffused among the whole population, as every one knows except medical writers upon the subject. Or, I should rather say, they know it too; only they take care to forget it at the moment when they take up their pens to write about it. So it is not to be wondered at that this hysterical girl of nearly nineteen, who had heard of the occurrence of such a method of sexual intercourse (sucking at the male organ), should have developed an unconscious phantasy of this sort and should have given it expression by an irritation in her throat and by coughing. Nor would it have been very extraordinary if she had arrived at such a phantasy even without having had any enlightenment from external sources - an occurrence which I have quite certainly observed in other patients. For in her case a noteworthy fact afforded the necessary somatic prerequisite for this independent creation of a phantasy which would coincide with the practices of perverts. She remembered very well that in her childhood she had been a thumb-sucker. Her father, too recollected breaking her of the habit after it had persisted into her fourth or fifth year. Dora herself had a clear picture of a scene from her early childhood in which she was sitting on the floor in a corner sucking her left thumb and at the same time tugging with her right hand at the lobe of her brother's ear as he sat quietly beside her. Here we have an instance of the complete form of self-gratification by sucking, as it has also been described to me by other patients, who had subsequently become anaesthetic and hysterical.

[1905e, 1388]

One of these patients gave me a piece of information which sheds a clear light on the origin of this curious habit. This young woman had never broken herself of the habit of sucking. She retained a memory of her childhood, dating back, according to her, to the first half of her second year, in which she saw herself sucking at her nurse's breast and at the same time pulling rhythmically at the lobe of her nurse's ear. No one will feel inclined to dispute, I think, that the mucous membrane of the lips and mouth is to be regarded as a primary 'erotogenic zone', since it preserves this earlier significance in the act of kissing, which is looked upon as normal. An intense activity of this erotogenic zone at an early age thus determines the subsequent presence of a somatic compliance on the part of the tract of mucous membrane which begins at the lips. Thus, at a time when the sexual object proper, that is, the male organ, has already become known, circumstances may arise which once more increase the excitation of the oral zone, whose erotogenic character has, as we have seen, been retained. It then needs very little creative power to substitute the sexual object of the moment (the penis) for the original object (the nipple) or for the finger which does duty for it, and to place the current sexual object in the situation in which gratification was originally obtained. So we see that this excessively repulsive and perverted phantasy of sucking at a penis has the most innocent origin. It is a new version of what may be described as a prehistoric impression of sucking at the mother's or nurse's breast - an impression which has usually been revived by contact with children who are being nursed. In most instances a cow's udder has aptly played the part of an image intermediate between a nipple and a penis.

[1905e, 1389]

I shall at this point introduce two technical terms. Let us call the person from whom sexual attraction proceeds the sexual object and the act towards which the instinct tends the sexual aim. Scientifically sifted observation, then, shows that numerous deviations occur in respect of both of these - the sexual object and the sexual aim. The relation between these deviations and what is assumed to be normal requires thorough investigation.

[1905d, 1464]
One would be glad on aesthetic grounds to be able to ascribe these and other severe aberrations of the sexual instinct to insanity; but that cannot be done. Experience shows that disturbances of the sexual instinct among the insane do not differ from those that occur among the healthy and in whole races or occupations. Thus the sexual abuse of children is found with uncanny frequency among school teachers and child attendants, simply because they have the best opportunity for it. The insane merely exhibit any such aberration to an intensified degree; or, what is particularly significant, it may become exclusive and replace normal sexual satisfaction entirely.

[1905d, 1475]

The very remarkable relation which thus holds between sexual variations and the descending scale from health to insanity gives us plenty of material for thought. I am inclined to believe that it may be explained by the fact that the impulses of sexual life are among those which, even normally, are the least controlled by the higher activities of the mind. In my experience anyone who is in any way, whether socially or ethically, abnormal mentally is invariably abnormal also in his sexual life. But many people are abnormal in their sexual life who in every other respect approximate to the average, and have, along with the rest, passed through the process of human cultural development, in which sexuality remains the weak spot.

[1905d, 1475]

The most general conclusion that follows from all these discussions seems, however, to be this. Under a great number of conditions and in surprisingly numerous individuals, the nature and importance of the sexual object recedes into the background. What is essential and constant in the sexual instinct is something else.¹

[1905d, 1475]

¹ [Footnote added 1910:] The most striking distinction between the erotic life of antiquity and our own no doubt lies in the fact that the ancients laid the stress upon the instinct itself, whereas we emphasize its object. The ancients glorified the instinct and were prepared on its account to honour even an inferior object; while we despise the instinctual activity in itself, and find excuses for it only in the merits of the object.

[1905d, 1475]

The normal sexual aim is regarded as being the union of the genitals in the act known as copulation, which leads to a release of the sexual tension and a temporary extinction of the sexual instinct - a satisfaction analogous to the satiating of hunger. But even in the most normal sexual process we may detect rudiments which, if they had developed, would have led to the deviations described as 'perversions'. For there are certain intermediate relations to the sexual object, such as touching and looking at it, which lie on the road towards copulation and are recognized as being preliminary sexual aims. On the one hand these activities are themselves accompanied by pleasure, and on the other hand they intensify the excitation, which should persist until the final sexual aim is attained. Moreover, the kiss, one particular contact of this kind, between the mucous membrane of the lips of the two people concerned, is held in high sexual esteem among many nations (including the most highly civilized ones), in spite of the fact that the parts of the body involved do not form part of the sexual apparatus but constitute the entrance to the digestive tract. Here, then, are factors which provide a point of contact between the perversions and normal sexual life and which can also serve as a basis for their classification. Perversions are sexual activities which either (a) extend, in an anatomical sense, beyond the regions of the body that are designed for sexual union, or (b) linger over the intermediate relations to the sexual object which should normally be traversed rapidly on the path towards the final sexual aim.

[1905d, 1476]
Under analysis, these perversions - and indeed most others - reveal a surprising variety of motives and determinants. The compulsion to exhibit, for instance, is also closely dependent on the castration complex: it is a means of constantly insisting upon the integrity of the subject's own (male) genitals and it reiterates his infantile satisfaction at the absence of a penis in those of women.

Nevertheless, in some of these perversions the quality of the new sexual aim is of a kind to demand special examination. Certain of them are so far removed from the normal in their content that we cannot avoid pronouncing them 'pathological'. This is especially so where (as, for instance, in cases of licking excrement or of intercourse with dead bodies) the sexual instinct goes to astonishing lengths in successfully overriding the resistances of shame, disgust, horror or pain. But even in such cases we should not be too ready to assume that people who act in this way will necessarily turn out to be insane or subject to grave abnormalities of other kinds. Here again we cannot escape from the fact that people whose behaviour is in other respects normal can, under the domination of the most unruly of all the instincts, put themselves in the category of sick persons in the single sphere of sexual life. On the other hand, manifest abnormality in the other relations of life can invariably be shown to have a background of abnormal sexual conduct.

As regards the origin of the perversions, I will add a word in anticipation of what is to come. There is reason to suppose that, just as in the case of fetishism, abortive beginnings of normal sexual development occur before the perversions become fixated. Analytic investigation has already been able to show in a few cases that perversions are a residue of development towards the Oedipus complex and that after the repression of that complex the components of the sexual instinct which are strongest in the disposition of the individual concerned emerge once more.

By demonstrating the part played by perverse impulses in the formation of symptoms in the psychoneuroses, we have quite remarkably increased the number of people who might be regarded as perverts. It is not only that neurotics in themselves constitute a very numerous class, but it must also be considered that an unbroken chain bridges the gap between the neuroses in all their manifestations and normality. After all, Moebius could say with justice that we are all to some extent hysterics. Thus the extraordinarily wide dissemination of the perversions forces us to suppose that the disposition to perversions is itself of no great rarity but must form a part of what passes as the normal constitution.
The time has arrived for me to attempt to summarize what I have said. We started out from the aberrations of the sexual instinct in respect of its object and of its aim and we were faced by the question of whether these arise from an innate disposition or are acquired as a result of experiences in life. We arrived at an answer to this question from an understanding, derived from psycho-analytic investigation, of the workings of the sexual instinct in psychoneurotics, a numerous class of people and one not far removed from the healthy. We found that in them tendencies to every kind of perversion can be shown to exist as unconscious forces and betray their presence as factors leading to the formation of symptoms. It was thus possible to say that neurosis is, as it were, the negative of perversion. In view of what was now seen to be the wide dissemination of tendencies to perversion we were driven to the conclusion that a disposition to perversions is an original and universal disposition of the human sexual instinct and that normal sexual behaviour is developed out of it as a result of organic changes and psychical inhibitions occurring in the course of maturation; we hoped to be able to show the presence of this original disposition in childhood. Among the forces restricting the direction taken by the sexual instinct we laid emphasis upon shame, disgust, pity and the structures of morality and authority erected by society. We were thus led to regard any established aberration from normal sexuality as an instance of developmental inhibition and infantilism. Though it was necessary to place in the foreground the importance of the variations in the original disposition, a co-operative and not an opposing relation was to be assumed as existing between them and the influences of actual life. It appeared, on the other hand, that since the original disposition is necessarily a complex one, the sexual instinct itself must be something put together from various factors, and that in the perversions it falls apart, as it were, into its components. The perversions were thus seen to be on the one hand inhibitions, and on the other hand dissociations, of normal development. Both these aspects were brought together in the supposition that the sexual instinct of adults arises from a combination of a number of impulses of childhood into a unity, an impulsion with a single aim.

The unsatisfactory conclusion, however, that emerges from these investigations of the disturbances of sexual life is that we know far too little of the biological processes constituting the essence of sexuality to be able to construct from our fragmentary information a theory adequate to the understanding alike of normal and of pathological conditions.

We are all familiar with the delusional imaginings of the paranoic, which are concerned with the greatness and the sufferings of his own self and which appear in forms that are quite typical and almost monotonous. We have also become acquainted, through numerous accounts, with the strange performances with which certain perverts stage their sexual satisfaction, whether in idea or reality. Nevertheless, it may be new to some readers to hear that quite analogous psychical structures are regularly present in all the psychoneuroses, particularly in hysteria, and that these latter - which are known as hysterical phantasies - can be seen to have important connections with the causation of the neurotic symptoms.

If we take the second of these stages as an average, we must point out that a number of people are, on account of their organization, not equal to meeting its demands. In whole classes of individuals the development of the sexual instinct, as we have described it above, from autoerotism to object-love with its aim of uniting the genitals, has not been carried out correctly and sufficiently fully. As a result of these disturbances of development two kinds of harmful deviation from normal sexuality - that is, sexuality which is serviceable to civilization - come about; and the relation between these two is almost that of positive and negative.
In the first place (disregarding people whose sexual instinct is altogether excessive and uninhibitable) there are the different varieties perverts, in whom an infantile fixation to a preliminary sexual aim has prevented the primacy of the reproductive function from being established, and the homosexuals or inverts, in whom, in a manner that is not yet quite understood, the sexual aim has been deflected away from the opposite sex. If the injurious effects of these two kinds of developmental disturbance are less than might be expected, this mitigation can be ascribed precisely to the complex way in which the sexual instinct is put together, which makes it possible for a person's sexual life to reach a serviceable final form even if one or more components of the instinct have been shut off from development. The constitution of people suffering from inversion - the homosexuals - is, indeed, often distinguished by their sexual instinct's possessing a special aptitude for cultural sublimation.

More pronounced forms of the perversions and of homosexuality, especially if they are exclusive, do, it is true, make those subject to them socially useless and unhappy, so that it must be recognized that the cultural requirements even of the second stage are a source of suffering for a certain proportion of mankind. The fate of these people who differ constitutionally from the rest varies, and depends on whether they have been born with a sexual instinct which by absolute standards is strong or comparatively weak. In the latter case - where the sexual instinct is in general weak - perverts succeed in totally suppressing the inclinations which bring them into conflict with the moral demands of their stage of civilization. But this, from the ideal point of view, is also the only thing they succeed in achieving; for, in order to effect this suppression of their sexual instinct, they use up the forces which they would otherwise employ in cultural activities. They are, as it were, inwardly inhibited and outwardly paralysed. What we shall be saying again later on about the abstinence demanded of men and women in the third stage of civilization applies to them too.

Where the sexual instinct is fairly intense, but perverse, there are two possible outcomes. The first, which we shall not discuss further, is that the person affected remains a pervert and has to put up with the consequences of his deviation from the standard of civilization. The second is far more interesting. It is that, under the influence of education and social demands, a suppression of the perverse instincts is indeed achieved, but it is a kind of suppression which is really no suppression at all. It can better be described as a suppression that has failed. The inhibited sexual instincts are, it is true, no longer expressed as such - and this constitutes the success of the process - but they find expression in other ways, which are quite as injurious to the subject and make him quite as useless for society as satisfaction of the suppressed instincts in an unmodified form would have done. This constitutes the failure of the process, which in the long run more than counterbalances its success. The substitutive phenomena which emerge in consequence of the suppression of the instinct amount to what we call nervous illness, or, more precisely, the psychoneuroses.¹ Neurotics are the class of people who, since they possess a recalcitrant organization, only succeed, under the influence of cultural requirements, in achieving a suppression of their instincts which is apparent and which becomes increasingly unsuccessful. They therefore only carry on their collaboration with cultural activities by a great expenditure of force and at the cost of an internal impoverishment, or are obliged at times to interrupt it and fall ill. I have described the neuroses as the 'negative' of the perversions because in the neuroses the perverse impulses, after being repressed, manifest themselves from the unconscious part of the mind - because the neuroses contain the same tendencies, though in a state of 'repression', as do the positive perversions.

¹[1908d, 1953]
The sternness of the demands of civilization and the difficulty of the task of abstinence have combined to make avoidance of the union of the genitals of the two opposite sexes into the central point of abstinence and to favour other kinds of sexual activity, which, it might be said, are equivalent to semi-obedience. Since normal intercourse has been so relentlessly persecuted by morality - and also, on account of the possibilities of infection, by hygiene - what are known as the perverse forms of intercourse between the two sexes, in which other parts of the body take over the role of the genitals, have undoubtedly increased in social importance. These activities cannot, however, be regarded as being as harmless as analogous extensions in love-relationships. They are ethically objectionable, for they degrade the relationships of love between two human beings from a serious matter to a convenient game, attended by no risk and no spiritual participation. A further consequence of the aggravation of the difficulties of normal sexual life is to be found in the spread of homosexual satisfaction; in addition to all those who are homosexuals in virtue of their organization, or who became so in their childhood, there must be reckoned the great number of those in whom, in their maturer years, a blocking of the main stream of their libido has caused a widening in the side-channel of homosexuality.

[1908d, 1961]

There is a dictum in general pathology, Gentlemen, which asserts that every developmental process carries with it the seed of a pathological disposition, in so far as that process may be inhibited, delayed, or may run its course incompletely. The same thing is true of the highly complicated development of the sexual function. It does not occur smoothly in every individual; and, if not, it leaves behind it either abnormalities or a predisposition to fall ill later, along the path of involution (i.e. regression). It may happen that not all the component instincts submit to the dominance of the genital zone. An instinct which remains in this way independent leads to what we describe as a perversion, and may substitute its own sexual aim for the normal one. It very often happens, as I have already said, that auto-erotism is not completely conquered, and evidence of this is given by a great variety of subsequent disturbances. The originally equal value attached to the two sexes as sexual objects may persist, and this will lead to a tendency in adult life to homosexual activity, which can in certain circumstances be intensified into exclusive homosexuality. These classes of disturbance represent direct inhibitions in the development of the sexual function; they comprise the perversions and, what is by no means rare, general infantilism in sexual life.

[1910a, 2231]

The ego ideal has imposed severe conditions upon the satisfaction of libido through objects; for it causes some of them to be rejected by means of its censor, as being incompatible. Where no such ideal has been formed, the sexual trend in question makes its appearance unchanged in the personality in the form of a perversion. To be their own ideal once more, in regard to sexual no less than other trends, as they were in childhood - this is what people strive to attain as their happiness.

[1914c, 2953]

Being in love consists in a flowing-over of ego-libido on to the object. It has the power to remove repressions and re-instate perversions. It exalts the sexual object into a sexual ideal. Since, with the object type (or attachment type), being in love occurs in virtue of the fulfilment of infantile conditions for loving, we may say that whatever fulfils that condition is idealized.
First and foremost, it is an untenable error to deny that children have a sexual life and to suppose that sexuality only begins at puberty with the maturation of the genitals. On the contrary, from the very first children have a copious sexual life, which differs at many points from what is later regarded as normal. What in adult life is described as ‘perverse’ differs from the normal in these respects: first, by disregarding the barrier of species (the gulf between men and animals), secondly, by overstepping the barrier against disgust, thirdly that against incest (the prohibition against seeking sexual satisfaction from near blood-relations), fourthly that against members of one’s own sex and fifthly the transferring of the part played by the genitals to other organs and areas of the body. None of these barriers existed from the beginning; they were only gradually erected in the course of development and education. Small children are free from them. They recognize no frightful gulf between human beings and animals; the arrogance with which men separate themselves from animals does not emerge until later. To begin with, children exhibit no disgust at excreta but acquire this slowly under the pressure of education; they attach no special importance to the distinction between the sexes, but attribute the same conformation of the genitals to both; they direct their first sexual lusts and their curiosity to those who are nearest and for other reasons dearest to them - parents, brothers and sisters, or nurses; and finally, they show (what later on breaks through once again at the climax of a love-relation) that they expect to derive pleasure not only from their sexual organs, but that many other parts of the body lay claim to the same sensitivity, afford them analogous feelings of pleasure and can accordingly play the part of genitals. Children may thus be described as ‘polymorphously perverse’, and if these impulses only show traces of activity, that is because on the one hand they are of less intensity compared with those in later life and on the other hand all a child’s sexual manifestations are at once energetically suppressed by education. This suppression is, as it were, extended into theory; for adults endeavour to overlook one portion of the sexual manifestations of children and to disguise another portion by misinterpreting its sexual nature, so that they can then disavow the whole of them. It is often the very same people who in the nursery are furious with any sexual naughtinesses of children and afterwards at their writing-tables defend the sexual purity of the same children. When children are left to themselves, or under the influence of seduction, they often bring about quite considerable achievements in the way of perverse sexual activity. Adults are of course right not to take this too seriously and to regard it as ‘childishness’, or ‘playfulness’, for children are not to be condemned as fully capable or fully responsible either before the judgement-seat of morals or before the law; but nonetheless these things exist. They have their importance both as indications of a child’s innate constitution and as causes and encouragements of later developments in him; they give us information on the sexual life of children and so on human sexual life in general. If, therefore, we once more find all these perverse wishful impulses behind our distorted dreams, that only means that in this field too dreams have taken a step backwards into the state of infancy.

[1916-1917, 3297]
On the whole, indeed, when we come to think of it, we are not quite at a loss in regard to what it is that people call sexual. Something which combines a reference to the contrast between the sexes, to the search for pleasure, to the reproductive function and to the characteristic of something that is improper and must be kept secret - some such combination will serve for all practical purposes in everyday life. But for science that is not enough. By means of careful investigations (only made possible, indeed, by disinterested self-discipline) we have come to know groups of individuals whose 'sexual life' deviates in the most striking way from the usual picture of the average. Some of these 'perverse' people have, we might say, struck the distinction between the sexes off their programme. Only members of their own sex can rouse their sexual wishes; those of the other sex, and especially their sexual parts, are not a sexual object for them at all, and in extreme cases are an object of disgust. This implies, of course, that they have abandoned any share in reproduction. We call such people homosexuals or inverted. They are men and women who are often, though not always, irreproachably fashioned in other respects, of high intellectual and ethical development, the victims only of this one fatal deviation. Through the mouth of their scientific spokesmen they represent themselves as a special variety of the human species - a 'third sex' which has a right to stand on an equal footing beside the other two. We shall perhaps have an opportunity of examining their claims critically. Of course they are not, as they also like to assert, an 'elite' of mankind; there are at least as many inferior and useless individuals among them as there are among those of a different sexual kind.

[1916-1917, 3376]

This class of perverts at any rate behave to their sexual objects in approximately the same way as normal people do to theirs. But we now come to a long series of abnormal people whose sexual activity diverges more and more widely from what seems desirable to a sensible person. In their multiplicity and strangeness they can only be compared to the grotesque monsters painted by Breughel for the temptation of St. Anthony or to the long procession of vanished gods and believers which Flaubert heads past, before the eyes of his pious penitent. Such a medley calls for some kind of arrangement if it is not to confuse our senses. We accordingly divide them into those in whom, like the homosexuals, the sexual object has been changed, and others in whom the sexual aim is what has primarily been altered. The first group includes those who have renounced the union of the two genitals and who replace the genitals of one of the couple engaged in the sexual act by some other part or region of the body; in this they disregard the lack of suitable organic arrangements as well as any impediment offered by feelings of disgust. (They replace the vulva, for instance, by the mouth or anus.) Others follow, who, it is true, still retain the genitals as an object - not, however, on account of their sexual function but of other functions in which the genital plays a part either for anatomical reasons or because of its propinquity. We find from them that the excretory functions, which have been put aside as improper during the upbringing of children, retain the ability to attract the whole of sexual interest. Then come others again, who have abandoned the genital as an object altogether, and have taken some other part of the body as the object they desire - a woman's breast, a foot or a plait of hair. After them come others for whom parts of the body are of no importance but whose every wish is satisfied by a piece of clothing, a shoe, a piece of underclothing - the fetishists. Later in the procession come people who require the whole object indeed, but make quite definite demands of it - strange or horrible - even that it must have become a defenceless corpse, and who, using criminal violence, make it into one so that they may enjoy it. But enough of this kind of horror!

[1916-1917, 3377]
The second group is led by perverts who have made what is normally only an introductory or preparatory act into the aim of their sexual wishes. They are people whose desire it is to look at the other person or to feel him or to watch him in the performance of his intimate actions, or who expose parts of their own bodies which should be covered, in the obscure expectation that they may be rewarded by a corresponding action in return. Next come the sadists, puzzling people whose tender endeavours have no other aim than to cause pain and torment to their object, ranging from humiliation to severe physical injuries; and, as though to counterbalance them, their counterparts, the masochists, whose only pleasure it is to suffer humiliations and torments of every kind from their loved object either symbolically or in reality. There are still others in whom several of these abnormal preconditions are united and intertwined; and lastly, we must learn that each of these groups is to be found in two forms: alongside of those who seek their sexual satisfaction in reality are those who are content merely to imagine that satisfaction, who need no real object at all, but can replace it by their phantasies.

Now there cannot be the slightest doubt that all these crazy, eccentric and horrible things really constitute the sexual activity of these people. Not only do they themselves regard them as such and are aware that they are substitutes for each other, but we must admit that they play the same part in their lives as normal sexual satisfaction does in ours; they make the same, often excessive sacrifices for them, and we can trace both in the rough and in finer detail the points at which these abnormalities are based on what is normal and the points at which they diverge from it. Nor can you fail to notice that here once again you find the characteristic of being improper, which clings to sexual activity, though here it is for the most part intensified to the point of being abominable.

Well, Ladies and Gentlemen, what attitude are we to adopt to these unusual kinds of sexual satisfaction? Indignation, an expression of our personal repugnance and an assurance that we ourselves do not share these lusts will obviously be of no help. Indeed, that is not what we have been asked for. When all is said and done, what we have here is a field of phenomena like any other. A denial in the form of an evasive suggestion that after all these are only rarities and curiosities would be easy to refute. On the contrary, we are dealing with quite common and widespread phenomena. If, however, it is argued that we need not allow our views of sexual life to be misled by them because they are one and all aberrations and deviations of the sexual instinct, a serious answer is called for. Unless we can understand these pathological forms of sexuality and can co-ordinate them with normal sexual life, we cannot understand normal sexuality either. In short, it remains an unavoidable task to give a complete theoretical account of how it is that these perversions can occur and of their connection with what is described as normal sexuality.
I know you have been wanting for a long time to interrupt me and exclaim: 'Enough of these atrocities! You tell us that defaecating is a source of sexual satisfaction, and already exploited in infancy! that faeces is a valuable substance and that the anus is a kind of genital! We don't believe all that but we do understand why paediatricians and educationists have given a wide berth to psycho-analysis and its findings.' No, Gentlemen. You have merely forgotten that I have been trying to introduce the facts of infantile sexual life to you in connection with the facts of the sexual perversions. Why should you not be aware that for a large number of adults, homosexual and heterosexual alike, the anus does really take over the role of the vagina in sexual intercourse? And that there are many people who retain a voluptuous feeling in defaecating all through their lives and describe it as being far from small? As regards interest in the act of defaecation and enjoyment in watching someone else defaecating, you can get children themselves to confirm the fact when they are a few years older and able to tell you about it. Of course, you must not have systematically intimidated them beforehand, or they will quite understand that they must be silent on the subject. And as to the other things that you are anxious not to believe, I will refer you to the findings of analysis and of the direct observation of children and will add that it calls for real ingenuity not to see all this or to see it differently. Nor do I complain if you find the kinship between infantile sexual activity and sexual perversions something very striking. But it is in fact self-evident: if a child has a sexual life at all it is bound to be of a perverse kind; for, except for a few obscure hints, children are without what makes sexuality into the reproductive function. On the other hand, the abandonment of the reproductive function is the common feature of all perversions. We actually describe a sexual activity as perverse if it has given up the aim of reproduction and pursues the attainment of pleasure as an aim independent of it. So, as you will see, the breach and turning-point in the development of sexual life lies in its becoming subordinate to the purposes of reproduction. Everything that happens before this turn of events and equally everything that disregards it and that aims solely at obtaining pleasure is given the uncomplimentary name of 'perverse' and as such is proscribed.

[1916-1917, 3386]

What makes the activity of perverts so unmistakably sexual in spite of all the strangeness of its objects and aims is the fact that as a rule an act of perverse satisfaction nevertheless ends in complete orgasm and voidance of the genital products. This is of course only the result of the people concerned being adults. In children orgasm and genital excretion are scarcely possible; their place is taken by hints which are once more not recognized as being clearly sexual.

[1916-1917, 3390]

Before we make use of our familiarity with the perversions to plunge once again into the study of infantile sexuality on the basis of clearer premisses, I must draw your attention to an important difference between them. Perverse sexuality is as a rule excellently centred: all its actions are directed to an aim - usually to a single one; one component instinct has gained the upper hand in it and is either the only one observable or has subjected the others to its purposes. In that respect there is no distinction between perverse and normal sexuality other than the fact that their dominating component instincts and consequently their sexual aims are different. In both of them, one might say, a well-organized tyranny has been established, but in each of the two a different family has seized the reins of power. Infantile sexuality, on the other hand, lacks, speaking generally, any such centring and organization; its separate component instincts have equal rights, each of them goes its own way to obtaining pleasure. Both the absence and the presence of centring harmonize well, of course, with the fact that both perverse and normal sexuality have arisen out of infantile sexuality. Incidentally, there are also cases of perverse sexuality which have a much greater resemblance to the infantile kind, since in them numerous component instincts have put through (or, more correctly, have persisted in) their aims independently of one another. It is better in such cases to speak of infantilism in sexual life rather than of a perversion.

[1916-1917, 3391]
Thus forearmed we can proceed to the consideration of a suggestion which we shall certainly not be spared. 'Why', we shall be asked, 'are you so obstinate in describing as being already sexuality what on your own evidence are indefinable manifestations in childhood out of which sexual life will later develop? Why should you not be content instead with giving them a physiological description and simply say that in an infant at the breast we already observe activities, such as sensual sucking or holding back the excreta, which show us that he is striving for "organ-pleasure"? In that way you would have avoided the hypothesis, so repugnant to every feeling, of the smallest babies having a sexual life.' - Indeed, Gentlemen, I have no objection at all to organ-pleasure. I know that even the supreme pleasure of sexual union is only an organ-pleasure attached to the activity of the genitals. But can you tell me when this originally indifferent organ-pleasure acquires the sexual character which it undoubtedly possesses in the later phases of development? Do we know any more about 'organ-pleasure' than about sexuality? You will reply that it gains its sexual character precisely when the genitals begin to play their part; 'sexual' coincides with 'genital'. You will even reject the objection raised by the perversions by pointing out to me that in the majority of perversions a genital orgasm is after all aimed at, even if it is arrived at by a method other than the union of the genitals. You are certainly taking up a much stronger position in determining the characteristics of what is sexual if you knock out of it the relation to reproduction which is made untenable by the perversions and put genital activity in its place. But, if so, we are no longer far apart: it is only a question of the genital organs versus the other organs. What are you going to do, however, about the numerous experiences which show you that the genitals can be represented as regards their yield of pleasure by other organs, as in the case of kissing or of the perverse practices of voluptuaries or of the symptoms of hysteria? In that neurosis it is quite usual for signs of stimulation, sensations and innervations, and even the processes of erection, which belong properly to the genitals, to be displaced on to other, remote regions of the body - as, for instance, by transposition upwards, to the head and face. Being thus convinced that you have nothing to catch hold of for your characterization of what is sexual, you will no doubt have to make up your minds to follow my example and extend the description of being 'sexual' to the activities of early childhood, too, which strive for organ-pleasure.

[1916-1917, 3392]

The tenacity with which the libido adheres to particular trends and objects - what may be described as the 'adhesiveness' of the libido - makes its appearance as an independent factor, varying from individual to individual, whose determinants are quite unknown to us, but whose significance for the aetiology of the neuroses we shall certainly no longer underestimate. We should not, on the other hand, over-estimate the intimacy of this connection. For a similar 'adhesiveness' of the libido occurs (for unknown reasons) under numerous conditions in normal people, and it is found as a determining factor in people who are in one sense the contrary of neurotics - in perverts. It was known even before the days of psycho-analysis (cf. Binet) that in the anamnesis of perverts a very early impression of an abnormal instinctual trend or choice of object was quite often found, to which the subject's libido remained attached all through his life. It is often impossible to say what it is that enabled this impression to exercise such an intense attraction on the libido. I will describe a case of this sort which I myself observed.

[1916-1917, 3410]

I may tell you at once that these first explanations of Abraham's have been accepted in psycho-analysis and have become the basis of our attitude to the psychoses. We thus slowly became familiar with the notion that the libido, which we find attached to objects and which is the expression of an effort to obtain satisfaction in connection with those objects, can also leave the objects and set the subject's own ego in their place; and this notion was gradually built up more and more consistently. The name for this way of allocating the libido - 'narcissism' - was borrowed by us from a perversion described by Paul Näcke in which an adult treats his own body with all the caresses that are usually devoted to an outside sexual object.

[1916-1917, 3461]
A perversion in childhood, as is well known, may become the basis for the construction of a perversion having a similar sense and persisting throughout life, one which consumes the subject's whole sexual life. On the other hand the perversion may be broken off and remain in the background of a normal sexual development, from which, however, it continues to withdraw a certain amount of energy. The first of these alternatives was already known before the days of analysis. Analytic investigation, however, of such fully-developed cases almost bridges the gulf between the two. For we find often enough with these perverts that they too made an attempt at developing normal sexual activity, usually at the age of puberty; but their attempt had not enough force in it and was abandoned in the face of the first obstacles which inevitably arise, whereupon they fell back upon their infantile fixation once and for all.

Narcissism. - A decisive advance was made when the analysis of dementia praecox and other psychotic disorders was ventured upon and thus the examination was begun of the ego itself, which had so far been known only as the agency of repression and opposition. It was found that the pathogenic process in dementia praecox is the withdrawal of the libido from objects and its introduction into the ego, while the clamorous symptoms of the disease arise from the vain struggles of the libido to find a pathway back to objects. It thus turned out to be possible for object-libido to change into cathexis of the ego and vice versa. Further reflection showed that this process must be presumed to occur on the largest scale and that the ego is to be regarded as a great reservoir of libido from which libido is sent out to objects and which is always ready to absorb libido flowing back from objects. Thus the instincts of self-preservation were also of a libidinal nature: they were sexual instincts which, instead of external objects, had taken the subject's own ego as an object. Clinical experience had made us familiar with people who behaved in a striking fashion as though they were in love with themselves and this perversion had been given the name of narcissism. The libido of the self-preservative instincts was now described as narcissistic libido and it was recognized that a high degree of this self-love constituted the primary and normal state of things. The earlier formula laid down for the transfERENCE neuroses consequently required to be modified, though not corrected. It was better, instead of speaking of a conflict between sexual instincts and ego instincts, to speak of a conflict between object-libido and ego-libido, or, since the nature of these instincts was the same, between the object-cathexes and the ego.

The detaching of sexuality from the genitals has the advantage of allowing us to bring the sexual activities of children and of perverts into the same scope as those of normal adults. The sexual activities of children have hitherto been entirely neglected and though those of perverts have been recognized it has been with moral indignation and without understanding. Looked at from the psycho-analytic standpoint, even the most eccentric and repellent perversions are explicable as manifestations of component instincts of sexuality which have freed themselves from the primacy of the genitals and are now in pursuit of pleasure on their own account as they were in the very early days of the libido's development. The most important of these perversions, homosexuality, scarcely deserves the name. It can be traced back to the constitutional bisexuality of all human beings and to the after-effects of the phallic primacy. Psycho-analysis enables us to point to some trace or other of a homosexual object-choice in everyone. If I have described children as 'polymorphously perverse', I was only using a terminology that was generally current; no moral judgement was implied by the phrase. Psycho-analysis has no concern whatever with such judgements of value.
The sexual life of children is of course different from that of adults. The sexual function, from its beginnings to the definitive form in which it is so familiar to us, undergoes a complicated process of development. It grows together from numerous component instincts with different aims and passes through several phases of organization till at last it comes into the service of reproduction. Not all the component instincts are equally serviceable for the final outcome; they must be diverted, remodelled and in part suppressed. Such a far-reaching course of development is not always passed through without a flaw; inhibitions in development take place, partial fixations at early stages of development. If obstacles arise later on to the exercise of the sexual function, the sexual urge - the libido, as we call it - is apt to hark back to these earlier points of fixation. The study of the sexuality of children and its transformations up to maturity has also given us the key to an understanding of what are known as the sexual perversions, which people used always to describe with all the requisite indications of disgust but whose origin they were never able to explain. The whole topic is of uncommon interest, but for the purposes of our conversation there is not much sense in telling you more about it. To find one's way about in it one of course needs anatomical and physiological knowledge, all of which is unfortunately not to be acquired in medical schools. But a familiarity with the history of civilization and with mythology is equally indispensable.

