We thus find ourselves convinced that the problem of anxiety occupies a place in the question of the psychology of the neuroses which may rightly be described as central. We have received a strong impression of the way in which the generation of anxiety is linked to the vicissitudes of the libido and the system of the unconscious. There is only a single point that we have found disconnected - a gap in our views: the single, yet scarcely disputable, fact that realistic anxiety must be regarded as a manifestation of the ego's self-preservative instincts. [1916-1917, 3457]

LADIES AND GENTLEMEN, - We have repeatedly (and only recently once again) had to deal with the distinction between the ego-instincts and the sexual instincts. In the first place, repression showed us that the two can come into opposition to each other, that the sexual instincts are then ostensibly subdued and are obliged to find satisfaction for themselves along regressive and roundabout paths, and that in doing so they are able to find compensation for their defeat in their indomitability. We next learnt that the two kinds of instincts are from the first differently related to Necessity the educator, so that their course of development is not the same and they do not enter into the same connection with the reality principle. Lastly, we seem to have found that the sexual instincts are linked by much closer bonds than the ego-instincts to the affective state of anxiety - a conclusion which seems incomplete in only one important respect. In order to establish it more firmly, therefore, I will bring forward the further noteworthy fact that if hunger and thirst (the two most elementary self-preservative instincts) are unsatisfied, the result is never their transformation into anxiety, whereas the changing of unsatisfied libido into anxiety is, as we have seen, among the best known and most frequently observed of phenomena. [1916-1917, 3458]
The psycho-analytic explanation of the neuroses does not, however, call for such far-ranging considerations. The separate following-up of the sexual and ego-instincts has helped us to find the key to an understanding of the group of transference neuroses. We have been able to trace them back to the basic situation in which the sexual instincts have come into a dispute with the self-preservative instincts, or, to put it in biological (though less precise) terms, a situation in which one aspect of the ego, as an independent individual organism, comes into conflict with its other aspect, as a member of a succession of generations. A dissension of this kind may perhaps only occur in human beings, and on that account neurosis may, generally speaking, constitute their prerogative over the animals. The excessive development of their libido and - what is perhaps made possible precisely by that - their development of a richly articulated mental life seem to have created the determinants for the occurrence of such a conflict. It is at once obvious that these are also the determinants for the great advances that human beings have made beyond what they have in common with the animals; so that their susceptibility to neurosis would only be the reverse side of their other endowments. But these too are only speculations, which are diverting us from our immediate task.

With the help of these ideas we are now able to explain a whole number of mental states or, to express it more modestly, to describe them in terms of the libido theory - states which we must reckon as belonging to normal life, such as the psychical behaviour of a person in love, during an organic illness or when asleep. As regards the state of sleep, we assumed that it was based on turning-away from the external world and adopting a wish to sleep. The mental activity during the night which is manifested in dreams takes place, we found, in obedience to a wish to sleep and is moreover dominated by purely egoistic motives. We may now add, on the lines of the libido theory, that sleep is a state in which all object-cathexes, libidinal as well as egoistic, are given up and withdrawn into the ego. May not this throw a fresh light on the recuperating effect of sleep and on the nature of fatigue in general? The picture of the blissful isolation of intra-uterine life which a sleeper conjures up once more before us every night is in this way completed on its psychical side as well. In a sleeper the primal state of distribution of the libido is restored - total narcissism, in which libido and ego-interest, still united and indistinguishable, dwell in the self-sufficing ego.
These are a few of the findings which have hitherto been reached from the application of psycho-analysis to the narcissistic disorders. No doubt there are not yet enough of them and they still lack the precision which can only be attained from established familiarity with a new field. We owe all of them to a use of the concept of ego-libido or narcissistic libido, by whose help we can extend to the narcissistic neuroses the views which have proved their value with the transference neuroses. Now, however, you will ask whether it is possible that we shall succeed in subsuming all the disturbances of the narcissistic illnesses and of the psychoses under the libido theory, whether we look upon the libidinal factor in mental life as universally guilty of the causation of illness, and need never attribute the responsibility for it to changes in the functioning of the self-preservative instinct. Well, Ladies and Gentlemen, this question seems to me to call for no urgent reply, and, above all, not to be ripe for judgement. We can confidently leave it over in expectation of the progress of our scientific work. I should not be surprised if it turned out that the power to produce pathogenic effects was in fact a prerogative of the libidinal instincts, so that the libido theory could celebrate its triumph all along the line from the simplest 'actual' neurosis to the most severe alienation of the personality. We after all know that it is a characteristic feature of the libido that it struggles against submitting to the reality of the universe - to Ananke. But I regard it as extremely probable that the ego-instincts are carried along secondarily by the pathogenic instigation of the libido and forced into functional disturbances. Nor can I think that it would be a disaster to the trend of our researches, if what lies before us is the discovery that in severe psychoses the ego-instincts themselves have gone astray as a primary fact. The future will give the answer - to you, at any rate.

[1916-1917, 3473]

But, Ladies and Gentlemen, who has so seriously misinformed you? A recommendation to the patient to 'live a full life' sexually could not possibly play a part in analytic therapy - if only because we ourselves have declared that an obstinate conflict is taking place in him between a libidinal impulse and sexual repression, between a sensual and an ascetic trend. This conflict would not be solved by our helping one of these trends to victory over its opponent. We see, indeed, that in neurotics asceticism has the upper hand; and the consequence of this is precisely that the suppressed sexual tendency finds a way out in symptoms. If, on the contrary, we were to secure victory for sensuality, then the sexual repression that had been put on one side would necessarily be replaced by symptom. Neither of these two alternative decisions could end the internal conflict; in either case one party to it would remain unsatisfied. There are only a few cases in which the conflict is so unstable that a factor such as the doctor's taking sides could decide it; and such cases do not in fact stand in need of analytic treatment. Anyone on whom the doctor could have so much influence would have found the same way out without the doctor. You must be aware that if an abstinent young man decides in favour of illicit sexual intercourse or if an unsatisfied wife seeks relief with another man, they have not as a rule waited for permission from a doctor or even from their analyst.

[1916-1917, 3476]
But you must not conclude from my eagerness in defending myself against the charge that neurotics are encouraged in analytic treatment to live a full life - you must not conclude from this that we influence them in favour of conventional virtue. That is at least as far from being the case. It is true that we are not reformers but merely observers; nevertheless, we cannot help observing with a critical eye and we have found it impossible to side with conventional sexual morality or to form a very high opinion of the manner in which society attempts the practical regulation of the problems of sexual life. We can present society with a blunt calculation that what is described as its morality calls for a bigger sacrifice than it is worth and that its proceedings are not based on honesty and do not display wisdom. We do not keep such criticisms from our patients’ ears, we accustom them to giving unprejudiced consideration to sexual matters no less than to any others; and if, having grown independent after the completion of their treatment, they decide on their own judgement in favour of some midway position between living a full life and absolute asceticism, we feel our conscience clear whatever their choice. We tell ourselves that anyone who has succeeded in educating himself to truth about himself is permanently defended against the danger of immorality, even though his standard of morality may differ in some respect from that which is customary in society. Moreover, we must guard against over-estimating the importance of the part played by the question of abstinence in influencing neuroses. Only in a minority of cases can the pathogenic situation of frustration and the subsequent damming-up of libido be brought to an end by the sort of sexual intercourse that can be procured without much trouble.

[1916-1917, 3477]

I will digress for a moment to ask if you know what is meant by a causal therapy. That is how we describe procedure which does not take the symptoms of an illness as its point of attack but sets about removing its causes. Well, then, is our psycho-analytic method a causal therapy or not? The reply is not a simple one, but it may perhaps give us an opportunity of realizing the worthlessness of a question framed in this way. In so far as analytic therapy does not make it its first task to remove the symptoms, it is behaving like a causal therapy. In another respect, you may say, it is not. For we long ago traced the causal chain back through the repressions to the instinctual dispositions, their relative intensities in the constitution and the deviations in the course of their development. Supposing, now, that it was possible, by some chemical means, perhaps, to interfere in this mechanism, to increase or diminish the quantity of libido present at a given time or to strengthen one instinct at the cost of another - this then would be a causal therapy in the true sense of the word, for which our analysis would have carried out the indispensable preliminary work of reconnaissance. At present, as you know, there is no question of any such method of influencing libidinal processes; with our psychical therapy we attack at a different point in the combination - not exactly at what we know are the roots of the phenomena, but nevertheless far enough away from the symptoms, at a point which has been made accessible to us by some very remarkable circumstances.

[1916-1917, 3478]
I will now complete my picture of the mechanism of cure by clothing it in the formulas of the libido theory. A neurotic is incapable of enjoyment and of efficiency - the former because his libido is not directed on to any real object and the latter because he is obliged to employ a great deal of this available energy on keeping his libido under repression and on warding off its assaults. He would become healthy if the conflict between his ego and his libido came to an end and if his ego had his libido again at its disposal. The therapeutic task consists, therefore, in freeing the libido from its present attachments, which are withdrawn from the ego, and in making it once more serviceable to the ego. Where, then, is the neurotic's libido situated? It is easily found: it is attached to the symptoms, which yield it the only substitutive satisfaction possible at the time. We must therefore make ourselves masters of the symptoms and resolve them - which is precisely the same thing that the patient requires of us. In order to resolve the symptoms, we must go back as far as their origin, we must renew the conflict from which they arose, and, with the help of motive forces which were not at the patient's disposal in the past, we must guide it to a different outcome. This revision of the process of repression can be accomplished only in part in connection with the memory traces of the processes which led to repression. The decisive part of the work is achieved by creating in the patient's relation to the doctor - in the 'transference' - new editions of the old conflicts; in these the patient would like to behave in the same way as he did in the past, while we, by summoning up every available mental force, compel him to come to a fresh decision. Thus the transference becomes the battlefield on which all the mutually struggling forces should meet one another.

In any case it may be maintained that analysis of children's neuroses can claim to possess a specially high theoretical interest. They afford us, roughly speaking, as much help towards a proper understanding of the neuroses of adults as do children's dreams in respect to the dreams of adults. Not, indeed, that they are more perspicuous or poorer in elements; in fact, the difficulty of feeling one's way into the mental life of a child makes them set the physician a particularly difficult task. But nevertheless, so many of the later deposits are wanting in them that the essence of the neurosis springs to the eyes with unmistakable distinctness. In the present phase of the battle which is raging round psycho-analysis the resistance to its findings has, as we know, taken on a new form. People were content formerly to dispute the reality of the facts which are asserted by analysis; and for this purpose the best technique seemed to be to avoid examining them. That procedure appears to be slowly exhausting itself; and people are now adopting another plan of recognizing the facts, but of eliminating, by means of twisted interpretations, the consequences that follow from them, so that the critics can still ward off the objectionable novelties as efficiently as ever. The study of children's neuroses exposes the complete inadequacy of these shallow or high-handed attempts at re-interpretation. It shows the predominant part that is played in the formation of neuroses by those libidinal motive forces which are so eagerly disavowed, and reveals the absence of any aspirations towards remote cultural aims, of which the child still knows nothing, and which cannot therefore be of any significance for him.

My present readers, I take it, have not so far had anything to do with the subject and I shall be obliged, therefore, to go back some distance. Out of a great number of individual observations and impressions something in the nature of a theory has at last shaped itself in psycho-analysis, and this is known by the name of the 'libido theory'. As is well known, psycho-analysis is concerned with the elucidation and removal of what are called nervous disorders. A starting-point had to be found from which to approach this problem, and it was decided to look for it in the instinctual life of the mind. Hypotheses about the instincts in man came to form the basis, therefore, of our conception of nervous disease.
With this as a starting-point we go on to make our first important discovery. We learn that, when we try to understand neurotic disorders, by far the greater significance attaches to the sexual instincts; that in fact neuroses are the specific disorders, so to speak, of the sexual function; that in general whether or not a person develops a neurosis depends on the quantity of his libido, and on the possibility of satisfying it and of discharging it through satisfaction; that the form taken by the disease is determined by the way in which the individual passes through the course of development of his sexual function, or, as we put it, by the fixations his libido has undergone in the course of its development; and, further, that by a special, not very simple technique for influencing the mind we are able to throw light on the nature of some groups of neuroses and at the same time to do away with them. Our therapeutic efforts have their greatest success with a certain class of neuroses which proceed from a conflict between the ego-instincts and the sexual instincts. For in human beings it may happen that the demands of the sexual instincts, whose reach of course extends far beyond the individual, seem to the ego to constitute a danger which threatens its self-preservation or its self-esteem. The ego then assumes the defensive, denies the sexual instincts the satisfaction they desire and forces them into those by-paths of substitutive satisfaction which become manifest as nervous symptoms.

What I have been trying to describe in this outline is the libido theory of the neuroses, upon which are founded all our conceptions of the nature of these morbid states, together with our therapeutic measures for relieving them. We naturally regard the premises of the libido theory as valid for normal behaviour as well. We speak of the narcissism of small children, and it is to the excessive narcissism of primitive man that we ascribe his belief in the omnipotence of his thoughts and his consequent attempts to influence the course of events in the external world by the technique of magic.

'Nothing has entered into you from without; a part of the activity of your own mind has been withdrawn from your knowledge and from the command of your will. That, too, is why you are so weak in your defence; you are using one part of your force to fight the other part and you cannot concentrate the whole of your force as you would against an external enemy. And it is not even the worst or least important part of your mental forces that has thus become antagonistic to you and independent of you. The blame, I am bound to say, lies with yourself. You over-estimated your strength when you thought you could treat your sexual instincts as you liked and could utterly ignore their intentions. The result is that they have rebelled and have taken their own obscure paths to escape this suppression; they have established their rights in a manner you cannot approve. How they have achieved this, and the paths which they have taken, have not come to your knowledge. All you have learned is the outcome of their work - the symptom which you experience as suffering. Thus you do not recognize it as a derivative of your own rejected instincts and do not know that it is a substitutive satisfaction of them.
Probably very few people can have realized the momentous significance for science and life of the recognition of unconscious mental processes. It was not psycho-analysis, however, let us hasten to add, which first took this step. There are famous philosophers who may be cited as forerunners - above all the great thinker Schopenhauer, whose unconscious 'Will' is equivalent to the mental instincts of psycho-analysis. It was this same thinker, moreover, who in words of unforgettable impressiveness admonished mankind of the importance, still so greatly underestimated by it, of its sexual craving. Psycho-analysis has this advantage only, that it has not affirmed these two propositions which are so distressing to narcissism - the psychical importance of sexuality and the unconsciousness of mental life - on an abstract basis, but has demonstrated them in matters that touch every individual personally and force him to take up some attitude towards these problems. It is just for this reason, however, that it brings on itself the aversion and resistances which still hold back in awe before the great name of the philosopher.

[1917a, 3615]

The theory of psycho-analysis (a theory based on observation) holds firmly to the view that the motive forces of repression must not be sexualized. Man's archaic heritage forms the nucleus of the unconscious mind; and whatever part of that heritage has to be left behind in the advance to later phases of development, because it is unserviceable or incompatible with what is new and harmful to it, falls a victim to the process of repression. This selection is made more successfully with one group of instincts than with the other. In virtue of special circumstances which have often been pointed out already, the latter group, that of the sexual instincts, are able to defeat the intentions of repression, and to enforce their representation by substitutive formations of a disturbing kind. For this reason infantile sexuality, which is held under repression, acts as the chief motive force in the formation of symptoms; and the essential part of its content, the Oedipus complex, is the nuclear complex of neuroses. I hope that in this paper I have raised an expectation that the sexual aberrations of childhood, as well as those of mature life, are ramifications of the same complex.

[1919e, 3662]

There is, however, no need to consider that these approaches to psycho-analysis imply any reconciliation or any appeasement of opposition. Suppose someone has hitherto rejected the whole of a complex of interdependent propositions, but now suddenly finds himself in a position to convince himself of the truth of one portion of the whole. It might be thought that he will begin to hesitate about his opposition in general and permit himself some degree of deferent expectation that the other portion, about which he has had no personal experience and can consequently form no judgement of his own, may also turn out to be true. This other portion of psycho-analytic theory, with which the study of the war neuroses did not come into contact, is to the effect that the motive forces which are expressed in the formation of symptoms are sexual and that neuroses arise from a conflict between the ego and the sexual instincts which it repudiates. ('Sexuality' in this context is to be understood in the extended sense in which it is used in psycho-analysis and is not to be confused with the narrower concept of 'genitality'.) Now it is quite true, as Ernest Jones remarks in his contribution to this volume, that this portion of the theory has not yet been proved to apply to the war neuroses. The work that might prove it has not yet been taken in hand. It may be that the war neuroses are altogether unsuitable material for the purpose. But the opponents of psycho-analysis, whose dislike of sexuality is evidently stronger than their logic, have been in a hurry to proclaim that the investigation of the war neuroses has finally disproved this portion of psycho-analytic theory. They have been guilty here of a slight confusion. If the investigation of the war neuroses (and a very superficial one at that) has not shown that the sexual theory of the neuroses is correct, that is something very different from its showing that that theory is incorrect. With the help of an impartial attitude and a little good will, it should not be hard to find the way to a further clarification of the subject.

[1919d, 3666]
Apart from this, the war neuroses are only traumatic neuroses, which, as we know, occur in peace-time too after frightening experiences or severe accidents, without any reference to a conflict in the ego.

[1919d, 3667]

The theory of the sexual aetiology of the neuroses, or, as we prefer to say, the libido theory of the neuroses, was originally put forward only in relation to the transference neuroses of peace-time and is easy to demonstrate in their case by the use of the technique of analysis. But its application to the other disorders which we later grouped together as the narcissistic neuroses already met with difficulties. An ordinary dementia praecox, a paranoia or a melancholia are essentially quite unsuitable material for demonstrating the validity of the libido theory or for serving as a first introduction to an understanding of it; and it is for that reason that psychiatrists, who neglect the transference neuroses, are unable to come to terms with it. But the traumatic neuroses of peace-time have always been regarded as the most refractory material of all in this respect; so that the emergence of the war neuroses could not introduce any new factor into the situation that already existed.

[1919d, 3667]

It only became possible to extend the libido theory to the narcissistic neuroses after the concept of a 'narcissistic libido' had been put forward and applied - a concept, that is, of amount of sexual energy attached to the ego itself and finding satisfaction in the ego just as satisfaction is usually found only in objects. This entirely legitimate development of the concept of sexuality promises to accomplish as much for the severer neuroses and for the psychoses as can be expected of a theory which is feeling its way forwards on an empirical basis. The traumatic neuroses of peace will also fit into the scheme as soon as a successful outcome has been reached of our investigations into the relations which undoubtedly exist between fright, anxiety and narcissistic libido.

[1919d, 3667]

The traumatic neuroses and war neuroses may proclaim too loudly the effects of mortal danger and may be silent or speak only in muted tones of the effects of frustration in love. But, on the other hand, the ordinary transference neuroses of peace-time set no aetiological store by the factor of mortal danger which, in the former class of neuroses, plays so mighty a part. It is even held that the peace-time neuroses are promoted by indulgence, good living and inactivity - which would afford an interesting contrast to the living-conditions under which the war neuroses develop. If they were to follow the example of their opponents, psycho-analysts, finding that their patients had fallen ill owing to frustration in love (owing to the claims of the libido being unsatisfied) would have to maintain that there can be no such things as danger-neuroses or that the disorders that appear after frightening experiences are not neuroses. They have, of course, no notion of maintaining any such thing. On the contrary, a convenient possibility occurs to them of bringing the two apparently divergent sets of facts together under a single hypothesis. In traumatic and war neuroses the human ego is defending itself from a danger which threatens it from without or which is embodied in a shape assumed by the ego itself. In the transference neuroses of peace the enemy from which the ego is defending itself is actually the libido, whose demands seem to it to be menacing. In both cases the ego is afraid of being damaged - in the latter case by the libido and in the former by external violence. It might, indeed, be said that in the case of the war neuroses, in contrast to the pure traumatic neuroses and in approximation to the transference neuroses, what is feared is nevertheless an internal enemy. The theoretical difficulties standing in the way of a unifying hypothesis of this kind do not seem insuperable: after all, we have a perfect right to describe repression, which lies at the basis of every neurosis, as a reaction to a trauma - as an elementary traumatic neurosis.

[1919d, 3668]
But let us pause for a moment and reflect. It cannot be so. The sexual instincts, to which the
theory of the neuroses gives a quite special place, appear under a very different aspect.
[1920g, 3741]

Instead of this I shall make an attempt at using the concept of libido for the purpose of
throwing light upon group psychology, a concept which has done us such good service in the
study of psychoneuroses.
[1921c, 3784]

The psycho-analytic investigation of the psychoneuroses has taught us that their symptoms
are to be traced back to directly sexual impulsions which are repressed but still remain active.
We can complete this formula by adding - 'or, to aim-inhibited impulsions, whose inhibition has
not been entirely successful or has made room for a return to the repressed sexual aim'. It is in
accordance with this that a neurosis should make its victim asocial and should remove him from
the usual group formations. It may be said that a neurosis has the same disintegrating effect
upon a group as being in love. On the other hand it appears that where a powerful impetus has
been given to group formation neuroses may diminish and, at all events temporarily, disappear.
Justifiable attempts have also been made to turn this antagonism between neuroses and group
formation to therapeutic account. Even those who do not regret the disappearance of religious
illusions from the civilized world of to-day will admit that so long as they were in force they
offered those who were bound by them the most powerful protection against the danger of
neurosis. Nor is it hard to discern that all the ties that bind people to mystico-religious or
philosophico-religious sects and communities are expressions of crooked cures of all kinds of
neuroses. All of this is correlated with the contrast between directly sexual impulsions and those
which are inhibited in their aims.
[1921c, 3833]

If he is left to himself, a neurotic is obliged to replace by his own symptom formations the
great group formations from which he is excluded. He creates his own world of imagination for
himself, his own religion, his own system of delusions, and thus recapitulates the institutions of
humanity in a distorted way which is clear evidence of the dominating part played by the directly
sexual impulsions.¹
[1921c, 3833]
The Aetiological Significance of Sexual Life. - The second novelty which emerged after the hypnotic technique had been replaced by free associations was of a clinical nature. It was discovered in the course of the prolonged search for the traumatic experiences from which hysterical symptoms appeared to be derived. The more carefully the search was pursued the more extensive seemed to be the network of aetiologically significant impressions involved, but the further back, too, did they reach into the patient's puberty or childhood. At the same time they assumed a uniform character and eventually it became inevitable to bow before the evidence and recognize that at the root of the formation of every symptom there were to be found traumatic experiences from early sexual life. Thus a sexual trauma stepped into the place of an ordinary trauma and the latter was seen to owe its aetiological significance to an associative or symbolic connection with the former, which had preceded it. An investigation of cases of common nervousness (falling into the two classes of neurasthenia and anxiety neurosis) which was simultaneously undertaken led to the conclusion that these disorders could be traced to contemporary abuses in the patients' sexual life and could be removed if these were brought to an end. It was thus easy to infer that neuroses in general are an expression of disturbances in sexual life, the so-called actual-neuroses being the consequences (by chemical agency) of contemporary injuries and the psycho-neuroses the consequences (by psychical modification) of bygone injuries to a biological function which had hitherto been gravely neglected by science. None of the theses of psycho-analysis has met with such tenacious scepticism or such embittered resistance as this assertion of the preponderating aetiological significance of sexual life in the neuroses. It should, however, be expressly remarked that, in its development up to the present day, psycho-analysis has found no reason to retreat from this opinion.

[1923a, 3920]

Transference. - If further proof were needed of the truth that the motive forces behind the formation of neurotic symptoms are of a sexual nature, it would be found in the fact that in the course of analytic treatment a special emotional relation is regularly formed between the patient and the physician. This goes far beyond rational limits. It varies between the most affectionate devotion and the most obstinate enmity and derives all of its characteristics from earlier erotic attitudes of the patient's which have become unconscious. This transference alike in its positive and its negative form is used as a weapon by the resistance; but in the hands of the physician it becomes the most powerful therapeutic instrument and it plays a part scarcely to be over-estimated in the dynamics of the process of cure.

[1923a, 3924]

In a far greater number of cases the neurosis is more autonomous and more independent of the interests of self-preservation and self-maintenance. In the conflict which creates the neurosis, what are at stake are either solely libidinal interests or libidinal interests in intimate connections with self-preservative ones. In all three instances the dynamics of the neurosis are the same. A dammed-up libido which cannot be satisfied in reality succeeds, with the help of a regression to old fixations, in finding discharge through the repressed unconscious. The sick man's ego, in so far as it can extract a 'gain from illness' out of this process, countenances the neurosis, although there can be no doubt of its injuriousness in its economic aspect.

[1923d, 4027]
A conflict between two groups of mental trends had to be looked on as the ground for repression and accordingly as the cause of every neurotic illness. And here experience taught us a new and surprising fact about the nature of the forces that were struggling against each other. Repression invariably proceeded from the sick person’s conscious personality (his ego) and took its stand on aesthetic and ethical motives; the impulses that were subjected to repression were those of selfishness and cruelty, which can be summed up in general as evil, but above all sexual wishful impulses, often of the crudest and most forbidden kind. Thus the symptoms were a substitute for forbidden satisfactions and the illness seemed to correspond to an incomplete subjugation of the immoral side of human beings.

[1924f, 4106]

After hypnosis was replaced by the technique of free association, Breuer’s cathartic procedure turned into psycho-analysis, which for more than a decade was developed by the author (Freud) alone. During that time psycho-analysis gradually acquired a theory which appeared to give a satisfactory account of the origin, meaning and purpose of neurotic symptoms and provided a rational basis for medical attempts at curing the complaint. I will once again enumerate the factors that go to make up this theory. They are: emphasis on instinctual life (affectivity), on mental dynamics, on the fact that even the apparently most obscure and arbitrary mental phenomena invariably have a meaning and a causation, the theory of psychical conflict and of the pathogenic nature of repression, the view that symptoms are substitutive satisfactions, the recognition of the aetiological importance of sexual life, and in particular of the beginnings of infantile sexuality. From a philosophical standpoint this theory was bound to adopt the view that the mental does not coincide with the conscious, that mental processes are in themselves unconscious and are only made conscious by the functioning of special organs (agencies or systems). By way of completing this list, I will add that among the affective attitudes of childhood the complicated emotional relation of children to their parents - what is known as the Oedipus complex - came into prominence. It became ever clearer that this was the nucleus of every case of neurosis, and in the patient’s behaviour towards his analysand certain phenomena of his emotional transference emerged which came to be of great importance for theory and technique alike.

[1924f, 4107]

This state of affairs is enough to account for the reluctant and hesitant reception of analysis in scientific quarters. But it does not explain the outbursts of indignation, derision and scorn which, in disregard of every standard of logic and good taste, have characterized the controversial methods of its opponents. A reaction of such a kind suggests that resistances other than purely intellectual ones were stirred up and that powerful emotional forces were aroused. And there are indeed plenty of things to be found in the theory of psycho-analysis calculated to produce such an effect as this upon the passions of men of every kind and not of scientists alone. Above all there is the very important place in the mental life of human beings which psycho-analysis assigns to what are known as the sexual instincts. Psycho-analytic theory maintained that the symptoms of neuroses are distorted substitutive satisfactions of sexual instinctual forces, the direct satisfaction of which has been frustrated by internal resistances. Later on, when analysis had extended beyond its original field of work and began to be applied to normal mental life, it sought to show that these same sexual components, which could be diverted from their immediate aims and directed to other things, made the most important contributions to the cultural achievements of the individual and of society. These views were not entirely new. The incomparable significance of sexual life had been proclaimed by the philosopher Schopenhauer in an intensely impressive passage. Moreover, what psycho-analysis called sexuality was by no means identical with the impulsion towards a union of the two sexes or towards producing a pleasurable sensation in the genitals; it had far more resemblance to the all-inclusive and all-preserving Eros of Plato’s Symposium.

[1925e, 4125]
If the account I have so far given has led the reader to expect that the *Studies on Hysteria* must, in all essentials of their material content, be the product of Breuer's mind, that is precisely what I myself have always maintained and what it has been my aim to repeat here. As regards the *theory* put forward in the book, I was partly responsible, but to an extent which it is to-day no longer possible to determine. That theory was in any case unpretentious and hardly went beyond the direct description of the observations. It did not seek to establish the nature of hysteria but merely to throw light upon the origin of its symptoms. Thus it laid stress upon the significance of the life of the emotions and upon the importance of distinguishing between mental acts which are unconscious and those which are conscious (or rather capable of being conscious); it introduced a dynamic factor, by supposing that a symptom arises through the damming-up of an affect, and an economic factor, by regarding that same symptom as the product of the transformation of an amount of energy which would otherwise have been employed in some other way. (This latter process was described as *conversion*.) Breuer spoke of our method as *cathartic*; its therapeutic aim was explained as being to provide that the quota of affect used for maintaining the symptom, which had got on to the wrong lines and had, as it were, become strangulated there, should be directed on to the normal path along which it could obtain discharge (or *abreaction*). The practical results of the cathartic procedure were excellent. Its defects, which became evident later, were those of all forms of hypnotic treatment. There are still a number of psychotherapists who have not gone beyond catharsis as Breuer understood it and who still speak in its favour. Its value as an abridged method of treatment was shown afresh by Simmel in his treatment of war neuroses in the German army during the Great War. The theory of catharsis had not much to say on the subject of sexuality. In the case histories which I contributed to the *Studies* sexual factors played a certain part, but scarcely more attention was paid to them than to other emotional excitations. Breuer wrote of the girl, who has since become famous as his first patient, that her sexual side was extraordinarily undeveloped. It would have been difficult to guess from the *Studies on Hysteria* what an importance sexuality has in the aetiology of the neuroses.

[1925d, 4200]

The theory which we had attempted to construct in the *Studies* remained, as I have said, very incomplete; and in particular we had scarcely touched on the problem of aetiology, on the question of the ground in which the pathogenic process takes root. I now learned from my rapidly increasing experience that it was not any kind of emotional excitation that was in action behind the phenomena of neurosis but habitually one of a sexual nature, whether it was a current sexual conflict or the effect of earlier sexual experiences. I was not prepared for this conclusion and my expectations played no part in it, for I had begun my investigation of neurotics quite unsuspectingly. While I was writing my 'History of the Psycho-Analytic Movement' in 1914, there recurred to my mind some remarks that had been made to me by Breuer, Charcot, and Chrobak, which might have led me to this discovery earlier. But at the time I heard them I did not understand what these authorities meant; indeed they had told me more than they knew themselves or were prepared to defend. What I heard from them lay dormant and inactive within me, until the chance of my cathartic experiments brought it out as an apparently original discovery. Nor was I then aware that in deriving hysteria from sexuality I was going back to the very beginnings of medicine and following up a thought of Plato's. It was not until later that I learnt this from an essay by Havelock Ellis.

[1925d, 4202]
Under the influence of my surprising discovery, I now took a momentous step. I went beyond the domain of hysteria and began to investigate the sexual life of the so-called neurasthenics who used to visit me in numbers during my consultation hours. This experiment cost me, it is true, my popularity as a doctor, but it brought me convictions which to-day, almost thirty years later, have lost none of their force. There was a great deal of equivocation and mystery-making to be overcome, but, once that had been done, it turned out that in all of these patients grave abuses of the sexual function were present. Considering how extremely widespread are these abuses on the one hand and neurasthenia on the other, a frequent coincidence between the two would not have proved much; but there was more in it than that one bald fact. Closer observation suggested to me that it was possible to pick out from the confused jumble of clinical pictures covered by the name of neurasthenia two fundamentally different types, which might appear in any degree of mixture but which were nevertheless to be observed in their pure forms. In the one type the central phenomenon was the anxiety attack with its equivalents, rudimentary forms and chronic substitutive symptoms; I consequently gave it the name of anxiety neurosis, and limited the term neurasthenia to the other type. Now it was easy to establish the fact that each of these types had a different abnormality of sexual life as its corresponding aetiological factor: in the former, coitus interruptus, unconsummated excitation and sexual abstinence, and in the latter, excessive masturbation and too numerous nocturnal emissions. In a few specially instructive cases, which had shown a surprising alteration in the clinical picture from one type to the other, it could be proved that there had been a corresponding change in the underlying sexual régime. If it was possible to put an end to the abuse and allow its place to be taken by normal sexual activity, a striking improvement in the condition was the reward.

I was thus led into regarding the neuroses as being without exception disturbances of the sexual function, the so-called 'actual neuroses' being the direct toxic expression of such disturbances and the psychoneuroses their mental expression. My medical conscience felt pleased at my having arrived at this conclusion. I hoped that I had filled up a gap in medical science, which, in dealing with a function of such great biological importance, had failed to take into account any injuries beyond those caused by infection or by gross anatomical lesions. The medical aspect of the matter was, moreover, supported by the fact that sexuality was not something purely mental. It had a somatic side as well, and it was possible to assign special chemical processes to it and to attribute sexual excitation to the presence of some particular, though at present unknown, substances. There must also have been some good reason why the true spontaneous neuroses resembled no group of diseases more closely than the phenomena of intoxication and abstinence, which are produced by the administration or privation of certain toxic substances, or than exophthalmic goitre, which is known to depend upon the product of the thyroid gland.
During the years that followed the publication of the *Studies*, having reached these conclusions upon the part played by sexuality in the aetiology of the neuroses, I read some papers on the subject before various medical societies, but was only met with incredulity and contradiction. Breuer did what he could for some time longer to throw the great weight of his personal influence into the scales in my favour, but he effected nothing and it was easy to see that he too shrank from recognizing the sexual aetiology of the neuroses. He might have crushed me or at least disconcerted me by pointing to his own first patient, in whose case sexual factors had ostensibly played no part whatever. But he never did so, and I could not understand why this was, until I came to interpret the case correctly and to reconstruct, from some remarks which he had made, the conclusion of his treatment of it. After the work of catharsis had seemed to be completed, the girl had suddenly developed a condition of 'transference love'; he had not connected this with her illness, and had therefore retired in dismay. It was obviously painful to him to be reminded of this apparent *contretemps*. His attitude towards me oscillated for some time between appreciation and sharp criticism; then accidental difficulties arose, as they never fail to do in a strained situation, and we parted.

I have already mentioned that my investigation of the precipitating and underlying causes of the neuroses led me more and more frequently to conflicts between the subject's sexual impulses and his resistances to sexuality. In my search for the pathogenic situations in which the repressions of sexuality had set in and in which the symptoms, as substitutes for what was repressed, had had their origin, I was carried further and further back into the patient's life and ended by reaching the first years of his childhood. What poets and students of human nature had always asserted turned out to be true: the impressions of that early period of life, though they were for the most part buried in amnesia, left ineradicable traces upon the individual's growth and in particular laid down the disposition to any nervous disorder that was to follow. But since these experiences of childhood were always concerned with sexual excitations and the reaction against them, I found myself faced by the fact of *infantile sexuality* - once again a novelty and a contradiction of one of the strongest of human prejudices. Childhood was looked upon as 'innocent' and free from the lusts of sex, and the fight with the demon of 'sensuality' was not thought to begin until the troubled age of puberty. Such occasional sexual activities as it had been impossible to overlook in children were put down as signs of degeneracy or premature depravity or as a curious freak of nature. Few of the findings of psycho-analysis have met with such universal contradiction or have aroused such an outburst of indignation as the assertion that the sexual function starts at the beginning of life and reveals its presence by important signs even in childhood. And yet no other finding of analysis can be demonstrated so easily and so completely.

The theories of resistance and of repression, of the unconscious, of the aetiological significance of sexual life and of the importance of infantile experiences - these form the principal constituents of the theoretical structure of psycho-analysis. In these pages, unfortunately, I have been able to describe only the separate elements and not their interconnections and their bearing upon one another. But I am obliged now to turn to the alterations which gradually took place in the technique of the analytic method.
The World War, which broke up so many other organizations, could do nothing against our 'International'. The first meeting after the war took place in 1920, at The Hague, on neutral ground. It was moving to see how hospitably the Dutch welcomed the starving and impoverished subjects of the Central European states; and I believe this was the first occasion in a ruined world on which Englishmen and Germans sat at the same table for the friendly discussion of scientific interests. Both in Germany and in the countries of Western Europe the war had actually stimulated interest in psycho-analysis. The observation of war neuroses had at last opened the eyes of the medical profession to the importance of psychogenesis in neurotic disturbances, and some of our psychological conceptions, such as the 'gain from illness' and the 'flight into illness', quickly became popular. The last Congress before the German collapse, which was held at Budapest in 1918, was attended by official representatives of the allied governments of the Central European powers, and they agreed to the establishment of psycho-analytic Centres for the treatment of war neuroses. But this point was never reached. Similarly too the comprehensive plans made by one of our leading members, Dr. Anton von Freund, for establishing in Budapest a centre for analytic study and treatment came to grief as a result of the political upheavals that followed soon afterwards and of the premature death of their irreplaceable author. At a later date some of his ideas were put into execution by Max Eitingon, who in 1920 founded a psycho-analytical clinic in Berlin. During the brief period of Bolshevik rule in Hungary, Ferenczi was still able to carry on a successful course of instruction as the official representative of psycho-analysis at the University of Budapest. After the war our opponents were pleased to announce that events had produced a conclusive argument against the validity of the theses of analysis. The war neuroses, they said, had proved that sexual factors were unnecessary to the aetiology of neurotic disorders. But their triumph was frivolous and premature. For on the one hand no one had been able to carry out a thorough analysis of a case of war neurosis, so that in fact nothing whatever was known for certain as to their motivation and no conclusions could be drawn from this uncertainty; while on the other hand psycho-analysis had long before arrived at the concept of narcissism and of narcissistic neuroses, in which the subject's libido is attached to his own ego instead of to an object. Though on other occasions, therefore, the charge was brought against psycho-analysis of having made an unjustifiable extension of the concept of sexuality, yet, when it became convenient for controversial ends, this crime was forgotten and we were once more held down to the narrowest meaning of the word.

I should not like to create an impression that during this last period of my work I have turned my back upon patient observation and have abandoned myself entirely to speculation. I have on the contrary always remained in the closest touch with the analytic material and have never ceased working at detailed points of clinical or technical importance. Even when I have moved away from observation, I have carefully avoided any contact with philosophy proper. This avoidance has been greatly facilitated by constitutional incapacity. I was always open to the ideas of G. T. Fechner and have followed that thinker upon many important points. The large extent to which psycho-analysis coincides with the philosophy of Schopenhauer - not only did he assert the dominance of the emotions and the supreme importance of sexuality but he was even aware of the mechanism of repression - is not to be traced to my acquaintance with his teaching. I read Schopenhauer very late in my life. Nietzsche, another philosopher whose guesses and intuitions often agree in the most astonishing way with the laborious findings of psycho-analysis, was for a long time avoided by me on that very account; I was less concerned with the question of priority than with keeping my mind unembarrassed.
The neuroses were the first subject of analysis, and for a long time they were the only one. No analyst could doubt that medical practice was wrong in separating those disorders from the psychoses and in attaching them to the organic nervous diseases. The theory of the neuroses belongs to psychiatry and is indispensable as an introduction to it. It would seem, however, that the analytic study of the psychoses is impracticable owing to its lack of therapeutic results. Mental patients are as a rule without the capacity for forming a positive transference, so that the principal instrument of analytic technique is inapplicable to them. There are nevertheless a number of methods of approach to be found. Transference is often not so completely absent but that it can be used to a certain extent; and analysis has achieved undoubted successes with cyclical depressions, light paranoic modifications, and partial schizophrenias. It has at least been a benefit to science that in many cases the diagnosis can oscillate for quite a long time between assuming the presence of a psychoneurosis or of a dementia praecox; for therapeutic attempts initiated in such cases have resulted in valuable discoveries before they have had to be broken off. But the chief consideration in this connection is that so many things that in the neuroses have to be laboriously fetched up from the depths are found in the psychoses on the surface, visible to every eye. For that reason the best subjects for the demonstration of many of the assertions of analysis are provided by the psychiatric clinic. It was thus bound to happen before long that analysis would find its way to the objects of psychiatric observation. I was able very early (1896) to establish in a case of paranoid dementia the presence of the same aetiological factors and the same emotional complexes as in the neuroses. Jung explained some most puzzling stereotypies in dements by bringing them into relation with the patients' life-histories; Bleuler demonstrated the existence in various psychoses of mechanisms like those which analysis had discovered in neurotics. Since then analysts have never relaxed their efforts to come to an understanding of the psychoses. Especially since it has been possible to work with the concept of narcissism, they have managed, now in this place and now in that, to get a glimpse beyond the wall. Most of all, no doubt, was achieved by Abraham in his elucidation of the melancholias. It is true that in this sphere all our knowledge is not yet converted into therapeutic power; but the mere theoretical gain is not to be despised, and we may be content to wait for its practical application. In the long run even the psychiatrists cannot resist the convincing force of their own clinical material. At the present time German psychiatry is undergoing a kind of 'peaceful penetration' by analytic views. While they continually declare that they will never be psycho-analysts, that they do not belong to the 'orthodox' school or agree with its exaggerations, and in particular that they do not believe in the predominance of the sexual factor, nevertheless the majority of the younger workers take over one piece or another of analytic theory and apply it in their own fashion to the material. All the signs point to the proximity of further developments in the same direction.

[1925d, 4235]
If anxiety is a reaction of the ego to danger, we shall be tempted to regard the traumatic neuroses, which so often follow upon a narrow escape from death, as a direct result of a fear of death (or fear for life) and to dismiss from our minds the question of castration and the dependent relationships of the ego. Most of those who observed the traumatic neuroses that occurred during the last war took this line, and triumphantly announced that proof was now forthcoming that a threat to the instinct of self-preservation could by itself produce a neurosis without any admixture of sexual factors and without requiring any of the complicated hypotheses of psycho-analysis. It is in fact greatly to be regretted that not a single analysis of a traumatic neurosis of any value is extant. And it is to be regretted, not because such an analysis would contradict the aetiological importance of sexuality - for any such contradiction has long since been disposed of by the introduction of the concept of narcissism, which brings the libidinal cathexis of the ego into line with the cathexes of objects and emphasizes the libidinal character of the instinct of self-preservation - but because, in the absence of any analyses of this kind, we have lost a most precious opportunity of drawing decisive conclusions about the relations between anxiety and the formation of symptoms. In view of all that we know about the structure of the comparatively simple neuroses of everyday life, it would seem highly improbable that a neurosis could come into being merely because of the objective presence of danger, without any participation of the deeper levels of the mental apparatus. But the unconscious seems to contain nothing that could give any content to our concept of the annihilation of life. Castration can be pictured on the basis of the daily experience of the faeces being separated from the body or on the basis of losing the mother's breast at weaning. But nothing resembling death can ever have been experienced; or if it has, as in fainting, it has left no observable traces behind. I am therefore inclined to adhere to the view that the fear of death should be regarded as analogous to the fear of castration and that the situation to which the ego is reacting is one of being abandoned by the protecting super-ego - the powers of destiny - so that it has no longer any safeguard against all the dangers that surround it. In addition, it must be remembered that in the experiences which lead to a traumatic neurosis the protective shield against external stimuli is broken through and excessive amounts of excitation impinge upon the mental apparatus; so that we have here a second possibility - that anxiety is not only being signalled as an affect but is also being freshly created out of the economic conditions of the situation.

[1926d, 4286]

On the other hand I cannot identify myself with the view that Rank's theory contradicts the aetiological importance of the sexual instincts as hitherto recognized by psycho-analysis. For his theory only has reference to the individual's relation to the danger-situation, so that it leaves it perfectly open to us to assume that if a person has not been able to master his first dangers he is bound to come to grief as well in later situations involving sexual danger and thus be driven into a neurosis.

[1926d, 4306]
And it must be so, firstly, because analysis is entirely founded on complete candour. Financial circumstances, for instance, are discussed with equal detail and openness: things are said that are kept back from every fellow-citizen, even if he is not a competitor or a tax-collector. I will not dispute - indeed, I will myself insist with energy - that this obligation to candour puts a grave moral responsibility on the analyst as well. And it must be so, secondly, because factors from sexual life play an extremely important, a dominating, perhaps even a *specific* part among the causes and precipitating factors of neurotic illnesses. What else can analysis do but keep close to its subject-matter, to the material brought up by the patient? The analyst never entices his patient on to the ground of sex. He does not say to him in advance: 'We shall be dealing with the intimacies of your sexual life!' He allows him to begin what he has to say whenever he pleases, and quietly waits until the patient himself touches on sexual things. I used always to warn my pupils: 'Our opponents have told us that we shall come upon cases in which the factor of sex plays no part. Let us be careful not to introduce it into our analyses and so spoil our chance of finding such a case.' But so far none of us has had that good fortune.

[1926e, 4350]

I am aware, of course, that our recognition of sexuality has become - whether admittedly or not - the strongest motive for other people's hostility to analysis. Can that shake our confidence? It merely shows us how neurotic our whole civilized life is, since ostensibly normal people do not behave very differently from neurotics. At a time when psycho-analysis was solemnly put on its trial before the learned societies of Germany - to-day things have grown altogether quieter - one of the speakers claimed to possess peculiar authority because, so he said, he even allowed his patients to talk: for diagnostic purposes, clearly, and to test the assertions of analysts. 'But', he added, 'if they begin to talk about sexual matters I shut their mouths.' What do you think of that as a method of demonstration? The learned society applauded the speaker to the echo instead of feeling suitably ashamed on his account. Only the triumphant certainty afforded by the consciousness of prejudices held in common can explain this speaker's want of logical thought. Years later a few of those who had at that time been my followers gave in to the need to free human society from the yoke of sexuality which psycho-analysis was seeking to impose on it. One of them explained that what is sexual does not mean sexuality at all, but something else, something abstract and mystical. And another actually declared that sexual life is merely one of the spheres in which human beings seek to put in action their driving need for power and domination. They have met with much applause, for the moment at least.

[1926e, 4350]

I confess, moreover, that the dislike that you yourself have betrayed of assigning to the factor of sexuality so great a part in the causation of neurosis - I confess that this scarcely seems to me consistent with your task as an Impartial Person. Are you not afraid that this antipathy may interfere with your passing a just judgement?

[1926e, 4351]
Our conviction that a portion of erotic life that has been abnormally employed lies at the basis of neuroses must be unshakeably strengthened by this experience. With this discovery we are once more on a firm footing and can venture to make this love itself the object of analysis. And we can make another observation. Analytic love is not manifested in every case as clearly and blatantly as I have tried to depict it. Why not? We can soon see. In proportion as the purely sensual and the hostile sides of his love try to show themselves, the patient's opposition to them is aroused. He struggles against them and tries to repress them before our very eyes. And now we understand what is happening. The patient is repeating in the form of falling in love with the analyst mental experiences which he has already been through once before; he has transferred on to the analyst mental attitudes that were lying ready in him and were intimately connected with his neurosis. He is also repeating before our eyes his old defensive actions; he would like best to repeat in his relation to the analyst all the history of that forgotten period of his life. So what he is showing us is the kernel of his intimate life history: he is reproducing it tangibly, as though it were actually happening, instead of remembering it. In this way the riddle of the transference-love is solved and the analysis can proceed on its way - with the help of the new situation which had seemed such a menace to it.
[1926e, 4368]

Only let us hold fast to this: the nodal point and pivot of the whole situation is the relative strength of the ego organization. We shall then find it easy to complete our aetiological survey. As what may be called the normal causes of neurotic illness we already know the feebleness of the childhood ego, the task of dealing with the early sexual impulses and the effects of the more or less chance experiences of childhood. Is it not possible, however, that yet other factors play a part, derived from the time before the beginning of the child's life? For instance, an innate strength and unruliness of the instinctual life in the id, which from the outset sets the ego tasks too hard for it? Or a special developmental feebleness of the ego due to unknown reasons? Such factors must of course acquire an aetiological importance, in some cases a transcendent one. We have invariably to reckon with the instinctual strength of the id; if it has developed to excess, the prospects of our therapy are poor. We still know too little of the causes of a developmental inhibition of the ego. These then would be the cases of neurosis with an essentially constitutional basis. Without some such constitutional, congenital favouring factors a neurosis can, no doubt, scarcely come about.
[1926e, 4383]

The first task of psycho-analysis was the elucidation of nervous disorders. The analytic theory of the neuroses is based on three corner-stones: the recognition of (1) 'repression', of (2) the importance of the sexual instinct and of (3) 'transference'.
[1926f, 4405]
(2) For cultural reasons the most intense repression falls upon the sexual instincts; but it is precisely in connection with them that repression most easily miscarries, so that neurotic symptoms are found to be substitutive satisfactions of repressed sexuality. The belief that in man sexual life begins only at puberty is incorrect. On the contrary, signs of it can be detected from the beginning of extra-uterine existence; it reaches a first culminating point at or before the fifth year ('early period'), after which it is inhibited or interrupted ('latency period') until the age of puberty, which is the second climax of its development. This diphasic onset of sexual development seems to be distinctive of the genus Homo. All experiences during the first period of childhood are of the greatest importance to the individual, and in combination with his inherited sexual constitution form the dispositions for the subsequent development of character and disease. It is wrong to make sexuality coincide with 'genitality'. The sexual instincts pass through a complicated course of development, and it is only at the end of it that the 'primacy of the genital zones' is attained. Before this there are a number of 'pregenital' organizations of the libido - points at which it may become 'fixated' and to which, in the event of subsequent repression, it will return ('regression'). The infantile fixations of the libido are what determine the form of any later neurosis. Thus the neuroses are to be regarded as inhibitions in the development of the libido. There are no specific causes of nervous disorders; the question whether a conflict finds a healthy solution or leads to a neurotic inhibition of function depends upon quantitative considerations.

[1926f, 4405]

The reasons for this hostility were to be found, from the medical point of view, in the fact that psycho-analysis lays stress upon psychical factors, and from the philosophical point of view, in its assuming as an underlying postulate the concept of unconscious mental activity; but the strongest reason was undoubtedly the general disinclination of mankind to concede to the factor of sexuality the importance that is assigned to it by psycho-analysis. In spite of this widespread opposition, however, the movement in favour of psycho-analysis was not to be checked. Its adherents formed themselves into an International Association, which passed successfully through the ordeal of the World War, and at the present time (1925) comprises local groups in Vienna, Berlin, Budapest, London, Switzerland, Holland, Moscow and Calcutta, as well as two in the United States. There are three periodicals representing the views of these societies: the Internationale Zeitschrift für Psychoanalyse, Imago (which is concerned with the application of psycho-analysis to non-medical fields of knowledge), and the International Journal of Psycho-Analysis.

[1926f, 4407]

² The view expressed above is supported by the following considerations. Man is an animal organism with (like others) an unmistakably bisexual disposition. The individual corresponds to a fusion of two symmetrical halves, of which, according to some investigators, one is purely male and the other female. It is equally possible that each half was originally hermaphrodite. Sex is a biological fact which, although it is of extraordinary importance in mental life, is hard to grasp psychologically. We are accustomed to say that every human being displays both male and female instinctual impulses, needs and attributes; but though anatomy, it is true, can point out the characteristic of maleness and femaleness, psychology cannot. For psychology the contrast between the sexes fades away into one between activity and passivity, in which we far too readily identify activity with maleness and passivity with femaleness, a view which is by no means universally confirmed in the animal kingdom. The theory of bisexuality is still surrounded by many obscurities and we cannot but feel it as a serious impediment in psycho-analysis that it has not yet found any link with the theory of the instincts. However this may be, if we assume it as a fact that each individual seeks to satisfy both male and female wishes in his sexual life, we are prepared for the possibility that those demands are not fulfilled by the same object, and that they interfere with each other unless they can be kept apart and each impulse guided into a particular channel that is suited to it. Another difficulty arises from the circumstance that there is so often associated with the erotic relationship, over and above its own sadistic components, a quota of plain inclination to aggression. The love-object will not always view these complications with the degree of understanding and tolerance shown by the peasant woman who complained that her husband did not love her any more, since he had not beaten her for a week.

[1930a, 4499]
Psycho-analytic work has shown us that it is precisely these frustrations of sexual life which people known as neurotics cannot tolerate. The neurotic creates substitutive satisfactions for himself in his symptoms, and these either cause him suffering in themselves or become sources of suffering for him by raising difficulties in his relations with his environment and the society he belongs to. The latter fact is easy to understand; the former presents us with a new problem. But civilization demands other sacrifices besides that of sexual satisfaction.

[1930a, 4500]

The supposition we have just made finds confirmation. Analytic experiences teach us that there is in fact one instinctual demand attempts to deal with which most easily fail or succeed imperfectly and that there is one period of life which comes in question exclusively or predominantly in connection with the generation of a neurosis. These two factors - the nature of the instinct and the period of life concerned - call for separate consideration, although they are closely enough connected.

[1940a [1938], 4992]

As regards the other point - the specific instinctual factor - we come upon an interesting discrepancy between theory and experience. Theoretically there is no objection to supposing that any sort of instinctual demand might occasion the same repressions and their consequences; but our observation shows us invariably, so far as we can judge, that the excitations that play this pathogenic part arise from the component instincts of sexual life. The symptoms of neuroses are, it might be said, without exception either a substitutive satisfaction of some sexual urge or measures to prevent such a satisfaction; and as a rule they are compromises between the two, of the kind that come about in accordance with the laws operating between contraries in the unconscious. The gap in our theory cannot at present be filled; our decision is made more difficult by the fact that most of the urges of sexual life are not of a purely erotic nature but have arisen from alloys of the erotic instinct with portions of the destructive instinct. But it cannot be doubted that the instincts which manifest themselves physiologically as sexuality play a prominent, unexpectedly large part in the causation of the neuroses - whether it is an exclusive one remains to be decided. It must also be borne in mind that in the course of cultural development no other function has been so energetically and extensively repudiated as precisely the sexual one. Theory must rest satisfied with a few hints that betray a deeper connection: the fact that the first period of childhood, during which the ego begins to be differentiated from the id, is also the period of the early sexual efflorescence which is brought to an end by the period of latency; that it can hardly be a matter of chance that this momentous early period subsequently falls a victim to infantile amnesia; and lastly, that biological changes in sexual life (such as the function's diphasic onset which we have already mentioned, the disappearance of the periodic character of sexual excitation and the transformation in the relation between female menstruation and male excitation) - that these innovations in sexuality must have been of high importance in the evolution of animals into man. It is left for the science of the future to bring these still isolated data together into a new understanding. It is not in psychology but in biology that there is a gap here. We shall not be wrong, perhaps, in saying that the weak point in the ego's organization seems to lie in its attitude to the sexual function, as though the biological antithesis between self-preservation and the preservation of the species had found a psychological expression at that point.

[1940a [1938], 4994]
The more one is concerned with the solution of dreams, the more one is driven to recognize that the majority of the dreams of adults deal with sexual material and give expression to erotic wishes. A judgement on this point can be formed only by those who really analyse dreams, that is to say, who make their way through their manifest content to the latent dream-thoughts, and never by those who are satisfied with making a note of the manifest content alone (like Näcke, for instance, in his writings on sexual dreams). Let me say at once that this fact is not in the least surprising but is in complete harmony with the principles of my explanation of dreams. No other instinct has been subjected since childhood to so much suppression as the sexual instinct with its numerous components (cf. my Three Essays on the Theory of Sexuality, 1905); from no other instinct are so many and such powerful unconscious wishes left over, ready to produce dreams in a state of sleep. In interpreting dreams we should never forget the significance of sexual complexes, though we should also, of course, avoid the exaggeration of attributing exclusive importance to them.

[1900a, 853]

The very remarkable relation which thus holds between sexual variations and the descending scale from health to insanity gives us plenty of material for thought. I am inclined to believe that it may be explained by the fact that the impulses of sexual life are among those which, even normally, are the least controlled by the higher activities of the mind. In my experience anyone who is in any way, whether socially or ethically, abnormal mentally is invariably abnormal also in his sexual life. But many people are abnormal in their sexual life who in every other respect approximate to the average, and have, along with the rest, passed through the process of human cultural development, in which sexuality remains the weak spot.

[1905d, 1475]

Nevertheless, in some of these perversions the quality of the new sexual aim is of a kind to demand special examination. Certain of them are so far removed from the normal in their content that we cannot avoid pronouncing them 'pathological'. This is especially so where (as, for instance, in cases of licking excrement or of intercourse with dead bodies) the sexual instinct goes to astonishing lengths in successfully overriding the resistances of shame, disgust, horror or pain. But even in such cases we should not be too ready to assume that people who act in this way will necessarily turn out to be insane or subject to grave abnormalities of other kinds. Here again we cannot escape from the fact that people whose behaviour is in other respects normal can, under the domination of the most unruly of all the instincts, put themselves in the category of sick persons in the single sphere of sexual life. On the other hand, manifest abnormality in the other relations of life can invariably be shown to have a background of abnormal sexual conduct.

[1905d, 1486]

THE MENTAL FACTOR IN THE PERVERSIONS. It is perhaps in connection precisely with the most repulsive perversions that the mental factor must be regarded as playing its largest part in the transformation of the sexual instinct. It is impossible to deny that in their case a piece of mental work has been performed which, in spite of its horrifying result, is the equivalent of an idealization of the instinct. The omnipotence of love is perhaps never more strongly proved than in such of its aberrations as these. The highest and the lowest are always closest to each other in the sphere of sexuality: 'vom Himmel durch die Welt zur Hölle.'

[1905d, 1487]
Among the institutions which cynical jokes are in the habit of attacking none is more important or more strictly guarded by moral regulations but at the same time more inviting to attack than the institution of marriage, at which, accordingly, the majority of cynical jokes are aimed. There is no more personal claim than that for sexual freedom and at no point has civilization tried to exercise severer suppression than in the sphere of sexuality. A single example will be enough for our purposes - the one mentioned on p. 1678, 'An Entry in Prince Carnival's Album':

I should like to go back once more to the instinctual life of obsessional neurotics and add one more remark upon it. It turned out that our patient, besides all his other characteristics, was a *renifleur*. By his own account, when he was a child he had recognized everyone by their smell, like a dog; and even when he was grown up he was more susceptible to sensations of smell than most people.¹ I have met with the same characteristic in other neurotics, both in hysterical and in obsessional patients, and I have come to recognize that a tendency to taking pleasure in smell, which has become extinct since childhood, may play a part in the genesis of neurosis.² And here I should like to raise the general question whether the atrophy of the sense of smell (which was an inevitable result of man's assumption of an erect posture) and the consequent organic repression of his pleasure in smell may not have had a considerable share in the origin of his susceptibility to nervous disease. This would afford us some explanation of why, with the advance of civilization, it is precisely the sexual life that must fall a victim to repression. For we have long known the intimate connection in the animal organization between the sexual instinct and the function of the olfactory organ.