[1926e, 4353]

The complicated structure of our mental apparatus admits, however, of a whole number of other influences. Just as a satisfaction of instinct spells happiness for us, so severe suffering is caused us if the external world lets us starve, if it refuses to sate our needs. One may therefore hope to be freed from a part of one's sufferings by influencing the instinctual impulses. This type of defence against suffering is no longer brought to bear on the sensory apparatus; it seeks to master the internal sources of our needs. The extreme form of this is brought about by killing off the instincts, as is prescribed by the worldly wisdom of the East and practised by Yoga. If it succeeds, then the subject has, it is true, given up all other activities as well - he has sacrificed his life; and, by another path, he has once more only achieved the happiness of quietness. We follow the same path when our aims are less extreme and we merely attempt to control our instinctual life. In that case, the controlling elements are the higher psychical agencies, which have subjected themselves to the reality principle. Here the aim of satisfaction is not by any means relinquished; but a certain amount of protection against suffering is secured, in that non-satisfaction is not so painfully felt in the case of instincts kept in dependence as in the case of uninhibited ones. As against this, there is an undeniable diminution in the potentialities of enjoyment. The feeling of happiness derived from the satisfaction of a wild instinctual impulse untamed by the ego is incomparably more intense than that derived from sating an instinct that has been tamed. The irresistibility of perverse instincts, and perhaps the attraction in general of forbidden things, finds an economic explanation here.

[1930a, 4478]
The tendency on the part of civilization to restrict sexual life is no less clear than its other tendency to expand the cultural unit. Its first, totemic, phase already brings with it the prohibition against an incestuous choice of object, and this is perhaps the most drastic mutilation which man's erotic life has in all time experienced. Taboos, laws and customs impose further restrictions, which affect both men and women. Not all civilizations go equally far in this; and the economic structure of the society also influences the amount of sexual freedom that remains. Here, as we already know, civilization is obeying the laws of economic necessity, since a large amount of the psychical energy which it uses for its own purposes has to be withdrawn from sexuality. In this respect civilization behaves towards sexuality as a people or a stratum of its population does which has subjected another one to its exploitation. Fear of a revolt by the suppressed elements drives it to stricter precautionary measures. A high-water mark in such a development has been reached in our Western European civilization. A cultural community is perfectly justified, psychologically, in starting by proscribing manifestations of the sexual life of children, for there would be no prospect of curbing the sexual lusts of adults if the ground had not been prepared for it in childhood. But such a community cannot in any way be justified in going to the length of actually disavowing such easily demonstrable, and, indeed, striking phenomena. As regards the sexually mature individual, the choice of an object is restricted to the opposite sex, and most extra-genital satisfactions are forbidden as perversions. The requirement, demonstrated in these prohibitions, that there shall be a single kind of sexual life for everyone, disregards the dissimilarities, whether innate or acquired, in the sexual constitution of human beings; it cuts off a fair number of them from sexual enjoyment, and so becomes the source of serious injustice. The result of such restrictive measures might be that in people who are normal - who are not prevented by their constitution - the whole of their sexual interests would flow without loss into the channels that are left open. But heterosexual genital love, which has remained exempt from outlawry, is itself restricted by further limitations, in the shape of insistence upon legitimacy and monogamy. Present-day civilization makes it plain that it will only permit sexual relationships on the basis of a solitary, indissoluble bond between one man and one woman, and that it does not like sexuality as a source of pleasure in its own right and is only prepared to tolerate it because there is so far no substitute for it as a means of propagating the human race.

[1930a, 4498]

One cannot very well doubt the importance of envy for the penis. You may take it as an instance of male injustice if I assert that envy and jealousy play an even greater part in the mental life of women than of men. It is not that I think these characteristics are absent in men or that I think they have no other roots in women than envy for the penis; but I am inclined to attribute their greater amount in women to this latter influence. Some analysts, however, have shown an inclination to depreciate the importance of this first instalment of penis-envy in the phallic phase. They are of opinion that what we find of this attitude in women is in the main a secondary structure which has come about on the occasion of later conflicts by regression to this early infantile impulse. This, however, is a general problem of depth psychology. In many pathological - or even unusual - instinctual attitudes (for instance, in all sexual perversions) the question arises of how much of their strength is to be attributed to early infantile fixations and how much to the influence of later experiences and developments. In such cases it is almost always a matter of complemental series such as we put forward in our discussion of the aetiology of the neuroses. Both factors play a part in varying amounts in the causation; a less on the one side is balanced by a more on the other. The infantile factor sets the pattern in all cases but does not always determine the issue, though it often does. Precisely in the case of penis-envy I should argue decidedly in favour of the preponderance of the infantile factor.

[1933a, 4727]
According to the prevailing view human sexual life consists essentially in an endeavour to bring one's own genitals into contact with those of someone of the opposite sex. With this are associated, as accessory phenomena and introductory acts, kissing this extraneous body, looking at it and touching it. This endeavour is supposed to make its appearance at puberty - that is, at the age of sexual maturity - and to serve the purposes of reproduction. Nevertheless, certain facts have always been known which do not fit into the narrow framework of this view. (1) It is a remarkable fact that there are people who are only attracted by individuals of their own sex and by their genitals. (2) It is equally remarkable that there are people whose desires behave exactly like sexual ones but who at the same time entirely disregard the sexual organs or their normal use; people of this kind are known as 'perverts'. (3) And lastly it is a striking thing that some children (who are on that account regarded as degenerate) take a very early interest in their genitals and show signs of excitation in them.

[1940a [1938], 4963]
VARIATION AND DISEASE  It is natural that medical men, who first studied perversions in outstanding examples and under special conditions, should have been inclined to regard them, like inversion, as indications of degeneracy or disease. Nevertheless, it is even easier to dispose of that view in this case than in that of inversion. Everyday experience has shown that most of these extensions, or at any rate the less severe of them, are constituents which are rarely absent from the sexual life of healthy people, and are judged by them no differently from other intimate events. If circumstances favour such an occurrence, normal people too can substitute a perversion of this kind for the normal sexual aim for quite a time, or can find place for the one alongside the other. No healthy person, it appears, can fail to make some addition that might be called perverse to the normal sexual aim; and the universality of this finding is in itself enough to show how inappropriate it is to use the word perversion as a term of reproach. In the sphere of sexual life we are brought up against peculiar and, indeed, insoluble difficulties as soon as we try to draw a sharp line to distinguish mere variations within the range of what is physiological from pathological symptoms.

It is not the case that the perversions alone would have obliged us to make the change in the concept of sexuality which has brought such violent contradictions down on us. The study of infantile sexuality had even more to do with it and it was the concurrence of the two which was decisive for us. But the manifestations of infantile sexuality, however unmistakable they may be in later childhood, seem to melt into indefiniteness towards their beginnings. Anyone who chooses to disregard the history of their development and their analytic context will deny that they are of a sexual character and will attribute some undifferentiated character to them instead. You must not forget that at the moment we are not in possession of any generally recognized criterion of the sexual nature of a process, apart, once again, from a connection with the reproductive function which we must reject as being too narrow-minded. The biological criteria, such as the periodicities of twenty-three and twenty-eight days postulated by Wilhelm Fliess, are still highly debatable; the chemical characteristics of the sexual process, which we may suspect, are still awaiting discovery. On the other hand, the sexual perversions of adults are something tangible and unambiguous. As is already shown by the name by which they are universally known, they are unquestionably sexual. Whether they are described as indications of degeneracy or in any other way, no one has yet had the courage to class them as anything but phenomena of sexual life. On their account alone we are justified in asserting that sexuality and reproduction do not coincide, for it is obvious that all of them disavow the aim of reproduction.

[1905d, 1486]

[1916-1917, 3389]
As regards the second kind of emotional reaction, which is not directed against me this time, but against my patient - supposing that my view of her is correct - and which regards the perverse nature of her phantasies as horrible, I should like to say emphatically that a medical man has no business to indulge in such passionate condemnation. I may also remark in passing that it seems to me superfluous for a physician who is writing upon the aberrations of the sexual instincts to seize every opportunity of inserting into the text expressions of his personal repugnance at such revolting things. We are faced by a fact; and it is to be hoped that we shall grow accustomed to it, when we have put our own tastes on one side. We must learn to speak without indignation of what we call the sexual perversions - instances in which the sexual function has extended its limits in respect either to the part of the body concerned or to the sexual object chosen. The uncertainty in regard to the boundaries of what is to be called normal sexual life, when we take different races and different epochs into account, should in itself be enough to cool the zealot's ardour. We surely ought not to forget that the perversion which is the most repellant to us, the sensual love of a man for a man, was not only tolerated by a people so far our superiors in cultivation as were the Greeks, but was actually entrusted by them with important social functions. The sexual life of each one of us extends to a slight degree - now in this direction, now in that - beyond the narrow lines imposed as the standard of normality. The perversions are neither bestial nor degenerate in the emotional sense of the word. They are a development of germs all of which are contained in the undifferentiated sexual disposition of the child, and which, by being suppressed or by being diverted to higher, asexual aims - by being 'sublimated' - are destined to provide the energy for a great number of our cultural achievements. When, therefore, any one has become a gross and manifest pervert, it would be more correct to say that he has remained one, for he exhibits a certain stage of inhibited development. All psychoneurotics are persons with strongly marked perverse tendencies, which have been repressed in the course of their development and have become unconscious. Consequently their unconscious phantasies show precisely the same content as the documentarily recorded actions of perverts - even though they have not read Krafft-Ebing's Psychopathia Sexualis, to which simple-minded people attribute such a large share of the responsibility for the production of perverse tendencies. Psychoneuroses are, so to speak, the negative of perversions. In neurotics their sexual constitution, under which the effects of heredity are included, operates in combination with any accidental influences in their life which may disturb the development of normal sexuality. A stream of water which meets with an obstacle in the river-bed is dammed up and flows back into old channels which had formerly seemed fated to run dry. The motive forces leading to the formation of hysterical symptoms draw their strength not only from repressed normal sexuality but also from unconscious perverse activities.¹

¹[1905e, 1387]

I shall at this point introduce two technical terms. Let up call the person from whom sexual attraction proceeds the sexual object and the act towards which the instinct tends the sexual aim. Scientifically sifted observation, then, shows that numerous deviations occur in respect of both of these - the sexual object and the sexual aim. The relation between these deviations and what is assumed to be normal requires thorough investigation.

[1905d, 1464]
The normal sexual aim is regarded as being the union of the genitals in the act known as copulation, which leads to a release of the sexual tension and a temporary extinction of the sexual instinct - a satisfaction analogous to the satiating of hunger. But even in the most normal sexual process we may detect rudiments which, if they had developed, would have led to the deviations described as 'perversions'. For there are certain intermediate relations to the sexual object, such as touching and looking at it, which lie on the road towards copulation and are recognized as being preliminary sexual aims. On the one hand these activities are themselves accompanied by pleasure, and on the other hand they intensify the excitation, which should persist until the final sexual aim is attained. Moreover, the kiss, one particular contact of this kind, between the mucous membrane of the lips of the two people concerned, is held in high sexual esteem among many nations (including the most highly civilized ones), in spite of the fact that the parts of the body involved do not form part of the sexual apparatus but constitute the entrance to the digestive tract. Here, then, are factors which provide a point of contact between the perversions and normal sexual life and which can also serve as a basis for their classification. Perversions are sexual activities which either (a) extend, in an anatomical sense, beyond the regions of the body that are designed for sexual union, or (b) linger over the intermediate relations to the sexual object which should normally be traversed rapidly on the path towards the final sexual aim.

It is, as we have seen, debatable whether the perversions go back to innate determinants or arise, as Binet assumed was the case with fetishism, owing to chance experiences. The conclusion now presents itself to us that there is indeed something innate lying behind the perversions but that it is something innate in everyone, though as a disposition it may vary in its intensity and may be increased by the influences of actual life. What is in question are the innate constitutional roots of the sexual instinct. In one class of cases (the perversions) these roots may grow into the actual vehicles of sexual activity; in others they may be submitted to an insufficient suppression (repression) and thus be able in a roundabout way to attract a considerable proportion of sexual energy to themselves as symptoms; while in the most favourable cases, which lie between these two extremes, they may by means of effective restriction and other kinds of modification bring about what is known as normal sexual life.
The time has arrived for me to attempt to summarize what I have said. We started out from the aberrations of the sexual instinct in respect of its object and of its aim and we were faced by the question of whether these arise from an innate disposition or are acquired as a result of experiences in life. We arrived at an answer to this question from an understanding, derived from psycho-analytic investigation, of the workings of the sexual instinct in psychoneurotics, a numerous class of people and one not far removed from the healthy. We found that in them tendencies to every kind of perversion can be shown to exist as unconscious forces and betray their presence as factors leading to the formation of symptoms. It was thus possible to say that neurosis is, as it were, the negative of perversion. In view of what was now seen to be the wide dissemination of tendencies to perversion we were driven to the conclusion that a disposition to perversions is an original and universal disposition of the human sexual instinct and that normal sexual behaviour is developed out of it as a result of organic changes and psychical inhibitions occurring in the course of maturation; we hoped to be able to show the presence of this original disposition in childhood. Among the forces restricting the direction taken by the sexual instinct we laid emphasis upon shame, disgust, pity and the structures of morality and authority erected by society. We were thus led to regard any established aberration from normal sexuality as an instance of developmental inhibition and infantilism. Though it was necessary to place in the foreground the importance of the variations in the original disposition, a co-operative and not an opposing relation was to be assumed as existing between them and the influences of actual life. It appeared, on the other hand, that since the original disposition is necessarily a complex one, the sexual instinct itself must be something put together from various factors, and that in the perversions it falls apart, as it were, into its components. The perversions were thus seen to be on the one hand inhibitions, and on the other hand dissociations, of normal development. Both these aspects were brought together in the supposition that the sexual instinct of adults arises from a combination of a number of impulses of childhood into a unity, an impulsion with a single aim.

[1905d, 1542]

I could not further elucidate this part of my theory without a detailed discussion of my views on repression. It will be enough here to refer to my *Three Essays* (1905d), in which I have attempted to throw some light - if only a feeble one - on the somatic processes in which the essential nature of sexuality is to be looked for. I have there shown that the constitutional sexual disposition of children is incomparably more variegated than might have been expected, that it deserves to be described as 'polymorphously perverse' and that what is spoken of as the normal behaviour of the sexual function emerges from this disposition after certain of its components have been repressed. By pointing out the infantile elements in sexuality I was able to establish a simple correlation between health, perversion and neurosis. I showed that normality is a result of the repression of certain component instincts and constituents of the infantile disposition and of the subordination of the remaining constituents under the primacy of the genital zones in the service of the reproductive function. I showed that perversions correspond to disturbances of this coalescence owing to the overpowering and compulsive development of certain of the component instincts, while neuroses can be traced back to an excessive repression of the libidinal trends. Since almost all the perverse instincts of the infantile disposition can be recognized as the forces concerned in the formation of symptoms in neuroses, though in a state of repression, I was able to describe neurosis as being the 'negative' of perversion.

[1906a, 1581]
The tracing back of the delusion and its resolution were now complete. What the author now adds is no doubt designed to serve as a harmonious end to his story. We cannot but feel reassured about the future when we hear that the young man, who had earlier been obliged to play the pitiable part of a person in urgent need of treatment, advanced still further on the road to recovery and succeeded in arousing in her some of the feelings under which he himself had suffered before. Thus it was that he made her jealous by mentioning the sympathetic young lady who had previously interrupted their tête-à-tête in the House of Meleager, and by confessing that she had been the first woman for whom he had felt a very great liking. Whereupon Zoe prepared to take a chilly leave of him, remarking that everything had now returned to reason - she herself not least; he could look up Gisa Hartleben (or whatever she was now called) again and give her some scientific assistance over the purpose of her visit to Pompeii; she herself, however, must go back to the Albergo del Sole where her father was expecting her for lunch; perhaps they would meet again some time at a party in Germany or in the moon. But once more he was able to make the troublesome fly an excuse for taking possession first of her cheek and then of her lips, and to set in motion the aggressiveness which is a man's inevitable duty in love making. Once only a shadow seemed to fall on their happiness, when Zoe declared that now she really must go back to her father or he will starve at the Sole. 'Your father? . . . what will happen? . . .' (147.) But the clever girl was able swiftly to quiet his concern. 'Probably nothing will happen. I'm not an indispensable part of his zoological collection. If I had been, perhaps I shouldn't have been so foolish as to give my heart to you.' In the exceptional event, however, of her father taking a different view from hers, there was a safe expedient. Hanold need only cross to Capri, catch a *Lacerta faraglionensis* there (he could practise the technique on her little finger), set the creature free over here, catch it again before the zoologist's eyes, and let him choose between a *faraglionensis* on the mainland and his daughter. The scheme, it is easy to see, was one in which the mockery was tinged with bitterness; it was a warning, as it were, to her fiancé not to keep too closely to the model on which she had chosen him. Here again Norbert Hanold reassures us, by showing by all sorts of apparently small signs the great transformation that had taken place in him. He proposed that he and his Zoe should come for their honeymoon to Italy and Pompeii, just as though he had never been indignant with the honeymooning Edwins and Angelinas. He had completely lost from his memory all his feelings against those happy pairs, who had so unnecessarily travelled more than a hundred miles from their German home. The author is certainly right in bringing forward a loss of memory like this as the most trustworthy sign of a change of attitude. Zoe's reply to the plan for the scene of their honeymoon suggested by 'her childhood friend who had also in a sense been dug out of the ruins again' (150.) was that she did not feel quite alive enough yet to make a geographical decision of that sort.

[1907a, 1840]

If we take the second of these stages as an average, we must point out that a number of people are, on account of their organization, not equal to meeting its demands. In whole classes of individuals the development of the sexual instinct, as we have described it above, from auto-erotism to object-love with its aim of uniting the genitals, has not been carried out correctly and sufficiently fully. As a result of these disturbances of development two kinds of harmful deviation from normal sexuality - that is, sexuality which is serviceable to civilization - come about; and the relation between these two is almost that of positive and negative.
In the first place (disregarding people whose sexual instinct is altogether excessive and uninhibitable) there are the different varieties perverts, in whom an infantile fixation to a preliminary sexual aim has prevented the primacy of the reproductive function from being established, and the homosexuals or inverts, in whom, in a manner that is not yet quite understood, the sexual aim has been deflected away from the opposite sex. If the injurious effects of these two kinds of developmental disturbance are less than might be expected, this mitigation can be ascribed precisely to the complex way in which the sexual instinct is put together, which makes it possible for a person's sexual life to reach a serviceable final form even if one or more components of the instinct have been shut off from development. The constitution of people suffering from inversion - the homosexuals - is, indeed, often distinguished by their sexual instinct's possessing a special aptitude for cultural sublimation. [1908d, 1953]

The sternness of the demands of civilization and the difficulty of the task of abstinence have combined to make avoidance of the union of the genitals of the two opposite sexes into the central point of abstinence and to favour other kinds of sexual activity, which, it might be said, are equivalent to semi-obedience. Since normal intercourse has been so relentlessly persecuted by morality - and also, on account of the possibilities of infection, by hygiene - what are known as the perverse forms of intercourse between the two sexes, in which other parts of the body take over the role of the genitals, have undoubtedly increased in social importance. These activities cannot, however, be regarded as being as harmless as analogous extensions in love-relationships. They are ethically objectionable, for they degrade the relationships of love between two human beings from a serious matter to a convenient game, attended by no risk and no spiritual participation. A further consequence of the aggravation of the difficulties of normal sexual life is to be found in the spread of homosexual satisfaction; in addition to all those who are homosexuals in virtue of their organization, or who became so in their childhood, there must be reckoned the great number of those in whom, in their maturer years, a blocking of the main stream of their libido has caused a widening in the side-channel of homosexuality. [1908d, 1961]
I know you have been wanting for a long time to interrupt me and exclaim: 'Enough of these atrocities! You tell us that defaecating is a source of sexual satisfaction, and already exploited in infancy! that faeces is a valuable substance and that the anus is a kind of genital! We don't believe all that but we do understand why paediatricians and educationists have given a wide berth to psycho-analysis and its findings.' No, Gentlemen. You have merely forgotten that I have been trying to introduce the facts of infantile sexual life to you in connection with the facts of the sexual perversions. Why should you not be aware that for a large number of adults, homosexual and heterosexual alike, the anus does really take over the role of the vagina in sexual intercourse? And that there are many people who retain a voluptuous feeling in defaecating all through their lives and describe it as being far from small? As regards interest in the act of defaecation and enjoyment in watching someone else defaecating, you can get children themselves to confirm the fact when they are a few years older and able to tell you about it. Of course, you must not have systematically intimidated them beforehand, or they will quite understand that they must be silent on the subject. And as to the other things that you are anxious not to believe, I will refer you to the findings of analysis and of the direct observation of children and will add that it calls for real ingenuity not to see all this or to see it differently. Nor do I complain if you find the kinship between infantile sexual activity and sexual perversions something very striking. But it is in fact self-evident: if a child has a sexual life at all it is bound to be of a perverse kind; for, except for a few obscure hints, children are without what makes sexuality into the reproductive function. On the other hand, the abandonment of the reproductive function is the common feature of all perversions. We actually describe a sexual activity as perverse if it has given up the aim of reproduction and pursues the attainment of pleasure as an aim independent of it. So, as you will see, the breach and turning-point in the development of sexual life lies in its becoming subordinate to the purposes of reproduction. Everything that happens before this turn of events and equally everything that disregards it and that aims solely at obtaining pleasure is given the uncomplimentary name of ‘perverse’ and as such is proscribed.

There is something else that I must add in order to complete our view of sexual perversions. However infamous they may be, however sharply they may be contrasted with normal sexual activity, quiet consideration will show that some perverse trait or other is seldom absent from the sexual life of normal people. Even a kiss can claim to be described as a perverse act, since it consists in the bringing together of two oral erotogenic zones instead of the two genitals. Yet no one rejects it as perverse; on the contrary, it is permitted in theatrical performances as a softened hint at the sexual act. But precisely kissing can easily turn into a complete perversion - if, that is to say, it becomes so intense that a genital discharge and orgasm follow upon it directly, an event that is far from rare. We can learn, too, that for one person feeling and looking at the object are indispensable preconditions of sexual enjoyment, that another person will pinch or bite at the climax of sexual excitation, that the highest pitch of excitement in lovers is not always provoked by the genitals but by some other region of the object's body, and any number of similar things besides. There is no sense in excluding people with individual traits of this kind from the class of the normal and putting them among the perverts. On the contrary, we shall recognize more and more clearly that the essence of the perversions lies not in the extension of the sexual aim, not in the replacement of the genitals, not even always in the variant choice of the object, but solely in the exclusiveness with which these deviations are carried out and as a result of which the sexual act serving the purpose of reproduction is put on one side. In so far as the perverse actions are inserted in the performance of the normal sexual act as preparatory or intensifying contributions, they are in reality not perversions at all. The gulf between normal and perverse sexuality is of course very much narrowed by facts of this kind. It is an easy conclusion that normal sexuality has emerged out of something that was in existence before it, by weeding out certain features of that material as unserviceable and collecting together the rest in order to subordinate them to a new aim, that of reproduction.
As regards the second kind of emotional reaction, which is not directed against me this time, but against my patient - supposing that my view of her is correct - and which regards the perverse nature of her phantasies as horrible, I should like to say emphatically that a medical man has no business to indulge in such passionate condemnation. I may also remark in passing that it seems to me superfluous for a physician who is writing upon the aberrations of the sexual instincts to seize every opportunity of inserting into the text expressions of his personal repugnance at such revolting things. We are faced by a fact; and it is to be hoped that we shall grow accustomed to it, when we have put our own tastes on one side. We must learn to speak without indignation of what we call the sexual perversions - instances in which the sexual function has extended its limits in respect either to the part of the body concerned or to the sexual object chosen. The uncertainty in regard to the boundaries of what is to be called normal sexual life, when we take different races and different epochs into account, should in itself be enough to cool the zealot's ardour. We surely ought not to forget that the perversion which is the most repellent to us, the sensual love of a man for a man, was not only tolerated by a people so far our superiors in cultivation as were the Greeks, but was actually entrusted by them with important social functions. The sexual life of each one of us extends to a slight degree - now in this direction, now in that - beyond the narrow lines imposed as the standard of normality. The perversions are neither bestial nor degenerate in the emotional sense of the word. They are a development of germs all of which are contained in the undifferentiated sexual disposition of the child, and which, by being suppressed or by being diverted to higher, asexual aims - by being 'sublimated' - are destined to provide the energy for a great number of our cultural achievements. When, therefore, any one has become a gross and manifest pervert, it would be more correct to say that he has remained one, for he exhibits a certain stage of inhibited development. All psychoneurotics are persons with strongly marked perverse tendencies, which have been repressed in the course of their development and have become unconscious. Consequently their unconscious phantasies show precisely the same content as the documentarily recorded actions of perverts - even though they have not read Krafft-Ebing's Psychopathia Sexualis, to which simple-minded people attribute such a large share of the responsibility for the production of perverse tendencies. Psychoneuroses are, so to speak, the negative of perversions. In neurotics their sexual constitution, under which the effects of heredity are included, operates in combination with any accidental influences in their life which may disturb the development of normal sexuality. A stream of water which meets with an obstacle in the river-bed is dammed up and flows back into old channels which had formerly seemed fated to run dry. The motive forces leading to the formation of hysterical symptoms draw their strength not only from repressed normal sexuality but also from unconscious perverse activities.¹

I shall at this point introduce two technical terms. Let us call the person from whom sexual attraction proceeds the sexual object and the act towards which the instinct tends the sexual aim. Scientifically sifted observation, then, shows that numerous deviations occur in respect of both of these - the sexual object and the sexual aim. The relation between these deviations and what is assumed to be normal requires thorough investigation.

SEXUAL USE OF THE ANAL ORIFICE Where the anus is concerned it becomes still clearer that it is disgust which stamps that sexual aim as a perversion. I hope, however, I shall not be accused of partisanship when I assert that people who try to account for this disgust by saying that the organ in question serves the function of excretion and comes in contact with excrement - a thing which is disgusting in itself - are not much more to the point than hysterical girls who account for their disgust at the male genital by saying that it serves to void urine.

¹

[1905e, 1387]

[1905d, 1464]

[1905d, 1479]
The part played by the erotogenic zones is immediately obvious in the case of those perversions which assign a sexual significance to the oral and anal orifices. These behave in every respect like a portion of the sexual apparatus. In hysteria these parts of the body and the neighbouring tracts of mucous membrane become the seat of new sensations and of changes in innervation - indeed, of processes that can be compared to erection - in just the same way as do the actual genitalia under the excitations of the normal sexual processes.

[1905d, 1493]

The time has arrived for me to attempt to summarize what I have said. We started out from the aberrations of the sexual instinct in respect of its object and of its aim and we were faced by the question of whether these arise from an innate disposition or are acquired as a result of experiences in life. We arrived at an answer to this question from an understanding, derived from psycho-analytic investigation, of the workings of the sexual instinct in psychoneurotics, a numerous class of people and one not far removed from the healthy. We found that in them tendencies to every kind of perversion can be shown to exist as unconscious forces and betray their presence as factors leading to the formation of symptoms. It was thus possible to say that neurosis is, as it were, the negative of perversion. In view of what was now seen to be the wide dissemination of tendencies to perversion we were driven to the conclusion that a disposition to perversions is an original and universal disposition of the human sexual instinct and that normal sexual behaviour is developed out of it as a result of organic changes and psychical inhibitions occurring in the course of maturation; we hoped to be able to show the presence of this original disposition in childhood. Among the forces restricting the direction taken by the sexual instinct we laid emphasis upon shame, disgust, pity and the structures of morality and authority erected by society. We were thus led to regard any established aberration from normal sexuality as an instance of developmental inhibition and infantilism. Though it was necessary to place in the foreground the importance of the variations in the original disposition, a co-operative and not an opposing relation was to be assumed as existing between them and the influences of actual life. It appeared, on the other hand, that since the original disposition is necessarily a complex one, the sexual instinct itself must be something put together from various factors, and that in the perversions it falls apart, as it were, into its components. The perversions were thus seen to be on the one hand inhibitions, and on the other hand dissociations, of normal development. Both these aspects were brought together in the supposition that the sexual instinct of adults arises from a combination of a number of impulses of childhood into a unity, an impulsion with a single aim.

[1905d, 1542]
I could not further elucidate this part of my theory without a detailed discussion of my views on repression. It will be enough here to refer to my *Three Essays* (1905d), in which I have attempted to throw some light - if only a feeble one - on the somatic processes in which the essential nature of sexuality is to be looked for. I have there shown that the constitutional sexual disposition of children is incomparably more variegated than might have been expected, that it deserves to be described as 'polymorphously perverse' and that what is spoken of as the normal behaviour of the sexual function emerges from this disposition after certain of its components have been repressed. By pointing out the infantile elements in sexuality I was able to establish a simple correlation between health, perversion and neurosis. I showed that normality is a result of the repression of certain component instincts and constituents of the infantile disposition and of the subordination of the remaining constituents under the primacy of the genital zones in the service of the reproductive function. I showed that perversions correspond to disturbances of this coalescence owing to the overpowering and compulsive development of certain of the component instincts, while neuroses can be traced back to an excessive repression of the libidinal trends. Since almost all the perverse instincts of the infantile disposition can be recognized as the forces concerned in the formation of symptoms in neuroses, though in a state of repression, I was able to describe neurosis as being the 'negative' of perversion. [1906a, 1581]

In the first place (disregarding people whose sexual instinct is altogether excessive and uninhibitable) there are the different varieties perverts, in whom an infantile fixation to a preliminary sexual aim has prevented the primacy of the reproductive function from being established, and the homosexuals or inverteds, in whom, in a manner that is not yet quite understood, the sexual aim has been deflected away from the opposite sex. If the injurious effects of these two kinds of developmental disturbance are less than might be expected, this mitigation can be ascribed precisely to the complex way in which the sexual instinct is put together, which makes it possible for a person's sexual life to reach a serviceable final form even if one or more components of the instinct have been shut off from development. The constitution of people suffering from inversion - the homosexuals - is, indeed, often distinguished by their sexual instinct's possessing a special aptitude for cultural sublimation. [1908d, 1953]

The sternness of the demands of civilization and the difficulty of the task of abstinence have combined to make avoidance of the union of the genitals of the two opposite sexes into the central point of abstinence and to favour other kinds of sexual activity, which, it might be said, are equivalent to semi-obedience. Since normal intercourse has been so relentlessly persecuted by morality - and also, on account of the possibilities of infection, by hygiene - what are known as the perverse forms of intercourse between the two sexes, in which other parts of the body take over the role of the genitals, have undoubtedly increased in social importance. These activities cannot, however, be regarded as being as harmless as analogous extensions in love-relationships. They are ethically objectionable, for they degrade the relationships of love between two human beings from a serious matter to a convenient game, attended by no risk and no spiritual participation. A further consequence of the aggravation of the difficulties of normal sexual life is to be found in the spread of homosexual satisfaction; in addition to all those who are homosexuals in virtue of their organization, or who became so in their childhood, there must be reckoned the great number of those in whom, in their maturer years, a blocking of the main stream of their libido has caused a widening in the side-channel of homosexuality. [1908d, 1961]
I know you have been wanting for a long time to interrupt me and exclaim: 'Enough of these atrocities! You tell us that defaecating is a source of sexual satisfaction, and already exploited in infancy! that faeces is a valuable substance and that the anus is a kind of genital! We don't believe all that but we do understand why paediatricians and educationists have given a wide berth to psycho-analysis and its findings.' No, Gentlemen. You have merely forgotten that I have been trying to introduce the facts of infantile sexual life to you in connection with the facts of the sexual perversions. Why should you not be aware that for a large number of adults, homosexual and heterosexual alike, the anus does really take over the role of the vagina in sexual intercourse? And that there are many people who retain a voluptuous feeling in defaecating all through their lives and describe it as being far from small? As regards interest in the act of defaecation and enjoyment in watching someone else defaecating, you can get children themselves to confirm the fact when they are a few years older and able to tell you about it. Of course, you must not have systematically intimidated them beforehand, or they will quite understand that they must be silent on the subject. And as to the other things that you are anxious not to believe, I will refer you to the findings of analysis and of the direct observation of children and will add that it calls for real ingenuity not to see all this or to see it differently. Nor do I complain if you find the kinship between infantile sexual activity and sexual perversions something very striking. But it is in fact self-evident: if a child has a sexual life at all it is bound to be of a perverse kind; for, except for a few obscure hints, children are without what makes sexuality into the reproductive function. On the other hand, the abandonment of the reproductive function is the common feature of all perversions. We actually describe a sexual activity as perverse if it has given up the aim of reproduction and pursues the attainment of pleasure as an aim independent of it. So, as you will see, the breach and turning-point in the development of sexual life lies in its becoming subordinate to the purposes of reproduction. Everything that happens before this turn of events and equally everything that disregards it and that aims solely at obtaining pleasure is given the uncomplimentary name of 'perverse' and as such is proscribed.

[1916-1917, 3386]

It is not the case that the perversions alone would have obliged us to make the change in the concept of sexuality which has brought such violent contradictions down on us. The study of infantile sexuality had even more to do with it and it was the concurrence of the two which was decisive for us. But the manifestations of infantile sexuality, however unmistakable they may be in later childhood, seem to melt into indefiniteness towards their beginnings. Anyone who chooses to disregard the history of their development and their analytic context will deny that they are of a sexual character and will attribute some undifferentiated character to them instead. You must not forget that at the moment we are not in possession of any generally recognized criterion of the sexual nature of a process, apart, once again, from a connection with the reproductive function which we must reject as being too narrow-minded. The biological criteria, such as the periodicities of twenty-three and twenty-eight days postulated by Wilhelm Fliess, are still highly debatable; the chemical characteristics of the sexual process, which we may suspect, are still awaiting discovery. On the other hand, the sexual perversions of adults are something tangible and unambiguous. As is already shown by the name by which they are universally known, they are unquestionably sexual. Whether they are described as indications of degeneracy or in any other way, no one has yet had the courage to class them as anything but phenomena of sexual life. On their account alone we are justified in asserting that sexuality and reproduction do not coincide, for it is obvious that all of them disavow the aim of reproduction.

[1916-1917, 3389]
There is something else that I must add in order to complete our view of sexual perversions. However infamous they may be, however sharply they may be contrasted with normal sexual activity, quiet consideration will show that some perverse trait or other is seldom absent from the sexual life of normal people. Even a kiss can claim to be described as a perverse act, since it consists in the bringing together of two oral erotogenic zones instead of the two genitals. Yet no one rejects it as perverse; on the contrary, it is permitted in theatrical performances as a softened hint at the sexual act. But precisely kissing can easily turn into a complete perversion - if, that is to say, it becomes so intense that a genital discharge and orgasm follow upon it directly, an event that is far from rare. We can learn, too, that for one person feeling and looking at the object are indispensable preconditions of sexual enjoyment, that another person will pinch or bite at the climax of sexual excitation, that the highest pitch of excitement in lovers is not always provoked by the genitals but by some other region of the object’s body, and any number of similar things besides. There is no sense in excluding people with individual traits of this kind from the class of the normal and putting them among the perverts. On the contrary, we shall recognize more and more clearly that the essence of the perversions lies not in the extension of the sexual aim, not in the replacement of the genitals, not even always in the variant choice of the object, but solely in the exclusiveness with which these deviations are carried out and as a result of which the sexual act serving the purpose of reproduction is put on one side. In so far as the perverse actions are inserted in the performance of the normal sexual act as preparatory or intensifying contributions, they are in reality not perversions at all. The gulf between normal and perverse sexuality is of course very much narrowed by facts of this kind. It is an easy conclusion that normal sexuality has emerged out of something that was in existence before it, by weeding out certain features of that material as unserviceable and collecting together the rest in order to subordinate them to a new aim, that of reproduction.

[1916-1917, 3391]

The detaching of sexuality from the genitals has the advantage of allowing us to bring the sexual activities of children and of perverts into the same scope as those of normal adults. The sexual activities of children have hitherto been entirely neglected and though those of perverts have been recognized it has been with moral indignation and without understanding. Looked at from the psycho-analytic standpoint, even the most eccentric and repellent perversions are explicable as manifestations of component instincts of sexuality which have freed themselves from the primacy of the genitals and are now in pursuit of pleasure on their own account as they were in the very early days of the libido’s development. The most important of these perversions, homosexuality, scarcely deserves the name. It can be traced back to the constitutional bisexuality of all human beings and to the after-effects of the phallic primacy. Psycho-analysis enables us to point to some trace or other of a homosexual object-choice in everyone. If I have described children as ‘polymorphously perverse’, I was only using a terminology that was generally current; no moral judgement was implied by the phrase. Psycho-analysis has no concern whatever with such judgements of value.

[1925d, 4213]
The tendency on the part of civilization to restrict sexual life is no less clear than its other tendency to expand the cultural unit. Its first, totemic, phase already brings with it the prohibition against an incestuous choice of object, and this is perhaps the most drastic mutilation which man's erotic life has in all time experienced. Taboos, laws and customs impose further restrictions, which affect both men and women. Not all civilizations go equally far in this; and the economic structure of the society also influences the amount of sexual freedom that remains. Here, as we already know, civilization is obeying the laws of economic necessity, since a large amount of the psychical energy which it uses for its own purposes has to be withdrawn from sexuality. In this respect civilization behaves towards sexuality as a people or a stratum of its population does which has subjected another one to its exploitation. Fear of a revolt by the suppressed elements drives it to stricter precautionary measures. A high-water mark in such a development has been reached in our Western European civilization. A cultural community is perfectly justified, psychologically, in starting by proscribing manifestations of the sexual life of children, for there would be no prospect of curbing the sexual lusts of adults if the ground had not been prepared for it in childhood. But such a community cannot in any way be justified in going to the length of actually disavowing such easily demonstrable, and, indeed, striking phenomena. As regards the sexually mature individual, the choice of an object is restricted to the opposite sex, and most extra-genital satisfactions are forbidden as perversions. The requirement, demonstrated in these prohibitions, that there shall be a single kind of sexual life for everyone, disregards the dissimilarities, whether innate or acquired, in the sexual constitution of human beings; it cuts off a fair number of them from sexual enjoyment, and so becomes the source of serious injustice. The result of such restrictive measures might be that in people who are normal - who are not prevented by their constitution - the whole of their sexual interests would flow without loss into the channels that are left open. But heterosexual genital love, which has remained exempt from outlawry, is itself restricted by further limitations, in the shape of insistence upon legitimacy and monogamy. Present-day civilization makes it plain that it will only permit sexual relationships on the basis of a solitary, indissoluble bond between one man and one woman, and that it does not like sexuality as a source of pleasure in its own right and is only prepared to tolerate it because there is so far no substitute for it as a means of propagating the human race.

1930a, 4498

Unfortunately what history tells us and what we ourselves have experienced does not speak in this sense but rather justifies a judgement that belief in the 'goodness' of human nature is one of those evil illusions by which mankind expect their lives to be beautified and made easier while in reality they only cause damage. We need not continue this controversy, since we have argued in favour of a special aggressive and destructive instinct in men not on account of the teachings of history or of our experience in life but on the basis of general considerations to which we were led by examining the phenomena of sadism and masochism. As you know, we call it sadism when sexual satisfaction is linked to the condition of the sexual object's suffering pain, ill-treatment and humiliation, and masochism when the need is felt of being the ill-treated object oneself. As you know too, a certain admixture of these two trends is included in normal sexual relations, and we speak of perversions when they push the other sexual aims into the background and replace them by their own aims. And you will scarcely have failed to notice that sadism has a more intimate relation with masculinity and masochism with femininity, as though there were a secret kinship present; though I must add that we have made no progress along that path. Both phenomena, sadism and masochism alike, but masochism quite especially, present a truly puzzling problem to the libido theory; and it is only proper if what was a stumbling-block for the one theory should become the cornerstone of the theory replacing it.

1933a, 4708
This process is not always performed faultlessly. Inhibitions in its development manifest themselves as the many sorts of disturbance in sexual life. When this is so, we find fixations of the libido to conditions in earlier phases, whose urge, which is independent of the normal sexual aim, is described as *perversion*. One such developmental inhibition, for instance, is homosexuality when it is manifest. Analysis shows that in every case a homosexual object-tie was present and in most cases persisted in a *latent* condition. The situation is complicated by the fact that as a rule the processes necessary for bringing about a normal outcome are not completely present or absent, but *partially* present, so that the final result remains dependent on these *quantitative* relations. In these circumstances the genital organization is, it is true, attained, but it lacks those portions of the libido which have not advanced with the rest and have remained fixated to pregenital objects and aims. This weakening shows itself in a tendency, if there is an absence of genital satisfaction or if there are difficulties in the real external world, for the libido to hark back to its earlier pregenital cathexes (*regression*). [1940a [1938], 4966]
I believe, then, that infantile amnesia, which turns everyone's childhood into something like a prehistoric epoch and conceals from him the beginnings of his own sexual life, is responsible for the fact that in general no importance is attached to childhood in the development of sexual life. The gaps in our knowledge which have arisen in this way cannot be bridged by a single observer. As long ago as in the year 1896 I insisted on the significance of the years of childhood in the origin of certain important phenomena connected with sexual life, and since then I have never ceased to emphasize the part played in sexuality, by the infantile factor.

[1905d, 1498]

INTERRUPTIONS OF THE LATENCY PERIOD We must not deceive ourselves as to the hypothetical nature and insufficient clarity of our knowledge concerning the processes of the infantile period of latency or deferment; but we shall be on firmer ground in pointing out that such an application of infantile sexuality represents an educational ideal from which individual development usually diverges at some point and often to a considerable degree. From time to time a fragmentary manifestation of sexuality which has evaded sublimation may break through; or some sexual activity may persist through the whole duration of the latency period until the sexual instinct emerges with greater intensity at puberty. In so far as educators pay any attention at all to infantile sexuality, they behave exactly as though they shared our views as to the construction of the moral defensive forces at the cost of sexuality, and as though they knew that sexual activity makes a child ineducable: for they stigmatize every sexual manifestation by children as a 'vice', without being able to do much against it. We, on the other hand, have every reason for turning our attention to these phenomena which are so much dreaded by education, for we may expect them to help us to discover the original configuration of the sexual instincts.

[1905d, 1501]

This failure of the function of the sexual mechanism owing to fore-pleasure is best avoided if the primacy of the genitals too is adumbrated in childhood; and indeed things seem actually arranged to bring this about in the second half of childhood (from the age of eight to puberty). During these years the genital zones already behave in much the same way as in maturity; they become the seat of sensations of excitation and of preparatory changes whenever any pleasure is felt from the satisfaction of other erotogenic zones, though this result is still without a purpose - that is to say, contributes nothing to a continuation of the sexual process. Already in childhood, therefore, alongside of the pleasure of satisfaction there is a certain amount of sexual tension, although it is less constant and less in quantity. We can now understand why, in discussing the sources of sexuality, we were equally justified in saying of a given process that it was sexually satisfying or sexually exciting. It will be noticed that in the course of our enquiry we began by exaggerating the distinction between infantile and mature sexual life, and that we are now setting this right. Not only the deviations from normal sexual life but its normal form as well are determined by the infantile manifestations of sexuality.

[1905d, 1528]
The time has arrived for me to attempt to summarize what I have said. We started out from the aberrations of the sexual instinct in respect of its object and of its aim and we were faced by the question of whether these arise from an innate disposition or are acquired as a result of experiences in life. We arrived at an answer to this question from an understanding, derived from psycho-analytic investigation, of the workings of the sexual instinct in psychoneurotics, a numerous class of people and one not far removed from the healthy. We found that in them tendencies to every kind of perversion can be shown to exist as unconscious forces and betray their presence as factors leading to the formation of symptoms. It was thus possible to say that neurosis is, as it were, the negative of perversion. In view of what was now seen to be the wide dissemination of tendencies to perversion we were driven to the conclusion that a disposition to perversions is an original and universal disposition of the human sexual instinct and that normal sexual behaviour is developed out of it as a result of organic changes and psychical inhibitions occurring in the course of maturation; we hoped to be able to show the presence of this original disposition in childhood. Among the forces restricting the direction taken by the sexual instinct we laid emphasis upon shame, disgust, pity and the structures of morality and authority erected by society. We were thus led to regard any established aberration from normal sexuality as an instance of developmental inhibition and infantilism. Though it was necessary to place in the foreground the importance of the variations in the original disposition, a co-operative and not an opposing relation was to be assumed as existing between them and the influences of actual life. It appeared, on the other hand, that since the original disposition is necessarily a complex one, the sexual instinct itself must be something put together from various factors, and that in the perversions it falls apart, as it were, into its components. The perversions were thus seen to be on the one hand inhibitions, and on the other hand dissociations, of normal development. Both these aspects were brought together in the supposition that the sexual instinct of adults arises from a combination of a number of impulses of childhood into a unity, an impulsion with a single aim.

I could not further elucidate this part of my theory without a detailed discussion of my views on repression. It will be enough here to refer to my *Three Essays* (1905d), in which I have attempted to throw some light - if only a feeble one - on the somatic processes in which the essential nature of sexuality is to be looked for. I have there shown that the constitutional sexual disposition of children is incomparably more variegated than might have been expected, that it deserves to be described as 'polymorphously perverse' and that what is spoken of as the normal behaviour of the sexual function emerges from this disposition after certain of its components have been repressed. By pointing out the infantile elements in sexuality I was able to establish a simple correlation between health, perversion and neurosis. I showed that normality is a result of the repression of certain component instincts and constituents of the infantile disposition and of the subordination of the remaining constituents under the primacy of the genital zones in the service of the reproductive function. I showed that perversions correspond to disturbances of this coalescence owing to the overpowering and compulsive development of certain of the component instincts, while neuroses can be traced back to an excessive repression of the libidinal trends. Since almost all the perverse instincts of the infantile disposition can be recognized as the forces concerned in the formation of symptoms in neuroses, though in a state of repression, I was able to describe neurosis as being the 'negative' of perversion.

[1905d, 1542]

[1906a, 1581]
I think it is worth emphasizing the fact that, whatever modifications my views on the aetiology of the psychoneuroses have passed through, there are two positions which I have never repudiated or abandoned - the importance of sexuality and of infantilism. Apart from this, accidental influences have been replaced by constitutional factors and 'defence' in the purely psychological sense has been replaced by organic 'sexual repression'. The question may, however, be raised of where convincing evidence is to be found in favour of the alleged aetiological importance of sexual factors in the psychoneuroses, in view of the fact that the onset of these illnesses may be observed in response to the most commonplace emotions or even to somatic precipitating causes, and since I have had to abandon a specific aetiology depending on the particular form of the childhood experiences concerned. To such a question I would reply that the psycho-analytic examination of neurotics is the source from which this disputed conviction of mine is derived. If we make use of that irreplaceable method of research, we discover that the patient's symptoms constitute his sexual activity (whether wholly or in part), which arises from the sources of the normal or perverse component instincts of sexuality. Not only is a large part of the symptomatology of hysteria derived directly from expressions of sexual excitement, not only do a number of erotogenic zones attain the significance of genitals during neuroses owing to an intensification of infantile characteristics, but the most complicated symptoms are themselves revealed as representing, by means of 'conversion', phantasies which have a sexual situation as their subject-matter. Anyone who knows how to interpret the language of hysteria will recognize that the neurosis is concerned only with the patient's repressed sexuality. The sexual function must, however, be understood in its true extent, as it is laid down by disposition in infancy. Wherever some commonplace emotion must be included among the determinants of the onset of the illness, analysis invariably shows that it is the sexual component of the traumatic experience - a component that is never lacking which has produced the pathogenic result.

[1906a, 1582]

Even these first observations begin to rouse an expectation that much, if not most, of what little Hans shows us will turn out to be typical of the sexual development of children in general. I once put forward the view² that there was no need to be too much horrified at finding in a woman the idea of sucking at a male organ. This repellent impulse, I argued, had a most innocent origin, since it was derived from sucking at the mother's breast; and in this connection, I went on, a cow's udder plays an apt part as an intermediate image, being in its nature a mamma and in its shape and position a penis. Little Hans's discovery confirms the latter part of my contention.

[1909b, 2003]
Before we make use of our familiarity with the perversions to plunge once again into the study of infantile sexuality on the basis of clearer premisses, I must draw your attention to an important difference between them. Perverse sexuality is as a rule excellently centred: all its actions are directed to an aim - usually to a single one; one component instinct has gained the upper hand in it and is either the only one observable or has subjected the others to its purposes. In that respect there is no distinction between perverse and normal sexuality other than the fact that their dominating component instincts and consequently their sexual aims are different. In both of them, one might say, a well-organized tyranny has been established, but in each of the two a different family has seized the reins of power. Infantile sexuality, on the other hand, lacks, speaking generally, any such centring and organization; its separate component instincts have equal rights, each of them goes its own way to obtaining pleasure. Both the absence and the presence of centring harmonize well, of course, with the fact that both perverse and normal sexuality have arisen out of infantile sexuality. Incidentally, there are also cases of perverse sexuality which have a much greater resemblance to the infantile kind, since in them numerous component instincts have put through (or, more correctly, have persisted in) their aims independently of one another. It is better in such cases to speak of infantilism in sexual life rather than of a perversion.
[1916-1917, 3391]
Having diagnosed a case of neurasthenic neurosis with certainty and having classified its symptoms correctly, we are in a position to translate the symptomatology into aetiology; and we may then boldly demand confirmation of our suspicions from the patient. We must not be led astray by initial denials. If we keep firmly to what we have inferred, we shall in the end conquer every resistance by emphasizing the unshakeable nature of our convictions. In this way we learn all sorts of things about the sexual life of men and women, which might well fill a useful and instructive volume; and we learn, too, to regret from every point of view that sexual science is even to-day still regarded as disreputable. Since minor deviations from a normal *vita sexualis* are much too common for us to attach any value to their discovery, we shall only allow a serious and long continued abnormality in the sexual life of a neurotic patient to carry weight as an explanation. Moreover, the idea that one might, by one's insistence, cause a patient who is psychically normal to accuse himself falsely of sexual misdemeanours - such an idea may safely be disregarded as an imaginary danger.

[1897b, 461]

As regards the second kind of emotional reaction, which is not directed against me this time, but against my patient - supposing that my view of her is correct - and which regards the perverse nature of her phantasies as horrible, I should like to say emphatically that a medical man has no business to indulge in such passionate condemnation. I may also remark in passing that it seems to me superfluous for a physician who is writing upon the aberrations of the sexual instincts to seize every opportunity of inserting into the text expressions of his personal repugnance at such revolting things. We are faced by a fact; and it is to be hoped that we shall grow accustomed to it, when we have put our own tastes on one side. We must learn to speak without indignation of what we call the sexual perversions - instances in which the sexual function has extended its limits in respect either to the part of the body concerned or to the sexual object chosen. The uncertainty in regard to the boundaries of what is to be called normal sexual life, when we take different races and different epochs into account, should in itself be enough to cool the zealot's ardour. We surely ought not to forget that the perversion which is the most repellant to us, the sensual love of a man for a man, was not only tolerated by a people so far our superiors in cultivation as were the Greeks, but was actually entrusted by them with important social functions. The sexual life of each one of us extends to a slight degree - now in this direction, now in that - beyond the narrow lines imposed as the standard of normality. The perversions are neither bestial nor degenerate in the emotional sense of the word. They are a development of germs all of which are contained in the undifferentiated sexual disposition of the child, and which, by being suppressed or by being diverted to higher, asexual aims - by being 'sublimated' - are destined to provide the energy for a great number of our cultural achievements. When, therefore, any one has become a gross and manifest pervert, it would be more correct to say that he has remained one, for he exhibits a certain stage of *inhibited development*. All psychoneurotics are persons with strongly marked perverse tendencies, which have been repressed in the course of their development and have become unconscious. Consequently their unconscious *phantasies* show precisely the same content as the documentarily recorded *actions* of perverts - even though they have not read Krafft-Ebing's *Psychopathia Sexualis*, to which simple-minded people attribute such a large share of the responsibility for the production of perverse tendencies. Psychoneuroses are, so to speak, the *negative* of perversions. In neurotics their sexual constitution, under which the effects of heredity are included, operates in combination with any accidental influences in their life which may disturb the development of normal sexuality. A stream of water which meets with an obstacle in the river-bed is dammed up and flows back into old channels which had formerly seemed fated to run dry. The motive forces leading to the formation of hysterical symptoms draw their strength not only from repressed normal sexuality but also from unconscious perverse activities.¹

[1905e, 1387]
The normal sexual aim is regarded as being the union of the genitals in the act known as
copulation, which leads to a release of the sexual tension and a temporary extinction of the
sexual instinct - a satisfaction analogous to the satiating of hunger. But even in the most normal
sexual process we may detect rudiments which, if they had developed, would have led to the
deviations described as 'perversions'. For there are certain intermediate relations to the sexual
object, such as touching and looking at it, which lie on the road towards copulation and are
recognized as being preliminary sexual aims. On the one hand these activities are themselves
accompanied by pleasure, and on the other hand they intensify the excitation, which should
persist until the final sexual aim is attained. Moreover, the kiss, one particular contact of this
kind, between the mucous membrane of the lips of the two people concerned, is held in high
sexual esteem among many nations (including the most highly civilized ones), in spite of the
fact that the parts of the body involved do not form part of the sexual apparatus but constitute
the entrance to the digestive tract. Here, then, are factors which provide a point of contact
between the perversions and normal sexual life and which can also serve as a basis for their
classification. Perversions are sexual activities which either (a) extend, in an anatomical sense,
beyond the regions of the body that are designed for sexual union, or (b) linger over the
intermediate relations to the sexual object which should normally be traversed rapidly on the
path towards the final sexual aim.
[1905d, 1476]

SEXUAL USE OF THE ANAL ORIFICE Where the anus is concerned it becomes still clearer that it
is disgust which stamps that sexual aim as a perversion. I
hope, however, I shall not be accused of partisanship when I assert that people who try to
account for this disgust by saying that the organ in question serves the function of excretion and
comes in contact with excrement - a thing which is disgusting in itself - are not much more to the
point than hysterical girls who account for their disgust at the male genital by saying that it
serves to void urine.
[1905d, 1479]

A transition to those cases of fetishism in which the sexual aim, whether normal or perverse,
is entirely abandoned is afforded by other cases in which the sexual object is required to fulfil a
fetishistic condition - such as the possession of some particular hair-colouring or clothing, or
even some bodily defect if the sexual aim is to be attained. No other variation of the sexual
instinct that borders on the pathological can lay so much claim to our interest as this one, such
is the peculiarity of the phenomena to which it gives rise. Some degree of diminution in the urge
towards the normal sexual aim (an executive weakness of the sexual apparatus) seems to be a
necessary precondition in every case.¹ The point of contact with the normal is provided by the
psychologically essential overvaluation of the sexual object, which inevitably extends to
everything that is associated with it. A certain degree of fetishism is thus habitually present in
normal love, especially in those stages of it in which the normal sexual aim seems unattainable
or its fulfilment prevented:
[1905d, 1480]

APPEARANCE OF NEW AIDS Every external or internal factor that hinders or postpones the
attainment of the normal sexual aim (such as impotence, the high
price of the sexual object or the danger of the sexual act) will evidently lend support to the
tendency to linger over the preparatory activities and to turn them into new sexual aims that can
take the place of the normal one. Attentive examination always shows that even what seem to
be the strangest of these new aims are already hinted at in the normal sexual process.
[1905d, 1483]
TOUCHING AND LOOKING  A certain amount of touching is indispensable (at all events among human beings) before the normal sexual aim can be attained. And everyone knows what a source of pleasure on the one hand and what an influx of fresh excitation on the other is afforded by tactile sensations of the skin of the sexual object. So that lingering over the stage of touching can scarcely be counted a perversion, provided that in the long run the sexual act is carried further.

[1905d, 1483]

The same holds true of seeing - an activity that is ultimately derived from touching. Visual impressions remain the most frequent pathway along which libidinal excitation is aroused; indeed, natural selection counts upon the accessibility of this pathway - if such a teleological form of statement is permissible - when it encourages the development of beauty in the sexual object. The progressive concealment of the body which goes along with civilization keeps sexual curiosity awake. This curiosity seeks to complete the sexual object by revealing its hidden parts. It can, however, be diverted ("sublimated") in the direction of art, if its interest can be shifted away from the genitals on to the shape of the body as a whole.¹ It is usual for most normal people to linger to some extent over the intermediate sexual aim of a looking that has a sexual tinge to it; indeed, this offers them a possibility of directing some proportion of their libido on to higher artistic aims. On the other hand, this pleasure in looking becomes a perversion (a) if it is restricted exclusively to the genitals, or (b) if it is connected with the overriding of disgust (as in the case of voyeurs or people who look on at excretory functions), or (c) if, instead of being preparatory to the normal sexual aim, it supplants it. This last is markedly true of exhibitionists, who, if I may trust the findings of several analyses, exhibit their own genitals in order to obtain a reciprocal view of the genitals of the other person.²

[1905d, 1483]

VARIATION AND DISEASE  It is natural that medical men, who first studied perversions in outstanding examples and under special conditions, should have been inclined to regard them, like inversion, as indications of degeneracy or disease. Nevertheless, it is even easier to dispose of that view in this case than in that of inversion. Everyday experience has shown that most of these extensions, or at any rate the less severe of them, are constituents which are rarely absent from the sexual life of healthy people, and are judged by them no differently from other intimate events. If circumstances favour such an occurrence, normal people too can substitute a perversion of this kind for the normal sexual aim for quite a time, or can find place for the one alongside the other. No healthy person, it appears, can fail to make some addition that might be called perversive to the normal sexual aim; and the universality of this finding is in itself enough to show how inappropriate it is to use the word perversion as a term of reproach. In the sphere of sexual life we are brought up against peculiar and, indeed, insoluble difficulties as soon as we try to draw a sharp line to distinguish mere variations within the range of what is physiological from pathological symptoms.

[1905d, 1486]
Nevertheless, in some of these perversions the quality of the new sexual aim is of a kind to demand special examination. Certain of them are so far removed from the normal in their content that we cannot avoid pronouncing them 'pathological'. This is especially so where (as, for instance, in cases of licking excrement or of intercourse with dead bodies) the sexual instinct goes to astonishing lengths in successfully overriding the resistances of shame, disgust, horror or pain. But even in such cases we should not be too ready to assume that people who act in this way will necessarily turn out to be insane or subject to grave abnormalities of other kinds. Here again we cannot escape from the fact that people whose behaviour is in other respects normal can, under the domination of the most unruly of all the instincts, put themselves in the category of sick persons in the single sphere of sexual life. On the other hand, manifest abnormality in the other relations of life can invariably be shown to have a background of abnormal sexual conduct.

[1905d, 1486]

In the majority of instances the pathological character in a perversion is found to lie not in the content of the new sexual aim but in its relation to the normal. If a perversion, instead of appearing merely alongside the normal sexual aim and object, and only when circumstances are unfavourable to them and favourable to it - if, instead of this, it ousts them completely and takes their place in all circumstances - if, in short, a perversion has the characteristics of exclusiveness and fixation - then we shall usually be justified in regarding it as a pathological symptom.

[1905d, 1486]

By demonstrating the part played by perverse impulses in the formation of symptoms in the psychoneuroses, we have quite remarkably increased the number of people who might be regarded as perverts. It is not only that neurotics in themselves constitute a very numerous class, but it must also be considered that an unbroken chain bridges the gap between the neuroses in all their manifestations and normality. After all, Moebius could say with justice that we are all to some extent hysterics. Thus the extraordinarily wide dissemination of the perversions forces us to suppose that the disposition to perversions is itself of no great rarity but must form a part of what passes as the normal constitution.

[1905d, 1495]

It is, as we have seen, debatable whether the perversions go back to innate determinants or arise, as Binet assumed was the case with fetishism, owing to chance experiences. The conclusion now presents itself to us that there is indeed something innate lying behind the perversions but that it is something innate in everyone, though as a disposition it may vary in its intensity and may be increased by the influences of actual life. What is in question are the innate constitutional roots of the sexual instinct. In one class of cases (the perversions) these roots may grow into the actual vehicles of sexual activity; in others they may be submitted to an insufficient suppression (repression) and thus be able in a roundabout way to attract a considerable proportion of sexual energy to themselves as symptoms; while in the most favourable cases, which lie between these two extremes, they may by means of effective restriction and other kinds of modification bring about what is known as normal sexual life.

[1905d, 1495]

We have, however, a further reflection to make. This postulated constitution, containing the germs of all the perversions, will only be demonstrable in children, even though in them it is only with modest degrees of intensity that any of the instincts can emerge. A formula begins to take shape which lays it down that the sexuality of neurotics has remained in, or been brought back to, an infantile state. Thus our interest turns to the sexual life of children, and we will now proceed to trace the play of influences which govern the evolution of infantile sexuality till its outcome in perversion, neurosis or normal sexual life.

[1905d, 1495]
POLYMORPHOUSLY PERVERSE DISPOSITION  It is an instructive fact that under the influence of seduction children can become polymorphously perverse, and can be led into all possible kinds of sexual irregularities. This shows that an aptitude for them is innately present in their disposition. There is consequently little resistance towards carrying them out, since the mental dams against sexual excesses - shame, disgust and morality - have either not yet been constructed at all or are only in course of construction, according to the age of the child. In this respect children behave in the same kind of way as an average uncultivated woman in whom the same polymorphously perverse disposition persists. Under ordinary conditions she may remain normal sexually, but if she is led on by a clever seducer she will find every sort of perversion to her taste, and will retain them as part of her own sexual activities. Prostitutes exploit the same polymorphous, that is, infantile, disposition for the purposes of their profession; and, considering the immense number of women who are prostitutes or who must be supposed to have an aptitude for prostitution without becoming engaged in it, it becomes impossible not to recognize that this same disposition to perversions of every kind is a general and fundamental human characteristic.

¹ [Footnote added 1920:] An inevitable consequence of these considerations is that we must regard each individual as possessing an oral erotism, an anal erotism, a urethral erotism, etc., and that the existence of mental complexes corresponding to these implies no judgement of abnormality or neurosis. The differences separating the normal from the abnormal can lie only in the relative strength of the individual components of the sexual instinct and in the use to which they are put in the course of development.

The time has arrived for me to attempt to summarize what I have said. We started out from the aberrations of the sexual instinct in respect of its object and of its aim and we were faced by the question of whether these arise from an innate disposition or are acquired as a result of experiences in life. We arrived at an answer to this question from an understanding, derived from psycho-analytic investigation, of the workings of the sexual instinct in psychoneurotics, a numerous class of people and one not far removed from the healthy. We found that in them tendencies to every kind of perversion can be shown to exist as unconscious forces and betray their presence as factors leading to the formation of symptoms. It was thus possible to say that neurosis is, as it were, the negative of perversion. In view of what was now seen to be the wide dissemination of tendencies to perversion we were driven to the conclusion that a disposition to perversions is an original and universal disposition of the human sexual instinct and that normal sexual behaviour is developed out of it as a result of organic changes and psychical inhibitions occurring in the course of maturation; we hoped to be able to show the presence of this original disposition in childhood. Among the forces restricting the direction taken by the sexual instinct we laid emphasis upon shame, disgust, pity and the structures of morality and authority erected by society. We were thus led to regard any established aberration from normal sexuality as an instance of developmental inhibition and infantilism. Though it was necessary to place in the foreground the importance of the variations in the original disposition, a co-operative and not an opposing relation was to be assumed as existing between them and the influences of actual life. It appeared, on the other hand, that since the original disposition is necessarily a complex one, the sexual instinct itself must be something put together from various factors, and that in the perversions it falls apart, as it were, into its components. The perversions were thus seen to be on the one hand inhibitions, and on the other hand dissociations, of normal development. Both these aspects were brought together in the supposition that the sexual instinct of adults arises from a combination of a number of impulses of childhood into a unity, an impulsion with a single aim.

[1905d, 1510]
It can only help to clarify things if at this point we go back to fundamental facts. A desire to see the organs peculiar to each sex exposed is one of the original components of our libido. It may itself be a substitute for something earlier and go back to a hypothetical primary desire to touch the sexual parts. As so often, looking has replaced touching.¹ The libido for looking and touching is present in everyone in two forms, active and passive, male and female; and, according to the preponderance of the sexual character, one form or the other predominates. It is easy to observe the inclination to self-exposure in young children. In cases in which the germ of this inclination escapes its usual fate of being buried and suppressed, it develops in men into the familiar perversion known as exhibitionism. In women the inclination to passive exhibitionism is almost invariably buried under the imposing reactive function of sexual modesty, but not without a loophole being left for it in relation to clothes. I need only hint at the elasticity and variability in the amount of exhibitionism that women are permitted to retain in accordance with differing convention and circumstances.

[1905c, 1695]

The tracing back of the delusion and its resolution were now complete. What the author now adds is no doubt designed to serve as a harmonious end to his story. We cannot but feel reassured about the future when we hear that the young man, who had earlier been obliged to play the pitiable part of a person in urgent need of treatment, advanced still further on the road to recovery and succeeded in arousing in her some of the feelings under which he himself had suffered before. Thus it was that he made her jealous by mentioning the sympathetic young lady who had previously interrupted their tête-à-tête in the House of Meleager, and by confessing that she had been the first woman for whom he had felt a very great liking. Whereupon Zoe prepared to take a chilly leave of him, remarking that everything had now returned to reason - she herself not least; he could look up Gisa Hartleben (or whatever she was now called) again and give her some scientific assistance over the purpose of her visit to Pompeii; she herself, however, must go back to the Albergo del Sole where her father was expecting her for lunch; perhaps they would meet again some time at a party in Germany or in the moon. But once more he was able to make the troublesome fly an excuse for taking possession first of her cheek and then of her lips, and to set in motion the aggressiveness which is a man's inevitable duty in love making. Once only a shadow seemed to fall on their happiness, when Zoe declared that now she really must go back to her father or he will starve at the Sole. 'Your father? . . . what will happen? . . .' (147.) But the clever girl was able swiftly to quiet his concern. 'Probably nothing will happen. I'm not an indispensable part of his zoological collection. If I had been, perhaps I shouldn't have been so foolish as to give my heart to you.' In the exceptional event, however, of her father taking a different view from hers, there was a safe expedient. Hanold need only cross to Capri, catch a *Lacerta faraglionensis* there (he could practise the technique on her little finger), set the creature free over here, catch it again before the zoologist's eyes, and let him choose between a *faraglionensis* on the mainland and his daughter. The scheme, it is easy to see, was one in which the mockery was tinged with bitterness; it was a warning, as it were, to her fiancé not to keep too closely to the model on which she had chosen him. Here again Norbert Hanold reassures us, by showing by all sorts of apparently small signs the great transformation that had taken place in him. He proposed that he and his Zoe should come for their honeymoon to Italy and Pompeii, just as though he had never been indignant with the honeymooning Edwins and Angelinas. He had completely lost from his memory all his feelings against those happy pairs, who had so unnecessarily travelled more than a hundred miles from their German home. The author is certainly right in bringing forward a loss of memory like this as the most trustworthy sign of a change of attitude. Zoe's reply to the plan for the scene of their honeymoon suggested by 'her childhood friend who had also in a sense been dug out of the ruins again' (150.) was that she did not feel quite alive enough yet to make a geographical decision of that sort.