I am aware that this assertion of mine will not be willingly believed. Even workers who are ready to follow my psychological studies are inclined to think that I over-estimate the part played by sexual factors; they meet me with the question why other mental excitations should not lead to the phenomena I have described of repression and the formation of substitutes. I can only answer that I do not know why they should not, and that I should have no objection to their doing so; but experience shows that they do not carry this weight, that at most they support the operation of the sexual factors but cannot replace them. Far from this position having been postulated by me theoretically, at the time of the joint publication of the *Studies* with Dr. Breuer in 1895 I had not yet adopted it; and I was only converted to it when my experiences became more numerous and penetrated into the subject more deeply. There are among my present audience a few of my closest friends and followers, who have travelled with me here to Worcester. Enquire from them, and you will hear that they all began by completely disbelieving my assertion that sexual aetiology was of decisive importance, until their own analytic experiences compelled them to accept it.

[1905c, 1704]

[1909d, 2193]

[1910a, 2227]
If, then, as we have learnt, psychogenic disturbances of vision depend on certain ideas connected with seeing being cut off from consciousness, we must, on the psycho-analytic view, assume that these ideas have come into opposition to other, more powerful ones, for which we use the collective concept of the 'ego'- a compound which is made up variously at different times - and have for that reason come under repression. But what can be the origin of this opposition, which makes for repression, between the ego and various groups of ideas? You will no doubt notice that it was not possible to frame such a question before the advent of psycho-analysis, for nothing was known earlier of psychical conflict and repression. Our researches, however, have put us in a position to give us the desired answer. Our attention has been drawn to the importance of the instincts in ideational life. We have discovered that every instinct tries to make itself effective by activating ideas that are in keeping with its aims. These instincts are not always compatible with one another; their interests often come into conflict. Opposition between ideas is only an expression of struggles between the various instincts. From the point of view of our attempted explanation, a quite specially important part is played by the undeniable opposition between the instincts which subserve sexuality, the attainment of sexual pleasure, and those other instincts, which have as their aim the self-preservation of the individual - the ego-instincts. As the poet has said, all the organic instincts that operate in our mind may be classified as 'hunger' or 'love'. We have traced the 'sexual instinct' from its first manifestations in children to its final form, which is described as 'normal'. We have found that it is put together from numerous 'component instincts' which are attached to excitations of regions of the body; and we have come to see that these separate instincts have to pass through a complicated development before they can be brought effectively to serve the aims of reproduction. The light thrown by psychology on the evolution of our civilization has shown us that it originates mainly at the cost of the sexual component instincts, and that these must be suppressed, restricted, transformed and directed to higher aims, in order that the mental constructions of civilization may be established. We have been able to recognize as a valuable outcome of these researches something that our colleagues have not yet been willing to believe, namely that the human ailments known as 'neuroses' are derived from the many different ways in which these processes of transformation in the sexual component instincts may miscarry. The 'ego' feels threatened by the claims of the sexual instincts and fends them off by repressions; these, however, do not always have the desired result, but lead to the formation of dangerous substitutes for the repressed and to burdensome reactions on the part of the ego. From these two classes of phenomena taken together there emerge what we call the symptoms of neuroses. [1910 i, 2368]

Now it is a very noteworthy fact that the sexual instincts and the self-preservative instincts do not behave in the same way towards real necessity. The self-preservative instincts, and everything to do with them, are much easier to educate: they learn early to comply with necessity and to arrange their developments in accordance with the instructions of reality. This is intelligible, since they could not obtain the objects they need in any other way; and without those objects the individual would inevitably perish. The sexual instincts are harder to educate, for at first they have no need of an object. Since they are attached like parasites, as it were, to the other bodily functions, and find their satisfaction auto-erotically on the subject's own body, they are to begin with withdrawn from the educative influence of real necessity, and they retain this characteristic of being self-willed and inaccessible to influence (what we describe as being 'unreasonable') in most people in some respect all through their lives. Moreover, as a rule the educability of a youthful individual is at an end when his sexual needs arise in their full strength. Educators are aware of this and act accordingly; but the findings of psycho-analysis may perhaps also induce them to shift the main impact of education on to the earliest years of childhood, from infancy onwards. The little creature is often completed by the fourth or fifth year of life, and after that merely brings gradually to light what is already within him. [1916-1917, 3415]
I have credited you with a wish that I might have started my description of the neuroses from
the behaviour of neurotic people, from an account of the manner in which they suffer under their
neurosis, of how they defend themselves against it and how they come to terms with it. No
doubt that is an interesting topic, worth investigating; nor would it be very difficult to handle. But
it would be of debatable wisdom to start with it. There would be a risk of not discovering the
unconscious and at the same time of overlooking the great importance of the libido and of
judging everything as it appears to the ego of the neurotic subject. It is obvious that this ego is
not a trustworthy or impartial agency. The ego is indeed the power which disavows the
unconscious and has degraded it into being repressed; so how can we trust it to be fair to the
unconscious? The most prominent elements in what is thus repressed are the repudiated
demands of sexuality, and it is quite self-evident that we should never be able to guess their
extent and importance from the ego's conceptions. From the moment the notion of repression
dawns on us, we are warned against making one of the two contesting parties (and the
victorious one, at that) into being judge in the dispute. We are prepared to find that the ego's
assertions will lead us astray. If we are to believe the ego, it was active at every point and itself
willed and created its symptoms. But we know that it puts up with a good amount of passivity,
which it afterwards tries to disguise and gloss over. It is true that it does not always venture on
such an attempt; in the symptoms of obsessional neurosis it is obliged to admit that there is
something alien which is confronting it and against which it can only defend itself with difficulty.
[1916-1917, 3433]

LADIES AND GENTLEMEN, - We have repeatedly (and only recently once again) had to deal with
the distinction between the ego-instincts and the sexual instincts. In the first place, repression
showed us that the two can come into opposition to each other, that the sexual instincts are
then ostensibly subdued and are obliged to find satisfaction for themselves along regressive
and roundabout paths, and that in doing so they are able to find compensation for their defeat in
their indomitability. We next learnt that the two kinds of instincts are from the first differently
related to Necessity the educator, so that their course of development is not the same and they
do not enter into the same connection with the reality principle. Lastly, we seem to have found
that the sexual instincts are linked by much closer bonds than the ego-instincts to the affective
state of anxiety - a conclusion which seems incomplete in only one important respect. In order
to establish it more firmly, therefore, I will bring forward the further noteworthy fact that if hunger
and thirst (the two most elementary self-preservative instincts) are unsatisfied, the result is
never their transformation into anxiety, whereas the changing of unsatisfied libido into anxiety is,
as we have seen, among the best known and most frequently observed of phenomena.
[1916-1917, 3458]
These are a few of the findings which have hitherto been reached from the application of psycho-analysis to the narcissistic disorders. No doubt there are not yet enough of them and they still lack the precision which can only be attained from established familiarity with a new field. We owe all of them to a use of the concept of ego-libido or narcissistic libido, by whose help we can extend to the narcissistic neuroses the views which have proved their value with the transference neuroses. Now, however, you will ask whether it is possible that we shall succeed in subsuming all the disturbances of the narcissistic illnesses and of the psychoses under the libido theory, whether we look upon the libidinal factor in mental life as universally guilty of the causation of illness, and need never attribute the responsibility for it to changes in the functioning of the self-preservative instinct. Well, Ladies and Gentlemen, this question seems to me to call for no urgent reply, and, above all, not to be ripe for judgement. We can confidently leave it over in expectation of the progress of our scientific work. I should not be surprised if it turned out that the power to produce pathogenic effects was in fact a prerogative of the libidinal instincts, so that the libido theory could celebrate its triumph all along the line from the simplest 'actual' neurosis to the most severe alienation of the personality. We after all know that it is a characteristic feature of the libido that it struggles against submitting to the reality of the universe - to Ananke. But I regard it as extremely probable that the ego-instincts are carried along secondarily by the pathogenic instigation of the libido and forced into functional disturbances. Nor can I think that it would be a disaster to the trend of our researches, if what lies before us is the discovery that in severe psychoses the ego-instincts themselves have gone astray as a primary fact. The future will give the answer - to you, at any rate.

[1916-1917, 3473]

It is thus that psycho-analysis has sought to educate the ego. But these two discoveries - that the life of our sexual instincts cannot be wholly tamed, and that mental processes are in themselves unconscious and only reach the ego and come under its control through incomplete and untrustworthy perceptions - these two discoveries amount to a statement that the ego is not master in its own house. Together they represent the third blow to man's self-love, what I may call the psychological one. No wonder, then, that the ego does not look favourably upon psycho-analysis and obstinately refuses to believe in it.

[1917a, 3614]

The theory of psycho-analysis (a theory based on observation) holds firmly to the view that the motive forces of repression must not be sexualized. Man's archaic heritage forms the nucleus of the unconscious mind; and whatever part of that heritage has to be left behind in the advance to later phases of development, because it is unserviceable or incompatible with what is new and harmful to it, falls a victim to the process of repression. This selection is made more successfully with one group of instincts than with the other. In virtue of special circumstances which have often been pointed out already, the latter group, that of the sexual instincts, are able to defeat the intentions of repression, and to enforce their representation by substitutive formations of a disturbing kind. For this reason infantile sexuality, which is held under repression, acts as the chief motive force in the formation of symptoms; and the essential part of its content, the Oedipus complex, is the nuclear complex of neuroses. I hope that in this paper I have raised an expectation that the sexual aberrations of childhood, as well as those of mature life, are ramifications of the same complex.

[1919e, 3662]
There can be no doubt, however, that the replacement of the pleasure principle by the reality principle can only be made responsible for a small number, and by no means the most intense, of unpleasurable experiences. Another occasion of the release of unpleasure, which occurs with no less regularity, is to be found in the conflicts and dissensions that take place in the mental apparatus while the ego is passing through its development into more highly composite organizations. Almost all the energy with which the apparatus is filled arises from its innate instinctual impulses. But these are not all allowed to reach the same phases of development. In the course of things it happens again and again that individual instincts or parts of instincts turn out to be incompatible in their aims or demands with the remaining ones, which are able to combine into the inclusive unity of the ego. The former are then split off from this unity by the process of repression, held back at lower levels of psychical development and cut off, to begin with, from the possibility of satisfaction. If they succeed subsequently, as can so easily happen with repressed sexual instincts, in struggling through, by roundabout paths, to a direct or to a substitutive satisfaction, that event, which would in other cases have been an opportunity for pleasure, is felt by the ego as unpleasure. As a consequence of the old conflict which ended in repression, a new breach has occurred in the pleasure principle at the very time when certain instincts were endeavouring, in accordance with the principle, to obtain fresh pleasure. The details of the process by which repression turns a possibility of pleasure into a source of unpleasure are not yet clearly understood or cannot be clearly represented; but there is no doubt that all neurotic unpleasure is of that kind - pleasure that cannot be felt as such.¹

Such a display of unfairness and lack of logic cries out for an explanation. Its origin is not hard to find. Human civilization rests upon two pillars, of which one is the control of natural forces and the other the restriction of our instincts. The ruler's throne rests upon fettered slaves. Among the instinctual components which are thus brought into service, the sexual instincts, in the narrower sense of the word, are conspicuous for their strength and savagery. Woe, if they should be set loose! The throne would be overturned and the ruler trampled under foot. Society is aware of this - and will not allow the topic to be mentioned.

But why not? What harm could the discussion do? Psycho-analysis has never said a word in favour of unfettering instincts that would injure our community; on the contrary it has issued a warning and an exhortation to us to mend our ways. But society refuses to consent to the ventilation of the question, because it has a bad conscience in more than one respect. In the first place it has set up a high ideal of morality - morality being restriction of the instincts - and insists that all its members shall fulfil that ideal without troubling itself with the possibility that obedience may bear heavily upon the individual. Nor is it sufficiently wealthy or well-organized to be able to compensate the individual for the amount of his instinctual renunciation. It is consequently left to the individual to decide how he can obtain, for the sacrifice he has made, enough compensation to enable him to preserve his mental balance. On the whole, however, he is obliged to live psychologically beyond his means, while the unsatisfied claims of his instincts make him feel the demands of civilization as a constant pressure upon him. Thus society maintains a condition of cultural hypocrisy which is bound to be accompanied by a sense of insecurity and a necessity for guarding what is an undeniably precarious situation by forbidding criticism and discussion. This line of thought holds good for all the instinctual impulses, including, therefore, the egoistic ones. The question whether it applies to all possible forms of civilization, and not merely to those which have evolved hitherto, cannot be discussed here. As regards the sexual instincts in the narrower sense, there is the further point that in most people they are tamed insufficiently and in a manner which is psychologically wrong and are therefore readier than the rest to break loose.
(2) For cultural reasons the most intense repression falls upon the sexual instincts; but it is precisely in connection with them that repression most easily miscarries, so that neurotic symptoms are found to be substitutive satisfactions of repressed sexuality. The belief that in man sexual life begins only at puberty is incorrect. On the contrary, signs of it can be detected from the beginning of extra-uterine existence; it reaches a first culminating point at or before the fifth year ('early period'), after which it is inhibited or interrupted ('latency period') until the age of puberty, which is the second climax of its development. This diphasic onset of sexual development seems to be distinctive of the genus Homo. All experiences during the first period of childhood are of the greatest importance to the individual, and in combination with his inherited sexual constitution form the dispositions for the subsequent development of character and disease. It is wrong to make sexuality coincide with 'genitality'. The sexual instincts pass through a complicated course of development, and it is only at the end of it that the 'primacy of the genital zones' is attained. Before this there are a number of 'pregenital' organizations of the libido - points at which it may become 'fixated' and to which, in the event of subsequent repression, it will return ('regression'). The infantile fixations of the libido are what determine the form of any later neurosis. Thus the neuroses are to be regarded as inhibitions in the development of the libido. There are no specific causes of nervous disorders; the question whether a conflict finds a healthy solution or leads to a neurotic inhibition of function depends upon quantitative considerations.

[1926f, 4405]

As regards the other point - the specific instinctual factor - we come upon an interesting discrepancy between theory and experience. Theoretically there is no objection to supposing that any sort of instinctual demand might occasion the same repressions and their consequences; but our observation shows us invariably, so far as we can judge, that the excitations that play this pathogenic part arise from the component instincts of sexual life. The symptoms of neuroses are, it might be said, without exception either a substitutive satisfaction of some sexual urge or measures to prevent such a satisfaction; and as a rule they are compromises between the two, of the kind that come about in accordance with the laws operating between contraries in the unconscious. The gap in our theory cannot at present be filled; our decision is made more difficult by the fact that most of the urges of sexual life are not of a purely erotic nature but have arisen from alloys of the erotic instinct with portions of the destructive instinct. But it cannot be doubted that the instincts which manifest themselves physiologically as sexuality play a prominent, unexpectedly large part in the causation of the neuroses - whether it is an exclusive one remains to be decided. It must also be borne in mind that in the course of cultural development no other function has been so energetically and extensively repudiated as precisely the sexual one. Theory must rest satisfied with a few hints that betray a deeper connection: the fact that the first period of childhood, during which the ego begins to be differentiated from the id, is also the period of the early sexual efflorescence which is brought to an end by the period of latency; that it can hardly be a matter of chance that this momentous early period subsequently falls a victim to infantile amnesia; and lastly, that biological changes in sexual life (such as the function's diphasic onset which we have already mentioned, the disappearance of the periodic character of sexual excitation and the transformation in the relation between female menstruation and male excitation) - that these innovations in sexuality must have been of high importance in the evolution of animals into man. It is left for the science of the future to bring these still isolated data together into a new understanding. It is not in psychology but in biology that there is a gap here. We shall not be wrong, perhaps, in saying that the weak point in the ego's organization seems to lie in its attitude to the sexual function, as though the biological antithesis between self-preservation and the preservation of the species had found a psychological expression at that point.

[1940a [1938], 4994]
Few details are known about the sexual behaviour of the great artist and scientist, but we may place confidence in the probability that the assertions of his contemporaries were not grossly erroneous. In the light of these traditions, then, he appears as a man whose sexual need and activity were exceptionally reduced, as if a higher aspiration had raised him above the common animal need of mankind. It may remain open to doubt whether he ever sought direct sexual satisfaction - and if so, in what manner - or whether he was able to dispense with it altogether. We are however justified in looking in him too for the emotional currents which drive other men imperatively on to perform the sexual act; for we cannot imagine the mental life of any human being in the formation of which sexual desire in the broadest sense - libido - did not have its share, even if that desire has departed far from its original aim, or has refrained from putting itself into effect.

[1910c, 2275]

The difficulty in understanding now lies else here. The anxiety which signifies a flight of the ego from its libido is after all supposed to be derived from that libido itself. This is obscure and it reminds us not to forget that after all a person's libido is fundamentally something of his and cannot be contrasted with him as something external. It is the topographical dynamics of the generation of anxiety which are still obscure to us - the question of what mental energies are produced in what process and from what mental systems they derive. This is once more a question which I cannot promise to answer: but there are two other tracks which we must not fail to follow and in doing so we shall once more be making use of direct observation and analytic enquiry as a help to our speculations. We will turn to the genesis of anxiety in children and to the source of the neurotic anxiety which is attached to phobias.

[1916-1917, 3452]

'Nothing has entered into you from without; a part of the activity of your own mind has been withdrawn from your knowledge and from the command of your will. That, too, is why you are so weak in your defence; you are using one part of your force to fight the other part and you cannot concentrate the whole of your force as you would against an external enemy. And it is not even the worst or least important part of your mental forces that has thus become antagonistic to you and independent of you. The blame, I am bound to say, lies with yourself. You over-estimated your strength when you thought you could treat your sexual instincts as you liked and could utterly ignore their intentions. The result is that they have rebelled and have taken their own obscure paths to escape this suppression; they have established their rights in a manner you cannot approve. How they have achieved this, and the paths which they have taken, have not come to your knowledge. All you have learned is the outcome of their work - the symptom which you experience as suffering. Thus you do not recognize it as a derivative of your own rejected instincts and do not know that it is a substitutive satisfaction of them.

[1917a, 3613]
Against this, Löwenfeld insists on the fact that in a number of cases 'states of anxiety appear immediately or shortly after a psychical shock (fright alone, or accidents which were accompanied by fright), and in such situations there are sometimes circumstances which make the simultaneous operation of sexual noxae of the kind mentioned extremely improbable.' He gives, shortly, as a particularly pregnant example, one clinical observation (to serve instead of many). This example concerns a woman of thirty, with a hereditary taint, who had been married for four years and who had had a first, difficult, confinement a year before. A few weeks after this event her husband had an attack of illness which frightened her, and in her agitation she ran about the cold room in her chemise. From that time on she was ill. First she had states of anxiety and palpitations in the evening, then came attacks of convulsive trembling, and after that phobias, and so on. It was the picture of a fully-developed anxiety neurosis. 'Here,' concludes Löwenfeld, 'the anxiety states are obviously of psychical origin, brought about by the single fright.'

But where there are grounds for regarding the neurosis as an acquired one, careful enquiry directed to that end reveals that a set of noxae and influences from sexual life . . .' Löwenfeld quotes this passage and adds the following gloss: 'From this it appears that Freud always regards a neurosis as "acquired" whenever incidental causes are to be found for it.'

If I consider this aetiological formula for anxiety neurosis in detail, I am able to add the following remarks. Whether a special personal constitution (which need not be produced by heredity) is absolutely necessary for the production of an anxiety neurosis, or whether any normal person can be made to have an anxiety neurosis by some given quantitative increase of the specific factor - this I am not able to decide with certainty; but I incline strongly to the latter view. -Hereditary disposition is the most important precondition for anxiety neurosis; but it is not an indispensable one, since it is absent in a class of borderline cases. -The presence of the specific sexual factor can, in the majority of cases, be demonstrated with certainty. In one series of cases (congenital ones) this factor is not separated from the precondition of heredity, but is fulfilled with the help of it. That is to say, in some patients this peculiarity of the vita sexualis - psychical inadequacy in mastering somatic sexual tension - is innate in the form of a stigma whereas ordinarily it is via that peculiarity that they acquire the neurosis. In another class of borderline cases the specific cause is contained in a contributory one. This is when the psychical inadequacy which I have just mentioned is brought about by exhaustion and such causes. All these cases fall into classes which melt into one another and do not form separate categories. In all of them, moreover, we find that the sexual tension undergoes the same vicissitudes; and for most of them the distinction between precondition, specific and auxiliary cause holds good, in conformity with the solution of the aetiological equation which I have given above.

(3) But what form the neurosis assumes - what direction the deviation takes - is solely determined by the specific aetiological factor arising from sexual life.
And now for the true exciting cause of the dream. It had been a hot summer afternoon; and during the evening I had delivered my lecture on the connection between hysteria and the perversions, and everything I had had to say displeased me intensely and seemed to me completely devoid of any value. I was tired and felt no trace of enjoyment in my difficult work; I longed to be away from all this grubbing about in human dirt and to be able to join my children and afterwards visit the beauties of Italy. In this mood I went from the lecture room to a café, where I had a modest snack in the open air, since I had no appetite for food. One of my audience, however, went with me and he begged leave to sit by me while I drank my coffee and choked over my crescent roll. He began to flatter me: telling me how much he had learnt from me, how he looked at everything now with fresh eyes, how I had cleansed the Augean stables of errors and prejudices in my theory of the neuroses. He told me, in short, that I was a very great man. My mood fitted ill with this paean of praise; I fought against my feeling of disgust, went home early to escape from him, and before going to sleep turned over the pages of Rabelais and read one of Conrad Ferdinand Meyer's short stories, ‘Die Leiden eines Knaben’ ['A Boy's Sorrows'].

² For example, the phantasies of hysterics concerning sexual and cruel maltreatment correspond, at times even down to details, with the complaints of persecuted paranoics. It is curious, but not unintelligible, that we meet the identical content in the form of reality in the contrivances of perverts for the satisfaction of their desires.

[1900a, 913]

[1901b, 1325]
As regards the second kind of emotional reaction, which is not directed against me this time, but against my patient - supposing that my view of her is correct - and which regards the perverse nature of her phantasies as horrible, I should like to say emphatically that a medical man has no business to indulge in such passionate condemnation. I may also remark in passing that it seems to me superfluous for a physician who is writing upon the aberrations of the sexual instincts to seize every opportunity of inserting into the text expressions of his personal repugnance at such revolting things. We are faced by a fact; and it is to be hoped that we shall grow accustomed to it, when we have put our own tastes on one side. We must learn to speak without indignation of what we call the sexual perversions - instances in which the sexual function has extended its limits in respect either to the part of the body concerned or to the sexual object chosen. The uncertainty in regard to the boundaries of what is to be called normal sexual life, when we take different races and different epochs into account, should in itself be enough to cool the zealot's ardour. We surely ought not to forget that the perversion which is the most repellent to us, the sensual love of a man for a man, was not only tolerated by a people so far our superiors in cultivation as were the Greeks, but was actually entrusted by them with important social functions. The sexual life of each one of us extends to a slight degree - now in this direction, now in that - beyond the narrow lines imposed as the standard of normality. The perversions are neither bestial nor degenerate in the emotional sense of the word. They are a development of germs all of which are contained in the undifferentiated sexual disposition of the child, and which, by being suppressed or by being diverted to higher, asexual aims - by being 'sublimated' - are destined to provide the energy for a great number of our cultural achievements. When, therefore, any one has become a gross and manifest pervert, it would be more correct to say that he has remained one, for he exhibits a certain stage of inhibited development. All psychoneurotics are persons with strongly marked perverse tendencies, which have been repressed in the course of their development and have become unconscious. Consequently their unconscious phantasies show precisely the same content as the documentarily recorded actions of perverts - even though they have not read Krafft-Ebing's Psychopathia Sexualis, to which simple-minded people attribute such a large share of the responsibility for the production of perverse tendencies. Psychoneuroses are, so to speak, the negative of perversions. In neurotics their sexual constitution, under which the effects of heredity are included, operates in combination with any accidental influences in their life which may disturb the development of normal sexuality. A stream of water which meets with an obstacle in the river-bed is dammed up and flows back into old channels which had formerly seemed fated to run dry. The motive forces leading to the formation of hysterical symptoms draw their strength not only from repressed normal sexuality but also from unconscious perverse activities.¹

[1905e, 1387]
I must now turn to consider a further complication to which I should certainly give no space if I were a man of letters engaged upon the creation of a mental state like this for a short story, instead of being a medical man engaged upon its dissection. The element to which I must now allude can only serve to obscure and efface the outlines of the fine poetic conflict which we have been able to ascribe to Dora. This element would rightly fall a sacrifice to the censorship of a writer, for he, after all, simplifies and abstracts when he appears in the character of a psychologist. But in the world of reality, which I am trying to depict here, a complication of motives, an accumulation and conjunction of mental activities - in a word, overdetermination - is the rule. For behind Dora's supervalent train of thought which was concerned with her father's relations with Frau K. there lay concealed a feeling of jealousy which had that lady as its object - a feeling, that is, which could only be based upon an affection on Dora's part for one of her own sex. It has long been known and often been pointed out that at the age of puberty boys and girls show clear signs, even in normal cases, of the existence of an affection for people of their own sex. A romantic and sentimental friendship with one of her school friends, accompanied by vows, kisses, promises of eternal correspondence, and all the sensibility of jealousy, is the common precursor of a girl's first serious passion for a man. Thenceforward, in favourable circumstances, the homosexual current of feeling often runs completely dry. But if a girl is not happy in her love for a man, the current is often set flowing again by the libido in later years and is increased up to a greater or lesser degree of intensity. If this much can be established without difficulty of healthy persons, and if we take into account what has already been said about the fuller development in neurotics of the normal germs of perversion, we shall expect to find in these latter too a fairly strong homosexual predisposition. It must, indeed, be so; for I have never yet come through a single psycho-analysis of a man or a woman without having to take into account a very considerable current of homosexuality. When, in a hysterical woman or girl, the sexual libido which is directed towards men has been energetically suppressed, it will regularly be found that the libido which is directed towards women has become vicariously reinforced and even to some extent conscious.

[1905e, 1397]
The reproaches against her father for having made her ill, together with the self-reproach underlying them, the leucorrhoea, the playing with the reticule, the bed-wetting after her sixth year, the secret which she would not allow the doctors to tear from her - the circumstantial evidence of her having masturbating in childhood seems to me complete and without a flaw. In the present case I had begun to suspect the masturbation when she had told me of her cousin's gastric pains, and had then identified herself with her by complaining for days together of similar painful sensations. It is well known that gastric pains occur especially often in those who masturbate. According to a personal communication made to me by Wilhelm Fliess, it is precisely gastralgias of this character which can be interrupted by an application of cocaine to the 'gastric spot' discovered by him in the nose, and which can be cured by the cauterization of the same spot. In confirmation of my suspicion Dora gave me two facts from her conscious knowledge: she herself had frequently suffered from gastric pains, and she had good reasons for believing that her cousin was a masturbator. It is a very common thing for patients to recognize in other people a connection which, on account of their emotional resistances, they cannot perceive in themselves. And, indeed, Dora no longer denied my supposition, although she still remembered nothing. Even the date which she assigned to the bed-wetting, when she said that it lasted 'till a short time before the appearance of the nervous asthma', appears to me to be of clinical significance. Hysterical symptoms hardly ever appear so long as children are masturbating, but only afterwards, when a period of abstinence has set in;¹ they form a substitute for masturbatory satisfaction, the desire for which continues to persist in the unconscious until another and more normal kind of satisfaction appears - where that is still attainable. For upon whether it is still attainable or not depends the possibility of a hysteria being cured by marriage and normal sexual intercourse. But if the satisfaction afforded in marriage is again removed - as it may be owing to coitus interruptus, psychological estrangement, or other causes - then the libido flows back again into its old channel and manifests itself once more in hysterical symptoms.

SIGNIFICANCE OF OTHER REGIONS OF THE BODY The extension of sexual interest to other regions of the body, with all its variations, offers us nothing that is new in principle; it adds nothing to our knowledge of the sexual instinct, which merely proclaims its intention in this way of getting possession of the sexual object in every possible direction. But these anatomical extensions inform us that, besides sexual overvaluation, there is a second factor at work which is strange to popular knowledge. Certain regions of the body, such as the mucous membrane of the mouth and anus, which are constantly appearing in these practices, seem, as it were, to be claiming that they should themselves be regarded and treated as genitals. We shall learn later that this claim is justified by the history of the development of the sexual instinct and that it is fulfilled in the symptomatology of certain pathological states.

NEUROSIS AND PERVERSION There is no doubt that a large part of the opposition to these views of mine is due to the fact that sexuality, to which I trace back psycho-neurotic symptoms, is regarded as though it coincided with the normal sexual instinct. But psycho-analytic teaching goes further than this. It shows that it is by no means only at the cost of the so-called normal sexual instinct that these symptoms originate - at any rate such is not exclusively or mainly the case; they also give expression (by conversion) to instincts which would be described as perverse in the widest sense of the word if they could be expressed directly in phantasy and action without being diverted from consciousness. Thus symptoms are formed in part at the cost of abnormal sexuality; neuroses are, so to say, the negative of the perversions.¹

[1905e, 1415]

[1905d, 1479]

[1905d, 1490]
The contents of the clearly conscious phantasies of perverts (which in favourable circumstances can be transformed into manifest behaviour), of the delusional fears of paranotics (which are projected in a hostile sense on to other people) and of the unconscious phantasies of hysterics (which psycho-analysis reveals behind their symptoms) - all of these coincide with one another even down to their details. [1905d, 1490]

The sexual instinct of psychoneurotics exhibits all the aberrations which we have studied as variations of normal, and as manifestations of abnormal, sexual life. [1905d, 1491]

(a) The unconscious mental life of all neurotics (without exception) shows inverted impulses, fixation of their libido upon persons of their own sex. It would be impossible without deep discussion to give any adequate appreciation of the importance of this factor in determining the form taken by the symptoms of the illness. I can only insist that an unconscious tendency to inversion is never absent and is of particular value in throwing light upon hysteria in men.¹ [1905d, 1491]

(b) It is possible to trace in the unconscious of psychoneurotics tendencies to every kind of anatomical extension of sexual activity and to show that those tendencies are factors in the formation of symptoms. Among them we find occurring with particular frequency those in which the mucous membrane of the mouth and anus are assigned the role of genitals. [1905d, 1491]

(c) An especially prominent part is played as factors in the formation of symptoms in psychoneuroses by the component instincts, which emerge for the most part as pairs of opposites and which we have met with as introducing new sexual aims - the scopophilic instinct and exhibitionism and the active and passive forms of the instinct for cruelty. The contribution made by the last of these is essential to the understanding of the fact that symptoms involve suffering, and it almost invariably dominates a part of the patient's social behaviour. It is also through the medium of this connection between libido and cruelty that the transformation of love into hate takes place, the transformation of affectionate into hostile impulses, which is characteristic of a great number of cases of neurosis, and indeed, it would seem, of paranoia in general. [1905d, 1491]

The interest of these findings is still further increased by certain special facts. [1905d, 1491]

(a) Whenever we find in the unconscious an instinct of this sort which is capable of being paired off with an opposite one, this second instinct will regularly be found in operation as well. Every active perversion is thus accompanied by its passive counterpart: anyone who is an exhibitionist in his unconscious is at the same time a voyeur; in anyone who suffers from the consequences of repressed sadistic impulses there is sure to be another determinant of his symptoms which has its source in masochistic inclinations. The complete agreement which is here shown with what we have found to exist in the corresponding 'positive' perversions is most remarkable, though in the actual symptoms one or other of the opposing tendencies plays the predominant part. [1905d, 1491]
In any fairly marked case of psychoneurosis it is unusual for only a single one of these perverse instincts to be developed. We usually find a considerable number and as a rule traces of them all. The degree of development of each particular instinct is, however, independent of that of the others. Here, too, the study of the ‘positive’ perversions provides an exact counterpart.

[1905d, 1491]

The preceding discussion may perhaps have placed the sexuality of psychoneurotics in a false light. It may have given the impression that, owing to their disposition, psychoneurotics approximate closely to perverts in their sexual behaviour and are proportionately remote from normal people. It may indeed very well be that the constitutional disposition of these patients (apart from their exaggerated degree of sexual repression and the excessive intensity of their sexual instinct) includes an unusual tendency to perversion, using that word in its widest sense. Nevertheless, investigation of comparatively slight cases shows that this last assumption is not absolutely necessary, or at least that in forming a judgement on these pathological developments there is a factor to be considered which weighs in the other direction. Most psychoneurotics only fall ill after the age of puberty as a result of the demands made upon them by normal sexual life. (It is most particularly against the latter that repression is directed.) Or else illnesses of this kind set in later, when the libido fails to obtain satisfaction along normal lines. In both these cases the libido behaves like a stream whose main bed has become blocked. It proceeds to fill up collateral channels which may hitherto have been empty. Thus, in the same way, what appears to be the strong tendency (though, it is true, a negative one) of psychoneurotics to perversion may be collaterally determined, and must, in any case, be collaterally intensified. The fact is that we must put sexual repression as an internal factor alongside such external factors as limitation of freedom, inaccessibility of a normal sexual object, the dangers of the normal sexual act, etc., which bring about perversions in persons who might perhaps otherwise have remained normal.

[1905d, 1494]

If we prefer to suppose, nevertheless, that a particularly strongly developed tendency to perversion is among the characteristics of psychoneurotic constitutions, we have before us the prospect of being able to distinguish a number of such constitutions according to the innate preponderance of one or the other of the erotogenic zones or of one or the other of the component instincts. The question whether a special relation holds between the perverse disposition and the particular form of illness adopted, has, like so much else in this field, not yet been investigated.

[1905d, 1494]

By demonstrating the part played by perverse impulses in the formation of symptoms in the psychoneuroses, we have quite remarkably increased the number of people who might be regarded as perverts. It is not only that neurotics in themselves constitute a very numerous class, but it must also be considered that an unbroken chain bridges the gap between the neuroses in all their manifestations and normality. After all, Moebius could say with justice that we are all to some extent hysterics. Thus the extraordinarily wide dissemination of the perversions forces us to suppose that the disposition to perversions is itself of no great rarity but must form a part of what passes as the normal constitution.

[1905d, 1495]
It is, as we have seen, debatable whether the perversions go back to innate determinants or arise, as Binet assumed was the case with fetishism, owing to chance experiences. The conclusion now presents itself to us that there is indeed something innate lying behind the perversions but that it is something innate in everyone, though as a disposition it may vary in its intensity and may be increased by the influences of actual life. What is in question are the innate constitutional roots of the sexual instinct. In one class of cases (the perversions) these roots may grow into the actual vehicles of sexual activity; in others they may be submitted to an insufficient suppression (repression) and thus be able in a roundabout way to attract a considerable proportion of sexual energy to themselves as symptoms; while in the most favourable cases, which lie between these two extremes, they may by means of effective restriction and other kinds of modification bring about what is known as normal sexual life. [1905d, 1495]

COMPONENT INSTINCTS Moreover, the effects of seduction do not help to reveal the early history of the sexual instinct; they rather confuse our view of it by presenting children prematurely with a sexual object for which the infantile sexual instinct at first shows no need. It must, however, be admitted that infantile sexual life, in spite of the preponderating dominance of erotogenic zones, exhibits components which from the very first involve other people as sexual objects. Such are the instincts of scopophilia, exhibitionism and cruelty, which appear in a sense independently of erotogenic zones; these instincts do not enter into intimate relations with genital life until later, but are already to be observed in childhood as independent impulses, distinct in the first instance from erotogenic sexual activity. Small children are essentially without shame, and at some periods of their earliest years show an unmistakable satisfaction in exposing their bodies, with especial emphasis on the sexual parts. The counterpart of this supposedly perverse inclination, curiosity to see other people's genitals, probably, does not become manifest until somewhat later in childhood, when the obstacle set up by a sense of shame has already reached a certain degree of development. Under the influence of seduction the scopophilic perversion can attain great importance in the sexual life of a child. But my researches into the early years of normal people, as well as of neurotic patients, force me to the conclusion that scopophilia can also appear in children as a spontaneous manifestation. Small children whose attention has once been drawn - as a rule by masturbation - to their own genitals usually take the further step without help from outside and develop a lively interest in the genitals of their playmates. Since opportunities for satisfying curiosity of this kind usually occur only in the course of satisfying the two kinds of need for excretion, children of this kind turn into voyeurs, eager spectators of the processes of micturition and defaecation. When repression of these inclinations sets in, the desire to see other people's genitals (whether of their own or the opposite sex) persists as a tormenting compulsion, which in some cases of neurosis later affords the strongest motive force for the formation of symptoms. [1905d, 1511]
The time has arrived for me to attempt to summarize what I have said. We started out from the aberrations of the sexual instinct in respect of its object and of its aim and we were faced by the question of whether these arise from an innate disposition or are acquired as a result of experiences in life. We arrived at an answer to this question from an understanding, derived from psycho-analytic investigation, of the workings of the sexual instinct in psychoneurotics, a numerous class of people and one not far removed from the healthy. We found that in them tendencies to every kind of perversion can be shown to exist as unconscious forces and betray their presence as factors leading to the formation of symptoms. It was thus possible to say that neurosis is, as it were, the negative of perversion. In view of what was now seen to be the wide dissemination of tendencies to perversion we were driven to the conclusion that a disposition to perversions is an original and universal disposition of the human sexual instinct and that normal sexual behaviour is developed out of it as a result of organic changes and psychical inhibitions occurring in the course of maturation; we hoped to be able to show the presence of this original disposition in childhood. Among the forces restricting the direction taken by the sexual instinct we laid emphasis upon shame, disgust, pity and the structures of morality and authority erected by society. We were thus led to regard any established aberration from normal sexuality as an instance of developmental inhibition and infantilism. Though it was necessary to place in the foreground the importance of the variations in the original disposition, a co-operative and not an opposing relation was to be assumed as existing between them and the influences of actual life. It appeared, on the other hand, that since the original disposition is necessarily a complex one, the sexual instinct itself must be something put together from various factors, and that in the perversions it falls apart, as it were, into its components. The perversions were thus seen to be on the one hand inhibitions, and on the other hand dissociations, of normal development. Both these aspects were brought together in the supposition that the sexual instinct of adults arises from a combination of a number of impulses of childhood into a unity, an impulsion with a single aim.
[1905d, 1542]
After having explained the preponderance of perverse tendencies in psychoneurotics by recognizing it as a collateral filling of subsidiary channels when the main current of the instinctual stream has been blocked by 'repression',¹ we proceeded to a consideration of sexual life in childhood. We found it a regrettable thing that the existence of the sexual instinct in childhood has been denied and that the sexual manifestations not infrequently to be observed in children have been described as irregularities. It seemed to us on the contrary that children bring germs of sexual activity with them into the world, that they already enjoy sexual satisfaction when they begin to take nourishment and that they persistently seek to repeat the experience in the familiar activity of 'thumb-sucking'. The sexual activity of children, however, does not, it appeared, develop pari passu with their other functions, but, after a short period of efflorescence from the ages of two to five, enters upon the so-called period of latency. During that period the production of sexual excitation is not by any means stopped but continues and produces a store of energy which is employed to a great extent for purposes other than sexual - namely, on the one hand in contributing the sexual components to social feelings and on the other hand (through repression and reaction-forming) in building up the subsequently developed barriers against sexuality. On this view, the forces destined to retain the sexual instinct upon certain lines are built up in childhood chiefly at the cost of perverse sexual impulses and with the assistance of education. A certain portion of the infantile sexual impulses would seem to evade these uses and succeed in expressing itself as sexual activity. We next found that sexual excitation in children springs from a multiplicity of forces. Satisfaction arises first and foremost from the appropriate sensory excitation of what we have described as erotogenic zones. It seems probable that any part of the skin and any sense-organ - probably, indeed, any organ - can function as an erotogenic zone, though there are some particularly marked erotogenic zones whose excitation would seem to be secured from the very first by certain organic contrivances. It further appears that sexual excitation arises as a by-product, as it were, of a large number of processes that occur in the organism, as soon as they reach a certain degree of intensity, and most especially of any relatively powerful emotion, even though it is of a distressing nature. The excitations from all these sources are not yet combined; but each follows its own separate aim, which is merely the attainment of a certain sort of pleasure. In childhood, therefore, the sexual instinct is not unified and is at first without an object, that is, auto-erotic.

[1905d, 1543]

The hereditary conditions in the case of positive perverts are less well known, for they know how to avoid investigation. Yet there are good reasons to suppose that what is true of the neuroses applies also to the perversions. For it is no rare thing to find perversions and psychoneuroses occurring in the same family, and distributed between the two sexes in such a way that the male members of the family, or one of them, are positive perverts, while the females, true to the tendency of their sex to repression, are negative perverts, that is, hysterics. This is good evidence of the essential connections which we have shown to exist between the two disorders.

[1905d, 1546]
REPRESSION  A different result is brought about if in the course of development some of the components which are of excessive strength in the disposition are submitted to the process of repression (which, it must be insisted, is not equivalent to their being abolished). If this happens, the excitations concerned continue to be generated as before; but they are prevented by psychical obstruction from attaining their aim and are diverted into numerous other channels till they find their way to expression as symptoms. The outcome may be an approximately normal sexual life - though usually a restricted one - but there is in addition psychoneurotic illness. These particular cases have become familiar to us from the psycho-analytic investigation of neurotics. Their sexual life begins like that of perverts, and a considerable part of their childhood is occupied with perverse sexual activity which occasionally extends far into maturity. A reversal due to repression then occurs, owing to internal causes (usually before puberty, but now and then even long afterwards), and from that time onwards neurosis takes the place of perversion, without the old impulses being extinguished. We are reminded of the proverb ‘Junge Hure, alte Betschwester’,¹ only that here youth has lasted all too short a time. The fact that perversion can be replaced by neurosis in the life of the same person, like the fact which we have already mentioned that perversion and neurosis can be distributed among different members of the same family, tallies with the view that neurosis is the negative of perversion.
[1905d, 1548]

SUBLIMATION  The third alternative result of an abnormal constitutional disposition is made possible by the process of sublimation. This enables excessively strong excitations arising from particular sources of sexuality to find an outlet and use in other fields, so that a not inconsiderable increase in psychical efficiency results from a disposition which is itself perilous. Here we have one of the origins of artistic activity; and, according to the completeness or incompleteness of the sublimation, a characterological analysis of a highly gifted individual, and in particular of one with an artistic disposition, may reveal a mixture, in every proportion, of efficiency, perversion and neurosis. A sub-species of sublimation is to be found in suppression by reaction-formation, which, as we have seen, begins during a child's period of latency and continues in favourable cases throughout his whole life. What we describe as a person's 'character' is built up to a considerable extent from the material of sexual excitations and is composed of instincts that have been fixed since childhood, of constructions achieved by means of sublimation, and of other constructions, employed for effectively holding in check perverse impulses which have been recognized as being unutilizable.¹ The multifariously perverse sexual disposition of childhood can accordingly be regarded as the source of a number of our virtues, in so far as through reaction-formation it stimulates their development.²
[1905d, 1549]
PREOCITY One such factor is spontaneous sexual precocity, whose presence at least can be demonstrated with certainty in the aetiology of the neuroses though, like other factors, it is not in itself a sufficient cause. It is manifested in the interruption, abbreviation or bringing to an end of the infantile period of latency; and it is a cause of disturbances by occasioning sexual manifestations which, owing on the one hand to the sexual inhibitions being incomplete and on the other hand to the genital system being undeveloped, are bound to be in the nature of perversions. These tendencies to perversion may thereafter either persist as such or, after repressions have set in, become the motive forces of neurotic symptoms. In any case sexual precocity makes more difficult the later control of the sexual instinct by the higher mental agencies which is so desirable, and it increases the impulsive quality which, quite apart from this, characterizes the psychical representations of the instinct. Sexual precocity often runs parallel with premature intellectual development and, linked in this way, is to be found in the childhood history of persons of the greatest eminence and capacity; under such conditions its effects do not seem to be so pathogenic as when it appears in isolation.

[1905d, 1551]

I could not further elucidate this part of my theory without a detailed discussion of my views on repression. It will be enough here to refer to my Three Essays (1905d), in which I have attempted to throw some light - if only a feeble one - on the somatic processes in which the essential nature of sexuality is to be looked for. I have there shown that the constitutional sexual disposition of children is incomparably more variegated than might have been expected, that it deserves to be described as 'polymorphously perverse' and that what is spoken of as the normal behaviour of the sexual function emerges from this disposition after certain of its components have been repressed. By pointing out the infantile elements in sexuality I was able to establish a simple correlation between health, perversion and neurosis. I showed that normality is a result of the repression of certain component instincts and constituents of the infantile disposition and of the subordination of the remaining constituents under the primacy of the genital zones in the service of the reproductive function. I showed that perversions correspond to disturbances of this coalescence owing to the overpowering and compulsive development of certain of the component instincts, while neuroses can be traced back to an excessive repression of the libidinal trends. Since almost all the perverse instincts of the infantile disposition can be recognized as the forces concerned in the formation of symptoms in neuroses, though in a state of repression, I was able to describe neurosis as being the 'negative' of perversion.

[1906a, 1581]
I think it is worth emphasizing the fact that, whatever modifications my views on the aetiology of the psychoneuroses have passed through, there are two positions which I have never repudiated or abandoned - the importance of sexuality and of infantilism. Apart from this, accidental influences have been replaced by constitutional factors and 'defence' in the purely psychological sense has been replaced by organic 'sexual repression'. The question may, however, be raised of where convincing evidence is to be found in favour of the alleged aetiological importance of sexual factors in the psychoneuroses, in view of the fact that the onset of these illnesses may be observed in response to the most commonplace emotions or even to somatic precipitating causes, and since I have had to abandon a specific aetiology depending on the particular form of the childhood experiences concerned. To such a question I would reply that the psycho-analytic examination of neurotics is the source from which this disputed conviction of mine is derived. If we make use of that irreplaceable method of research, we discover that *the patient's symptoms constitute his sexual activity* (whether wholly or in part), which arises from the sources of the normal or perverse component instincts of sexuality. Not only is a large part of the symptomatology of hysteria derived directly from expressions of sexual excitement, not only do a number of erotogenic zones attain the significance of genitals during neuroses owing to an intensification of infantile characteristics, but the most complicated symptoms are themselves revealed as representing, by means of 'conversion', phantasies which have a sexual situation as their subject-matter. Anyone who knows how to interpret the language of hysteria will recognize that the neurosis is concerned only with the patient's repressed sexuality. The sexual function must, however, be understood in its true extent, as it is laid down by disposition in infancy. Wherever some commonplace emotion must be included among the determinants of the onset of the illness, analysis invariably shows that it is the sexual component of the traumatic experience - a component that is never lacking which has produced the pathogenic result.

[1906a, 1582]

The sexual material which forms the content of smut includes more than what is peculiar to each sex; it also includes what is common to both sexes and to which the feeling of shame extends - that is to say, what is excremental in the most comprehensive sense. This is, however, the sense covered by sexuality in childhood, an age at which there is, as it were, a cloaca within which what is sexual and what is excremental are barely or not at all distinguished.¹ Throughout the whole range of the psychology of the neuroses, what is sexual includes what is excremental, and is understood in the old, infantile, sense.

[1905c, 1694]

This method of psycho-analytic investigation, which leads from the conspicuous symptoms to the hidden unconscious phantasies, tells us everything that can be known about the sexuality of psychoneurotics, including the fact which is to be the main subject-matter of this short preliminary publication.

[1908a, 1935]
This connection between symptoms and phantasies makes it easy to arrive from a psycho-
alysis of the former at a knowledge of the components of the sexual instincts which dominate
the individual, as I have demonstrated in my *Three Essays on the Theory of Sexuality*. In some
cases, however, investigation by this means yields an unexpected result. It shows that there are
many symptoms where the uncovering of a sexual phantasy (or of a number of phantasies, one
of which, the most significant and the earliest, is of a sexual nature) is not enough to bring about
a resolution of the symptoms. To resolve it one has to have two sexual phantasies, of which one
has a masculine and the other a feminine character. Thus one of these phantasies springs from
a homosexual impulse. This new finding does not alter our seventh formula. It remains true that
a hysterical symptom must necessarily represent a compromise between a libidinal and a
repressing impulse; but it may also represent a union of two libidinal phantasies of an opposite
sexual character.

[1908a, 1937]

I must expressly state that I cannot claim the same general validity for this formula as I have
done for the others. As far as I can see, it applies neither to all the symptoms of a given case
nor to all cases. On the contrary, it is not hard to adduce cases in which the impulses belonging
to the opposite sexes have found separate symptomatic expression, so that the symptoms of
heterosexuality and those of homosexuality can be as clearly distinguished from each other as
the phantasies concealed behind them. Nevertheless, the condition of things stated in the ninth
formula is common enough, and, when it occurs, important enough to deserve special
emphas. It seems to me to mark the highest degree of complexity to which the determination
of a hysterical symptom can attain, and one may therefore only expect to find it in a neurosis
which has persisted for a long time and within which a great deal of organization has taken
place.¹

[1908a, 1938]

The bisexual nature of hysterical symptoms, which can in any event be demonstrated in
numerous cases, is an interesting confirmation of my view that the postulated existence of an
innate bisexual disposition in man is especially clearly visible in the analysis of
psychoneurotics.² An exactly analogous state of affairs occurs in the same field when a person
who is masturbating tries in his conscious phantasies to have the feelings both of the man and
of the woman in the situation which he is picturing. Further counterparts are to be found in
certain hysterical attacks in which the patient simultaneously plays both parts in the underlying
sexual phantasy. In one case which I observed, for instance, the patient pressed her dress up
against her body with one hand (as the woman), while she tried to tear it off with the other (as
the man). This simultaneity of contradictory actions serves to a large extent to obscure the
situation, which is otherwise so plastically portrayed in the attack, and it is thus well suited to
conceal the unconscious phantasy that is at work.

[1908a, 1938]
Since it is precisely the remarks in my *Three Essays on the Theory of Sexuality* about the anal erotism of infants that have particularly scandalized uncomprehending readers, I venture at this point to interpolate an observation for which I have to thank a very intelligent patient. 'A friend of mine', he told me, 'who has read your *Three Essays on the Theory of Sexuality*, was talking about the book. He entirely agreed with it, but there was one passage, which - though of course he accepted and understood its meaning like that of the rest - struck him as so grotesque and comic that he sat down and laughed over it for a quarter of an hour. This passage ran: "One of the clearest signs of subsequent eccentricity or nervousness is to be seen when a baby obstinately refuses to empty his bowels when he is put on the pot - that is, when his nurse wants him to - and holds back that function till he himself chooses to exercise it. He is naturally not concerned with dirtying the bed, he is only anxious not to miss the subsidiary pleasure attached to defaecating." The picture of this baby sitting on the pot and deliberating whether he would put up with a restriction of this kind upon his personal freedom of will, and feeling anxious, too, not to miss the pleasure attached to defaecating, - this caused my friend the most intense amusement. About twenty minutes afterwards, as we were having some cocoa, he suddenly remarked without any preliminary: "I say, seeing the cocoa in front of me has suddenly made me think of an idea that I always had when I was a child. I used always to pretend to myself that I was the cocoa-manufacturer Van Houten" (he pronounced the name Van "Houten") "and that I possessed a great secret for the manufacture of this cocoa. Everybody was trying to get hold of this secret that was a boon to humanity but I kept it carefully to myself. I don't know why I should have hit specially upon Van Houten. Probably his advertisements impressed me more than any others." Laughing, and without thinking at the time that my words had any deep meaning, I said: "Wann haut'n die Mutter?" ['When does mother smack?'] The first two words in the German phrase are pronounced exactly like 'Van Houten'.] It was only later that I realized that my pun in fact contained the key to the whole of my friend's sudden childhood recollection, and I then recognized it as a brilliant example of a screen-phantasy. My friend's phantasy, while keeping to the situation, actually involved (the nutritional process) and making use of phonetic associations ('Kakao' ['cocoa'. - 'Kaka' is the common German nursery word for 'faeces'] and "Wann haut'n"), pacified his sense of guilt by making a complete reversal in the content of his recollection: there was a displacement from the back of the body to the front, excreting food became taking food in, and something that was shameful and had to be concealed became a secret that was a boon to humanity. I was interested to see how, only a quarter of an hour after my friend had fended the phantasy off (though, it is true, in the comparatively mild form of raising an objection on formal grounds) - he was, quite involuntarily, presented with the most convincing evidence by his own unconscious.'

If we take the second of these stages as an average, we must point out that a number of people are, on account of their organization, not equal to meeting its demands. In whole classes of individuals the development of the sexual instinct, as we have described it above, from autoerotism to object-love with its aim of uniting the genitals, has not been carried out correctly and sufficiently fully. As a result of these disturbances of development two kinds of harmful deviation from normal sexuality - that is, sexuality which is serviceable to civilization - come about; and the relation between these two is almost that of positive and negative.'
Where the sexual instinct is fairly intense, but perverse, there are two possible outcomes. The first, which we shall not discuss further, is that the person affected remains a pervert and has to put up with the consequences of his deviation from the standard of civilization. The second is far more interesting. It is that, under the influence of education and social demands, a suppression of the perverse instincts is indeed achieved, but it is a kind of suppression which is really no suppression at all. It can better be described as a suppression that has failed. The inhibited sexual instincts are, it is true, no longer expressed as such - and this constitutes the success of the process - but they find expression in other ways, which are quite as injurious to the subject and make him quite as useless for society as satisfaction of the suppressed instincts in an unmodified form would have done. This constitutes the failure of the process, which in the long run more than counterbalances its success. The substitutive phenomena which emerge in consequence of the suppression of the instinct amount to what we call nervous illness, or, more precisely, the psychoneuroses.¹ Neurotics are the class of people who, since they possess a recalcitrant organization, only succeed, under the influence of cultural requirements, in achieving a suppression of their instincts which is apparent and which becomes increasingly unsuccessful. They therefore only carry on their collaboration with cultural activities by a great expenditure of force and at the cost of an internal impoverishment, or are obliged at times to interrupt it and fall ill. I have described the neuroses as the ‘negative’ of the perversions because in the neuroses the perverse impulses, after being repressed, manifest themselves from the unconscious part of the mind - because the neuroses contain the same tendencies, though in a state of ‘repression’, as do the positive perversions.

Experience teaches us that for most people there is a limit beyond which their constitution cannot comply with the demands of civilization. All who wish to be more noble-minded than their constitution allows fall victims to neurosis; they would have been more healthy if it could have been possible for them to be less good. The discovery that perversions and neuroses stand in the relation of positive and negative is often unmistakably confirmed by observations made on the members of one generation of a family. Quite frequently a brother is a sexual pervert, while his sister, who, being a woman, possesses a weaker sexual instinct, is a neurotic whose symptoms express the same inclinations as the perversions of her sexually more active brother. And correspondingly, in many families the men are healthy, but from a social point of view immoral to an undesirable degree, while the women are high-minded and over-refined, but severely neurotic.

These considerations have been based so far on the requirement laid down by the second of the stages of civilization which we have postulated, the requirement that every sexual activity of the kind described as perverse is prohibited, while what is called normal sexual intercourse is freely permitted. We have found that even when the line between sexual freedom and restriction is drawn at this point, a number of individuals are ruled out as perverts, and a number of others, who make efforts not to be perverts whilst constitutionally they should be so, are forced into nervous illness. It is easy to predict the result that will follow if sexual freedom is still further circumscribed and the requirements of civilization are raised to the level of the third stage, which bans all sexual activity outside legal marriage. The number of strong natures who openly oppose the demands of civilization will increase enormously, and so will the number of weaker ones who, faced with the conflict between the pressure of cultural influences and the resistance of their constitution, take flight into neurotic illness.
In considering the question of abstinence, the distinction is not nearly strictly enough made between two forms of it - namely abstention from any sexual activity whatever and abstention from sexual intercourse with the opposite sex. Many people who boast of succeeding in being abstinent have only been able to do so with the help of masturbation and similar satisfactions which are linked with the auto-erotic sexual activities of early childhood. But precisely because of this connection such substitutive means of sexual satisfaction are by no means harmless; they predispose to the numerous varieties of neuroses and psychoses which are conditional on an involution of sexual life to its infantile forms. Masturbation, moreover, is far from meeting the ideal demands of civilized sexual morality, and consequently drives young people into the same conflicts with the ideals of education which they hoped to escape by abstinence. Furthermore, it vitiates the character through indulgence, and this in more than one way. In the first place, it teaches people to achieve important aims without taking trouble and by easy paths instead of through an energetic exertion of force - that is, it follows the principle that sexuality lays down the pattern of behaviour; secondly, in the phantasies that accompany satisfaction the sexual object is raised to a degree of excellence which is not easily found again in reality. A witty writer (Karl Kraus in the Vienna paper Die Fackel) once expressed this truth in reverse by cynically remarking: 'Copulation is no more than an unsatisfying substitute for masturbation.'

A sexual constitution like that of little Hans does not appear to carry with it a predisposition to the development either of perversions or of their negative (we will limit ourselves to a consideration of hysteria). As far as my experience goes (and there is still a real need for speaking with caution on this point) the innate constitution of hysterics - that this is also true of perverts is almost self-evident - is marked by the genital zone being relatively less prominent than the other erotogenic zones. But we must expressly except from this rule one particular 'aberration' of sexual life. In those who later become homosexuals we meet with the same predominance in infancy of the genital zone (and especially of the penis) as in normal persons.¹ Indeed it is the high esteem felt by the homosexual for the male organ which decides his fate. In his childhood he chooses women as his sexual object, so long as he assumes that they too possess what in his eyes is an indispensable part of the body; when he becomes convinced that women have deceived him in this particular, they cease to be acceptable to him as a sexual object. He cannot forgo a penis in any one who is to attract him to sexual intercourse; and if circumstances are favourable he will fix his libido upon the 'woman with a penis', a youth of feminine appearance. Homosexuals, then, are persons who, owing to the erotogenic importance of their own genitals, cannot do without a similar feature in their sexual object. In the course of their development from auto-erotism to object-love, they have remained at a point of fixation between the two.