[1907a, 1840]
In the first place (disregarding people whose sexual instinct is altogether excessive and uninhibitable) there are the different varieties perverts, in whom an infantile fixation to a preliminary sexual aim has prevented the primacy of the reproductive function from being established, and the homosexuals or inverts, in whom, in a manner that is not yet quite understood, the sexual aim has been deflected away from the opposite sex. If the injurious effects of these two kinds of developmental disturbance are less than might be expected, this mitigation can be ascribed precisely to the complex way in which the sexual instinct is put together, which makes it possible for a person's sexual life to reach a serviceable final form even if one or more components of the instinct have been shut off from development. The constitution of people suffering from inversion - the homosexuals - is, indeed, often distinguished by their sexual instinct's possessing a special aptitude for cultural sublimation. [1908d, 1953]

If however we turn our attention not to an extension of the concept of psychical impotence, but to the gradations in its symptomatology, we cannot escape the conclusion that the behaviour in love of men in the civilized world to-day bears the stamp altogether of psychical impotence. There are only a very few educated people in whom the two currents of affection and sensuality have become properly fused; the man almost always feels his respect for the woman acting as a restriction on his sexual activity, and only develops full potency when he is with a debased sexual object; and this in its turn is partly caused by the entrance of perverse components into his sexual aims, which he does not venture to satisfy with a woman he respects. He is assured of complete sexual pleasure only when he can devote himself unreservedly to obtaining satisfaction, which with his well-brought-up wife, for instance, he does not dare to do. This is the source of his need for a debased sexual object, a woman who is ethnically inferior, to whom he need attribute no aesthetic scruples, who does not know him in his other social relations and cannot judge him in them. It is to such a woman that he prefers to devote his sexual potency, even when the whole of his affection belongs to a woman of a higher kind. It is possible, too, that the tendency so often observed in men of the highest classes of society to choose a woman of a lower class as a permanent mistress or even as a wife is nothing but a consequence of their need for a debased sexual object, to whom, psychologically, the possibility of complete satisfaction is linked. [1912d, 2342]

Psycho-analysis further shows that, to begin with, excremental and sexual instincts are not distinct from each other in children. The divorce between them only occurs later and it remains incomplete. Their original affinity, which is established by the anatomy of the human body, still makes itself felt in many ways in normal adults. Finally, it should not be forgotten that these developments can no more be expected to yield a perfect result than any others. Some portion of the old preferences persist, some part of the coprophilic inclinations continue to operate in later life and are expressed in the neuroses, perversions and bad habits of adults. [1913k, 2641]

Now there cannot be the slightest doubt that all these crazy, eccentric and horrible things really constitute the sexual activity of these people. Not only do they themselves regard them as such and are aware that they are substitutes for each other, but we must admit that they play the same part in their lives as normal sexual satisfaction does in ours; they make the same, often excessive sacrifices for them, and we can trace both in the rough and in finer detail the points at which these abnormalities are based on what is normal and the points at which they diverge from it. Nor can you fail to notice that here once again you find the characteristic of being improper, which clings to sexual activity, though here it is for the most part intensified to the point of being abominable. [1916-1917, 3378]
Well, Ladies and Gentlemen, what attitude are we to adopt to these unusual kinds of sexual satisfaction? Indignation, an expression of our personal repugnance and an assurance that we ourselves do not share these lusts will obviously be of no help. Indeed, that is not what we have been asked for. When all is said and done, what we have here is a field of phenomena like any other. A denial in the form of an evasive suggestion that after all these are only rarities and curiosities would be easy to refute. On the contrary, we are dealing with quite common and widespread phenomena. If, however, it is argued that we need not allow our views of sexual life to be misled by them because they are one and all aberrations and deviations of the sexual instinct, a serious answer is called for. Unless we can understand these pathological forms of sexuality and can co-ordinate them with normal sexual life, we cannot understand normal sexuality either. In short, it remains an unavoidable task to give a complete theoretical account of how it is that these perversions can occur and of their connection with what is described as normal sexuality.

[1916-1917, 3379]

We shall be helped in this by a piece of information and two fresh observations. We owe the former to Iwan Bloch. It corrects the view that all these perversions are 'signs of degeneracy' by showing that aberrations of this kind from the sexual aim, loosenings like these of the tie with the sexual object, have occurred from time immemorial, in all periods known to us, among all peoples, the most primitive and the most civilized, and have occasionally obtained toleration and general recognition. The two observations were derived from the psycho-analytic investigation of neurotics; they are bound to have a decisive influence on our view of the sexual perversions.

[1916-1917, 3379]

For the moment, perhaps, you may have an impression that I have confused rather than explained the relation between normal and perverse sexuality. But you must bear the following consideration in mind. If it is true that increased difficulty in obtaining normal sexual satisfaction in real life, or deprivation of that satisfaction, brings out perverse inclinations in people who had not shown any previously, we must suppose that there was something in these people which came half-way to meet the perversions; or, if you prefer it, the perversions must have been present in them in a latent form.

[1916-1917, 3381]

But if the existence of sexual perversions is such a decisive argument in this question, why has it not long since had its effect and settled the matter? I really cannot say. I think it is connected with the fact that these sexual perversions are subject to a quite special ban, which has even affected theory and has stood in the way of the scientific consideration of them. It is as though no one could forget that they are not only something disgusting but also something monstrous and dangerous - as though people felt them as seductive, and had at bottom to fight down a secret envy of those who were enjoying them. One is reminded of the admission made by the condemnatory Landgraf in the famous Tannhäuser parody:

'Im Venusberg vergass er Ehr und Pflicht!
- Merkwürdig, unser einem passiert
  so etwas nicht.'

In reality perverts are poor wretches, rather, who have to pay extremely dear for their hard-won satisfaction.

[1916-1917, 3390]
There is something else that I must add in order to complete our view of sexual perversions. However infamous they may be, however sharply they may be contrasted with normal sexual activity, quiet consideration will show that some perverse trait or other is seldom absent from the sexual life of normal people. Even a kiss can claim to be described as a perverse act, since it consists in the bringing together of two oral erotogenic zones instead of the two genitals. Yet no one rejects it as perverse; on the contrary, it is permitted in theatrical performances as a softened hint at the sexual act. But precisely kissing can easily turn into a complete perversion - if, that is to say, it becomes so intense that a genital discharge and orgasm follow upon it directly, an event that is far from rare. We can learn, too, that for one person feeling and looking at the object are indispensable preconditions of sexual enjoyment, that another person will pinch or bite at the climax of sexual excitation, that the highest pitch of excitement in lovers is not always provoked by the genitals but by some other region of the object's body, and any number of similar things besides. There is no sense in excluding people with individual traits of this kind from the class of the normal and putting them among the perverts. On the contrary, we shall recognize more and more clearly that the essence of the perversions lies not in the extension of the sexual aim, not in the replacement of the genitals, not even always in the variant choice of the object, but solely in the exclusiveness with which these deviations are carried out and as a result of which the sexual act serving the purpose of reproduction is put on one side. In so far as the perverse actions are inserted in the performance of the normal sexual act as preparatory or intensifying contributions, they are in reality not perversions at all. The gulf between normal and perverse sexuality is of course very much narrowed by facts of this kind. It is an easy conclusion that normal sexuality has emerged out of something that was in existence before it, by weeding out certain features of that material as unserviceable and collecting together the rest in order to subordinate them to a new aim, that of reproduction. [1916-1917, 3391]

Before we make use of our familiarity with the perversions to plunge once again into the study of infantile sexuality on the basis of clearer premisses, I must draw your attention to an important difference between them. Perverse sexuality is as a rule excellently centred: all its actions are directed to an aim - usually to a single one; one component instinct has gained the upper hand in it and is either the only one observable or has subjected the others to its purposes. In that respect there is no distinction between perverse and normal sexuality other than the fact that their dominating component instincts and consequently their sexual aims are different. In both of them, one might say, a well-organized tyranny has been established, but in each of the two a different family has seized the reins of power. Infantile sexuality, on the other hand, lacks, speaking generally, any such centring and organization; its separate component instincts have equal rights, each of them goes its own way to obtaining pleasure. Both the absence and the presence of centring harmonize well, of course, with the fact that both perverse and normal sexuality have arisen out of infantile sexuality. Incidentally, there are also cases of perverse sexuality which have a much greater resemblance to the infantile kind, since in them numerous component instincts have put through (or, more correctly, have persisted in) their aims independently of one another. It is better in such cases to speak of infantilism in sexual life rather than of a perversion. [1916-1917, 3391]
Reflection will quickly suggest that if any such fixation of the libido to the subject's own body and personality, instead of to an object does occur, it cannot be an exception or a trivial event. On the contrary it is probable that this narcissism is the universal and original state of things, from which object-love is only later developed, without the narcissism necessarily disappearing on that account. Indeed we had to recall from the history of the development of object-libido that many sexual instincts begin by finding satisfaction in the subject's own body - *auto-erotically*, as we say - and that this capacity for auto-erotism is the basis of the lagging-behind of sexuality in the process of education in the reality principle. Auto-erotism would thus be the sexual activity of the narcissistic stage of allocation of the libido.

A perversion in childhood, as is well known, may become the basis for the construction of a perversion having a similar sense and persisting throughout life, one which consumes the subject's whole sexual life. On the other hand the perversion may be broken off and remain in the background of a normal sexual development, from which, however, it continues to withdraw a certain amount of energy. The first of these alternatives was already known before the days of analysis. Analytic investigation, however, of such fully-developed cases almost bridges the gulf between the two. For we find often enough with these perverts that they too made an attempt at developing normal sexual activity, usually at the age of puberty; but their attempt had not enough force in it and was abandoned in the face of the first obstacles which inevitably arise, where upon they fell back upon their infantile fixation once and for all.

Unfortunately what history tells us and what we ourselves have experienced does not speak in this sense but rather justifies a judgement that belief in the 'goodness' of human nature is one of those evil illusions by which mankind expect their lives to be beautified and made easier while in reality they only cause damage. We need not continue this controversy, since we have argued in favour of a special aggressive and destructive instinct in men not on account of the teachings of history or of our experience in life but on the basis of general considerations to which we were led by examining the phenomena of sadism and masochism. As you know, we call it sadism when sexual satisfaction is linked to the condition of the sexual object's suffering pain, ill-treatment and humiliation, and masochism when the need is felt of being the ill-treated object oneself. As you know too, a certain admixture of these two trends is included in normal sexual relations, and we speak of perversions when they push the other sexual aims into the background and replace them by their own aims. And you will scarcely have failed to notice that sadism has a more intimate relation with masculinity and masochism with femininity, as though there were a secret kinship present; though I must add that we have made no progress along that path. Both phenomena, sadism and masochism alike, but masochism quite especially, present a truly puzzling problem to the libido theory; and it is only proper if what was a stumbling-block for the one theory should become the cornerstone of the theory replacing it.

[1916-1917, 3461]

[1919e, 3653]

[1933a, 4708]
As regards the second kind of emotional reaction, which is not directed against me this time, but against my patient - supposing that my view of her is correct - and which regards the perverse nature of her phantasies as horrible, I should like to say emphatically that a medical man has no business to indulge in such passionate condemnation. I may also remark in passing that it seems to me superfluous for a physician who is writing upon the aberrations of the sexual instincts to seize every opportunity of inserting into the text expressions of his personal repugnance at such revolting things. We are faced by a fact; and it is to be hoped that we shall grow accustomed to it, when we have put our own tastes on one side. We must learn to speak without indignation of what we call the sexual perversions - instances in which the sexual function has extended its limits in respect either to the part of the body concerned or to the sexual object chosen. The uncertainty in regard to the boundaries of what is to be called normal sexual life, when we take different races and different epochs into account, should in itself be enough to cool the zealot's ardour. We surely ought not to forget that the perversion which is the most repellent to us, the sensual love of a man for a man, was not only tolerated by a people so far our superiors in cultivation as were the Greeks, but was actually entrusted by them with important social functions. The sexual life of each one of us extends to a slight degree - now in this direction, now in that - beyond the narrow lines imposed as the standard of normality. The perversions are neither bestial nor degenerate in the emotional sense of the word. They are a development of germs all of which are contained in the undifferentiated sexual disposition of the child, and which, by being suppressed or by being diverted to higher, asexual aims - by being 'sublimated' - are destined to provide the energy for a great number of our cultural achievements. When, therefore, any one has become a gross and manifest pervert, it would be more correct to say that he has remained one, for he exhibits a certain stage of inhibited development. All psychoneurotics are persons with strongly marked perverse tendencies, which have been repressed in the course of their development and have become unconscious. Consequently their unconscious phantasies show precisely the same content as the documentarily recorded actions of perverts - even though they have not read Krafft-Ebing's Psychopathia Sexualis, to which simple-minded people attribute such a large share of the responsibility for the production of perverse tendencies. Psychoneuroses are, so to speak, the negative of perversions. In neurotics their sexual constitution, under which the effects of heredity are included, operates in combination with any accidental influences in their life which may disturb the development of normal sexuality. A stream of water which meets with an obstacle in the river-bed is dammed up and flows back into old channels which had formerly seemed fated to run dry. The motive forces leading to the formation of hysterical symptoms draw their strength not only from repressed normal sexuality but also from unconscious perverse activities.¹

[1905e, 1387]

By demonstrating the part played by perverse impulses in the formation of symptoms in the psychoneuroses, we have quite remarkably increased the number of people who might be regarded as perverts. It is not only that neurotics in themselves constitute a very numerous class, but it must also be considered that an unbroken chain bridges the gap between the neuroses in all their manifestations and normality. After all, Moebius could say with justice that we are all to some extent hysterics. Thus the extraordinarily wide dissemination of the perversions forces us to suppose that the disposition to perversions is itself of no great rarity but must form a part of what passes as the normal constitution.

[1905d, 1495]
DANGERS OF FORE-PLEASURE   The connection between fore-pleasure and infantile sexual life is, however, made clearer by the pathogenic part which it can come to play. The attainment of the normal sexual aim can clearly be endangered by the mechanism in which fore-pleasure is involved. This danger arises if at any point in the preparatory sexual processes the fore-pleasure turns out to be too great and the element of tension too small. The motive for proceeding further with the sexual process then disappears, the whole path is cut short, and the preparatory act in question takes the place of the normal sexual aim. Experience has shown that the precondition for this damaging event is that the erotogenic zone concerned or the corresponding component instinct shall already during childhood have contributed an unusual amount of pleasure. If further factors then come into play, tending to bring about a fixation, a compulsion may easily arise in later life which resists the incorporation of this particular fore-pleasure into a new context. Such is in fact the mechanism of many perversions, which consist in a lingering over the preparatory acts of the sexual process.
[1905d, 1528]

This failure of the function of the sexual mechanism owing to fore-pleasure is best avoided if the primacy of the genitals too is adumbrated in childhood; and indeed things seem actually arranged to bring this about in the second half of childhood (from the age of eight to puberty). During these years the genital zones already behave in much the same way as in maturity; they become the seat of sensations of excitation and of preparatory changes whenever any pleasure is felt from the satisfaction of other erotogenic zones, though this result is still without a purpose - that is to say, contributes nothing to a continuation of the sexual process. Already in childhood, therefore, alongside of the pleasure of satisfaction there is a certain amount of sexual tension, although it is less constant and less in quantity. We can now understand why, in discussing the sources of sexuality, we were equally justified in saying of a given process that it was sexually satisfying or sexually exciting. It will be noticed that in the course of our enquiry we began by exaggerating the distinction between infantile and mature sexual life, and that we are now setting this right. Not only the deviations from normal sexual life but its normal form as well are determined by the infantile manifestations of sexuality.
[1905d, 1528]
The time has arrived for me to attempt to summarize what I have said. We started out from the aberrations of the sexual instinct in respect of its object and of its aim and we were faced by the question of whether these arise from an innate disposition or are acquired as a result of experiences in life. We arrived at an answer to this question from an understanding, derived from psycho-analytic investigation, of the workings of the sexual instinct in psychoneurotics, a numerous class of people and one not far removed from the healthy. We found that in them tendencies to every kind of perversion can be shown to exist as unconscious forces and betray their presence as factors leading to the formation of symptoms. It was thus possible to say that neurosis is, as it were, the negative of perversion. In view of what was now seen to be the wide dissemination of tendencies to perversion we were driven to the conclusion that a disposition to perversions is an original and universal disposition of the human sexual instinct and that normal sexual behaviour is developed out of it as a result of organic changes and psychical inhibitions occurring in the course of maturation; we hoped to be able to show the presence of this original disposition in childhood. Among the forces restricting the direction taken by the sexual instinct we laid emphasis upon shame, disgust, pity and the structures of morality and authority erected by society. We were thus led to regard any established aberration from normal sexuality as an instance of developmental inhibition and infantilism. Though it was necessary to place in the foreground the importance of the variations in the original disposition, a co-operative and not an opposing relation was to be assumed as existing between them and the influences of actual life. It appeared, on the other hand, that since the original disposition is necessarily a complex one, the sexual instinct itself must be something put together from various factors, and that in the perversions it falls apart, as it were, into its components. The perversions were thus seen to be on the one hand inhibitions, and on the other hand dissociations, of normal development. Both these aspects were brought together in the supposition that the sexual instinct of adults arises from a combination of a number of impulses of childhood into a unity, an impulsion with a single aim.

[1905d, 1542]

REPRESSION A different result is brought about if in the course of development some of the components which are of excessive strength in the disposition are submitted to the process of repression (which, it must be insisted, is not equivalent to their being abolished). If this happens, the excitations concerned continue to be generated as before; but they are prevented by psychical obstruction from attaining their aim and are diverted into numerous other channels till they find their way to expression as symptoms. The outcome may be an approximately normal sexual life - though usually a restricted one - but there is in addition psychoneurotic illness. These particular cases have become familiar to us from the psycho-analytic investigation of neurotics. Their sexual life begins like that of perverts, and a considerable part of their childhood is occupied with perverse sexual activity which occasionally extends far into maturity. A reversal due to repression then occurs, owing to internal causes (usually before puberty, but now and then even long afterwards), and from that time onwards neurosis takes the place of perversion, without the old impulses being extinguished. We are reminded of the proverb 'Junge Hure, alte Betschwester', only that here youth has lasted all too short a time. The fact that perversion can be replaced by neurosis in the life of the same person, like the fact which we have already mentioned that perversion and neurosis can be distributed among different members of the same family, tallies with the view that neurosis is the negative of perversion.

[1905d, 1548]
The ground prepared by the psychical factors which have just been enumerated affords a favourable basis for such stimulations of infantile sexuality as are experienced accidentally. The latter (first and foremost, seduction by other children or by adults) provide the material which, with the help of the former, can become fixated as a permanent disorder. A good proportion of the deviations from normal sexual life which are later observed both in neurotics and in perverts are thus established from the very first by the impressions of childhood - a period which is regarded as being devoid of sexuality. The causation is shared between a compliant constitution, precocity, the characteristic of increased pertinacity of early impressions and the chance stimulation of the sexual instinct by extraneous influences.

It can only help to clarify things if at this point we go back to fundamental facts. A desire to see the organs peculiar to each sex exposed is one of the original components of our libido. It may itself be a substitute for something earlier and go back to a hypothetical primary desire to touch the sexual parts. As so often, looking has replaced touching.¹ The libido for looking and touching is present in everyone in two forms, active and passive, male and female; and, according to the preponderance of the sexual character, one form or the other predominates. It is easy to observe the inclination to self-exposure in young children. In cases in which the germ of this inclination escapes its usual fate of being buried and suppressed, it develops in men into the familiar perversion known as exhibitionism. In women the inclination to passive exhibitionism is almost invariably buried under the imposing reactive function of sexual modesty, but not without a loophole being left for it in relation to clothes. I need only hint at the elasticity and variability in the amount of exhibitionism that women are permitted to retain in accordance with differing convention and circumstances.

If we take the second of these stages as an average, we must point out that a number of people are, on account of their organization, not equal to meeting its demands. In whole classes of individuals the development of the sexual instinct, as we have described it above, from auto-erotism to object-love with its aim of uniting the genitals, has not been carried out correctly and sufficiently fully. As a result of these disturbances of development two kinds of harmful deviation from normal sexuality - that is, sexuality which is serviceable to civilization - come about; and the relation between these two is almost that of positive and negative.¹

In the first place (disregarding people whose sexual instinct is altogether excessive and uninhibitable) there are the different varieties perverts, in whom an infantile fixation to a preliminary sexual aim has prevented the primacy of the reproductive function from being established, and the homosexuals or inverters, in whom, in a manner that is not yet quite understood, the sexual aim has been deflected away from the opposite sex. If the injurious effects of these two kinds of developmental disturbance are less than might be expected, this mitigation can be ascribed precisely to the complex way in which the sexual instinct is put together, which makes it possible for a person's sexual life to reach a serviceable final form even if one or more components of the instinct have been shut off from development. The constitution of people suffering from inversion - the homosexuals - is, indeed, often distinguished by their sexual instinct's possessing a special aptitude for cultural sublimation.
The sternness of the demands of civilization and the difficulty of the task of abstinence have combined to make avoidance of the union of the genitals of the two opposite sexes into the central point of abstinence and to favour other kinds of sexual activity, which, it might be said, are equivalent to semi-obedience. Since normal intercourse has been so relentlessly persecuted by morality - and also, on account of the possibilities of infection, by hygiene - what are known as the perverse forms of intercourse between the two sexes, in which other parts of the body take over the role of the genitals, have undoubtedly increased in social importance. These activities cannot, however, be regarded as being as harmless as analogous extensions in love-relationships. They are ethically objectionable, for they degrade the relationships of love between two human beings from a serious matter to a convenient game, attended by no risk and no spiritual participation. A further consequence of the aggravation of the difficulties of normal sexual life is to be found in the spread of homosexual satisfaction; in addition to all those who are homosexuals in virtue of their organization, or who became so in their childhood, there must be reckoned the great number of those in whom, in their maturer years, a blocking of the main stream of their libido has caused a widening in the side-channel of homosexuality.

[1908d, 1961]

For this reason it not uncommonly happens that obsessional neurotics, who are troubled with self-reproaches but have connected their affects with the wrong causes, will also tell the physician the true causes, without any suspicion that their self-reproaches have simply become detached from them. In relating such an incident they will sometimes add with astonishment or even with an air of pride: ‘But I think nothing of that.’ This happened in the first case of obsessional neurosis which gave me an insight many years ago into the nature of the malady. The patient, who was a government official, was troubled by innumerable scruples. He was the man whose compulsive act in connection with the branch in the park at Schönbrunn I have already described. I was struck by the fact that the florin notes with which he paid his consultation fees were invariably clean and smooth. (This was before we had a silver coinage in Austria.) I once remarked to him that one could always tell a government official by the brand-new florins that he drew from the State treasury, and he then informed me that his florins were by no means new, but that he had them ironed out at home. It was a matter of conscience with him, he explained, not to hand any one dirty paper florins; for they harboured all sorts of dangerous bacteria and might do some harm to the recipient. At that time I already had a vague suspicion of the connection between neuroses and sexual life, so on another occasion I ventured to ask the patient how he stood in regard to that matter. ‘Oh, that's quite all right,’ he answered airily. ‘I'm not at all badly off in that respect. I play the part of a dear old uncle in a number of respectable families, and now and then I make use of my position to invite some young girl to go out with me for a day's excursion in the country. Then I arrange that we shall miss the train home and be obliged to spend the night out of town. I always engage two rooms - I do things most handsomely; but when the girl has gone to bed I go in to her and masturbate her with my fingers.’ - ‘But aren't you afraid of doing her some harm, fiddling about in her genitals with your dirty hand?’ - At this he flared up: ‘Harm? Why, what harm should it do her? It hasn't done a single one of them any harm yet, and they've all of them enjoyed it. Some of them are married now, and it hasn't done them any harm at all.’ - He took my remonstrance in very bad part, and never appeared again. But I could only account for the contrast between his fastidiousness with the paper florins and his unscrupulousness in abusing the girls entrusted to him by supposing that the self-reproachful affect had become displaced. The aim of this displacement was obvious enough: if his self-reproaches had been allowed to remain where they belonged he would have had to abandon a form of sexual gratification to which he was probably impelled by some powerful infantile determinants. The displacement therefore ensured his deriving a considerable advantage from his illness.

[1909d, 2155]
To this unimpeachable body of evidence we shall be able to add fresh material, if we turn to the history of the masturbatory side of our patient's sexual activities. There is a conflict between the opinions of doctors and patients on this subject which has not hitherto been properly appreciated. The patients are unanimous in their belief that masturbation, by which they mean masturbation during puberty, is the root and origin of all their troubles. The doctors are, upon the whole, unable to decide what line to take; but, influenced by the knowledge that not only neurotics but most normal people pass through a period of masturbation during their puberty, the majority of them are inclined to dismiss the patients' assertions as gross exaggerations. In my opinion the patients are once again nearer to a correct view than the doctors; for the patients have some glimmering notion of the truth, while the doctors are in danger of overlooking an essential point. The thesis propounded by the patients certainly does not correspond to the facts in the sense in which they themselves construe it, namely, that masturbation during puberty (which may almost be described as a typical occurrence) is responsible for all neurotic disturbances. Their thesis requires interpretation. The masturbation of puberty is in fact no more than a revival of the masturbation of infancy, a subject which has hitherto invariably been neglected. Infantile masturbation reaches a kind of climax, as a rule, between the ages of three and four or five; and it is the clearest expression of a child's sexual constitution, in which the aetiology of subsequent neuroses must be sought. In this disguised way, therefore, the patients are putting the blame for their illnesses upon their infantile sexuality; and they are perfectly right in doing so. On the other hand, the problem of masturbation becomes insoluble if we attempt to treat it as a clinical unit, and forget that it can represent the discharge of every variety of sexual component and of every sort of phantasy to which such components can give rise. The injurious effects of masturbation are only in a very small degree autonomous - that is to say, determined by its own nature. They are in substance merely part and parcel of the pathogenic significance of the subject's sexual life as a whole. The fact that so many people can tolerate masturbation - that is, a certain amount of it - without injury merely shows that their sexual constitution and the course of development of their sexual life have been such as to allow them to exercise the sexual function within the limits of what is culturally permissible; whereas other people, because their sexual constitution has been less favourable or their development has been disturbed, fall ill as a result of their sexuality - they cannot, that is, achieve the necessary suppression or sublimation of their sexual components without having recourse to inhibitions or substitutes.¹

A young man who has hitherto satisfied his libido by means of phantasies ending in masturbation, and who now seeks to replace a régime approximating to auto-erotism by the choice of a real object - or a girl who has given her whole affection to her father or brother and who must now, for the sake of a man who is courting her, allow her hitherto unconscious incestuous libidoal wishes to become conscious - or a married woman who would like to renounce her polygamous inclinations and phantasies of prostitution so as to become a faithful consort to her husband and a perfect mother to her child - all of these fall ill from the most laudable efforts, if the earlier fixations of their libido are powerful enough to resist a displacement; and this point will be decided, once again, by the factors of disposition, constitution and infantile experience. All of them, it might be said, meet with the fate of the little tree in the Grimms' fairy tale, which wished it had different leaves. From the hygienic point of view - which, to be sure, is not the only one to be taken into account - one could only wish for them that they had continued to be as undeveloped, as inferior and as useless as they were before they fell ill. The change which the patients strive after, but bring about only imperfectly or not at all, invariably has the value of a step forward from the point of view of real life. It is otherwise if we apply ethical standards: we see people falling ill just as often when they discard an ideal as when they seek to attain it.

¹[1909d, 2159]

[1912c, 2562]
I shall now take my footing once more on the clinical observation of an individual case. Over a long period I studied a woman patient whose neurosis underwent an unusual change. It began, after a traumatic experience, as a straightforward anxiety hysteria and retained that character for a few years. One day, however, it suddenly changed into an obsessional neurosis of the severest type. A case of this kind could not fail to become significant in more than one direction. On the one hand, it might perhaps claim to be looked upon like a bilingual document and to show how an identical content could be expressed by the two neuroses in different languages. On the other hand, it threatened to contradict completely our theory that disposition arises from developmental inhibition, unless we were prepared to accept the supposition that a person could innately possess more than one weak spot in his libidinal development. I told myself that we had no right to dismiss this latter possibility; but I was greatly interested to arrive at an understanding of the case.

And this brings us to the second novelty that I announced to you. For psycho-analytic research has had to concern itself, too, with the sexual life of children, and this is because the memories and associations arising during the analysis of symptoms regularly led back to the early years of childhood. What we inferred from these analyses was later confirmed point by point by direct observations of children. And it then turned out that all these inclinations to perversion had their roots in childhood, that children have a predisposition to all of them and carry them out to an extent corresponding to their immaturity - in short, that perverse sexuality is nothing else than a magnified infantile sexuality split up into its separate impulses.

Before we make use of our familiarity with the perversions to plunge once again into the study of infantile sexuality on the basis of clearer premisses, I must draw your attention to an important difference between them. Perverse sexuality is as a rule excellently centred: all its actions are directed to an aim - usually to a single one; one component instinct has gained the upper hand in it and is either the only one observable or has subjected the others to its purposes. In that respect there is no distinction between perverse and normal sexuality other than the fact that their dominating component instincts and consequently their sexual aims are different. In both of them, one might say, a well-organized tyranny has been established, but in each of the two a different family has seized the reins of power. Infantile sexuality, on the other hand, lacks, speaking generally, any such centring and organization; its separate component instincts have equal rights, each of them goes its own way to obtaining pleasure. Both the absence and the presence of centring harmonize well, of course, with the fact that both perverse and normal sexuality have arisen out of infantile sexuality. Incidentally, there are also cases of perverse sexuality which have a much greater resemblance to the infantile kind, since in them numerous component instincts have put through (or, more correctly, have persisted in) their aims independently of one another. It is better in such cases to speak of infantilism in sexual life rather than of a perversion.
Nor is it a fact that psycho-analysis has paid no attention whatever to the non-sexual part of the personality. It is precisely the distinction between the ego and sexuality which has enabled us to recognize with special clarity that the ego instincts pass through an important process of development - a development which is neither completely independent of the libido nor without a counter-effect upon it. Nevertheless, we are far less well acquainted with the development of the ego than of the libido, since it is only the study of the narcissistic neuroses that promises to give us an insight into the structure of the ego. We already have before us, however, a notable attempt by Ferenczi to make a theoretical construction of the stages of development of the ego, and there are at least two points at which we have a solid basis for judging that development. It is not our belief that a person's libidinal interests are from the first in opposition to his self-preservative interests; on the contrary, the ego endeavours at every stage to remain in harmony with its sexual organization as it is at the time and to fit itself into it. The succession of the different phases of libidinal development probably follows a prescribed programme. But the possibility cannot be rejected that this course of events can be influenced by the ego, and we may expect equally to find a certain parallelism, a certain correspondence, between the developmental phases of the ego and the libido; indeed a disturbance of that correspondence might provide a pathogenic factor. We are now faced by the important consideration of how the ego behaves if its libido leaves a strong fixation behind at some point in its (the libido's) development. The ego may accept this and consequently become to that extent perverse or, what is the same thing, infantile. It may, however, adopt a non-compliant attitude to the libido's settling down in this position, in which case the ego experiences a repression where the libido has experienced a fixation.

[1916-1917, 3412]

A perversion in childhood, as is well known, may become the basis for the construction of a perversion having a similar sense and persisting throughout life, one which consumes the subject's whole sexual life. On the other hand the perversion may be broken off and remain in the background of a normal sexual development, from which, however, it continues to withdraw a certain amount of energy. The first of these alternatives was already known before the days of analysis. Analytic investigation, however, of such fully-developed cases almost bridges the gulf between the two. For we find often enough with these perverts that they too made an attempt at developing normal sexual activity, usually at the age of puberty; but their attempt had not enough force in it and was abandoned in the face of the first obstacles which inevitably arise, whereupon they fell back upon their infantile fixation once and for all.

[1919e, 3653]

It would naturally be important to know whether the origin of infantile perversions from the Oedipus complex can be asserted as a general principle. While this cannot be decided without further investigation, it does not seem impossible. When we recall the anamneses which have been obtained in adult cases of perversion we cannot fail to notice that the decisive impression, the 'first experience', of all these perverts, fetishists, etc., is scarcely ever referred back to a time earlier than the sixth year. At this time, however, the dominance of the Oedipus complex is already over; the experience which is recalled, and which has been effective in such a puzzling way, may very well have represented the legacy of that complex. The connections between the experience and the complex which is by this time repressed are bound to remain obscure so long as analysis has not thrown any light on the time before the first 'pathogenic' impression. So it may be imagined how little value is to be attached, for instance, to an assertion that a case of homosexuality is congenital, when the ground given for this belief is that ever since his eighth or sixth year the person in question has felt inclinations only towards his own sex.

[1919e, 3653]
If, however, the derivation of perversions from the Oedipus complex can be generally established, our estimate of its importance will have gained added strength. For in our opinion the Oedipus complex is the actual nucleus of neuroses, and the infantile sexuality which culminates in this complex is the true determinant of neuroses. What remains of the complex in the unconscious represents the disposition to the later development of neuroses in the adult. In this way the beating-phantasy and other analogous perverse fixations would also only be precipitates of the Oedipus complex, scars, so to say, left behind after the process has ended, just as the notorious 'sense of inferiority' corresponds to a narcissistic scar of the same sort. In taking this view of the matter I must express my unreserved agreement with Marcinowski (1918), who has recently put it forward most happily. As is well known, this neurotic delusion of inferiority is only a partial one, and is completely compatible with the existence of a self-overvaluation derived from other sources. The origin of the Oedipus complex itself, and the destiny which compels man, probably alone among all animals, to begin his sexual life twice over, first like all other creatures in his early childhood, and then after a long interruption once more at the age of puberty - all the problems that are connected with man's 'archaic heritage' - have been discussed by me elsewhere, and I have no intention of going into them in this place. [1919e, 3654]

The theory of psycho-analysis (a theory based on observation) holds firmly to the view that the motive forces of repression must not be sexualized. Man's archaic heritage forms the nucleus of the unconscious mind; and whatever part of that heritage has to be left behind in the advance to later phases of development, because it is unserviceable or incompatible with what is new and harmful to it, falls a victim to the process of repression. This selection is made more successfully with one group of instincts than with the other. In virtue of special circumstances which have often been pointed out already, the latter group, that of the sexual instincts, are able to defeat the intentions of repression, and to enforce their representation by substitutive formations of a disturbing kind. For this reason infantile sexuality, which is held under repression, acts as the chief motive force in the formation of symptoms; and the essential part of its content, the Oedipus complex, is the nuclear complex of neuroses. I hope that in this paper I have raised an expectation that the sexual aberrations of childhood, as well as those of mature life, are ramifications of the same complex. [1919e, 3662]

Advance in knowledge made ever clearer the enormous part played in mental life by sexual wishful impulses, and led to a detailed study of the nature and development of the sexual instinct.¹ But we also came upon another purely empirical finding, in the discovery that the experiences and conflicts of the first years of childhood play an unsuspectedly important part in the individual's development and leave behind them ineffaceable dispositions bearing upon the period of maturity. This led to the revelation of something that had hitherto been fundamentally overlooked by science - infantile sexuality, which, from the tenderest age onwards, is manifested both in physical reactions and in mental attitudes. In order to bring together this sexuality of children with what is described as the normal sexuality of adults and the abnormal sexual life of perverts, the concept of what was sexual had itself to be corrected and widened in a manner which could be justified by the evolution of the sexual instinct. [1924f, 4107]
The detaching of sexuality from the genitals has the advantage of allowing us to bring the sexual activities of children and of perverts into the same scope as those of normal adults. The sexual activities of children have hitherto been entirely neglected and though those of perverts have been recognized it has been with moral indignation and without understanding. Looked at from the psycho-analytic standpoint, even the most eccentric and repellent perversions are explicable as manifestations of component instincts of sexuality which have freed themselves from the primacy of the genitals and are now in pursuit of pleasure on their own account as they were in the very early days of the libido's development. The most important of these perversions, homosexuality, scarcely deserves the name. It can be traced back to the constitutional bisexuality of all human beings and to the after-effects of the phallic primacy. Psycho-analysis enables us to point to some trace or other of a homosexual object-choice in everyone. If I have described children as 'polymorphously perverse', I was only using a terminology that was generally current; no moral judgement was implied by the phrase. Psycho-analysis has no concern whatever with such judgements of value.
[1925d, 4213]
If we put together what we have learned from our investigation of positive and negative perversions, it seems plausible to trace them back to a number of 'component instincts', which, however, are not of a primary nature, but are susceptible to further analysis. By an 'instinct' is provisionally to be understood the psychical representative of an endosomatic, continuously flowing source of stimulation, as contrasted with a 'stimulus', which is set up by single excitations coming from without. The concept of instinct is thus one of those lying on the frontier between the mental and the physical. The simplest and likeliest assumption as to the nature of instincts would seem to be that in itself an instinct is without quality, and, so far as mental life is concerned, is only to be regarded as a measure of the demand made upon the mind for work. What distinguishes the instincts from one another and endows them with specific qualities is their relation to their somatic sources and to their aims. The source of an instinct is a process of excitation occurring in an organ and the immediate aim of the instinct lies in the removal of this organic stimulus.¹

DANGERS OF FORE-PLEASURE The connection between fore-pleasure and infantile sexual life is, however, made clearer by the pathogenic part which it can come to play. The attainment of the normal sexual aim can clearly be endangered by the mechanism in which fore-pleasure is involved. This danger arises if at any point in the preparatory sexual processes the fore-pleasure turns out to be too great and the element of tension too small. The motive for proceeding further with the sexual process then disappears, the whole path is cut short, and the preparatory act in question takes the place of the normal sexual aim. Experience has shown that the precondition for this damaging event is that the erotogenic zone concerned or the corresponding component instinct shall already during childhood have contributed an unusual amount of pleasure. If further factors then come into play, tending to bring about a fixation, a compulsion may easily arise in later life which resists the incorporation of this particular fore-pleasure into a new context. Such is in fact the mechanism of many perversions, which consist in a lingering over the preparatory acts of the sexual process. [1905d, 1528]
The time has arrived for me to attempt to summarize what I have said. We started out from the aberrations of the sexual instinct in respect of its object and of its aim and we were faced by the question of whether these arise from an innate disposition or are acquired as a result of experiences in life. We arrived at an answer to this question from an understanding, derived from psycho-analytic investigation, of the workings of the sexual instinct in psychoneurotics, a numerous class of people and one not far removed from the healthy. We found that in them tendencies to every kind of perversion can be shown to exist as unconscious forces and betray their presence as factors leading to the formation of symptoms. It was thus possible to say that neurosis is, as it were, the negative of perversion. In view of what was now seen to be the wide dissemination of tendencies to perversion we were driven to the conclusion that a disposition to perversions is an original and universal disposition of the human sexual instinct and that normal sexual behaviour is developed out of it as a result of organic changes and psychical inhibitions occurring in the course of maturation; we hoped to be able to show the presence of this original disposition in childhood. Among the forces restricting the direction taken by the sexual instinct we laid emphasis upon shame, disgust, pity and the structures of morality and authority erected by society. We were thus led to regard any established aberration from normal sexuality as an instance of developmental inhibition and infantilism. Though it was necessary to place in the foreground the importance of the variations in the original disposition, a co-operative and not an opposing relation was to be assumed as existing between them and the influences of actual life. It appeared, on the other hand, that since the original disposition is necessarily a complex one, the sexual instinct itself must be something put together from various factors, and that in the perversions it falls apart, as it were, into its components. The perversions were thus seen to be on the one hand inhibitions, and on the other hand dissociations, of normal development. Both these aspects were brought together in the supposition that the sexual instinct of adults arises from a combination of a number of impulses of childhood into a unity, an impulsion with a single aim.

And this brings us to the second novelty that I announced to you. For psycho-analytic research has had to concern itself, too, with the sexual life of children, and this is because the memories and associations arising during the analysis of symptoms regularly led back to the early years of childhood. What we inferred from these analyses was later confirmed point by point by direct observations of children. And it then turned out that all these inclinations to perversion had their roots in childhood, that children have a predisposition to all of them and carry them out to an extent corresponding to their immaturity - in short, that perverse sexuality is nothing else than a magnified infantile sexuality split up into its separate impulses.

Allow me, therefore, to proceed with my brief account of infantile sexuality. What I have already reported of two systems of organs might be confirmed in reference to the others. A child's sexual life is indeed made up entirely of the activities of a number of component instincts which seek, independently of one another, to obtain pleasure, in part from the subject's own body and in part already from an external object. Among these organs the genitals come into prominence very soon. There are people in whom obtaining pleasure from their own genitals, without the assistance of any other genitals or of an object, continues uninterruptedly from infantile masturbation to the unavoidable masturbation of puberty and persists for an indefinite length of time afterwards. Incidentally, the topic of masturbation is not one that can be so easily disposed of: it is something that calls for examination from many angles.
Before we make use of our familiarity with the perversions to plunge once again into the study of infantile sexuality on the basis of clearer premisses, I must draw your attention to an important difference between them. Perverse sexuality is as a rule excellently centred: all its actions are directed to an aim - usually to a single one; one component instinct has gained the upper hand in it and is either the only one observable or has subjected the others to its purposes. In that respect there is no distinction between perverse and normal sexuality other than the fact that their dominating component instincts and consequently their sexual aims are different. In both of them, one might say, a well-organized tyranny has been established, but in each of the two a different family has seized the reins of power. Infantile sexuality, on the other hand, lacks, speaking generally, any such centring and organization; its separate component instincts have equal rights, each of them goes its own way to obtaining pleasure. Both the absence and the presence of centring harmonize well, of course, with the fact that both perverse and normal sexuality have arisen out of infantile sexuality. Incidentally, there are also cases of perverse sexuality which have a much greater resemblance to the infantile kind, since in them numerous component instincts have put through (or, more correctly, have persisted in) their aims independently of one another. It is better in such cases to speak of infantilism in sexual life rather than of a perversion.

[1916-1917, 3391]

The detaching of sexuality from the genitals has the advantage of allowing us to bring the sexual activities of children and of perverts into the same scope as those of normal adults. The sexual activities of children have hitherto been entirely neglected and though those of perverts have been recognized it has been with moral indignation and without understanding. Looked at from the psycho-analytic standpoint, even the most eccentric and repellent perversions are explicable as manifestations of component instincts of sexuality which have freed themselves from the primacy of the genitals and are now in pursuit of pleasure on their own account as they were in the very early days of the libido’s development. The most important of these perversions, homosexuality, scarcely deserves the name. It can be traced back to the constitutional bisexuality of all human beings and to the after-effects of the phallic primacy. Psycho-analysis enables us to point to some trace or other of a homosexual object-choice in everyone. If I have described children as ‘polymorphously perverse’, I was only using a terminology that was generally current; no moral judgement was implied by the phrase. Psycho-analysis has no concern whatever with such judgements of value.

[1925d, 4213]
In the second place we have found that some of the perversions which we have examined are only made intelligible if we assume the convergence of several motive forces. If such perversions admit of analysis, that is, if they can be taken to pieces, then they must be of a composite nature. This gives us a hint that perhaps the sexual instinct itself may be no simple thing, but put together from components which have come apart again in the perversions. If this is so, the clinical observation of these abnormalities will have drawn our attention to amalgamations which have been lost to view in the uniform behaviour of normal people.

[1905d, 1487]

The time has arrived for me to attempt to summarize what I have said. We started out from the aberrations of the sexual instinct in respect of its object and of its aim and we were faced by the question of whether these arise from an innate disposition or are acquired as a result of experiences in life. We arrived at an answer to this question from an understanding, derived from psycho-analytic investigation, of the workings of the sexual instinct in psychoneurotics, a numerous class of people and one not far removed from the healthy. We found that in them tendencies to every kind of perversion can be shown to exist as unconscious forces and betray their presence as factors leading to the formation of symptoms. It was thus possible to say that neurosis is, as it were, the negative of perversion. In view of what was now seen to be the wide dissemination of tendencies to perversion we were driven to the conclusion that a disposition to perversions is an original and universal disposition of the human sexual instinct and that normal sexual behaviour is developed out of it as a result of organic changes and psychical inhibitions occurring in the course of maturation; we hoped to be able to show the presence of this original disposition in childhood. Among the forces restricting the direction taken by the sexual instinct we laid emphasis upon shame, disgust, pity and the structures of morality and authority erected by society. We were thus led to regard any established aberration from normal sexuality as an instance of developmental inhibition and infantilism. Though it was necessary to place in the foreground the importance of the variations in the original disposition, a co-operative and not an opposing relation was to be assumed as existing between them and the influences of actual life. It appeared, on the other hand, that since the original disposition is necessarily a complex one, the sexual instinct itself must be something put together from various factors, and that in the perversions it falls apart, as it were, into its components. The perversions were thus seen to be on the one hand inhibitions, and on the other hand dissociations, of normal development. Both these aspects were brought together in the supposition that the sexual instinct of adults arises from a combination of a number of impulses of childhood into a unity, an impulsion with a single aim.

[1905d, 1542]

And this brings us to the second novelty that I announced to you. For psycho-analytic research has had to concern itself, too, with the sexual life of children, and this is because the memories and associations arising during the analysis of symptoms regularly led back to the early years of childhood. What we inferred from these analyses was later confirmed point by point by direct observations of children. And it then turned out that all these inclinations to perversion had their roots in childhood, that children have a predisposition to all of them and carry them out to an extent corresponding to their immaturity - in short, that perverse sexuality is nothing else than a magnified infantile sexuality split up into its separate impulses.

[1916-1917, 3381]
Before we make use of our familiarity with the perversions to plunge once again into the study of infantile sexuality on the basis of clearer premisses, I must draw your attention to an important difference between them. Perverse sexuality is as a rule excellently centred: all its actions are directed to an aim - usually to a single one; one component instinct has gained the upper hand in it and is either the only one observable or has subjected the others to its purposes. In that respect there is no distinction between perverse and normal sexuality other than the fact that their dominating component instincts and consequently their sexual aims are different. In both of them, one might say, a well-organized tyranny has been established, but in each of the two a different family has seized the reins of power. Infantile sexuality, on the other hand, lacks, speaking generally, any such centring and organization; its separate component instincts have equal rights, each of them goes its own way to obtaining pleasure. Both the absence and the presence of centring harmonize well, of course, with the fact that both perverse and normal sexuality have arisen out of infantile sexuality. Incidentally, there are also cases of perverse sexuality which have a much greater resemblance to the infantile kind, since in them numerous component instincts have put through (or, more correctly, have persisted in) their aims independently of one another. It is better in such cases to speak of infantilism in sexual life rather than of a perversion.

The Development of the Libido. - The sexual instinct, the dynamic manifestation of which in mental life we shall call 'libido', is made up of component instincts into which it may once more break up and which are only gradually united into well-defined organizations. The sources of these component instincts are the organs of the body and in particular certain specially marked erotogenic zones; but contributions are made to libido from every important functional process in the body. At first the individual component instincts strive for satisfaction independently of one another, but in the course of development they become more and more convergent and concentrated. The first (pregenital) stage of organization to be discerned is the oral one, in which - in conformity with the suckling's predominant interest - the oral zone plays the leading part. This is followed by the sadistic-anal organization, in which the anal zone and the component instinct of sadism are particularly prominent; at this stage the difference between the sexes is represented by the contrast between active and passive. The third and final stage of organization is that in which the majority of the component instincts converge under the primacy of the genital zones. As a rule this development is passed through swiftly and unobtrusively; but some individual portions of the instincts remain behind at the prodromal stages of the process and thus give rise to fixations of libido, which are important as constituting predispositions for subsequent irruptions of repressed impulses and which stand in a definite relation to the later development of neuroses and perversions. (See the article on 'The Libido Theory'.)

The detaching of sexuality from the genitals has the advantage of allowing us to bring the sexual activities of children and of perverts into the same scope as those of normal adults. The sexual activities of children have hitherto been entirely neglected and though those of perverts have been recognized it has been with moral indignation and without understanding. Looked at from the psycho-analytic standpoint, even the most eccentric and repellent perversions are explicable as manifestations of component instincts of sexuality which have freed themselves from the primacy of the genitals and are now in pursuit of pleasure on their own account as they were in the very early days of the libido's development. The most important of these perversions, homosexuality, scarcely deserves the name. It can be traced back to the constitutional bisexuality of all human beings and to the after-effects of the phallic primacy. Psycho-analysis enables us to point to some trace or other of a homosexual object-choice in everyone. If I have described children as 'polymorphously perverse', I was only using a terminology that was generally current; no moral judgement was implied by the phrase. Psycho-analysis has no concern whatever with such judgements of value.
The part played by the erotogenic zones is immediately obvious in the case of those perversions which assign a sexual significance to the oral and anal orifices. These behave in every respect like a portion of the sexual apparatus. In hysteria these parts of the body and the neighbouring tracts of mucous membrane become the seat of new sensations and of changes in innervation - indeed, of processes that can be compared to erection - in just the same way as do the actual genitalia under the excitations of the normal sexual processes. [1905d, 1493]

The significance of the erotogenic zones as apparatuses subordinate to the genitals and as substitutes for them is, among all the psychoneuroses, most clearly to be seen in hysteria; but this does not imply that that significance is any the less in the other forms of illness. It is only that in them it is less recognizable, because in their case (obsessional neurosis and paranoia) the formation of the symptoms takes place in regions of the mental apparatus which are more remote from the particular centres concerned with somatic control. In obsessional neurosis what is more striking is the significance of those impulses which create new sexual aims and seem independent of erotogenic zones. Nevertheless, in scopophilia and exhibitionism the eye corresponds to an erotogenic zone; while in the case of those components of the sexual instinct which involve pain and cruelty the same role is assumed by the skin - the skin, which in particular parts of the body has become differentiated into sense organs or modified into mucous membrane, and is thus the erotogenic zone par excellence."¹ [1905d, 1493]

DANGERS OF FORE-PLEASURE The connection between fore-pleasure and infantile sexual life is, however, made clearer by the pathogenic part which it can come to play. The attainment of the normal sexual aim can clearly be endangered by the mechanism in which fore-pleasure is involved. This danger arises if at any point in the preparatory sexual processes the fore-pleasure turns out to be too great and the element of tension too small. The motive for proceeding further with the sexual process then disappears, the whole path is cut short, and the preparatory act in question takes the place of the normal sexual aim. Experience has shown that the precondition for this damaging event is that the erotogenic zone concerned or the corresponding component instinct shall already during childhood have contributed an unusual amount of pleasure. If further factors then come into play, tending to bring about a fixation, a compulsion may easily arise in later life which resists the incorporation of this particular fore-pleasure into a new context. Such is in fact the mechanism of many perversions, which consist in a lingering over the preparatory acts of the sexual process. [1905d, 1528]

This failure of the function of the sexual mechanism owing to fore-pleasure is best avoided if the primacy of the genitals too is adumbrated in childhood; and indeed things seem actually arranged to bring this about in the second half of childhood (from the age of eight to puberty). During these years the genital zones already behave in much the same way as in maturity; they become the seat of sensations of excitation and of preparatory changes whenever any pleasure is felt from the satisfaction of other erotogenic zones, though this result is still without a purpose - that is to say, contributes nothing to a continuation of the sexual process. Already in childhood, therefore, alongside of the pleasure of satisfaction there is a certain amount of sexual tension, although it is less constant and less in quantity. We can now understand why, in discussing the sources of sexuality, we were equally justified in saying of a given process that it was sexually satisfying or sexually exciting. It will be noticed that in the course of our enquiry we began by exaggerating the distinction between infantile and mature sexual life, and that we are now setting this right. Not only the deviations from normal sexual life but its normal form as well are determined by the infantile manifestations of sexuality. [1905d, 1528]
The part played by the erotogenic zones is immediately obvious in the case of those perversions which assign a sexual significance to the oral and anal orifices. These behave in every respect like a portion of the sexual apparatus. In hysteria these parts of the body and the neighbouring tracts of mucous membrane become the seat of new sensations and of changes in innervation - indeed, of processes that can be compared to erection - in just the same way as do the actual genitalia under the excitations of the normal sexual processes.

[1905d, 1493]

The significance of the erotogenic zones as apparatuses subordinate to the genitals and as substitutes for them is, among all the psychoneuroses, most clearly to be seen in hysteria; but this does not imply that that significance is any the less in the other forms of illness. It is only that in them it is less recognizable, because in their case (obsessional neurosis and paranoia) the formation of the symptoms takes place in regions of the mental apparatus which are more remote from the particular centres concerned with somatic control. In obsessional neurosis what is more striking is the significance of those impulses which create new sexual aims and seem independent of erotogenic zones. Nevertheless, in scopophilia and exhibitionism the eye corresponds to an erotogenic zone; while in the case of those components of the sexual instinct which involve pain and cruelty the same role is assumed by the skin - the skin, which in particular parts of the body has become differentiated into sense organs or modified into mucous membrane, and is thus the erotogenic zone *par excellence.*

[1905d, 1493]
TWO CONCLUSIONS   Our study of the perversions has shown us that the sexual instinct has to struggle against certain mental forces which act as resistances, and of which shame and disgust are the most prominent. It is permissible to suppose that these forces play a part in restraining that instinct within the limits that are regarded as normal; and if they develop in the individual before the sexual instinct has reached its full strength, it is no doubt they that will determine the course of its development.²

[1905d, 1487]

In the second place we have found that some of the perversions which we have examined are only made intelligible if we assume the convergence of several motive forces. If such perversions admit of analysis, that is, if they can be taken to pieces, then they must be of a composite nature. This gives us a hint that perhaps the sexual instinct itself may be no simple thing, but put together from components which have come apart again in the perversions. If this is so, the clinical observation of these abnormalities will have drawn our attention to amalgamations which have been lost to view in the uniform behaviour of normal people.³

[1905d, 1487]

² [Footnote added 1915:] On the other hand, these forces which act like dams upon sexual development - disgust, shame and morality - must also be regarded as historical precipitates of the external inhibitions to which the sexual instinct has been subjected during the psychogenesis of the human race. We can observe the way in which, in the development of individuals, they arise at the appropriate moment, as though spontaneously, when upbringing and external influence give the signal.

[1905d, 1487]

³ [Footnote added 1920:] As regards the origin of the perversions, I will add a word in anticipation of what is to come. There is reason to suppose that, just as in the case of fetishism, abortive beginnings of normal sexual development occur before the perversions become fixated. Analytic investigation has already been able to show in a few cases that perversions are a residue of development towards the Oedipus complex and that after the repression of that complex the components of the sexual instinct which are strongest in the disposition of the individual concerned emerge once more.

[1905d, 1487]

It is, as we have seen, debatable whether the perversions go back to innate determinants or arise, as Binet assumed was the case with fetishism, owing to chance experiences. The conclusion now presents itself to us that there is indeed something innate lying behind the perversions but that it is something innate in everyone, though as a disposition it may vary in its intensity and may be increased by the influences of actual life. What is in question are the innate constitutional roots of the sexual instinct. In one class of cases (the perversions) these roots may grow into the actual vehicles of sexual activity; in others they may be submitted to an insufficient suppression (repression) and thus be able in a roundabout way to attract a considerable proportion of sexual energy to themselves as symptoms; while in the most favourable cases, which lie between these two extremes, they may by means of effective restriction and other kinds of modification bring about what is known as normal sexual life.

[1905d, 1495]
The time has arrived for me to attempt to summarize what I have said. We started out from the aberrations of the sexual instinct in respect of its object and of its aim and we were faced by the question of whether these arise from an innate disposition or are acquired as a result of experiences in life. We arrived at an answer to this question from an understanding, derived from psycho-analytic investigation, of the workings of the sexual instinct in psychoneurotics, a numerous class of people and one not far removed from the healthy. We found that in them tendencies to every kind of perversion can be shown to exist as unconscious forces and betray their presence as factors leading to the formation of symptoms. It was thus possible to say that neurosis is, as it were, the negative of perversion. In view of what was now seen to be the wide dissemination of tendencies to perversion we were driven to the conclusion that a disposition to perversions is an original and universal disposition of the human sexual instinct and that normal sexual behaviour is developed out of it as a result of organic changes and psychical inhibitions occurring in the course of maturation; we hoped to be able to show the presence of this original disposition in childhood. Among the forces restricting the direction taken by the sexual instinct we laid emphasis upon shame, disgust, pity and the structures of morality and authority erected by society. We were thus led to regard any established aberration from normal sexuality as an instance of developmental inhibition and infantilism. Though it was necessary to place in the foreground the importance of the variations in the original disposition, a co-operative and not an opposing relation was to be assumed as existing between them and the influences of actual life. It appeared, on the other hand, that since the original disposition is necessarily a complex one, the sexual instinct itself must be something put together from various factors, and that in the perversions it falls apart, as it were, into its components. The perversions were thus seen to be on the one hand inhibitions, and on the other hand dissociations, of normal development. Both these aspects were brought together in the supposition that the sexual instinct of adults arises from a combination of a number of impulses of childhood into a unity, an impulsion with a single aim.

¹ [Footnote added 1915:] This does not apply only to the 'negative' tendencies to perversion which appear in neuroses but equally to the 'positive,' properly so-called, perversions. Thus these latter are to be derived not merely from a fixation of infantile tendencies but also from a regression to those tendencies as a result of other channels of the sexual current being blocked. It is for this reason that the positive perversions also are accessible to psycho-analytic therapy.

If the relation between all the different dispositions - a relation which we will assume to be abnormal - persists and grows stronger at maturity, the result can only be a perverse sexual life. The analysis of abnormal constitutional dispositions of this kind has not yet been properly taken in hand. But we already know cases which can easily be explained on such a basis as this. Writers on the subject, for instance, have asserted that the necessary preconditions of a whole number of perverse fixations lies in an innate weakness of the sexual instinct. In this form the view seems to me untenable. It makes sense, however, if what is meant is a constitutional weakness of one particular factor in the sexual instinct, namely the genital zone - a zone which takes over the function of combining the separate sexual activities for the purposes of reproduction. For if the genital zone is weak, this combination, which is required to take place at puberty, is bound to fail, and the strongest of the other components of sexuality will continue its activity as a perversion.

¹ [Footnote added 1915:] In such circumstances one often finds that at puberty a normal sexual current begins to operate at first, but that, as a result of its internal weakness, it breaks down in face of the first external obstacles and is then replaced by regression to the perverse fixation.
It can only help to clarify things if at this point we go back to fundamental facts. A desire to see the organs peculiar to each sex exposed is one of the original components of our libido. It may itself be a substitute for something earlier and go back to a hypothetical primary desire to touch the sexual parts. As so often, looking has replaced touching.¹ The libido for looking and touching is present in everyone in two forms, active and passive, male and female; and, according to the preponderance of the sexual character, one form or the other predominates. It is easy to observe the inclination to self-exposure in young children. In cases in which the germ of this inclination escapes its usual fate of being buried and suppressed, it develops in men into the familiar perversion known as exhibitionism. In women the inclination to passive exhibitionism is almost invariably buried under the imposing reactive function of sexual modesty, but not without a loophole being left for it in relation to clothes. I need only hint at the elasticity and variability in the amount of exhibitionism that women are permitted to retain in accordance with differing convention and circumstances.

[1905c, 1695]

If we take the second of these stages as an average, we must point out that a number of people are, on account of their organization, not equal to meeting its demands. In whole classes of individuals the development of the sexual instinct, as we have described it above, from auto-eroticism to object-love with its aim of uniting the genitals, has not been carried out correctly and sufficiently fully. As a result of these disturbances of development two kinds of harmful deviation from normal sexuality - that is, sexuality which is serviceable to civilization - come about; and the relation between these two is almost that of positive and negative.¹

[1908d, 1953]

In the first place (disregarding people whose sexual instinct is altogether excessive and uninhibitable) there are the different varieties perverts, in whom an infantile fixation to a preliminary sexual aim has prevented the primacy of the reproductive function from being established, and the homosexuals or inverters, in whom, in a manner that is not yet quite understood, the sexual aim has been deflected away from the opposite sex. If the injurious effects of these two kinds of developmental disturbance are less than might be expected, this mitigation can be ascribed precisely to the complex way in which the sexual instinct is put together, which makes it possible for a person's sexual life to reach a serviceable final form even if one or more components of the instinct have been shut off from development. The constitution of people suffering from inversion - the homosexuals - is, indeed, often distinguished by their sexual instinct's possessing a special aptitude for cultural sublimation.

[1908d, 1953]

The sternness of the demands of civilization and the difficulty of the task of abstinence have combined to make avoidance of the union of the genitals of the two opposite sexes into the central point of abstinence and to favour other kinds of sexual activity, which, it might be said, are equivalent to semi-obedience. Since normal intercourse has been so relentlessly persecuted by morality - and also, on account of the possibilities of infection, by hygiene - what are known as the perverse forms of intercourse between the two sexes, in which other parts of the body take over the role of the genitals, have undoubtedly increased in social importance. These activities cannot, however, be regarded as being as harmless as analogous extensions in love-relationships. They are ethically objectionable, for they degrade the relationships of love between two human beings from a serious matter to a convenient game, attended by no risk and no spiritual participation. A further consequence of the aggravation of the difficulties of normal sexual life is to be found in the spread of homosexual satisfaction; in addition to all those who are homosexuals in virtue of their organization, or who became so in their childhood, there must be reckoned the great number of those in whom, in their maturer years, a blocking of the main stream of their libido has caused a widening in the side-channel of homosexuality.

[1908d, 1961]
A sexual constitution like that of little Hans does not appear to carry with it a predisposition to the development either of perversions or of their negative (we will limit ourselves to a consideration of hysteria). As far as my experience goes (and there is still a real need for speaking with caution on this point) the innate constitution of hysterics - that this is also true of perverts is almost self-evident - is marked by the genital zone being relatively less prominent than the other erotogenic zones. But we must expressly except from this rule one particular 'aberration' of sexual life. In those who later become homosexuals we meet with the same predominance in infancy of the genital zone (and especially of the penis) as in normal persons.¹ Indeed it is the high esteem felt by the homosexual for the male organ which decides his fate. In his childhood he chooses women as his sexual object, so long as he assumes that they too possess what in his eyes is an indispensable part of the body; when he becomes convinced that women have deceived him in this particular, they cease to be acceptable to him as a sexual object. He cannot forgo a penis in any one who is to attract him to sexual intercourse; and if circumstances are favourable he will fix his libido upon the 'woman with a penis', a youth of feminine appearance. Homosexuals, then, are persons who, owing to the erotogenic importance of their own genitals, cannot do without a similar feature in their sexual object. In the course of their development from auto-erotism to object-love, they have remained at a point of fixation between the two.

[1909b, 2093]

I should not have much difficulty in giving you a far more intimate picture of the relations between perversion and neurosis; but I think what I have already said will serve our purpose. We must however guard against being misled by what I have told you of the meaning of symptoms into over-estimating the frequency and intensity of people's perverse inclinations. It is possible, as you have heard, to fall ill of a neurosis as a result of a frustration of normal sexual satisfaction. But when a real frustration like this occurs, the need moves over on to abnormal methods of sexual excitation. You will later learn the way in which this happens. But in any case you will realize that as a result of this 'collateral' damming-back the perverse impulses must emerge more strongly than they would have if normal sexual satisfaction had met with no obstacle in the real world. Moreover a similar influence is to be recognized also as affecting the manifest perversions. In some cases they are provoked or made active if the normal satisfaction of the sexual instinct encounters too great difficulties for temporary reasons or because of permanent social regulations. In other cases, it is true, the inclination to perversions is quite independent of such favouring conditions; they are, we might say, the normal species of sexual life for those particular individuals.

[1916-1917, 3381]

It would naturally be important to know whether the origin of infantile perversions from the Oedipus complex can be asserted as a general principle. While this cannot be decided without further investigation, it does not seem impossible. When we recall the anamneses which have been obtained in adult cases of perversion we cannot fail to notice that the decisive impression, the 'first experience', of all these perverts, fetishists, etc., is scarcely ever referred back to a time earlier than the sixth year. At this time, however, the dominance of the Oedipus complex is already over; the experience which is recalled, and which has been effective in such a puzzling way, may very well have represented the legacy of that complex. The connections between the experience and the complex which is by this time repressed are bound to remain obscure so long as analysis has not thrown any light on the time before the first 'pathogenic' impression. So it may be imagined how little value is to be attached, for instance, to an assertion that a case of homosexuality is congenital, when the ground given for this belief is that ever since his eighth or sixth year the person in question has felt inclinations only towards his own sex.

[1919e, 3653]
This process is not always performed faultlessly. Inhibitions in its development manifest themselves as the many sorts of disturbance in sexual life. When this is so, we find fixations of the libido to conditions in earlier phases, whose urge, which is independent of the normal sexual aim, is described as *perversion*. One such developmental inhibition, for instance, is homosexuality when it is manifest. Analysis shows that in every case a homosexual object-tie was present and in most cases persisted in a *latent* condition. The situation is complicated by the fact that as a rule the processes necessary for bringing about a normal outcome are not completely present or absent, but *partially* present, so that the final result remains dependent on these *quantitative* relations. In these circumstances the genital organization is, it is true, attained, but it lacks those portions of the libido which have not advanced with the rest and have remained fixated to pregenital objects and aims. This weakening shows itself in a tendency, if there is an absence of genital satisfaction or if there are difficulties in the real external world, for the libido to hark back to its earlier pregenital cathexes (*regression*).

[1940a [1938], 4966]

Analytic experience has convinced us of the complete truth of the assertion so often to be heard that the child is psychologically father to the adult and that the events of his first years are of paramount importance for his whole later life. It will thus be of special interest to us if there is something that may be described as the central experience of this period of childhood. Our attention is first attracted by the effects of certain influences which do not apply to all children, though they are common enough - such as the sexual abuse of children by adults, their seduction by other children (brothers or sisters) slightly their seniors, and, what we should not expect, their being deeply stirred by seeing or hearing at first hand sexual behaviour between adults (their parents) mostly at a time at which one would not have thought they could either be interested in or understand any such impressions, or be capable of remembering them later. It is easy to confirm the extent to which such experiences arouse a child's susceptibility and force his own sexual urges into certain channels from which they cannot afterwards depart. Since these impressions are subjected to repression either at once or as soon as they seek to return as memories, they constitute the determinant for the neurotic compulsion which will subsequently make it impossible for the ego to control the sexual function and will probably cause it to turn away from that function permanently. If this latter reaction occurs, the result will be a neurosis; if it is absent, a variety of perversions will develop, or the function, which is of immense importance not only for reproduction but also for the entire shaping of life, will become totally unmanageable.