¹ [1909b, 2093]
The events in his sixth or seventh year which the patient described in the first hour of his treatment were not merely, as he supposed, the beginning of his illness, but were already the illness itself. It was a complete obsessional neurosis, wanting in no essential element, at once the nucleus and the prototype of the later disorder, - an elementary organism, as it were, the study of which could alone enable us to obtain a grasp of the complicated organization of his subsequent illness. The child, as we have seen, was under the domination of a component of the sexual instinct, the desire to look, as a result of which there was a constant recurrence in him of a very intense wish connected with persons of the female sex who pleased him - the wish, that is, to see them naked. This wish corresponds to the later obsessional or compulsive idea; and if the quality of compulsion was not yet present in the wish, this was because the ego had not yet placed itself in complete opposition to it and did not yet regard it as something foreign to itself. Nevertheless, opposition to this wish from some source or other was already in activity, for its occurrence was regularly accompanied by a distressing affect.¹ A conflict was evidently in progress in the mind of this young libertine. Side by side with the obsessive wish, and intimately associated with it, was an obsessive fear: every time he had a wish of this kind he could not help fearing that something dreadful would happen. This something dreadful was already clothed in a characteristic indeterminateness which was thenceforward to be an invariable feature of every manifestation of the neurosis. But in a child it is not hard to discover what it is that is veiled behind an indeterminateness of this kind. If the patient can once be induced to give a particular instance in place of the vague generalities which characterize an obsessional neurosis, it may be confidently assumed that the instance is the original and actual thing which has tried to hide itself behind the generalization. Our present patient's obsessive fear, therefore, when restored to its original meaning, would run as follows: 'If I have this wish to see a woman naked, my father will be bound to die.' The distressing affect was distinctly coloured with a tinge of uncanniness and superstition, and was already beginning to give rise to impulses to do something to ward off the impending evil. These impulses were subsequently to develop into the protective measures which the patient adopted.

[1909d, 2133]

The predisposition to neurosis is traceable to impaired sexual development in a different way. Neuroses are related to perversions as negative to positive. The same instinctual components as in the perversions can be observed in the neuroses as vehicles of complexes and constructors of symptoms, but in the latter case they operate from the unconscious. Thus they have undergone repression, but have been able, in defiance of it, to persist in the unconscious. Psycho-analysis makes it clear that an excessively strong manifestation of these instincts at a very early age leads to a kind of partial fixation, which then constitutes a weak point in the structure of the sexual function. If in maturity the performance of the normal sexual function comes up against obstacles, the repression that took place during the course of development will be broken through at the precise points at which the infantile fixations occurred.

[1910a, 2231]
Let us start with the latter, the *scientific* errors. The doctor's advice to the lady shows clearly in what sense he understands the expression 'sexual life' - in the popular sense, namely, in which by sexual needs nothing is meant but the need for coitus or analogous acts producing orgasm and emission of the sexual substances. He cannot have remained unaware, however, that psycho-analysis is commonly reproached with having extended the concept of what is sexual far beyond its usual range. The fact is undisputed; I shall not discuss here whether it may justly be used as a reproach. In psycho-analysis the concept of what is sexual comprises far more; it goes lower and also higher than its popular sense. This extension is justified genetically; we reckon as belonging to 'sexual life' all the activities of the tender feelings which have primitive sexual impulses as their source, even when those impulses have become inhibited in regard to their original sexual aim or have exchanged this aim for another which is no longer sexual. For this reason we prefer to speak of *psychosexuality*, thus laying stress on the point that the mental factor in sexual life should not be overlooked or underestimated. We use the word 'sexuality' in the same comprehensive sense as that in which the German language uses the word *lieben* ['to love']. We have long known, too, that mental absence of satisfaction with all its consequences can exist where there is no lack of normal sexual intercourse; and as therapists we always bear in mind that the unsatisfied sexual trends (whose substitutive satisfactions in the form of nervous symptoms we combat) can often find only very inadequate outlet in coitus or other sexual acts.

[1910k, 2375]

(2) An equally plausible objection can be based upon Schreber's case history, as well as upon many others. For it can be urged that the delusions of persecution (which were directed against Flechsig) unquestionably made their appearance at an earlier date than the phantasy of the end of the world; so that what is supposed to have been a return of the repressed actually preceded the repression itself - and this is patent nonsense. In order to meet this objection we must leave the high ground of generalization and descend to the detailed consideration of actual circumstances, which are undoubtedly very much more complicated. We must admit the possibility that a detachment of the libido such as we are discussing might just as easily be a partial one, a drawing back from some single complex, as a general one. A partial detachment should be by far the commoner of the two, and should precede a general one, since to begin with it is only for a partial detachment that the influences of life provide a motive. The process may then stop at the stage of a partial detachment or it may spread to a general one, which will loudly proclaim its presence in the symptoms of megalomania. Thus the detachment of the libido from the figure of Flechsig may nevertheless have been what was primary in the case of Schreber; it was immediately followed by the appearance of the delusion, which brought back the libido on to Flechsig again (though with a negative sign to mark the fact that repression had taken place) and thus annulled the work of repression. And now the battle of repression broke out anew, but this time with more powerful weapons. In proportion as the object of contention became the most important thing in the external world, trying on the one hand to draw the whole of the libido on to itself, and on the other hand mobilizing all the resistances against itself, so the struggle raging around this single object became more and more comparable to a general engagement; till at length a victory for the forces of repression found expression in a conviction that the world had come to an end and that the self alone survived. If we review the ingenious constructions which were raised by Schreber's delusion in the domain of religion - the hierarchy of God, the proved souls, the fore-courts of Heaven, the lower and the upper God - we can gauge in retrospect the wealth of sublimations which were brought down in ruin by the catastrophe of the general detachment of his libido.

[1911c, 2439]
Before I wind up these remarks on beginning analytic treatment, I must say a word about a certain ceremonial which concerns the position in which the treatment is carried out. I hold to the plan of getting the patient to lie on a sofa while I sit behind him out of his sight. This arrangement has a historical basis; it is the remnant of the hypnotic method out of which psycho-analysis was evolved. But it deserves to be maintained for many reasons. The first is a personal motive, but one which others may share with me. I cannot put up with being stared at by other people for eight hours a day (or more). Since, while I am listening to the patient, I, too, give myself over to the current of my unconscious thoughts, I do not wish my expressions of face to give the patient material for interpretations or to influence him in what he tells me. The patient usually regards being made to adopt this position as a hardship and rebels against it, especially if the instinct for looking (scopophilia) plays an important part in his neurosis. I insist on this procedure, however, for its purpose and result are to prevent the transference from mingling with the patient's associations imperceptibly, to isolate the transference and to allow it to come forward in due course sharply defined as a resistance. I know that many analysts work in a different way, but I do not know whether this deviation is due more to a craving for doing things differently or to some advantage which they find they gain by it.

Our work on the question of the disposition to neurotic affections has added the 'infantile' factor to the somatic and hereditary ones hitherto recognized. Psycho-analysis was obliged to trace back patients' mental life to their early infancy, and the conclusion was reached that inhibitions of mental development ('infantilisms') present a disposition to neurosis. In particular, we have learnt from our investigations of sexual life that there really is such a thing as 'infantile sexuality', that the sexual instinct is made up of many components and passes through a complicated course of development, the final outcome of which, after many restrictions and transformations, is the 'normal' sexuality of adults. The puzzling perversions of the sexual instinct which occur in adults appear to be either inhibitions of development, fixations or lop-sided growths. Thus neuroses are the negative of perversions.

The view may be taken that all the difficulties and complications involved in this can be avoided by denying that there is any pregenital organization of sexual life and by holding that sexual life coincides with the genital and reproductive function and begins with it. It would then be asserted, having regard to the unmistakable findings of analytic research, that the neuroses are compelled by the process of sexual repression to give expression to sexual trends through other, non-sexual instincts, and thus to sexualize the latter by way of compensation. But this line of argument would place us outside psycho-analysis. It would place us where we were before psycho-analysis and would mean abandoning the understanding which psycho-analysis has given us of the relations between health, perversion and neurosis. Psycho-analysis stands or falls with the recognition of the sexual component instincts, of the erotogenic zones and of the extension thus made possible of the concept of a 'sexual function' in contrast to the narrower 'genital function'. Moreover the observation of the normal development of children is in itself enough to make us reject any such temptation.

Psycho-analysis further shows that, to begin with, excremental and sexual instincts are not distinct from each other in children. The divorce between them only occurs later and it remains incomplete. Their original affinity, which is established by the anatomy of the human body, still makes itself felt in many ways in normal adults. Finally, it should not be forgotten that these developments can no more be expected to yield a perfect result than any others. Some portion of the old preferences persist, some part of the coprophilic inclinations continue to operate in later life and are expressed in the neuroses, perversions and bad habits of adults.
If we examine sexuality in the adult with the help of psycho-analysis, and consider the life of children in the light of the knowledge thus gained, we perceive that sexuality is not merely a function serving the purposes of reproduction, on a par with digestion, respiration, etc. It is something far more independent, which stands in contrast to all the individual's other activities and is only forced into an alliance with the individual's economy after a complicated course of development involving the imposition of numerous restrictions. Cases, theoretically quite conceivable, in which the interests of these sexual impulses fail to coincide with the self-preservation of the individual seem actually to be presented by the group of neurotic illnesses. For the final formula which psycho-analysis has arrived at on the nature of the neuroses runs thus: The primal conflict which leads to neuroses is one between the sexual instincts and those which maintain the ego. The neuroses represent a more or less partial overpowering of the ego by sexuality after the ego's attempts at suppressing sexuality have failed.

When educators have become familiar with the findings of psycho-analysis, it will be easier for them to reconcile themselves to certain phases of infantile development and they will, among other things, not be in danger of over-estimating the importance of the socially unserviceable or perverse instinctual impulses which emerge in children. On the contrary they will refrain from any attempt at forcibly suppressing such impulses, when they learn that efforts of this kind often produce no less undesirable results than the alternative, which is so much dreaded by educators, of giving free play to children's naughtiness. The forcible suppression of strong instincts by external means never has the effect in a child of these instincts being extinguished or brought under control; it leads to repression, which establishes a predisposition to later nervous illness. Psycho-analysis has frequent opportunities of observing the part played by inopportune and undiscerning severity of upbringing in the production of neuroses, or the price, in loss of efficiency and of capacity for enjoyment, which has to be paid for the normality upon which the educator insists. And psycho-analysis can also show what precious contributions to the formation of character are made by these asocial and perverse instincts in the child, if they are not subjected to repression but are diverted from their original aims to more valuable ones by the process known as 'sublimation'. Our highest virtues have grown up, as reaction formations and sublimations, out of our worst dispositions. Education should scrupulously refrain from burying these precious springs of action and should restrict itself to encouraging the processes by which these energies are led along safe paths. Whatever we can expect in the way of prophylaxis against neurosis in the individual lies in the hands of a psycho-analytically enlightened education.

We shall not be able to dismiss a second objection so easily. If you survey a fairly long series of interpretations of symptoms, you will probably start by judging that the concept of a substitutive sexual satisfaction has been stretched to its extreme limits in them. You will not fail to emphasize the fact that these symptoms offer nothing real in the way of satisfaction, that often enough they are restricted to the revival of a sensation or the representation of a phantasy derived from a sexual complex. And you will further point out that these supposed sexual satisfactions often take on a childish and discreditable form, approximate to an act of masturbation perhaps, or recall dirty kinds of naughtiness which are forbidden even to children - habits of which they have been broken. And, going on from this, you will also express surprise that we are representing as a sexual satisfaction what would rather have to be described as the satisfaction of lusts that are cruel or horrible or would even have to be called unnatural. We shall come to no agreement, Gentlemen, on this latter point till we have made a thorough investigation of the sexual life of human beings and till, in doing so, we have decided what it is that we are justified in calling 'sexual'.

[1913], 2817

[1916-1917, 3374]
I have said that neurotic symptoms are substitutes for sexual satisfaction, and I indicated to you that the confirmation of this assertion by the analysis of symptoms would come up against a number of difficulties. For it can only be justified if under 'sexual satisfaction' we include the satisfaction of what are called perverse sexual needs, since an interpretation of symptoms of that kind is forced upon us with surprising frequency. The claim made by homosexuals or inverteds to being exceptions collapses at once when we learn that homosexual impulses are invariably discovered in every single neurotic, and that a fair number of symptoms give expression to this latent inversion. Those who call themselves homosexuals are only the conscious and manifest inverteds, whose number is nothing compared to that of the latent homosexuals. We are compelled, however, to regard choice of an object of one's own sex as a divergence in erotic life which is of positively habitual occurrence, and we are learning more and more to ascribe an especially high importance to it. No doubt this does not do away with the differences between manifest homosexuality and a normal attitude; their practical significance remains, but their theoretical value is greatly diminished. We have even found that a particular disease, paranoia, which is not to be counted among the transference neuroses, regularly arises from an attempt to fend off excessively strong homosexual impulses. You will perhaps recall that one of our patients (p. 3343) behaved in her obsessional action like a man, her own husband whom she had left; neurotic women very commonly produce symptoms in this way in the character of a man. Even if this is not actually to be regarded as homosexuality, it is closely related to its preconditions.

[1916-1917, 3379]

As you probably know, the hysterical neurosis can produce its symptoms in any system of organs and so disturb any function. Analysis shows that in this way all the so-called perverse impulses which seek to replace the genital by some other organ manifest themselves; these organs are then behaving like substitutive genitals. The symptoms of hysteria have actually led us to the view that the bodily organs, besides the functional part they play, must be recognized as having a sexual (erotogenic) significance, and that the execution of the first of these tasks is disturbed if the second of them makes too many claims. Countless sensations and innervations which we come across as symptoms of hysteria in organs that have no apparent connection with sexuality are in this way revealed to us as being in the nature of fulfilments of perverse sexual impulses in relation to which other organs have acquired the significance of the sexual parts. We learn too to what a large extent the organs for the intake of nourishment and for excretion can in particular become the vehicles of sexual excitation. Here, then, we have the same thing that we were shown by the perversions; only in their case it was visible easily and unmistakably, whereas in hysteria we have to take a circuitous path by way of the interpretation of symptoms, and do not then ascribe the perverse sexual impulses concerned to the subject's consciousness but locate them in his unconscious.

[1916-1917, 3380]
Of the many symptomatic pictures in which obsessional neurosis appears, the most important turn out to be those provoked by the pressure of excessively strong sadistic sexual impulses (perverse, therefore, in their aim). The symptoms, indeed, in accordance with the structure of an obsessional neurosis, serve predominantly as a *defence* against these wishes or give expression to the struggle between satisfaction and defence. But satisfaction does not come off too badly either; it succeeds in roundabout ways in putting itself into effect in the patients’ behaviour and is preferably directed against themselves and makes them into self-tormentors. Other forms of the neurosis, the brooding kinds, correspond to an excessive sexualization of actions which ordinarily have their place on the path to normal sexual satisfaction - an excessive sexualization of wanting to look or to touch or to explore. Here we have the explanation of the great importance of the fear of touching and of the obsession for washing. An unsuspectedly large proportion of obsessional actions may be traced back to masturbation, of which they are disguised repetitions and modifications; it is a familiar fact that masturbation, though a single and uniform action, accompanies the most various forms of sexual phantasying.

The path to perversion branches off sharply from that to neurosis. If these regressions rouse no objection from the ego, no neurosis will come about either; and the libido will arrive at some real, even though no longer normal, satisfaction. But if the ego, which has under its control not only consciousness but also the approaches to motor innervation and accordingly to the realization of mental desires, does not agree with these regressions, conflict will follow. The libido is, as it were, cut off and must try to escape in some direction where, in accordance with the requirements of the pleasure principle, it can find a discharge for its cathexis of energy. It must withdraw from the ego. An escape of this kind is offered it by the fixations on the path of its development which it has now entered on regressively - fixations from which the ego had protected itself in the past by repressions. By cathecting these repressed positions as it flows backward, the libido has withdrawn from the ego and its laws, and has at the same time renounced all the education it has acquired under the ego’s influence. It was docile so long as satisfaction beckoned to it; but under the double pressure of external and internal frustration it becomes refractory, and recalls earlier and better times. Such is the libido’s fundamentally unchangeable character. The ideas to which it now transfers its energy as a cathexis belong to the system of the unconscious and are subject to the processes which are possible there, particularly to condensation and displacement. In this way conditions are established which completely resemble those in dream-construction. The dream proper, which has been completed in the unconscious and is the fulfilment of an unconscious wishful phantasy, is brought up against a portion of (pre)conscious activity which exercises the office of censorship and which, when it has been indemnified, permits the formation of the manifest dream as a compromise. In the same way, what represents the libido in the unconscious has to reckon with the power of the preconscious ego. The opposition which had been raised against it in the ego pursues it as an ‘anticathexis’ and compels it to choose a form of expression which can at the same time become an expression of the opposition itself. Thus the symptom emerges as a many-times-distorted derivative of the unconscious libidinal wish-fulfilment, an ingeniously chosen piece of ambiguity with two meanings in complete mutual contradiction. In this last respect, however, there is a distinction between the construction of a dream and of a symptom. For in dream-formation the preconscious purpose is merely concerned to preserve sleep, to allow nothing that would disturb it to make its way into consciousness; it does not insist upon calling out sharply ‘*No!* on the contrary!’ to the unconscious wishful impulse. It can afford to be more tolerant because the situation of someone sleeping is less perilous. The state of sleep in itself bars any outlet into reality.
Since the column of faeces stimulates the erotogenic mucous membrane of the bowel, it plays the part of an active organ in regard to it; it behaves just as the penis does to the vaginal mucous membrane, and acts as if it were as its forerunner during the cloacal epoch. The handing over of faeces for the sake of (out of love for) some one else becomes a prototype of castration; it is the first occasion upon which an individual parts with a piece of his own body¹ in order to gain the favour of some other person whom he loves. So that a person's love of his own penis, which is in other respects narcissistic, is not without an element of anal erotism. Faeces', 'baby' and 'penis' thus form a unity, an unconscious concept (si venia verbo) - the concept, namely, of 'a little one' that can become separated from one's body. Along these paths of association the libidinal cathectsis may become displaced or intensified in ways which are pathologically important and which are revealed by analysis.

[1918b, 3566]
I must now turn to consider a further complication to which I should certainly give no space if I were a man of letters engaged upon the creation of a mental state like this for a short story, instead of being a medical man engaged upon its dissection. The element to which I must now allude can only serve to obscure and efface the outlines of the fine poetic conflict which we have been able to ascribe to Dora. This element would rightly fall a sacrifice to the censorship of a writer, for he, after all, simplifies and abstracts when he appears in the character of a psychologist. But in the world of reality, which I am trying to depict here, a complication of motives, an accumulation and conjunction of mental activities - in a word, overdetermination - is the rule. For behind Dora's supervalent train of thought which was concerned with her father's relations with Frau K. there lay concealed a feeling of jealousy which had that lady as its object - a feeling, that is, which could only be based upon an affection on Dora's part for one of her own sex. It has long been known and often been pointed out that at the age of puberty boys and girls show clear signs, even in normal cases, of the existence of an affection for people of their own sex. A romantic and sentimental friendship with one of her school friends, accompanied by vows, kisses, promises of eternal correspondence, and all the sensibility of jealousy, is the common precursor of a girl's first serious passion for a man. Thenceforward, in favourable circumstances, the homosexual current of feeling often runs completely dry. But if a girl is not happy in her love for a man, the current is often set flowing again by the libido in later years and is increased up to a greater or lesser degree of intensity. If this much can be established without difficulty of healthy persons, and if we take into account what has already been said about the fuller development in neurotics of the normal germs of perversion, we shall expect to find in these latter too a fairly strong homosexual predisposition. It must, indeed, be so; for I have never yet come through a single psycho-analysis of a man or a woman without having to take into account a very considerable current of homosexuality. When, in a hysterical woman or girl, the sexual libido which is directed towards men has been energetically suppressed, it will regularly be found that the libido which is directed towards women has become vicariously reinforced and even to some extent conscious.
[1905e, 1397]
I shall not in this place go any further into this important subject, which is especially indispensable to an understanding of hysteria in men, because Dora's analysis came to an end before it could throw any light on this side of her mental life. But I should like to recall the governess, whom I have already mentioned, and with whom Dora had at first enjoyed the closest interchange of thought, until she discovered that she was being admired and fondly treated not for her own sake but for her father's; whereupon she had obliged the governess to leave. She used also to dwell with noticeable frequency and a peculiar emphasis on the story of another estrangement which appeared inexplicable even to herself. She had always been on particularly good terms with the younger of her two cousins the girl who had later on become engaged - and had shared all sorts of secrets with her. When, for the first time after Dora had broken off her stay by the lake, her father was going back to B--, she had naturally refused to go with him. This cousin had then been asked to travel with him instead, and she had accepted the invitation. From that time forward Dora had felt a coldness towards her, and she herself was surprised to find how indifferent she had become, although, as she admitted, she had very little ground for complaint against her. These instances of sensitiveness led me to inquire what her relations with Frau K. had been up till the time of the breach. I then found that the young woman and the scarcely grown girl had lived for years on a footing of the closest intimacy. When Dora stayed with the K.'s she used to share a bedroom with Frau K., and the husband used to be quartered elsewhere. She had been the wife's confidante and adviser in all the difficulties of her married life. There was nothing they had not talked about. Medea had been quite content that Creusa should make friends with her two children; and she certainly did nothing to interfere with the relations between the girl and the children's father. How Dora managed to fall in love with the man about whom her beloved friend had so many bad things to say is an interesting psychological problem. We shall not be far from solving it when we realize that thoughts in the unconscious live very comfortably side by side, and even contraries get on together without disputes - a state of things which persists often enough even in the conscious.

¹ The longer the interval of time that separates me from the end of this analysis, the more probable it seems to me that the fault in my technique lay in this omission: I failed to discover in time and to inform the patient that her homosexual (gynaecophilic) love for Frau K. was the strongest unconscious current in her mental life. I ought to have guessed that the main source of her knowledge of sexual matters could have been no one but Frau K. - the very person who later on charged her with being interested in those same subjects. Her knowing all about such things and, at the same time, her always pretending not to know where her knowledge came from was really too remarkable. I ought to have attacked this riddle and looked for the motive of such an extraordinary piece of repression. If I had done this, the second dream would have given me my answer. The remorseless craving for revenge expressed in that dream was suited as nothing else was to conceal the current of feeling that ran contrary to it - the magnanimity with which she forgave the treachery of the friend she loved and concealed from every one the fact that it was this friend who had herself revealed to her the knowledge which had later been the ground of the accusations against her. Before I had learnt the importance of the homosexual current of feeling in psychoneurotics, I was often brought to a standstill in the treatment of my cases or found myself in complete perplexity.

[1905e, 1398]

[1905e, 1453]
Psycho-analytic research is most decidedly opposed to any attempt at separating off homosexuals from the rest of mankind as a group of a special character. By studying sexual excitations other than those that are manifestly displayed, it has found that all human beings are capable of making a homosexual object-choice and have in fact made one in their unconscious. Indeed, libidinal attachments to persons of the same sex play no less a part as factors in normal mental life, and a greater part as a motive force for illness, than do similar attachments to the opposite sex. On the contrary, psycho-analysis considers that a choice of an object independently of its sex - freedom to range equally over male and female objects - as it is found in childhood, in primitive states of society and early periods of history, is the original basis from which, as a result of restriction in one direction or the other, both the normal and the inverted types develop. Thus from the point of view of psycho-analysis the exclusive sexual interest felt by men for women is also a problem that needs elucidating and is not a self-evident fact based upon an attraction that is ultimately of a chemical nature. A person's final sexual attitude is not decided until after puberty and is the result of a number of factors, not all of which are yet known; some are of a constitutional nature but others are accidental. No doubt a few of these factors may happen to carry so much weight that they influence the result in their sense. But in general the multiplicity of determining factors is reflected in the variety of manifest sexual attitudes in which they find their issue in mankind. In inverted types, a predominance of archaic constitutions and primitive psychical mechanisms is regularly to be found. Their most essential characteristics seem to be a coming into operation of narcissistic object-choice and a retention of the erotic significance of the anal zone. There is nothing to be gained, however, by separating the most extreme types of inversion from the rest on the basis of constitutional peculiarities of that kind. What we find as an apparently sufficient explanation of these types can be equally shown to be present, though less strongly, in the constitution of transitional types and of those whose manifest attitude is normal. The differences in the end-products may be of a qualitative nature, but analysis shows that the differences between their determinants are only quantitative. Among the accidental factors that influence object-choice we have found that frustration (in the form of an early deterrence, by fear, from sexual activity) deserves attention, and we have observed that the presence of both parents plays an important part. The absence of a strong father in childhood not infrequently favours the occurrence of inversion. Finally, it may be insisted that the concept of inversion in respect of the sexual object should be sharply distinguished from that of the occurrence in the subject of a mixture of sexual characters. In the relation between these two factors, too, a certain degree of reciprocal independence is unmistakably present.

(a) The unconscious mental life of all neurotics (without exception) shows inverted impulses, fixation of their libido upon persons of their own sex. It would be impossible without deep discussion to give any adequate appreciation of the importance of this factor in determining the form taken by the symptoms of the illness. I can only insist that an unconscious tendency to inversion is never absent and is of particular value in throwing light upon hysteria in men.

¹ Psychoneuroses are also very often associated with manifest inversion. In such cases the heterosexual current of feeling has undergone complete suppression. It is only fair to say that my attention was first drawn to the necessary universality of the tendency to inversion in psychoneurotics by Wilhelm Fliess of Berlin, after I had discussed its presence in individual cases. - [Added 1920:] This fact, which has not been sufficiently appreciated, cannot fail to have a decisive influence on any theory of homosexuality.
The bisexual nature of hysterical symptoms, which can in any event be demonstrated in numerous cases, is an interesting confirmation of my view that the postulated existence of an innate bisexual disposition in man is especially clearly visible in the analysis of psychoneurotics.² An exactly analogous state of affairs occurs in the same field when a person who is masturbating tries in his conscious phantasies to have the feelings both of the man and of the woman in the situation which he is picturing. Further counterparts are to be found in certain hysterical attacks in which the patient simultaneously plays both parts in the underlying sexual phantasy. In one case which I observed, for instance, the patient pressed her dress up against her body with one hand (as the woman), while she tried to tear it off with the other (as the man). This simultaneity of contradictory actions serves to a large extent to obscure the situation, which is otherwise so plastically portrayed in the attack, and it is thus well suited to conceal the unconscious phantasy that is at work.

[1908a, 1938]

In psycho-analytic treatment it is very important to be prepared for a symptom's having a bisexual meaning. We need not then be surprised or misled if a symptom seems to persist undiminished although we have already resolved one of its sexual meanings; for it is still being maintained by the - perhaps unsuspected - one belonging to the opposite sex. In the treatment of such cases, moreover, one may observe how the patient avails himself, during the analysis of the one sexual meaning, of the convenient possibility of constantly switching his associations, as though on to an adjoining track, into the field of the contrary meaning.

[1908a, 1939]

Speaking as a whole, hysterical attacks, like hysteria in general, revive a piece of sexual activity in women which existed during their childhood and at that time revealed an essentially masculine character. It can often be observed that girls who have shown a boyish nature and inclinations up to the years before puberty are precisely those who become hysterical from puberty onwards. In a whole number of cases the hysterical neurosis merely represents an excessive accentuation of the typical wave of repression which, by doing away with her masculine sexuality, allows the woman to emerge.²

[1909a, 1984]

He had a friend, he told me, of whom he had an extraordinarily high opinion. He used always to go to him when he was tormented by some criminal impulse, and ask him whether he despised him as a criminal. His friend used then to give him moral support by assuring him that he was a man of irreproachable conduct, and had probably been in the habit, from his youth onwards, of taking a dark view of his own life. At an earlier date, he went on, another person had exercised a similar influence over him. This was a nineteen-year-old student (he himself had been fourteen or fifteen at the time) who had taken a liking to him, and had raised his self-esteem to an extraordinary degree, so that he appeared to himself to be a genius. This student had subsequently become his tutor, and had suddenly altered his behaviour and begun treating him as though he were an idiot. At length he had noticed that the student was interested in one of his sisters, and had realized that he had only taken him up in order to gain admission into the house. This had been the first great blow of his life.

[1909d, 2130]
In my *Three Essays on the Theory of Sexuality* I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics *endeavour to protect themselves against any such sexualization of their social instinctual cathexes*, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) *schizophrenia*; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients’ dispositional fixations.

(2) An equally plausible objection can be based upon Schreber's case history, as well as upon many others. For it can be urged that the delusions of persecution (which were directed against Flechsig) unquestionably made their appearance at an earlier date than the phantasy of the end of the world; so that what is supposed to have been a return of the repressed actually preceded the repression itself - and this is patent nonsense. In order to meet this objection we must leave the high ground of generalization and descend to the detailed consideration of actual circumstances, which are undoubtedly very much more complicated. We must admit the possibility that a detachment of the libido such as we are discussing might just as easily be a partial one, a drawing back from some single complex, as a general one. A partial detachment should be by far the commoner of the two, and should precede a general one, since to begin with it is only for a partial detachment that the influences of life provide a motive. The process may then stop at the stage of a partial detachment or it may spread to a general one, which will loudly proclaim its presence in the symptoms of megalomania. Thus the detachment of the libido from the figure of Flechsig may nevertheless have been what was primary in the case of Schreber; it was immediately followed by the appearance of the delusion, which brought back the libido on to Flechsig again (though with a negative sign to mark the fact that repression had taken place) and thus annulled the work of repression. And now the battle of repression broke out anew, but this time with more powerful weapons. In proportion as the object of contention became the most important thing in the external world, trying on the one hand to draw the whole of the libido on to itself, and on the other hand mobilizing all the resistances against itself, so the struggle raging around this single object became more and more comparable to a general engagement; till at length a victory for the forces of repression found expression in a conviction that the world had come to an end and that the self alone survived. If we review the ingenious constructions which were raised by Schreber's delusion in the domain of religion - the hierarchy of God, the proved souls, the fore-courts of Heaven, the lower and the upper God - we can gauge in retrospect the wealth of sublimations which were brought down in ruin by the catastrophe of the general detachment of his libido.
I have said that neurotic symptoms are substitutes for sexual satisfaction, and I indicated to you that the confirmation of this assertion by the analysis of symptoms would come up against a number of difficulties. For it can only be justified if under 'sexual satisfaction' we include the satisfaction of what are called perverse sexual needs, since an interpretation of symptoms of that kind is forced upon us with surprising frequency. The claim made by homosexuals or inverts to being exceptions collapses at once when we learn that homosexual impulses are invariably discovered in every single neurotic, and that a fair number of symptoms give expression to this latent inversion. Those who call themselves homosexuals are only the conscious and manifest inverts, whose number is nothing compared to that of the latent homosexuals. We are compelled, however, to regard choice of an object of one's own sex as a divergence in erotic life which is of positively habitual occurrence, and we are learning more and more to ascribe an especially high importance to it. No doubt this does not do away with the differences between manifest homosexuality and a normal attitude; their practical significance remains, but their theoretical value is greatly diminished. We have even found that a particular disease, paranoia, which is not to be counted among the transference neuroses, regularly arises from an attempt to fend off excessively strong homosexual impulses. You will perhaps recall that one of our patients (p. 3343) behaved in her obsessional action like a man, her own husband whom she had left; neurotic women very commonly produce symptoms in this way in the character of a man. Even if this is not actually to be regarded as homosexuality, it is closely related to its preconditions. [1916-1917, 3379]

What makes hatred of the father unacceptable is fear of the father; castration is terrible, whether as a punishment or as the price of love. Of the two factors which repress hatred of the father, the first, the direct fear of punishment and castration, may be called the normal one; its pathogenic intensification seems to come only with the addition of the second factor, the fear of the feminine attitude. Thus a strong innate bisexual disposition becomes one of the preconditions or reinforcements of neurosis. Such a disposition must certainly be assumed in Dostoevsky, and it shows itself in a viable form (as latent homosexuality) in the important part played by male friendships in his life, in his strangely tender attitude towards rivals in love and in his remarkable understanding of situations which are explicable only by repressed homosexuality, as many examples from his novels show. [1928b, 4560]
Psychoneuroses are also very often associated with manifest inversion. In such cases the heterosexual current of feeling has undergone complete suppression. It is only fair to say that my attention was first drawn to the necessary universality of the tendency to inversion in psychoneurotics by Wilhelm Fliess of Berlin, after I had discussed its presence in individual cases. - [Added 1920:] This fact, which has not been sufficiently appreciated, cannot fail to have a decisive influence on any theory of homosexuality.

[1905d, 1491]

In psycho-analytic treatment it is very important to be prepared for a symptom's having a bisexual meaning. We need not then be surprised or misled if a symptom seems to persist undiminished although we have already resolved one of its sexual meanings; for it is still being maintained by the - perhaps unsuspected - one belonging to the opposite sex. In the treatment of such cases, moreover, one may observe how the patient avails himself, during the analysis of the one sexual meaning, of the convenient possibility of constantly switching his associations, as though on to an adjoining track, into the field of the contrary meaning.

[1908a, 1939]
The reproaches against her father for having made her ill, together with the self-reproach underlying them, the leucorrhoea, the playing with the reticule, the bed-wetting after her sixth year, the secret which she would not allow the doctors to tear from her - the circumstantial evidence of her having masturbated in childhood seems to me complete and without a flaw. In the present case I had begun to suspect the masturbation when she had told me of her cousin's gastric pains, and had then identified herself with her by complaining for days together of similar painful sensations. It is well known that gastric pains occur especially often in those who masturbate. According to a personal communication made to me by Wilhelm Fliess, it is precisely gastralgias of this character which can be interrupted by an application of cocaine to the 'gastric spot' discovered by him in the nose, and which can be cured by the cauterization of the same spot. In confirmation of my suspicion Dora gave me two facts from her conscious knowledge: she herself had frequently suffered from gastric pains, and she had good reasons for believing that her cousin was a masturbator. It is a very common thing for patients to recognize in other people a connection which, on account of their emotional resistances, they cannot perceive in themselves. And, indeed, Dora no longer denied my supposition, although she still remembered nothing. Even the date which she assigned to the bed-wetting, when she said that it lasted 'till a short time before the appearance of the nervous asthma', appears to me to be of clinical significance. Hysterical symptoms hardly ever appear so long as children are masturbating, but only afterwards, when a period of abstinence has set in;¹ they form a substitute for masturbatory satisfaction, the desire for which continues to persist in the unconscious until another and more normal kind of satisfaction appears - where that is still attainable. For upon whether it is still attainable or not depends the possibility of a hysteria being cured by marriage and normal sexual intercourse. But if the satisfaction afforded in marriage is again removed - as it may be owing to coitus interruptus, psychological estrangement, or other causes - then the libido flows back again into its old channel and manifests itself once more in hysterical symptoms.

¹[1905e, 1415]

The preceding discussion may perhaps have placed the sexuality of psychoneurotics in a false light. It may have given the impression that, owing to their disposition, psychoneurotics approximate closely to perverts in their sexual behaviour and are proportionately remote from normal people. It may indeed very well be that the constitutional disposition of these patients (apart from their exaggerated degree of sexual repression and the excessive intensity of their sexual instinct) includes an unusual tendency to perversion, using that word in its widest sense. Nevertheless, investigation of comparatively slight cases shows that this last assumption is not absolutely necessary, or at least that in forming a judgement on these pathological developments there is a factor to be considered which weighs in the other direction. Most psychoneurotics only fall ill after the age of puberty as a result of the demands made upon them by normal sexual life. (It is most particularly against the latter that repression is directed.) Or else illnesses of this kind set in later, when the libido fails to obtain satisfaction along normal lines. In both these cases the libido behaves like a stream whose main bed has become blocked. It proceeds to fill up collateral channels which may hitherto have been empty. Thus, in the same way, what appears to be the strong tendency (though, it is true, a negative one) of psychoneurotics to perversion may be collaterally determined, and must, in any case, be collaterally intensified. The fact is that we must put sexual repression as an internal factor alongside such external factors as limitation of freedom, inaccessibility of a normal sexual object, the dangers of the normal sexual act, etc., which bring about perversions in persons who might perhaps otherwise have remained normal.

¹[1905d, 1494]
In this respect different cases of neurosis may behave differently: in one case the preponderating factor may be the innate strength of the tendency to perversion, in another it may be the collateral increase of that tendency owing to the libido being forced away from a normal sexual aim and sexual object. It would be wrong to represent as opposition what is in fact a co-operative relation. Neurosis will always produce its greatest effects when constitution and experience work together in the same direction. Where the constitution is a marked one it will perhaps not require the support of actual experiences; while a great shock in real life will perhaps bring about a neurosis even in an average constitution. (Incidentally, this view of the relative aetiological importance of what is innate and what is accidentally experienced applies equally in other fields.)

[1905d, 1494]

After having explained the preponderance of perverse tendencies in psychoneurotics by recognizing it as a collateral filling of subsidiary channels when the main current of the instinctual stream has been blocked by 'repression',¹ we proceeded to a consideration of sexual life in childhood. We found it a regrettable thing that the existence of the sexual instinct in childhood has been denied and that the sexual manifestations not infrequently to be observed in children have been described as irregularities. It seemed to us on the contrary that children bring germs of sexual activity with them into the world, that they already enjoy sexual satisfaction when they begin to take nourishment and that they persistently seek to repeat the experience in the familiar activity of 'thumb-sucking'. The sexual activity of children, however, does not, it appeared, develop pari passu with their other functions, but, after a short period of efflorescence from the ages of two to five, enters upon the so-called period of latency. During that period the production of sexual excitation is not by any means stopped but continues and produces a store of energy which is employed to a great extent for purposes other than sexual - namely, on the one hand in contributing the sexual components to social feelings and on the other hand (through repression and reaction-forming) in building up the subsequently developed barriers against sexuality. On this view, the forces destined to retain the sexual instinct upon certain lines are built up in childhood chiefly at the cost of perverse sexual impulses and with the assistance of education. A certain portion of the infantile sexual impulses would seem to evade these uses and succeed in expressing itself as sexual activity. We next found that sexual excitation in children springs from a multiplicity of forces. Satisfaction arises first and foremost from the appropriate sensory excitation of what we have described as erotogenic zones. It seems probable that any part of the skin and any sense-organ - probably, indeed, any organ - can function as an erotogenic zone, though there are some particularly marked erotogenic zones whose excitation would seem to be secured from the very first by certain organic contrivances. It further appears that sexual excitation arises as a by-product, as it were, of a large number of processes that occur in the organism, as soon as they reach a certain degree of intensity, and most especially of any relatively powerful emotion, even though it is of a distressing nature. The excitations from all these sources are not yet combined; but each follows its own separate aim, which is merely the attainment of a certain sort of pleasure. In childhood, therefore, the sexual instinct is not unified and is at first without an object, that is, auto-erotic.

[1905d, 1543]

¹ [Footnote added 1915:] This does not apply only to the 'negative' tendencies to perversion which appear in neuroses but equally to the 'positive,' properly so-called, perversions. Thus these latter are to be derived not merely from a fixation of infantile tendencies but also from a regression to those tendencies as a result of other channels of the sexual current being blocked. It is for this reason that the positive perversions also are accessible to psycho-analytic therapy.

[1905d, 1543]
In men a high degree of this trend persists as a portion of their libido, and it serves to introduce the sexual act. When this urge makes itself felt at the first approach to a woman, it must make use of words, for two reasons; firstly, to announce itself to her, and secondly, because if the idea is aroused by speech it may induce a corresponding excitement in the woman herself and may awaken an inclination in her to passive exhibitionism. A wooing speech like this is not yet smut, but it passes over into it. If the woman's readiness emerges quickly the obscene speech has a short life; it yields at once to a sexual action. It is otherwise if quick readiness on the woman's part is not to be counted on, and if in place of it defensive reactions appear. In that case the sexually exciting speech becomes an aim in itself in the shape of smut. Since the sexual aggressiveness is held up in its advance towards the act, it pauses at the evocation of the excitement and derives pleasure from the signs of it in the woman. In so doing, the aggressiveness is no doubt altering its character as well, just as any libidinal impulse will if it is met by an obstacle. It becomes positively hostile and cruel, and it thus summons to its help against the obstacle the sadistic components of the sexual instinct.

The question of why this outburst of homosexual libido overtook the patient precisely at this period (that is, between the dates of his appointment and of his move to Dresden) cannot be answered in the absence of more precise knowledge of the story of his life. Generally speaking, every human being oscillates all through his life between heterosexual and homosexual feelings, and any frustration or disappointment in the one direction is apt to drive him over into the other. We know nothing of these factors in Schreber's case, but we must not omit to draw attention to a somatic factor which may very well have been relevant. At the time of this illness Dr. Schreber was fifty-one years old, and he had therefore reached an age which is of critical importance in sexual life. It is a period at which in women the sexual function, after a phase of intensified activity, enters upon a process of far-reaching involution; nor do men appear to be exempt from its influence, for men as well as women are subject to a 'climacteric' and to the susceptibilities to disease which go along with it.¹

In my *Three Essays on the Theory of Sexuality* I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics *endeavour to protect themselves against any such sexualization of their social instinctual cathexes*, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) *schizophrenia*; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.

¹ [1905c, 1695]

[1911c, 2418]
I should not have much difficulty in giving you a far more intimate picture of the relations between perversion and neurosis; but I think what I have already said will serve our purpose. We must however guard against being misled by what I have told you of the meaning of symptoms into over-estimating the frequency and intensity of people's perverse inclinations. It is possible, as you have heard, to fall ill of a neurosis as a result of a frustration of normal sexual satisfaction. But when a real frustration like this occurs, the need moves over on to abnormal methods of sexual excitation. You will later learn the way in which this happens. But in any case you will realize that as a result of this 'collateral' damming-back the perverse impulses must emerge more strongly than they would have if normal sexual satisfaction had met with no obstacle in the real world. Moreover a similar influence is to be recognized also as affecting the manifest perversions. In some cases they are provoked or made active if the normal satisfaction of the sexual instinct encounters too great difficulties for temporary reasons or because of permanent social regulations. In other cases, it is true, the inclination to perversions is quite independent of such favouring conditions; they are, we might say, the normal species of sexual life for those particular individuals.

[1916-1917, 3381]

For the moment, perhaps, you may have an impression that I have confused rather than explained the relation between normal and perverse sexuality. But you must bear the following consideration in mind. If it is true that increased difficulty in obtaining normal sexual satisfaction in real life, or deprivation of that satisfaction, brings out perverse inclinations in people who had not shown any previously, we must suppose that there was something in these people which came half-way to meet the perversions; or, if you prefer it, the perversions must have been present in them in a latent form.

[1916-1917, 3381]

I hope to be able to give you adequate replies to these questions, even though the replies may be reduced to schematic dimensions. The conflict is conjured up by frustration, as a result of which the libido, deprived of satisfaction, is driven to look for other objects and paths. The necessary precondition of the conflict is that these other paths and objects arouse displeasure in one part of the personality, so that a veto is imposed which makes the new method of satisfaction impossible as it stands. From this point the construction of symptoms pursues its course, which we shall follow later. The repudiated libidinal trends nevertheless succeed in getting their way by certain roundabout paths, though not, it is true, without taking the objection into account by submitting to some distortions and mitigations. The roundabout paths are those taken by the construction of symptoms; the symptoms are the fresh or substitute satisfaction which has become necessary owing to the fact of frustration.

[1916-1917, 3411]
As regards the second kind of emotional reaction, which is not directed against me this time, but against my patient - supposing that my view of her is correct - and which regards the perverse nature of her phantasies as horrible, I should like to say emphatically that a medical man has no business to indulge in such passionate condemnation. I may also remark in passing that it seems to me superfluous for a physician who is writing upon the aberrations of the sexual instincts to seize every opportunity of inserting into the text expressions of his personal repugnance at such revolting things. We are faced by a fact; and it is to be hoped that we shall grow accustomed to it, when we have put our own tastes on one side. We must learn to speak without indignation of what we call the sexual perversions - instances in which the sexual function has extended its limits in respect either to the part of the body concerned or to the sexual object chosen. The uncertainty in regard to the boundaries of what is to be called normal sexual life, when we take different races and different epochs into account, should in itself be enough to cool the zealot's ardour. We surely ought not to forget that the perversion which is the most repellent to us, the sensual love of a man for a man, was not only tolerated by a people so far our superiors in cultivation as were the Greeks, but was actually entrusted by them with important social functions. The sexual life of each one of us extends to a slight degree - now in this direction, now in that - beyond the narrow lines imposed as the standard of normality. The perversions are neither bestial nor degenerate in the emotional sense of the word. They are a development of germs all of which are contained in the undifferentiated sexual disposition of the child, and which, by being suppressed or by being diverted to higher, asexual aims - by being 'sublimated' - are destined to provide the energy for a great number of our cultural achievements. When, therefore, any one has become a gross and manifest pervert, it would be more correct to say that he has remained one, for he exhibits a certain stage of inhibited development. All psychoneurotics are persons with strongly marked perverse tendencies, which have been repressed in the course of their development and have become unconscious. Consequently their unconscious phantasies show precisely the same content as the documentarily recorded actions of perverts - even though they have not read Krafft-Ebing's *Psychopathia Sexualis*, to which simple-minded people attribute such a large share of the responsibility for the production of perverse tendencies. Psychoneuroses are, so to speak, the negative of perversions. In neurotics their sexual constitution, under which the effects of heredity are included, operates in combination with any accidental influences in their life which may disturb the development of normal sexuality. A stream of water which meets with an obstacle in the river-bed is dammed up and flows back into old channels which had formerly seemed fated to run dry. The motive forces leading to the formation of hysterical symptoms draw their strength not only from repressed normal sexuality but also from unconscious perverse activities.¹

[1905e, 1387]
The reproaches against her father for having made her ill, together with the self-reproach underlying them, the leukorrhoea, the playing with the reticule, the bed-wetting after her sixth year, the secret which she would not allow the doctors to tear from her - the circumstantial evidence of her having masturbated in childhood seems to me complete and without a flaw. In the present case I had begun to suspect the masturbation when she had told me of her cousin's gastric pains, and had then identified herself with her by complaining for days together of similar painful sensations. Thus, in the same way, what appears to be the strong tendency (though, it is true, a negative one) of psychoneurotics to perversion may be collaterally determined, and must, in any case, be collaterally intensified. The fact is that we must put sexual repression as an internal factor alongside such external factors as limitation of freedom, inaccessibility of a normal sexual object, the dangers of the normal sexual act, etc., which bring about perversions in persons who might perhaps otherwise have remained normal.

[1905d, 1494]
After having explained the preponderance of perverse tendencies in psychoneurotics by recognizing it as a collateral filling of subsidiary channels when the main current of the instinctual stream has been blocked by 'repression',¹ we proceeded to a consideration of sexual life in childhood. We found it a regrettable thing that the existence of the sexual instinct in childhood has been denied and that the sexual manifestations not infrequently to be observed in children have been described as irregularities. It seemed to us on the contrary that children bring germs of sexual activity with them into the world, that they already enjoy sexual satisfaction when they begin to take nourishment and that they persistently seek to repeat the experience in the familiar activity of 'thumb-sucking'. The sexual activity of children, however, does not, it appeared, develop pari passu with their other functions, but, after a short period of efflorescence from the ages of two to five, enters upon the so-called period of latency. During that period the production of sexual excitation is not by any means stopped but continues and produces a store of energy which is employed to a great extent for purposes other than sexual - namely, on the one hand in contributing the sexual components to social feelings and on the other hand (through repression and reaction-forming) in building up the subsequently developed barriers against sexuality. On this view, the forces destined to retain the sexual instinct upon certain lines are built up in childhood chiefly at the cost of perverse sexual impulses and with the assistance of education. A certain portion of the infantile sexual impulses would seem to evade these uses and succeed in expressing itself as sexual activity. We next found that sexual excitation in children springs from a multiplicity of forces. Satisfaction arises first and foremost from the appropriate sensory excitation of what we have described as erotogenic zones. It seems probable that any part of the skin and any sense-organ - probably, indeed, any organ - can function as an erotogenic zone, though there are some particularly marked erotogenic zones whose excitation would seem to be secured from the very first by certain organic contrivances. It further appears that sexual excitation arises as a by-product, as it were, of a large number of processes that occur in the organism, as soon as they reach a certain degree of intensity, and most especially of any relatively powerful emotion, even though it is of a distressing nature. The excitations from all these sources are not yet combined; but each follows its own separate aim, which is merely the attainment of a certain sort of pleasure. In childhood, therefore, the sexual instinct is not unified and is at first without an object, that is, auto-erotic.

¹ [Footnote added 1915:] This does not apply only to the 'negative' tendencies to perversion which appear in neuroses but equally to the 'positive,' properly so-called, perversions. Thus these latter are to be derived not merely from a fixation of infantile tendencies but also from a regression to those tendencies as a result of other channels of the sexual current being blocked. It is for this reason that the positive perversions also are accessible to psycho-analytic therapy.

[1905d, 1543]
In the first place, it must be emphasized that Breuer's patient, in almost all her pathogenic situations, was obliged to suppress a powerful emotion instead of allowing its discharge in the appropriate signs of emotion, words or actions. In the episode of her lady-companion's dog, she suppressed any manifestation of her very intense disgust, out of consideration for the woman's feelings; while she watched at her father's bedside she was constantly on the alert to prevent the sick man from observing her anxiety and her painful depression. When subsequently she reproduced these scenes in her doctor's presence the affect which had been inhibited at the time emerged with peculiar violence, as though it had been saved up for a long time. Indeed, the symptom which was left over from one of these scenes would reach its highest pitch of intensity at the time when its determining cause was being approached, only to vanish when that cause had been fully ventilated. On the other hand, it was found that no result was produced by the recollection of a scene in the doctor's presence if for some reason the recollection took place without any generation of affect. Thus it was what happened to these affects, which might be regarded as displaceable magnitudes, that was the decisive factor both for the onset of illness and for recovery. One was driven to assume that the illness occurred because the affects generated in the pathogenic situations had their normal outlet blocked, and that the essence of the illness lay in the fact that these 'strangulated' affects were then put to an abnormal use. In part they remained as a permanent burden upon the patient's mental life and a source of constant excitation for it; and in part they underwent a transformation into unusual somatic innervations and inhibitions, which manifested themselves as the physical symptoms of the case. For this latter process we coined the term 'hysterical conversion'. Quite apart from this, a certain portion of our mental excitation is normally directed along the paths of somatic innervation and produces what we know as an 'expression of the emotions'. Hysterical conversion exaggerates this portion of the discharge of an emotionally cathected mental process; it represents a far more intense expression of the emotions, which has entered upon a new path. When the bed of a stream is divided into two channels, then, if the current in one of them is brought up against an obstacle, the other will at once be overfilled. As you see, we are on the point of arriving at a purely psychological theory of hysteria, with affective processes in the front rank.

In my *Three Essays on the Theory of Sexuality* I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics *endeavour to protect themselves against any such sexualization of their social instinctual cathexes*, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) *schizophrenia*; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.

[1910a, 2207]

[1911c, 2431]
The sexual material which forms the content of smut includes more than what is *peculiar* to each sex; it also includes what is *common* to both sexes and to which the feeling of shame extends - that is to say, what is excremental in the most comprehensive sense. This is, however, the sense covered by sexuality in childhood, an age at which there is, as it were, a cloaca within which what is sexual and what is excremental are barely or not at all distinguished.¹ Throughout the whole range of the psychology of the neuroses, what is sexual includes what is excremental, and is understood in the old, infantile, sense.

[1905c, 1694]
With the psychoneuroses, the influence of heredity is more marked and the causation less transparent. A peculiar method of investigation known as psycho-analysis has, however, enabled us to recognize that the symptoms of these disorders (hysteria, obsessional neurosis, etc.) are psychogenic and depend upon the operation of unconscious (repressed) ideational complexes. This same method has also taught us what those unconscious complexes are and has shown that, quite generally speaking, they have a sexual content. They spring from the sexual needs of people who are unsatisfied and represent for them a kind of substitutive satisfaction. We must therefore view all factors which impair sexual life, suppress its activity or distort its aims as being pathogenic factors in the psychoneuroses as well.

The answer to the first question touches on a problem which has often been discussed and cannot be exhaustively treated here - that of sexual abstinence. Our third stage of civilization demands of individuals of both sexes that they shall practise abstinence until they are married and that all who do not contract a legal marriage shall remain abstinent throughout their lives. The position, agreeable to all the authorities, that sexual abstinence is not harmful and not difficult to maintain, has also been widely supported by the medical profession. It may be asserted, however, that the task of mastering such a powerful impulse as that of the sexual instinct by any other means than satisfying it is one which can call for the whole of a man's forces. Mastering it by sublimation, by deflecting the sexual instinctual forces away from their sexual aim to higher cultural aims, can be achieved by a minority and then only intermittently, and least easily during the period of ardent and vigorous youth. Most of the rest become neurotic or are harmed in one way or another. Experience shows that the majority of the people who make up our society are constitutionally unfit to face the task of abstinence. Those who would have fallen ill under milder sexual restrictions fall ill all the more readily and more severely before the demands of our cultural sexual morality of to-day; for we know no better safe-guard against the threat to normal sexual life offered by defective innate dispositions or disturbances of development than sexual satisfaction itself. The more a person is disposed to neurosis, the less can he tolerate abstinence; instincts which have been withdrawn from normal development, in the sense in which it has been described above, become at the same time all the more uninhibitable. But even those people who would have retained their health under the requirements of the second stage of civilization will now succumb to neurosis in great numbers. For the psychical value of sexual satisfaction increases with its frustration. The dammed-up libido is now put in a position to detect one or other of the weaker spots which are seldom absent in the structure of sexual life, and there to break through and obtain substitutive satisfaction of a neurotic kind in the form of pathological symptoms. Anyone who is able to penetrate the determinants of nervous illness will soon become convinced that its increase in our society arises from the intensification of sexual restrictions.

LADIES AND GENTLEMEN, - With the discovery of infantile sexuality and the tracing back of neurotic symptoms to erotic instinctual components we have arrived at some unexpected formulas concerning the nature and purposes of neurotic illnesses. We see that human beings fall ill when, as a result of external obstacles or of an internal lack of adaptation, the satisfaction of their erotic needs in reality frustrated. We see that they then take flight into illness in order that by its help they may find a satisfaction to take the place of what has been frustrated. We recognize that the pathological symptoms constitute a portion of the subject's sexual activity or even the whole of his sexual life, and we find that the withdrawal from reality is the main purpose of the illness but also the main damage caused by it. We suspect that our patients' resistance to recovery is no simple one, but compounded of several motives. Not only does the patient's ego rebel against giving up the repressions by means of which it has risen above its original disposition, but the sexual instincts are unwilling to renounce their substitutive satisfaction so long as it is uncertain whether reality will offer them anything better.
In virtue of a special disposition, the third type, which is the rarest and most perfect, escapes both inhibition of thought and neurotic compulsive thinking. It is true that here too sexual repression comes about, but it does not succeed in relegating a component instinct of sexual desire to the unconscious. Instead, the libido evades the fate of repression by being sublimated from the very beginning into curiosity and by becoming attached to the powerful instinct for research as a reinforcement. Here, too, the research becomes to some extent compulsive and a substitute for sexual activity; but owing to the complete difference in the underlying psychical processes (sublimation instead of an irruption from the unconscious) the quality of neurosis is absent; there is no attachment to the original complexes of infantile sexual research, and the instinct can operate freely in the service of intellectual interest. Sexual repression, which has made the instinct so strong through the addition to it of sublimated libido, is still taken into account by the instinct, in that it avoids any concern with sexual themes.

[1910c, 2257]

(3) Finally, I have to explain to you what I mean by the 'general effect' of our work, and how I come to set hopes on it. What we have here is a very remarkable therapeutic constellation, the like of which is perhaps not to be found anywhere else and which will appear strange to you too at first, until you recognize in it something you have long been familiar with. You know, of course, that the psychoneuroses are substitutive satisfactions of some instinct the presence of which one is obliged to deny to oneself and others. Their capacity to exist depends on this distortion and lack of recognition. When the riddle they present is solved and the solution is accepted by the patients these diseases cease to be able to exist. There is hardly anything like this in medicine, though in fairy tales you hear of evil spirits whose power is broken as soon as you can tell them their name - the name which they have kept secret.

[1910d, 2312]

Let us start with the latter, the scientific errors. The doctor's advice to the lady shows clearly in what sense he understands the expression 'sexual life' - in the popular sense, namely, in which by sexual needs nothing is meant but the need for coitus or analogous acts producing orgasm and emission of the sexual substances. He cannot have remained unaware, however, that psycho-analysis is commonly reproached with having extended the concept of what is sexual far beyond its usual range. The fact is undisputed; I shall not discuss here whether it may justly be used as a reproach. In psycho-analysis the concept of what is sexual comprises far more; it goes lower and also higher than its popular sense. This extension is justified genetically; we reckon as belonging to 'sexual life' all the activities of the tender feelings which have primitive sexual impulses as their source, even when those impulses have become inhibited in regard to their original sexual aim or have exchanged this aim for another which is no longer sexual. For this reason we prefer to speak of psychosexuality, thus laying stress on the point that the mental factor in sexual life should not be overlooked or underestimated. We use the word 'sexuality' in the same comprehensive sense as that in which the German language uses the word lieben ['to love']. We have long known, too, that mental absence of satisfaction with all its consequences can exist where there is no lack of normal sexual intercourse; and as therapists we always bear in mind that the unsatisfied sexual trends (whose substitutive satisfactions in the form of nervous symptoms we combat) can often find only very inadequate outlet in coitus or other sexual acts.

[1910k, 2375]
You will recollect that, in the two cases whose symptoms we submitted to a detailed investigation, the analysis initiated us into these patients' most intimate sexual life. In the first case we further recognized with particular clarity the intention or purpose of the symptom we were examining; in the second case this was perhaps somewhat concealed by a factor which will be mentioned later. Well, every other case that we submit to analysis would show us the same thing that we have found in these two examples. In every instance we should be introduced by the analysis into the patient's sexual experiences and wishes; and in every instance we should be bound to see that the symptoms served the same intention. We find that this intention is the satisfaction of sexual wishes; the symptoms serve for the patients' sexual satisfaction; they are a substitute for satisfaction of this kind, which the patients are without in their lives.

[1916-1917, 3371]

I should like to anticipate, Gentlemen, the qualifications which I shall have to make later in the universal validity of these statements. I will therefore point out to you that all I have said here about repression and the formation and meaning of symptoms was derived from three forms of neurosis - anxiety hysteria, conversion hysteria and obsessional neurosis - and that in the first instance it is also valid only for these forms. These three disorders, which we are accustomed to group together as 'transference neuroses', also circumscribe the region in which psychoanalytic therapy can function. The other neuroses have been far less thoroughly studied by psycho-analysis; in one group of them the impossibility of therapeutic influence has been a reason for this neglect. Nor should you forget that psycho-analysis is still a very young science, that preparing for it costs much trouble and time, and that not at all long ago it was being practised single-handed. Nevertheless, we are everywhere on the point of penetrating to an understanding of these other disorders which are not transference neuroses. I hope later to be able to introduce you to the extensions of our hypotheses and findings which result from adaptation to this new material, and to show you that these further studies have not led to contradictions but to the establishment of higher unities. If, then, everything I am saying here applies to the transference neuroses, let me first increase the value of symptoms by a new piece of information. For a comparative study of the determining causes of falling ill leads to a result which can be expressed in a formula: these people fall ill in one way or another of frustration, when reality prevents them from satisfying their sexual wishes. You see how excellently these two findings tally with each other. It is only thus that symptoms can be properly viewed as substitutive satisfactions for what is missed in life.