[1940a [1938], 4995]
A transition to those cases of fetishism in which the sexual aim, whether normal or perverse, is entirely abandoned is afforded by other cases in which the sexual object is required to fulfil a fetishistic condition - such as the possession of some particular hair-colouring or clothing, or even some bodily defect if the sexual aim is to be attained. No other variation of the sexual instinct that borders on the pathological can lay so much claim to our interest as this one, such is the peculiarity of the phenomena to which it gives rise. Some degree of diminution in the urge towards the normal sexual aim (an executive weakness of the sexual apparatus) seems to be a necessary precondition in every case.

The point of contact with the normal is provided by the psychologically essential overvaluation of the sexual object, which inevitably extends to everything that is associated with it. A certain degree of fetishism is thus habitually present in normal love, especially in those stages of it in which the normal sexual aim seems unattainable or its fulfilment prevented:

¹ [Footnote added 1915:] This weakness would represent the constitutional precondition. Psychoanalysis has found that the phenomenon can also be accidentally determined, by the occurrence of an early deterrence from sexual activity owing to fear, which may divert the subject from the normal sexual aim and encourage him to seek a substitute for it.

¹ [Footnote added 1920:] Deeper-going psycho-analytic research has raised a just criticism of Binet's assertion. All the observations dealing with this point have recorded a first meeting with the fetish at which it already aroused sexual interest without there being anything in the accompanying circumstances to explain the fact. Moreover, all of these 'early' sexual impressions relate to a time after the age of five or six, whereas psycho-analysis makes it doubtful whether fresh pathological fixations can occur so late as this. The true explanation is that behind the first recollection of the fetish's appearance there lies a submerged and forgotten phase of sexual development. The fetish, like a 'screen memory', represents this phase and is thus a remnant and precipitate of it. The fact that this early infantile phase turns in the direction of fetishism, as well as the choice of the fetish itself, are constitutionally determined.

In this respect different cases of neurosis may behave differently: in one case the preponderating factor may be the innate strength of the tendency to perversion, in another it may be the collateral increase of that tendency owing to the libido being forced away from a normal sexual aim and sexual object. It would be wrong to represent as opposition what is in fact a co-operative relation. Neurosis will always produce its greatest effects when constitution and experience work together in the same direction. Where the constitution is a marked one it will perhaps not require the support of actual experiences; while a great shock in real life will perhaps bring about a neurosis even in an average constitution. (Incidentally, this view of the relative aetiological importance of what is innate and what is accidentally experienced applies equally in other fields.)

It is, as we have seen, debatable whether the perversions go back to innate determinants or arise, as Binet assumed was the case with fetishism, owing to chance experiences. The conclusion now presents itself to us that there is indeed something innate lying behind the perversions but that it is something innate in everyone, though as a disposition it may vary in its intensity and may be increased by the influences of actual life. What is in question are the innate constitutional roots of the sexual instinct. In one class of cases (the perversions) these roots may grow into the actual vehicles of sexual activity; in others they may be submitted to an insufficient suppression (repression) and thus be able in a roundabout way to attract a considerable proportion of sexual energy to themselves as symptoms; while in the most favourable cases, which lie between these two extremes, they may by means of effective restriction and other kinds of modification bring about what is known as normal sexual life.
An inevitable consequence of these considerations is that we must regard each individual as possessing an oral erotism, an anal erotism, a urethral erotism, etc., and that the existence of mental complexes corresponding to these implies no judgement of abnormality or neurosis. The differences separating the normal from the abnormal can lie only in the relative strength of the individual components of the sexual instinct and in the use to which they are put in the course of development.

1 [Footnote added 1920:] An inevitable consequence of these considerations is that we must regard each individual as possessing an oral erotism, an anal erotism, a urethral erotism, etc., and that the existence of mental complexes corresponding to these implies no judgement of abnormality or neurosis. The differences separating the normal from the abnormal can lie only in the relative strength of the individual components of the sexual instinct and in the use to which they are put in the course of development.

[1905d, 1523]

DANGERS OF FORE-PLEASURE The connection between fore-pleasure and infantile sexual life is, however, made clearer by the pathogenic part which it can come to play. The attainment of the normal sexual aim can clearly be endangered by the mechanism in which fore-pleasure is involved. This danger arises if at any point in the preparatory sexual processes the fore-pleasure turns out to be too great and the element of tension too small. The motive for proceeding further with the sexual process then disappears, the whole path is cut short, and the preparatory act in question takes the place of the normal sexual aim. Experience has shown that the precondition for this damaging event is that the erotogenic zone concerned or the corresponding component instinct shall already during childhood have contributed an unusual amount of pleasure. If further factors then come into play, tending to bring about a fixation, a compulsion may easily arise in later life which resists the incorporation of this particular fore-pleasure into a new context. Such is in fact the mechanism of many perversions, which consist in a lingering over the preparatory acts of the sexual process.

[1905d, 1528]

The time has arrived for me to attempt to summarize what I have said. We started out from the aberrations of the sexual instinct in respect of its object and of its aim and we were faced by the question of whether these arise from an innate disposition or are acquired as a result of experiences in life. We arrived at an answer to this question from an understanding, derived from psycho-analytic investigation, of the workings of the sexual instinct in psychoneurotics, a numerous class of people and one not far removed from the healthy. We found that in them tendencies to every kind of perversion can be shown to exist as unconscious forces and betray their presence as factors leading to the formation of symptoms. It was thus possible to say that neurosis is, as it were, the negative of perversion. In view of what was now seen to be the wide dissemination of tendencies to perversion we were driven to the conclusion that a disposition to perversions is an original and universal disposition of the human sexual instinct and that normal sexual behaviour is developed out of it as a result of organic changes and psychical inhibitions occurring in the course of maturation; we hoped to be able to show the presence of this original disposition in childhood. Among the forces restricting the direction taken by the sexual instinct we laid emphasis upon shame, disgust, pity and the structures of morality and authority erected by society. We were thus led to regard any established aberration from normal sexuality as an instance of developmental inhibition and infantilism. Though it was necessary to place in the foreground the importance of the variations in the original disposition, a co-operative and not an opposing relation was to be assumed as existing between them and the influences of actual life. It appeared, on the other hand, that since the original disposition is necessarily a complex one, the sexual instinct itself must be something put together from various factors, and that in the perversions it falls apart, as it were, into its components. The perversions were thus seen to be on the one hand inhibitions, and on the other hand dissociations, of normal development. Both these aspects were brought together in the supposition that the sexual instinct of adults arises from a combination of a number of impulses of childhood into a unity, an impulsion with a single aim.

[1905d, 1542]
The hereditary conditions in the case of positive perverts are less well known, for they know how to avoid investigation. Yet there are good reasons to suppose that what is true of the neuroses applies also to the perversions. For it is no rare thing to find perversions and psychoneuroses occurring in the same family, and distributed between the two sexes in such a way that the male members of the family, or one of them, are positive perverts, while the females, true to the tendency of their sex to repression, are negative perverts, that is, hysterics. This is good evidence of the essential connections which we have shown to exist between the two disorders.

[1905d, 1546]

FURTHER MODIFICATION On the other hand, it is not possible to adopt the view that the form to be taken by sexual life is unambiguously decided, once and for all, with the inception of the different components of the sexual constitution. On the contrary, the determining process continues, and further possibilities arise according to the vicissitudes of the tributary streams of sexuality springing from their separate sources. This further modification is clearly what brings the decisive outcome, and constitutions which might be described as the same can lead to three different final results: -

[1905d, 1547]

If the relation between all the different dispositions - a relation which we will assume to be abnormal - persists and grows stronger at maturity, the result can only be a perverse sexual life. The analysis of abnormal constitutional dispositions of this kind has not yet been properly taken in hand. But we already know cases which can easily be explained on such a basis as this. Writers on the subject, for instance, have asserted that the necessary precondition of a whole number of perverse fixations lies in an innate weakness of the sexual instinct. In this form the view seems to me untenable. It makes sense, however, if what is meant is a constitutional weakness of one particular factor in the sexual instinct, namely the genital zone - a zone which takes over the function of combining the separate sexual activities for the purposes of reproduction. For if the genital zone is weak, this combination, which is required to take place at puberty, is bound to fail, and the strongest of the other components of sexuality will continue its activity as a perversion.¹

[1905d, 1547]

¹ [Footnote added 1915:] In such circumstances one often finds that at puberty a normal sexual current begins to operate at first, but that, as a result of its internal weakness, it breaks down in face of the first external obstacles and is then replaced by regression to the perverse fixation.

[1905d, 1547]

If we take the second of these stages as an average, we must point out that a number of people are, on account of their organization, not equal to meeting its demands. In whole classes of individuals the development of the sexual instinct, as we have described it above, from auto-erotism to object-love with its aim of uniting the genitals, has not been carried out correctly and sufficiently fully. As a result of these disturbances of development two kinds of harmful deviation from normal sexuality - that is, sexuality which is serviceable to civilization - come about; and the relation between these two is almost that of positive and negative.²

[1908d, 1953]
More pronounced forms of the perversions and of homosexuality, especially if they are exclusive, do, it is true, make those subject to them socially useless and unhappy, so that it must be recognized that the cultural requirements even of the second stage are a source of suffering for a certain proportion of mankind. The fate of these people who differ constitutionally from the rest varies, and depends on whether they have been born with a sexual instinct which by absolute standards is strong or comparatively weak. In the latter case - where the sexual instinct is in general weak - perverts succeed in totally suppressing the inclinations which bring them into conflict with the moral demands of their stage of civilization. But this, from the ideal point of view, is also the only thing they succeed in achieving; for, in order to effect this suppression of their sexual instinct, they use up the forces which they would otherwise employ in cultural activities. They are, as it were, inwardly inhibited and outwardly paralysed. What we shall be saying again later on about the abstinence demanded of men and women in the third stage of civilization applies to them too.

Where the sexual instinct is fairly intense, but perverse, there are two possible outcomes. The first, which we shall not discuss further, is that the person affected remains a pervert and has to put up with the consequences of his deviation from the standard of civilization. The second is far more interesting. It is that, under the influence of education and social demands, a suppression of the perverse instincts is indeed achieved, but it is a kind of suppression which is really no suppression at all. It can better be described as a suppression that has failed. The inhibited sexual instincts are, it is true, no longer expressed as such - and this constitutes the success of the process - but they find expression in other ways, which are quite as injurious to the subject and make him quite as useless for society as satisfaction of the suppressed instincts in an unmodified form would have done. This constitutes the failure of the process, which in the long run more than counterbalances its success. The substitutive phenomena which emerge in consequence of the suppression of the instinct amount to what we call nervous illness, or, more precisely, the psychoneuroses.¹ Neurotics are the class of people who, since they possess a recalcitrant organization, only succeed, under the influence of cultural requirements, in achieving a suppression of their instincts which is apparent and which becomes increasingly unsuccessful. They therefore only carry on their collaboration with cultural activities by a great expenditure of force and at the cost of an internal impoverishment, or are obliged at times to interrupt it and fall ill. I have described the neuroses as the 'negative' of the perversions because in the neuroses the perverse impulses, after being repressed, manifest themselves from the unconscious part of the mind - because the neuroses contain the same tendencies, though in a state of 'repression', as do the positive perversions.

The sternness of the demands of civilization and the difficulty of the task of abstinence have combined to make avoidance of the union of the genitals of the two opposite sexes into the central point of abstinence and to favour other kinds of sexual activity, which, it might be said, are equivalent to semi-obedience. Since normal intercourse has been so relentlessly persecuted by morality - and also, on account of the possibilities of infection, by hygiene - what are known as the perverse forms of intercourse between the two sexes, in which other parts of the body take over the role of the genitals, have undoubtedly increased in social importance. These activities cannot, however, be regarded as being as harmless as analogous extensions in love-relationships. They are ethically objectionable, for they degrade the relationships of love between two human beings from a serious matter to a convenient game, attended by no risk and no spiritual participation. A further consequence of the aggravation of the difficulties of normal sexual life is to be found in the spread of homosexual satisfaction; in addition to all those who are homosexuals in virtue of their organization, or who became so in their childhood, there must be reckoned the great number of those in whom, in their maturer years, a blocking of the main stream of their libido has caused a widening in the side-channel of homosexuality.

¹ [1908d, 1954]
A sexual constitution like that of little Hans does not appear to carry with it a predisposition to
the development either of perversions or of their negative (we will limit ourselves to a
consideration of hysteria). As far as my experience goes (and there is still a real need for
speaking with caution on this point) the innate constitution of hysterics - that this is also true of
pervers is almost self-evident - is marked by the genital zone being relatively less prominent
than the other erotogenic zones. But we must expressly except from this rule one particular
'aberration' of sexual life. In those who later become homosexuals we meet with the same
predominance in infancy of the genital zone (and especially of the penis) as in normal persons.¹
Indeed it is the high esteem felt by the homosexual for the male organ which decides his fate. In
his childhood he chooses women as his sexual object, so long as he assumes that they too
possess what in his eyes is an indispensable part of the body; when he becomes convinced that
women have deceived him in this particular, they cease to be acceptable to him as a sexual
object. He cannot forgo a penis in any one who is to attract him to sexual intercourse; and if
circumstances are favourable he will fix his libido upon the 'woman with a penis', a youth of
feminine appearance. Homosexuals, then, are persons who, owing to the erotogenic
importance of their own genitals, cannot do without a similar feature in their sexual object. In the
course of their development from auto-erotism to object-love, they have remained at a point of
fixation between the two.
[1909b, 2093]

To this unimpeachable body of evidence we shall be able to add fresh material, if we turn to
the history of the masturbatory side of our patient's sexual activities. There is a conflict between
the opinions of doctors and patients on this subject which has not hitherto been properly
appreciated. The patients are unanimous in their belief that masturbation, by which they mean
masturbation during puberty, is the root and origin of all their troubles. The doctors are, upon
the whole, unable to decide what line to take; but, influenced by the knowledge that not only
neurotics but most normal people pass through a period of masturbation during their puberty,
the majority of them are inclined to dismiss the patients' assertions as gross exaggerations. In
my opinion the patients are once again nearer to a correct view than the doctors; for the
patients have some glimmering notion of the truth, while the doctors are in danger of
overlooking an essential point. The thesis propounded by the patients certainly does not
 correspond to the facts in the sense in which they themselves construe it, namely, that
masturbation during puberty (which may almost be described as a typical occurrence) is
responsible for all neurotic disturbances. Their thesis requires interpretation. The masturbation
of puberty is in fact no more than a revival of the masturbation of infancy, a subject which has
hitherto invariably been neglected. Infantile masturbation reaches a kind of climax, as a rule,
between the ages of three and four or five; and it is the clearest expression of a child's sexual
constitution, in which the aetiology of subsequent neuroses must be sought. In this disguised
way, therefore, the patients are putting the blame for their illnesses upon their infantile sexuality;
and they are perfectly right in doing so. On the other hand, the problem of masturbation
becomes insoluble if we attempt to treat it as a clinical unit, and forget that it can represent the
discharge of every variety of sexual component and of every sort of phantasy to which such
components can give rise. The injurious effects of masturbation are only in a very small degree
autonomous - that is to say, determined by its own nature. They are in substance merely part
and parcel of the pathogenic significance of the subject's sexual life as a whole. The fact that so
many people can tolerate masturbation - that is, a certain amount of it - without injury merely
shows that their sexual constitution and the course of development of their sexual life have
been such as to allow them to exercise the sexual function within the limits of what is culturally
permissible; whereas other people, because their sexual constitution has been less favourable
or their development has been disturbed, fall ill as a result of their sexuality - they cannot, that
is, achieve the necessary suppression or sublimation of their sexual components without having
recourse to inhibitions or substitutes.¹
[1909d, 2159]
A certain practical importance may readily be allowed to these types of onset. They are to be met with in their pure form, indeed, in individual cases; we should not have noticed the third and fourth types if they had not in some subjects constituted the sole precipitating causes of the illness. The first type keeps before our eyes the extraordinarily powerful influence of the external world, and the second the no less important influence - which opposes the former one - of the subject's peculiar individuality. Pathology could not do justice to the problem of the precipitating factors in the neuroses so long as it was merely concerned with deciding whether those affections were of an 'endogenous' or 'exogenous' nature. It was bound to meet every observation which pointed to the importance of abstinence (in the widest sense of the word) as a precipitating cause with the objection that other people tolerate the same experiences without falling ill. If, however, it sought to lay stress on the peculiar individuality of the subject as being the essential factor decisive between illness and health, it was obliged to put up with the proviso that people possessing such a peculiarity can remain healthy indefinitely, just so long as they are able to retain that peculiarity. Psycho-analysis has warned us that we must give up the unfruitful contrast between external and internal factors, between experience and constitution, and has taught us that we shall invariably find the cause of the onset of neurotic illness in a particular psychical situation which can be brought about in a variety of ways.

To return to masochism. Masochism comes under our observation in three forms: as a condition imposed on sexual excitation, as an expression of the feminine nature, and as a norm of behaviour. We may, accordingly, distinguish an erotogenic, a feminine and a moral masochism. The first, the erotogenic, masochism - pleasure in pain - lies at the bottom of the other two forms as well. Its basis must be sought along biological and constitutional lines and it remains incomprehensible unless one decides to make certain assumptions about matters that are extremely obscure. The third, and in some respects the most important, form assumed by masochism has only recently been recognized by psycho-analysis as a sense of guilt which is mostly unconscious; but it can already be completely explained and fitted into the rest of our knowledge. Feminine masochism, on the other hand, is the one that is most accessible to our observation and least problematical, and it can be surveyed in all its relations. We will begin our discussion with it.

In my *Three Essays on the Theory of Sexuality*, in the section on the sources of infantile sexuality, I put forward the proposition that 'in the case of a great number of internal processes sexual excitation arises as a concomitant effect, as soon as the intensity of those processes passes beyond certain quantitative limits'. Indeed, 'it may well be that nothing of considerable importance can occur in the organism without contributing some component to the excitation of the sexual instinct'. In accordance with this, the excitation of pain and unpleasure would be bound to have the same result, too. The occurrence of such a libidinal sympathetic excitation when there is tension due to pain and unpleasure would be an infantile physiological mechanism which ceases to operate later on. It would attain a varying degree of development in different sexual constitutions; but in any case it would provide the physiological foundation on which the psychical structure of erotogenic masochism would afterwards be erected.
The tendency on the part of civilization to restrict sexual life is no less clear than its other tendency to expand the cultural unit. Its first, totemic, phase already brings with it the prohibition against an incestuous choice of object, and this is perhaps the most drastic mutilation which man's erotic life has in all time experienced. Taboos, laws and customs impose further restrictions, which affect both men and women. Not all civilizations go equally far in this; and the economic structure of the society also influences the amount of sexual freedom that remains. Here, as we already know, civilization is obeying the laws of economic necessity, since a large amount of the psychical energy which it uses for its own purposes has to be withdrawn from sexuality. In this respect civilization behaves towards sexuality as a people or a stratum of its population does which has subjected another one to its exploitation. Fear of a revolt by the suppressed elements drives it to stricter precautionary measures. A high-water mark in such a development has been reached in our Western European civilization. A cultural community is perfectly justified, psychologically, in starting by proscribing manifestations of the sexual life of children, for there would be no prospect of curbing the sexual lusts of adults if the ground had not been prepared for it in childhood. But such a community cannot in any way be justified in going to the length of actually disavowing such easily demonstrable, and, indeed, striking phenomena. As regards the sexually mature individual, the choice of an object is restricted to the opposite sex, and most extra-genital satisfactions are forbidden as perversions. The requirement, demonstrated in these prohibitions, that there shall be a single kind of sexual life for everyone, disregards the dissimilarities, whether innate or acquired, in the sexual constitution of human beings; it cuts off a fair number of them from sexual enjoyment, and so becomes the source of serious injustice. The result of such restrictive measures might be that in people who are normal - who are not prevented by their constitution - the whole of their sexual interests would flow without loss into the channels that are left open. But heterosexual genital love, which has remained exempt from outlawry, is itself restricted by further limitations, in the shape of insistence upon legitimacy and monogamy. Present-day civilization makes it plain that it will only permit sexual relationships on the basis of a solitary, indissoluble bond between one man and one woman, and that it does not like sexuality as a source of pleasure in its own right and is only prepared to tolerate it because there is so far no substitute for it as a means of propagating the human race.

[1930a, 4498]
¹ [Footnote added 1915:] This weakness would represent the constitutional precondition. Psycho-analysis has found that the phenomenon can also be accidentally determined, by the occurrence of an early deterrence from sexual activity owing to fear, which may divert the subject from the normal sexual aim and encourage him to seek a substitute for it. [1905d, 1480]

Binet (1888) was the first to maintain (what has since been confirmed by a quantity of evidence) that the choice of a fetish is an after-effect of some sexual impression received as a rule in early childhood. (This may be brought into line with the proverbial durability of first loves: on revient toujours à ses premiers amours.) This derivation is particularly obvious in cases where there is merely a fetishistic condition attached to the sexual object. We shall come across the importance of early sexual impressions again in another connection.¹ [1905d, 1481]

THE MENTAL FACTOR IN THE PERVERSIONS It is perhaps in connection precisely with the most repulsive perversions that the mental factor must be regarded as playing its largest part in the transformation of the sexual instinct. It is impossible to deny that in their case a piece of mental work has been performed which, in spite of its horrifying result, is the equivalent of an idealization of the instinct. The omnipotence of love is perhaps never more strongly proved than in such of its aberrations as these. The highest and the lowest are always closest to each other in the sphere of sexuality: 'vom Himmel durch die Welt zur Hölle.'¹ [1905d, 1487]

It is, as we have seen, debatable whether the perversions go back to innate determinants or arise, as Binet assumed was the case with fetishism, owing to chance experiences. The conclusion now presents itself to us that there is indeed something innate lying behind the perversions but that it is something innate in everyone, though as a disposition it may vary in its intensity and may be increased by the influences of actual life. What is in question are the innate constitutional roots of the sexual instinct. In one class of cases (the perversions) these roots may grow into the actual vehicles of sexual activity; in others they may be submitted to an insufficient suppression (repression) and thus be able in a roundabout way to attract a considerable proportion of sexual energy to themselves as symptoms; while in the most favourable cases, which lie between these two extremes, they may by means of effective restriction and other kinds of modification bring about what is known as normal sexual life. [1905d, 1495]
The time has arrived for me to attempt to summarize what I have said. We started out from the aberrations of the sexual instinct in respect of its object and of its aim and we were faced by the question of whether these arise from an innate disposition or are acquired as a result of experiences in life. We arrived at an answer to this question from an understanding, derived from psycho-analytic investigation, of the workings of the sexual instinct in psychoneurotics, a numerous class of people and one not far removed from the healthy. We found that in them tendencies to every kind of perversion can be shown to exist as unconscious forces and betray their presence as factors leading to the formation of symptoms. It was thus possible to say that neurosis is, as it were, the negative of perversion. In view of what was now seen to be the wide dissemination of tendencies to perversion we were driven to the conclusion that a disposition to perversions is an original and universal disposition of the human sexual instinct and that normal sexual behaviour is developed out of it as a result of organic changes and psychical inhibitions occurring in the course of maturation; we hoped to be able to show the presence of this original disposition in childhood. Among the forces restricting the direction taken by the sexual instinct we laid emphasis upon shame, disgust, pity and the structures of morality and authority erected by society. We were thus led to regard any established aberration from normal sexuality as an instance of developmental inhibition and infantilism. Though it was necessary to place in the foreground the importance of the variations in the original disposition, a co-operative and not an opposing relation was to be assumed as existing between them and the influences of actual life.

It appeared, on the other hand, that since the original disposition is necessarily a complex one, the sexual instinct itself must be something put together from various factors, and that in the perversions it falls apart, as it were, into its components. The perversions were thus seen to be on the one hand inhibitions, and on the other hand dissociations, of normal development. Both these aspects were brought together in the supposition that the sexual instinct of adults arises from a combination of a number of impulses of childhood into a unity, an impulsion with a single aim.

[1905d, 1542]

¹ [Footnote added 1915:] This does not apply only to the 'negative' tendencies to perversion which appear in neuroses but equally to the 'positive,' properly so-called, perversions. Thus these latter are to be derived not merely from a fixation of infantile tendencies but also from a regression to those tendencies as a result of other channels of the sexual current being blocked. It is for this reason that the positive perversions also are accessible to psycho-analytic therapy.

[1905d, 1543]

The sternness of the demands of civilization and the difficulty of the task of abstinence have combined to make avoidance of the union of the genitals of the two opposite sexes into the central point of abstinence and to favour other kinds of sexual activity, which, it might be said, are equivalent to semi-obedience. Since normal intercourse has been so relentlessly persecuted by morality - and also, on account of the possibilities of infection, by hygiene - what are known as the perverse forms of intercourse between the two sexes, in which other parts of the body take over the role of the genitals, have undoubtedly increased in social importance. These activities cannot, however, be regarded as being as harmless as analogous extensions in love-relationships. They are ethically objectionable, for they degrade the relationships of love between two human beings from a serious matter to a convenient game, attended by no risk and no spiritual participation. A further consequence of the aggravation of the difficulties of normal sexual life is to be found in the spread of homosexual satisfaction; in addition to all those who are homosexuals in virtue of their organization, or who became so in their childhood, there must be reckoned the great number of those in whom, in their maturer years, a blocking of the main stream of their libido has caused a widening in the side-channel of homosexuality.

[1908d, 1961]
The tendency on the part of civilization to restrict sexual life is no less clear than its other
tendency to expand the cultural unit. Its first, totemic, phase already brings with it the prohibition
against an incestuous choice of object, and this is perhaps the most drastic mutilation which
man's erotic life has in all time experienced. Taboos, laws and customs impose further
restrictions, which affect both men and women. Not all civilizations go equally far in this; and the
economic structure of the society also influences the amount of sexual freedom that remains.
Here, as we already know, civilization is obeying the laws of economic necessity, since a large
amount of the psychical energy which it uses for its own purposes has to be withdrawn from
sexuality. In this respect civilization behaves towards sexuality as a people or a stratum of its
population does which has subjected another one to its exploitation. Fear of a revolt by the
suppressed elements drives it to stricter precautionary measures. A high-water mark in such a
development has been reached in our Western European civilization. A cultural community is
perfectly justified, psychologically, in starting by proscribing manifestations of the sexual life of
children, for there would be no prospect of curbing the sexual lusts of adults if the ground had
not been prepared for it in childhood. But such a community cannot in any way be justified in
going to the length of actually disavowing such easily demonstrable, and, indeed, striking
phenomena. As regards the sexually mature individual, the choice of an object is restricted to
the opposite sex, and most extra-genital satisfactions are forbidden as perversions. The
requirement, demonstrated in these prohibitions, that there shall be a single kind of sexual life
for everyone, disregards the dissimilarities, whether innate or acquired, in the sexual
constitution of human beings; it cuts off a fair number of them from sexual enjoyment, and so
becomes the source of serious injustice. The result of such restrictive measures might be that in
people who are normal - who are not prevented by their constitution - the whole of their sexual
interests would flow without loss into the channels that are left open. But heterosexual genital
love, which has remained exempt from outlawry, is itself restricted by further limitations, in the

it will only permit sexual relationships on the basis of a solitary, indissoluble bond between one
man and one woman, and that it does not like sexuality as a source of pleasure in its own right
and is only prepared to tolerate it because there is so far no substitute for it as a means of
propagating the human race.
[1930a, 4498]

One cannot very well doubt the importance of envy for the penis. You may take it as an
instance of male injustice if I assert that envy and jealousy play an even greater part in the
mental life of women than of men. It is not that I think these characteristics are absent in men or
that I think they have no other roots in women than envy for the penis; but I am inclined to
attribute their greater amount in women to this latter influence. Some analysts, however, have
shown an inclination to depreciate the importance of this first instalment of penis-envy in the
phallic phase. They are of opinion that what we find of this attitude in women is in the main a
secondary structure which has come about on the occasion of later conflicts by regression to
this early infantile impulse. This, however, is a general problem of depth psychology. In many
pathological - or even unusual - instinctual attitudes (for instance, in all sexual perversions) the
question arises of how much of their strength is to be attributed to early infantile fixations and
how much to the influence of later experiences and developments. In such cases it is almost
always a matter of complemental series such as we put forward in our discussion of the
aetiology of the neuroses. Both factors play a part in varying amounts in the causation; a less
on the one side is balanced by a more on the other. The infantile factor sets the pattern in all
cases but does not always determine the issue, though it often does. Precisely in the case of
penis-envy I should argue decidedly in favour of the preponderance of the infantile factor.
[1933a, 4727]
Analytic experience has convinced us of the complete truth of the assertion so often to be heard that the child is psychologically father to the adult and that the events of his first years are of paramount importance for his whole later life. It will thus be of special interest to us if there is something that may be described as the central experience of this period of childhood. Our attention is first attracted by the effects of certain influences which do not apply to all children, though they are common enough - such as the sexual abuse of children by adults, their seduction by other children (brothers or sisters) slightly their seniors, and, what we should not expect, their being deeply stirred by seeing or hearing at first hand sexual behaviour between adults (their parents) mostly at a time at which one would not have thought they could either be interested in or understand any such impressions, or be capable of remembering them later. It is easy to confirm the extent to which such experiences arouse a child’s susceptibility and force his own sexual urges into certain channels from which they cannot afterwards depart. Since these impressions are subjected to repression either at once or as soon as they seek to return as memories, they constitute the determinant for the neurotic compulsion which will subsequently make it impossible for the ego to control the sexual function and will probably cause it to turn away from that function permanently. If this latter reaction occurs, the result will be a neurosis; if it is absent, a variety of perversions will develop, or the function, which is of immense importance not only for reproduction but also for the entire shaping of life, will become totally unmanageable.

[1940a [1938], 4995]
Footnote added 1915: This does not apply only to the 'negative' tendencies to perversion which appear in neuroses but equally to the 'positive,' properly so-called, perversions. Thus these latter are to be derived not merely from a fixation of infantile tendencies but also from a regression to those tendencies as a result of other channels of the sexual current being blocked. It is for this reason that the positive perversions also are accessible to psycho-analytic therapy.

[1905d, 1543]

If we take the second of these stages as an average, we must point out that a number of people are, on account of their organization, not equal to meeting its demands. In whole classes of individuals the development of the sexual instinct, as we have described it above, from auto-erotism to object-love with its aim of uniting the genitals, has not been carried out correctly and sufficiently fully. As a result of these disturbances of development two kinds of harmful deviation from normal sexuality - that is, sexuality which is serviceable to civilization - come about; and the relation between these two is almost that of positive and negative.

[1908d, 1953]

In the first place (disregarding people whose sexual instinct is altogether excessive and uninhibitable) there are the different varieties perverts, in whom an infantile fixation to a preliminary sexual aim has prevented the primacy of the reproductive function from being established, and the homosexuals or inverts, in whom, in a manner that is not yet quite understood, the sexual aim has been deflected away from the opposite sex. If the injurious effects of these two kinds of developmental disturbance are less than might be expected, this mitigation can be ascribed precisely to the complex way in which the sexual instinct is put together, which makes it possible for a person's sexual life to reach a serviceable final form even if one or more components of the instinct have been shut off from development. The constitution of people suffering from inversion - the homosexuals - is, indeed, often distinguished by their sexual instinc't's possessing a special aptitude for cultural sublimation.

[1908d, 1953]

There is a dictum in general pathology, Gentlemen, which asserts that every developmental process carries with it the seed of a pathological disposition, in so far as that process may be inhibited, delayed, or may run its course incompletely. The same thing is true of the highly complicated development of the sexual function. It does not occur smoothly in every individual; and, if not, it leaves behind it either abnormalities or a predisposition to fall ill later, along the path of involution (i.e. regression). It may happen that not all the component instincts submit to the dominance of the genital zone. An instinct which remains in this way independent leads to what we describe as a perversion, and may substitute its own sexual aim for the normal one. It very often happens, as I have already said, that auto-erotism is not completely conquered, and evidence of this is given by a great variety of subsequent disturbances. The originally equal value attached to the two sexes as sexual objects may persist, and this will lead to a tendency in adult life to homosexual activity, which can in certain circumstances be intensified into exclusive homosexuality. These classes of disturbance represent direct inhibitions in the development of the sexual function; they comprise the perversions and, what is by no means rare, general infantilism in sexual life.

[1910a, 2231]
The tenacity with which the libido adheres to particular trends and objects - what may be described as the 'adhesiveness' of the libido - makes its appearance as an independent factor, varying from individual to individual, whose determinants are quite unknown to us, but whose significance for the aetiology of the neuroses we shall certainly no longer underestimate. We should not, on the other hand, over-estimate the intimacy of this connection. For a similar 'adhesiveness' of the libido occurs (for unknown reasons) under numerous conditions in normal people, and it is found as a determining factor in people who are in one sense the contrary of neurotics - in perverts. It was known even before the days of psycho-analysis (cf. Binet) that in the anamnesis of perverts a very early impression of an abnormal instinctual trend or choice of object was quite often found, to which the subject's libido remained attached all through his life. It is often impossible to say what it is that enabled this impression to exercise such an intense attraction on the libido. I will describe a case of this sort which I myself observed.

The subject was a man who is to-day quite indifferent to the genitals and other attractions of women, but who can be plunged into irresistible sexual excitement only by a foot of a particular form wearing a shoe. He can recall an event from his sixth year which was decisive for the fixation of his libido. He was sitting on a stool beside the governess who was to give him lessons in English. The governess, who was an elderly, dried-up, plain-looking spinster, with pale-blue eyes and a snub nose, had something wrong with her foot that day, and on that account kept it, wearing a velvet slipper, stretched out on a cushion. Her leg itself was most decently concealed. A thin, scraggy foot, like the one he had then seen belonging to his governess, thereupon became (after a timid attempt at normal sexual activity at puberty) his only sexual object; and the man was irresistibly attracted if a foot of this kind was associated with other features besides which recalled the type of the English governess. This fixation of his libido, however, made him, not into a neurotic, but into a pervert - what we call a foot-fetishist. You see, then, that although an excessive, and moreover premature, fixation of the libido is indispensable for the causation of neuroses, the area of its effects extends far beyond the field of the neuroses. This determinant, too, is as little decisive in itself as is the frustration which we have already talked about.
Nor is it a fact that psycho-analysis has paid no attention whatever to the non-sexual part of the personality. It is precisely the distinction between the ego and sexuality which has enabled us to recognize with special clarity that the ego instincts pass through an important process of development - a development which is neither completely independent of the libido nor without a counter-effect upon it. Nevertheless, we are far less well acquainted with the development of the ego than of the libido, since it is only the study of the narcissistic neuroses that promises to give us an insight into the structure of the ego. We already have before us, however, a notable attempt by Ferenczi to make a theoretical construction of the stages of development of the ego, and there are at least two points at which we have a solid basis for judging that development. It is not our belief that a person's libidinal interests are from the first in opposition to his self-preservation interests; on the contrary, the ego endeavours at every stage to remain in harmony with its sexual organization as it is at the time and to fit itself into it. The succession of the different phases of libidinal development probably follows a prescribed programme. But the possibility cannot be rejected that this course of events can be influenced by the ego, and we may expect equally to find a certain parallelism, a certain correspondence, between the developmental phases of the ego and the libido; indeed a disturbance of that correspondence might provide a pathogenic factor. We are now faced by the important consideration of how the ego behaves if its libido leaves a strong fixation behind at some point in its (the libido's) development. The ego may accept this and consequently become to that extent perverse or, what is the same thing, infantile. It may, however, adopt a non-compliant attitude to the libido's settling down in this position, in which case the ego experiences a repression where the libido has experienced a fixation.

A perversion in childhood, as is well known, may become the basis for the construction of a perversion having a similar sense and persisting throughout life, one which consumes the subject's whole sexual life. On the other hand the perversion may be broken off and remain in the background of a normal sexual development, from which, however, it continues to withdraw a certain amount of energy. The first of these alternatives was already known before the days of analysis. Analytic investigation, however, of such fully-developed cases almost bridges the gulf between the two. For we find often enough with these perverts that they too made an attempt at developing normal sexual activity, usually at the age of puberty; but their attempt had not enough force in it and was abandoned in the face of the first obstacles which inevitably arise, whereupon they fell back upon their infantile fixation once and for all.

One cannot very well doubt the importance of envy for the penis. You may take it as an instance of male injustice if I assert that envy and jealousy play an even greater part in the mental life of women than of men. It is not that I think these characteristics are absent in men or that I think they have no other roots in women than envy for the penis; but I am inclined to attribute their greater amount in women to this latter influence. Some analysts, however, have shown an inclination to depreciate the importance of this first instalment of penis-envy in the phallic phase. They are of opinion that what we find of this attitude in women is in the main a secondary structure which has come about on the occasion of later conflicts by regression to this early infantile impulse. This, however, is a general problem of depth psychology. In many pathological - or even unusual - instinctual attitudes (for instance, in all sexual perversions) the question arises of how much of their strength is to be attributed to early infantile fixations and how much to the influence of later experiences and developments. In such cases it is almost always a matter of complemental series such as we put forward in our discussion of the aetiology of the neuroses. Both factors play a part in varying amounts in the causation; a less on the one side is balanced by a more on the other. The infantile factor sets the pattern in all cases but does not always determine the issue, though it often does. Precisely in the case of penis-envy I should argue decidedly in favour of the preponderance of the infantile factor.
This process is not always performed faultlessly. Inhibitions in its development manifest themselves as the many sorts of disturbance in sexual life. When this is so, we find fixations of the libido to conditions in earlier phases, whose urge, which is independent of the normal sexual aim, is described as *perversion*. One such developmental inhibition, for instance, is homosexuality when it is manifest. Analysis shows that in every case a homosexual object-tie was present and in most cases persisted in a *latent* condition. The situation is complicated by the fact that as a rule the processes necessary for bringing about a normal outcome are not completely present or absent, but *partially* present, so that the final result remains dependent on these *quantitative* relations. In these circumstances the genital organization is, it is true, attained, but it lacks those portions of the libido which have not advanced with the rest and have remained fixated to pregenital objects and aims. This weakening shows itself in a tendency, if there is an absence of genital satisfaction or if there are difficulties in the real external world, for the libido to hark back to its earlier pregenital cathexes (*regression*). [1940a [1938], 4966]
I could not further elucidate this part of my theory without a detailed discussion of my views on repression. It will be enough here to refer to my Three Essays (1905d), in which I have attempted to throw some light - if only a feeble one - on the somatic processes in which the essential nature of sexuality is to be looked for. I have there shown that the constitutional sexual disposition of children is incomparably more variegated than might have been expected, that it deserves to be described as 'polymorphously perverse' and that what is spoken of as the normal behaviour of the sexual function emerges from this disposition after certain of its components have been repressed. By pointing out the infantile elements in sexuality I was able to establish a simple correlation between health, perversion and neurosis. I showed that normality is a result of the repression of certain component instincts and constituents of the infantile disposition and of the subordination of the remaining constituents under the primacy of the genital zones in the service of the reproductive function. I showed that perversions correspond to disturbances of this coalescence owing to the overpowering and compulsive development of certain of the component instincts, while neuroses can be traced back to an excessive repression of the libidinal trends. Since almost all the perverse instincts of the infantile disposition can be recognized as the forces concerned in the formation of symptoms in neuroses, though in a state of repression, I was able to describe neurosis as being the 'negative' of perversion.

[1906a, 1581]

If we take the second of these stages as an average, we must point out that a number of people are, on account of their organization, not equal to meeting its demands. In whole classes of individuals the development of the sexual instinct, as we have described it above, from autoerotism to object-love with its aim of uniting the genitals, has not been carried out correctly and sufficiently fully. As a result of these disturbances of development two kinds of harmful deviation from normal sexuality - that is, sexuality which is serviceable to civilization - come about; and the relation between these two is almost that of positive and negative.¹

[1908d, 1953]

Nor is it a fact that psycho-analysis has paid no attention whatever to the non-sexual part of the personality. It is precisely the distinction between the ego and sexuality which has enabled us to recognize with special clarity that the ego instincts pass through an important process of development - a development which is neither completely independent of the libido nor without a counter-effect upon it. Nevertheless, we are far less well acquainted with the development of the ego than of the libido, since it is only the study of the narcissistic neuroses that promises to give us an insight into the structure of the ego. We already have before us, however, a notable attempt by Ferenczi to make a theoretical construction of the stages of development of the ego, and there are at least two points at which we have a solid basis for judging that development. It is not our belief that a person's libidinal interests are from the first in opposition to his self-preservation interests; on the contrary, the ego endeavours at every stage to remain in harmony with its sexual organization as it is at the time and to fit itself into it. The succession of the different phases of libidinal development probably follows a prescribed programme. But the possibility cannot be rejected that this course of events can be influenced by the ego, and we may expect equally to find a certain parallelism, a certain correspondence, between the developmental phases of the ego and the libido; indeed a disturbance of that correspondence might provide a pathogenic factor. We are now faced by the important consideration of how the ego behaves if its libido leaves a strong fixation behind at some point in its (the libido's) development. The ego may accept this and consequently become to that extent perverse or, what is the same thing, infantile. It may, however, adopt a non-compliant attitude to the libido's settling down in this position, in which case the ego experiences a repression where the libido has experienced a fixation.

[1916-1917, 3412]
A perversion in childhood, as is well known, may become the basis for the construction of a perversion having a similar sense and persisting throughout life, one which consumes the subject's whole sexual life. On the other hand the perversion may be broken off and remain in the background of a normal sexual development, from which, however, it continues to withdraw a certain amount of energy. The first of these alternatives was already known before the days of analysis. Analytic investigation, however, of such fully-developed cases almost bridges the gulf between the two. For we find often enough with these perverts that they too made an attempt at developing normal sexual activity, usually at the age of puberty; but their attempt had not enough force in it and was abandoned in the face of the first obstacles which inevitably arise, where upon they fell back upon their infantile fixation once and for all.

[1919e, 3653]

This process is not always performed faultlessly. Inhibitions in its development manifest themselves as the many sorts of disturbance in sexual life. When this is so, we find fixations of the libido to conditions in earlier phases, whose urge, which is independent of the normal sexual aim, is described as perversion. One such developmental inhibition, for instance, is homosexuality when it is manifest. Analysis shows that in every case a homosexual object-tie was present and in most cases persisted in a latent condition. The situation is complicated by the fact that as a rule the processes necessary for bringing about a normal outcome are not completely present or absent, but partially present, so that the final result remains dependent on these quantitative relations. In these circumstances the genital organization is, it is true, attained, but it lacks those portions of the libido which have not advanced with the rest and have remained fixated to pregenital objects and aims. This weakening shows itself in a tendency, if there is an absence of genital satisfaction or if there are difficulties in the real external world, for the libido to hark back to its earlier pregenital cathexes (regression).

[1940a [1938], 4966]
APPEARANCE OF NEW AIMS  Every external or internal factor that hinders or postpones the attainment of the normal sexual aim (such as impotence, the high price of the sexual object or the danger of the sexual act) will evidently lend support to the tendency to linger over the preparatory activities and to turn them into new sexual aims that can take the place of the normal one. Attentive examination always shows that even what seem to be the strangest of these new aims are already hinted at in the normal sexual process.

[1905d, 1483]

¹ [Footnote added 1924:] My opinion of masochism has been to a large extent altered by later reflection, based upon certain hypotheses as to the structure of the apparatus of the mind and the classes of instincts operating in it. I have been led to distinguish a primary or erotogenic masochism, out of which two later forms, feminine and moral masochism, have developed. Sadism which cannot find employment in actual life is turned round upon the subject's own self and so produces a secondary masochism, which is superadded to the primary kind. (Cf. Freud, 1924c.)

[1905d, 1484]

In this respect different cases of neurosis may behave differently: in one case the preponderating factor may be the innate strength of the tendency to perversion, in another it may be the collateral increase of that tendency owing to the libido being forced away from a normal sexual aim and sexual object. It would be wrong to represent as opposition what is in fact a co-operative relation. Neurosis will always produce its greatest effects when constitution and experience work together in the same direction. Where the constitution is a marked one it will perhaps not require the support of actual experiences; while a great shock in real life will perhaps bring about a neurosis even in an average constitution. (Incidentally, this view of the relative aetiological importance of what is innate and what is accidentally experienced applies equally in other fields.)

[1905d, 1494]

¹ [Footnote added 1915:] This does not apply only to the 'negative' tendencies to perversion which appear in neuroses but equally to the 'positive,' properly so-called, perversions. Thus these latter are to be derived not merely from a fixation of infantile tendencies but also from a regression to those tendencies as a result of other channels of the sexual current being blocked. It is for this reason that the positive perversions also are accessible to psycho-analytic therapy.

[1905d, 1543]

The sternness of the demands of civilization and the difficulty of the task of abstinence have combined to make avoidance of the union of the genitals of the two opposite sexes into the central point of abstinence and to favour other kinds of sexual activity, which, it might be said, are equivalent to semi-obedience. Since normal intercourse has been so relentlessly persecuted by morality - and also, on account of the possibilities of infection, by hygiene - what are known as the perverse forms of intercourse between the two sexes, in which other parts of the body take over the role of the genitals, have undoubtedly increased in social importance. These activities cannot, however, be regarded as being as harmless as analogous extensions in love-relationships. They are ethically objectionable, for they degrade the relationships of love between two human beings from a serious matter to a convenient game, attended by no risk and no spiritual participation. A further consequence of the aggravation of the difficulties of normal sexual life is to be found in the spread of homosexual satisfaction; in addition to all those who are homosexuals in virtue of their organization, or who became so in their childhood, there must be reckoned the great number of those in whom, in their maturer years, a blocking of the main stream of their libido has caused a widening in the side-channel of homosexuality.

[1908d, 1961]
The question of why this outburst of homosexual libido overtook the patient precisely at this period (that is, between the dates of his appointment and of his move to Dresden) cannot be answered in the absence of more precise knowledge of the story of his life. Generally speaking, every human being oscillates all through his life between heterosexual and homosexual feelings, and any frustration or disappointment in one direction is apt to drive him over into the other. We know nothing of these factors in Schreber's case, but we must not omit to draw attention to a somatic factor which may very well have been relevant. At the time of this illness Dr. Schreber was fifty-one years old, and he had therefore reached an age which is of critical importance in sexual life. It is a period at which in women the sexual function, after a phase of intensified activity, enters upon a process of far-reaching involution; nor do men appear to be exempt from its influence, for men as well as women are subject to a 'climacteric' and to the susceptibilities to disease which go along with it.¹

In my *Three Essays on the Theory of Sexuality* I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics *endeavour to protect themselves against any such sexualization of their social instinctual cathexes*, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-eroticism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) *schizophrenia*; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.

I should not have much difficulty in giving you a far more intimate picture of the relations between perversion and neurosis; but I think what I have already said will serve our purpose. We must however guard against being misled by what I have told you of the meaning of symptoms into over-estimating the frequency and intensity of people's perverse inclinations. It is possible, as you have heard, to fall ill of a neurosis as a result of a frustration of normal sexual satisfaction. But when a real frustration like this occurs, the need moves over on to abnormal methods of sexual excitation. You will later learn the way in which this happens. But in any case you will realize that as a result of this 'collateral' damming-back the perverse impulses must emerge more strongly than they would have if normal sexual satisfaction had met with no obstacle in the real world. Moreover a similar influence is to be recognized also as affecting the *manifest* perversions. In some cases they are provoked or made active if the normal satisfaction of the sexual instinct encounters too great difficulties for temporary reasons or because of permanent social regulations. In other cases, it is true, the inclination to perversions is quite independent of such favouring conditions; they are, we might say, the normal species of sexual life for those particular individuals.

¹ [1911c, 2418]

[1911c, 2431]
For the moment, perhaps, you may have an impression that I have confused rather than explained the relation between normal and perverse sexuality. But you must bear the following consideration in mind. If it is true that increased difficulty in obtaining normal sexual satisfaction in real life, or deprivation of that satisfaction, brings out perverse inclinations in people who had not shown any previously, we must suppose that there was something in these people which came half-way to meet the perversions; or, if you prefer it, the perversions must have been present in them in a latent form.
[1916-1917, 3381]

A perversion in childhood, as is well known, may become the basis for the construction of a perversion having a similar sense and persisting throughout life, one which consumes the subject's whole sexual life. On the other hand the perversion may be broken off and remain in the background of a normal sexual development, from which, however, it continues to withdraw a certain amount of energy. The first of these alternatives was already known before the days of analysis. Analytic investigation, however, of such fully-developed cases almost bridges the gulf between the two. For we find often enough with these perverts that they too made an attempt at developing normal sexual activity, usually at the age of puberty; but their attempt had not enough force in it and was abandoned in the face of the first obstacles which inevitably arise, where upon they fell back upon their infantile fixation once and for all.
[1919e, 3653]

This process is not always performed faultlessly. Inhibitions in its development manifest themselves as the many sorts of disturbance in sexual life. When this is so, we find fixations of the libido to conditions in earlier phases, whose urge, which is independent of the normal sexual aim, is described as perversion. One such developmental inhibition, for instance, is homosexuality when it is manifest. Analysis shows that in every case a homosexual object-tie was present and in most cases persisted in a latent condition. The situation is complicated by the fact that as a rule the processes necessary for bringing about a normal outcome are not completely present or absent, but partially present, so that the final result remains dependent on these quantitative relations. In these circumstances the genital organization is, it is true, attained, but it lacks those portions of the libido which have not advanced with the rest and have remained fixated to pregenital objects and aims. This weakening shows itself in a tendency, if there is an absence of genital satisfaction or if there are difficulties in the real external world, for the libido to hark back to its earlier pregenital cathexes (regression).
[1940a [1938], 4966]
¹ [Footnote added 1915:] In such circumstances one often finds that at puberty a normal sexual current begins to operate at first, but that, as a result of its internal weakness, it breaks down in face of the first external obstacles and is then replaced by regression to the perverse fixation.
[1905d, 1547]

In obsessional neurosis, on the contrary, it is the regression of the libido to the preliminary stage of the sadistic-anal organization that is the most striking fact and the one which is decisive for what is manifested in symptoms. The love-impulse is obliged, when this has happened, to disguise itself as a sadistic impulse. The obsessional idea 'I should like to kill you', when it has been freed from certain additions which are not a matter of chance but are indispensable, means at bottom nothing other than 'I should like to enjoy you in love'. If you consider further that there has been a simultaneous regression in regard to the object, so that these impulses apply only to those who are nearest and dearest to the patient, you can form some idea of the horror which these obsessions arouse in him and at the same time of the alien appearance which they present to his conscious perception. But repression, too, plays a great part in the mechanism of these neuroses, though in a cursory introduction like ours this is not easily demonstrated. A regression of the libido without repression would never produce a neurosis but would lead to a perversion. From this you can see that repression is the process which is most peculiar to neuroses and is most characteristic of them. Perhaps I may have an opportunity later of telling you what we know of the mechanism of the perversions, and you will see that in their case too things are not so simple as we should be glad to make them out.
[1916-1917, 3407]

A perversion in childhood, as is well known, may become the basis for the construction of a perversion having a similar sense and persisting throughout life, one which consumes the subject's whole sexual life. On the other hand the perversion may be broken off and remain in the background of a normal sexual development, from which, however, it continues to withdraw a certain amount of energy. The first of these alternatives was already known before the days of analysis. Analytic investigation, however, of such fully-developed cases almost bridges the gulf between the two. For we find often enough with these perverts that they too made an attempt at developing normal sexual activity, usually at the age of puberty; but their attempt had not enough force in it and was abandoned in the face of the first obstacles which inevitably arise, where upon they fell back upon their infantile fixation once and for all.
[1919e, 3653]
Little light is thrown upon the genesis of masochism by our discussion of the beating-phantasy. To begin with, there seems to be a confirmation of the view that masochism is not the manifestation of a primary instinct, but originates from sadism which has been turned round upon the self - that is to say, by means of regression from an object to the ego.¹ Instincts with a passive aim must be taken for granted as existing, especially among women. But passivity is not the whole of masochism. The characteristic of unpleasure belongs to it as well, - a bewildering accompaniment to the satisfaction of an instinct. The transformation of sadism into masochism appears to be due to the influence of the sense of guilt which takes part in the act of repression. Thus repression is operative here in three ways: it renders the consequences of the genital organization unconscious, it compels that organization itself to regress to the earlier sadistic-anal stage, and it transforms the sadism of this stage into masochism, which is passive and again in a certain sense narcissistic. The second of these three effects is made possible by the weakness of the genital organization, which must be presupposed in these cases. The third becomes necessary because the sense of guilt takes as much objection to sadism as to incestuous object-choice genitally conceived. Again, the analyses do not tell us the origin of the sense of guilt itself. It seems to be brought along by the new phase upon which the child is entering, and, if it afterwards persists, it seems to correspond to a scar-like formation which is similar to the sense of inferiority. According to our present orientation in the structure of the ego, which is as yet uncertain, we should assign it to the agency in the mind which sets itself up as a critical conscience over against the rest of the ego, which produces Silberer's functional phenomenon in dreams, and which cuts itself loose from the ego in delusions of being watched. [1919e, 3654]

This process is not always performed faultlessly. Inhibitions in its development manifest themselves as the many sorts of disturbance in sexual life. When this is so, we find fixations of the libido to conditions in earlier phases, whose urge, which is independent of the normal sexual aim, is described as perversion. One such developmental inhibition, for instance, is homosexuality when it is manifest. Analysis shows that in every case a homosexual object-tie was present and in most cases persisted in a latent condition. The situation is complicated by the fact that as a rule the processes necessary for bringing about a normal outcome are not completely present or absent, but partially present, so that the final result remains dependent on these quantitative relations. In these circumstances the genital organization is, it is true, attained, but it lacks those portions of the libido which have not advanced with the rest and have remained fixated to pregenital objects and aims. This weakening shows itself in a tendency, if there is an absence of genital satisfaction or if there are difficulties in the real external world, for the libido to hark back to its earlier pregenital cathexes (regression). [1940a [1938], 4966]
We are all familiar with the delusional imaginings of the paranoic, which are concerned with the greatness and the sufferings of his own self and which appear in forms that are quite typical and almost monotonous. We have also become acquainted, through numerous accounts, with the strange performances with which certain perverts stage their sexual satisfaction, whether in idea or reality. Nevertheless, it may be new to some readers to hear that quite analogous psychical structures are regularly present in all the psychoneuroses, particularly in hysteria, and that these latter - which are known as hysterical phantasies - can be seen to have important connections with the causation of the neurotic symptoms.

[1908a, 1932]

We have sufficient acquaintance with this kind of masochism in men (to whom, owing to the material at my command, I shall restrict my remarks), derived from masochistic - and therefore often impotent - subjects whose phantasies either terminate in an act of masturbation or represent a sexual satisfaction in themselves. The real-life performances of masochistic perverts tally completely with these phantasies, whether the performances are carried out as an end in themselves or serve to induce potency and to lead to the sexual act. In both cases - for the performances are, after all, only a carrying-out of the phantasies in play - the manifest content is of being gagged, bound, painfully beaten, whipped, in some way maltreated, forced into unconditional obedience, dirtied and debased. It is far more rare for mutilations to be included in the content, and then only subject to strict limitations. The obvious interpretation, and one easily arrived at, is that the masochist wants to be treated like a small and helpless child, but, particularly, like a naughty child. It is unnecessary to quote cases to illustrate this; for the material is very uniform and is accessible to any observer, even to non-analysts. But if one has an opportunity of studying cases in which the masochistic phantasies have been especially richly elaborated, one quickly discovers that they place the subject in a characteristically female situation; they signify, that is, being castrated, or copulated with, or giving birth to a baby. For this reason I have called this form of masochism, a potiori as it were, the feminine form, although so many of its features point to infantile life. This superimposed stratification of the infantile and the feminine will find a simple explanation later on. Being castrated - or being blinded, which stands for it - often leaves a negative trace of itself in phantasies, in the condition that no injury is to occur precisely to the genitals or the eyes. (Masochistic tortures, incidentally, rarely make such a serious impression as the cruelties of sadism, whether imagined or performed.) A sense of guilt, too, finds expression in the manifest content of masochistic phantasies; the subject assumes that he has committed some crime (the nature of which is left indefinite) which is to be expiated by all these painful and tormenting procedures. This looks like a superficial rationalization of the masochistic subject-matter, but behind it there lies a connection with infantile masturbation. On the other hand, this factor of guilt provides a transition to the third, moral, form of masochism.

[1924c, 4074]
The fact that moral masochism is unconscious leads us to an obvious clue. We were able to translate the expression 'unconscious sense of guilt' as meaning a need for punishment at the hands of a parental power. We now know that the wish, which so frequently appears in phantasies, to be beaten by the father stands very close to the other wish, to have a passive (feminine) sexual relation to him and is only a regressive distortion of it. If we insert this explanation into the content of moral masochism, its hidden meaning becomes clear to us. Conscience and morality have arisen through the overcoming, the desexualization, of the Oedipus complex; but through moral masochism morality becomes sexualized once more, the Oedipus complex is revived and the way is opened for a regression from morality to the Oedipus complex. This is to the advantage neither of morality nor of the person concerned. An individual may, it is true, have preserved the whole or some measure of ethical sense alongside of his masochism; but, alternatively, a large part of his conscience may have vanished into his masochism. Again, masochism creates a temptation to perform 'sinful' actions, which must then be expiated by the reproaches of the sadistic conscience (as is exemplified in so many Russian character-types) or by chastisement from the great parental power of Destiny. In order to provoke punishment from this last representative of the parents, the masochist must do what is inexpedient, must act against his own interests, must ruin the prospects which open out to him in the real world and must, perhaps, destroy his own real existence.

[1924c, 4081]
Nevertheless, in some of these perversions the quality of the new sexual aim is of a kind to demand special examination. Certain of them are so far removed from the normal in their content that we cannot avoid pronouncing them ‘pathological’. This is especially so where (as, for instance, in cases of licking excrement or of intercourse with dead bodies) the sexual instinct goes to astonishing lengths in successfully overriding the resistances of shame, disgust, horror or pain. But even in such cases we should not be too ready to assume that people who act in this way will necessarily turn out to be insane or subject to grave abnormalities of other kinds. Here again we cannot escape from the fact that people whose behaviour is in other respects normal can, under the domination of the most unruly of all the instincts, put themselves in the category of sick persons in the single sphere of sexual life. On the other hand, manifest abnormality in the other relations of life can invariably be shown to have a background of abnormal sexual conduct.

TWO CONCLUSIONS Our study of the perversions has shown us that the sexual instinct has to struggle against certain mental forces which act as resistances, and of which shame and disgust are the most prominent. It is permissible to suppose that these forces play a part in restraining that instinct within the limits that are regarded as normal; and if they develop in the individual before the sexual instinct has reached its full strength, it is no doubt they that will determine the course of its development.²

² [Footnote added 1915:] On the other hand, these forces which act like dams upon sexual development - disgust, shame and morality - must also be regarded as historical precipitates of the external inhibitions to which the sexual instinct has been subjected during the psychogenesis of the human race. We can observe the way in which, in the development of individuals, they arise at the appropriate moment, as though spontaneously, when upbringing and external influence give the signal.

SEXUAL INHIBITIONS It is during this period of total or only partial latency that are built up the mental forces which are later to impede the course of the sexual instinct and, like dams, restrict its flow - disgust, feelings of shame and the claims of aesthetic and moral ideals. One gets an impression from civilized children that the construction of these dams is a product of education, and no doubt education has much to do with it. But in reality this development is organically determined and fixed by heredity, and it can occasionally occur without any help at all from education. Education will not be trespassing beyond its appropriate domain if it limits itself to following the lines which have already been laid down organically and to impressing them somewhat more clearly and deeply.

REACTION-FORMATION AND SUBLIMATION What is it that goes to the making of these constructions which are so important for the growth of a civilized and normal individual? They probably emerge at the cost of the infantile sexual impulses themselves. Thus the activity of those impulses does not cease even during this period of latency, though their energy is diverted, wholly or in great part, from their sexual use and directed to other ends. Historians of civilization appear to be at one in assuming that powerful components are acquired for every kind of cultural achievement by this diversion of sexual instinctual forces from sexual aims and their direction to new ones - a process which deserves the name of ‘sublimation’. To this we would add, accordingly, that the same process plays a part in the development of the individual and we would place its beginning in the period of sexual latency of childhood.¹

¹ [1905d, 1500]
It is possible further to form some idea of the mechanism of this process of sublimation. On the one hand, it would seem, the sexual impulses cannot be utilized during these years of childhood, since the reproductive functions have been deferred - a fact which constitutes the main feature of the period of latency. On the other hand, these impulses would seem in themselves to be perverse - that is, to arise from erotogenic zones and to derive their activity from instincts which, in view of the direction of the subject's development, can only arouse unpleasurable feelings. They consequently evoke opposing mental forces (reacting impulses) which, in order to suppress this unpleasure effectively, build up the mental dams that have already mentioned - disgust, shame and morality.²

POLYMORPHOUSLY PERVERSE DISPOSITION It is an instructive fact that under the influence of seduction children can become polymorphously perverse, and can be led into all possible kinds of sexual irregularities. This shows that an aptitude for them is innately present in their disposition. There is consequently little resistance towards carrying them out, since the mental dams against sexual excesses - shame, disgust and morality - have either not yet been constructed at all or are only in course of construction, according to the age of the child. In this respect children behave in the same kind of way as an average uncultivated woman in whom the same polymorphously perverse disposition persists. Under ordinary conditions she may remain normal sexually, but if she is led on by a clever seducer she will find every sort of perversion to her taste, and will retain them as part of her own sexual activities. Prostitutes exploit the same polymorphous, that is, infantile, disposition for the purposes of their profession; and, considering the immense number of women who are prostitutes or who must be supposed to have an aptitude for prostitution without becoming engaged in it, it becomes impossible not to recognize that this same disposition to perversions of every kind is a general and fundamental human characteristic.

² [1905d, 1500] [1905d, 1510]
COMPONENT INSTINCTS   Moreover, the effects of seduction do not help to reveal the early history of the sexual instinct; they rather confuse our view of it by presenting children prematurely with a sexual object for which the infantile sexual instinct at first shows no need. It must, however, be admitted that infantile sexual life, in spite of the preponderating dominance of erotogenic zones, exhibits components which from the very first involve other people as sexual objects. Such are the instincts of scopophilia, exhibitionism and cruelty, which appear in a sense independently of erotogenic zones; these instincts do not enter into intimate relations with genital life until later, but are already to be observed in childhood as independent impulses, distinct in the first instance from erotogenic sexual activity. Small children are essentially without shame, and at some periods of their earliest years show an unmistakable satisfaction in exposing their bodies, with especial emphasis on the sexual parts. The counterpart of this supposedly perverse inclination, curiosity to see other people's genitals, probably, does not become manifest until somewhat later in childhood, when the obstacle set up by a sense of shame has already reached a certain degree of development. Under the influence of seduction the scopophilic perversion can attain great importance in the sexual life of a child. But my researches into the early years of normal people, as well as of neurotic patients, force me to the conclusion that scopophilia can also appear in children as a spontaneous manifestation. Small children whose attention has once been drawn - as a rule by masturbation - to their own genitals usually take the further step without help from outside and develop a lively interest in the genitals of their playmates. Since opportunities for satisfying curiosity of this kind usually occur only in the course of satisfying the two kinds of need for excretion, children of this kind turn into voyeurs, eager spectators of the processes of micturition and defaecation. When repression of these inclinations sets in, the desire to see other people's genitals (whether of their own or the opposite sex) persists as a tormenting compulsion, which in some cases of neurosis later affords the strongest motive force for the formation of symptoms.

[1905d, 1511]

The time has arrived for me to attempt to summarize what I have said. We started out from the aberrations of the sexual instinct in respect of its object and of its aim and we were faced by the question of whether these arise from an innate disposition or are acquired as a result of experiences in life. We arrived at an answer to this question from an understanding, derived from psycho-analytic investigation, of the workings of the sexual instinct in psychoneurotics, a numerous class of people and one not far removed from the healthy. We found that in them tendencies to every kind of perversion can be shown to exist as unconscious forces and betray their presence as factors leading to the formation of symptoms. It was thus possible to say that neurosis is, as it were, the negative of perversion. In view of what was now seen to be the wide dissemination of tendencies to perversion we were driven to the conclusion that a disposition to perversions is an original and universal disposition of the human sexual instinct and that normal sexual behaviour is developed out of it as a result of organic changes and psychical inhibitions occurring in the course of maturation; we hoped to be able to show the presence of this original disposition in childhood. Among the forces restricting the direction taken by the sexual instinct we laid emphasis upon shame, disgust, pity and the structures of morality and authority erected by society. We were thus led to regard any established aberration from normal sexuality as an instance of developmental inhibition and infantilism. Though it was necessary to place in the foreground the importance of the variations in the original disposition, a co-operative and not an opposing relation was to be assumed as existing between them and the influences of actual life. It appeared, on the other hand, that since the original disposition is necessarily a complex one, the sexual instinct itself must be something put together from various factors, and that in the perversions it falls apart, as it were, into its components. The perversions were thus seen to be on the one hand inhibitions, and on the other hand dissociations, of normal development. Both these aspects were brought together in the supposition that the sexual instinct of adults arises from a combination of a number of impulses of childhood into a unity, an impulsion with a single aim.

[1905d, 1542]
We know what is meant by 'smut': the intentional bringing into prominence of sexual facts and relations by speech. This definition, however, is no more valid than other definitions. In spite of this definition, a lecture on the anatomy of the sexual organs or the physiology of procreation need not have a single point of contact with smut. It is a further relevant fact that smut is directed to a particular person, by whom one is sexually excited and who, on hearing it, is expected to become aware of the speaker's excitement and as a result to become sexually excited in turn. Instead of this excitement the other person may be led to feel shame or embarrassment, which is only a reaction against the excitement and, in a roundabout way, is an admission of it. Smut is thus originally directed towards women and may be equated with attempts at seduction. If a man in a company of men enjoys telling or listening to smut, the original situation, which owing to social inhibitions cannot be realized, is at the same time imagined. A person who laughs at smut that he hears is laughing as though he were the spectator of an act of sexual aggression.

[1905c, 1694]

The sexual material which forms the content of smut includes more than what is peculiar to each sex; it also includes what is common to both sexes and to which the feeling of shame extends - that is to say, what is excremental in the most comprehensive sense. This is, however, the sense covered by sexuality in childhood, an age at which there is, as it were, a cloaca within which what is sexual and what is excremental are barely or not at all distinguished.¹ Throughout the whole range of the psychology of the neuroses, what is sexual includes what is excremental, and is understood in the old, infantile, sense.