[1916-1917, 3372]
No doubt all kinds of objections can still be raised to the assertion that neurotic symptoms are substitutes for sexual satisfactions. I will mention two of them to-day. When you yourselves have carried out analytic examinations of a considerable number of neurotics, you will perhaps tell me, shaking your head, that in a lot of cases my assertion is simply not true; the symptoms seem rather to have the contrary purpose of excluding or of stopping sexual satisfaction. I will not dispute the correctness of your interpretation. The facts in psycho-analysis have a habit of being rather more complicated than we like. If they were as simple as all that, perhaps it might not have needed psycho-analysis to bring them to light. Indeed, some of the features of our second patient's ceremonial show signs of this ascetic character with its hostility to sexual satisfaction: when, for instance, she got rid of the clocks and watches, which had the magical meaning of avoiding erections during the night, or when she tried to guard against flower-pots falling and breaking, which was equivalent to protecting her virginity. In some other cases of bed ceremonials, which I have been able to analyse, this negative character was far more outspoken; the ceremonial might consist exclusively of defensive measures against sexual memories and temptations. However, we have already found often enough that in psycho-analysis opposites imply no contradiction. We might extend our thesis and say that symptoms aim either at a sexual satisfaction or at fending it off, and that on the whole the positive, wish-fulfilling character prevails in hysteria and the negative, ascetic one in obsessional neurosis. If symptoms can serve the purpose both of sexual satisfaction and of its opposite, there is an excellent basis for this double-sidedness or polarity in a part of their mechanism which I have so far not been able to mention. For, as we shall hear, they are the products of a compromise and arise from the mutual interference between two opposing currents; they represent not only the repressed but also the repressing force which had a share in their origin. One side or the other may be more strongly represented; but it is rarely that one influence is entirely absent. In hysteria a convergence of both intentions in the same symptom is usually achieved. In obsessional neurosis the two portions are often separated; the symptom then becomes diphasic and consists in two actions, one after the other, which cancel each other out.

We shall not be able to dismiss a second objection so easily. If you survey a fairly long series of interpretations of symptoms, you will probably start by judging that the concept of a substitutive sexual satisfaction has been stretched to its extreme limits in them. You will not fail to emphasize the fact that these symptoms offer nothing real in the way of satisfaction, that often enough they are restricted to the revival of a sensation or the representation of a phantasy derived from a sexual complex. And you will further point out that these supposed sexual satisfactions often take on a childish and discreditable form, approximate to an act of masturbation perhaps, or recall dirty kinds of naughtiness which are forbidden even to children - habits of which they have been broken. And, going on from this, you will also express surprise that we are representing as a sexual satisfaction what would rather have to be described as the satisfaction of lusts that are cruel or horrible or would even have to be called unnatural. We shall come to no agreement, Gentlemen, on this latter point till we have made a thorough investigation of the sexual life of human beings and till, in doing so, we have decided what it is that we are justified in calling 'sexual'.

[1916-1917, 3374]
I have said that neurotic symptoms are substitutes for sexual satisfaction, and I indicated to you that the confirmation of this assertion by the analysis of symptoms would come up against a number of difficulties. For it can only be justified if under 'sexual satisfaction' we include the satisfaction of what are called perverse sexual needs, since an interpretation of symptoms of that kind is forced upon us with surprising frequency. The claim made by homosexuals or invert to being exceptions collapses at once when we learn that homosexual impulses are invariably discovered in every single neurotic, and that a fair number of symptoms give expression to this latent inversion. Those who call themselves homosexuals are only the conscious and manifest inverts, whose number is nothing compared to that of the latent homosexuals. We are compelled, however, to regard choice of an object of one's own sex as a divergence in erotic life which is of positively habitual occurrence, and we are learning more and more to ascribe an especially high importance to it. No doubt this does not do away with the differences between manifest homosexuality and a normal attitude; their practical significance remains, but their theoretical value is greatly diminished. We have even found that a particular disease, paranoia, which is not to be counted among the transference neuroses, regularly arises from an attempt to fend off excessively strong homosexual impulses. You will perhaps recall that one of our patients (p. 3343) behaved in her obsessional action like a man, her own husband whom she had left; neurotic women very commonly produce symptoms in this way in the character of a man. Even if this is not actually to be regarded as homosexuality, it is closely related to its preconditions.

[1916-1917, 3379]

I hope to be able to give you adequate replies to these questions, even though the replies may be reduced to schematic dimensions. The conflict is conjured up by frustration, as a result of which the libido, deprived of satisfaction, is driven to look for other objects and paths. The necessary precondition of the conflict is that these other paths and objects arouse displeasure in one part of the personality, so that a veto is imposed which makes the new method of satisfaction impossible as it stands. From this point the construction of symptoms pursues its course, which we shall follow later. The repudiated libidinal trends nevertheless succeed in getting their way by certain roundabout paths, though not, it is true, without taking the objection into account by submitting to some distortions and mitigations. The roundabout paths are those taken by the construction of symptoms; the symptoms are the fresh or substitute satisfaction which has become necessary owing to the fact of frustration.

[1916-1917, 3411]
It is something else besides that makes symptoms seem strange to us and incomprehensible as a means of libidinal satisfaction. They do not remind us in the very least of anything from which we are in the habit of normally expecting satisfaction. Usually they disregard objects and in so doing abandon their relation to external reality. We can see that this is a consequence of turning away from the reality principle and of returning to the pleasure principle. But it is also a return to a kind of extended auto-erotism, of the sort that offered the sexual instinct its first satisfactions. In place of a change in the external world these substitute a change in the subject's own body: they set an internal act in place of an external one, an adaptation in place of an action - once again, something that corresponds, phylogenetically, to a highly significant regression. We shall only understand this in connection with something new that we have still to learn from the analytic researches into the formation of symptoms. We must further remember that the same processes belonging to the unconscious play a part in the formation of symptoms as in the formation of dreams - namely, condensation and displacement. A symptom, like a dream, represents something as fulfilled: a satisfaction in the infantile manner. But by means of extreme condensation that satisfaction can be compressed into a single sensation or innervation, and by means of extreme displacement it can be restricted to one small detail of the entire libidinal complex. It is not to be wondered at if we, too, often have difficulty in recognizing in a symptom the libidinal satisfaction whose presence we suspect and which is invariably confirmed.

[1916-1917, 3423]

A noteworthy relation between the symptoms of the 'actual' neuroses and of the psychoneuroses makes a further important contribution to our knowledge of the formation of symptoms in the latter. For a symptom of an 'actual' neurosis is often the nucleus and first stage of a psychoneurotic symptom. A relation of this kind can be most clearly observed between neurasthenia and the transference neurosis known as 'conversion hysteria', between anxiety neurosis and anxiety hysteria, but also between hypochondria and the forms of disorder which will be mentioned later under the name of paraphrenia (dementia praecox and paranoia). Let us take as an example a case of hysterical headache or lumbar pain. Analysis shows us that, by condensation and displacement, it has become a substitutive satisfaction for a whole number of libidinal phantasies or memories. But this pain was also at one time a real one and it was then a direct sexual-toxic symptom, the somatic expression of a libidinal excitation. We are far from asserting that all hysterical symptoms contain a nucleus of this kind. But it remains a fact that this is especially often the case and that whatever somatic influences (whether normal or pathological) are brought about by libidinal excitation are preferred for the construction of hysterical symptoms. In such cases they play the part of the grain of sand which a mollusc coats with layers of mother-of-pearl. In the same way, the passing indications of sexual excitement which accompany the sexual act are employed by the psychoneurosis as the most convenient and appropriate material for the construction of symptoms.

[1916-1917, 3441]
But, Ladies and Gentlemen, who has so seriously misinformed you? A recommendation to the patient to 'live a full life' sexually could not possibly play a part in analytic therapy - if only because we ourselves have declared that an obstinate conflict is taking place in him between a libidinal impulse and sexual repression, between a sensual and an ascetic trend. This conflict would not be solved by our helping one of these trends to victory over its opponent. We see, indeed, that in neurotics asceticism has the upper hand; and the consequence of this is precisely that the suppressed sexual tendency finds a way out in symptoms. If, on the contrary, we were to secure victory for sensuality, then the sexual repression that had been put on one side would necessarily be replaced by symptom. Neither of these two alternative decisions could end the internal conflict; in either case one party to it would remain unsatisfied. There are only a few cases in which the conflict is so unstable that a factor such as the doctor's taking sides could decide it; and such cases do not in fact stand in need of analytic treatment. Anyone on whom the doctor could have so much influence would have found the same way out without the doctor. You must be aware that if an abstinent young man decides in favour of illicit sexual intercourse or if an unsatisfied wife seeks relief with another man, they have not as a rule waited for permission from a doctor or even from their analyst.

[1916-1917, 3476]

The transference possesses this extraordinary, and for the treatment, positively central, importance in hysteria, anxiety hysteria and obsessional neurosis, which are for that reason rightly classed together as 'transference neuroses'. No one who has taken in a full impression of the fact of transference from his analytic work will any longer doubt the nature of the suppressed impulses that obtain expression in the symptoms of these neuroses, and will call for no more powerful evidence of their libidinal character. It may be said that our conviction of the significance of symptoms as substitutive satisfactions of the libido only received its final confirmation after the enlistment of the transference.

[1916-1917, 3487]

I will now complete my picture of the mechanism of cure by clothing it in the formulas of the libido theory. A neurotic is incapable of enjoyment and of efficiency - the former because his libido is not directed on to any real object and the latter because he is obliged to employ a great deal of this available energy on keeping his libido under repression and on warding off its assaults. He would become healthy if the conflict between his ego and his libido came to an end and if his ego had his libido again at its disposal. The therapeutic task consists, therefore, in freeing the libido from its present attachments, which are withdrawn from the ego, and in making it once more serviceable to the ego. Where, then, is the neurotic's libido situated? It is easily found: it is attached to the symptoms, which yield it the only substitutive satisfaction possible at the time. We must therefore make ourselves masters of the symptoms and resolve them - which is precisely the same thing that the patient requires of us. In order to resolve the symptoms, we must go back as far as their origin, we must renew the conflict from which they arose, and, with the help of motive forces which were not at the patient's disposal in the past, we must guide it to a different outcome. This revision of the process of repression can be accomplished only in part in connection with the memory traces of the processes which led to repression. The decisive part of the work is achieved by creating in the patient's relation to the doctor - in the 'transference' - new editions of the old conflicts; in these the patient would like to behave in the same way as he did in the past, while we, by summoning up every available mental force, compel him to come to a fresh decision. Thus the transference becomes the battlefield on which all the mutually struggling forces should meet one another.

[1916-1917, 3494]
There can be no doubt, however, that the replacement of the pleasure principle by the reality principle can only be made responsible for a small number, and by no means the most intense, of unpleasurable experiences. Another occasion of the release of unpleasure, which occurs with no less regularity, is to be found in the conflicts and dissensions that take place in the mental apparatus while the ego is passing through its development into more highly composite organizations. Almost all the energy with which the apparatus is filled arises from its innate instinctual impulses. But these are not all allowed to reach the same phases of development. In the course of things it happens again and again that individual instincts or parts of instincts turn out to be incompatible in their aims or demands with the remaining ones, which are able to combine into the inclusive unity of the ego. The former are then split off from this unity by the process of repression, held back at lower levels of psychical development and cut off, to begin with, from the possibility of satisfaction. If they succeed subsequently, as can so easily happen with repressed sexual instincts, in struggling through, by roundabout paths, to a direct or to a substitutive satisfaction, that event, which would in other cases have been an opportunity for pleasure, is felt by the ego as unpleasure. As a consequence of the old conflict which ended in repression, a new breach has occurred in the pleasure principle at the very time when certain instincts were endeavouring, in accordance with the principle, to obtain fresh pleasure. The details of the process by which repression turns a possibility of pleasure into a source of unpleasure are not yet clearly understood or cannot be clearly represented; but there is no doubt that all neurotic unpleasure is of that kind - pleasure that cannot be felt as such.¹

¹ [1920g, 3717]

The psycho-analytic investigation of the psychoneuroses has taught us that their symptoms are to be traced back to directly sexual impulsions which are repressed but still remain active. We can complete this formula by adding - 'or, to aim-inhibited impulsions, whose inhibition has not been entirely successful or has made room for a return to the repressed sexual aim'. It is in accordance with this that a neurosis should make its victim asocial and should remove him from the usual group formations. It may be said that a neurosis has the same disintegrating effect upon a group as being in love. On the other hand it appears that where a powerful impetus has been given to group formation neuroses may diminish and, at all events temporarily, disappear. Justifiable attempts have also been made to turn this antagonism between neuroses and group formation to therapeutic account. Even those who do not regret the disappearance of religious illusions from the civilized world of to-day will admit that so long as they were in force they offered those who were bound by them the most powerful protection against the danger of neurosis. Nor is it hard to discern that all the ties that bind people to mystico-religious or philosophico-religious sects and communities are expressions of crooked cures of all kinds of neuroses. All of this is correlated with the contrast between directly sexual impulsions and those which are inhibited in their aims.

¹ [1921c, 3833]
The Theory of Repression. - These theoretical considerations, taken together with the immediate impressions derived from analytic work, lead to a view of the neuroses which may be described in the roughest outline as follows. The neuroses are the expression of conflicts between the ego and such of the sexual impulses as seem to the ego incompatible with its integrity or with its ethical standards. Since these impulses are not ego-syntonic, the ego has repressed them: that is to say, it has withdrawn its interest from them and has shut them off from becoming conscious as well as from obtaining satisfaction by motor discharge. If in the course of analytic work one attempts to make these repressed impulses conscious, one becomes aware of the repressive forces in the form of resistance. But the achievement of repression fails particularly readily in the case of the sexual instincts. Their dammed-up libido finds other ways out from the unconscious: for it regresses to earlier phases of development and earlier attitudes towards objects, and, at weak points in the libidinal development where there are infantile fixations, it breaks through into consciousness and obtains discharge. What results is a symptom and consequently in its essence a substitutive sexual satisfaction. Nevertheless the symptom cannot entirely escape from the repressive forces of the ego and must therefore submit to modifications and displacements exactly as happens with dreams - by means of which its characteristic of being a sexual satisfaction becomes unrecognizable. Consequently symptoms are in the nature of compromises between the repressed sexual instincts and the repressing ego-instincts; they represent a wish-fulfilment for both partners to the conflict simultaneously, but one which is incomplete for each of them. This is quite strictly true of the symptoms of hysteria, while in the symptoms of obsessional neurosis there is often a stronger emphasis upon the side of the repressing function owing to the erection of reaction-formations, which are assurances against sexual satisfaction.

This state of affairs is enough to account for the reluctant and hesitant reception of analysis in scientific quarters. But it does not explain the outbursts of indignation, derision and scorn which, in disregard of every standard of logic and good taste, have characterized the controversial methods of its opponents. A reaction of such a kind suggests that resistances other than purely intellectual ones were stirred up and that powerful emotional forces were aroused. And there are indeed plenty of things to be found in the theory of psycho-analysis calculated to produce such an effect as this upon the passions of men of every kind and not of scientists alone. Above all there is the very important place in the mental life of human beings which psycho-analysis assigns to what are known as the sexual instincts. Psycho-analytic theory maintained that the symptoms of neuroses are distorted substitutive satisfactions of sexual instinctual forces, the direct satisfaction of which has been frustrated by internal resistances. Later on, when analysis had extended beyond its original field of work and began to be applied to normal mental life, it sought to show that these same sexual components, which could be diverted from their immediate aims and directed to other things, made the most important contributions to the cultural achievements of the individual and of society. These views were not entirely new. The incomparable significance of sexual life had been proclaimed by the philosopher Schopenhauer in an intensely impressive passage. Moreover, what psycho-analysis called sexuality was by no means identical with the impulse towards a union of the two sexes or towards producing a pleasurable sensation in the genitals; it had far more resemblance to the all-inclusive and all-preserving Eros of Plato's Symposium.
(2) For cultural reasons the most intense repression falls upon the sexual instincts; but it is precisely in connection with them that repression most easily miscarries, so that neurotic symptoms are found to be substitutive satisfactions of repressed sexuality. The belief that in man sexual life begins only at puberty is incorrect. On the contrary, signs of it can be detected from the beginning of extra-uterine existence; it reaches a first culminating point at or before the fifth year ('early period'), after which it is inhibited or interrupted ('latency period') until the age of puberty, which is the second climax of its development. This diphasic onset of sexual development seems to be distinctive of the genus Homo. All experiences during the first period of childhood are of the greatest importance to the individual, and in combination with his inherited sexual constitution form the dispositions for the subsequent development of character and disease. It is wrong to make sexuality coincide with 'genitality'. The sexual instincts pass through a complicated course of development, and it is only at the end of it that the 'primacy of the genital zones' is attained. Before this there are a number of 'pregenital' organizations of the libido - points at which it may become 'fixated' and to which, in the event of subsequent repression, it will return ('regression'). The infantile fixations of the libido are what determine the form of any later neurosis. Thus the neuroses are to be regarded as inhibitions in the development of the libido. There are no specific causes of nervous disorders; the question whether a conflict finds a healthy solution or leads to a neurotic inhibition of function depends upon quantitative considerations.

Psycho-analytic work has shown us that it is precisely these frustrations of sexual life which people known as neurotics cannot tolerate. The neurotic creates substitutive satisfactions for himself in his symptoms, and these either cause him suffering in themselves or become sources of suffering for him by raising difficulties in his relations with his environment and the society he belongs to. The latter fact is easy to understand; the former presents us with a new problem. But civilization demands other sacrifices besides that of sexual satisfaction.

I am tempted to extract a first advantage from this more restricted view of the case by applying it to the process of repression. As we have learned, neurotic symptoms are, in their essence, substitutive satisfactions for unfulfilled sexual wishes. In the course of our analytic work we have discovered to our surprise that perhaps every neurosis conceals a quota of unconscious sense of guilt, which in its turn fortifies the symptoms by making use of them as a punishment. It now seems plausible to formulate the following proposition. When an instinctual trend undergoes repression, its libidinal elements are turned into symptoms, and its aggressive components into a sense of guilt. Even if this proposition is only an average approximation to the truth, it is worthy of our interest.
Unless we have first come to a complete agreement upon the terminology involved, it is not easy to decide whether a particular case is to be reckoned as a hysteria or some other neurosis (I am speaking here of neuroses which are not of a purely neurasthenic type; and we have still to await the directing hand which shall set up boundary-marks in the region of the commonly occurring mixed neuroses and which shall bring out the features essential for their characterization. If, accordingly, we are still accustomed to diagnosing a hysteria, in the narrower sense of the term, from its similarity to familiar typical cases, we shall scarcely be able to dispute the fact that the case of Frau Emmy von N. was one of hysteria. The mildness of her deliria and hallucinations (while her other mental activities remained intact), the change in her personality and store of memories when she was in a state of artificial somnambulism, the anaesthesia in her painful leg, certain data revealed in her anamnesis, her ovarian neuralgia, etc., admit of no doubt as to the hysterical nature of the illness, or at least of the patient. That the question can be raised at all is due only to one particular feature of the case, which also provides an opportunity for a comment that is of general validity. As we have explained in the 'Preliminary Communication' which appears at the beginning of this volume, we regard hysterical symptoms as the effects and residues of excitations which have acted upon the nervous system as traumas. Residues of this kind are not left behind if the original excitation has been discharged by abreaction or thought-activity. It is impossible any longer at this point to avoid introducing the idea of quantities (even though not measurable ones). We must regard the process as though a sum of excitation impinging on the nervous system is transformed into chronic symptoms in so far as it has not been employed for external action in proportion to its amount. Now we are accustomed to find in hysteria that a considerable part of this 'sum of excitation' of the trauma is transformed into purely somatic symptoms. It is this characteristic of hysteria which has so long stood in the way of its being recognized as a psychical disorder.

This aptitude does not, in itself, exclude psychical health; and it only leads to hysteria in the event of there being a psychical incompatibility or an accumulation of excitation. In taking this view, Breuer and I are coming closer to Oppenheim's\(^1\) and Strümpell's\(^2\) well-known definitions of hysteria, and are diverging from Janet, who assigns too great an importance to the splitting of consciousness in his characterization of hysteria.\(^3\) The presentation given here may claim to have made intelligible the connection between conversion and the hysterical splitting of consciousness.

For the rest, I might have been spared having to defend myself against these two objections of Löwenfeld's, if my respected opponent had paid greater attention to my paper itself. In it, both these objections are anticipated and answered. I have only been able to repeat here what I said there; and I have even purposely analysed the same cases over again. Moreover the aetiological formulas on which I have just laid weight are contained in the text of my paper. I will repeat them once more. I maintain that there exists a specific aetiological factor for anxiety neurosis which can be replaced in its operation by stock noxae in a QUANTITATIVE sense, but not in a QUALITATIVE one; I furthermore maintain that this specific factor determines above all the FORM of the neurosis; whether a neurotic illness occurs at all depends on the total load upon the nervous system (in proportion to its capacity to carry the load). As a rule the neuroses are overdetermined; that is to say, several factors operate together in their aetiology.

In order to meet every possibility, let us assume that the aetiological factors we are concerned with are capable of a quantitative change - that is of increase or decrease.
Whether a neurotic illness occurs at all depends upon a quantitative factor - upon the total load on the nervous system as compared with the latter's capacity for resistance. Everything which can keep this quantitative factor below a certain threshold-value, or can bring it back to that level, has a therapeutic effect, since by so doing it keeps the aetiological equation unsatisfied.

On the basis of a laborious examination of the facts, I shall maintain that this last supposition is quite in agreement with reality, that each of the major neuroses which I have enumerated has as its immediate cause one particular disturbance of the economics of the nervous system, and that these functional pathological modifications have as their common source the subject's sexual life, whether they lie in a disorder of his contemporary sexual life or in important events in his past life.

I am quite sure that this theory will call up a storm of contradictions from contemporary physicians. But this is not the place in which to present the documents and the experiences which have forced me to my convictions, nor to explain the true meaning of the rather vague expression 'disorders of the economics of the nervous system'. This will be done, most fully, I hope, in a work on the subject which I have in preparation. In the present paper I limit myself to reporting my findings.

A reply to objections made by Löwenfeld to the content of No. XXXII. The problem of the aetiology of the pathology of the neuroses is dealt with here, to justify the division into three categories of the aetiological factors that appear: (a) preconditions, (b) specific causes and (c) concurrent or auxiliary causes. What are called preconditions are the factors which, though they are indispensable for producing the effect, cannot by themselves produce it but need in addition the specific causes. The specific causes are distinguished from the preconditions by the fact that they figure in only a few aetiological formulas, while the preconditions play the same part in numerous affections. Auxiliary causes are such as neither need invariably be present nor are able by themselves to produce the effect in question. - In the case of neuroses it is possible that the precondition may be heredity; the specific cause lies in sexual factors; everything else that is brought up apart from these as forming the aetiology of the neuroses (overwork, emotion, physical illness) is an auxiliary cause and can never entirely take the place of the specific factor, though it can no doubt serve as a substitute for it in the matter of quantity. The form of a neurosis depends on the nature of the specific sexual cause; whether there shall be a neurotic illness at all is determined by factors operating quantitatively; heredity works like a multiplier inserted in an electric circuit.
The theory of the psychoneuroses asserts as an indisputable and invariable fact that only sexual wishful impulses from infancy, which have undergone repression (i.e., a transformation of their affect) during the developmental period of childhood, are capable of being revived during later developmental periods (whether as a result of the subject's sexual constitution, which is derived from an initial bisexuality, or as a result of unfavourable influences acting upon the course of his sexual life) and are thus able to furnish the motive force for the formation of psychoneurotic symptoms of every kind. It is only by reference to these sexual forces that we can close the gaps that are still patent in the theory of repression. I will leave it an open question whether these sexual and infantile factors are equally required in the theory of dreams: I will leave that theory incomplete at this point, since I have already gone a step beyond what can be demonstrated in assuming that dream-wishes are invariably derived from the unconscious.¹ Nor do I propose to enquire further into the nature of the distinction between the play of psychical forces in the formation of dreams and in that of hysterical symptoms: we are still without a sufficiently accurate knowledge of one of the two objects of the comparison.²

By analysing dreams we can take a step forward in our understanding of the composition of that most marvellous and most mysterious of all instruments. Only a small step, no doubt; but a beginning. And this beginning will enable us to proceed further with its analysis, on the basis of other structures which must be termed pathological. For illnesses - those, at least, which are rightly named 'functional' - do not presuppose the disintegration of the apparatus or the production of fresh splits in its interior. They are to be explained on a dynamic basis - by the strengthening and weakening of the various components in the interplay of forces, so many of whose effects are hidden from view while functions are normal. I hope to be able to show elsewhere how the compounding of the apparatus out of two agencies makes it possible for the normal mind too to function with greater delicacy than would be possible with only one of them.²

It should be the task of a libido theory of neurotic and psychotic disorders to express all the observed phenomena and inferred processes in terms of the economics of the libido. It is easy to guess that the vicissitudes of the ego-libido will have the major part to play in this connection, especially when it is a question of explaining the deeper psychotic disturbances. We are then faced by the difficulty that our method of research, psycho-analysis, for the moment affords us assured information only on the transformations that take place in the object-libido,² but is unable to make any immediate distinction between the ego-libido and the other forms of energy operating in the ego.³

¹ [1900a, 1033]
² [1900a, 1035]
³ [1905d, 1532]
The sexual instinct - or, more correctly, the sexual instincts, for analytic investigation teaches us that the sexual instinct is made up of many separate constituents or component instincts - is probably more strongly developed in man than in most of the higher animals; it is certainly more constant, since it has almost entirely overcome the periodicity to which it is tied in animals. It places extraordinarily large amounts of force at the disposal of civilized activity, and it does this in virtue of its especially marked characteristic of being able to displace its aim without materially diminishing in intensity. This capacity to exchange its originally sexual aim for another one, which is no longer sexual but which is psychically related to the first aim, is called the capacity for sublimation. In contrast to this displaceability, in which its value for civilization lies, the sexual instinct may also exhibit a particularly obstinate fixation which renders it unserviceable and which sometimes causes it to degenerate into what are described as abnormalities. The original strength of the sexual instinct probably varies in each individual; certainly the proportion of it which is suitable for sublimation varies. It seems to us that it is the innate constitution of each individual which decides in the first instance how large a part of his sexual instinct it will be possible to sublimate and make use of. In addition to this, the effects of experience and the intellectual influences upon his mental apparatus succeed in bringing about the sublimation of a further portion of it. To extend this process of displacement indefinitely is, however, certainly not possible, any more than is the case with the transformation of heat into mechanical energy in our machines. A certain amount of direct sexual satisfaction seems to be indispensable for most organizations, and a deficiency in this amount, which varies from individual to individual, is visited by phenomena which, on account of their detrimental effects on functioning and their subjective quality of unpleasure, must be regarded as an illness.

Experience teaches us that for most people there is a limit beyond which their constitution cannot comply with the demands of civilization. All who wish to be more noble-minded than their constitution allows fall victims to neurosis; they would have been more healthy if it could have been possible for them to be less good. The discovery that perversions and neuroses stand in the relation of positive and negative is often unmistakably confirmed by observations made on the members of one generation of a family. Quite frequently a brother is a sexual pervert, while his sister, who, being a woman, possesses a weaker sexual instinct, is a neurotic whose symptoms express the same inclinations as the perversions of her sexually more active brother. And correspondingly, in many families the men are healthy, but from a social point of view immoral to an undesirable degree, while the women are high-minded and over-refined, but severely neurotic.

It is one of the obvious social injustices that the standard of civilization should demand from everyone the same conduct of sexual life - conduct which can be followed without any difficulty by some people, thanks to their organization, but which imposes the heaviest psychical sacrifices on others; though, indeed, the injustice is as a rule wiped out by disobedience to the injunctions of morality.
The answer to the first question touches on a problem which has often been discussed and cannot be exhaustively treated here - that of sexual abstinence. Our third stage of civilization demands of individuals of both sexes that they shall practise abstinence until they are married and that all who do not contract a legal marriage shall remain abstinent throughout their lives. The position, agreeable to all the authorities, that sexual abstinence is not harmful and not difficult to maintain, has also been widely supported by the medical profession. It may be asserted, however, that the task of mastering such a powerful impulse as that of the sexual instinct by any other means than satisfying it is one which can call for the whole of a man's forces. Mastering it by sublimation, by deflecting the sexual instinctual forces away from their sexual aim to higher cultural aims, can be achieved by a minority and then only intermittently, and least easily during the period of ardent and vigorous youth. Most of the rest become neurotic or are harmed in one way or another. Experience shows that the majority of the people who make up our society are constitutionally unfit to face the task of abstinence. Those who would have fallen ill under milder sexual restrictions fall ill all the more readily and more severely before the demands of our cultural sexual morality of to-day; for we know no better safe-guard against the threat to normal sexual life offered by defective innate dispositions or disturbances of development than sexual satisfaction itself. The more a person is disposed to neurosis, the less can he tolerate abstinence; instincts which have been withdrawn from normal development, in the sense in which it has been described above, become at the same time all the more uninhibitable. But even those people who would have retained their health under the requirements of the second stage of civilization will now succumb to neurosis in great numbers. For the psychical value of sexual satisfaction increases with its frustration. The dammed-up libido is now put in a position to detect one or other of the weaker spots which are seldom absent in the structure of sexual life, and there to break through and obtain substitutive satisfaction of a neurotic kind in the form of pathological symptoms. Anyone who is able to penetrate the determinants of nervous illness will soon become convinced that its increase in our society arises from the intensification of sexual restrictions.

[1908d, 1956]

The retardation of sexual development and sexual activity at which our education and civilization aim is certainly not injurious to begin with. It is seen to be a necessity, when one considers the late age at which young people of the educated classes reach independence and are able to earn a living. (This reminds one, incidentally, of the intimate interconnection between all our cultural institutions and of the difficulty of altering any part of them without regard to the whole.) But abstinence continued long after the age of twenty is no longer unobjectionable for a young man; and it leads to other damage even when it does not lead to neurosis. People say, to be sure, that the struggle against such a powerful instinct, and the strengthening of all the ethical and aesthetic forces which are necessary for this struggle, 'steel' the character; and this is true for a few specially favourably organized natures. It must also be admitted that the differentiation of individual character, which is so marked in our day, has only become possible with the existence of sexual restriction. But in the vast majority of cases the struggle against sexuality eats up the energy available in a character and this at the very time when a young man is in need of all his forces in order to win his share and place in society. The relationship between the amount of sublimation possible and the amount of sexual activity necessary naturally varies very much from person to person and even from one calling to another. An abstinent artist is hardly conceivable; but an abstinent young savant is certainly no rarity. The latter can, by his self-restraint, liberate forces for his studies; while the former probably finds his artistic achievements powerfully stimulated by his sexual experience. In general I have not gained the impression that sexual abstinence helps to bring about energetic and self-reliant men of action or original thinkers or bold emancipators and reformers. Far more often it goes to produce well-behaved weaklings who later become lost in the great mass of people that tends to follow, unwillingly, the leads given by strong individuals.

[1908d, 1958]
I return now to my earlier assertion that, in judging the neuroses, their full importance is not as a rule taken into account. I do not mean by this the undervaluation of these states shown in their frivolous dismissal by relatives and in the boasting assurances by doctors that a few weeks of cold water treatment or a few months of rest and convalescence will cure the condition. These are merely the opinions of quite ignorant doctors and laymen and are mostly no more than words intended to give the sufferer a short-lived consolation. It is, on the contrary, a well-known fact that a chronic neurosis, even if it does not totally put an end to the subject's capacity for existence, represents a severe handicap in his life, of the same order, perhaps, as tuberculosis or a cardiac defect. The situation would even be tolerable if neurotic illness were to exclude from civilized activities only a number of individuals who were in any case of the weaker sort, and allowed the rest to play their part in it at the cost of troubles that were merely subjective. But, far from this being so, I must insist upon the view that neuroses, whatever their extent and wherever they occur, always succeed in frustrating the purposes of civilization, and in that way actually perform the work of the suppressed mental forces that are hostile to civilization. Thus, when society pays for obedience to its far-reaching regulations by an increase in nervous illness, it cannot claim to have purchased a gain at the price of sacrifices; it cannot claim a gain at all. Let us, for instance, consider the very common case of a woman who does not love her husband, because, owing to the conditions under which she entered marriage, she has no reason to love him, but who very much wants to love him, because that alone corresponds to the ideal of marriage to which she has been brought up. She will in that case suppress every impulse which would express the truth and contradict her endeavours to fulfil her ideal, and she will make special efforts to play the part of a loving, affectionate and attentive wife. The outcome of this self-suppression will be a neurotic illness; and this neurosis will in a short time have taken revenge on the unloved husband and have caused him just as much lack of satisfaction and worry as would have resulted from an acknowledgement of the true state of affairs. This example is completely typical of what a neurosis achieves. A similar failure to obtain compensation is to be seen after the suppression of impulses inimical to civilization which are not directly sexual. If a man, for example, has become over-kind as a result of a violent suppression of a constitutional inclination to harshness and cruelty, he often loses so much energy in doing this that he fails to carry out all that his compensatory impulses require, and he may, after all, do less good on the whole than he would have done without the suppression. [1908d, 1962]
I do not think much of the objection that neurotics are a special class of people, marked by an innate disposition that is 'degenerate', from whose childhood life we must not be allowed to infer anything about the childhood of other people. Neurotics are people much like others. They cannot be sharply differentiated from normal people, and in their childhood they are not always easily distinguishable from those who remain healthy in later life. It is one of the most valuable results of our psycho-analytic investigations to have discovered that the neuroses of such people have no special mental content that is peculiar to them, but that, as Jung has expressed it, they fall ill of the same complexes against which we healthy people struggle as well. The only difference is that healthy people know how to overcome those complexes without any gross damage demonstrable in practical life, whereas in nervous cases the suppression of the complexes succeeds only at the price of costly substitutive formations - that is to say, from a practical point of view it is a failure. In childhood neurotic and normal people naturally approximate to each other much more closely than they do in later life, so that I cannot regard it as a methodological error to make use of the communications of neurotics about their childhood for drawing conclusions by analogy about normal childhood life. But since those who later become neurotics very often have in their inborn constitution an especially strong sexual instinct and a tendency to precocity and to a premature expression of that instinct, they make it possible for us to recognize a great deal of infantile activity more sharply and clearly than our capacity for observation (which is in any case a blunted one) would enable us to do in other children. But we shall of course only be able to assess the true value of these communications made by neurotic adults when, following Havelock Ellis's example, we shall have thought it worth while to collect the childhood memories of healthy adults as well.

[1908c, 1967]

The onset of hysterical attacks follows laws that are easily understandable. Since the repressed complex consists of a libidinal cathexis and an ideational content (the phantasy), the attack can be evoked (1) **associatively**, when the content of the complex (if sufficiently cathected) is touched on by something connected with it in conscious life; (2) **organically**, when, for internal somatic reasons and as a result of psychical influences from outside, the libidinal cathexis rises above a certain degree; (3) in the service of the **primary purpose** - as an expression of a 'flight into illness', when reality becomes distressing or frightening - that is, as a **consolation**; (4) in the service of the **secondary purposes**, with which the illness allies itself, as soon as, by producing an attack, the patient can achieve an aim that is useful to him. In the last case the attack is directed at particular individuals; it can be put off till they are present, and it gives an impression of being consciously simulated.

[1909a, 1983]

Investigation of the childhood history of hysterical patients shows that the hysterical attack is designed to take the **place of an auto-erotic satisfaction** previously practised and since given up. In a great number of cases this satisfaction (masturbation by contact or by pressure of the thighs, or, again, by movements of the tongue, and so on) recurs during the attack itself, while the subject's consciousness is deflected. Moreover, the onset of an attack that is due to an increase of libido and is in the service of the primary purpose - as a consolation - exactly repeats the conditions under which, at the earlier time, the patient had intentionally sought this auto-erotic satisfaction. The anamnesis of the patient shows the following stages: (a) auto-erotic satisfaction, without ideational content; (b) the same satisfaction, connected with a phantasy which leads to the act of satisfaction; (c) renunciation of the act, with retention of the phantasy; (d) repression of the phantasy, which then comes into effect as a hysterical attack, either in an unchanged form, or in a modified one and adapted to new environmental impressions. Furthermore, (e) the phantasy may even reinstate the act of satisfaction belonging to it which had ostensibly been given up. This is a typical cycle of infantile sexual activity: repression, failure of repression, and return of the repressed.

[1909a, 1983]
Then again, there were the states into which he fell on two consecutive evenings before going to sleep, and which were characterized by anxiety mingled with clear traces of tenderness. These states show that at the beginning of his illness there was as yet no phobia whatever present, whether of streets or of walking or even of horses. If there had been, his evening states would be inexplicable; for who bothers at bed time about streets and walking? On the other hand it becomes quite clear why he was so fearful in the evening, if we suppose that at bedtime he was overwhelmed by an intensification of his libido - for its object was his mother, and its aim may perhaps have been to sleep with her. He had besides learnt from his experience that at Gmunden his mother could be prevailed upon, when he got into such moods, to take him into her bed, and he wanted to gain the same ends here in Vienna. Nor must we forget that for part of the time at Gmunden he had been alone with his mother, as his father had not been able to spend the whole of the holidays there, and further, that in the country his affections had been divided among a number of playmates and friends of both sexes, while in Vienna he had none, so that his libido was in a position to return undivided to his mother.

[1909b, 2018]

Let us, further, picture to ourselves the general conditions under which the formation of the patient's great obsessional idea occurred. His libido had been increased by a long period of abstinence coupled with the friendly welcome which a young officer can always reckon upon receiving when he goes among women. Moreover, at the time when he had started for the manoeuvres, there had been a certain coolness between himself and his lady. This intensification of his libido had inclined him to a renewal of his ancient struggle against his father's authority, and he had dared to think of having sexual intercourse with other women. His loyalty to his father's memory had grown weaker, his doubts as to his lady's merits had increased; and in that frame of mind he let himself be dragged into insulting the two of them, and had then punished himself for it. In doing so he had copied an old model. And when at the end of the manoeuvres he had hesitated so long whether he should travel to Vienna or whether he should stop and fulfil his vow, he had represented in a single picture the two conflicts by which he had from the very first been torn - whether or no he should remain obedient to his father and whether or no he should remain faithful to his beloved.¹

[1909d, 2170]

If we consider a number of analyses of obsessional neurotics we shall find it impossible to escape the impression that a relation between love and hatred such as we have found in our present patient is among the most frequent, the most marked, and probably, therefore, the most important characteristics of obsessional neurosis. But however tempting it may be to bring the problem of the ‘choice of neurosis’ into connection with instinctual life, there are reasons enough for avoiding such a course. For we must remember that in every neurosis we come upon the same suppressed instincts behind the symptoms. After all, hatred, kept suppressed in the unconscious by love, plays a great part in the pathogenesis of hysteria and paranoia. We know too little of the nature of love to be able to arrive at any definite conclusion here; and, in particular, the relation between the negative factor¹ in love and the sadistic components of the libido remains completely obscure. What follows is therefore to be regarded as no more than a provisional explanation. We may suppose, then, that in the cases of unconscious hatred with which we are concerned the sadistic components of love have, from constitutional causes, been exceptionally strongly developed, and have consequently undergone a premature and all too thorough suppression, and that the neurotic phenomena we have observed arise on the one hand from conscious feelings of affection which have become exaggerated as a reaction, and on the other hand from sadism persisting in the unconscious in the form of hatred.

[1909d, 2187]
The predisposition to neurosis is traceable to impaired sexual development in a different way. Neuroses are related to perversions as negative to positive. The same instinctual components as in the perversions can be observed in the neuroses as vehicles of complexes and constructors of symptoms, but in the latter case they operate from the unconscious. Thus they have undergone repression, but have been able, in defiance of it, to persist in the unconscious. Psycho-analysis makes it clear that an excessively strong manifestation of these instincts at a very early age leads to a kind of partial fixation, which then constitutes a weak point in the structure of the sexual function. If in maturity the performance of the normal sexual function comes up against obstacles, the repression that took place during the course of development will be broken through at the precise points at which the infantile fixations occurred.

Let me at this point state the principal finding to which we have been led by the psycho-analytic investigation of neurotics. The neuroses have no psychical content that is peculiar to them and that might not equally be found in healthy people. Or, as Jung has expressed it, neurotics fall ill of the same complexes against which we healthy people struggle as well. Whether that struggle ends in health, in neurosis, or in a countervailing superiority of achievement, depends on quantitative considerations, on the relative strength of the conflicting forces.

Psycho-analytic studies of psychical impotence have already been carried out and published by several writers.¹ Every analyst can confirm the explanations provided by them from his own clinical experience. It is in fact a question of the inhibitory influence of certain psychical complexes which are withdrawn from the subject's knowledge. An incestuous fixation on mother or sister, which has never been surmounted, plays a prominent part in this pathogenic material and is its most universal content. In addition there is the influence to be considered of accidental distressing impressions connected with infantile sexual activity, and also those factors which in a general way reduce the libido that is to be directed on to the female sexual object.²

We have reduced psychical impotence to the failure of the affectionate and the sensual currents in love to combine, and this developmental inhibition has in turn been explained as being due to the influences of strong childhood fixations and of later frustration in reality through the intervention of the barrier against incest. There is one principal objection to the theory we advance; it does too much. It explains why certain people suffer from psychical impotence, but it leaves us with the apparent mystery of how others have been able to escape this disorder. Since we must recognize that all the relevant factors known to us - the strong childhood fixation, the incest-barrier and the frustration in the years of development after puberty - are to be found in practically all civilized human beings, we should be justified in expecting psychical impotence to be a universal affliction under civilization and not a disorder confined to some individuals.
The fact that the curb put upon love by civilization involves a universal tendency to debase sexual objects will perhaps lead us to turn our attention from the object to the instincts themselves. The damage caused by the initial frustration of sexual pleasure is seen in the fact that the freedom later given to that pleasure in marriage does not bring full satisfaction. But at the same time, if sexual freedom is unrestricted from the outset the result is no better. It can easily be shown that the psychological value of erotic needs is reduced as soon as their satisfaction becomes easy. An obstacle is required in order to heighten libido; and where natural resistances to satisfaction have not been sufficient men have at all times erected conventional ones so as to be able to enjoy love. This is true both of individuals and of nations. In times in which there were no difficulties standing in the way of sexual satisfaction, such as perhaps during the decline of the ancient civilizations, love became worthless and life empty, and strong reaction-formations were required to restore indispensable affective values. In this connection it may be claimed that the ascetic current in Christianity created psychological values for love which pagan antiquity was never able to confer on it. This current assumed its greatest importance with the ascetic monks, whose lives were almost entirely occupied with the struggle against libidinal temptation.

[1912d, 2344]

One's first inclination is no doubt to trace back the difficulties revealed here to universal characteristics of our organic instincts. It is no doubt also true in general that the psychological importance of an instinct rises in proportion to its frustration. Suppose a number of totally different human beings were all equally exposed to hunger. As their imperative need for food mounted, all the individual differences would disappear and in their place one would see the uniform manifestations of the one unappeased instinct. But is it also true that with the satisfaction of an instinct its psychological value always falls just as sharply? Consider, for example, the relation of a drinker to wine. Is it not true that wine always provides the drinker with the same toxic satisfaction, which in poetry has so often been compared to erotic satisfaction - a comparison acceptable from the scientific point of view as well? Has one ever heard of the drinker being obliged constantly to change his drink because he soon grows tired of keeping to the same one? On the contrary, habit constantly tightens the bond between a man and the kind of wine he drinks. Does one ever hear of a drinker who needs to go to a country where wine is dearer or drinking is prohibited, so that by introducing obstacles he can reinforce the dwindling satisfaction that he obtains? Not at all. If we listen to what our great alcoholics, such as Böcklin,¹ say about their relation to wine, it sounds like the most perfect harmony, a model of a happy marriage. Why is the relation of the lover to his sexual object so very different?

[1912d, 2345]

Psycho-analysis, too, accepts the assumptions of dissociation and the unconscious, but relates them differently to each other. Its view is a dynamic one, which traces mental life back to an interplay between forces that favour or inhibit one another. If in any instance one group of ideas remains in the unconscious, psycho-analysis does not infer that there is a constitutional incapacity for synthesis which is showing itself in this particular dissociation, but maintains that the isolation and state of unconsciousness of this group of ideas have been caused by an active opposition on the part of other groups. The process owing to which it has met with this fate is known as 'repression' and we regard it as something analogous to a condemnation in the field of logic. Psycho-analysis points out that repressions of this kind play an extraordinarily important part in our mental life, but that they may also frequently fail and that such failures of repression are the precondition of the formation of symptoms.

[1910i, 2368]
Psycho-analysis is unjustly reproached, Gentlemen, for leading to purely psychological theories of pathological problems. The emphasis which it lays on the pathogenic role of sexuality, which, after all, is certainly not an exclusively psychical factor should alone protect it from this reproach. Psycho-analysts never forget that the mental is based on the organic, although their work can only carry them as far as this basis and no beyond it. Thus psycho-analysis is ready to admit, and indeed to postulate, that not all disturbances of vision need be psychogenic, like those that are evoked by the repression of erotic scopophilia. If an organ which serves the two sorts of instinct increases its erotogenic role, it is in general to be expected that this will not occur without the excitability and innervation of the organ undergoing changes which will manifest themselves as disturbances of its function in the service of the ego. Indeed, if we find that an organ normally serving the purpose of sense-perception begins to behave like an actual genital when its erotogenic role is increased, we shall not regard it as improbable that toxic changes are also occurring in it. For lack of a better name we must retain the old unsuitable term of 'neurotic' disturbances for both classes of functional disturbances - those of physiological as well as those of toxic origin - which follow from an increase in the erotogenic factor. Generally speaking, the neurotic disturbances of vision stand in the same relation to the psychogenic ones as the 'actual neuroses' do to the psychoneuroses: psychogenic visual disturbances can no doubt hardly ever appear without neurotic ones, but the latter can appear without the former. These neurotic symptoms are unfortunately little appreciated and understood even today; for they are not directly accessible to psycho-analysis, and other methods of research have left the standpoint of sexuality out of account.

Yet another line of thought extending into organic research branches off from psycho-analysis. We may ask ourselves whether the suppression of sexual component instincts which is brought about by environmental influences is sufficient in itself to call up functional disturbances in organs, or whether special constitutional conditions must be present in order that the organs may be led to an exaggeration of their erotogenic role and consequently provoke repression of the instincts. We should have to see in those conditions the constitutional part of the disposition to fall ill of psychogenic and neurotic disorders. This is the factor to which, as applied to hysteria, I gave the provisional name of 'somatic compliance'.

The question of why this outburst of homosexual libido overtook the patient precisely at this period (that is, between the dates of his appointment and of his move to Dresden) cannot be answered in the absence of more precise knowledge of the story of his life. Generally speaking, every human being oscillates all through his life between heterosexual and homosexual feelings, and any frustration or disappointment in the one direction is apt to drive him over into the other. We know nothing of these factors in Schreber's case, but we must not omit to draw attention to a somatic factor which may very well have been relevant. At the time of this illness Dr. Schreber was fifty-one years old, and he had therefore reached an age which is of critical importance in sexual life. It is a period at which in women the sexual function, after a phase of intensified activity, enters upon a process of far-reaching involution; nor do men appear to be exempt from its influence, for men as well as women are subject to a 'climacteric' and to the susceptibilities to disease which go along with it.¹
Perhaps I may be allowed to add a few words with a view to establishing the causes of this conflict that broke out in relation to the feminine wishful phantasy. As we know, when a wishful phantasy makes its appearance, our business is to bring it into connection with some frustration, some privation in real life. Now Schreber admits having suffered a privation of the kind. His marriage, which he describes as being in other respects a happy one, brought him no children; and in particular it brought him no son who might have consoled him for the loss of his father and brother and upon whom he might have drained off his unsatisfied homosexual affections.¹ His family line threatened to die out, and it seems that he felt no little pride in his birth and lineage. "Both the Flechsigs and the Schrebers were members of "the highest nobility of Heaven", as the phrase went. The Schrebers in particular bore the title of "Margraves of Tuscany and Tasmania"; for souls, urged by some sort of personal vanity, have a custom of adorning themselves with somewhat high-sounding titles borrowed from this world."² (24.) The great Napoleon obtained a divorce from Josephine (though only after severe internal struggles) because she could not propagate the dynasty.³ Dr. Schreber may have formed a phantasy that if he were a woman he would manage the business of having children more successfully; and he may thus have found his way back into the feminine attitude towards his father which he had exhibited in the earliest years of his childhood. If that were so, then his delusion that as a result of his emasculation the world was to be peopled with 'a new race of men, born from the spirit of Schreber' (288) - a delusion the realization of which he was continually postponing to a more and more remote future - would also be designed to offer him an escape from his childlessness. If the 'little men' whom Schreber himself finds so puzzling were children, then we should have no difficulty in understanding why they were collected in such great numbers on his head (158): they were in truth the 'children of his spirit'.⁴

In my Three Essays on the Theory of Sexuality I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics endeavour to protect themselves against any such sexualization of their social instinctual cathexes, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-eroticism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) schizophrenia; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.⁵

[1911c, 2428]
(2) The second phase of repression is that of repression proper - the phase to which most attention has hitherto been given. It emanates from the more highly developed systems of the ego - systems which are capable of being conscious - and may in fact be described as a process of 'after-pressure'. It gives an impression of being an essentially active process, while fixation appears in fact to be a passive lagging behind. What undergo repression may either be the psychical derivatives of the original lagging instincts, when these have become reinforced and so come into conflict with the ego (or ego-syntonic instincts), or they may be psychical trends which have for other reasons aroused strong aversion. But this aversion would not in itself lead to repression, unless some connection had been established between the unwelcome trends which have to be repressed and those which have been repressed already. Where this is so, the repulsion exercised by the conscious system and the attraction exercised by the unconscious one tend in the same direction towards bringing about repression. The two possibilities which are here treated separately may in practice, perhaps, be less sharply differentiated, and the distinction between them may merely depend upon the greater or lesser degree in which the primarily repressed instincts contribute to the result.

[1911c, 2435]

(d) Just as the third type has brought the dispositional determinant before us almost in isolation, so the fourth type, which now follows, draws our attention to another factor, which comes into consideration in every single case and might easily for that very reason be overlooked in a theoretical discussion. We see people fall ill who have hitherto been healthy, who have met with no fresh experience and whose relation to the external world has undergone no change, so that the onset of their illness inevitably gives an impression of spontaneity. A closer consideration of such cases, however, shows us that none the less a change has taken place in them whose importance we must rate very highly as a cause of illness. As a result of their having reached a particular period of life, and in conformity with regular biological processes, the quantity of libido in their mental economy has experienced an increase which is in itself enough to upset the equilibrium of their health and to set up the necessary conditions for a neurosis. It is well known that more or less sudden increases of libido of this kind are habitually associated with puberty and the menopause - with the attainment of a certain age in women; in some people they may in addition be manifested in periodicities that are still unknown. Here the damming-up of libido is the primary factor; it becomes pathogenic as a consequence of a relative frustration on the part of the external world, which would still have granted satisfaction to a smaller claim by the libido. The unsatisfied and dammed-up libido can once again open up paths to regression and kindle the same conflicts which we have demonstrated in the case of absolute external frustration. We are reminded in this way that the quantitative factor should not be left out of account in any consideration of the precipitating causes of illness. All the other factors - frustration, fixation, developmental inhibition - remain ineffective unless they affect a certain amount of libido and bring about a damming-up of libido of a certain height. It is true that we are unable to measure this amount of libido which seems to us indispensable for a pathogenic effect; we can only postulate it after the resulting illness has started. There is only one direction in which we can determine it more precisely. We may assume that it is not a question of an absolute quantity, but of the relation between the quota of libido in operation and the quantity of libido which the individual ego is able to deal with - that is, to hold under tension, to sublimate or to employ directly. For this reason a relative increase in the quantity of libido may have the same effects as an absolute one. An enfeeblement of the ego owing to organic illness or owing to some special demand upon its energy will be able to cause the emergence of neuroses which would otherwise have remained latent in spite of any disposition that might be present.

[1912c, 2563]
The importance in the causation of illness which must be ascribed to quantity of libido is in satisfactory agreement with two main theses of the theory of the neuroses to which psycho-analysis has led us: first, the thesis that the neuroses are derived from the conflict between the ego and the libido, and secondly, the discovery that there is no qualitative distinction between the determinants of health and those of neurosis, and that, on the contrary, healthy people have to contend with the same tasks of mastering their libido - they have simply succeeded better in them.

[1912c, 2563]

It remains to say a few words on the relation of these types to the facts of observation. If I survey the set of patients on whose analysis I am at the moment engaged, I must record that not one of them is a pure example of any of the four types of onset. In each of them, rather, I find a portion of frustration operating alongside of a portion of incapacity to adapt to the demands of reality; inhibition in development, which coincides, of course, with inflexibility of fixations, has to be reckoned with in all of them, and, as I have already said, the importance of quantity of libido must never be neglected. I find, indeed, that in several of these patients their illness has appeared in successive waves, between which there have been healthy intervals, and that each of these waves has been traceable to a different type of precipitating cause. Thus the erection of these four types cannot lay claim to any high theoretical value; they are merely different ways of establishing a particular pathogenic constellation in the mental economy - namely the damming-up of libido, which the ego cannot, with the means at its command, ward off without damage. But this situation itself only becomes pathogenic as a result of a quantitative factor; it does not come as a novelty to mental life and is not created by the impact of what is spoken of as a 'cause of illness'.

[1912c, 2564]

Stekel shares with many non-psycho-analytic writers an inclination to reject the morphological differentiations which we have made within the jumble of the neuroses and to lump them all together under one heading - under psychasthenia, perhaps. We have often contradicted him on this, and have held fast to our expectation that the morphologico-clinical differences will prove valuable as indications that have not yet been understood of essentially distinct processes. When he - justly - points out to us that he has regularly found the same complexes present in what are termed neurasthenics as in other neurotics, his argument fails to meet the point at issue. We have long known that the same complexes and conflicts are to be looked for, too, in all normal and healthy people. In fact, we have grown accustomed to attributing to every civilized human being a certain amount of repression of perverse impulses, a certain amount of anal erotism, of homosexuality and so on, as well as a piece of father-complex and mother-complex and of other complexes besides - just as in the chemical analysis of an organic substance we have every hope of finding certain elements: carbon, oxygen, hydrogen, nitrogen and a trace of sulphur. What distinguishes organic substances from one another is the relative amounts of these elements and the way in which the links between them are constituted. In the same way, in the case of normal and neurotic people what is in question is not whether these complexes and conflicts exist but whether they have become pathogenic and, if so, by means of what mechanisms they have become so.

[1912f, 2570]
Like the majority of you, I am inclined to refuse to give a general answer to the question. It partly coincides with another, more comprehensive question: when does sexual activity in general become pathogenic for particular people? If we put this consideration on one side, we are left with a question of detail relating to the characteristics of masturbation in so far as it represents a special manner and form of sexual satisfaction. Here it would be to the point to repeat what is already known to us and has been discussed in other connections - to assess the influence of the *quantitative* factor and of the combined operation of several pathogenic factors. Above all, however, we should have to leave a wide field for what are known as an individual's constitutional dispositions. But it must be confessed that dealing with these is an awkward business. For we are in the habit of forming our opinion of individual dispositions *ex post facto*: we attribute this or that disposition to people after the event, when they have already fallen ill. We have no method of discovering it beforehand. We behave, in fact, like the Scottish King in one of Victor Hugo's novels, who boasted of an infallible method of recognizing witchcraft. He had the accused woman stewed in boiling water and then tasted the broth. He then judged according to the taste: 'Yes, that was a witch', or 'No, that was not one.'

The first task confronting psycho-analysis was to explain the neuroses; it used the two facts of resistance and transference as starting-points, and, taking into consideration the third fact of amnesia, accounted for them with its theories of repression, of the sexual motive forces in neurosis and of the unconscious. Psycho-analysis has never claimed to provide a complete theory of human mentality in general, but only expected that what it offered should be applied to supplement and correct the knowledge acquired by other means. Adler's theory, however, goes far beyond this point; it seeks at one stroke to explain the behaviour and character of human beings as well as their neurotic and psychotic illnesses. It is actually more suited to any other field than that of neurosis, although for reasons connected with the history of its development it still places this in the foreground. For many years I had opportunities of studying Dr. Adler and have never refused to recognize his unusual ability, combined with a particularly speculative disposition. As an instance of the 'persecution' to which he asserts he has been subjected by me, I can point to the fact that after the Association was founded I made over to him the leadership of the Vienna group. It was not until urgent demands were put forward by all the members of the society that I let myself be persuaded to take the chair again at its scientific meetings. When I perceived how little gift Adler had precisely for judging unconscious material, my view changed to an expectation that he would succeed in discovering the connections of psycho-analysis with psychology and with the biological foundations of instinctual processes - an expectation which was in some sense justified by the valuable work he had done on 'organ-inferiority'. And he did in fact effect something of the kind; but his work conveys an impression 'as if' - to speak in his own 'jargon' - it was intended to prove that psycho-analysis was wrong in everything and that it had only attributed so much importance to sexual motive forces because of its credulity in accepting the assertions of neurotics. I may even speak publicly of the personal motive for his work, since he himself announced it in the presence of a small circle of members of the Vienna group: - 'Do you think it gives me such great pleasure to stand in your shadow my whole life long?' To be sure, I see nothing reprehensible in a younger man freely admitting his ambition, which one would in any case guess was among the incentives for his work. But even though a man is dominated by a motive of this kind he should know how to avoid being what the English, with their fine social tact, call 'unfair' - which in German can only be expressed by a much cruder word. How little Adler has succeeded in this is shown by the profusion of petty outbursts of malice which disfigure his writings and by the indications they contain of an uncontrolled craving for priority. At the Vienna Psycho-Analytical Society we once actually heard him claim priority for the conception of the 'unity of the neuroses' and for the 'dynamic view' of them. This came as a great surprise to me, for I had always believed that these two principles were stated by me before I ever made Adler's acquaintance.
The economic standpoint has hitherto received little attention in psycho-analytic writings. I would mention as an exception a paper by Victor Tausk (1913) on motives for repression devalued by recompenses.

You may now have an impression that deprivation has been reduced to insignificance owing to all these methods of tolerating it. But no, it retains its pathogenic power. The countermeasures are on the whole insufficient. There is a limit to the amount of unsatisfied libido that human beings on the average can put up with. The plasticity or free mobility of the libido is by no means fully preserved in everyone, and sublimation is never able to deal with more than a certain fraction of libido, quite apart from the fact that many people are gifted with only a small amount of capacity to sublimate. The most important of these limitations is evidently that upon the mobility of the libido, since it makes a person's satisfaction depend on the attainment of only a very small number of aims and objects. You have only to recall that an imperfect development of the libido leaves behind it very fertile and perhaps, too, very numerous libidinal fixations to early phases of the organization and of the finding of objects, which are for the most part incapable of real satisfaction, and you will recognize in libidinal fixation the second powerful factor which combines with frustration as the cause of illness. You can declare, as a schematic abbreviation, that libidinal fixation represents the predisposing, internal factor in the aetiology of the neuroses, while frustration represents the accidental, external one.

In order to appreciate the full significance of the difference which I have pointed out between the two groups of instincts, we shall have to go back a long way and introduce one of those considerations which deserve to be described as economic. This leads us to one of the most important, but unluckily also one of the most obscure, regions of psycho-analysis. We may ask whether in the operation of our mental apparatus a main purpose can be detected, and we may reply as a first approximation that that purpose is directed to obtaining pleasure. It seems as though our total mental activity is directed towards achieving pleasure and avoiding unpleasure - that it is automatically regulated by the pleasure principle. We should of all things like to know, then, what determines the generation of pleasure and unpleasure; but that is just what we are ignorant of. We can only venture to say this much: that pleasure is in some way connected with the diminution, reduction or extinction of the amounts of stimulus prevailing in the mental apparatus, and that similarly unpleasure is connected with their increase. An examination of the most intense pleasure which is accessible to human beings, the pleasure of accomplishing the sexual act, leaves little doubt on this point. Since in such processes related to pleasure it is a question of what happens to quantities of mental excitation or energy, we call considerations of this kind economic. It will be noticed that we can describe the tasks and achievements of the mental apparatus in another and more general way than by stressing the acquisition of pleasure. We can say that the mental apparatus serves the purpose of mastering and disposing of the amounts of stimulus and sums of excitation that impinge on it from outside and inside. It is immediately obvious that the sexual instincts, from beginning to end of their development, work towards obtaining pleasure; they retain their original function unaltered. The other instincts, the ego-instincts, have the same aim to start with. But under the influence of the instructress Necessity, they soon learn to replace the pleasure principle by a modification of it. For them the task of avoiding unpleasure turns out to be almost as important as that of obtaining pleasure. The ego discovers that it is inevitable for it to renounce immediate satisfaction, to postpone the obtaining of pleasure, to put up with a little unpleasure and to abandon certain sources of pleasure altogether. An ego thus educated has become 'reasonable'; it no longer lets itself be governed by the pleasure principle, but obeys the reality principle, which also at bottom seeks to obtain pleasure, but pleasure which is assured through taking account of reality, even though it is pleasure postponed and diminished.
You will no doubt have observed that in these last discussions I have introduced a fresh factor into the structure of the aetiological chain - namely the quantity, the magnitude, of the energies concerned. We have still to take this factor into account everywhere. A purely qualitative analysis of the aetiological determinants is not enough. Or, to put it another way, a merely dynamic view of these mental processes is insufficient; an economic line of approach is also needed. We must tell ourselves that the conflict between two trends does not break out till certain intensities of cathexis have been reached, even though the determinants for it have long been present so far as their subject-matter is concerned. In the same way, the pathogenic significance of the constitutional factors must be weighed according to how much more of one component instinct than of another is present in the inherited disposition. It may even be supposed that the disposition of all human beings is qualitatively alike and that they differ only owing to these quantitative conditions. The quantitative factor is no less decisive as regards capacity to resist neurotic illness. It is a matter of what quota of unemployed libido a person is able to hold in suspension and of how large a fraction of his libido he is able to divert from sexual to sublimated aims. The ultimate aim of mental activity, which may be described qualitatively as an endeavour to obtain pleasure and avoid unpleasure, emerges, looked at from the economic point of view, as the task of mastering the amounts of excitation (mass of stimuli) operating in the mental apparatus and of keeping down their accumulation which creates unpleasure.

[1916-1917, 3429]

Of course, the sexual abstinence now so warmly recommended by doctors only has the same importance in generating anxiety states when the libido which is prevented from finding a satisfying discharge is correspondingly strong and has not been dealt with for the greater part by sublimation. Indeed, the decision on whether the outcome is to be illness or not always lies with quantitative factors. Even where what is in question is not illness but the form assumed by a person's character, it is easy to recognize that sexual restriction goes hand in hand with some kind of anxiousness and hesitancy, while intrepidity and impudent daring bring along with them a free indulgence of sexual needs. However much these relations are altered and complicated by a variety of cultural influences, it nevertheless remains true of the average of mankind that anxiety has a close connection with sexual limitation.

[1916-1917, 3449]

If, then, there are children who come some way to meet this education in anxiety, and who go on to find dangers themselves that they have not been warned against, this is sufficiently explained by the fact that they have a greater amount of innate libidinal need in their constitution or have been prematurely spoiled by libidinal satisfaction. It is not to be wondered at if such children include, too, the later neurotics: as we know, what most facilitates the development of a neurosis is an incapacity to tolerate a considerable damming-up of libido over any great length of time. You will observe that here once more the constitutional factor comes into its rights - and these, indeed, we have never sought to dispute. We are only on our guard against those who in its favour neglect all other claims, and who introduce the constitutional factor at points at which the combined results of observation and analysis show that it does not belong or must take the last place.

[1916-1917, 3454]
With this as a starting-point we go on to make our first important discovery. We learn that, when we try to understand neurotic disorders, by far the greater significance attaches to the sexual instincts; that in fact neuroses are the specific disorders, so to speak, of the sexual function; that in general whether or not a person develops a neurosis depends on the quantity of his libido, and on the possibility of satisfying it and of discharging it through satisfaction; that the form taken by the disease is determined by the way in which the individual passes through the course of development of his sexual function, or, as we put it, by the fixations his libido has undergone in the course of its development; and, further, that by a special, not very simple technique for influencing the mind we are able to throw light on the nature of some groups of neuroses and at the same time to do away with them. Our therapeutic efforts have their greatest success with a certain class of neuroses which proceed from a conflict between the ego-instincts and the sexual instincts. For in human beings it may happen that the demands of the sexual instincts, whose reach of course extends far beyond the individual, seem to the ego to constitute a danger which threatens its self-preservation or its self-esteem. The ego then assumes the defensive, denies the sexual instincts the satisfaction they desire and forces them into those by-paths of substitutive satisfaction which become manifest as nervous symptoms.

[1917a, 3609]

For a time psycho-analysis seemed fated to merge into psychology without being able to show why the psychology of the sick differed from that of the normal. In the course of its advance, however, it came up against the problem of dreams, which are abnormal products of the mind created by normal men under regularly recurrent physiological conditions. When psycho-analysis had solved the problem of dreams, it had discovered in unconscious psychical processes the common ground in which the highest and the lowest of mental impulses have their roots and from which spring the most normal as well as the most morbid and erratic of mental productions. The new picture of the workings of the mind began to grow ever clearer and more complete. It was a picture of obscure instinctual forces organic in origin, striving towards inborn aims, and, above them, of an agency comprising more highly organized mental structures - acquisitions of human evolution made under the impact of human history -, an agency which has taken over portions of the instinctual impulses, has developed them further or has even directed them towards higher aims, but which in any case binds them firmly and manipulates their energy to suit its own purposes. This higher organization, however, which is known to us as the ego, has rejected another portion of these same elementary instinctual impulses as being unserviceable because they cannot be fitted into the organic unity of the individual or because they rebel against the individual's cultural aims. The ego is not in a position to exterminate these unsubdued mental powers, but it turns its back on them, lets them remain at the lowest psychological level, defends itself from their demands by the energetic erection of protective and antithetical barriers or seeks to come to terms with them by means of substitutive satisfactions. These instincts which have fallen victim to repression - untamed and indestructible, yet inhibited from any kind of activity - together with their primitive mental representatives, constitute the mental underworld, the nucleus of the true unconscious, and are at every moment ready to assert their demands and, by hook or by crook, to force their way forward to satisfaction. To this is due the instability of the proud superstructure of the mind, the emergence at night of the proscribed and repressed material in the form of dreams, and the tendency to fall ill with neuroses and psychoses as soon as the balance of power between the ego and the repressed shifts to the disadvantage of the ego.

[1919g, 3703]
It seems to me that we have here an important discovery - namely, that the qualitative factor, the presence of certain neurotic formations, has less practical significance than the quantitative factor, the degree of attention or, more correctly, the amount of cathexis that these structures are able to attract to themselves. Our consideration of the first case, the jealous paranoia, led to a similar estimate of the importance of the quantitative factor, by showing that there also the abnormality essentially consisted in the hypercathexis of the interpretations of someone else's unconscious. We have long known of an analogous fact in the analysis of hysteria. The pathogenic phantasies, derivatives of repressed instinctual impulses, are for a long time tolerated alongside the normal life of the mind, and have no pathogenic effect until by a revolution in the libidinal economy they receive a hypercathexis; not till then does the conflict which leads to the formation of symptoms break out. Thus as our knowledge grows we are increasingly impelled to bring the economic point of view into the foreground. I should also like to throw out the question whether this quantitative factor that I am now dwelling on does not suffice to cover the phenomena which Bleuler and others have lately proposed to name 'switching'. One need only assume that an increase in resistance in the course taken by the psychical current in one direction results in a hypercathexis of another path and thus causes the flow to be switched into that path.

[1922b, 3905]

I had already made attempts at earlier stages of my work to arrive at some more general points of view on the basis of psycho-analytic observation. In a short essay, 'Formulations on the Two Principles of Mental Functioning', I drew attention (and there was, of course, nothing original in this) to the domination of the pleasure-unpleasure principle in mental life and to its displacement by what is called the reality principle. Later on I made an attempt to produce a 'Metapsychology'. By this I meant a method of approach according to which every mental process is considered in relation to three co-ordinates, which I described as dynamic, topographical, and economic respectively; and this seemed to me to represent the furthest goal that psychology could attain. The attempt remained no more than a torso; after writing two or three papers - 'Instincts and their Vicissitudes', 'Repression', 'The Unconscious', 'Mourning and Melancholia', etc. - I broke off, wisely perhaps, since the time for theoretical predcations of this kind had not yet come. In my latest speculative works I have set about the task of dissecting our mental apparatus on the basis of the analytic view of pathological facts and have divided it into an ego, an id, and a super-ego.' The super-ego is the heir of the Oedipus complex and represents the ethical standards of mankind.

[1925d, 4234]

Only let us hold fast to this: the nodal point and pivot of the whole situation is the relative strength of the ego organization. We shall then find it easy to complete our aetiological survey. As what may be called the normal causes of neurotic illness we already know the feebleness of the childhood ego, the task of dealing with the early sexual impulses and the effects of the more or less chance experiences of childhood. Is it not possible, however, that yet other factors play a part, derived from the time before the beginning of the child's life? For instance, an innate strength and unruliness of the instinctual life in the id, which from the outset sets the ego tasks too hard for it? Or a special developmental feebleness of the ego due to unknown reasons? Such factors must of course acquire an aetiological importance, in some cases a transcendent one. We have invariably to reckon with the instinctual strength of the id; if it has developed to excess, the prospects of our therapy are poor. We still know too little of the causes of a developmental inhibition of the ego. These then would be the cases of neurosis with an essentially constitutional basis. Without some such constitutional, congenital favouring factors a neurosis can, no doubt, scarcely come about.

[1926e, 4383]
In order to remain faithful to our customary phraseology, we shall have to speak, not of transposing the psychical accent, but of displacing large amounts of cathexis. The question then is whether we are entitled to picture extensive displacements like this from one agency of the mental apparatus to another. It looks like a new hypothesis constructed ad hoc. Yet we may remind ourselves that we have repeatedly (even though not sufficiently often) taken a factor of this kind into account in our attempts at a metapsychological picture of mental events. Thus, for instance, we supposed that the difference between an ordinary erotic object-cathexis and the state of being in love is that in the latter incomparably more cathexis passes over to the object and that the ego empties itself as it were in favour of the object. In studying some cases of paranoia I was able to establish the fact that ideas of persecution are formed early and exist for a long time without any perceptible effect, until, as the result of some particular precipitating event, they receive sufficient amounts of cathexis to cause them to become dominant. The cure, too, of such paranoid attacks would lie not so much in a resolution and correction of the delusional ideas as in a withdrawal from them of the cathexis which has been lent to them. The alternations between melancholia and mania, between a cruel suppression of the ego by the super-ego and a liberation of the ego after that pressure, suggests a shift of cathexis of this kind; such a shift, moreover, would have to be brought in to explain a whole number of phenomena belonging to normal mental life. If this has been done hitherto only to a very limited extent, that is on account of our usual caution - something which deserves only praise. The region in which we feel secure is that of the pathology of mental life; it is here that we make our observations and acquire our convictions. For the present we venture to form a judgement on the normal mind only in so far as we can discern what is normal in the isolations and distortions of the pathological material. When once we have overcome this hesitancy we shall recognize what a large contribution is made to the understanding of mental processes by the static conditions as well as by the dynamic changes in the quantity of energetic cathexis. [1927d, 4544]
And now, only one more remark on the problem of anxiety. Neurotic anxiety has changed in our hands into realistic anxiety, into fear of particular external situations of danger. But we cannot stop there, we must take another step - though it will be a step backward. We ask ourselves what it is that is actually dangerous and actually feared in a situation of danger of this kind. It is plainly not the injury to the subject as judged objectively, for this need be of no significance psychologically, but something brought about by it in the mind. Birth, for instance, our model for an anxiety state, can after all scarcely be regarded on its own account as an injury, although it may involve a danger of injuries. The essential thing about birth, as about every situation of danger, is that it calls up in mental experience a state of highly tense excitation, which is felt as displeasure and which one is not able to master by discharging it. Let us call a state of this kind, before which the efforts of the pleasure principle break down, a 'traumatic' moment. Then, if we take in succession neurotic anxiety, realistic anxiety and the situation of danger, we arrive at this simple proposition: what is feared, what is the object of the anxiety, is invariably the emergence of a traumatic moment, which cannot be dealt with by the normal rules of the pleasure principle. We understand at once that our endowment with the pleasure principle does not guarantee us against objective injuries but only against a particular injury to our psychical economics. It is a long step from the pleasure principle to the self-preservation instinct; the intentions of the two of them are very far from coinciding from the start. But we see something else besides; perhaps it is the solution we are in search of. Namely, that in all this it is a question of relative quantities. It is only the magnitude of the sum of excitation that turns an impression into a traumatic moment, paralyses the function of the pleasure principle and gives the situation of danger its significance. And if that is how things are, if these puzzles can be solved so prosaically, why should it not be possible for similar traumatic moments to arise in mental life without reference to hypothetical situations of danger - traumatic moments, then, in which anxiety is not aroused as a signal but is generated anew for a fresh reason. Clinical experience declares decidedly that such is in fact the case. It is only the later repressions that exhibit the mechanism we have described, in which anxiety is awakened as a signal of an earlier situation of danger. The first and original repressions arise directly from traumatic moments, when the ego meets with an excessively great libidinal demand; they construct their anxiety afresh, although, it is true, on the model of birth. The same may apply to the generation of anxiety in anxiety neurosis owing to somatic damage to the sexual function. We shall no longer maintain that it is the libido itself that is turned into anxiety in such cases. But I can see no objection to there being a twofold origin of anxiety - one as a direct consequence of the traumatic moment and the other as a signal threatening a repetition of such a moment.

[1933a, 4700]

During the study of the sexual functions we have been able to gain a first, preliminary conviction, or rather a suspicion, of two discoveries which will later be found to be important over the whole of our field. Firstly, the normal and abnormal manifestations observed by us (that is, the phenomenology of the subject) need to be described from the point of view of their dynamics and economics (in our case, from the point of view of the quantitative distribution of the libido). And secondly, the aetiology of the disorders which we study is to be looked for in the individual's developmental history - that is to say, in his early life.

[1940a [1938], 4966]
We already know a number of things preliminary to such an undertaking. According to our hypothesis it is the ego's task to meet the demands raised by its three dependent relations to reality, to the id and to the super-ego - and nevertheless at the same time to preserve its own organization and maintain its own autonomy. The necessary precondition of the pathological states under discussion can only be a relative or absolute weakening of the ego which makes the fulfilment of its tasks impossible. The severest demand on the ego is probably the keeping down of the instincual claims of the id, to accomplish which it is obliged to maintain large expenditures of energy on anticathexes. But the demands made by the super-ego too may become so powerful and so relentless that the ego may be paralysed, as it were, in the face of its other tasks. We may suspect that, in the economic conflicts which arise at this point, the id and the super-ego often make common cause against the hard-pressed ego which tries to cling to reality in order to retain its normal state. If the other two become too strong, they succeed in loosening and altering the ego's organization, so that its proper relation to reality is disturbed or even brought to an end. We have seen it happen in dreaming: when the ego is detached from the reality of the external world, it slips down, under the influence of the internal world, into psychosis.

[1940a [1938], 4982]

The material on the other side is equally unambiguous. Twice in the course of individual development certain instincts are considerably reinforced: at puberty, and, in women, at the menopause. We are not in the least surprised if a person who was not neurotic before becomes so at these times. When his instincts were not so strong, he succeeded in taming them; but when they are reinforced he can no longer do so. The repressions behave like dams against the pressure of water. The same effects which are produced by these two physiological reinforcements of instinct, may be brought about in an irregular fashion by accidental causes at any other period of life. Such reinforcements may be set up by fresh traumas, enforced frustrations, or the collateral influence of instincts upon one another. The result is always the same, and it underlines the irresistible power of the quantitative factor in the causation of illness.

[1937c, 5024]

I feel as though I ought to be ashamed of so much ponderous exposition, seeing that everything I have said has long been familiar and self-evident. It is a fact that we have always behaved as if we knew all this; but, for the most part, our theoretical concepts have neglected to attach the same importance to the economic line of approach as they have to the dynamic and topographical ones. My excuse is therefore that I am drawing attention to this neglect.

[1937c, 5024]
Before we decide on an answer to this question, however, we must consider an objection whose force lies in the fact that we are probably predisposed in its favour. Our arguments, it will be said, are all deduced from the processes which take place spontaneously between the ego and the instincts, and they presuppose that analytic therapy can accomplish nothing which does not, under favourable and normal conditions, occur of itself. But is this really so? Is it not precisely the claim of our theory that analysis produces a state which never does arise spontaneously in the ego and that this newly created state constitutes the essential difference between a person who has been analysed and a person who has not? Let us bear in mind what this claim is based on. All repressions take place in early childhood; they are primitive defensive measures taken by the immature, feeble ego. In later years no fresh repressions are carried out; but the old ones persist, and their services continue to be made use of by the ego for mastering the instincts. New conflicts are disposed of by what we call 'after-repression'. We may apply to these infantile repressions our general statement that repressions depend absolutely and entirely on the relative strength of the forces involved and that they cannot hold out against an increase in the strength of the instincts. Analysis, however, enables the ego, which has attained greater maturity and strength, to undertake a revision of these old repressions; a few are demolished, while others are recognized but constructed afresh out of more solid material. These new dams are of quite a different degree of firmness from the earlier ones; we may be confident that they will not give way so easily before a rising flood of instinctual strength. Thus the real achievement of analytic therapy would be the subsequent correction of the original process of repression, a correction which puts an end to the dominance of the quantitative factor.

[1937c, 5024]

Applying these remarks to our present problem, I think that the answer to the question of how to explain the variable results of our analytic therapy might well be that we, too, in endeavouring to replace repressions that are insecure by reliable ego-syntonic controls, do not always achieve our aim to its full extent - that is, do not achieve it thoroughly enough. The transformation is achieved, but often only partially: portions of the old mechanisms remain untouched by the work of analysis. It is difficult to prove that this is really so; for we have no other way of judging what happens but by the outcome which we are trying to explain. Nevertheless, the impressions one receives during the work of analysis do not contradict this assumption; indeed, they seem rather to confirm it. But we must not take the clarity of our own insight as a measure of the conviction which we produce in the patient. His conviction may lack 'depth', as one might say; it is always a question of the quantitative factor, which is so easily overlooked. If this is the correct answer to our question, we may say that analysis, in claiming to cure neuroses by ensuring control over instinct, is always right in theory but not always right in practice. And this is because it does not always succeed in ensuring to a sufficient degree the foundations on which a control of instinct is based. The cause of such a partial failure is easily discovered. In the past, the quantitative factor of instinctual strength opposed the ego's defensive efforts; for that reason we called in the work of analysis to help; and now that same factor sets a limit to the efficacy of this new effort. If the strength of the instinct is excessive, the mature ego, supported by analysis, fails in its task, just as the helpless ego failed formerly. Its control over instinct is improved, but it remains imperfect because the transformation in the defensive mechanism is only incomplete. There is nothing surprising in this, since the power of the instruments with which analysis operates is not unlimited but restricted, and the final upshot always depends on the relative strength of the psychical agencies which are struggling with one another.

[1937c, 5026]
We started from the question of how we can shorten the inconveniently long duration of analytic treatment, and, still with this question of time in mind, we went on to consider whether it is possible to achieve a permanent cure or even to prevent future illness by prophylactic treatment. In doing so, we found that the factors which were decisive for the success of our therapeutic efforts were the influence of traumatic aetiology, the relative strength of the instincts which have to be controlled, and something which we have called an alteration of the ego. Only the second of these factors has been discussed by us in any detail, and in connection with it we have had occasion to recognize the paramount importance of the quantitative factor and to stress the claim of the metapsychological line of approach to be taken into account in any attempt at explanation.

[1937c, 5030]
You will no doubt have observed that in these last discussions I have introduced a fresh factor into the structure of the aetiological chain - namely the quantity, the magnitude, of the energies concerned. We have still to take this factor into account everywhere. A purely qualitative analysis of the aetiological determinants is not enough. Or, to put it another way, a merely dynamic view of these mental processes is insufficient; an economic line of approach is also needed. We must tell ourselves that the conflict between two trends does not break out till certain intensities of cathexis have been reached, even though the determinants for it have long been present so far as their subject-matter is concerned. In the same way, the pathogenic significance of the constitutional factors must be weighed according to how much more of one component instinct than of another is present in the inherited disposition. It may even be supposed that the disposition of all human beings is qualitatively alike and that they differ only owing to these quantitative conditions. The quantitative factor is no less decisive as regards capacity to resist neurotic illness. It is a matter of what quota of unemployed libido a person is able to hold in suspension and of how large a fraction of his libido he is able to divert from sexual to sublimated aims. The ultimate aim of mental activity, which may be described qualitatively as an endeavour to obtain pleasure and avoid unpleasure, emerges, looked at from the economic point of view, as the task of mastering the amounts of excitation (mass of stimuli) operating in the mental apparatus and of keeping down their accumulation which creates unpleasure.

[1916-1917, 3429]

For a time psycho-analysis seemed fated to merge into psychology without being able to show why the psychology of the sick differed from that of the normal. In the course of its advance, however, it came up against the problem of dreams, which are abnormal products of the mind created by normal men under regularly recurrent physiological conditions. When psycho-analysis had solved the problem of dreams, it had discovered in unconscious psychical processes the common ground in which the highest and the lowest of mental impulses have their roots and from which spring the most normal as well as the most morbid and erratic of mental productions. The new picture of the workings of the mind began to grow ever clearer and more complete. It was a picture of obscure instinctual forces organic in origin, striving towards inborn aims, and, above them, of an agency comprising more highly organized mental structures - acquisitions of human evolution made under the impact of human history -, an agency which has taken over portions of the instinctual impulses, has developed them further or has even directed them towards higher aims, but which in any case binds them firmly and manipulates their energy to suit its own purposes. This higher organization, however, which is known to us as the ego, has rejected another portion of these same elementary instinctual impulses as being unserviceable because they cannot be fitted into the organic unity of the individual or because they rebel against the individual's cultural aims. The ego is not in a position to exterminate these unsubdued mental powers, but it turns its back on them, lets them remain at the lowest psychological level, defends itself from their demands by the energetic erection of protective and antithetical barriers or seeks to come to terms with them by means of substitutive satisfactions. These instincts which have fallen victim to repression - untamed and indestructible, yet inhibited from any kind of activity - together with their primitive mental representatives, constitute the mental underworld, the nucleus of the true unconscious, and are at every moment ready to assert their demands and, by hook or by crook, to force their way forward to satisfaction. To this is due the instability of the proud superstructure of the mind, the emergence at night of the proscribed and repressed material in the form of dreams, and the tendency to fall ill with neuroses and psychoses as soon as the balance of power between the ego and the repressed shifts to the disadvantage of the ego.

[1919g, 3703]
It seems to me that we have here an important discovery - namely, that the qualitative factor, the presence of certain neurotic formations, has less practical significance than the quantitative factor, the degree of attention or, more correctly, the amount of cathexis that these structures are able to attract to themselves. Our consideration of the first case, the jealous paranoia, led to a similar estimate of the importance of the quantitative factor, by showing that there also the abnormality essentially consisted in the hypercathexis of the interpretations of someone else's unconscious. We have long known of an analogous fact in the analysis of hysteria. The pathogenic phantasies, derivatives of repressed instinctual impulses, are for a long time tolerated alongside the normal life of the mind, and have no pathogenic effect until by a revolution in the libidinal economy they receive a hypercathexis; not till then does the conflict which leads to the formation of symptoms break out. Thus as our knowledge grows we are increasingly impelled to bring the *economic* point of view into the foreground. I should also like to throw out the question whether this quantitative factor that I am now dwelling on does not suffice to cover the phenomena which Bleuler and others have lately proposed to name 'switching'. One need only assume that an increase in resistance in the course taken by the psychical current in one direction results in a hypercathexis of another path and thus causes the flow to be switched into that path.

[1922b, 3905]

Only let us hold fast to this: the nodal point and pivot of the whole situation is the relative strength of the ego organization. We shall then find it easy to complete our aetiological survey. As what may be called the normal causes of neurotic illness we already know the feebleness of the childhood ego, the task of dealing with the early sexual impulses and the effects of the more or less chance experiences of childhood. Is it not possible, however, that yet other factors play a part, derived from the time before the beginning of the child's life? For instance, an innate strength and unruliness of the instinctual life in the id, which from the outset sets the ego tasks too hard for it? Or a special developmental feebleness of the ego due to unknown reasons? Such factors must of course acquire an aetiological importance, in some cases a transcendent one. We have invariably to reckon with the instinctual strength of the id; if it has developed to excess, the prospects of our therapy are poor. We still know too little of the causes of a developmental inhibition of the ego. These then would be the cases of neurosis with an essentially constitutional basis. Without some such constitutional, congenital favouring factors a neurosis can, no doubt, scarcely come about.

[1926e, 4383]

But if the relative feebleness of the ego is the decisive factor for the genesis of a neurosis, it must also be possible for a later physical illness to produce a neurosis, provided that it can bring about an enfeeblement of the ego. And that, once again, is very frequently found. A physical disorder of this kind can affect the instinctual life in the id and increase the strength of the instincts beyond the limit up to which the ego is capable of coping with them. The normal model of such processes is perhaps the alteration in women caused by the disturbances of menstruation and the menopause. Or again, a general somatic illness, indeed an organic disease of the nervous central organ, may attack the nutritional conditions of the mental apparatus and compel it to reduce its functioning and to bring to a halt its more delicate workings, one of which is the maintenance of the ego organization. In all these cases approximately the same picture of neurosis emerges; neurosis always has the same psychological mechanism, but, as we see, a most varied and often very complex aetiology.

[1926e, 4383]
(2) For cultural reasons the most intense repression falls upon the sexual instincts; but it is precisely in connection with them that repression most easily miscarries, so that neurotic symptoms are found to be substitutive satisfactions of repressed sexuality. The belief that in man sexual life begins only at puberty is incorrect. On the contrary, signs of it can be detected from the beginning of extra-uterine existence; it reaches a first culminating point at or before the fifth year ('early period'), after which it is inhibited or interrupted ('latency period') until the age of puberty, which is the second climax of its development. This diphasic onset of sexual development seems to be distinctive of the genus Homo. All experiences during the first period of childhood are of the greatest importance to the individual, and in combination with his inherited sexual constitution form the dispositions for the subsequent development of character and disease. It is wrong to make sexuality coincide with 'genitality'. The sexual instincts pass through a complicated course of development, and it is only at the end of it that the 'primacy of the genital zones' is attained. Before this there are a number of 'pregenital' organizations of the libido - points at which it may become 'fixated' and to which, in the event of subsequent repression, it will return ('regression'). The infantile fixations of the libido are what determine the form of any later neurosis. Thus the neuroses are to be regarded as inhibitions in the development of the libido. There are no specific causes of nervous disorders; the question whether a conflict finds a healthy solution or leads to a neurotic inhibition of function depends upon quantitative considerations.

[1926f, 4405]

We already know a number of things preliminary to such an undertaking. According to our hypothesis it is the ego's task to meet the demands raised by its three dependent relations to reality, to the id and to the super-ego - and nevertheless at the same time to preserve its own organization and maintain its own autonomy. The necessary precondition of the pathological states under discussion can only be a relative or absolute weakening of the ego which makes the fulfilment of its tasks impossible. The severest demand on the ego is probably the keeping down of the instinctual claims of the id, to accomplish which it is obliged to maintain large expenditures of energy on anticathexes. But the demands made by the super-ego too may become so powerful and so relentless that the ego may be paralysed, as it were, in the face of its other tasks. We may suspect that, in the economic conflicts which arise at this point, the id and the super-ego often make common cause against the hard-pressed ego which tries to cling to reality in order to retain its normal state. If the other two become too strong, they succeed in loosening and altering the ego's organization, so that its proper relation to reality is disturbed or even brought to an end. We have seen it happen in dreaming: when the ego is detached from the reality of the external world, it slips down, under the influence of the internal world, into psychosis.

[1940a [1938], 4982]

We need not be at a loss to find an answer to this question. Quantitative disharmonies are what must be held responsible for the inadequacy and sufferings of neurotics. The determining cause of all the forms taken by human mental life, is, indeed, to be sought in the reciprocal action between innate dispositions and accidental experiences. Now a particular instinct may be too strong or too weak innately, or a particular capacity may be stunted or insufficiently developed in life. On the other hand, external impressions and experiences may make demands of differing strength on different people; and what one person's constitution can deal with may prove an unmanageable task for another's. These quantitative differences will determine the variety of the results.

[1940a [1938], 4992]
The material on the other side is equally unambiguous. Twice in the course of individual development certain instincts are considerably reinforced: at puberty, and, in women, at the menopause. We are not in the least surprised if a person who was not neurotic before becomes so at these times. When his instincts were not so strong, he succeeded in taming them; but when they are reinforced he can no longer do so. The repressions behave like dams against the pressure of water. The same effects which are produced by these two physiological reinforcements of instinct, may be brought about in an irregular fashion by accidental causes at any other period of life. Such reinforcements may be set up by fresh traumas, enforced frustrations, or the collateral influence of instincts upon one another. The result is always the same, and it underlines the irresistible power of the quantitative factor in the causation of illness.
[1937c, 5024]
It should be the task of a libido theory of neurotic and psychotic disorders to express all the observed phenomena and inferred processes in terms of the economics of the libido. It is easy to guess that the vicissitudes of the ego-libido will have the major part to play in this connection, especially when it is a question of explaining the deeper psychotic disturbances. We are then faced by the difficulty that our method of research, psycho-analysis, for the moment affords us assured information only on the transformations that take place in the object-libido,² but is unable to make any immediate distinction between the ego-libido and the other forms of energy operating in the ego.³

For a time psycho-analysis seemed fated to merge into psychology without being able to show why the psychology of the sick differed from that of the normal. In the course of its advance, however, it came up against the problem of dreams, which are abnormal products of the mind created by normal men under regularly recurrent physiological conditions. When psycho-analysis had solved the problem of dreams, it had discovered in unconscious psychical processes the common ground in which the highest and the lowest of mental impulses have their roots and from which spring the most normal as well as the most morbid and erratic of mental productions. The new picture of the workings of the mind began to grow ever clearer and more complete. It was a picture of obscure instinctual forces organic in origin, striving towards inborn aims, and, above them, of an agency comprising more highly organized mental structures - acquisitions of human evolution made under the impact of human history -, an agency which has taken over portions of the instinctual impulses, has developed them further or has even directed them towards higher aims, but which in any case binds them firmly and manipulates their energy to suit its own purposes. This higher organization, however, which is known to us as the ego, has rejected another portion of these same elementary instinctual impulses as being unserviceable because they cannot be fitted into the organic unity of the individual or because they rebel against the individual's cultural aims. The ego is not in a position to exterminate these unsubdued mental powers, but it turns its back on them, lets them remain at the lowest psychological level, defends itself from their demands by the energetic erection of protective and antithetical barriers or seeks to come to terms with them by means of substitutive satisfactions. These instincts which have fallen victim to repression - untamed and indestructible, yet inhibited from any kind of activity - together with their primitive mental representatives, constitute the mental underworld, the nucleus of the true unconscious, and are at every moment ready to assert their demands and, by hook or by crook, to force their way forward to satisfaction. To this is due the instability of the proud superstructure of the mind, the emergence at night of the proscribed and repressed material in the form of dreams, and the tendency to fall ill with neuroses and psychoses as soon as the balance of power between the ego and the repressed shifts to the disadvantage of the ego.

²[1905d, 1532]
³[1919g, 3703]
We have reduced psychical impotence to the failure of the affectionate and the sensual currents in love to combine, and this developmental inhibition has in turn been explained as being due to the influences of strong childhood fixations and of later frustration in reality through the intervention of the barrier against incest. There is one principal objection to the theory we advance; it does too much. It explains why certain people suffer from psychical impotence, but it leaves us with the apparent mystery of how others have been able to escape this disorder. Since we must recognize that all the relevant factors known to us - the strong childhood fixation, the incest-barrier and the frustration in the years of development after puberty - are to be found in practically all civilized human beings, we should be justified in expecting psychical impotence to be a universal affliction under civilization and not a disorder confined to some individuals.

You will no doubt have observed that in these last discussions I have introduced a fresh factor into the structure of the aetiological chain - namely the quantity, the magnitude, of the energies concerned. We have still to take this factor into account everywhere. A purely qualitative analysis of the aetiological determinants is not enough. Or, to put it another way, a merely dynamic view of these mental processes is insufficient; an economic line of approach is also needed. We must tell ourselves that the conflict between two trends does not break out till certain intensities of cathexis have been reached, even though the determinants for it have long been present so far as their subject-matter is concerned. In the same way, the pathogenic significance of the constitutional factors must be weighed according to how much more of one component instinct than of another is present in the inherited disposition. It may even be supposed that the disposition of all human beings is qualitatively alike and that they differ only owing to these quantitative conditions. The quantitative factor is no less decisive as regards capacity to resist neurotic illness. It is a matter of what quota of unemployed libido a person is able to hold in suspension and of how large a fraction of his libido he is able to divert from sexual to sublimated aims. The ultimate aim of mental activity, which may be described qualitatively as an endeavour to obtain pleasure and avoid unpleasure, emerges, looked at from the economic point of view, as the task of mastering the amounts of excitation (mass of stimuli) operating in the mental apparatus and of keeping down their accumulation which creates unpleasure.

It seems to me that we have here an important discovery - namely, that the qualitative factor, the presence of certain neurotic formations, has less practical significance than the quantitative factor, the degree of attention or, more correctly, the amount of cathexis that these structures are able to attract to themselves. Our consideration of the first case, the jealous paranoia, led to a similar estimate of the importance of the quantitative factor, by showing that there also the abnormality essentially consisted in the hypercathexis of the interpretations of someone else's unconscious. We have long known of an analogous fact in the analysis of hysteria. The pathogenic phantasies, derivatives of repressed instinctual impulses, are for a long time tolerated alongside the normal life of the mind, and have no pathogenic effect until by a revolution in the libidinal economy they receive a hypercathexis; not till then does the conflict which leads to the formation of symptoms break out. Thus as our knowledge grows we are increasingly impelled to bring the economic point of view into the foreground. I should also like to throw out the question whether this quantitative factor that I am now dwelling on does not suffice to cover the phenomena which Bleuler and others have lately proposed to name 'switching'. One need only assume that an increase in resistance in the course taken by the psychical current in one direction results in a hypercathexis of another path and thus causes the flow to be switched into that path.
But if the relative feebleness of the ego is the decisive factor for the genesis of a neurosis, it must also be possible for a later physical illness to produce a neurosis, provided that it can bring about an enfeeblement of the ego. And that, once again, is very frequently found. A physical disorder of this kind can affect the instinctual life in the id and increase the strength of the instincts beyond the limit up to which the ego is capable of coping with them. In all these cases approximately the same picture of neurosis emerges; neurosis always has the same psychological mechanism, but, as we see, a most varied and often very complex aetiology. [1926e, 4383]
More pronounced forms of the perversions and of homosexuality, especially if they are exclusive, do, it is true, make those subject to them socially useless and unhappy, so that it must be recognized that the cultural requirements even of the second stage are a source of suffering for a certain proportion of mankind. The fate of these people who differ constitutionally from the rest varies, and depends on whether they have been born with a sexual instinct which by absolute standards is strong or comparatively weak. In the latter case - where the sexual instinct is in general weak - perverts succeed in totally suppressing the inclinations which bring them into conflict with the moral demands of their stage of civilization. But this, from the ideal point of view, is also the only thing they succeed in achieving; for, in order to effect this suppression of their sexual instinct, they use up the forces which they would otherwise employ in cultural activities. They are, as it were, inwardly inhibited and outwardly paralysed. What we shall be saying again later on about the abstinence demanded of men and women in the third stage of civilization applies to them too.

Where the sexual instinct is fairly intense, but perverse, there are two possible outcomes. The first, which we shall not discuss further, is that the person affected remains a pervert and has to put up with the consequences of his deviation from the standard of civilization. The second is far more interesting. It is that, under the influence of education and social demands, a suppression of the perverse instincts is indeed achieved, but it is a kind of suppression which is really no suppression at all. It can better be described as a suppression that has failed. The inhibited sexual instincts are, it is true, no longer expressed as such - and this constitutes the success of the process - but they find expression in other ways, which are quite as injurious to the subject and make him quite as useless for society as satisfaction of the suppressed instincts in an unmodified form would have done. This constitutes the failure of the process, which in the long run more than counterbalances its success. The substitutive phenomena which emerge in consequence of the suppression of the instinct amount to what we call nervous illness, or, more precisely, the psychoneuroses.¹ Neurotics are the class of people who, since they possess a recalcitrant organization, only succeed, under the influence of cultural requirements, in achieving a suppression of their instincts which is apparent and which becomes increasingly unsuccessful. They therefore only carry on their collaboration with cultural activities by a great expenditure of force and at the cost of an internal impoverishment, or are obliged at times to interrupt it and fall ill. I have described the neuroses as the ‘negative’ of the perversions because in the neuroses the perverse impulses, after being repressed, manifest themselves from the unconscious part of the mind - because the neuroses contain the same tendencies, though in a state of ‘repression’, as do the positive perversions.

[1908d, 1954]
The retardation of sexual development and sexual activity at which our education and civilization aim is certainly not injurious to begin with. It is seen to be a necessity, when one considers the late age at which young people of the educated classes reach independence and are able to earn a living. (This reminds one, incidentally, of the intimate interconnection between all our cultural institutions and of the difficulty of altering any part of them without regard to the whole.) But abstinence continued long after the age of twenty is no longer unobjectionable for a young man; and it leads to other damage even when it does not lead to neurosis. People say, to be sure, that the struggle against such a powerful instinct, and the strengthening of all the ethical and aesthetic forces which are necessary for this struggle, 'steel' the character; and this is true for a few specially favourably organized natures. It must also be admitted that the differentiation of individual character, which is so marked in our day, has only become possible with the existence of sexual restriction. But in the vast majority of cases the struggle against sexuality eats up the energy available in a character and this at the very time when a young man is in need of all his forces in order to win his share and place in society. The relationship between the amount of sublimation possible and the amount of sexual activity necessary naturally varies very much from person to person and even from one calling to another. An abstinent artist is hardly conceivable; but an abstinent young savant is certainly no rarity. The latter can, by his self-restraint, liberate forces for his studies; while the former probably finds his artistic achievements powerfully stimulated by his sexual experience. In general I have not gained the impression that sexual abstinence helps to bring about energetic and self-reliant men of action or original thinkers or bold emancipators and reformers. Far more often it goes to produce well-behaved weaklings who later become lost in the great mass of people that tends to follow, unwillingly, the leads given by strong individuals.

[1908d, 1958]
I return now to my earlier assertion that, in judging the neuroses, their full importance is not as a rule taken into account. I do not mean by this the undervaluation of these states shown in their frivolous dismissal by relatives and in the boasting assurances by doctors that a few weeks of cold water treatment or a few months of rest and convalescence will cure the condition. These are merely the opinions of quite ignorant doctors and laymen and are mostly no more than words intended to give the sufferer a short-lived consolation. It is, on the contrary, a well-known fact that a chronic neurosis, even if it does not totally put an end to the subject's capacity for existence, represents a severe handicap in his life, of the same order, perhaps, as tuberculosis or a cardiac defect. The situation would even be tolerable if neurotic illness were to exclude from civilized activities only a number of individuals who were in any case of the weaker sort, and allowed the rest to play their part in it at the cost of troubles that were merely subjective. But, far from this being so, I must insist upon the view that neuroses, whatever their extent and wherever they occur, always succeed in frustrating the purposes of civilization, and in that way actually perform the work of the suppressed mental forces that are hostile to civilization. Thus, when society pays for obedience to its far-reaching regulations by an increase in nervous illness, it cannot claim to have purchased a gain at the price of sacrifices; it cannot claim a gain at all. Let us, for instance, consider the very common case of a woman who does not love her husband, because, owing to the conditions under which she entered marriage, she has no reason to love him, but who very much wants to love him, because that alone corresponds to the ideal of marriage to which she has been brought up. She will in that case suppress every impulse which would express the truth and contradict her endeavours to fulfil her ideal, and she will make special efforts to play the part of a loving, affectionate and attentive wife. The outcome of this self-suppression will be a neurotic illness; and this neurosis will in a short time have taken revenge on the unloved husband and have caused him just as much lack of satisfaction and worry as would have resulted from an acknowledgement of the true state of affairs. This example is completely typical of what a neurosis achieves. A similar failure to obtain compensation is to be seen after the suppression of impulses inimical to civilization which are not directly sexual. If a man, for example, has become over-kind as a result of a violent suppression of a constitutional inclination to harshness and cruelty, he often loses so much energy in doing this that he fails to carry out all that his compensatory impulses require, and he may, after all, do less good on the whole than he would have done without the suppression.

(2) I have said that we had much to expect from the increase in authority which must accrue to us as time goes on. I need not say much to you about the importance of authority. Only very few civilized people are capable of existing without reliance on others or are even capable of coming to an independent opinion. You cannot exaggerate the intensity of people’s inner lack of resolution and craving for authority. The extraordinary increase in neuroses since the power of religions has waned may give you a measure of it. The impoverishment of the ego due to the large expenditure of energy on repression demanded of every individual by civilization may be one of the principal causes of this state of things.
Are we, then, to abandon our efforts to explain the hidden meaning of neurosis as being in the last resort dangerous to the individual and harmful to the workings of society? Are we to give up drawing the practical conclusion from a piece of scientific insight? No; I think that in spite of this our duty lies in the other direction. The gain from illness provided by the neuroses is nevertheless on the whole and in the end detrimental to individuals as well as to society. The unhappiness that our work of enlightenment may cause will after all only affect some individuals. The change-over to a more realistic and creditable attitude on the part of society will not be bought too dearly by these sacrifices. But above all, all the energies which are to-day consumed in the production of neurotic symptoms serving the purposes of a world of phantasy isolated from reality, will, even if they cannot at once be put to uses in life, help to strengthen the clamour for the changes in our civilization through which alone we can look for the well-being of future generations.

If, then, as we have learnt, psychogenic disturbances of vision depend on certain ideas connected with seeing being cut off from consciousness, we must, on the psycho-analytic view, assume that these ideas have come into opposition to other, more powerful ones, for which we use the collective concept of the 'ego'- a compound which is made up variously at different times - and have for that reason come under repression. But what can be the origin of this opposition, which makes for repression, between the ego and various groups of ideas? You will no doubt notice that it was not possible to frame such a question before the advent of psycho-analysis, for nothing was known earlier of psychical conflict and repression. Our researches, however, have put us in a position to give us the desired answer. Our attention has been drawn to the importance of the instincts in ideational life. We have discovered that every instinct tries to make itself effective by activating ideas that are in keeping with its aims. These instincts are not always compatible with one another; their interests often come into conflict. Opposition between ideas is only an expression of struggles between the various instincts. From the point of view of our attempted explanation, a quite specially important part is played by the undeniable opposition between the instincts which subserve sexuality, the attainment of sexual pleasure, and those other instincts, which have as their aim the self-preservation of the individual - the ego-instincts. As the poet has said, all the organic instincts that operate in our mind may be classified as 'hunger' or 'love'. We have traced the 'sexual instinct' from its first manifestations in children to its final form, which is described as 'normal'. We have found that it is put together from numerous 'component instincts' which are attached to excitations of regions of the body; and we have come to see that these separate instincts have to pass through a complicated development before they can be brought effectively to serve the aims of reproduction. The light thrown by psychology on the evolution of our civilization has shown us that it originates mainly at the cost of the sexual component instincts, and that these must be suppressed, restricted, transformed and directed to higher aims, in order that the mental constructions of civilization may be established. We have been able to recognize as a valuable outcome of these researches something that our colleagues have not yet been willing to believe, namely that the human ailments known as 'neuroses' are derived from the many different ways in which these processes of transformation in the sexual component instincts may miscarry. The 'ego' feels threatened by the claims of the sexual instincts and fend them off by repressions; these, however, do not always have the desired result, but lead to the formation of dangerous substitutes for the repressed and to burdensome reactions on the part of the ego. From these two classes of phenomena taken together there emerge what we call the symptoms of neuroses.
Symptoms - and of course we are dealing now with psychical (or psychogenic) symptoms and psychical illness - are acts detrimental, or at least useless, to the subject's life as a whole, often complained of by him as unwelcome and bringing unpleasure or suffering to him. The main damage they do resides in the mental expenditure which they themselves involve and in the further expenditure that becomes necessary for fighting against them. Where there is an extensive formation of symptoms, these two sorts of expenditure can result in an extraordinary impoverishment of the subject in regard to the mental energy available to him and so in paralysing him for all the important tasks of life. Since this outcome depends mainly on the quantity of the energy which is thus absorbed, you will easily see that 'being ill' is in its essence a practical concept. But if you take up a theoretical point of view and disregard this matter of quantity, you may quite well say that we are all ill - that is, neurotic - since the preconditions for the formation of symptoms can also be observed in normal people.

I will now complete my picture of the mechanism of cure by clothing it in the formulas of the libido theory. A neurotic is incapable of enjoyment and of efficiency - the former because his libido is not directed on to any real object and the latter because he is obliged to employ a great deal of this available energy on keeping his libido under repression and on warding off its assaults. He would become healthy if the conflict between his ego and his libido came to an end and if his ego had his libido again at its disposal. The therapeutic task consists, therefore, in freeing the libido from its present attachments, which are withdrawn from the ego, and in making it once more serviceable to the ego. Where, then, is the neurotic's libido situated? It is easily found: it is attached to the symptoms, which yield it the only substitutive satisfaction possible at the time. We must therefore make ourselves masters of the symptoms and resolve them - which is precisely the same thing that the patient requires of us. In order to resolve the symptoms, we must go back as far as their origin, we must renew the conflict from which they arose, and, with the help of motive forces which were not at the patient's disposal in the past, we must guide it to a different outcome. This revision of the process of repression can be accomplished only in part in connection with the memory traces of the processes which led to repression. The decisive part of the work is achieved by creating in the patient's relation to the doctor - in the 'transference' - new editions of the old conflicts; in these the patient would like to behave in the same way as he did in the past, while we, by summoning up every available mental force, compel him to come to a fresh decision. Thus the transference becomes the battlefield on which all the mutually struggling forces should meet one another.

The more generalized inhibitions of the ego obey a different mechanism of a simple kind. When the ego is involved in a particularly difficult psychical task, as occurs in mourning, or when there is some tremendous suppression of affect or when a continual flood of sexual phantasies has to be kept down, it loses so much of the energy at its disposal that it has to cut down the expenditure of it at many points at once. It is in the position of a speculator whose money has become tied up in his various enterprises. I came across an instructive example of this kind of intense, though short-lived, general inhibition. The patient, an obsessional neurotic, used to be overcome by a paralysing fatigue which lasted for one or more days whenever something occurred which should obviously have thrown him into a rage. We have here a point from which it should be possible to reach an understanding of the condition of general inhibition which characterizes states of depression, including the gravest form of them, melancholia.
As regards inhibitions, then, we may say in conclusion that they are restrictions of the functions of the ego which have been either imposed as a measure of precaution or brought about as a result of an impoverishment of energy; and we can see without difficulty in what respect an inhibition differs from a symptom: for a symptom cannot any longer be described as a process that takes place within, or acts upon, the ego.

[1926d, 4251]

Again, I attach no great importance to the argument that a lay analyst, because he must be prepared to consult a doctor, will have no authority in the eyes of his patients and will be treated with no more respect than such people as bone-setters or masseurs. Once again, the analogy is an imperfect one - quite apart from the fact that what governs patients in their recognition of authority is usually their emotional transference and that the possession of a medical diploma does not impress them nearly so much as doctors believe. A professional lay analyst will have no difficulty in winning as much respect as is due to a secular pastoral worker. Indeed, the words, 'secular pastoral worker', might well serve as a general formula for describing the function which the analyst, whether he is a doctor or a layman, has to perform in his relation to the public. Our friends among the protestant clergy, and more recently among the catholic clergy as well, are often able to relieve their parishioners of the inhibitions of their daily life by confirming their faith - after having first offered them a little analytic information about the nature of their conflicts. Our opponents, the Adlerian 'individual psychologists', endeavour to produce a similar result in people who have become unstable and inefficient by arousing their interest in the social community after having first thrown some light upon a single corner of their mental life and shown them the part played in their illness by their egoistic and distrustful impulses. Both of these procedures, which derive their power from being based on analysis, have their place in psychotherapy. We who are analysts set before us as our aim the most complete and profoundest possible analysis of whoever may be our patient. We do not seek to bring him relief by receiving him into the catholic, protestant or socialist community. We seek rather to enrich him from his own internal sources, by putting at the disposal of his ego those energies which, owing to repression, are inaccessibly confined in his unconscious, as well as those which his ego is obliged to squander in the fruitless task of maintaining these repressions. Such activity as this is pastoral work in the best sense of the words. Have we set ourselves too high an aim? Are the majority of our patients worth the pains that this work requires of us? Would it not be more economical to prop up their weaknesses from without rather than to rebuild them from within? I cannot say; but there is something else that I do know. In psycho-analysis there has existed from the very first an inseparable bond between cure and research. Knowledge brought therapeutic success. It was impossible to treat a patient without learning something new; it was impossible to gain fresh insight without perceiving its beneficent results. Our analytic procedure is the only one in which this precious conjunction is assured. It is only by carrying on our analytic pastoral work that we can deepen our dawning comprehension of the human mind. This prospect of scientific gain has been the proudest and happiest feature of analytic work. Are we to sacrifice it for the sake of any considerations of a practical sort?

[1926e, 4396]
We already know a number of things preliminary to such an undertaking. According to our hypothesis it is the ego's task to meet the demands raised by its three dependent relations to reality, to the id and to the super-ego - and nevertheless at the same time to preserve its own organization and maintain its own autonomy. The necessary precondition of the pathological states under discussion can only be a relative or absolute weakening of the ego which makes the fulfilment of its tasks impossible. The severest demand on the ego is probably the keeping down of the instinctual claims of the id, to accomplish which it is obliged to maintain large expenditures of energy on anticathexes. But the demands made by the super-ego too may become so powerful and so relentless that the ego may be paralysed, as it were, in the face of its other tasks. We may suspect that, in the economic conflicts which arise at this point, the id and the super-ego often make common cause against the hard-pressed ego which tries to cling to reality in order to retain its normal state. If the other two become too strong, they succeed in loosening and altering the ego's organization, so that its proper relation to reality is disturbed or even brought to an end. We have seen it happen in dreaming: when the ego is detached from the reality of the external world, it slips down, under the influence of the internal world, into psychosis.
[1940a [1938], 4982]
With the psychoneuroses, the influence of heredity is more marked and the causation less transparent. A peculiar method of investigation known as psycho-analysis has, however, enabled us to recognize that the symptoms of these disorders (hysteria, obsessional neurosis, etc.) are psychogenic and depend upon the operation of unconscious (repressed) ideational complexes. This same method has also taught us what those unconscious complexes are and has shown that, quite generally speaking, they have a sexual content. They spring from the sexual needs of people who are unsatisfied and represent for them a kind of substitutive satisfaction. We must therefore view all factors which impair sexual life, suppress its activity or distort its aims as being pathogenic factors in the psychoneuroses as well.

[1908d, 1951]

LADIES AND GENTLEMEN, - With the discovery of infantile sexuality and the tracing back of neurotic symptoms to erotic instinctual components we have arrived at some unexpected formulas concerning the nature and purposes of neurotic illnesses. We see that human beings fall ill when, as a result of external obstacles or of an internal lack of adaptation, the satisfaction of their erotic needs in reality frustrated. We see that they then take flight into illness in order that by its help they may find a satisfaction to take the place of what has been frustrated. We recognize that the pathological symptoms constitute a portion of the subject's sexual activity or even the whole of his sexual life, and we find that the withdrawal from reality is the main purpose of the illness but also the main damage caused by it. We suspect that our patients' resistance to recovery is no simple one, but compounded of several motives. Not only does the patient's ego rebel against giving up the repressions by means of which it has risen above its original disposition, but the sexual instincts are unwilling to renounce their substitutive satisfaction so long as it is uncertain whether reality will offer them anything better.

[1910a, 2234]

The deeper you penetrate into the pathogenesis of nervous illness, the more you will find revealed the connection between the neuroses and other productions of the human mind, including the most valuable. You will be taught that we humans, with the high standards of our civilization and under the pressure of our internal repressions, find reality unsatisfying quite generally, and for that reason entertain a life of phantasy in which we like to make up for the insufficiencies of reality by the production of wish-fulfilments. These phantasies include a great deal of the true constitutional essence of the subject's personality as well as of those of his impulses which are repressed where reality is concerned. The energetic and successful man is one who succeeds by his efforts in turning his wishful phantasies into reality. Where this fails, as a result of the resistances of the external world and of the subject's own weakness, he begins to turn away from reality and withdraws into his more satisfying world of phantasy, the content of which is transformed into symptoms should he fall ill. In certain favourable circumstances, it still remains possible for him to find another path leading from these phantasies to reality, instead of becoming permanently estranged from it by regressing to infancy. If a person who is at loggerheads with reality possesses an artistic gift (a thing that is still a psychological mystery to us), he can transform his phantasies into artistic creations instead of into symptoms. In this manner he can escape the doom of neurosis and by this roundabout path regain his contact with reality. (Cf. Rank, 1907.) If there is persistent rebellion against the real world and if this precious gift is absent or insufficient, it is almost inevitable that the libido, keeping to the sources of the phantasies, will follow the path of regression, and will revive infantile wishes and end in neurosis. To-day neurosis takes the place of the monasteries which used to be the refuge of all whom life had disappointed or who felt too weak to face it.

[1910a, 2235]
The fact that the curb put upon love by civilization involves a universal tendency to debase sexual objects will perhaps lead us to turn our attention from the object to the instincts themselves. The damage caused by the initial frustration of sexual pleasure is seen in the fact that the freedom later given to that pleasure in marriage does not bring full satisfaction. But at the same time, if sexual freedom is unrestricted from the outset the result is no better. It can easily be shown that the psychical value of erotic needs is reduced as soon as their satisfaction becomes easy. An obstacle is required in order to heighten libido; and where natural resistances to satisfaction have not been sufficient men have at all times erected conventional ones so as to be able to enjoy love. This is true both of individuals and of nations. In times in which there were no difficulties standing in the way of sexual satisfaction, such as perhaps during the decline of the ancient civilizations, love became worthless and life empty, and strong reaction-formations were required to restore indispensable affective values. In this connection it may be claimed that the ascetic current in Christianity created psychical values for love which pagan antiquity was never able to confer on it. This current assumed its greatest importance with the ascetic monks, whose lives were almost entirely occupied with the struggle against libidinal temptation.

[1912d, 2344]

One's first inclination is no doubt to trace back the difficulties revealed here to universal characteristics of our organic instincts. It is no doubt also true in general that the psychical importance of an instinct rises in proportion to its frustration. Suppose a number of totally different human beings were all equally exposed to hunger. As their imperative need for food mounted, all the individual differences would disappear and in their place one would see the uniform manifestations of the one unappeased instinct. But is it also true that with the satisfaction of an instinct its psychical value always falls just as sharply? Consider, for example, the relation of a drinker to wine. Is it not true that wine always provides the drinker with the same toxic satisfaction, which in poetry has so often been compared to erotic satisfaction - a comparison acceptable from the scientific point of view as well? Has one ever heard of the drinker being obliged constantly to change his drink because he soon grows tired of keeping to the same one? On the contrary, habit constantly tightens the bond between a man and the kind of wine he drinks. Does one ever hear of a drinker who needs to go to a country where wine is dearer or drinking is prohibited, so that by introducing obstacles he can reinforce the dwindling satisfaction that he obtains? Not at all. If we listen to what our great alcoholics, such as Böcklin,¹ say about their relation to wine, it sounds like the most perfect harmony, a model of a happy marriage. Why is the relation of the lover to his sexual object so very different?