[1905c, 1694]

I know that no one is prepared to believe in a state of things so long as it appears to be unintelligible and to offer no angle from which an explanation can be attempted. But we can at least bring the underlying factors nearer to our understanding by the help of the postulates I laid down in my *Three Essays on the Theory of Sexuality* in 1905. I there attempted to show that the sexual instinct of man is highly complex and is put together from contributions made by numerous constituents and component instincts. Important contributions to 'sexual excitation' are furnished by the peripheral excitations of certain specially designated parts of the body (the genitals, mouth, anus, urethra), which therefore deserve to be described as 'erotogenic zones'. But the amounts of excitation coming in from these parts of the body do not all undergo the same vicissitudes, nor is the fate of all of them the same at every period of life. Generally speaking, only a part of them is made use of in sexual life; another part is deflected from sexual aims and directed towards others - a process which deserves the name of 'sublimation'. During the period of life which may be called the period of 'sexual latency' - i.e. from the completion of the fifth year to the first manifestations of puberty (round about the eleventh year) - reaction-formations, or counter-forces, such as shame, disgust and morality, are created in the mind. They are actually formed at the expense of the excitations proceeding from the erotogenic zones, and they rise like dams to oppose the later activity of the sexual instincts. Now anal erotism is one of the components of the instinct which, in the course of development and in accordance with the education demanded by our present civilization, have become unserviceable for sexual aims. It is therefore plausible to suppose that these character-traits of orderliness, parsimony and obstinacy, which are so often prominent in people who were formerly anal erotics, are to be regarded as the first and most constant results of the sublimation of anal erotism.²

[1908b, 1943]
SEXUAL USE OF THE MUCOUS MEMBRANE OF THE LIPS AND MOUTH

The use of the mouth as a sexual organ is regarded as a perversion if the lips (or tongue) of one person are brought into contact with the genitals of another, but not if the mucous membranes of the lips of both of them come together. This exception is the point of contact with what is normal. Those who condemn the other practices (which have no doubt been common among mankind from primaeval times) as being perversions, are giving way to an unmistakable feeling of disgust, which protects them from accepting sexual aims of the kind. The limits of such disgust are, however, often purely conventional: a man who will kiss a pretty girl's lips passionately, may perhaps be disgusted at the idea of using her toothbrush, though there are no grounds for supposing that his own oral cavity, for which he feels no disgust, is any cleaner than the girl's. Here, then, our attention is drawn to the factor of disgust, which interferes with the libidinal overvaluation of the sexual object but can in turn be overridden by libido. Disgust seems to be one of the forces which have led to a restriction of the sexual aim. These forces do not as a rule extend to the genitals themselves. But there is no doubt that the genitals of the opposite sex can in themselves be an object of disgust and that such an attitude is one of the characteristics of all hysterics, and especially of hysterical women. The sexual instinct in its strength enjoys overriding this disgust. (See below.)

[1905d, 1478]

The force which opposes scopophilia, but which may be overridden by it (in a manner parallel to what we have previously seen in the case of disgust), is shame.

[1905d, 1483]
In the perversions which are directed towards looking and being looked at, we come across a very remarkable characteristic with which we shall be still more intensely concerned in the aberration that we shall consider next: in these perversions the sexual aim occurs in two forms, an active and a passive one.

[1905d, 1483]

But the most remarkable feature of this perversion is that its active and passive forms are habitually found to occur together in the same individual. A person who feels pleasure in producing pain in someone else in a sexual relationship is also capable of enjoying as pleasure any pain which he may himself derive from sexual relations. A sadist is always at the same time a masochist, although the active or the passive aspect of the perversion may be the more strongly developed in him and may represent his predominant sexual activity.³

[1905d, 1485]

We find, then, that certain among the impulses to perversion occur regularly as pairs of opposites; and this, taken in conjunction with material which will be brought forward later, has a high theoretical significance. It is, moreover, a suggestive fact that the existence of the pair of opposites formed by sadism and masochism cannot be attributed merely to the element of aggressiveness. We should rather be inclined to connect the simultaneous presence of these opposites with the opposing masculinity and femininity which are combined in bisexuality - a contrast which often has to be replaced in psycho-analysis by that between activity and passivity.

[1905d, 1485]

² [Footnote added 1924:] The enquiry mentioned above has led me to assign a peculiar position, based upon the origin of the instincts, to the pair of opposites constituted by sadism and masochism, and to place them outside the class of the remaining 'perversions'.

[1905d, 1485]

³ Instead of multiplying the evidence for this statement, I will quote a passage from Havelock Ellis (1913, 119): 'The investigation of histories of sadism and masochism, even those given by Krafft-Ebing (as indeed Colin Scott and Féré have already pointed out), constantly reveals traces of both groups of phenomena in the same individual.'

[1905d, 1485]

(a) Whenever we find in the unconscious an instinct of this sort which is capable of being paired off with an opposite one, this second instinct will regularly be found in operation as well. Every active perversion is thus accompanied by its passive counterpart: anyone who is an exhibitionist in his unconscious is at the same time a voyeur; in anyone who suffers from the consequences of repressed sadistic impulses there is sure to be another determinant of his symptoms which has its source in masochistic inclinations. The complete agreement which is here shown with what we have found to exist in the corresponding 'positive' perversions is most remarkable, though in the actual symptoms one or other of the opposing tendencies plays the predominant part.

[1905d, 1491]
If we put together what we have learned from our investigation of positive and negative perversions, it seems plausible to trace them back to a number of 'component instincts', which, however, are not of a primary nature, but are susceptible to further analysis. By an 'instinct' is provisionally to be understood the psychical representative of an endosomatic, continuously flowing source of stimulation, as contrasted with a 'stimulus', which is set up by single excitations coming from without. The concept of instinct is thus one of those lying on the frontier between the mental and the physical. The simplest and likeliest assumption as to the nature of instincts would seem to be that in itself an instinct is without quality, and, so far as mental life is concerned, is only to be regarded as a measure of the demand made upon the mind for work. What distinguishes the instincts from one another and endows them with specific qualities is their relation to their somatic sources and to their aims. The source of an instinct is a process of excitation occurring in an organ and the immediate aim of the instinct lies in the removal of this organic stimulus.¹

It can only help to clarify things if at this point we go back to fundamental facts. A desire to see the organs peculiar to each sex exposed is one of the original components of our libido. It may itself be a substitute for something earlier and go back to a hypothetical primary desire to touch the sexual parts. As so often, looking has replaced touching.¹ The libido for looking and touching is present in everyone in two forms, active and passive, male and female; and, according to the preponderance of the sexual character, one form or the other predominates. It is easy to observe the inclination to self-exposure in young children. In cases in which the germ of this inclination escapes its usual fate of being buried and suppressed, it develops in men into the familiar perversion known as exhibitionism. In women the inclination to passive exhibitionism is almost invariably buried under the imposing reactive function of sexual modesty, but not without a loophole being left for it in relation to clothes. I need only hint at the elasticity and variability in the amount of exhibitionism that women are permitted to retain in accordance with differing convention and circumstances.

The pleasure which a person takes in his own sexual organ may become associated with scopophilia (or sexual pleasure in looking) in its active and passive forms, in a manner which has been very aptly described by Alfred Adler (1908) as 'confluence of instincts'. So little Hans began to try to get a sight of other people's widdlers; his sexual curiosity developed, and at the same time he liked to exhibit his own widdler. One of his dreams, dating from the beginning of his period of repression, expressed a wish that one of his little girl friends should assist him in widdling, that is, that she should share the spectacle. The dream shows, therefore, that up till then this wish had subsisted unrepressed, and later information confirmed the fact that he had been in the habit of gratifying it. The active side of his sexual scopophilia soon became associated in him with a definite theme. He repeatedly expressed both to his father and his mother his regret that he had never yet seen their widdlers; and it was probably the need for making a comparison which impelled him to do this. The ego is always the standard by which one measures the external world; one learns to understand it by means of a constant comparison with oneself. Hans had observed that large animals had widdlers that were correspondingly larger than his; he consequently suspected that the same was true of his parents, and was anxious to make sure of this. His mother, he thought, must certainly have a widdler 'like a horse'. He was then prepared with the comforting reflection that his widdler would grow with him. It was as though the child's wish to be bigger had been concentrated on his genitals.²

[1905d, 1492]

[1905c, 1695]

[1909b, 2091]
Infantile sexuality exhibits two other characteristics which are of importance from a biological point of view. It turns out to be put together from a number of component instincts which seem to be attached to certain regions of the body ('erotogenic zones') and some of which emerge from the beginning in pairs of opposites - instincts with an active and a passive aim. Just as in later life what is loved is not merely the object's sexual organs but his whole body, so from the very first it is not merely the genitals but many other parts of the body which are the seat of sexual excitation and respond to appropriate stimuli with sexual pleasure. This fact is closely related to the second characteristic of infantile sexuality - namely that to start with it is attached to the functions of nutrition and excretion, and, in all probability, of muscular excitation and sensory activity.

Examples of the first process are met with in the two pairs of opposites: sadism-masochism and scopophilia-exhibitionism. The reversal affects only the aims of the instincts. The active aim (to torture, to look at) is replaced by the passive aim (to be tortured, to be looked at). Reversal of content is found in the single instance of the transformation of love into hate.

The third antithesis of loving, the transformation of loving into being loved, corresponds to the operation of the polarity of activity and passivity, and is to be judged in the same way as the cases of scopophilia and sadism.

These primitive impulses undergo a lengthy process of development before they are allowed to become active in the adult. They are inhibited, directed towards other aims and fields, become commingled, alter their objects, and are to some extent turned back upon their possessor. Reaction-formations against certain instincts take the deceptive form of a change in their content, as though egoism had changed into altruism, or cruelty into pity. These reaction-formations are facilitated by the circumstance that some instinctual impulses make their appearance almost from the first in pairs of opposites - a very remarkable phenomenon, and one strange to the lay public, which is termed 'ambivalence of feeling'. The most easily observed and comprehensible instance of this is the fact that intense love and intense hatred are so often to be found together in the same person. Psycho-analysis adds that the two opposed feelings not infrequently have the same person for their object.

The second group is led by perverts who have made what is normally only an introductory or preparatory act into the aim of their sexual wishes. They are people whose desire it is to look at the other person or to feel him or to watch him in the performance of his intimate actions, or who expose parts of their own bodies which should be covered, in the obscure expectation that they may be rewarded by a corresponding action in return. Next come the sadists, puzzling people whose tender endeavours have no other aim than to cause pain and torment to their object, ranging from humiliation to severe physical injuries; and, as though to counterbalance them, their counterparts, the masochists, whose only pleasure it is to suffer humiliations and torments of every kind from their loved object either symbolically or in reality. There are still others in whom several of these abnormal preconditions are united and intertwined; and lastly, we must learn that each of these groups is to be found in two forms: alongside of those who seek their sexual satisfaction in reality are those who are content merely to imagine that satisfaction, who need no real object at all, but can replace it by their phantasies.
No doubt was left in the analysis that these passive trends had made their appearance at the same time as the active-sadistic ones, or very soon after them.¹ This is in accordance with the unusually clear, intense, and constant ambivalence of the patient, which was shown here for the first time in the even development of both members of the pairs of contrary component instincts. Such behaviour was also characteristic of his later life, and so was this further trait: no position of the libido which had once been established was ever completely replaced by a later one. It was rather left in existence side by side with all the others, and this allowed him to maintain an incessant vacillation which proved to be incompatible with the acquisition of a stable character.

[1918b, 3517]

The inadequacy of this explanation is seen, however, in the fact that it throws no light on the regular and close connections of masochism with its counterpart in instinctual life, sadism. If we go back a little further, to our hypothesis of the two classes of instincts which we regard as operative in the living organism, we arrive at another derivation of masochism, which, however, is not in contradiction with the former one. In (multicellular) organisms the libido meets the instinct of death, or destruction, which is dominant in them and which seeks to disintegrate the cellular organism and to conduct each separate unicellular organism into a state of inorganic stability (relative though this may be). The libido has the task of making the destroying instinct innocuous, and it fulfils the task by diverting that instinct to a great extent outwards - soon with the help of a special organic system, the muscular apparatus - towards objects in the external world. The instinct is then called the destructive instinct, the instinct for mastery, or the will to power. A portion of the instinct is placed directly in the service of the sexual function, where it has an important part to play. This is sadism proper. Another portion does not share in this transposition outwards; it remains inside the organism and, with the help of the accompanying sexual excitation described above, becomes libidinally bound there. It is in this portion that we have to recognize the original, erotogenic masochism.

[1924c, 4075]

The sexual function, as I found, is in existence from the very beginning of the individual's life, though at first it is attached to the other vital functions and does not become independent of them until later; it has to pass through a long and complicated process of development before it becomes what we are familiar with as the normal sexual life of the adult. It begins by manifesting itself in the activity of a whole number of component instincts. These are dependent upon erotogenic zones in the body; some of them make their appearance in pairs of opposite impulses (such as sadism and masochism or the impulses to look and to be looked at); they operate independently of one another in a search for pleasure, and they find their object for the most part in the subject's own body. Thus at first the sexual function is non-centralized and predominantly auto-erotic. Later, syntheses begin to appear in it; a first stage of organization is reached under the dominance of the oral components, an anal-sadistic stage follows, and it is only after the third stage has at last been reached that the primacy of the genitals is established and that the sexual function begins to serve the ends of reproduction. In the course of this process of development a number of elements of the various component instincts turn out to be unserviceable for this last end and are therefore left on one side or turned to other uses, while others are diverted from their aims and carried over into the genital organization. I gave the name of libido to the energy of the sexual instincts and to that form of energy alone. I was next driven to suppose that the libido does not always pass through its prescribed course of development smoothly. As a result either of the excessive strength of certain of the components or of experiences involving premature satisfaction, fixations of the libido may occur at various points in the course of its development. If subsequently a repression takes place, the libido flows back to these points (a process described as regression), and it is from them that the energy breaks through in the form of a symptom. Later on it further became clear that the localization of the point of fixation is what determines the choice of neurosis, that is, the form in which the subsequent illness makes its appearance.

[1925d, 4211]

CONCLUSION   It will be seen that we are not in a position to base a satisfactory explanation of the origin of inversion upon the material at present before us. Nevertheless our investigation has put us in possession of a piece of knowledge which may turn out to be of greater importance to us than the solution of that problem. It has been brought to our notice that we have been in the habit of regarding the connection between the sexual instinct and the sexual object as more intimate than it in fact is. Experience of the cases that are considered abnormal has shown us that in them the sexual instinct and the sexual object are merely soldered together - a fact which we have been in danger of overlooking in consequence of the uniformity of the normal picture, where the object appears to form part and parcel of the instinct. We are thus warned to loosen the bond that exists in our thoughts between instinct and object. It seems probable that the sexual instinct is in the first instance independent of its object; nor is its origin likely to be due to its object's attractions.

People whose sexual objects belong to the normally inappropriate sex - that is, inverts - strike the observer as a collection of individuals who may be quite sound in other respects. On the other hand, cases in which sexually immature persons (children) are chosen as sexual objects are instantly judged as sporadic aberrations. It is only exceptionally that children are the exclusive sexual objects in such a case. They usually come to play that part when someone who is cowardly or has become impotent adopts them as a substitute, or when an urgent instinct (one which will not allow of postponement) cannot at the moment get possession of any more appropriate object. Nevertheless, a light is thrown on the nature of the sexual instinct by the fact that it permits of so much variation in its objects and such a cheapening of them - which hunger, with its far more energetic retention of its objects, would only permit in the most extreme instances. A similar consideration applies to sexual intercourse with animals, which is by no means rare, especially among country people, and in which sexual attraction seems to override the barriers of species.

One would be glad on aesthetic grounds to be able to ascribe these and other severe aberrations of the sexual instinct to insanity; but that cannot be done. Experience shows that disturbances of the sexual instinct among the insane do not differ from those that occur among the healthy and in whole races or occupations. Thus the sexual abuse of children is found with uncanny frequency among school teachers and child attendants, simply because they have the best opportunity for it. The insane merely exhibit any such aberration to an intensified degree; or, what is particularly significant, it may become exclusive and replace normal sexual satisfaction entirely.

The most general conclusion that follows from all these discussions seems, however, to be this. Under a great number of conditions and in surprisingly numerous individuals, the nature and importance of the sexual object recedes into the background. What is essential and constant in the sexual instinct is something else.¹

¹ [Footnote added 1910:] The most striking distinction between the erotic life of antiquity and our own no doubt lies in the fact that the ancients laid the stress upon the instinct itself, whereas we emphasize its object. The ancients glorified the instinct and were prepared on its account to honour even an inferior object; while we despise the instinctual activity in itself, and find excuses for it only in the merits of the object.
There is absolutely no justification for distinguishing a special homosexual instinct. What constitutes a homosexual is a peculiarity not in his instinctual life but in his choice of an object. Let me recall what I have said in my *Three Essays* to the effect that we have mistakenly imagined the bond between instinct and object in sexual life as being more intimate than it really is. A homosexual may have normal instincts, but he is unable to disengage them from a class of objects defined by a particular determinant. And in his childhood, since at that period this determinant is taken for granted as being of universal application, he is able to behave like little Hans, who showed his affection to little boys and girls indiscriminately, and once described his friend Fritzl as 'the girl he was fondest of'. Hans was a homosexual (as all children may very well be), quite consistently with the fact, which must always be kept in mind, that *he was acquainted with only one kind of genital organ* - a genital organ like his own.¹

[1909b, 2094]
The time has arrived for me to attempt to summarize what I have said. We started out from the aberrations of the sexual instinct in respect of its object and of its aim and we were faced by the question of whether these arise from an innate disposition or are acquired as a result of experiences in life. We arrived at an answer to this question from an understanding, derived from psycho-analytic investigation, of the workings of the sexual instinct in psychoneurotics, a numerous class of people and one not far removed from the healthy. We found that in them tendencies to every kind of perversion can be shown to exist as unconscious forces and betray their presence as factors leading to the formation of symptoms. It was thus possible to say that neurosis is, as it were, the negative of perversion. In view of what was now seen to be the wide dissemination of tendencies to perversion we were driven to the conclusion that a disposition to perversions is an original and universal disposition of the human sexual instinct and that normal sexual behaviour is developed out of it as a result of organic changes and psychical inhibitions occurring in the course of maturation; we hoped to be able to show the presence of this original disposition in childhood. Among the forces restricting the direction taken by the sexual instinct we laid emphasis upon shame, disgust, pity and the structures of morality and authority erected by society. We were thus led to regard any established aberration from normal sexuality as an instance of developmental inhibition and infantilism. Though it was necessary to place in the foreground the importance of the variations in the original disposition, a co-operative and not an opposing relation was to be assumed as existing between them and the influences of actual life. It appeared, on the other hand, that since the original disposition is necessarily a complex one, the sexual instinct itself must be something put together from various factors, and that in the perversions it falls apart, as it were, into its components. The perversions were thus seen to be on the one hand inhibitions, and on the other hand dissociations, of normal development. Both these aspects were brought together in the supposition that the sexual instinct of adults arises from a combination of a number of impulses of childhood into a unity, an impulsion with a single aim.  

[1905d, 1542]

Where the sexual instinct is fairly intense, but perverse, there are two possible outcomes. The first, which we shall not discuss further, is that the person affected remains a pervert and has to put up with the consequences of his deviation from the standard of civilization. The second is far more interesting. It is that, under the influence of education and social demands, a suppression of the perverse instincts is indeed achieved, but it is a kind of suppression which is really no suppression at all. It can better be described as a suppression that has failed. The inhibited sexual instincts are, it is true, no longer expressed as such - and this constitutes the success of the process - but they find expression in other ways, which are quite as injurious to the subject and make him quite as useless for society as satisfaction of the suppressed instincts in an unmodified form would have done. This constitutes the failure of the process, which in the long run more than counterbalances its success. The substitutive phenomena which emerge in consequence of the suppression of the instinct amount to what we call nervous illness, or, more precisely, the psychoneuroses.¹ Neurotics are the class of people who, since they possess a recalcitrant organization, only succeed, under the influence of cultural requirements, in achieving a suppression of their instincts which is apparent and which becomes increasingly unsuccessful. They therefore only carry on their collaboration with cultural activities by a great expenditure of force and at the cost of an internal impoverishment, or are obliged at times to interrupt it and fall ill. I have described the neuroses as the ‘negative’ of the perversions because in the neuroses the perverse impulses, after being repressed, manifest themselves from the unconscious part of the mind - because the neuroses contain the same tendencies, though in a state of ‘repression’, as do the positive perversions.  

[1908d, 1954]
I have said that neurotic symptoms are substitutes for sexual satisfaction, and I indicated to you that the confirmation of this assertion by the analysis of symptoms would come up against a number of difficulties. For it can only be justified if under 'sexual satisfaction' we include the satisfaction of what are called perverse sexual needs, since an interpretation of symptoms of that kind is forced upon us with surprising frequency. The claim made by homosexuals or inverteds to being exceptions collapses at once when we learn that homosexual impulses are invariably discovered in every single neurotic, and that a fair number of symptoms give expression to this latent inversion. Those who call themselves homosexuals are only the conscious and manifest inverteds, whose number is nothing compared to that of the latent homosexuals. We are compelled, however, to regard choice of an object of one's own sex as a divergence in erotic life which is of positively habitual occurrence, and we are learning more and more to ascribe an especially high importance to it. No doubt this does not do away with the differences between manifest homosexuality and a normal attitude; their practical significance remains, but their theoretical value is greatly diminished. We have even found that a particular disease, paranoia, which is not to be counted among the transference neuroses, regularly arises from an attempt to fend off excessively strong homosexual impulses. You will perhaps recall that one of our patients (p. 3343) behaved in her obsessional action like a man, her own husband whom she had left; neurotic women very commonly produce symptoms in this way in the character of a man. Even if this is not actually to be regarded as homosexuality, it is closely related to its preconditions. [1916-1917, 3379]

Since the column of faeces stimulates the erotogenic mucous membrane of the bowel, it plays the part of an active organ in regard to it; it behaves just as the penis does to the vaginal mucous membrane, and acts as it were as its forerunner during the cloacal epoch. The handing over of faeces for the sake of (out of love for) some one else becomes a prototype of castration; it is the first occasion upon which an individual parts with a piece of his own body¹ in order to gain the favour of some other person whom he loves. So that a person's love of his own penis, which is in other respects narcissistic, is not without an element of anal erotism. 'Faeces', 'baby' and 'penis' thus form a unity, an unconscious concept (sit venia verbo) - the concept, namely, of 'a little one' that can become separated from one's body. Along these paths of association the libidinal cathexis may become displaced or intensified in ways which are pathologically important and which are revealed by analysis. [1918b, 3566]
It is, as we have seen, debatable whether the perversions go back to innate determinants or arise, as Binet assumed was the case with fetishism, owing to chance experiences. The conclusion now presents itself to us that there is indeed something innate lying behind the perversions but that it is something innate in everyone, though as a disposition it may vary in its intensity and may be increased by the influences of actual life. What is in question are the innate constitutional roots of the sexual instinct. In one class of cases (the perversions) these roots may grow into the actual vehicles of sexual activity; in others they may be submitted to an insufficient suppression (repression) and thus be able in a roundabout way to attract a considerable proportion of sexual energy to themselves as symptoms; while in the most favourable cases, which lie between these two extremes, they may by means of effective restriction and other kinds of modification bring about what is known as normal sexual life.

We have, however, a further reflection to make. This postulated constitution, containing the germs of all the perversions, will only be demonstrable in children, even though in them it is only with modest degrees of intensity that any of the instincts can emerge. A formula begins to take shape which lays it down that the sexuality of neurotics has remained in, or been brought back to, an infantile state. Thus our interest turns to the sexual life of children, and we will now proceed to trace the play of influences which govern the evolution of infantile sexuality till its outcome in perversion, neurosis or normal sexual life.

The time has arrived for me to attempt to summarize what I have said. We started out from the aberrations of the sexual instinct in respect of its object and of its aim and we were faced by the question of whether these arise from an innate disposition or are acquired as a result of experiences in life. We arrived at an answer to this question from an understanding, derived from psycho-analytic investigation, of the workings of the sexual instinct in psychoneurotics, a numerous class of people and one not far removed from the healthy. We found that in them tendencies to every kind of perversion can be shown to exist as unconscious forces and betray their presence as factors leading to the formation of symptoms. It was thus possible to say that neurosis is, as it were, the negative of perversion. In view of what was now seen to be the wide dissemination of tendencies to perversion we were driven to the conclusion that a disposition to perversions is an original and universal disposition of the human sexual instinct and that normal sexual behaviour is developed out of it as a result of organic changes and psychical inhibitions occurring in the course of maturation; we hoped to be able to show the presence of this original disposition in childhood. Among the forces restricting the direction taken by the sexual instinct we laid emphasis upon shame, disgust, pity and the structures of morality and authority erected by society. We were thus led to regard any established aberration from normal sexuality as an instance of developmental inhibition and infantilism. Though it was necessary to place in the foreground the importance of the variations in the original disposition, a co-operative and not an opposing relation was to be assumed as existing between them and the influences of actual life. It appeared, on the other hand, that since the original disposition is necessarily a complex one, the sexual instinct itself must be something put together from various factors, and that in the perversions it falls apart, as it were, into its components. The perversions were thus seen to be on the one hand inhibitions, and on the other hand dissociations, of normal development. Both these aspects were brought together in the supposition that the sexual instinct of adults arises from a combination of a number of impulses of childhood into a unity, an impulsion with a single aim.
FURTHER MODIFICATION  On the other hand, it is not possible to adopt the view that the form to be taken by sexual life is unambiguously decided, once and for all, with the inception of the different components of the sexual constitution. On the contrary, the determining process continues, and further possibilities arise according to the vicissitudes of the tributary streams of sexuality springing from their separate sources. This further modification is clearly what brings the decisive outcome, and constitutions which might be described as the same can lead to three different final results. -

[1905d, 1547]

REPRESSION A different result is brought about if in the course of development some of the components which are of excessive strength in the disposition are submitted to the process of repression (which, it must be insisted, is not equivalent to their being abolished). If this happens, the excitations concerned continue to be generated as before; but they are prevented by psychical obstruction from attaining their aim and are diverted into numerous other channels till they find their way to expression as symptoms. The outcome may be an approximately normal sexual life - though usually a restricted one - but there is in addition psychoneurotic illness. These particular cases have become familiar to us from the psychoanalytic investigation of neurotics. Their sexual life begins like that of perverts, and a considerable part of their childhood is occupied with perverse sexual activity which occasionally extends far into maturity. A reversal due to repression then occurs, owing to internal causes (usually before puberty, but now and then even long afterwards), and from that time onwards neurosis takes the place of perversion, without the old impulses being extinguished. We are reminded of the proverb 'Junge Hure, alte Betschwester',¹ only that here youth has lasted all too short a time. The fact that perversion can be replaced by neurosis in the life of the same person, like the fact which we have already mentioned that perversion and neurosis can be distributed among different members of the same family, tallies with the view that neurosis is the negative of perversion.

[1905d, 1548]

If we take the second of these stages as an average, we must point out that a number of people are, on account of their organization, not equal to meeting its demands. In whole classes of individuals the development of the sexual instinct, as we have described it above, from autoerotism to object-love with its aim of uniting the genitals, has not been carried out correctly and sufficiently fully. As a result of these disturbances of development two kinds of harmful deviation from normal sexuality - that is, sexuality which is serviceable to civilization - come about; and the relation between these two is almost that of positive and negative.¹

[1908d, 1953]

These considerations have been based so far on the requirement laid down by the second of the stages of civilization which we have postulated, the requirement that every sexual activity of the kind described as perverse is prohibited, while what is called normal sexual intercourse is freely permitted. We have found that even when the line between sexual freedom and restriction is drawn at this point, a number of individuals are ruled out as perverts, and a number of others, who make efforts not to be perverts whilst constitutionally they should be so, are forced into nervous illness. It is easy to predict the result that will follow if sexual freedom is still further circumscribed and the requirements of civilization are raised to the level of the third stage, which bans all sexual activity outside legal marriage. The number of strong natures who openly oppose the demands of civilization will increase enormously, and so will the number of weaker ones who, faced with the conflict between the pressure of cultural influences and the resistance of their constitution, take flight into neurotic illness.

[1908d, 1955]
This class of perverts at any rate behave to their sexual objects in approximately the same way as normal people do to theirs. But we now come to a long series of abnormal people whose sexual activity diverges more and more widely from what seems desirable to a sensible person. In their multiplicity and strangeness they can only be compared to the grotesque monsters painted by Breughel for the temptation of St. Anthony or to the long procession of vanished gods and believers which Flaubert heads past, before the eyes of his pious penitent. Such a medley calls for some kind of arrangement if it is not to confuse our senses. We accordingly divide them into those in whom, like the homosexuals, the sexual object has been changed, and others in whom the sexual aim is what has primarily been altered. The first group includes those who have renounced the union of the two genitals and who replace the genitals of one of the couple engaged in the sexual act by some other part or region of the body; in this they disregard the lack of suitable organic arrangements as well as any impediment offered by feelings of disgust. (They replace the vulva, for instance, by the mouth or anus.) Others follow, who, it is true, still retain the genitals as an object - not, however, on account of their sexual function but of other functions in which the genital plays a part either for anatomical reasons or because of its propinquity. We find from them that the excretory functions, which have been put aside as improper during the upbringing of children, retain the ability to attract the whole of sexual interest. Then come others again, who have abandoned the genital as an object altogether, and have taken some other part of the body as the object they desire - a woman's breast, a foot or a plait of hair. After them come others for whom parts of the body are of no importance but whose every wish is satisfied by a piece of clothing, a shoe, a piece of underclothing - the fetishists. Later in the procession come people who require the whole object indeed, but make quite definite demands of it - strange or horrible - even that it must have become a defenceless corpse, and who, using criminal violence, make it into one so that they may enjoy it. But enough of this kind of horror!

[1916-1917, 3377]
I shall at this point introduce two technical terms. Let us call the person from whom sexual attraction proceeds the *sexual object* and the act towards which the instinct tends the *sexual aim*. Scientifically sifted observation, then, shows that numerous deviations occur in respect of both of these - the sexual object and the sexual aim. The relation between these deviations and what is assumed to be normal requires thorough investigation.

[1905d, 1464]

The normal sexual aim is regarded as being the union of the genitals in the act known as copulation, which leads to a release of the sexual tension and a temporary extinction of the sexual instinct - a satisfaction analogous to the sating of hunger. But even in the most normal sexual process we may detect rudiments which, if they had developed, would have led to the deviations described as 'perversions'. For there are certain intermediate relations to the sexual object, such as touching and looking at it, which lie on the road towards copulation and are recognized as being preliminary sexual aims. On the one hand these activities are themselves accompanied by pleasure, and on the other hand they intensify the excitation, which should persist until the final sexual aim is attained. Moreover, the kiss, one particular contact of this kind, between the mucous membrane of the lips of the two people concerned, is held in high sexual esteem among many nations (including the most highly civilized ones), in spite of the fact that the parts of the body involved do not form part of the sexual apparatus but constitute the entrance to the digestive tract. Here, then, are factors which provide a point of contact between the perversions and normal sexual life and which can also serve as a basis for their classification. Perversions are sexual activities which either (a) extend, in an anatomical sense, beyond the regions of the body that are designed for sexual union, or (b) linger over the intermediate relations to the sexual object which should normally be traversed rapidly on the path towards the final sexual aim.

[1905d, 1476]

OVERVALUATION OF THE SEXUAL OBJECT   It is only in the rarest instances that the psychical valuation that is set on the sexual object, as being the goal of the sexual instinct, stops short at its genitals. The appreciation extends to the whole body of the sexual object and tends to involve every sensation derived from it. The same overvaluation spreads over into the psychological sphere: the subject becomes, as it were, intellectually infatuated (that is, his powers of judgement are weakened) by the mental achievements and perfections of the sexual object and he submits to the latter's judgements with credulity. Thus the credulity of love becomes in important, if not the most fundamental, source of authority.¹

[1905d, 1477]
SEXUAL USE OF THE MUCOUS MEMBRANE OF THE LIPS AND MOUTH  The use of the mouth as a sexual organ is regarded as a perversion if the lips (or tongue) of one person are brought into contact with the genitals of another, but not if the mucous membranes of the lips of both of them come together. This exception is the point of contact with what is normal. Those who condemn the other practices (which have no doubt been common among mankind from primaeval times) as being perversions, are giving way to an unmistakable feeling of disgust, which protects them from accepting sexual aims of the kind. The limits of such disgust are, however, often purely conventional: a man who will kiss a pretty girl's lips passionately, may perhaps be disgusted at the idea of using her tooth-brush, though there are no grounds for supposing that his own oral cavity, for which he feels no disgust, is any cleaner than the girl's. Here, then, our attention is drawn to the factor of disgust, which interferes with the libidinal overvaluation of the sexual object but can in turn be overridden by libido. Disgust seems to be one of the forces which have led to a restriction of the sexual aim. These forces do not as a rule extend to the genitals themselves. But there is no doubt that the genitals of the opposite sex can in themselves be an object of disgust and that such an attitude is one of the characteristics of all hysterics, and especially of hysterical women. The sexual instinct in its strength enjoys overriding this disgust. (See below.) [1905d, 1478]

SEXUAL USE OF THE ANAL ORIFICE  Where the anus is concerned it becomes still clearer that it is disgust which stamps that sexual aim as a perversion. I hope, however, I shall not be accused of partisanship when I assert that people who try to account for this disgust by saying that the organ in question serves the function of excretion and comes in contact with excrement - a thing which is disgusting in itself - are not much more to the point than hysterical girls who account for their disgust at the male genital by saying that it serves to void urine. [1905d, 1479]