[1912d, 2345]

The question of why this outburst of homosexual libido overtook the patient precisely at this period (that is, between the dates of his appointment and of his move to Dresden) cannot be answered in the absence of more precise knowledge of the story of his life. Generally speaking, every human being oscillates all through his life between heterosexual and homosexual feelings, and any frustration or disappointment in the one direction is apt to drive him over into the other. We know nothing of these factors in Schreber's case, but we must not omit to draw attention to a somatic factor which may very well have been relevant. At the time of this illness Dr. Schreber was fifty-one years old, and he had therefore reached an age which is of critical importance in sexual life. It is a period at which in women the sexual function, after a phase of intensified activity, enters upon a process of far-reaching involution; nor do men appear to be exempt from its influence, for men as well as women are subject to a 'climacteric' and to the susceptibilities to disease which go along with it.¹

[1911c, 2418]
Perhaps I may be allowed to add a few words with a view to establishing the causes of this conflict that broke out in relation to the feminine wishful phantasy. As we know, when a wishful phantasy makes its appearance, our business is to bring it into connection with some frustration, some privation in real life. Now Schreber admits having suffered a privation of the kind. His marriage, which he describes as being in other respects a happy one, brought him no children; and in particular it brought him no son who might have consoled him for the loss of his father and brother and upon whom he might have drained off his unsatisfied homosexual affections.¹ His family line threatened to die out, and it seems that he felt no little pride in his birth and lineage. 'Both the Flechsigs and the Schrebers were members of "the highest nobility of Heaven", as the phrase went. The Schrebers in particular bore the title of "Margraves of Tuscany and Tasmania"; for souls, urged by some sort of personal vanity, have a custom of adorning themselves with somewhat high-sounding titles borrowed from this world.'² (24.) The great Napoleon obtained a divorce from Josephine (though only after severe internal struggles) because she could not propagate the dynasty.³ Dr. Schreber may have formed a phantasy that if he were a woman he would manage the business of having children more successfully; and he may thus have found his way back into the feminine attitude towards his father which he had exhibited in the earliest years of his childhood. If that were so, then his delusion that as a result of his emasculation the world was to be peopled with 'a new race of men, born from the spirit of Schreber' (288) - a delusion the realization of which he was continually postponing to a more and more remote future - would also be designed to offer him an escape from his childlessness. If the 'little men' whom Schreber himself finds so puzzling were children, then we should have no difficulty in understanding why they were collected in such great numbers on his head (158): they were in truth the 'children of his spirit'.⁴

In my Three Essays on the Theory of Sexuality I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics endeavour to protect themselves against any such sexualization of their social instinctual cathexes, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) schizophrenia; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.

[1911c, 2428]
Our second problem - the problem of why transference appears in psycho-analysis as resistance - has been left for the moment untouched; and we must now approach it more closely. Let us picture the psychological situation during the treatment. An invariable and indispensable precondition of every onset of a psychoneurosis is the process to which Jung has given the appropriate name of 'introversion'.¹ That is to say: the portion of libido which is capable of becoming conscious and is directed towards reality is diminished, and the portion which is directed away from reality and is unconscious, and which, though it may still feed the subject's phantasies, nevertheless belongs to the unconscious, is proportionately increased. The libido (whether wholly or in part) has entered on a regressive course and has revived the subject's infantile imagos.² The analytic treatment now proceeds to follow it; it seeks to track down the libido, to make it accessible to consciousness and, in the end, serviceable for reality. Where the investigations of analysis come upon the libido withdrawn into its hiding-place, a struggle is bound to break out; all the forces which have caused the libido to regress will rise up as 'resistances' against the work of analysis, in order to conserve the new state of things. For if the libido's introversion or regression had not been justified by a particular relation between the subject and the external world - stated in the most general terms, by the frustration of satisfaction - and if it had not for the moment even become expedient, it could never have taken place at all. But the resistances from this source are not the only ones or indeed the most powerful. The libido at the disposal of the subject's personality had always been under the influence of the attraction of his unconscious complexes (or more correctly, of the portions of those complexes belonging to the unconscious), and it entered on a regressive course because the attraction of reality had diminished. In order to liberate it, this attraction of the unconscious has to be overcome; that is, the repression of the unconscious instincts and of their productions, which has meanwhile been set up in the subject, must be removed. This is responsible for by far the largest part of the resistance, which so often causes the illness to persist even after the turning away from reality has lost its temporary justification. The analysis has to struggle against the resistances from both these sources. The resistance accompanies the treatment step by step. Every single association, every act of the person under treatment must reckon with the resistance and represents a compromise between the forces that are striving towards recovery and the opposing ones which I have described.

[1912b, 2459]

(a) The most obvious, the most easily discoverable and the most intelligible precipitating cause of an onset of neurosis is to be seen in the external factor which may be described in general terms as frustration. The subject was healthy so long at his need for love was satisfied by a real object in the external world; he becomes neurotic as soon as this object is withdrawn from him without a substitute taking its place. Here happiness coincides with health and unhappiness with neurosis. It is easier for fate to bring about a cure than for the physician; for it can offer the patient a substitute for the possibility of satisfaction which he has lost.

[1912c, 2560]
Thus with this type, to which, no doubt, the majority of human beings on the whole belong, the possibility of falling ill arises only when there is abstinence. And it may be judged from this what an important part in the causation of neuroses may be played by the limitation imposed by civilization on the field of accessible satisfactions. Frustration has a pathogenic effect because it dams up libido, and so submits the subject to a test as to how long he can tolerate this increase in psychical tension and as to what methods he will adopt for dealing with it. There are only two possibilities for remaining healthy when there is a persistent frustration of satisfaction in the real world. The first is by transforming the psychical tension into active energy which remains directed towards the external world and eventually extorts a real satisfaction of the libido from it. The second is by renouncing libidinal satisfaction, sublimating the dammed-up libido and turning it to the attainment of aims which are no longer erotic and which escape frustration. That these two possibilities are realized in men’s lives proves that unhappiness does not coincide with neurosis and that frustration does not alone decide whether its victim remains healthy or falls ill. The immediate effect of frustration lies in its bringing into play the dispositional factors which have hitherto been inoperative.

Where these are present and sufficiently strongly developed, there is a risk of the libido becoming 'introverted'.¹ It turns away from reality, which, owing to the obstinate frustration, has lost its value for the subject, and turns towards the life of phantasy, in which it creates new wishful structures and revives the traces of earlier, forgotten ones. In consequence of the intimate connection between the activity of phantasy and material present in everyone which is infantile and repressed and has become unconscious, and thanks to the exceptional position enjoyed by the life of phantasy in regard to reality-testing,² the libido may thenceforward move on a backward course; it may follow the path of regression along infantile lines, and strive after aims that correspond with them. If these strivings, which are incompatible with the subject’s present-day individuality, acquire enough intensity, a conflict must result between them and the other portion of his personality, which has maintained its relation to reality. This conflict is resolved by the formation of symptoms, and is followed by the onset of manifest illness. The fact that the whole process originated from frustration in the real world is reflected in the resulting event that the symptoms, in which the ground of reality is reached once more, represent substitutive satisfactions.

(b) The second type of precipitating cause of falling ill is by no means so obvious as the first; and it was in fact only possible to discover it through searching analytic investigations following on the Zurich school’s theory of complexes.¹ Here the subject does not fall ill as a result of a change in the external world which has replaced satisfaction by frustration, but as a result of an internal effort to obtain the satisfaction which is accessible to him in reality. He falls ill of his attempt to adapt himself to reality and to fulfil the demands of reality - an attempt in the course of which he comes up against insurmountable internal difficulties.
It is advisable to draw a sharp distinction between the two types of onset of illness - a sharper distinction than observation as a rule permits. In the first type what is prominent is a change in the external world; in the second type the accent falls on an internal change. In the first type the subject falls ill from an experience; in the second type it is from a developmental process. In the first case he is faced by the task of renouncing satisfaction, and he falls ill from his incapacity for resistance; in the second case his task is to exchange one kind of satisfaction for another, and he breaks down from his inflexibility. In the second case the conflict, which is between the subject's effort to remain as he is and the effort to change himself in order to meet fresh purposes and fresh demands from reality, is present from the first. In the former case the conflict only arises after the dammed-up libido has chosen other, and incompatible, possibilities of satisfaction. The part played by the conflict and the previous fixation of the libido is incomparably more obvious in the second type than in the first, in which such unserviceable fixations may perhaps only emerge as a result of the external frustration.

[1912c, 2561]

In spite of the very clear differences between the two types of onset of illness that we have described, they nevertheless coincide in essentials and can without difficulty be brought together into a unity. Falling ill from frustration may also be regarded as incapacity for adaptation to reality - in the particular case, that is, in which reality frustrates satisfaction of libido. Falling ill under the conditions of the second type leads directly to a special case of frustration. It is true that reality does not here frustrate every kind of satisfaction; but it frustrates the one kind which the subject declares is the only possible one. Nor does the frustration come immediately from the external world, but primarily from certain trends in the subject's ego. Nevertheless, frustration remains the common factor and the more inclusive one. In consequence of the conflict which immediately sets in in the second type, both kinds of satisfaction - the habitual one as well as the one aimed at - are equally inhibited; a damming-up of libido, with all its consequences, comes about just as it does in the first case. The psychical events leading to the formation of symptoms are if anything easier to follow in the second type than in the first; for in the second type the pathogenic fixations of the libido do not need to be freshly established, but have already been in force while the subject was healthy. A certain amount of introversion of libido is, as a rule, already present; and there is a saving of some part of the subject's regression to the infantile stage, owing to the fact that his forward development has not yet completed its course.

[1912c, 2562]

It remains to say a few words on the relation of these types to the facts of observation. If I survey the set of patients on whose analysis I am at the moment engaged, I must record that not one of them is a pure example of any of the four types of onset. In each of them, rather, I find a portion of frustration operating alongside of a portion of incapacity to adapt to the demands of reality; inhibition in development, which coincides, of course, with inflexibility of fixations, has to be reckoned with in all of them, and, as I have already said, the importance of quantity of libido must never be neglected. I find, indeed, that in several of these patients their illness has appeared in successive waves, between which there have been healthy intervals, and that each of these waves has been traceable to a different type of precipitating cause. Thus the erection of these four types cannot lay claim to any high theoretical value; they are merely different ways of establishing a particular pathogenic constellation in the mental economy - namely the damming-up of libido, which the ego cannot, with the means at its command, ward off without damage. But this situation itself only becomes pathogenic as a result of a quantitative factor; it does not come as a novelty to mental life and is not created by the impact of what is spoken of as a 'cause of illness'.

[1912c, 2564]
A certain practical importance may readily be allowed to these types of onset. They are to be met with in their pure form, indeed, in individual cases; we should not have noticed the third and fourth types if they had not in some subjects constituted the sole precipitating causes of the illness. The first type keeps before our eyes the extraordinarily powerful influence of the external world, and the second the no less important influence - which opposes the former one - of the subject's peculiar individuality. Pathology could not do justice to the problem of the precipitating factors in the neuroses so long as it was merely concerned with deciding whether those affections were of an 'endogenous' or 'exogenous' nature. It was bound to meet every observation which pointed to the importance of abstinence (in the widest sense of the word) as a precipitating cause with the objection that other people tolerate the same experiences without falling ill. If, however, it sought to lay stress on the peculiar individuality of the subject as being the essential factor decisive between illness and health, it was obliged to put up with the proviso that people possessing such a peculiarity can remain healthy indefinitely, just so long as they are able to retain that peculiarity. Psycho-analysis has warned us that we must give up the unfruitful contrast between external and internal factors, between experience and constitution, and has taught us that we shall invariably find the cause of the onset of neurotic illness in a particular psychical situation which can be brought about in a variety of ways.

[1912c, 2564]

A woman who is now seriously ill in consequence of a frustration in life was in her earlier years a particularly capable, truth-loving, serious and virtuous girl, and became an affectionate wife. But still earlier, in the first years of her life, she had been a wilful and discontented child, and, though she had changed fairly quickly into an excessively good and conscientious one, there were occurrences in her schooldays, which, when she fell ill, caused her deep self-reproaches, and were regarded by her as proofs of fundamental depravity. Her memory told her that in those days she had often bragged and lied. Once on the way to school a school-fellow had said boastfully: "Yesterday we had ice at dinner." She replied: "Oh we have ice every day." In reality she did not know what ice at dinner could mean; she only knew ice in the long blocks in which it is carted about, but she assumed that there must be something grand in having it for dinner, so she refused to be outdone by her school-fellow.

[1913g, 2619]

Unfortunately I am unable, for familiar reasons, to enter into the history of the case as far as I should like, and I must restrict myself to the account which follows. Up to the time of her falling ill the patient had been a happy and almost completely satisfied wife. She wanted to have children, from motives based on an infantile fixation of her wishes, and she fell ill when she learned that it was impossible for her to have any by the husband who was the only object of her love. The anxiety hysteria with which she reacted to this frustration corresponded, as she herself soon learned to understand, to the repudiation of phantasies of seduction in which her firmly implanted wish for a child found expression. She now did all she could to prevent her husband from guessing that she had fallen ill owing to the frustration of which he was the cause. But I have had good reason for asserting that everyone possesses in his own unconscious an instrument with which he can interpret the utterances of the unconscious in other people. Her husband understood, without any admission or explanation on her part, what his wife's anxiety meant; he felt hurt, without showing it, and in his turn reacted neurotically by - for the first time - failing in sexual intercourse with her. Immediately afterwards he started on a journey. His wife believed that he had become permanently impotent, and produced her first obsessional symptoms on the day before his expected return.

[1913i, 2626]
At this point a portion of our case history fits in, which I have so far kept back. The patient's sexual life began in her earliest childhood with beating-phantasies. After they were suppressed, an unusually long period of latency set in, during which the girl passed through a period of exalted moral growth, without any awakening of female sexual feelings. Her marriage, which took place at an early age, opened a time of normal sexual activity. This period, during which she was a happy wife, continued for a number of years, until her first great frustration brought on the hysterical neurosis. When this was followed by her genital life losing all its value, her sexual life, as I have said, returned to the infantile stage of sadism.

[1913i, 2627]

Psycho-analysis has established an intimate connection between these psychical achievements of individuals on the one hand and societies on the other by postulating one and the same dynamic source for both of them. It starts out from the basic idea that the principal function of the mental mechanism is to relieve the individual from the tensions created in him by his needs. One part of this task can be achieved by extracting satisfaction from the external world; and for this purpose it is essential to have control over the real world. But the satisfaction of another part of these needs - among them certain affective impulses - is regularly frustrated by reality. This leads to the further task of finding some other means of dealing with the unsatisfied impulses. The whole course of the history of civilization is no more than an account of the various methods adopted by mankind for 'binding' their unsatisfied wishes, which, according to changing conditions (modified, moreover, by technological advances) have been met by reality sometimes with favour and sometimes with frustration.

[1913j, 2822]

Our knowledge of the neurotic illnesses of individuals has been of much assistance to our understanding of the great social institutions. For the neuroses themselves have turned out to be attempts to find individual solutions for the problems of compensating for unsatisfied wishes, while the institutions seek to provide social solutions for these same problems. The recession of the social factor and the predominance of the sexual one turns these neurotic solutions of the psychological problem into caricatures which are of no service except to help us in explaining such important questions.

[1913j, 2822]

Since the publication of a work by Abraham (1908) - which that conscientious author has attributed to my instigation - we have tried to base our characterization of Kraepelin's 'dementia praecox' (Bleuler's 'schizophrenia') on its position with reference to the antithesis between ego and object. In the transference neuroses (anxiety hysteria, conversion hysteria and obsessional neurosis) there was nothing to give special prominence to this antithesis. We knew, indeed, that frustration in regard to the object brings on the outbreak of the neurosis and that the neurosis involves a renunciation of the real object; we knew too that the libido that is withdrawn from the real object reverts first to a phantasied object and then to one that had been repressed (introversion). But in these disorders object-cathexis in general is retained with great energy, and more detailed examination of the process of repression has obliged us to assume that object-cathexis persists in the system Ucs. in spite of - or rather in consequence of - repression. Indeed, the capacity for transference, of which we make use for therapeutic purposes in these affections, presupposes an unimpaired object-cathexis.

[1915e, 3018]
Psycho-analytic work has furnished us with the thesis that people fall ill of a neurosis as a result of frustration. What is meant is the frustration of the satisfaction of their libidinal wishes, and some digression is necessary in order to make the thesis intelligible. For a neurosis to be generated there must be a conflict between a person's libidinal wishes and the part of his personality we call his ego, which is the expression of his instinct of self-preservation and which also includes his ideals of his personality. A pathogenic conflict of this kind takes place only when the libido tries to follow paths and aims which the ego has long since overcome and condemned and has therefore prohibited forever; and this the libido only does if it is deprived of the possibility of an ideal ego-syntonic satisfaction. Hence privation, frustration of a real satisfaction, is the first condition for the generation of a neurosis, although, indeed, it is far from being the only one.

[1916d, 3104]

I should like to anticipate, Gentlemen, the qualifications which I shall have to make later in the universal validity of these statements. I will therefore point out to you that all I have said here about repression and the formation and meaning of symptoms was derived from three forms of neurosis - anxiety hysteria, conversion hysteria and obsessional neurosis - and that in the first instance it is also valid only for these forms. These three disorders, which we are accustomed to group together as 'transference neuroses', also circumscribe the region in which psychoanalytic therapy can function. The other neuroses have been far less thoroughly studied by psycho-analysis; in one group of them the impossibility of therapeutic influence has been a reason for this neglect. Nevertheless, we are everywhere on the point of penetrating to an understanding of these other disorders which are not transference neuroses. I hope later to be able to introduce you to the extensions of our hypotheses and findings which result from adaptation to this new material, and to show you that these further studies have not led to contradictions but to the establishment of higher unities.

[1916-1917, 3372]

I think, Gentlemen, that you will best come to terms with what you have just been told about fixation and regression of the libido if you will regard it as a preparation for research into the aetiology of the neuroses. Hitherto I have only given you one piece of information about this: namely that people fall ill of a neurosis if they are deprived of the possibility of satisfying their libido - that they fall ill owing to 'frustration', as I put it - and that their symptoms are precisely a substitute for their frustrated satisfaction. This is not supposed to mean, of course, that every frustration of a libidinal satisfaction makes the person it affects neurotic, but merely that the factor of frustration could be discerned in every case of neurosis that has been examined. Thus the proposition is not convertible. No doubt, too, you will have understood that this assertion does not claim to reveal the whole secret of the aetiology of neuroses but is only bringing into prominence one important and indispensable determinant.

[1916-1917, 3407]
In further pursuing the discussion of this thesis, are we to consider the nature of the frustration or the peculiar character of those who are affected by it? It is extremely seldom, after all, that frustration is universal and absolute. In order to operate pathogenically it must no doubt affect the mode of satisfaction which alone the subject desires, of which alone he is capable. There are in general very many ways of tolerating deprivation of libidinal satisfaction without falling ill as a result. In the first place, we know people who are able to put up with a deprivation of this kind without being injured: they are not happy, they suffer from longing, but they do not fall ill. Next, we must bear in mind that the sexual instinctual impulses in particular are extraordinarily plastic, if I may so express it. One of them can take the place of another, one of them can take over another's intensity; if the satisfaction of one of them is frustrated by reality, the satisfaction of another can afford complete compensation. They are related to one another like a network of intercommunicating channels filled with a liquid; and this is so in spite of their being subject to the primacy of the genitals - a state of affairs that is not at all easily combined in a single picture. Further, the component instincts of sexuality, as well as the sexual current which is compounded from them, exhibit a large capacity for changing their object, for taking another in its place - and one, therefore, that is more easily attainable. This displaceability and readiness to accept a substitute must operate powerfully against the pathogenic effect of a frustration. Among these protective processes against falling ill owing to deprivation there is one which has gained special cultural significance. It consists in the sexual trend abandoning its aim of obtaining a component or a reproductive pleasure and taking on another which is related genetically to the abandoned one but is itself no longer sexual and must be described as social. We call this process 'sublimation', in accordance with the general estimate that places social aims higher than the sexual ones, which are at bottom self-interested. Sublimation is, incidentally, only a special case of the way in which sexual trends are attached to other, non-sexual ones. We shall have to discuss it again in another connection.

You may now have an impression that deprivation has been reduced to insignificance owing to all these methods of tolerating it. But no, it retains its pathogenic power. The countermeasures are on the whole insufficient. There is a limit to the amount of unsatisfied libido that human beings on the average can put up with. The plasticity or free mobility of the libido is by no means fully preserved in everyone, and sublimation is never able to deal with more than a certain fraction of libido, quite apart from the fact that many people are gifted with only a small amount of capacity to sublimate. The most important of these limitations is evidently that upon the mobility of the libido, since it makes a person's satisfaction depend on the attainment of only a very small number of aims and objects. You have only to recall that an imperfect development of the libido leaves behind it very fertile and perhaps, too, very numerous libidinal fixations to early phases of the organization and of the finding of objects, which are for the most part incapable of real satisfaction, and you will recognize in libidinal fixation the second powerful factor which combines with frustration as the cause of illness. You can declare, as a schematic abbreviation, that libidinal fixation represents the predisposing, internal factor in the aetiology of the neuroses, while frustration represents the accidental, external one.
I hope to be able to give you adequate replies to these questions, even though the replies may be reduced to schematic dimensions. The conflict is conjured up by frustration, as a result of which the libido, deprived of satisfaction, is driven to look for other objects and paths. The necessary precondition of the conflict is that these other paths and objects arouse displeasure in one part of the personality, so that a veto is imposed which makes the new method of satisfaction impossible as it stands. From this point the construction of symptoms pursues its course, which we shall follow later. The repudiated libidinal trends nevertheless succeed in getting their way by certain roundabout paths, though not, it is true, without taking the objection into account by submitting to some distortions and mitigations. The roundabout paths are those taken by the construction of symptoms; the symptoms are the fresh or substitute satisfaction which has become necessary owing to the fact of frustration.
[1916-1917, 3411]

The meaning of psychical conflict can be adequately expressed in another way by saying that for an external frustration to become pathogenic an internal frustration must be added to it. In that case, of course, the external and internal frustration relate to different paths and objects. The external frustration removes one possibility of satisfaction and the internal frustration seeks to exclude another possibility, about which the conflict then breaks out. I prefer this way of representing the matter because it has a secret content. For it hints at the probability that the internal impediments arose from real external obstacles during the prehistoric periods of human development.
[1916-1917, 3411]

Thus we discover that the third factor in the aetiology of the neuroses, the tendency to conflict, is as much dependent on the development of the ego as on that of the libido. Our insight into the causation of the neuroses is thus made more complete. First there is the most general precondition - frustration; next, fixation of the libido which forces it into particular directions; and thirdly, the tendency to conflict, arising from the development of the ego, which rejects these libidinal impulses. The situation, then, is not so very confused and hard to penetrate as it probably seemed to you during the course of my remarks. It is true, however, that we shall find we have not yet finished with it. There is something new to be added and something already familiar to be further examined.
[1916-1917, 3413]
Think it over! You have learnt all that is essential about the determinants of falling ill as well as all the factors that come into effect after the patient has fallen ill. Where do these leave room for any therapeutic influence? In the first place there is hereditary disposition. We have not talked about it very often because it is emphatically stressed from other directions and we have nothing new to say about it. But do not suppose that we underestimate it; precisely as therapists we come to realize its power clearly enough. In any case we can do nothing to alter it; we too must take it as something given, which sets a limit to our efforts. Next there is the influence of early experiences in childhood, to which we are in the habit of giving prominence in analysis: they belong to the past and we cannot undo them. Then comes everything that we have summarized as ‘real frustration’ - the misfortunes of life from which arise deprivation of love, poverty, family quarrels, ill-judged choice of a partner in marriage, unfavourable social circumstances, and the strictness of the ethical standards to whose pressure the individual is subject. Here, to be sure, there would be handles enough for a very effective therapy, but it would have to be of the kind which Viennese folklore attributes to the Emperor Joseph - the benevolent interference of a powerful personage before whose will people bow and difficulties vanish. But who are we, that we should be able to adopt benevolence of this kind as an instrument of our therapy? Poor ourselves and socially powerless, and compelled to earn our livelihood from our medical activity, we are not even in a position to extend our efforts to people without means, as other doctors with other methods of treatment are after all able to do. Our therapy is too time-consuming and too laborious for that to be possible. Perhaps, however, you are clutching at one of the factors I have mentioned and believe that there you have found the point at which our influence can make its attack. If the ethical restrictions demanded by society play a part in the deprivation imposed on the patient, treatment can, after all, give him the courage, or perhaps a direct injunction, to disregard those barriers and achieve satisfaction and recovery while forgoing the fulfilment of an ideal that is exalted, but so often not adhered to, by society. The patient will thus become healthy by ‘living a full life’ sexually. This, it is true, casts a shadow on analytic treatment for not serving general morality. What it has given to the individual it will have taken from the community.

[1916-1917, 3475]

You will remember that it was a frustration that made the patient ill, and that his symptoms serve him as substitutive satisfactions. It is possible to observe during the treatment that every improvement in his condition reduces the rate at which he recovers and diminishes the instinctual force impelling him towards recovery. But this instinctual force is indispensible; reduction of it endangers our aim - the patient's restoration to health. What, then, is the conclusion that forces itself inevitably upon us? Cruel though it may sound, we must see to it that the patient's suffering, to a degree that is in some way or other effective, does not come to an end prematurely. If, owing to the symptoms having been taken apart and having lost their value, his suffering becomes mitigated, we must reinstate it elsewhere in the form of some appreciable privation; otherwise we run the danger of never achieving any improvements except quite insignificant and transitory ones.

[1919a, 3632]
The traumatic neuroses and war neuroses may proclaim too loudly the effects of mortal danger and may be silent or speak only in muted tones of the effects of frustration in love. But, on the other hand, the ordinary transference neuroses of peace-time set no aetiological store by the factor of mortal danger which, in the former class of neuroses, plays so mighty a part. It is even held that the peace-time neuroses are promoted by indulgence, good living and inactivity - which would afford an interesting contrast to the living-conditions under which the war neuroses develop. If they were to follow the example of their opponents, psycho-analysts, finding that their patients had fallen ill owing to frustration in love (owing to the claims of the libido being unsatisfied) would have to maintain that there can be no such things as danger-neuroses or that the disorders that appear after frightening experiences are not neuroses. They have, of course, no notion of maintaining any such thing. On the contrary, a convenient possibility occurs to them of bringing the two apparently divergent sets of facts together under a single hypothesis. In traumatic and war neuroses the human ego is defending itself from a danger which threatens it from without or which is embodied in a shape assumed by the ego itself. In the transference neuroses of peace the enemy from which the ego is defending itself is actually the libido, whose demands seem to it to be menacing. In both cases the ego is afraid of being damaged - in the latter case by the libido and in the former by external violence. It might, indeed, be said that in the case of the war neuroses, in contrast to the pure traumatic neuroses and in approximation to the transference neuroses, what is feared is nevertheless an internal enemy. The theoretical difficulties standing in the way of a unifying hypothesis of this kind do not seem insuperable: after all, we have a perfect right to describe repression, which lies at the basis of every neurosis, as a reaction to a trauma - as an elementary traumatic neurosis.

[1919d, 3668]

On the other side, it is equally easy, from the knowledge we have so far gained of the mechanism of the psychoses, to adduce examples which point to a disturbance in the relationship between the ego and the external world. In Meynert's amentia - an acute hallucinatory confusion which is perhaps the most extreme and striking form of psychosis - either the external world is not perceived at all, or the perception of it has no effect whatever. Normally, the external world governs the ego in two ways: firstly, by current, present perceptions which are always renewable, and secondly, by the store of memories of earlier perceptions which, in the shape of an 'internal world', form a possession of the ego and a constituent part of it. In amentia, not only is the acceptance of new perceptions refused, but the internal world, too, which, as a copy of the external world, has up till now represented it, loses its significance (its cathexis) - The ego creates, autocratically, a new external and internal world; and there can be no doubt of two facts - that this new world is constructed in accordance with the id's wishful impulses, and that the motive of this dissociation from the external world is some very serious frustration by reality of a wish - a frustration which seems intolerable. The close affinity of this psychosis to normal dreams is unmistakable. A precondition of dreaming, moreover, is a state of sleep, and one of the features of sleep is a complete turning away from perception and the external world.

[1924b, 4066]
The aetiology common to the onset of a psychoneurosis and of a psychosis always remains the same. It consists in a frustration, a non-fulfilment of one of those childhood wishes which are for ever undefeated and which are so deeply rooted in our phylogenetically determined organization. This frustration is in the last resort always an external one; but in the individual case it may proceed from the internal agency (in the super-ego) which has taken over the representation of the demands of reality. The pathogenic effect depends on whether, in a conflictual tension of this kind, the ego remains true to its dependence on the external world and attempts to silence the id, or whether it lets itself be overcome by the id and thus torn away from reality. A complication is introduced into this apparently simple situation, however, by the existence of the super-ego, which, though a link that is not yet clear to us, unites in itself influences coming from the id as well as from the external world, and is to some extent an ideal model of what the whole endeavour of the ego is aiming at - a reconciliation between its various dependent relationships. The attitude of the super-ego should be taken into account - which has not hitherto been done - in every form of psychical illness. We may provisionally assume that there must also be illnesses which are based on a conflict between the ego and the super-ego. Analysis gives us a right to suppose that melancholia is a typical example of this group; and we would set aside the name of 'narcissistic psychoneuroses' for disorders of that kind. Nor will it clash with our impressions if we find reasons for separating states like melancholia from the other psychoses. We now see that we have been able to make our simple genetic formula more complete, without dropping it. Transference neuroses correspond to a conflict between the ego and the id; narcissistic neuroses, to a conflict between the ego and the super-ego; and psychoses, to one between the ego and the external world. It is true that we cannot tell at once whether we have really gained any new knowledge by this, or have only enriched our store of formulas; but I think that this possible application of the proposed differentiation of the mental apparatus into an ego, a super-ego and an id cannot fail to give us courage to keep that hypothesis steadily in view.

This state of affairs is enough to account for the reluctant and hesitant reception of analysis in scientific quarters. But it does not explain the outbursts of indignation, derision and scorn which, in disregard of every standard of logic and good taste, have characterized the controversial methods of its opponents. A reaction of such a kind suggests that resistances other than purely intellectual ones were stirred up and that powerful emotional forces were aroused. And there are indeed plenty of things to be found in the theory of psycho-analysis calculated to produce such an effect as this upon the passions of men of every kind and not of scientists alone. Above all there is the very important place in the mental life of human beings which psycho-analysis assigns to what are known as the sexual instincts. Psycho-analytic theory maintained that the symptoms of neuroses are distorted substitutive satisfactions of sexual instinctual forces, the direct satisfaction of which has been frustrated by internal resistances. Later on, when analysis had extended beyond its original field of work and began to be applied to normal mental life, it sought to show that these same sexual components, which could be diverted from their immediate aims and directed to other things, made the most important contributions to the cultural achievements of the individual and of society. These views were not entirely new. The incomparable significance of sexual life had been proclaimed by the philosopher Schopenhauer in an intensely impressive passage. Moreover, what psycho-analysis called sexuality was by no means identical with the impulse towards a union of the two sexes or towards producing a pleasurable sensation in the genitals; it had far more resemblance to the all-inclusive and all-preserving Eros of Plato's Symposium.

[1924b, 4067]

[1925e, 4125]
A feebleness of the ego of this sort is to be found in all of us in childhood; and that is why the experiences of the earliest years of childhood are of such great importance for later life. Under the extraordinary burden of this period of childhood we have in a few years to cover the enormous developmental distance between stone-age primitive men and the participants in contemporary civilization, and, at the same time and in particular, we have to fend off the instincual impulses of the early sexual period - under this burden, then, our ego takes refuge in repression and lays itself open to a childhood neurosis, the precipitate of which it carries with it into maturity as a disposition to a later nervous illness. Everything now depends on how the growing organism is treated by fate. If life becomes too hard, if the gulf between instincual claims and the demands of reality becomes too great, the ego may fail in its efforts to reconcile the two, and the more readily, the more it is inhibited by the disposition carried over by it from infancy. The process of repression is then repeated, the instincts tear themselves away from the ego's domination, find their substitutive satisfactions along the paths of regression, and the poor ego has become helplessly neurotic.

For the sake of a uniform terminology we will describe the fact that an instinct cannot be satisfied as a 'frustration', the regulation by which this frustration is established as a 'prohibition' and the condition which is produced by the prohibition as a 'privation'. The first step is to distinguish between privations which affect everyone and privations which do not affect everyone but only groups, classes or even single individuals. The former are the earliest; with the prohibitions that established them, civilization - who knows how many thousands of years ago? - began to detach man from his primordial animal condition. We have found to our surprise that these privations are still operative and still form the kernel of hostility to civilization. The instincual wishes that suffer under them are born afresh with every child; there is a class of people, the neurotics, who already react to these frustrations with asocial behaviour. Among these instincual wishes are those of incest, cannibalism and lust for killing. It sounds strange to place alongside one another wishes which everyone seems united in repudiating and others about which there is so much lively dispute in our civilization as to whether they shall be permitted or frustrated; but psychologically it is justifiable to do so. Nor is the attitude of civilization to these oldest instincual wishes by any means uniform. Cannibalism alone seems to be universally proscribed and - to the non-psycho-analytic view - to have been completely surmounted. The strength of the incestuous wishes can still be detected behind the prohibition against them; and under certain conditions killing is still practised, and indeed commanded, by our civilization. It is possible that cultural developments lie ahead of us in which the satisfaction of yet other wishes, which are entirely permissible to-day, will appear just as unacceptable as cannibalism does now.

Psycho-analytic work has shown us that it is precisely these frustrations of sexual life which people known as neurotics cannot tolerate. The neurotic creates substitutive satisfactions for himself in his symptoms, and these either cause him suffering in themselves or become sources of suffering for him by raising difficulties in his relations with his environment and the society he belongs to. The latter fact is easy to understand; the former presents us with a new problem. But civilization demands other sacrifices besides that of sexual satisfaction.

It is a familiar fact that the aetiological preconditions of neurosis are not yet known with certainty. The precipitating causes of it are frustrations and internal conflicts: conflicts between the three major psychical agencies, conflicts arising within the libidinal economy in consequence of our bisexual disposition and conflicts between the erotic and the aggressive instincual components. It is the endeavour of the psychology of the neuroses to discover what makes these processes, which belong to the normal course of mental life, become pathogenic.
When we have established the existence of a phenomenon, the next question is of course as to its cause. Incredulity of this kind is obviously an attempt to repudiate a piece of reality; but there is something strange about it. We should not be in the least astonished if an attempt of this kind were aimed at a piece of reality that threatened to bring unpleasure: the mechanism of our mind is, so to speak, planned to work along just such lines. But why should such incredulity arise in something which, on the contrary, promises to bring a high degree of pleasure? Truly paradoxical behaviour! But I recollect that on a previous occasion I dealt with the similar case of the people who, as I put it, are 'wrecked by success'. As a rule people fall ill as a result of frustration, of the non-fulfilment of some vital necessity or desire. But with these people the opposite is the case; they fall ill, or even go entirely to pieces, because an overwhelmingly powerful wish of theirs has been fulfilled. But the contrast between the two situations is not so great as it seems at first. What happens in the paradoxical case is merely that the place of the external frustration is taken by an internal one. The sufferer does not permit himself happiness: the internal frustration commands him to cling to the external one. But why? Because - so runs the answer in a number of cases - one cannot expect Fate to grant one anything so good. In fact, another instance of 'too good to be true', the expression of a pessimism of which a large portion seems to find a home in many of us. In another set of cases, just as in those who are wrecked by success, we find a sense of guilt or inferiority, which can be translated: 'I'm not worthy of such happiness, I don't deserve it.' But these two motives are essentially the same, for one is only a projection of the other. For, as has long been known, the Fate which we expect to treat us so badly is a materialization of our conscience, of the severe super-ego within us, itself a residue of the punitive agency of our childhood.

[1936a, 4826]
The fact that the curb put upon love by civilization involves a universal tendency to debase
sexual objects will perhaps lead us to turn our attention from the object to the instincts
themselves. The damage caused by the initial frustration of sexual pleasure is seen in the fact
that the freedom later given to that pleasure in marriage does not bring full satisfaction. But at
the same time, if sexual freedom is unrestricted from the outset the result is no better. It can
easily be shown that the psychical value of erotic needs is reduced as soon as their satisfaction
becomes easy. An obstacle is required in order to heighten libido; and where natural
resistances to satisfaction have not been sufficient men have at all times erected conventional
ones so as to be able to enjoy love. This is true both of individuals and of nations. In times in
which there were no difficulties standing in the way of sexual satisfaction, such as perhaps
during the decline of the ancient civilizations, love became worthless and life empty, and strong
reaction-formations were required to restore indispensable affective values. In this connection it
may be claimed that the ascetic current in Christianity created psychical values for love which
pagan antiquity was never able to confer on it. This current assumed its greatest importance
with the ascetic monks, whose lives were almost entirely occupied with the struggle against
libidinal temptation.
[1912d, 2344]

(a) The most obvious, the most easily discoverable and the most intelligible precipitating
cause of an onset of neurosis is to be seen in the external factor which may be described in
general terms as frustration. The subject was healthy so long at his need for love was satisfied
by a real object in the external world; he becomes neurotic as soon as this object is withdrawn
from him without a substitute taking its place. Here happiness coincides with health and
unhappiness with neurosis. It is easier for fate to bring about a cure than for the physician; for it
can offer the patient a substitute for the possibility of satisfaction which he has lost.
[1912c, 2560]

In spite of the very clear differences between the two types of onset of illness that we have
described, they nevertheless coincide in essentials and can without difficulty be brought
together into a unity. Falling ill from frustration may also be regarded as incapacity for
adaptation to reality - in the particular case, that is, in which reality frustrates satisfaction of
libido. Falling ill under the conditions of the second type leads directly to a special case of
frustration. It is true that reality does not here frustrate every kind of satisfaction; but it frustrates
the one kind which the subject declares is the only possible one. Nor does the frustration come
immediately from the external world, but primarily from certain trends in the subject's ego.
Nevertheless, frustration remains the common factor and the more inclusive one. In
consequence of the conflict which immediately sets in in the second type, both kinds of
satisfaction - the habitual one as well as the one aimed at - are equally inhibited; a damming-up
of libido, with all its consequences, comes about just as it does in the first case. The psychical
events leading to the formation of symptoms are if anything easier to follow in the second type
than in the first; for in the second type the pathogenic fixations of the libido do not need to be
freshly established, but have already been in force while the subject was healthy. A certain
amount of introversion of libido is, as a rule, already present; and there is a saving of some part
of the subject's regression to the infantile stage, owing to the fact that his forward development
has not yet completed its course.
[1912c, 2562]
(d) Just as the third type has brought the dispositional determinant before us almost in isolation, so the fourth type, which now follows, draws our attention to another factor, which comes into consideration in every single case and might easily for that very reason be overlooked in a theoretical discussion. We see people fall ill who have hitherto been healthy, who have met with no fresh experience and whose relation to the external world has undergone no change, so that the onset of their illness inevitably gives an impression of spontaneity. A closer consideration of such cases, however, shows us that none the less a change has taken place in them whose importance we must rate very highly as a cause of illness. As a result of their having reached a particular period of life, and in conformity with regular biological processes, the quantity of libido in their mental economy has experienced an increase which is in itself enough to upset the equilibrium of their health and to set up the necessary conditions for a neurosis. It is well known that more or less sudden increases of libido of this kind are habitually associated with puberty and the menopause - with the attainment of a certain age in women; in some people they may in addition be manifested in periodicities that are still unknown. Here the damming-up of libido is the primary factor; it becomes pathogenic as a consequence of a relative frustration on the part of the external world, which would still have granted satisfaction to a smaller claim by the libido. The unsatisfied and dammed-up libido can once again open up paths to regression and kindle the same conflicts which we have demonstrated in the case of absolute external frustration. We are reminded in this way that the quantitative factor should not be left out of account in any consideration of the precipitating causes of illness. All the other factors - frustration, fixation, developmental inhibition - remain ineffective unless they affect a certain amount of libido and bring about a damming-up of libido of a certain height. It is true that we are unable to measure this amount of libido which seems to us indispensable for a pathogenic effect; we can only postulate it after the resulting illness has started. There is only one direction in which we can determine it more precisely. We may assume that it is not a question of an absolute quantity, but of the relation between the quota of libido in operation and the quantity of libido which the individual ego is able to deal with - that is, to hold under tension, to sublimate or to employ directly. For this reason a relative increase in the quantity of libido may have the same effects as an absolute one. An enfeeblement of the ego owing to organic illness or owing to some special demand upon its energy will be able to cause the emergence of neuroses which would otherwise have remained latent in spite of any disposition that might be present.

[1912c, 2563]

It remains to say a few words on the relation of these types to the facts of observation. If I survey the set of patients on whose analysis I am at the moment engaged, I must record that not one of them is a pure example of any of the four types of onset. In each of them, rather, I find a portion of frustration operating alongside of a portion of incapacity to adapt to the demands of reality; inhibition in development, which coincides, of course, with inflexibility of fixations, has to be reckoned with in all of them, and, as I have already said, the importance of quantity of libido must never be neglected. I find, indeed, that in several of these patients their illness has appeared in successive waves, between which there have been healthy intervals, and that each of these waves has been traceable to a different type of precipitating cause. Thus the erection of these four types cannot lay claim to any high theoretical value; they are merely different ways of establishing a particular pathogenic constellation in the mental economy - namely the damming-up of libido, which the ego cannot, with the means at its command, ward off without damage. But this situation itself only becomes pathogenic as a result of a quantitative factor; it does not come as a novelty to mental life and is not created by the impact of what is spoken of as a 'cause of illness'.

[1912c, 2564]
Naturally this does not answer all the questions that we might ask in connection with this case. On the contrary, the case bristles with further problems—some that have in general not yet become soluble and others which could not be solved owing to the particular circumstances being unfavourable. For instance, why did this lady who was happily married fall in love with her son-in-law? and why did the relief, which might have been possible in other ways, take the form of this mirror-image this projection of her state on to her husband? You must no: think it is otiose or frivolous to raise such questions. We already have some material at our disposal which might possibly serve to answer them. The lady was at a critical age, at which sexual needs in women suffer a sudden and undesired increase; that alone might account for the event. Or it may further have been that her excellent and faithful husband had for some years no longer enjoyed the sexual capacity which the well-preserved woman required for her satisfaction. Experience has shown us that it is precisely men in this position, whose faithfulness can consequently be taken for granted, who are distinguished by treating their wives with unusual tenderness, and by showing particular forbearance for their nervous troubles. Or, again, it may not be without significance that the object of this pathogenic love was precisely the young husband of one of her daughters. A powerful erotic tie with a daughter, which goes back in the last resort to the mother's sexual constitution, often finds a way of persisting in a transformation of this sort. In this connection I may perhaps remind you that the relation between mother-in-law and son-in-law has been regarded from the earliest times of the human race as a particularly awkward one and that among primitive people it has given rise to very powerful taboo regulations and 'avoidances'. The relation is frequently excessive by civilized standards both in a positive and negative direction. Which of these three factors became operative in our case, or whether two of them or perhaps all three came together, I cannot, it is true, tell you; but that is only because I was not permitted to continue the analysis of the case for more than two sessions.

[1916-1917, 3335]

I should like to anticipate, Gentlemen, the qualifications which I shall have to make later in the universal validity of these statements. I will therefore point out to you that all I have said here about repression and the formation and meaning of symptoms was derived from three forms of neurosis - anxiety hysteria, conversion hysteria and obsessional neurosis - and that in the first instance it is also valid only for these forms. These three disorders, which we are accustomed to group together as 'transference neuroses', also circumscribe the region in which psychoanalytic therapy can function. The other neuroses have been far less thoroughly studied by psycho-analysis; in one group of them the impossibility of therapeutic influence has been a reason for this neglect. Nor should you forget that psycho-analysis is still a very young science, that preparing for it costs much trouble and time, and that not at all long ago it was being practised single-handed. Nevertheless, we are everywhere on the point of penetrating to an understanding of these other disorders which are not transference neuroses. I hope later to be able to introduce you to the extensions of our hypotheses and findings which result from adaptation to this new material, and to show you that these further studies have not led to contradictions but to the establishment of higher unities. If, then, everything I am saying here applies to the transference neuroses, let me first increase the value of symptoms by a new piece of information. For a comparative study of the determining causes of falling ill leads to a result which can be expressed in a formula: these people fall ill in one way or another of frustration, when reality prevents them from satisfying their sexual wishes. You see how excellently these two findings tally with each other. It is only thus that symptoms can be properly viewed as substitutive satisfactions for what is missed in life.

[1916-1917, 3372]
I should not have much difficulty in giving you a far more intimate picture of the relations between perversion and neurosis; but I think what I have already said will serve our purpose. We must however guard against being misled by what I have told you of the meaning of symptoms into over-estimating the frequency and intensity of people's perverse inclinations. It is possible, as you have heard, to fall ill of a neurosis as a result of a frustration of normal sexual satisfaction. But when a real frustration like this occurs, the need moves over on to abnormal methods of sexual excitement. You will later learn the way in which this happens. But in any case you will realize that as a result of this 'collateral' damming-back the perverse impulses must emerge more strongly than they would have if normal sexual satisfaction had met with no obstacle in the real world. Moreover a similar influence is to be recognized also as affecting the manifest perversions. In some cases they are provoked or made active if the normal satisfaction of the sexual instinct encounters too great difficulties for temporary reasons or because of permanent social regulations. In other cases, it is true, the inclination to perversions is quite independent of such favouring conditions; they are, we might say, the normal species of sexual life for those particular individuals.

[1916-1917, 3381]

I think, Gentlemen, that you will best come to terms with what you have just been told about fixation and regression of the libido if you will regard it as a preparation for research into the aetiology of the neuroses. Hitherto I have only given you one piece of information about this: namely that people fall ill of a neurosis if they are deprived of the possibility of satisfying their libido - that they fall ill owing to 'frustration', as I put it - and that their symptoms are precisely a substitute for their frustrated satisfaction. This is not supposed to mean, of course, that every frustration of a libidinal satisfaction makes the person it affects neurotic, but merely that the factor of frustration could be discerned in every case of neurosis that has been examined. Thus the proposition is not convertible. No doubt, too, you will have understood that this assertion does not claim to reveal the whole secret of the aetiology of neuroses but is only bringing into prominence one important and indispensable determinant.

[1916-1917, 3407]
In further pursuing the discussion of this thesis, are we to consider the nature of the frustration or the peculiar character of those who are affected by it? It is extremely seldom, after all, that frustration is universal and absolute. In order to operate pathogenically it must no doubt affect the mode of satisfaction which alone the subject desires, of which alone he is capable. There are in general very many ways of tolerating deprivation of libidinal satisfaction without falling ill as a result. In the first place, we know people who are able to put up with a deprivation of this kind without being injured: they are not happy, they suffer from longing, but they do not fall ill. Next, we must bear in mind that the sexual instinctual impulses in particular are extraordinarily plastic, if I may so express it. One of them can take the place of another, one of them can take over another's intensity; if the satisfaction of one of them is frustrated by reality, the satisfaction of another can afford complete compensation. They are related to one another like a network of intercommunicating channels filled with a liquid; and this is so in spite of their being subject to the primacy of the genitals - a state of affairs that is not at all easily combined in a single picture. Further, the component instincts of sexuality, as well as the sexual current which is compounded from them, exhibit a large capacity for changing their object, for taking another in its place - and one, therefore, that is more easily attainable. This displaceability and readiness to accept a substitute must operate powerfully against the pathogenic effect of a frustration. Among these protective processes against falling ill owing to deprivation there is one which has gained special cultural significance. It consists in the sexual trend abandoning its aim of obtaining a component or a reproductive pleasure and taking on another which is related genetically to the abandoned one but is itself no longer sexual and must be described as social. We call this process 'sublimation', in accordance with the general estimate that places social aims higher than the sexual ones, which are at bottom self-interested. Sublimation is, incidentally, only a special case of the way in which sexual trends are attached to other, non-sexual ones. We shall have to discuss it again in another connection.

You may now have an impression that deprivation has been reduced to insignificance owing to all these methods of tolerating it. But no, it retains its pathogenic power. The countermeasures are on the whole insufficient. There is a limit to the amount of unsatisfied libido that human beings on the average can put up with. The plasticity or free mobility of the libido is by no means fully preserved in everyone, and sublimation is never able to deal with more than a certain fraction of libido, quite apart from the fact that many people are gifted with only a small amount of capacity to sublimate. The most important of these limitations is evidently that upon the mobility of the libido, since it makes a person's satisfaction depend on the attainment of only a very small number of aims and objects. You have only to recall that an imperfect development of the libido leaves behind it very fertile and perhaps, too, very numerous libidinal fixations to early phases of the organization and of the finding of objects, which are for the most part incapable of real satisfaction, and you will recognize in libidinal fixation the second powerful factor which combines with frustration as the cause of illness. You can declare, as a schematic abbreviation, that libidinal fixation represents the predisposing, internal factor in the aetiology of the neuroses, while frustration represents the accidental, external one.

[1916-1917, 3408]
I hope to be able to give you adequate replies to these questions, even though the replies may be reduced to schematic dimensions. The conflict is conjured up by frustration, as a result of which the libido, deprived of satisfaction, is driven to look for other objects and paths. The necessary precondition of the conflict is that these other paths and objects arouse displeasure in one part of the personality, so that a veto is imposed which makes the new method of satisfaction impossible as it stands. From this point the construction of symptoms pursues its course, which we shall follow later. The repudiated libidinal trends nevertheless succeed in getting their way by certain roundabout paths, though not, it is true, without taking the objection into account by submitting to some distortions and mitigations. The roundabout paths are those taken by the construction of symptoms; the symptoms are the fresh or substitute satisfaction which has become necessary owing to the fact of frustration.

[1916-1917, 3411]

The path to perversion branches off sharply from that to neurosis. If these regressions rouse no objection from the ego, no neurosis will come about either; and the libido will arrive at some real, even though no longer normal, satisfaction. But if the ego, which has under its control not only consciousness but also the approaches to motor innervation and accordingly to the realization of mental desires, does not agree with these regressions, conflict will follow. The libido is, as it were, cut off and must try to escape in some direction where, in accordance with the requirements of the pleasure principle, it can find a discharge for its cathexis of energy. It must withdraw from the ego. An escape of this kind is offered it by the fixations on the path of its development which it has now entered on regressively - fixations from which the ego had protected itself in the past by repressions. By cathecting these repressed positions as it flows backward, the libido has withdrawn from the ego and its laws, and has at the same time renounced all the education it has acquired under the ego's influence. It was docile so long as satisfaction beckoned to it; but under the double pressure of external and internal frustration it becomes refractory, and recalls earlier and better times. Such is the libido's fundamentally unchangeable character. The ideas to which it now transfers its energy as a cathexis belong to the system of the unconscious and are subject to the processes which are possible there, particularly to condensation and displacement. In this way conditions are established which completely resemble those in dream-construction. The dream proper, which has been completed in the unconscious and is the fulfilment of an unconscious wishful phantasy, is brought up against a portion of (pre)conscious activity which exercises the office of censorship and which, when it has been indemnified, permits the formation of the manifest dream as a compromise. In the same way, what represents the libido in the unconscious has to reckon with the power of the preconscious ego. The opposition which had been raised against it in the ego pursues it as an 'anticathexis' and compels it to choose a form of expression which can at the same time become an expression of the opposition itself. Thus the symptom emerges as a many-times-distorted derivative of the unconscious libidinal wish-fulfilment, an ingeniously chosen piece of ambiguity with two meanings in complete mutual contradiction. In this last respect, however, there is a distinction between the construction of a dream and of a symptom. For in dream-formation the preconscious purpose is merely concerned to preserve sleep, to allow nothing that would disturb it to make its way into consciousness; it does not insist upon calling out sharply 'No! on the contrary!' to the unconscious wishful impulse. It can afford to be more tolerant because the situation of someone sleeping is less perilous. The state of sleep in itself bars any outlet into reality.

[1916-1917, 3418]
Of course, the sexual abstinence now so warmly recommended by doctors only has the same importance in generating anxiety states when the libido which is prevented from finding a satisfying discharge is correspondingly strong and has not been dealt with for the greater part by sublimation. Indeed, the decision on whether the outcome is to be illness or not always lies with quantitative factors. Even where what is in question is not illness but the form assumed by a person's character, it is easy to recognize that sexual restriction goes hand in hand with some kind of anxiousness and hesitancy, while intrepidity and impudent daring bring along with them a free indulgence of sexual needs. However much these relations are altered and complicated by a variety of cultural influences, it nevertheless remains true of the average of mankind that anxiety has a close connection with sexual limitation.

If, then, there are children who come some way to meet this education in anxiety, and who go on to find dangers themselves that they have not been warned against, this is sufficiently explained by the fact that they have a greater amount of innate libidinal need in their constitution or have been prematurely spoiled by libidinal satisfaction. It is not to be wondered at if such children include, too, the later neurotics: as we know, what most facilitates the development of a neurosis is an incapacity to tolerate a considerable damming-up of libido over any great length of time. You will observe that here once more the constitutional factor comes into its rights - and these, indeed, we have never sought to dispute. We are only on our guard against those who in its favour neglect all other claims, and who introduce the constitutional factor at points at which the combined results of observation and analysis show that it does not belong or must take the last place.

Think it over! You have learnt all that is essential about the determinants of falling ill as well as all the factors that come into effect after the patient has fallen ill. Where do these leave room for any therapeutic influence? In the first place there is hereditary disposition. We have not talked about it very often because it is emphatically stressed from other directions and we have nothing new to say about it. But do not suppose that we underestimate it; precisely as therapists we come to realize its power clearly enough. In any case we can do nothing to alter it; we too must take it as something given, which sets a limit to our efforts. Next there is the influence of early experiences in childhood, to which we are in the habit of giving prominence in analysis: they belong to the past and we cannot undo them. Then comes everything that we have summarized as 'real frustration' - the misfortunes of life from which arise deprivation of love, poverty, family quarrels, ill-judged choice of a partner in marriage, unfavourable social circumstances, and the strictness of the ethical standards to whose pressure the individual is subject. Here, to be sure, there would be handles enough for a very effective therapy, but it would have to be of the kind which Viennese folklore attributes to the Emperor Joseph - the benevolent interference of a powerful personage before whose will people bow and difficulties vanish. But who are we, that we should be able to adopt benevolence of this kind as an instrument of our therapy? Poor ourselves and socially powerless, and compelled to earn our livelihood from our medical activity, we are not even in a position to extend our efforts to people without means, as other doctors with other methods of treatment are after all able to do. Our therapy is too time-consuming and too laborious for that to be possible. Perhaps, however, you are clutching at one of the factors I have mentioned and believe that there you have found the point at which our influence can make its attack. If the ethical restrictions demanded by society play a part in the deprivation imposed on the patient, treatment can, after all, give him the courage, or perhaps a direct injunction, to disregard those barriers and achieve satisfaction and recovery while forgoing the fulfilment of an ideal that is exalted, but so often not adhered to, by society. The patient will thus become healthy by 'living a full life' sexually. This, it is true, casts a shadow on analytic treatment for not serving general morality. What it has given to the individual it will have taken from the community.
But you must not conclude from my eagerness in defending myself against the charge that neurotics are encouraged in analytic treatment to live a full life - you must not conclude from this that we influence them in favour of conventional virtue. That is at least as far from being the case. It is true that we are not reformers but merely observers; nevertheless, we cannot help observing with a critical eye and we have found it impossible to side with conventional sexual morality or to form a very high opinion of the manner in which society attempts the practical regulation of the problems of sexual life. We can present society with a blunt calculation that what is described as its morality calls for a bigger sacrifice than it is worth and that its proceedings are not based on honesty and do not display wisdom. We do not keep such criticisms from our patients’ ears, we accustom them to giving unprejudiced consideration to sexual matters no less than to any others; and if, having grown independent after the completion of their treatment, they decide on their own judgement in favour of some midway position between living a full life and absolute asceticism, we feel our conscience clear whatever their choice. We tell ourselves that anyone who has succeeded in educating himself to truth about himself is permanently defended against the danger of immorality, even though his standard of morality may differ in some respect from that which is customary in society. Moreover, we must guard against over-estimating the importance of the part played by the question of abstinence in influencing neuroses. Only in a minority of cases can the pathogenic situation of frustration and the subsequent damming-up of libido be brought to an end by the sort of sexual intercourse that can be procured without much trouble.

[1916-1917, 3477]

With this as a starting-point we go on to make our first important discovery. We learn that, when we try to understand neurotic disorders, by far the greater significance attaches to the sexual instincts; that in fact neuroses are the specific disorders, so to speak, of the sexual function; that in general whether or not a person develops a neurosis depends on the quantity of his libido, and on the possibility of satisfying it and of discharging it through satisfaction; that the form taken by the disease is determined by the way in which the individual passes through the course of development of his sexual function, or, as we put it, by the fixations his libido has undergone in the course of its development; and, further, that by a special, not very simple technique for influencing the mind we are able to throw light on the nature of some groups of neuroses and at the same time to do away with them. Our therapeutic efforts have their greatest success with a certain class of neuroses which proceed from a conflict between the ego-instincts and the sexual instincts. For in human beings it may happen that the demands of the sexual instincts, whose reach of course extends far beyond the individual, seem to the ego to constitute a danger which threatens its self-preservation or its self-esteem. The ego then assumes the defensive, denies the sexual instincts the satisfaction they desire and forces them into those by-paths of substitutive satisfaction which become manifest as nervous symptoms.

[1917a, 3609]
The traumatic neuroses and war neuroses may proclaim too loudly the effects of mortal danger and may be silent or speak only in muted tones of the effects of frustration in love. But, on the other hand, the ordinary transference neuroses of peace-time set no aetiological store by the factor of mortal danger which, in the former class of neuroses, plays so mighty a part. It is even held that the peace-time neuroses are promoted by indulgence, good living and inactivity - which would afford an interesting contrast to the living-conditions under which the war neuroses develop. If they were to follow the example of their opponents, psycho-analysts, finding that their patients had fallen ill owing to frustration in love (owing to the claims of the libido being unsatisfied) would have to maintain that there can be no such things as danger-neuroses or that the disorders that appear after frightening experiences are not neuroses. They have, of course, no notion of maintaining any such thing. On the contrary, a convenient possibility occurs to them of bringing the two apparently divergent sets of facts together under a single hypothesis. In traumatic and war neuroses the human ego is defending itself from a danger which threatens it from without or which is embodied in a shape assumed by the ego itself. In the transference neuroses of peace the enemy from which the ego is defending itself is actually the libido, whose demands seem to it to be menacing. In both cases the ego is afraid of being damaged - in the latter case by the libido and in the former by external violence. It might, indeed, be said that in the case of the war neuroses, in contrast to the pure traumatic neuroses and in approximation to the transference neuroses, what is feared is nevertheless an internal enemy. The theoretical difficulties standing in the way of a unifying hypothesis of this kind do not seem insuperable: after all, we have a perfect right to describe repression, which lies at the basis of every neurosis, as a reaction to a trauma - as an elementary traumatic neurosis.

[1919d, 3668]

In a far greater number of cases the neurosis is more autonomous and more independent of the interests of self-preservation and self-maintenance. In the conflict which creates the neurosis, what are at stake are either solely libidinal interests or libidinal interests in intimate connections with self-preservative ones. In all three instances the dynamics of the neurosis are the same. A dammed-up libido which cannot be satisfied in reality succeeds, with the help of a regression to old fixations, in finding discharge through the repressed unconscious. The sick man's ego, in so far as it can extract a 'gain from illness' out of this process, countenances the neurosis, although there can be no doubt of its injuriousness in its economic aspect.

[1923d, 4027]
This state of affairs is enough to account for the reluctant and hesitant reception of analysis in scientific quarters. But it does not explain the outbursts of indignation, derision and scorn which, in disregard of every standard of logic and good taste, have characterized the controversial methods of its opponents. A reaction of such a kind suggests that resistances other than purely intellectual ones were stirred up and that powerful emotional forces were aroused. And there are indeed plenty of things to be found in the theory of psycho-analysis calculated to produce such an effect as this upon the passions of men of every kind and not of scientists alone. Above all there is the very important place in the mental life of human beings which psycho-analysis assigns to what are known as the sexual instincts. Psycho-analytic theory maintained that the symptoms of neuroses are distorted substitutive satisfactions of sexual instinctual forces, the direct satisfaction of which has been frustrated by internal resistances. Later on, when analysis had extended beyond its original field of work and began to be applied to normal mental life, it sought to show that these same sexual components, which could be diverted from their immediate aims and directed to other things, made the most important contributions to the cultural achievements of the individual and of society. These views were not entirely new. The incomparable significance of sexual life had been proclaimed by the philosopher Schopenhauer in an intensely impressive passage. Moreover, what psycho-analysis called sexuality was by no means identical with the impulsion towards a union of the two sexes or towards producing a pleasurable sensation in the genitals; it had far more resemblance to the all-inclusive and all-preserving Eros of Plato's *Symposium*.

[1925e, 4125]

Psycho-analytic work has shown us that it is precisely these frustrations of sexual life which people known as neurotics cannot tolerate. The neurotic creates substitutive satisfactions for himself in his symptoms, and these either cause him suffering in themselves or become sources of suffering for him by raising difficulties in his relations with his environment and the society he belongs to. The latter fact is easy to understand; the former presents us with a new problem. But civilization demands other sacrifices besides that of sexual satisfaction.

[1930a, 4500]
I will now attempt to discover whether the aetiological conditions for anxiety neurosis which I set out above exhibit the common character that I have just attributed to them. The first aetiological factor I postulated for men was intentional abstinence. Abstinence consists in the withholding of the specific action which ordinarily follows upon libido. Such withholding may have two consequences. In the first place, the somatic excitation accumulates; it is then deflected into other paths, which hold out greater promise of discharge than does the path through the psyche. Thus the libido will in the end sink, and the excitation will manifest itself subcortically as anxiety. In the second place, if the libido is not diminished, or if the somatic excitation is expended, by a short cut, in emissions, or if, in consequence of being forced back, the excitation really ceases, then all kinds of things other than an anxiety neurosis will ensue. Abstinence, then, leads to anxiety neurosis in the manner described above. But it is also the operative agent in my second aetiological group, that of unconsummated excitation. My third group, that of coitus reservatus with consideration for the woman, operates by disturbing the man's psychical preparedness for the sexual process, in that it introduces alongside of the task of mastering the sexual affect another psychical task, one of a deflecting sort. In consequence of this psychical deflection, once more, libido gradually disappears, and the further course of things is then the same as in the case of abstinence. Anxiety in senescence (the male climacteric) requires another explanation. Here there is no diminution of libido; but, as in the female climacteric, so great an increase occurs in the production of somatic excitation that the psyche proves relatively insufficient to master it.

The aetiological conditions applying to women can be brought into the framework of my scheme with no greater difficulties than in the case of men. Virginal anxiety is a particularly clear example. For here the groups of ideas to which the somatic sexual excitation should become attached are not yet enough developed. In the newly-married woman who is anaesthetic, anxiety only appears if the first cohabitations arouse a sufficient amount of somatic excitation. When the local indications of such excitement (spontaneous sensations of stimulation, desire to micturate and so on) are lacking, anxiety is also absent. The case of ejaculatio praecox and of coitus interruptus can be explained on the same lines as in men, namely that the libidinal desire for the psychically unsatisfying act gradually disappears, while the excitation which has been aroused during the act is expended subcortically. The alienation between the somatic and the psychical sphere is established more readily and is more difficult to remove in women than in men. The cases of widowhood and of voluntary abstinence, and also that of the climacteric, are dealt with in the same way in both sexes; but where abstinence is concerned there is in the case of women no doubt the further matter of intentional repression of the sexual circle of ideas, to which an abstinent woman, in her struggle against temptation, must often make up her mind. The horror which, at the time of the menopause, an ageing woman feels at her unduly increased libido may act in a similar sense.
Against Löwenfeld's further assertion - that anxiety-states only appear under certain conditions and fail to appear when those conditions are avoided, regardless of what the subject's *vita sexualis* may be - it must be pointed out that he clearly has in mind here only the anxiety of phobias, as, indeed, is shown by the examples attached to the passage I have quoted. He says nothing at all about the spontaneous anxiety attacks which take the form of vertigo, palpitation, dyspnoea, trembling, sweating, and so on. My theory, on the contrary, seems by no means unequal to explaining the emergence or non-emergence of these attacks of anxiety. For in a whole number of such cases of anxiety neurosis there does in fact appear to be a periodicity in the emergence of the states of anxiety, similar to what has been observed in epilepsy, except that in the latter the mechanism of the periodicity is more transparent. On closer examination we discover the presence, with great regularity, of an excitatory sexual process (that is, a process which is able to generate somatic sexual tension), and which, after the lapse of a definite and often constant interval of time, is followed by the anxiety attack. This role is played, in abstinent women, by menstrual excitation; it is played, too, by nocturnal pollutions, which also recur periodically. Above all, it is played by sexual intercourse itself (harmful from its being incomplete), which carries over its own periodicity to the effects it brings about, viz. to the anxiety attacks. If anxiety attacks occur which break through the usual periodicity, it is generally possible to trace them back to an incidental cause of rare and irregular occurrence - to a single sexual experience, something read or seen, and the like. The interval I have mentioned varies from a few hours to two days; it is the same as that which elapses in other people between the occurrence of the same causes and the onset of the well-known sexual migraine, which has well-established connections with the syndrome of anxiety neurosis. [1895f, 361]

The fact that the sexual instinct behaves in general in a self-willed and inflexible fashion is also seen in the results produced by efforts at abstinence. Civilized education may only attempt to suppress the instinct temporarily, till marriage, intending to give it free rein afterwards with the idea of then making use of it. But extreme measures are more successful against it than attempts at moderating it; thus the suppression often goes too far, with the unwished-for result that when the instinct is set free it turns out to be permanently impaired. For this reason complete abstinence in youth is often not the best preparation for marriage for a young man. Women sense this, and prefer among their suitors those who have already proved their masculinity with other women. The harmful results which the strict demand for abstinence before marriage produces in women's natures are quite especially apparent. It is clear that education is far from underestimating the task of suppressing a girl's sensuality till her marriage, for it makes use of the most drastic measures. Not only does it forbid sexual intercourse and set a high premium on the preservation of female chastity, but it also protects the young woman from temptation as she grows up, by keeping her ignorant of all the facts of the part she is to play and by not tolerating any impulse of love in her which cannot lead to marriage. The result is that when the girl's parental authorities suddenly allow her to fall in love, she is unequal to this psychical achievement and enters marriage uncertain of her own feelings. In consequence of this artificial retardation in her function of love, she has nothing but disappointments to offer the man who has saved up all his desire for her. In her mental feelings she is still attached to her parents, whose authority has brought about the suppression of her sexuality; and in her physical behaviour she shows herself frigid, which deprives the man of any high degree of sexual enjoyment. I do not know whether the anaesthetic type of woman exists apart from civilized education, though I consider it probable. But in any case such education actually breeds it, and these women who conceive without pleasure show little willingness afterwards to face the pains of frequent childbirth. In this way, the preparation for marriage frustrates the aims of marriage itself. When later on the retardation in the wife's development has been overcome and her capacity to love is awakened at the climax of her life as a woman, her relations to her husband have long since been ruined; and, as a reward for her previous docility, she is left with the choice between unappeased desire, unfaithfulness or a neurosis. [1908d, 1959]
A powerful wave of repression brought this childhood excess to an end, and established the dispositions which were to become manifest in the years of puberty. The most obvious result of the transformation was the avoidance of every crudely sensual activity; Leonardo was enabled to live in abstinence and to give the impression of being an asexual human being. When the excitations of puberty came in their flood upon the boy they did not, however, make him ill by forcing him to develop substitutive structures of a costly and harmful kind. Owing to his very early inclination towards sexual curiosity the greater portion of the needs of his sexual instinct could be sublimated into a general urge to know, and thus evaded repression. A much smaller portion of his libido continued to be devoted to sexual aims and represented a stunted adult sexual life. Because his love for his mother had been repressed, this portion was driven to take up a homosexual attitude and manifested itself in ideal love for boys. The fixation on his mother and on the blissful memories of his relations with her continued to be preserved in the unconscious, but for the time being it remained in an inactive state. In this way repression, fixation and sublimation all played their part in disposing of the contributions which the sexual instinct made to Leonardo's mental life.

At the summit of his life, when he was in his early fifties - a time when in women the sexual characters have already undergone involution and when in men the libido not infrequently makes a further energetic advance - a new transformation came over him. Still deeper layers of the contents of his mind became active once more: but this further regression was to the benefit of his art, which was in the process of becoming stunted. He met the woman who awakened his memory of his mother's happy smile of sensual rapture; and, influenced by this revived memory, he recovered the stimulus that guided him at the beginning of his artistic endeavours, at the time when he modelled the smiling women. He painted the Mona Lisa, the 'St. Anne with Two Others' and the series of mysterious pictures which are characterized by the enigmatic smile. With the help of the oldest of all his erotic impulses he enjoyed the triumph of once more conquering the inhibition in his art. This final development is obscured from our eyes in the shadows of approaching age. Before this his intellect had soared upwards to the highest realizations of a conception of the world that left his epoch far behind it.

The question of why this outburst of homosexual libido overtook the patient precisely at this period (that is, between the dates of his appointment and of his move to Dresden) cannot be answered in the absence of more precise knowledge of the story of his life. Generally speaking, every human being oscillates all through his life between heterosexual and homosexual feelings, and any frustration or disappointment in the one direction is apt to drive him over into the other. We know nothing of these factors in Schreber's case, but we must not omit to draw attention to a somatic factor which may very well have been relevant. At the time of this illness Dr. Schreber was fifty-one years old, and he had therefore reached an age which is of critical importance in sexual life. It is a period at which in women the sexual function, after a phase of intensified activity, enters upon a process of far-reaching involution; nor do men appear to be exempt from its influence, for men as well as women are subject to a 'climacteric' and to the susceptibilities to disease which go along with it.
(d) Just as the third type has brought the dispositional determinant before us almost in isolation, so the fourth type, which now follows, draws our attention to another factor, which comes into consideration in every single case and might easily for that very reason be overlooked in a theoretical discussion. We see people fall ill who have hitherto been healthy, who have met with no fresh experience and whose relation to the external world has undergone no change, so that the onset of their illness inevitably gives an impression of spontaneity. A closer consideration of such cases, however, shows us that none the less a change has taken place in them whose importance we must rate very highly as a cause of illness. As a result of their having reached a particular period of life, and in conformity with regular biological processes, the quantity of libido in their mental economy has experienced an increase which is in itself enough to upset the equilibrium of their health and to set up the necessary conditions for a neurosis. It is well known that more or less sudden increases of libido of this kind are habitually associated with puberty and the menopause - with the attainment of a certain age in women; in some people they may in addition be manifested in periodicities that are still unknown. Here the damming-up of libido is the primary factor; it becomes pathogenic as a consequence of a relative frustration on the part of the external world, which would still have granted satisfaction to a smaller claim by the libido. The unsatisfied and dammed-up libido can once again open up paths to regression and kindle the same conflicts which we have demonstrated in the case of absolute external frustration. We are reminded in this way that the quantitative factor should not be left out of account in any consideration of the precipitating causes of illness. All the other factors - frustration, fixation, developmental inhibition - remain ineffective unless they affect a certain amount of libido and bring about a damming-up of libido of a certain height. It is true that we are unable to measure this amount of libido which seems to us indispensable for a pathogenic effect; we can only postulate it after the resulting illness has started. There is only one direction in which we can determine it more precisely. We may assume that it is not a question of an absolute quantity, but of the relation between the quota of libido in operation and the quantity of libido which the individual ego is able to deal with - that is, to hold under tension, to sublimate or to employ directly. For this reason a relative increase in the quantity of libido may have the same effects as an absolute one. An enfeeblement of the ego owing to organic illness or owing to some special demand upon its energy will be able to cause the emergence of neuroses which would otherwise have remained latent in spite of any disposition that might be present.

[1912c, 2563]
Naturally this does not answer all the questions that we might ask in connection with this case. On the contrary, the case bristles with further problems—some that have in general not yet become soluble and others which could not be solved owing to the particular circumstances being unfavourable. For instance, why did this lady who was happily married fall in love with her son-in-law? and why did the relief, which might have been possible in other ways, take the form of this mirror-image this projection of her state on to her husband? You must no: think it is otiose or frivolous to raise such questions. We already have some material at our disposal which might possibly serve to answer them. The lady was at a critical age, at which sexual needs in women suffer a sudden and undesired increase; that alone might account for the event. Or it may further have been that her excellent and faithful husband had for some years no longer enjoyed the sexual capacity which the well-preserved woman required for her satisfaction. Experience has shown us that it is precisely men in this position, whose faithfulness can consequently be taken for granted, who are distinguished by treating their wives with unusual tenderness, and by showing particular forbearance for their nervous troubles. Or, again, it may not be without significance that the object of this pathogenic love was precisely the young husband of one of her daughters. A powerful erotic tie with a daughter, which goes back in the last resort to the mother's sexual constitution, often finds a way of persisting in a transformation of this sort. In this connection I may perhaps remind you that the relation between mother-in-law and son-in-law has been regarded from the earliest times of the human race as a particularly awkward one and that among primitive people it has given rise to very powerful taboo regulations and 'avoidances'. The relation is frequently excessive by civilized standards both in a positive and negative direction. Which of these three factors became operative in our case, or whether two of them or perhaps all three came together, I cannot, it is true, tell you; but that is only because I was not permitted to continue the analysis of the case for more than two sessions.

I am far from having told you of all the observations that speak in favour of the genetic relation I have asserted to exist between libido and anxiety. Among them, for instance, is the influence on anxiety disorders of certain phases of life to which, as in the case of puberty and the time of the menopause, a considerable increase in the production of libido may be attributed. In some states of excitement, too, it is possible to observe directly a mixture of libido and anxiety and the final replacement of libido by anxiety. The impression one gains from all these facts is twofold: first, that what is in question is an accumulation of libido which is kept away from its normal employment, and secondly, that here we are entirely in the sphere of somatic processes. How anxiety arises from libido is not at first discernible; we can only recognize that libido is absent and that anxiety is observed in its place.

But if the relative feebleness of the ego is the decisive factor for the genesis of a neurosis, it must also be possible for a later physical illness to produce a neurosis, provided that it can bring about an enfeeblement of the ego. And that, once again, is very frequently found. A physical disorder of this kind can affect the instinctual life in the id and increase the strength of the instincts beyond the limit up to which the ego is capable of coping with them. The normal model of such processes is perhaps the alteration in women caused by the disturbances of menstruation and the menopause. Or again, a general somatic illness, indeed an organic disease of the nervous central organ, may attack the nutritional conditions of the mental apparatus and compel it to reduce its functioning and to bring to a halt its more delicate workings, one of which is the maintenance of the ego organization. In all these cases approximately the same picture of neurosis emerges; neurosis always has the same psychological mechanism, but, as we see, a most varied and often very complex aetiology.
And now let us enquire about latency, which, in view of the analogy, is bound to interest us especially. A trauma in childhood may be followed immediately by a neurotic outbreak, an infantile neurosis, with an abundance of efforts at defence, and accompanied by the formation of symptoms. This neurosis may last a considerable time and cause marked disturbances, but it may also run a latent course and be overlooked. As a rule defence retains the upper hand in it; in any case alterations of the ego, comparable to scars, are left behind. It is only rarely that an infantile neurosis continues without interruption into an adult one. Far more often it is succeeded by a period of apparently undisturbed development - a course of things which is supported or made possible by the intervention of the physiological period of latency. Not until later does the change take place with which the definitive neurosis becomes manifest as a belated effect of the trauma. This occurs either at the irruption of puberty or some while later. In the former case it happens because the instincts, intensified by physical maturation, are able now to take up the struggle again in which they were at first defeated by the defence. In the latter case it happens because the reactions and alterations of the ego brought about by the defence now prove a hindrance in dealing with the new tasks of life, so that severe conflicts come about between the demands of the real external world and the ego, which seeks to maintain the organization which it has painstakingly achieved in its defensive struggle. The phenomenon of a latency of the neurosis between the first reactions to the trauma and the later outbreak of the illness must be regarded as typical. This latter illness may also be looked upon as an attempt at cure - as an effort once more to reconcile with the rest those portions of the ego that have been split off by the influence of the trauma and to unite them into a powerful whole vis-à-vis the external world. An attempt of this kind seldom succeeds, however, unless the work of analysis comes to its help, and even then not always; it ends often enough in a complete devastation or fragmentation of the ego or in its being overwhelmed by the portion which was early split off and which is dominated by the trauma.

The repressed retains its upward urge, its effort to force its way to consciousness. It achieves its aim under three conditions: (1) if the strength of the anticathexis is diminished by pathological processes which overtake the other part, what we call the ego, or by a different distribution of the cathetic energies in that ego, as happens regularly in the state of sleep; (2) if the instinctual elements attaching to the repressed receive a special reinforcement (of which the best example is the processes during puberty); and (3) if at any time in recent experience impressions or experiences occur which resemble the repressed so closely that they are able to awaken it. In the last case the recent experience is reinforced by the latent energy of the repressed, and the repressed comes into operation behind the recent experience and with its help. In none of these three alternatives does what has hitherto been repressed enter consciousness smoothly and unaltered; it must always put up with distortions which testify to the influence of the resistance (not entirely overcome) arising from the anticathexis, or to the modifying influence of the recent experience or to both.
Of the three factors which we have recognized as being decisive for the success or otherwise of analytic treatment - the influence of traumas, the constitutional strength of the instincts and alterations of the ego - what concerns us here is only the second, the strength of the instincts. A moment's reflection raises a doubt whether the restrictive use of the adjective 'constitutional' (or 'congenital') is essential. However true it may be that the constitutional factor is of decisive importance from the very beginning, it is nevertheless conceivable that a reinforcement of instinct coming later in life might produce the same effects. If so, we should have to modify our formula and say 'the strength of the instincts at the time' instead of 'the constitutional strength of the instincts'. The first of our questions was: 'Is it possible by means of analytic therapy to dispose of a conflict between an instinct and the ego, or of a pathogenic instinctual demand upon the ego, permanently and definitively?' To avoid misunderstanding it is not unnecessary, perhaps, to explain more exactly what is meant by 'permanently disposing of an instinctual demand'. Certainly not 'causing the demand to disappear so that nothing more is ever heard from it again'. This is in general impossible, nor is it at all to be desired. No, we mean something else, something which may be roughly described as a 'taming' of the instinct. That is to say, the instinct is brought completely into the harmony of the ego, becomes accessible to all the influences of the other trends in the ego and no longer seeks to go its independent way to satisfaction. If we are asked by what methods and means this result is achieved, it is not easy to find an answer. We can only say: 'So muss denn doch die Hexe dran!' - the Witch Metapsychology. Without metapsychological speculation and theorizing - I had almost said 'phantasying' - we shall not get another step forward. Unfortunately, here as elsewhere, what our Witch reveals is neither very clear nor very detailed. We have only a single clue to start from - though it is a clue of the highest value - namely, the antithesis between the primary and the secondary processes; and to that antithesis I shall at this point turn.

The material on the other side is equally unambiguous. Twice in the course of individual development certain instincts are considerably reinforced: at puberty, and, in women, at the menopause. We are not in the least surprised if a person who was not neurotic before becomes so at these times. When his instincts were not so strong, he succeeded in taming them; but when they are reinforced he can no longer do so. The repressions behave like dams against the pressure of water. The same effects which are produced by these two physiological reinforcements of instinct, may be brought about in an irregular fashion by accidental causes at any other period of life. Such reinforcements may be set up by fresh traumas, enforced frustrations, or the collateral influence of instincts upon one another. The result is always the same, and it underlines the irresistible power of the quantitative factor in the causation of illness.

We started from the question of how we can shorten the inconveniently long duration of analytic treatment, and, still with this question of time in mind, we went on to consider whether it is possible to achieve a permanent cure or even to prevent future illness by prophylactic treatment. In doing so, we found that the factors which were decisive for the success of our therapeutic efforts were the influence of traumatic aetiology, the relative strength of the instincts which have to be controlled, and something which we have called an alteration of the ego. Only the second of these factors has been discussed by us in any detail, and in connection with it we have had occasion to recognize the paramount importance of the quantitative factor and to stress the claim of the metapsychological line of approach to be taken into account in any attempt at explanation.
The reproaches against her father for having made her ill, together with the self-reproach underlying them, the leucorrhoea, the playing with the reticule, the bed-wetting after her sixth year, the secret which she would not allow the doctors to tear from her - the circumstantial evidence of her having masturbated in childhood seems to me complete and without a flaw. In the present case I had begun to suspect the masturbation when she had told me of her cousin's gastric pains, and had then identified herself with her by complaining for days together of similar painful sensations. It is well known that gastric pains occur especially often in those who masturbate. According to a personal communication made to me by Wilhelm Fliess, it is precisely gastralgias of this character which can be interrupted by an application of cocaine to the 'gastric spot' discovered by him in the nose, and which can be cured by the cauterization of the same spot. In confirmation of my suspicion Dora gave me two facts from her conscious knowledge: she herself had frequently suffered from gastric pains, and she had good reasons for believing that her cousin was a masturbator. It is a very common thing for patients to recognize in other people a connection which, on account of their emotional resistances, they cannot perceive in themselves. And, indeed, Dora no longer denied my supposition, although she still remembered nothing. Even the date which she assigned to the bed-wetting, when she said that it lasted 'till a short time before the appearance of the nervous asthma', appears to me to be of clinical significance. Hysterical symptoms hardly ever appear so long as children are masturbating, but only afterwards, when a period of abstinence has set in;¹ they form a substitute for masturbatory satisfaction, the desire for which continues to persist in the unconscious until another and more normal kind of satisfaction appears - where that is still attainable. For upon whether it is still attainable or not depends the possibility of a hysteria being cured by marriage and normal sexual intercourse. But if the satisfaction afforded in marriage is again removed - as it may be owing to coitus interruptus, psychological estrangement, or other causes - then the libido flows back again into its old channel and manifests itself once more in hysterical symptoms.

[1905e, 1415]

At this juncture another remark is perhaps not out of place. I know that the emphasis which I lay upon the part played by sexuality in creating the psychoneuroses has become generally known. But I know, too, that qualifications and exact particularization are of little use with the general public; there is very little room in the memory of the multitude; it only retains the bare gist of any thesis and fabricates an extreme version which is easy to remember. It may be, too, that some physicians vaguely apprehend the content of my doctrine to be that I regard sexual privation as the ultimate cause of the neuroses. In the conditions of life in modern society there is certainly no lack of sexual privation. On this basis, would it not be simpler to aim directly at recovery by recommending sexual activity as a therapeutic measure, instead of pursuing the circuitous and laborious path of mental treatment? (I know of nothing which could impel me to suppress such an inference if it were justified. The real state of things, however, is otherwise. Sexual need and privation are merely one factor at work in the mechanism of neurosis; if there were no others the result would be dissipation, not disease. The other, no less essential, factor, which is all too readily forgotten, is the neurotic's aversion from sexuality, his incapacity for loving, that feature of the mind which I have called 'repression'. Not until there is a conflict between the two tendencies does nervous illness break out, and therefore to advise sexual activity in the psychoneuroses can only very rarely be described as good advice.

[1905a, 1572]
The answer to the first question touches on a problem which has often been discussed and cannot be exhaustively treated here - that of sexual abstinence. Our third stage of civilization demands of individuals of both sexes that they shall practise abstinence until they are married and that all who do not contract a legal marriage shall remain abstinent throughout their lives. The position, agreeable to all the authorities, that sexual abstinence is not harmful and not difficult to maintain, has also been widely supported by the medical profession. It may be asserted, however, that the task of mastering such a powerful impulse as that of the sexual instinct by any other means than satisfying it is one which can call for the whole of a man's forces. Mastering it by sublimation, by deflecting the sexual instinctual forces away from their sexual aim to higher cultural aims, can be achieved by a minority and then only intermittently, and least easily during the period of ardent and vigorous youth. Most of the rest become neurotic or are harmed in one way or another. Experience shows that the majority of the people who make up our society are constitutionally unfit to face the task of abstinence. Those who would have fallen ill under milder sexual restrictions fall ill all the more readily and more severely before the demands of our cultural sexual morality of to-day; for we know no better safe-guard against the threat to normal sexual life offered by defective innate dispositions or disturbances of development than sexual satisfaction itself. The more a person is disposed to neurosis, the less can he tolerate abstinence; instincts which have been withdrawn from normal development, in the sense in which it has been described above, become at the same time all the more uninhibitable. But even those people who would have retained their health under the requirements of the second stage of civilization will now succumb to neurosis in great numbers. For the psychical value of sexual satisfaction increases with its frustration. The dammed-up libido is now put in a position to detect one or other of the weaker spots which are seldom absent in the structure of sexual life, and there to break through and obtain substitutive satisfaction of a neurotic kind in the form of pathological symptoms. Anyone who is able to penetrate the determinants of nervous illness will soon become convinced that its increase in our society arises from the intensification of sexual restrictions.

[1908d, 1956]

The fact that the curb put upon love by civilization involves a universal tendency to debase sexual objects will perhaps lead us to turn our attention from the object to the instincts themselves. The damage caused by the initial frustration of sexual pleasure is seen in the fact that the freedom later given to that pleasure in marriage does not bring full satisfaction. But at the same time, if sexual freedom is unrestricted from the outset the result is no better. It can easily be shown that the psychical value of erotic needs is reduced as soon as their satisfaction becomes easy. An obstacle is required in order to heighten libido; and where natural resistances to satisfaction have not been sufficient men have at all times erected conventional ones so as to be able to enjoy love. This is true both of individuals and of nations. In times in which there were no difficulties standing in the way of sexual satisfaction, such as perhaps during the decline of the ancient civilizations, love became worthless and life empty, and strong reaction-formations were required to restore indispensable affective values. In this connection it may be claimed that the ascetic current in Christianity created psychical values for love which pagan antiquity was never able to confer on it. This current assumed its greatest importance with the ascetic monks, whose lives were almost entirely occupied with the struggle against libidinal temptation.

[1912d, 2344]
The question of why this outburst of homosexual libido overtook the patient precisely at this period (that is, between the dates of his appointment and of his move to Dresden) cannot be answered in the absence of more precise knowledge of the story of his life. Generally speaking, every human being oscillates all through his life between heterosexual and homosexual feelings, and any frustration or disappointment in the one direction is apt to drive him over into the other. We know nothing of these factors in Schreber's case, but we must not omit to draw attention to a somatic factor which may very well have been relevant. At the time of this illness Dr. Schreber was fifty-one years old, and he had therefore reached an age which is of critical importance in sexual life. It is a period at which in women the sexual function, after a phase of intensified activity, enters upon a process of far-reaching involution; nor do men appear to be exempt from its influence, for men as well as women are subject to a 'climacteric' and to the susceptibilities to disease which go along with it.¹

In my *Three Essays on the Theory of Sexuality* I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics *endeavour to protect themselves against any such sexualization of their social instinctual cathexes*, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) *schizophrenia*; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.

Thus with this type, to which, no doubt, the majority of human beings on the whole belong, the possibility of falling ill arises only when there is abstinence. And it may be judged from this what an important part in the causation of neuroses may be played by the limitation imposed by civilization on the field of accessible satisfactions. Frustration has a pathogenic effect because it dams up libido, and so submits the subject to a test as to how long he can tolerate this increase in psychical tension and as to what methods he will adopt for dealing with it. There are only two possibilities for remaining healthy when there is a persistent frustration of satisfaction in the real world. The first is by transforming the psychical tension into active energy which remains directed towards the external world and eventually extorts a real satisfaction of the libido from it. The second is by renouncing libidinal satisfaction, sublimating the dammed-up libido and turning it to the attainment of aims which are no longer erotic and which escape frustration. That these two possibilities are realized in men's lives proves that unhappiness does not coincide with neurosis and that frustration does not alone decide whether its victim remains healthy or falls ill. The immediate effect of frustration lies in its bringing into play the dispositional factors which have hitherto been inoperative.
(d) Just as the third type has brought the dispositional determinant before us almost in isolation, so the fourth type, which now follows, draws our attention to another factor, which comes into consideration in every single case and might easily for that very reason be overlooked in a theoretical discussion. We see people fall ill who have hitherto been healthy, who have met with no fresh experience and whose relation to the external world has undergone no change, so that the onset of their illness inevitably gives an impression of spontaneity. A closer consideration of such cases, however, shows us that none the less a change has taken place in them whose importance we must rate very highly as a cause of illness. As a result of their having reached a particular period of life, and in conformity with regular biological processes, the quantity of libido in their mental economy has experienced an increase which is in itself enough to upset the equilibrium of their health and to set up the necessary conditions for a neurosis. It is well known that more or less sudden increases of libido of this kind are habitually associated with puberty and the menopause - with the attainment of a certain age in women; in some people they may in addition be manifested in periodicities that are still unknown. Here the damming-up of libido is the primary factor; it becomes pathogenic as a consequence of a relative frustration on the part of the external world, which would still have granted satisfaction to a smaller claim by the libido. The unsatisfied and dammed-up libido can once again open up paths to regression and kindle the same conflicts which we have demonstrated in the case of absolute external frustration. We are reminded in this way that the quantitative factor should not be left out of account in any consideration of the precipitating causes of illness. All the other factors - frustration, fixation, developmental inhibition - remain ineffective unless they affect a certain amount of libido and bring about a damming-up of libido of a certain height. It is true that we are unable to measure this amount of libido which seems to us indispensable for a pathogenic effect; we can only postulate it after the resulting illness has started. There is only one direction in which we can determine it more precisely. We may assume that it is not a question of an absolute quantity, but of the relation between the quota of libido in operation and the quantity of libido which the individual ego is able to deal with - that is, to hold under tension, to sublimate or to employ directly. For this reason a relative increase in the quantity of libido may have the same effects as an absolute one. An enfeeblement of the ego owing to organic illness or owing to some special demand upon its energy will be able to cause the emergence of neuroses which would otherwise have remained latent in spite of any disposition that might be present.

[1912c, 2563]

We see that, if we follow up this line of thought, we come up against the problem not only of hypochondria, but of the other 'actual' neuroses - neurasthenia and anxiety neurosis. Let us therefore stop at this point. It is not within the scope of a purely psychological inquiry to penetrate so far behind the frontiers of physiological research. I will merely mention that from this point of view we may suspect that the relation of hypochondria to paraphrenia is similar to that of the other 'actual' neuroses to hysteria and obsessional neurosis: we may suspect, that is, that it is dependent on ego-libido just as the others are on object-libido, and that hypochondriacal anxiety is the counterpart, as coming from ego-libido, to neurotic anxiety. Further, since we are already familiar with the idea that the mechanism of falling ill and of the formation of symptoms in the transference neuroses - the path from introversion to regression - is to be linked to a damming-up of object-libido,¹ we may come to closer quarters with the idea of a damming-up of ego-libido as well and may bring this idea into relation with the phenomena of hypochondria and paraphrenia.

[1914c, 2940]
We have recognized our mental apparatus as being first and foremost a device designed for mastering excitations which would otherwise be felt as distressing or would have pathogenic effects. Working them over in the mind helps remarkably towards an internal draining away of excitations which are incapable of direct discharge outwards, or for which such a discharge is for the moment undesirable. In the first instance, however, it is a matter of indifference whether this internal process of working-over is carried out upon real or imaginary objects. The difference does not appear till later - if the turning of the libido on to unreal objects (introversion) has led to its being dammed up. In paraphrenics, megalomania allows of a similar internal working-over of libido which has returned to the ego; perhaps it is only when the megalomania fails that the damming-up of libido in the ego becomes pathogenic and starts the process of recovery which gives us the impression of being a disease.

[1914c, 2940]

Psycho-analysis is able to show us other things as well which are important for understanding the effects of repression in the psychoneuroses. It shows us, for instance, that the instinctual representation develops with less interference and more profusely if it is withdrawn by repression from conscious influence. It proliferates in the dark, as it were, and takes on extreme forms of expression, which when they are translated and presented to the neurotic are not only bound to seem alien to him, but frighten him by giving him the picture of an extraordinary and dangerous strength of instinct. This deceptive strength of instinct is the result of an uninhibited development in phantasy and of the damming-up consequent on frustrated satisfaction. The fact that this last result is bound up with repression points the direction in which the true significance of repression has to be looked for.

[1915d, 2980]

I should not have much difficulty in giving you a far more intimate picture of the relations between perversion and neurosis; but I think what I have already said will serve our purpose. We must however guard against being misled by what I have told you of the meaning of symptoms into over-estimating the frequency and intensity of people's perverse inclinations. It is possible, as you have heard, to fall ill of a neurosis as a result of a frustration of normal sexual satisfaction. But when a real frustration like this occurs, the need moves over on to abnormal methods of sexual excitation. You will later learn the way in which this happens. But in any case you will realize that as a result of this 'collateral' damming-back the perverse impulses must emerge more strongly than they would have if normal sexual satisfaction had met with no obstacle in the real world. Moreover a similar influence is to be recognized also as affecting the manifest perversions. In some cases they are provoked or made active if the normal satisfaction of the sexual instinct encounters too great difficulties for temporary reasons or because of permanent social regulations. In other cases, it is true, the inclination to perversions is quite independent of such favouring conditions; they are, we might say, the normal species of sexual life for those particular individuals.

[1916-1917, 3381]

I hope to be able to give you adequate replies to these questions, even though the replies may be reduced to schematic dimensions. The conflict is conjured up by frustration, as a result of which the libido, deprived of satisfaction, is driven to look for other objects and paths. The necessary precondition of the conflict is that these other paths and objects arouse displeasure in one part of the personality, so that a veto is imposed which makes the new method of satisfaction impossible as it stands. From this point the construction of symptoms pursues its course, which we shall follow later. The repudiated libidinal trends nevertheless succeed in getting their way by certain roundabout paths, though not, it is true, without taking the objection into account by submitting to some distortions and mitigations. The roundabout paths are those taken by the construction of symptoms; the symptoms are the fresh or substitute satisfaction which has become necessary owing to the fact of frustration.
The libido's retreat to phantasy is an intermediate stage on the path to the formation of symptoms and it seem to call for a special name. C. G. Jung coined the very appropriate one of 'introversion', but then most inexpediently gave it another meaning as well. We will continue to take it that introversion denotes the turning away of the libido from the possibilities of real satisfaction and the hypercathexis of phantasies which have hitherto been tolerated as innocent. An introvert is not yet a neurotic, but he is in an unstable situation: he is sure to develop symptoms at the next shift of forces, unless he finds some other outlets for his dammed-up libido. The unreal character of neurotic satisfaction and the neglect of the distinction between phantasy and reality are on the other hand already determined by the fact of lingering at the stage of introversion.

[1916-1917, 3429]

Your second observation, too, raises a justifiable question, but it is aimed in the wrong direction. It is true that a withdrawal of the object-libido into the ego is not directly pathogenic; it takes place, indeed, as we know, every time before we go to sleep, only to be reversed when we wake up. The amoeba withdraws its protrusions only to send them out again at the first opportunity. But it is quite a different thing when a particular, very energetic process forces a withdrawal of libido from objects. Here the libido that has become narcissistic cannot find its way back to objects, and this interference with the libido's mobility certainly becomes pathogenic. It seems that an accumulation of narcissistic libido beyond a certain amount is not tolerated. We may even imagine that it was for that very reason that object-cathexes originally came about, that the ego was obliged to send out its libido so as not to fall ill as a result of its being dammed up. If it lay within our plan to go more deeply into dementia praecox, I would show you that the process which detaches the libido from objects and cuts off its return to them is closely related to the process of repression and is to be looked at as as its counterpart. But you would, first and foremost, find yourselves on familiar ground when you learnt that the determinants of this process are almost identical - so far as we know at present - with those of repression. The conflict seems to be the same and to be carried on between the same forces. If the outcome is so different from, for instance, that in hysteria, the reason can only depend on a difference in innate disposition. The weak spot in the libidinal development of these patients lies in a different phase; the determining fixation, which, as you will recollect, permits the irruption that leads to the formation of symptoms, lies elsewhere, probably in the stage of primitive narcissism to which dementia praecox returns in its final outcome. It is very remarkable that in the case of all the narcissistic neuroses we have to assume fixation points for the libido going back to far earlier phases of development than in hysteria or obsessional neurosis. As you heard, however, the concepts which we arrived at during our study of the transference neuroses are adequate in helping us to find our way about in the narcissistic neuroses which are so much more severe in practice. The conformities go very far; at bottom the field of phenomena is the same. And you can imagine how small a prospect anyone has of explaining these disorders (which belong within the sphere of psychiatry) who is not forearmed for his task with an analytic knowledge of the transference neuroses.

[1916-1917, 3466]
But you must not conclude from my eagerness in defending myself against the charge that neurotics are encouraged in analytic treatment to live a full life - you must not conclude from this that we influence them in favour of conventional virtue. That is at least as far from being the case. It is true that we are not reformers but merely observers; nevertheless, we cannot help observing with a critical eye and we have found it impossible to side with conventional sexual morality or to form a very high opinion of the manner in which society attempts the practical regulation of the problems of sexual life. We can present society with a blunt calculation that what is described as its morality calls for a bigger sacrifice than it is worth and that its proceedings are not based on honesty and do not display wisdom. We do not keep such criticisms from our patients' ears, we accustom them to giving unprejudiced consideration to sexual matters no less than to any others; and if, having grown independent after the completion of their treatment, they decide on their own judgement in favour of some midway position between living a full life and absolute asceticism, we feel our conscience clear whatever their choice. We tell ourselves that anyone who has succeeded in educating himself to truth about himself is permanently defended against the danger of immorality, even though his standard of morality may differ in some respect from that which is customary in society. Moreover, we must guard against over-estimating the importance of the part played by the question of abstinence in influencing neuroses. Only in a minority of cases can the pathogenic situation of frustration and the subsequent damming-up of libido be brought to an end by the sort of sexual intercourse that can be procured without much trouble.

[1916-1917, 3477]

In a far greater number of cases the neurosis is more autonomous and more independent of the interests of self-preservation and self-maintenance. In the conflict which creates the neurosis, what are at stake are either solely libidinal interests or libidinal interests in intimate connections with self-preservation ones. In all three instances the dynamics of the neurosis are the same. A dammed-up libido which cannot be satisfied in reality succeeds, with the help of a regression to old fixations, in finding discharge through the repressed unconscious. The sick man's ego, in so far as it can extract a 'gain from illness' out of this process, countenances the neurosis, although there can be no doubt of its injuriousness in its economic aspect.

[1923d, 4027]
The reproaches against her father for having made her ill, together with the self-reproach underlying them, the leucorrhoea, the playing with the reticule, the bed-wetting after her sixth year, the secret which she would not allow the doctors to tear from her - the circumstantial evidence of her having masturbated in childhood seems to me complete and without a flaw. In the present case I had begun to suspect the masturbation when she had told me of her cousin's gastric pains, and had then identified herself with her by complaining for days together of similar painful sensations. It is well known that gastric pains occur especially often in those who masturbate. According to a personal communication made to me by Wilhelm Flies, it is precisely gastralgias of this character which can be interrupted by an application of cocaine to the 'gastric spot' discovered by him in the nose, and which can be cured by the cauterization of the same spot. In confirmation of my suspicion Dora gave me two facts from her conscious knowledge: she herself had frequently suffered from gastric pains, and she had good reasons for believing that her cousin was a masturbator. It is a very common thing for patients to recognize in other people a connection which, on account of their emotional resistances, they cannot perceive in themselves. And, indeed, Dora no longer denied my supposition, although she still remembered nothing. Even the date which she assigned to the bed-wetting, when she said that it lasted 'till a short time before the appearance of the nervous asthma', appears to me to be of clinical significance. Hysterical symptoms hardly ever appear so long as children are masturbating, but only afterwards, when a period of abstinence has set in;¹ they form a substitute for masturbatory satisfaction, the desire for which continues to persist in the unconscious until another and more normal kind of satisfaction appears - where that is still attainable. For upon whether it is still attainable or not depends the possibility of a hysteria being cured by marriage and normal sexual intercourse. But if the satisfaction afforded in marriage is again removed - as it may be owing to coitus interruptus, psychological estrangement, or other causes - then the libido flows back again into its old channel and manifests itself once more in hysterical symptoms.

¹[1905e, 1415]

**Appearance of New Aims** Every external or internal factor that hinders or postpones the attainment of the normal sexual aim (such as impotence, the high price of the sexual object or the danger of the sexual act) will evidently lend support to the tendency to linger over the preparatory activities and to turn them into new sexual aims that can take the place of the normal one. Attentive examination always shows that even what seem to be the strangest of these new aims are already hinted at in the normal sexual process.

[1905d, 1483]
The preceding discussion may perhaps have placed the sexuality of psychoneurotics in a false light. It may have given the impression that, owing to their disposition, psychoneurotics approximate closely to perverts in their sexual behaviour and are proportionately remote from normal people. It may indeed very well be that the constitutional disposition of these patients (apart from their exaggerated degree of sexual repression and the excessive intensity of their sexual instinct) includes an unusual tendency to perversion, using that word in its widest sense. Nevertheless, investigation of comparatively slight cases shows that this last assumption is not absolutely necessary, or at least that in forming a judgement on these pathological developments there is a factor to be considered which weighs in the other direction. Most psychoneurotics only fall ill after the age of puberty as a result of the demands made upon them by normal sexual life. (It is most particularly against the latter that repression is directed.) Or else illnesses of this kind set in later, when the libido fails to obtain satisfaction along normal lines. In both these cases the libido behaves like a stream whose main bed has become blocked. It proceeds to fill up collateral channels which may hitherto have been empty. Thus, in the same way, what appears to be the strong tendency (though, it is true, a negative one) of psychoneurotics to perversion may be collaterally determined, and must, in any case, be collaterally intensified. The fact is that we must put sexual repression as an internal factor alongside such external factors as limitation of freedom, inaccessibility of a normal sexual object, the dangers of the normal sexual act, etc., which bring about perversions in persons who might perhaps otherwise have remained normal.

[1905d, 1494]

In this respect different cases of neurosis may behave differently: in one case the preponderating factor may be the innate strength of the tendency to perversion, in another it may be the collateral increase of that tendency owing to the libido being forced away from a normal sexual aim and sexual object. It would be wrong to represent as opposition what is in fact a co-operative relation. Neurosis will always produce its greatest effects when constitution and experience work together in the same direction. Where the constitution is a marked one it will perhaps not require the support of actual experiences; while a great shock in real life will perhaps bring about a neurosis even in an average constitution. (Incidentally, this view of the relative aetiological importance of what is innate and what is accidentally experienced applies equally in other fields.)

[1905d, 1494]

The question of why this outburst of homosexual libido overtook the patient precisely at this period (that is, between the dates of his appointment and of his move to Dresden) cannot be answered in the absence of more precise knowledge of the story of his life. Generally speaking, every human being oscillates all through his life between heterosexual and homosexual feelings, and any frustration or disappointment in one direction is apt to drive him over into the other. We know nothing of these factors in Schreber's case, but we must not omit to draw attention to a somatic factor which may very well have been relevant. At the time of this illness Dr. Schreber was fifty-one years old, and he had therefore reached an age which is of critical importance in sexual life. It is a period at which in women the sexual function, after a phase of intensified activity, enters upon a process of far-reaching involution; nor do men appear to be exempt from its influence, for men as well as women are subject to a 'climacteric' and to the susceptibilities to disease which go along with it.¹

[1911c, 2418]
In my *Three Essays on the Theory of Sexuality* I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics *endeavour to protect themselves against any such sexualization of their social instinctual cathexes*, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) *schizophrenia*; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.

I should not have much difficulty in giving you a far more intimate picture of the relations between perversion and neurosis; but I think what I have already said will serve our purpose. We must however guard against being misled by what I have told you of the meaning of symptoms into over-estimating the frequency and intensity of people's perverse inclinations. It is possible, as you have heard, to fall ill of a neurosis as a result of a frustration of normal sexual satisfaction. But when a real frustration like this occurs, the need moves over on to abnormal methods of sexual excitation. You will later learn the way in which this happens. But in any case you will realize that as a result of this 'collateral' damming-back the perverse impulses must emerge more strongly than they would have if normal sexual satisfaction had met with no obstacle in the real world. Moreover a similar influence is to be recognized also as affecting the *manifest* perversions. In some cases they are provoked or made active if the normal satisfaction of the sexual instinct encounters too great difficulties for temporary reasons or because of permanent social regulations. In other cases, it is true, the inclination to perversions is quite independent of such favouring conditions; they are, we might say, the normal species of sexual life for those particular individuals.

For the moment, perhaps, you may have an impression that I have confused rather than explained the relation between normal and perverse sexuality. But you must bear the following consideration in mind. If it is true that increased difficulty in obtaining normal sexual satisfaction in real life, or deprivation of that satisfaction, brings out perverse inclinations in people who had not shown any previously, we must suppose that there was something in these people which came half-way to meet the perversions; or, if you prefer it, the perversions must have been present in them in a latent form.
The preceding discussion may perhaps have placed the sexuality of psychoneurotics in a false light. It may have given the impression that, owing to their disposition, psychoneurotics approximate closely to perverts in their sexual behaviour and are proportionately remote from normal people. It may indeed very well be that the constitutional disposition of these patients (apart from their exaggerated degree of sexual repression and the excessive intensity of their sexual instinct) includes an unusual tendency to perversion, using that word in its widest sense. Nevertheless, investigation of comparatively slight cases shows that this last assumption is not absolutely necessary, or at least that in forming a judgement on these pathological developments there is a factor to be considered which weighs in the other direction. Most psychoneurotics only fall ill after the age of puberty as a result of the demands made upon them by normal sexual life. (It is most particularly against the latter that repression is directed.) Or else illnesses of this kind set in later, when the libido fails to obtain satisfaction along normal lines. In both these cases the libido behaves like a stream whose main bed has become blocked. It proceeds to fill up collateral channels which may hitherto have been empty. Thus, in the same way, what appears to be the strong tendency (though, it is true, a negative one) of psychoneurotics to perversion may be collaterally determined, and must, in any case, be collaterally intensified. The fact is that we must put sexual repression as an internal factor alongside such external factors as limitation of freedom, inaccessibility of a normal sexual object, the dangers of the normal sexual act, etc., which bring about perversions in persons who might perhaps otherwise have remained normal.

In my Three Essays on the Theory of Sexuality I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics endeavour to protect themselves against any such sexualization of their social instinctual cathexes, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) schizophrenia; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.

[1905d, 1494]

[1911c, 2431]
The contradiction between such experiences and the rule that what induces illness is frustration is not insoluble. It disappears if we make a distinction between an external and an internal frustration. If the object in which the libido can find its satisfaction is withheld in reality, this is an external frustration. In itself it is inoperative, not pathogenic, until an internal frustration is joined to it. This latter must proceed from the ego, and must dispute the access by the libido to other objects, which it now seeks to get hold of. Only then does a conflict arise, and the possibility of a neurotic illness, i.e. of a substitutive satisfaction reached circuitously by way of the repressed unconscious. Internal frustration is potentially present, therefore, in every case, only it does not come into operation until external, real frustration has prepared the ground for it. In those exceptional cases in which people are made ill by success, the internal frustration has operated by itself; indeed it has only made its appearance after an external frustration has been replaced by fulfilment of a wish. At first sight there is something strange about this; but on closer consideration we shall reflect that it is not at all unusual for the ego to tolerate a wish as harmless so long as it exists in phantasy alone and seems remote from fulfilment, whereas the ego will defend itself hotly against such a wish as soon as it approaches fulfilment and threatens to become a reality. The distinction between this and familiar situations in neurosis-formation is merely that ordinarily it is internal intensifications of the libidinal cathexis that turn the phantasy, which has hitherto been thought little of and tolerated, into a dreaded opponent; while in these cases of ours the signal for the outbreak of conflict is given by a real external change.
[1916d, 3105]

The meaning of psychical conflict can be adequately expressed in another way by saying that for an external frustration to become pathogenic an internal frustration must be added to it. In that case, of course, the external and internal frustration relate to different paths and objects. The external frustration removes one possibility of satisfaction and the internal frustration seeks to exclude another possibility, about which the conflict then breaks out. I prefer this way of representing the matter because it has a secret content. For it hints at the probability that the internal impediments arose from real external obstacles during the prehistoric periods of human development.
[1916-1917, 3411]
The path to perversion branches off sharply from that to neurosis. If these regressions rouse no objection from the ego, no neurosis will come about either; and the libido will arrive at some real, even though no longer normal, satisfaction. But if the ego, which has under its control not only consciousness but also the approaches to motor innervation and accordingly to the realization of mental desires, does not agree with these regressions, conflict will follow. The libido is, as it were, cut off and must try to escape in some direction where, in accordance with the requirements of the pleasure principle, it can find a discharge for its cathexis of energy. It must withdraw from the ego. An escape of this kind is offered it by the fixations on the path of its development which it has now entered on regressively - fixations from which the ego had protected itself in the past by repressions. By cathecting these repressed positions as it flows backward, the libido has withdrawn from the ego and its laws, and has at the same time renounced all the education it has acquired under the ego's influence. It was docile so long as satisfaction beckoned to it; but under the double pressure of external and internal frustration it becomes refractory, and recalls earlier and better times. Such is the libido's fundamentally unchangeable character. The ideas to which it now transfers its energy as a cathexis belong to the system of the unconscious and are subject to the processes which are possible there, particularly to condensation and displacement. In this way conditions are established which completely resemble those in dream-construction. The dream proper, which has been completed in the unconscious and is the fulfilment of an unconscious wishful phantasy, is brought up against a portion of (pre)conscious activity which exercises the office of censorship and which, when it has been indemnified, permits the formation of the manifest dream as a compromise. In the same way, what represents the libido in the unconscious has to reckon with the power of the preconscious ego. The opposition which had been raised against it in the ego pursues it as an 'anticathexis' and compels it to choose a form of expression which can at the same time become an expression of the opposition itself. Thus the symptom emerges as a many-times-distorted derivative of the unconscious libidinal wish-fulfilment, an ingeniously chosen piece of ambiguity with two meanings in complete mutual contradiction. In this last respect, however, there is a distinction between the construction of a dream and of a symptom. For in dream-formation the preconscious purpose is merely concerned to preserve sleep, to allow nothing that would disturb it to make its way into consciousness; it does not insist upon calling out sharply 'No! on the contrary!' to the unconscious wishful impulse. It can afford to be more tolerant because the situation of someone sleeping is less perilous. The state of sleep in itself bars any outlet into reality.

[1916-1917, 3418]
Think it over! You have learnt all that is essential about the determinants of falling ill as well as all the factors that come into effect after the patient has fallen ill. Where do these leave room for any therapeutic influence? In the first place there is hereditary disposition. We have not talked about it very often because it is emphatically stressed from other directions and we have nothing new to say about it. But do not suppose that we underestimate it; precisely as therapists we come to realize its power clearly enough. In any case we can do nothing to alter it; we too must take it as something given, which sets a limit to our efforts. Next there is the influence of early experiences in childhood, to which we are in the habit of giving prominence in analysis: they belong to the past and we cannot undo them. Then comes everything that we have summarized as 'real frustration' - the misfortunes of life from which arise deprivation of love, poverty, family quarrels, ill-judged choice of a partner in marriage, unfavourable social circumstances, and the strictness of the ethical standards to whose pressure the individual is subject. Here, to be sure, there would be handles enough for a very effective therapy, but it would have to be of the kind which Viennese folklore attributes to the Emperor Joseph - the benevolent interference of a powerful personage before whose will people bow and difficulties vanish. But who are we, that we should be able to adopt benevolence of this kind as an instrument of our therapy? Poor ourselves and socially powerless, and compelled to earn our livelihood from our medical activity, we are not even in a position to extend our efforts to people without means, as other doctors with other methods of treatment are after all able to do. Our therapy is too time-consuming and too laborious for that to be possible. Perhaps, however, you are clutching at one of the factors I have mentioned and believe that there you have found the point at which our influence can make its attack. If the ethical restrictions demanded by society play a part in the deprivation imposed on the patient, treatment can, after all, give him the courage, or perhaps a direct injunction, to disregard those barriers and achieve satisfaction and recovery while forgoing the fulfilment of an ideal that is exalted, but so often not adhered to, by society. The patient will thus become healthy by 'living a full life' sexually. This, it is true, casts a shadow on analytic treatment for not serving general morality. What it has given to the individual it will have taken from the community.

[1916-1917, 3475]
The aetiology common to the onset of a psychoneurosis and of a psychosis always remains the same. It consists in a frustration, a non-fulfilment of one of those childhood wishes which are for ever undefeated and which are so deeply rooted in our phylogenetically determined organization. This frustration is in the last resort always an external one; but in the individual case it may proceed from the internal agency (in the super-ego) which has taken over the representation of the demands of reality. The pathogenic effect depends on whether, in a conflictual tension of this kind, the ego remains true to its dependence on the external world and attempts to silence the id, or whether it lets itself be overcome by the id and thus torn away from reality. A complication is introduced into this apparently simple situation, however, by the existence of the super-ego, which, though a link that is not yet clear to us, unites in itself influences coming from the id as well as from the external world, and is to some extent an ideal model of what the whole endeavour of the ego is aiming at - a reconciliation between its various dependent relationships. The attitude of the super-ego should be taken into account - which has not hitherto been done - in every form of psychical illness. We may provisionally assume that there must also be illnesses which are based on a conflict between the ego and the super-ego. Analysis gives us a right to suppose that melancholia is a typical example of this group; and we would set aside the name of 'narcissistic psychoneuroses' for disorders of that kind. Nor will it clash with our impressions if we find reasons for separating states like melancholia from the other psychoses. We now see that we have been able to make our simple genetic formula more complete, without dropping it. Transference neuroses correspond to a conflict between the ego and the id; narcissistic neuroses, to a conflict between the ego and the super-ego; and psychoses, to one between the ego and the external world. It is true that we cannot tell at once whether we have really gained any new knowledge by this, or have only enriched our store of formulas; but I think that this possible application of the proposed differentiation of the mental apparatus into an ego, a super-ego and an id cannot fail to give us courage to keep that hypothesis steadily in view.

[1924b, 4067]

When we have established the existence of a phenomenon, the next question is of course as to its cause. Incredulity of this kind is obviously an attempt to repudiate a piece of reality; but there is something strange about it. We should not be in the least astonished if an attempt of this kind were aimed at a piece of reality that threatened to bring unpleasure: the mechanism of our mind is, so to speak, planned to work along just such lines. But why should such incredulity arise in something which, on the contrary, promises to bring a high degree of pleasure? Truly paradoxical behaviour! But I recollect that on a previous occasion I dealt with the similar case of the people who, as I put it, are 'wrecked by success'. As a rule people fall ill as a result of frustration, of the non-fulfilment of some vital necessity or desire. But with these people the opposite is the case; they fall ill, or even go entirely to pieces, because an overwhelmingly powerful wish of theirs has been fulfilled. But the contrast between the two situations is not so great as it seems at first. What happens in the paradoxical case is merely that the place of the external frustration is taken by an internal one. The sufferer does not permit himself happiness: the internal frustration commands him to cling to the external one. But why? Because - so runs the answer in a number of cases - one cannot expect Fate to grant one anything so good. In fact, another instance of 'too good to be true', the expression of a pessimism of which a large portion seems to find a home in many of us. In another set of cases, just as in those who are wrecked by success, we find a sense of guilt or inferiority, which can be translated: 'I'm not worthy of such happiness, I don't deserve it.' But these two motives are essentially the same, for one is only a projection of the other. For, as has long been known, the Fate which we expect to treat us so badly is a materialization of our conscience, of the severe super-ego within us, itself a residue of the punitive agency of our childhood.

[1936a, 4826]
If the id in a human being gives rise to an instinctual demand of an erotic or aggressive nature, the simplest and most natural thing is that the ego, which has the apparatus of thought and the muscular apparatus at its disposal, should satisfy the demand by an action. This satisfaction of the instinct is felt by the ego as pleasure, just as its non-satisfaction would undoubtedly have become a source of unpleasure. Now a case may arise in which the ego abstains from satisfying the instinct in view of external obstacles - namely, if it perceives that the action in question would provoke a serious danger to the ego. An abstention from satisfaction of this kind, the renunciation of an instinct on account of an external hindrance - or, as we say, in obedience to the reality principle - is not pleasurable in any event. The renunciation of the instinct would lead to a lasting tension owing to unpleasure, if it were not possible to reduce the strength of the instinct itself by displacements of energy. Instinctual renunciation can, however, also be imposed for other reasons, which we correctly describe as internal. In the course of an individual's development a portion of the inhibiting forces in the external world are internalized and an agency is constructed in the ego which confronts the rest of the ego in an observing, criticizing and prohibiting sense. We call this new agency the super-ego. Thenceforward the ego, before putting to work the instinctual satisfactions demanded by the id, has to take into account not merely the dangers of the external world but also the objections of the super-ego, and it will have all the more grounds for abstaining from satisfying the instinct. But whereas instinctual renunciation, when it is for external reasons, is only unpleasurable, when it is for internal reasons, in obedience to the super-ego, it has a different economic effect. In addition to the inevitable unpleasurable consequences it also brings the ego a yield of pleasure - a substitutive satisfaction, as it were. The ego feels elevated; it is proud of the instinctual renunciation, as though it were a valuable achievement. We believe we can understand the mechanism of this yield of pleasure. The super-ego is the successor and representative of the individual's parents (and educators) who had supervised his actions in the first period of his life; it carries on their functions almost unchanged. It keeps the ego in a permanent state of dependence and exercises a constant pressure on it. Just as in childhood, the ego is apprehensive about risking the love of its supreme master; it feels his approval as liberation and satisfaction and his reproaches as pangs of conscience. When the ego has brought the super-ego the sacrifice of an instinctual renunciation, it expects to be rewarded by receiving more love from it. The consciousness of deserving this love is felt by it as pride. At the time when the authority had not yet been internalized as a super-ego, there could be the same relation between the threat of loss of love and the claims of instinct: there was a feeling of security and satisfaction when one had achieved an instinctual renunciation out of love for one's parents. But this happy feeling could only assume the peculiar narcissistic character of pride after the authority had itself become a portion of the ego.

[1939a, 4936]
APPEARANCE OF NEW AIMS  Every external or internal factor that hinders or postpones the attainment of the normal sexual aim (such as impotence, the high price of the sexual object or the danger of the sexual act) will evidently lend support to the tendency to linger over the preparatory activities and to turn them into new sexual aims that can take the place of the normal one. Attentive examination always shows that even what seem to be the strangest of these new aims are already hinted at in the normal sexual process.

[1905d, 1483]

The preceding discussion may perhaps have placed the sexuality of psychoneurotics in a false light. It may have given the impression that, owing to their disposition, psychoneurotics approximate closely to perverts in their sexual behaviour and are proportionately remote from normal people. It may indeed very well be that the constitutional disposition of these patients (apart from their exaggerated degree of sexual repression and the excessive intensity of their sexual instinct) includes an unusual tendency to perversion, using that word in its widest sense. Nevertheless, investigation of comparatively slight cases shows that this last assumption is not absolutely necessary, or at least that in forming a judgement on these pathological developments there is a factor to be considered which weighs in the other direction. Most psychoneurotics only fall ill after the age of puberty as a result of the demands made upon them by normal sexual life. (It is most particularly against the latter that repression is directed.) Or else illnesses of this kind set in later, when the libido fails to obtain satisfaction along normal lines. In both these cases the libido behaves like a stream whose main bed has become blocked. It proceeds to fill up collateral channels which may hitherto have been empty. Thus, in the same way, what appears to be the strong tendency (though, it is true, a negative one) of psychoneurotics to perversion may be collaterally determined, and must, in any case, be collaterally intensified. The fact is that we must put sexual repression as an internal factor alongside such external factors as limitation of freedom, inaccessibility of a normal sexual object, the dangers of the normal sexual act, etc., which bring about perversions in persons who might perhaps otherwise have remained normal.

[1905d, 1494]

I do not hesitate to make the two factors at work in psychical impotence in the strict sense - the factors of intense incestuous fixation in childhood and the frustration by reality in adolescence - responsible, too, for this extremely common characteristic of the love of civilized men. It sounds not only disagreeable but also paradoxical, yet it must nevertheless be said that anyone who is to be really free and happy in love must have surmounted his respect for women and have come to terms with the idea of incest with his mother or sister. Anyone who subjects himself to a serious self-examination on the subject of this requirement will be sure to find that he regards the sexual act basically as something degrading, which defiles and pollutes not only the body. The origin of this low opinion, which he will certainly not willingly acknowledge, must be looked for in the period of his youth in which the sensual current in him was already strongly developed but its satisfaction with an object outside the family was almost as completely prohibited as it was with an incestuous one.

[1912d, 2343]
It is advisable to draw a sharp distinction between the two types of onset of illness - a sharper
distinction than observation as a rule permits. In the first type what is prominent is a change in the
external world; in the second type the accent falls on an internal change. In the first type the
subject falls ill from an experience; in the second type it is from a developmental process. In the
first case he is faced by the task of renouncing satisfaction, and he falls ill from his incapacity for
resistance; in the second case his task is to exchange one kind of satisfaction for another, and he
breaks down from his inflexibility. In the second case the conflict, which is between the subject's
effort to remain as he is and the effort to change himself in order to meet fresh purposes and
fresh demands from reality, is present from the first. In the former case the conflict only arises
after the dammed-up libido has chosen other, and incompatible, possibilities of satisfaction. The
part played by the conflict and the previous fixation of the libido is incomparably more obvious in
the second type than in the first, in which such unserviceable fixations may perhaps only emerge
as a result of the external frustration.
[1912c, 2561]

For the rest, most of the problems of artistic creation and appreciation await further study, which
will throw the light of analytic knowledge on them and assign them their place in the complex
structure presented by the compensation for human wishes. Art is a conventionally accepted
reality in which, thanks to artistic illusion, symbols and substitutes are able to provoke real
emotions. Thus art constitutes a region half-way between a reality which frustrates wishes and
the wish-fulfilling world of the imagination - a region in which, as it were, primitive man's strivings
for omnipotence are still in full force.
[1913j, 2823]

The contradiction between such experiences and the rule that what induces illness is frustration
is not insoluble. It disappears if we make a distinction between an external and an internal
frustration. If the object in which the libido can find its satisfaction is withheld in reality, this is an
external frustration. In itself it is inoperative, not pathogenic, until an internal frustration is joined to
it. This latter must proceed from the ego, and must dispute the access by the libido to other
objects, which it now seeks to get hold of. Only then does a conflict arise, and the possibility of a
neurotic illness, i.e. of a substitutive satisfaction reached circuitously by way of the repressed
unconscious. Internal frustration is potentially present, therefore, in every case, only it does not
come into operation until external, real frustration has prepared the ground for it. In those
exceptional cases in which people are made ill by success, the internal frustration has operated
by itself; indeed it has only made its appearance after an external frustration has been replaced
by fulfilment of a wish. At first sight there is something strange about this; but on closer
consideration we shall reflect that it is not at all unusual for the ego to tolerate a wish as harmless
so long as it exists in phantasy alone and seems remote from fulfilment, whereas the ego will
defend itself hotly against such a wish as soon as it approaches fulfilment and threatens to
become a reality. The distinction between this and familiar situations in neurosis-formation is
merely that ordinarily it is internal intensifications of the libidinal cathexis that turn the phantasy,
which has hitherto been thought little of and tolerated, into a dreaded opponent; while in these
cases of ours the signal for the outbreak of conflict is given by a real external change.
[1916d, 3105]

The meaning of psychical conflict can be adequately expressed in another way by saying that
for an external frustration to become pathogenic an internal frustration must be added to it. In that
case, of course, the external and internal frustration relate to different paths and objects. The
external frustration removes one possibility of satisfaction and the internal frustration seeks to
exclude another possibility, about which the conflict then breaks out. I prefer this way of
representing the matter because it has a secret content. For it hints at the probability that the
internal impediments arose from real external obstacles during the prehistoric periods of human
development.
[1916-1917, 3411]
The path to perversion branches off sharply from that to neurosis. If these regressions rouse no objection from the ego, no neurosis will come about either; and the libido will arrive at some real, even though no longer normal, satisfaction. But if the ego, which has under its control not only consciousness but also the approaches to motor innervation and accordingly to the realization of mental desires, does not agree with these regressions, conflict will follow. The libido is, as it were, cut off and must try to escape in some direction where, in accordance with the requirements of the pleasure principle, it can find a discharge for its cathexis of energy. It must withdraw from the ego. An escape of this kind is offered it by the fixations on the path of its development which it has now entered on regressively - fixations from which the ego had protected itself in the past by repressions. By cathecting these repressed positions as it flows backward, the libido has withdrawn from the ego and its laws, and has at the same time renounced all the education it has acquired under the ego's influence. It was docile so long as satisfaction beckoned to it; but under the double pressure of external and internal frustration it becomes refractory, and recalls earlier and better times. Such is the libido's fundamentally unchangeable character. The ideas to which it now transfers its energy as a cathexis belong to the system of the unconscious and are subject to the processes which are possible there, particularly to condensation and displacement. In this way conditions are established which completely resemble those in dream-construction. The dream proper, which has been completed in the unconscious and is the fulfilment of an unconscious wishful phantasy, is brought up against a portion of (pre)conscious activity which exercises the office of censorship and which, when it has been indemnified, permits the formation of the manifest dream as a compromise. In the same way, what represents the libido in the unconscious has to reckon with the power of the preconscious ego. The opposition which had been raised against it in the ego pursues it as an 'anticathexis' and compels it to choose a form of expression which can at the same time become an expression of the opposition itself. Thus the symptom emerges as a many-times-distorted derivative of the unconscious libidinal wish-fulfilment, an ingeniously chosen piece of ambiguity with two meanings in complete mutual contradiction. In this last respect, however, there is a distinction between the construction of a dream and of a symptom. For in dream-formation the preconscious purpose is merely concerned to preserve sleep, to allow nothing that would disturb it to make its way into consciousness; it does not insist upon calling out sharply 'No! on the contrary!' to the unconscious wishful impulse. It can afford to be more tolerant because the situation of someone sleeping is less perilous. The state of sleep in itself bars any outlet into reality.

[1916-1917, 3418]
The things I have just been discussing, Gentlemen, compel me to enter more closely into the origin and significance of the mental activity which is described as 'phantasy'. As you are aware, it enjoys a universally high reputation, without its position in mental life having become clear. I have the following remarks to make about it. The human ego is, as you know, slowly educated by the pressure of external necessity to appreciate reality and obey the reality principle; in the course of this process it is obliged to renounce, temporarily or permanently, a variety of the objects and aims at which its striving for pleasure, and not only for sexual pleasure, is directed. But men have always found it hard to renounce pleasure; they cannot bring themselves to do it without some kind of compensation. They have therefore retained a mental activity in which all these abandoned sources of pleasure and methods of achieving pleasure are granted a further existence - a form of existence in which they are left free from the claims of reality and of what we call 'reality-testing'. Every desire takes before long the form of picturing its own fulfilment; there is no doubt that dwelling upon imaginary wish-fulfilments brings satisfaction with it, although it does not interfere with a knowledge that what is concerned is not real. Thus in the activity of phantasy human beings continue to enjoy the freedom from external compulsion which they have long since renounced in reality. They have contrived to alternate between remaining an animal of pleasure and being once more a creature of reason. Indeed, they cannot subsist on the scanty satisfaction which they can extort from reality. 'We cannot do without auxiliary constructions', as Theodor Fontane once said. The creation of the mental realm of phantasy finds a perfect parallel in the establishment of 'reservations' or 'nature reserves' in places where the requirements of agriculture, communications and industry threaten to bring about changes in the original face of the earth which will quickly make it unrecognizable. A nature reserve preserves its original state which everywhere else has to our regret been sacrificed to necessity. Everything, including what is useless and even what is noxious, can grow and proliferate there as it pleases. The mental realm of phantasy is just such a reservation withdrawn from the reality principle.

[1916-1917, 3427]
Think it over! You have learnt all that is essential about the determinants of falling ill as well as all the factors that come into effect after the patient has fallen ill. Where do these leave room for any therapeutic influence? In the first place there is hereditary disposition. We have not talked about it very often because it is emphatically stressed from other directions and we have nothing new to say about it. But do not suppose that we underestimate it; precisely as therapists we come to realize its power clearly enough. In any case we can do nothing to alter it; we too must take it as something given, which sets a limit to our efforts. Next there is the influence of early experiences in childhood, to which we are in the habit of giving prominence in analysis: they belong to the past and we cannot undo them. Then comes everything that we have summarized as 'real frustration' - the misfortunes of life from which arise deprivation of love, poverty, family quarrels, ill-judged choice of a partner in marriage, unfavourable social circumstances, and the strictness of the ethical standards to whose pressure the individual is subject. Here, to be sure, there would be handles enough for a very effective therapy, but it would have to be of the kind which Viennese folklore attributes to the Emperor Joseph - the benevolent interference of a powerful personage before whose will people bow and difficulties vanish. But who are we, that we should be able to adopt benevolence of this kind as an instrument of our therapy? Poor ourselves and socially powerless, and compelled to earn our livelihood from our medical activity, we are not even in a position to extend our efforts to people without means, as other doctors with other methods of treatment are after all able to do. Our therapy is too time-consuming and too laborious for that to be possible. Perhaps, however, you are clutching at one of the factors I have mentioned and believe that there you have found the point at which our influence can make its attack. If the ethical restrictions demanded by society play a part in the deprivation imposed on the patient, treatment can, after all, give him the courage, or perhaps a direct injunction, to disregard those barriers and achieve satisfaction and recovery while forgoing the fulfilment of an ideal that is exalted, but so often not adhered to, by society. The patient will thus become healthy by 'living a full life' sexually. This, it is true, casts a shadow on analytic treatment for not serving general morality. What it has given to the individual it will have taken from the community.

When we have established the existence of a phenomenon, the next question is of course as to its cause. Incredulity of this kind is obviously an attempt to repudiate a piece of reality; but there is something strange about it. We should not be in the least astonished if an attempt of this kind were aimed at a piece of reality that threatened to bring unpleasure: the mechanism of our mind is, so to speak, planned to work along just such lines. But why should such incredulity arise in something which, on the contrary, promises to bring a high degree of pleasure? Truly paradoxical behaviour! But I recollect that on a previous occasion I dealt with the similar case of the people who, as I put it, are 'wrecked by success'. As a rule people fall ill as a result of frustration, of the non-fulfilment of some vital necessity or desire. But with these people the opposite is the case; they fall ill, or even go entirely to pieces, because an overwhelmingly powerful wish of theirs has been fulfilled. But the contrast between the two situations is not so great as it seems at first. What happens in the paradoxical case is merely that the place of the external frustration is taken by an internal one. The sufferer does not permit himself happiness: the internal frustration commands him to cling to the external one. But why? Because - so runs the answer in a number of cases - one cannot expect Fate to grant one anything so good. In fact, another instance of 'too good to be true', the expression of a pessimism of which a large portion seems to find a home in many of us. In another set of cases, just as in those who are wrecked by success, we find a sense of guilt or inferiority, which can be translated: 'I'm not worthy of such happiness, I don't deserve it.' But these two motives are essentially the same, for one is only a projection of the other. For, as has long been known, the Fate which we expect to treat so badly is a materialization of our conscience, of the severe super-ego within us, itself a residue of the punitive agency of our childhood.

[1916-1917, 3475]

[1936a, 4826]
If the id in a human being gives rise to an instinctual demand of an erotic or aggressive nature, the simplest and most natural thing is that the ego, which has the apparatus of thought and the muscular apparatus at its disposal, should satisfy the demand by an action. This satisfaction of the instinct is felt by the ego as pleasure, just as its non-satisfaction would undoubtedly have become a source of unpleasure. Now a case may arise in which the ego abstains from satisfying the instinct in view of external obstacles - namely, if it perceives that the action in question would provoke a serious danger to the ego. An abstention from satisfaction of this kind, the renunciation of an instinct on account of an external hindrance - or, as we say, in obedience to the reality principle - is not pleasurable in any event. The renunciation of the instinct would lead to a lasting tension owing to unpleasure, if it were not possible to reduce the strength of the instinct itself by displacements of energy. Instinctual renunciation can, however, also be imposed for other reasons, which we correctly describe as internal. In the course of an individual's development a portion of the inhibiting forces in the external world are internalized and an agency is constructed in the ego which confronts the rest of the ego in an observing, criticizing and prohibiting sense. We call this new agency the super-ego. Thenceforward the ego, before putting to work the instinctual satisfactions demanded by the id, has to take into account not merely the dangers of the external world but also the objections of the super-ego, and it will have all the more grounds for abstaining from satisfying the instinct. But whereas instinctual renunciation, when it is for external reasons, is only unpleasurable, when it is for internal reasons, in obedience to the super-ego, it has a different economic effect. In addition to the inevitable unpleasurable consequences it also brings the ego a yield of pleasure - a substitutive satisfaction, as it were. The ego feels elevated; it is proud of the instinctual renunciation, as though it were a valuable achievement. We believe we can understand the mechanism of this yield of pleasure. The super-ego is the successor and representative of the individual's parents (and educators) who had supervised his actions in the first period of his life; it carries on their functions almost unchanged. It keeps the ego in a permanent state of dependence and exercises a constant pressure on it. Just as in childhood, the ego is apprehensive about risking the love of its supreme master; it feels his approval as liberation and satisfaction and his reproaches as pangs of conscience. When the ego has brought the super-ego the sacrifice of an instinctual renunciation, it expects to be rewarded by receiving more love from it. The consciousness of deserving this love is felt by it as pride. At the time when the authority had not yet been internalized as a super-ego, there could be the same relation between the threat of loss of love and the claims of instinct: there was a feeling of security and satisfaction when one had achieved an instinctual renunciation out of love for one's parents. But this happy feeling could only assume the peculiar narcissistic character of pride after the authority had itself become a portion of the ego.

[1939a, 4936]
APPEARANCE OF NEW AIMS  Every external or internal factor that hinders or postpones the attainment of the normal sexual aim (such as impotence, the high price of the sexual object or the danger of the sexual act) will evidently lend support to the tendency to linger over the preparatory activities and to turn them into new sexual aims that can take the place of the normal one. Attentive examination always shows that even what seem to be the strangest of these new aims are already hinted at in the normal sexual process. [1905d, 1483]

The preceding discussion may perhaps have placed the sexuality of psychoneurotics in a false light. It may have given the impression that, owing to their disposition, psychoneurotics approximate closely to perverts in their sexual behaviour and are proportionately remote from normal people. It may indeed very well be that the constitutional disposition of these patients (apart from their exaggerated degree of sexual repression and the excessive intensity of their sexual instinct) includes an unusual tendency to perversion, using that word in its widest sense. Nevertheless, investigation of comparatively slight cases shows that this last assumption is not absolutely necessary, or at least that in forming a judgement on these pathological developments there is a factor to be considered which weighs in the other direction. Most psychoneurotics only fall ill after the age of puberty as a result of the demands made upon them by normal sexual life. (It is most particularly against the latter that repression is directed.) Or else illnesses of this kind set in later, when the libido fails to obtain satisfaction along normal lines. In both these cases the libido behaves like a stream whose main bed has become blocked. It proceeds to fill up collateral channels which may hitherto have been empty. Thus, in the same way, what appears to be the strong tendency (though, it is true, a negative one) of psychoneurotics to perversion may be collaterally determined, and must, in any case, be collaterally intensified. The fact is that we must put sexual repression as an internal factor alongside such external factors as limitation of freedom, inaccessibility of a normal sexual object, the dangers of the normal sexual act, etc., which bring about perversions in persons who might perhaps otherwise have remained normal. [1905d, 1494]

The fact that the curb put upon love by civilization involves a universal tendency to debase sexual objects will perhaps lead us to turn our attention from the object to the instincts themselves. The damage caused by the initial frustration of sexual pleasure is seen in the fact that the freedom later given to that pleasure in marriage does not bring full satisfaction. But at the same time, if sexual freedom is unrestricted from the outset the result is no better. It can easily be shown that the psychical value of erotic needs is reduced as soon as their satisfaction becomes easy. An obstacle is required in order to heighten libido; and where natural resistances to satisfaction have not been sufficient men have at all times erected conventional ones so as to be able to enjoy love. This is true both of individuals and of nations. In times in which there were no difficulties standing in the way of sexual satisfaction, such as perhaps during the decline of the ancient civilizations, love became worthless and life empty, and strong reaction-formations were required to restore indispensable affective values. In this connection it may be claimed that the ascetic current in Christianity created psychical values for love which pagan antiquity was never able to confer on it. This current assumed its greatest importance with the ascetic monks, whose lives were almost entirely occupied with the struggle against libidinal temptation. [1912d, 2344]

(b) The second type of precipitating cause of falling ill is by no means so obvious as the first; and it was in fact only possible to discover it through searching analytic investigations following on the Zurich school's theory of complexes.¹ Here the subject does not fall ill as a result of a change in the external world which has replaced satisfaction by frustration, but as a result of an internal effort to obtain the satisfaction which is accessible to him in reality. He falls ill of his attempt to adapt himself to reality and to fulfil the demands of reality - an attempt in the course of which he comes up against insurmountable internal difficulties. [1912c, 2561]
It is advisable to draw a sharp distinction between the two types of onset of illness - a sharper
distinction than observation as a rule permits. In the first type what is prominent is a change in the
external world; in the second type the accent falls on an internal change. In the first type the
subject falls ill from an experience; in the second type it is from a developmental process. In the
first case he is faced by the task of renouncing satisfaction, and he falls ill from his incapacity for
resistance; in the second case his task is to exchange one kind of satisfaction for another, and he
breaks down from his inflexibility. In the second case the conflict, which is between the subject's
effort to remain as he is and the effort to change himself in order to meet fresh purposes and
fresh demands from reality, is present from the first. In the former case the conflict only arises
after the dammed-up libido has chosen other, and incompatible, possibilities of satisfaction. The
part played by the conflict and the previous fixation of the libido is incomparably more obvious in
the second type than in the first, in which such unserviceable fixations may perhaps only emerge
as a result of the external frustration.

A young man who has hitherto satisfied his libido by means of phantasies ending in
masturbation, and who now seeks to replace a régime approximating to auto-erotism by the
choice of a real object - or a girl who has given her whole affection to her father or brother and
who must now, for the sake of a man who is courting her, allow her hitherto unconscious
incestuous libidinal wishes to become conscious - or a married woman who would like to
renounce her polygamous inclinations and phantasies of prostitution so as to become a faithful
consort to her husband and a perfect mother to her child - all of these fall ill from the most
laudable efforts, if the earlier fixations of their libido are powerful enough to resist a displacement;
and this point will be decided, once again, by the factors of disposition, constitution and infantile
experience. All of them, it might be said, meet with the fate of the little tree in the Grimms' fairy
tale, which wished it had different leaves. From the hygienic point of view - which, to be sure, is
not the only one to be taken into account - one could only wish for them that they had continued
to be as undeveloped, as inferior and as useless as they were before they fell ill. The change
which the patients strive after, but bring about only imperfectly or not at all, invariably has the
value of a step forward from the point of view of real life. It is otherwise if we apply ethical
standards: we see people falling ill just as often when they discard an ideal as when they seek to
attain it.

In spite of the very clear differences between the two types of onset of illness that we have
described, they nevertheless coincide in essentials and can without difficulty be brought together
into a unity. Falling ill from frustration may also be regarded as incapacity for adaptation to reality
- in the particular case, that is, in which reality frustrates satisfaction of libido. Falling ill under the
conditions of the second type leads directly to a special case of frustration. It is true that reality
does not here frustrate every kind of satisfaction; but it frustrates the one kind which the subject
declares is the only possible one. Nor does the frustration come immediately from the external
world, but primarily from certain trends in the subject's ego. Nevertheless, frustration remains the
common factor and the more inclusive one. In consequence of the conflict which immediately sets
in in the second type, both kinds of satisfaction - the habitual one as well as the one aimed at -
are equally inhibited; a damming-up of libido, with all its consequences, comes about just as it
does in the first case. The psychical events leading to the formation of symptoms are if anything
easier to follow in the second type than in the first; for in the second type the pathogenic fixations
of the libido do not need to be freshly established, but have already been in force while the
subject was healthy. A certain amount of introversion of libido is, as a rule, already present; and
there is a saving of some part of the subject's regression to the infantile stage, owing to the fact
that his forward development has not yet completed its course.

[1912c, 2561]

[1912c, 2562]
It remains to say a few words on the relation of these types to the facts of observation. If I survey the set of patients on whose analysis I am at the moment engaged, I must record that not one of them is a pure example of any of the four types of onset. In each of them, rather, I find a portion of frustration operating alongside of a portion of incapacity to adapt to the demands of reality; inhibition in development, which coincides, of course, with inflexibility of fixations, has to be reckoned with in all of them, and, as I have already said, the importance of quantity of libido must never be neglected. I find, indeed, that in several of these patients their illness has appeared in successive waves, between which there have been healthy intervals, and that each of these waves has been traceable to a different type of precipitating cause. Thus the erection of these four types cannot lay claim to any high theoretical value; they are merely different ways of establishing a particular pathogenic constellation in the mental economy - namely the damming-up of libido, which the ego cannot, with the means at its command, ward off without damage. But this situation itself only becomes pathogenic as a result of a quantitative factor; it does not come as a novelty to mental life and is not created by the impact of what is spoken of as a 'cause of illness'.

[1912c, 2564]

The contradiction between such experiences and the rule that what induces illness is frustration is not insoluble. It disappears if we make a distinction between an external and an internal frustration. If the object in which the libido can find its satisfaction is withheld in reality, this is an external frustration. In itself it is inoperative, not pathogenic, until an internal frustration is joined to it. This latter must proceed from the ego, and must dispute the access by the libido to other objects, which it now seeks to get hold of. Only then does a conflict arise, and the possibility of a neurotic illness, i.e. of a substitutive satisfaction reached circuitously by way of the repressed unconscious. Internal frustration is potentially present, therefore, in every case, only it does not come into operation until external, real frustration has prepared the ground for it. In those exceptional cases in which people are made ill by success, the internal frustration has operated by itself; indeed it has only made its appearance after an external frustration has been replaced by fulfilment of a wish. At first sight there is something strange about this; but on closer consideration we shall reflect that it is not at all unusual for the ego to tolerate a wish as harmless so long as it exists in phantasy alone and seems remote from fulfilment, whereas the ego will defend itself hotly against such a wish as soon as it approaches fulfilment and threatens to become a reality. The distinction between this and familiar situations in neurosis-formation is merely that ordinarily it is internal intensifications of the libidinal cathexis that turn the phantasy, which has hitherto been thought little of and tolerated, into a dreaded opponent; while in these cases of ours the signal for the outbreak of conflict is given by a real external change.

[1916d, 3105]

The meaning of psychical conflict can be adequately expressed in another way by saying that for an external frustration to become pathogenic an internal frustration must be added to it. In that case, of course, the external and internal frustration relate to different paths and objects. The external frustration removes one possibility of satisfaction and the internal frustration seeks to exclude another possibility, about which the conflict then breaks out. I prefer this way of representing the matter because it has a secret content. For it hints at the probability that the internal impediments arose from real external obstacles during the prehistoric periods of human development.

[1916-1917, 3411]
The path to perversion branches off sharply from that to neurosis. If these regressions rouse no objection from the ego, no neurosis will come about either; and the libido will arrive at some real, even though no longer normal, satisfaction. But if the ego, which has under its control not only consciousness but also the approaches to motor innervation and accordingly to the realization of mental desires, does not agree with these regressions, conflict will follow. The libido is, as it were, cut off and must try to escape in some direction where, in accordance with the requirements of the pleasure principle, it can find a discharge for its cathexis of energy. It must withdraw from the ego. An escape of this kind is offered it by the fixations on the path of its development which it has now entered on regressively - fixations from which the ego had protected itself in the past by repressions. By cathecting these repressed positions as it flows backward, the libido has withdrawn from the ego and its laws, and has at the same time renounced all the education it has acquired under the ego's influence. It was docile so long as satisfaction beckoned to it; but under the double pressure of external and internal frustration it becomes refractory, and recalls earlier and better times. Such is the libido's fundamentally unchangeable character. The ideas to which it now transfers its energy as a cathexis belong to the system of the unconscious and are subject to the processes which are possible there, particularly to condensation and displacement. In this way conditions are established which completely resemble those in dream-construction. The dream proper, which has been completed in the unconscious and is the fulfilment of an unconscious wishful phantasy, is brought up against a portion of (pre)conscious activity which exercises the office of censorship and which, when it has been indemnified, permits the formation of the manifest dream as a compromise. In the same way, what represents the libido in the unconscious has to reckon with the power of the preconscious ego. The opposition which had been raised against it in the ego pursues it as an 'anticathexis' and compels it to choose a form of expression which can at the same time become an expression of the opposition itself. Thus the symptom emerges as a many-times-distorted derivative of the unconscious libidinal wish-fulfilment, an ingeniously chosen piece of ambiguity with two meanings in complete mutual contradiction. In this last respect, however, there is a distinction between the construction of a dream and of a symptom. For in dream-formation the preconscious purpose is merely concerned to preserve sleep, to allow nothing that would disturb it to make its way into consciousness; it does not insist upon calling out sharply 'No! on the contrary!' to the unconscious wishful impulse. It can afford to be more tolerant because the situation of someone sleeping is less perilous. The state of sleep in itself bars any outlet into reality.

[1916-1917, 3418]
This state of affairs is enough to account for the reluctant and hesitant reception of analysis in scientific quarters. But it does not explain the outbursts of indignation, derision and scorn which, in disregard of every standard of logic and good taste, have characterized the controversial methods of its opponents. A reaction of such a kind suggests that resistances other than purely intellectual ones were stirred up and that powerful emotional forces were aroused. And there are indeed plenty of things to be found in the theory of psycho-analysis calculated to produce such an effect as this upon the passions of men of every kind and not of scientists alone. Above all there is the very important place in the mental life of human beings which psycho-analysis assigns to what are known as the sexual instincts. Psycho-analytic theory maintained that the symptoms of neuroses are distorted substitutive satisfactions of sexual instinctual forces, the direct satisfaction of which has been frustrated by internal resistances. Later on, when analysis had extended beyond its original field of work and began to be applied to normal mental life, it sought to show that these same sexual components, which could be diverted from their immediate aims and directed to other things, made the most important contributions to the cultural achievements of the individual and of society. These views were not entirely new. The incomparable significance of sexual life had been proclaimed by the philosopher Schopenhauer in an intensely impressive passage. Moreover, what psycho-analysis called sexuality was by no means identical with the impulsion towards a union of the two sexes or towards producing a pleasurable sensation in the genitals; it had far more resemblance to the all-inclusive and all-preserving Eros of Plato's Symposium.

When we have established the existence of a phenomenon, the next question is of course as to its cause. Incredulity of this kind is obviously an attempt to repudiate a piece of reality; but there is something strange about it. We should not be in the least astonished if an attempt of this kind were aimed at a piece of reality that threatened to bring unpleasure: the mechanism of our mind is, so to speak, planned to work along just such lines. But why should such incredulity arise in something which, on the contrary, promises to bring a high degree of pleasure? Truly paradoxical behaviour! But I recollect that on a previous occasion I dealt with the similar case of the people who, as I put it, are 'wrecked by success'. As a rule people fall ill as a result of frustration, of the non-fulfilment of some vital necessity or desire. But with these people the opposite is the case; they fall ill, or even go entirely to pieces, because an overwhelmingly powerful wish of theirs has been fulfilled. But the contrast between the two situations is not so great as it seems at first. What happens in the paradoxical case is merely that the place of the external frustration is taken by an internal one. The sufferer does not permit himself happiness: the internal frustration commands him to cling to the external one. But why? Because - so runs the answer in a number of cases - one cannot expect Fate to grant one anything so good. In fact, another instance of 'too good to be true', the expression of a pessimism of which a large portion seems to find a home in many of us. In another set of cases, just as in those who are wrecked by success, we find a sense of guilt or inferiority, which can be translated: 'I'm not worthy of such happiness, I don't deserve it.' But these two motives are essentially the same, for one is only a projection of the other. For, as has long been known, the Fate which we expect to treat us so badly is a materialization of our conscience, of the severe super-ego within us, itself a residue of the punitive agency of our childhood.
If the id in a human being gives rise to an instinctual demand of an erotic or aggressive nature, the simplest and most natural thing is that the ego, which has the apparatus of thought and the muscular apparatus at its disposal, should satisfy the demand by an action. This satisfaction of the instinct is felt by the ego as pleasure, just as its non-satisfaction would undoubtedly have become a source of unpleasure. Now a case may arise in which the ego abstains from satisfying the instinct in view of external obstacles - namely, if it perceives that the action in question would provoke a serious danger to the ego. An abstention from satisfaction of this kind, the renunciation of an instinct on account of an external hindrance - or, as we say, in obedience to the reality principle - is not pleasurable in any event. The renunciation of the instinct would lead to a lasting tension owing to unpleasure, if it were not possible to reduce the strength of the instinct itself by displacements of energy. Instinctual renunciation can, however, also be imposed for other reasons, which we correctly describe as internal. In the course of an individual's development a portion of the inhibiting forces in the external world are internalized and an agency is constructed in the ego which confronts the rest of the ego in an observing, criticizing and prohibiting sense. We call this new agency the super-ego. Thenceforward the ego, before putting to work the instinctual satisfactions demanded by the id, has to take into account not merely the dangers of the external world but also the objections of the super-ego, and it will have all the more grounds for abstaining from satisfying the instinct. But whereas instinctual renunciation, when it is for external reasons, is only unpleasurable, when it is for internal reasons, in obedience to the super-ego, it has a different economic effect. In addition to the inevitable unpleasurable consequences it also brings the ego a yield of pleasure - a substitutive satisfaction, as it were. The ego feels elevated; it is proud of the instinctual renunciation, as though it were a valuable achievement. We believe we can understand the mechanism of this yield of pleasure. The super-ego is the successor and representative of the individual's parents (and educators) who had supervised his actions in the first period of his life; it carries on their functions almost unchanged. It keeps the ego in a permanent state of dependence and exercises a constant pressure on it. Just as in childhood, the ego is apprehensive about risking the love of its supreme master; it feels his approval as liberation and satisfaction and his reproaches as pangs of conscience. When the ego has brought the super-ego the sacrifice of an instinctual renunciation, it expects to be rewarded by receiving more love from it. The consciousness of deserving this love is felt by it as pride. At the time when the authority had not yet been internalized as a super-ego, there could be the same relation between the threat of loss of love and the claims of instinct: there was a feeling of security and satisfaction when one had achieved an instinctual renunciation out of love for one's parents. But this happy feeling could only assume the peculiar narcissistic character of pride after the authority had itself become a portion of the ego.
[1939a, 4936]
Further information now became available relating to people who had remained normal; and this led to the unexpected finding that the sexual history of their childhood did not necessarily differ in essentials from that of neurotics, and, in particular, that the part played by seduction was the same in both cases. As a consequence, accidental influences receded still further into the background as compared with 'repression' (as I now began to say instead of 'defence'). Thus it was no longer a question of what sexual experiences a particular individual had had in his childhood, but rather of his reaction to those experiences - of whether he had reacted to them by 'repression' or not. It could be shown how in the course of development a spontaneous infantile sexual activity was often broken off by an act of repression. Thus a mature neurotic individual was invariably pursued by a certain amount of 'sexual repression' from his childhood; this found expression when he was faced by the demands of real life, and the psycho-analyses of hysterics showed that they fell ill as a result of the conflict between their libido and their sexual repression and that their symptoms were in the nature of compromises between the two mental currents. [1906a, 1580]

One day the patient mentioned quite casually an event which I could not fail to recognize as the precipitating cause of his illness, or at least as the immediate occasion of the attack which had begun some six years previously and had persisted to that day. He himself had no notion that he had brought forward anything of importance; he could not remember that he had ever attached any importance to the event; and moreover he had never forgotten it. Such an attitude on his part calls for some theoretical consideration. [1909d, 2154]
It must be pointed out, however, that sexual overvaluation is not developed in the case of every mechanism of object-choice. We shall become acquainted later on with another and more direct explanation of the sexual role assumed by the other parts of the body. The factor of 'craving for stimulation' has been put forward by Noche and Bloch as an explanation of the extension of sexual interest to parts of the body other than the genitals; but it does not seem to me to deserve such an important place. The various channels along which the libido passes are related to each other from the very first like inter-communicating pipes, and we must take the phenomenon of collateral flow into account.

[1905d, 1477]

In further pursuing the discussion of this thesis, are we to consider the nature of the frustration or the peculiar character of those who are affected by it? It is extremely seldom, after all, that frustration is universal and absolute. In order to operate pathogenically it must no doubt affect the mode of satisfaction which alone the subject desires, of which alone he is capable. There are in general very many ways of tolerating deprivation of libidinal satisfaction without falling ill as a result. In the first place, we know people who are able to put up with a deprivation of this kind without being injured: they are not happy, they suffer from longing, but they do not fall ill. Next, we must bear in mind that the sexual instinctual impulses in particular are extraordinarily plastic, if I may so express it. One of them can take the place of another, one of them can take over another's intensity; if the satisfaction of one of them is frustrated by reality, the satisfaction of another can afford complete compensation. They are related to one another like a network of intercommunicating channels filled with a liquid; and this is so in spite of their being subject to the primacy of the genitals - a state of affairs that is not at all easily combined in a single picture. Further, the component instincts of sexuality, as well as the sexual current which is compounded from them, exhibit a large capacity for changing their object, for taking another in its place - and one, therefore, that is more easily attainable. This displaceability and readiness to accept a substitute must operate powerfully against the pathogenic effect of a frustration. Among these protective processes against falling ill owing to deprivation there is one which has gained special cultural significance. It consists in the sexual trend abandoning its aim of obtaining a component or a reproductive pleasure and taking on another which is related genetically to the abandoned one but is itself no longer sexual and must be described as social. We call this process 'sublimation', in accordance with the general estimate that places social aims higher than the sexual ones, which are at bottom self-interested. Sublimation is, incidentally, only a special case of the way in which sexual trends are attached to other, non-sexual ones. We shall have to discuss it again in another connection.

[1916-1917, 3408]
It seems to me that we have here an important discovery - namely, that the qualitative factor, the presence of certain neurotic formations, has less practical significance than the quantitative factor, the degree of attention or, more correctly, the amount of cathexis that these structures are able to attract to themselves. Our consideration of the first case, the jealous paranoia, led to a similar estimate of the importance of the quantitative factor, by showing that there also the abnormality essentially consisted in the hypercathexis of the interpretations of someone else's unconscious. We have long known of an analogous fact in the analysis of hysteria. The pathogenic phantasies, derivatives of repressed instinctual impulses, are for a long time tolerated alongside the normal life of the mind, and have no pathogenic effect until by a revolution in the libidinal economy they receive a hypercathexis; not till then does the conflict which leads to the formation of symptoms break out. Thus as our knowledge grows we are increasingly impelled to bring the economic point of view into the foreground. I should also like to throw out the question whether this quantitative factor that I am now dwelling on does not suffice to cover the phenomena which Bleuler and others have lately proposed to name 'switching'. One need only assume that an increase in resistance in the course taken by the psychical current in one direction results in a hypercathexis of another path and thus causes the flow to be switched into that path.
[1922b, 3905]
The preceding discussion may perhaps have placed the sexuality of psychoneurotics in a false light. It may have given the impression that, owing to their disposition, psychoneurotics approximate closely to perverts in their sexual behaviour and are proportionately remote from normal people. It may indeed very well be that the constitutional disposition of these patients (apart from their exaggerated degree of sexual repression and the excessive intensity of their sexual instinct) includes an unusual tendency to perversion, using that word in its widest sense. Nevertheless, investigation of comparatively slight cases shows that this last assumption is not absolutely necessary, or at least that in forming a judgement on these pathological developments there is a factor to be considered which weighs in the other direction. Most psychoneurotics only fall ill after the age of puberty as a result of the demands made upon them by normal sexual life. (It is most particularly against the latter that repression is directed.) Or else illnesses of this kind set in later, when the libido fails to obtain satisfaction along normal lines. In both these cases the libido behaves like a stream whose main bed has become blocked. It proceeds to fill up collateral channels which may hitherto have been empty. Thus, in the same way, what appears to be the strong tendency (though, it is true, a negative one) of psychoneurotics to perversion may be collaterally determined, and must, in any case, be collaterally intensified. The fact is that we must put sexual repression as an internal factor alongside such external factors as limitation of freedom, inaccessibility of a normal sexual object, the dangers of the normal sexual act, etc., which bring about perversions in persons who might perhaps otherwise have remained normal.

[1905d, 1494]

In this respect different cases of neurosis may behave differently: in one case the preponderating factor may be the innate strength of the tendency to perversion, in another it may be the collateral increase of that tendency owing to the libido being forced away from a normal sexual aim and sexual object. It would be wrong to represent as opposition what is in fact a co-operative relation. Neurosis will always produce its greatest effects when constitution and experience work together in the same direction. Where the constitution is a marked one it will perhaps not require the support of actual experiences; while a great shock in real life will perhaps bring about a neurosis even in an average constitution. (Incidentally, this view of the relative aetiological importance of what is innate and what is accidentally experienced applies equally in other fields.)

[1905d, 1494]
After having explained the preponderance of perverse tendencies in psychoneurotics by recognizing it as a collateral filling of subsidiary channels when the main current of the instinctual stream has been blocked by 'repression',¹ we proceeded to a consideration of sexual life in childhood. We found it a regrettable thing that the existence of the sexual instinct in childhood has been denied and that the sexual manifestations not infrequently to be observed in children have been described as irregularities. It seemed to us on the contrary that children bring germs of sexual activity with them into the world, that they already enjoy sexual satisfaction when they begin to take nourishment and that they persistently seek to repeat the experience in the familiar activity of 'thumb-sucking'. The sexual activity of children, however, does not, it appeared, develop pari passu with their other functions, but, after a short period of efflorescence from the ages of two to five, enters upon the so-called period of latency. During that period the production of sexual excitation is not by any means stopped but continues and produces a store of energy which is employed to a great extent for purposes other than sexual - namely, on the one hand in contributing the sexual components to social feelings and on the other hand (through repression and reaction-forming) in building up the subsequently developed barriers against sexuality. On this view, the forces destined to retain the sexual instinct upon certain lines are built up in childhood chiefly at the cost of perverse sexual impulses and with the assistance of education. A certain portion of the infantile sexual impulses would seem to evade these uses and succeed in expressing itself as sexual activity. We next found that sexual excitation in children springs from a multiplicity of forces. Satisfaction arises first and foremost from the appropriate sensory excitation of what we have described as erotogenic zones. It seems probable that any part of the skin and any sense-organ - probably, indeed, any organ - can function as an erotogenic zone, though there are some particularly marked erotogenic zones whose excitation would seem to be secured from the very first by certain organic contrivances. It further appears that sexual excitation arises as a by-product, as it were, of a large number of processes that occur in the organism, as soon as they reach a certain degree of intensity, and most especially of any relatively powerful emotion, even though it is of a distressing nature. The excitations from all these sources are not yet combined; but each follows its own separate aim, which is merely the attainment of a certain sort of pleasure. In childhood, therefore, the sexual instinct is not unified and is at first without an object, that is, auto-erotic.

¹ [Footnote added 1915:] This does not apply only to the 'negative' tendencies to perversion which appear in neuroses but equally to the 'positive,' properly so-called, perversions. Thus these latter are to be derived not merely from a fixation of infantile tendencies but also from a regression to those tendencies as a result of other channels of the sexual current being blocked. It is for this reason that the positive perversions also are accessible to psycho-analytic therapy.
In my *Three Essays on the Theory of Sexuality* I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics *endeavour to protect themselves against any such sexualization of their social instinctual catheces*, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) *schizophrenia*; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.

I should not have much difficulty in giving you a far more intimate picture of the relations between perversion and neurosis; but I think what I have already said will serve our purpose. We must however guard against being misled by what I have told you of the meaning of symptoms into over-estimating the frequency and intensity of people's perverse inclinations. It is possible, as you have heard, to fall ill of a neurosis as a result of a frustration of normal sexual satisfaction. But when a real frustration like this occurs, the need moves over on to abnormal methods of sexual excitation. You will later learn the way in which this happens. But in any case you will realize that as a result of this 'collateral' damming-back the perverse impulses must emerge more strongly than they would have if normal sexual satisfaction had met with no obstacle in the real world. Moreover a similar influence is to be recognized also as affecting the *manifest* perversions. In some cases they are provoked or made active if the normal satisfaction of the sexual instinct encounters too great difficulties for temporary reasons or because of permanent social regulations. In other cases, it is true, the inclination to perversions is quite independent of such favouring conditions; they are, we might say, the normal species of sexual life for those particular individuals.

The material on the other side is equally unambiguous. Twice in the course of individual development certain instincts are considerably reinforced: at puberty, and, in women, at the menopause. We are not in the least surprised if a person who was not neurotic before becomes so at these times. When his instincts were not so strong, he succeeded in taming them; but when they are reinforced he can no longer do so. The repressions behave like dams against the pressure of water. The same effects which are produced by these two physiological reinforcements of instinct, may be brought about in an irregular fashion by accidental causes at any other period of life. Such reinforcements may be set up by fresh traumas, enforced frustrations, or the collateral influence of instincts upon one another. The result is always the same, and it underlines the irresistible power of the quantitative factor in the causation of illness.
Observations such as these seem to us to establish an analogy between the pathogenesis of common hysteria and that of the traumatic neuroses, and to justify an extension of the concept of traumatic hysteria. In traumatic neuroses the operative cause of the illness is not the trifling physical injury but the affect of fright - the psychical trauma. In an analogous manner, our investigations reveal, for many, if not for most, hysterical symptoms, precipitating causes which can only be described as psychical traumas. Any experience which calls up distressing affects - such as those of fright, anxiety, shame or physical pain - may operate as a trauma of this kind; and whether it in fact does so depends naturally enough on the susceptibility of the person affected (as well as on another condition which will be mentioned later). In the case of common hysteria it not infrequently happens that, instead of a single, major trauma, we find a number of partial traumas forming a group of provoking causes. These have only been able to exercise a traumatic effect by summation and they belong together in so far as they are in part components of a single story of suffering. There are other cases in which an apparently trivial circumstance combines with the actually operative event or occurs at a time of peculiar susceptibility to stimulation and in this way attains the dignity of a trauma which it would not otherwise have possessed but which thenceforward persists.

[1895d, 8]

Unless we have first come to a complete agreement upon the terminology involved, it is not easy to decide whether a particular case is to be reckoned as a hysteria or some other neurosis (I am speaking here of neuroses which are not of a purely neurasthenic type; and we have still to await the directing hand which shall set up boundary-marks in the region of the commonly occurring mixed neuroses and which shall bring out the features essential for their characterization. If, accordingly, we are still accustomed to diagnosing a hysteria, in the narrower sense of the term, from its similarity to familiar typical cases, we shall scarcely be able to dispute the fact that the case of Frau Emmy von N. was one of hysteria. The mildness of her deliria and hallucinations (while her other mental activities remained intact), the change in her personality and store of memories when she was in a state of artificial somnambulism, the anaesthesia in her painful leg, certain data revealed in her anamnesis, her ovarian neuralgia, etc., admit of no doubt as to the hysterical nature of the illness, or at least of the patient. That the question can be raised at all is due only to one particular feature of the case, which also provides an opportunity for a comment that is of general validity. As we have explained in the 'Preliminary Communication' which appears at the beginning of this volume, we regard hysterical symptoms as the effects and residues of excitations which have acted upon the nervous system as traumas. Residues of this kind are not left behind if the original excitation has been discharged by abreaction or thought-activity. It is impossible any longer at this point to avoid introducing the idea of quantities (even though not measurable ones). We must regard the process as though a sum of excitation impinging on the nervous system is transformed into chronic symptoms in so far as it has not been employed for external action in proportion to its amount. Now we are accustomed to find in hysteria that a considerable part of this 'sum of excitation' of the trauma is transformed into purely somatic symptoms. It is this characteristic of hysteria which has so long stood in the way of its being recognized as a psychical disorder.
Stated in terms of the conversion theory, this incontrovertible fact of the summation of traumas and of the preliminary latency of symptoms tells us that conversion can result equally from fresh symptoms and from recollected ones. This hypothesis completely explains the apparent contradiction that we observed between the events of Fräulein Elisabeth von R.'s illness and her analysis. There is no doubt that the continued existence in consciousness of ideas whose affect has not been dealt with can be tolerated by healthy individuals up to a great amount. The view which I have just been putting forward does no more than bring the behaviour of hysterical people nearer to that of healthy ones. What we are concerned with is clearly a quantitative factor - the question of how much affective tension of this kind an organism can tolerate. Even a hysteric can retain a certain amount of affect that has not been dealt with; if, owing to the occurrence of similar provoking causes, that amount is increased by summation to a point beyond the subject's tolerance, the impetus to conversion is given. Thus when we say that the construction of hysterical symptoms can proceed on the strength of recollected affects as well as fresh ones, we shall not be making any unfamiliar assertion, but stating something that is almost accepted as a postulate.

In addition, these latter remarks contain an assumption which is not in itself improbable, to the effect that a sexual noxa like coitus interruptus comes into force through summation. A shorter or longer time is needed - depending on the individual's disposition and any other inherited weaknesses of his nervous system - before the effect of this summation becomes visible. Those individuals who apparently tolerate coitus interruptus without harm, in fact become disposed by it to the disorders of anxiety neurosis, and these may break out at some time or other, either spontaneously or after a stock trauma which would not ordinarily suffice for this; just as, by the path of summation, a chronic alcoholic will in the end develop a cirrhosis or some other illness, or will, under the influence of a fever, fall a victim to delirium.

This concept of the mechanism of anxiety neurosis can be made clearer if one accepts the following view of the sexual process, which applies, in the first instance, to men. In the sexually mature male organism somatic sexual excitation is produced probably continuously - and periodically becomes a stimulus to the psyche. In order to make our ideas on this point firmer, I will add by way of interpolation that this somatic excitation is manifested as a pressure on the walls of the seminal vesicles, which are lined with nerve endings; thus this visceral excitation will develop continuously, but it will have to reach a certain height before it is able to overcome the resistance of the intervening path of conduction to the cerebral cortex and express itself as a psychical stimulus. When this has happened, however, the group of sexual ideas which is present in the psyche becomes supplied with energy and there comes into being the psychical state of libidinal tension which brings with it an urge to remove that tension. A psychical unloading of this kind is only possible by means of what I shall call specific or adequate action. This adequate action consists, for the male sexual instinct, in a complicated spinal reflex act which brings about the unloading of the nerve-endings, and in all the psychical preparations which have to be made in order to set off that reflex. Anything other than the adequate action would be fruitless, for once the somatic sexual excitation has reached threshold value it is turned continuously into psychical excitation, and something must positively take place which will free the nerve endings from the load of pressure on them - which will, accordingly, remove the whole of the existing somatic excitation and allow the subcortical path of conduction to re-establish its resistance.

Löwenfeld says further that he has repeatedly seen anxiety states appear and disappear where a change in the subject's sexual life had certainly not taken place but where other factors were in play.
What can the other factors be which the ‘specific aetiology’ of hysteria still needs in order actually to produce the neurosis? That, Gentlemen, is a theme in itself, which I do not propose to enter upon. To-day I need only indicate the point of contact at which the two parts of the topic - the specific and the auxiliary aetiology - fit into one another. No doubt a considerable quantity of factors will have to be taken into account. There will be the subject's inherited and personal constitution, the inherent importance of the infantile sexual experiences, and, above all, their number: a brief relationship with a strange boy, who afterwards becomes indifferent, will leave a less powerful effect on a girl than intimate sexual relations of several years' standing with her own brother. In the aetiology of the neuroses quantitative preconditions are as important as qualitative ones; there are threshold-values which have to be crossed before the illness can become manifest. Moreover, I do not myself regard this aetiological series as complete; nor does it solve the riddle of why hysteria is not more common among the lower classes. (You will remember, by the way, what a surprisingly large incidence of hysteria was reported by Charcot among working-class men). I may also remind you that a few years ago I myself pointed out a factor, hitherto little considered, to which I attribute the leading role in provoking hysteria after puberty. I then put forward the view that the outbreak of hysteria may almost invariably be traced to a psychical conflict arising through an incompatible idea setting in action a defence on the part of the ego and calling up a demand for repression. What the circumstances are in which a defensive endeavour of this kind has the pathological effect of actually thrusting the memory which is distressing to the ego into the unconscious and of creating a hysterical symptom in its place I was not able to say at that time. But to-day I can repair the omission. The defence achieves its purpose of thrusting the incompatible idea out of consciousness if there are infantile sexual scenes present in the (hitherto normal) subject in the form of unconscious memories, and if the idea that is to be repressed can be brought into logical or associative connection with an infantile experience of that kind.

A reply to objections made by Löwenfeld to the content of No. XXXII. The problem of the aetiology of the pathology of the neuroses is dealt with here, to justify the division into three categories of the aetiological factors that appear: (a) preconditions, (b) specific causes and (c) concurrent or auxiliary causes. What are called preconditions are the factors which, though they are indispensable for producing the effect, cannot by themselves produce it but need in addition the specific causes. The specific causes are distinguished from the preconditions by the fact that they figure in only a few aetiological formulas, while the preconditions play the same part in numerous affections. Auxiliary causes are such as neither need invariably be present nor are able by themselves to produce the effect in question. - In the case of neuroses it is possible that the precondition may be heredity; the specific cause lies in sexual factors; everything else that is brought up apart from these as forming the aetiology of the neuroses (overwork, emotion, physical illness) is an auxiliary cause and can never entirely take the place of the specific factor, though it can no doubt serve as a substitute for it in the matter of quantity. The form of a neurosis depends on the nature of the specific sexual cause; whether there shall be a neurotic illness at all is determined by factors operating quantitatively; heredity works like a multiplier inserted in an electric circuit.
It is under such conditions, extremely frequent in modern society, especially among women, that anxiety neurosis (of which phobias are a psychical manifestation) develops.

The anxiety neurosis exhibits a much richer clinical picture: irritability, states of anxious expectation, phobias, anxiety attacks, complete or rudimentary, attacks of fear and of vertigo, tremors, sweating, congestion, dyspnoea, tachycardia, etc., chronic diarrhoea, chronic locomotor vertigo, hyperaesthesia, insomnia, etc.¹ It is easily revealed as being the specific effect of various disorders of sexual life which possess a characteristic common to all of them. Enforced abstinence, unconsummated genital excitation (excitation which is not relieved by a sexual act), coition which is imperfect or interrupted (which does not end in gratification), sexual efforts which exceed the subject's psychical capacity, etc. - all these agents, which occur only too frequently in modern life, seem to agree in the fact that they disturb the equilibrium of the psychical and somatic functions in sexual acts, and that they prevent the psychical participation necessary in order to free the nervous economy from sexual tension.

The sexual causes, too, are the ones which most readily offer the physician a foothold for his therapeutic influence. Heredity is no doubt an important factor, when it is present; it enables a strong pathological effect to come about where otherwise only a very slight one would have resulted. But heredity is inaccessible to the physician's influence; everyone is born with his own hereditary tendencies to illness, and we can do nothing to change them. Nor should we forget that it is precisely in regard to the aetiology of the neurasthenias that we must necessarily deny the first place to heredity. Neurasthenia (in both its forms) is one of those affections which anyone may easily acquire without having any hereditary taint. If it were otherwise, the enormous increase in neurasthenia, of which all the authorities complain, would be unthinkable. In what concerns civilization, among whose sins people so often include responsibility for neurasthenia, these authorities may indeed be right (although the way in which this comes about is probably quite different from what they imagine). Yet the state of our civilization is, once again, something that is unalterable for the individual. Moreover this factor, being common to all the members of the same society, can never explain the fact of selectivity in the incidence of the illness. The physician who is not neurasthenic is exposed to the same influence of an allegedly detrimental civilization as the neurasthenic patient whom he has to treat. Subject to these limitations, the factors of exhaustion retain their significance. But the element of 'overwork', which physicians are so fond of producing to their patients as the cause of their neurosis, is too often unduly misused. It is quite true that anyone who, owing to sexual noxae, has made himself disposed to neurasthenia, tolerates intellectual work and the psychical exigencies of life badly; but no one ever becomes neurotic through work or excitement alone. Intellectual work is rather a protection against falling ill of neurasthenia; it is precisely the most unremitting intellectual workers who remain exempt from neurasthenia, and what neurasthenics complain of as 'overwork that is making them ill' does not as a rule deserve to be called 'intellectual work' at all, either in its quality or quantity. Physicians will have to become accustomed to explaining to an office-worker who has been 'overworked' at his desk or to a housewife for whom her domestic activities have become too heavy, that they have fallen ill, not because they have tried to carry out duties which are in fact easily performed by a civilized brain, but because all the while they have been grossly neglecting and damaging their sexual life.

¹ It is easily revealed as being the specific effect of various disorders of sexual life which possess a characteristic common to all of them.
Accordingly, the aetiology of the neuroses comprises everything which can act in a detrimental manner upon the processes serving the sexual function. In the forefront, then, are to be ranked the noxae which affect the sexual function itself - in so far as these are regarded as injurious by the sexual constitution, varying as it does with different degrees of culture and education. In the next place comes every other kind of noxa and trauma which, by causing general damage to the organism, may lead secondarily to injury to its sexual processes. It should not, however, be forgotten that the aetiological problem in the case of the neuroses is at least as complicated as the causative factors of any other illness. A single pathogenic influence is scarcely ever sufficient; in the large majority of cases a number of aetiological factors are required, which support one another and must therefore not be regarded as being in mutual opposition. For this reason a state of neurotic illness cannot be sharply differentiated from health. The onset of the illness is the product of a summation and the necessary total of aetiological determinants can be completed from any direction. To look for the aetiology of the neuroses exclusively in heredity or in the constitution would be just as one-sided as to attribute that aetiology solely to the accidental influences brought to bear upon sexuality in the course of the subject's life - whereas better insight shows that the essence of these illnesses lies solely in a disturbance of the organism's sexual processes.

[1906a, 1583]

If we take the second of these stages as an average, we must point out that a number of people are, on account of their organization, not equal to meeting its demands. In whole classes of individuals the development of the sexual instinct, as we have described it above, from auto-erotism to object-love with its aim of uniting the genitals, has not been carried out correctly and sufficiently fully. As a result of these disturbances of development two kinds of harmful deviation from normal sexuality - that is, sexuality which is serviceable to civilization - come about; and the relation between these two is almost that of positive and negative.¹

[1908d, 1953]

Experience teaches us that for most people there is a limit beyond which their constitution cannot comply with the demands of civilization. All who wish to be more noble-minded than their constitution allows fall victims to neurosis; they would have been more healthy if it could have been possible for them to be less good. The discovery that perversions and neuroses stand in the relation of positive and negative is often unmistakably confirmed by observations made on the members of one generation of a family. Quite frequently a brother is a sexual pervert, while his sister, who, being a woman, possesses a weaker sexual instinct, is a neurotic whose symptoms express the same inclinations as the perversions of her sexually more active brother. And correspondingly, in many families the men are healthy, but from a social point of view immoral to an undesirable degree, while the women are high-minded and over-refined, but severely neurotic.

[1908d, 1955]
The answer to the first question touches on a problem which has often been discussed and cannot be exhaustively treated here - that of sexual abstinence. Our third stage of civilization demands of individuals of both sexes that they shall practise abstinence until they are married and that all who do not contract a legal marriage shall remain abstinent throughout their lives. The position, agreeable to all the authorities, that sexual abstinence is not harmful and not difficult to maintain, has also been widely supported by the medical profession. It may be asserted, however, that the task of mastering such a powerful impulse as that of the sexual instinct by any other means than satisfying it is one which can call for the whole of a man's forces. Mastering it by sublimation, by deflecting the sexual instinctual forces away from their sexual aim to higher cultural aims, can be achieved by a minority and then only intermittently, and least easily during the period of ardent and vigorous youth. Most of the rest become neurotic or are harmed in one way or another. Experience shows that the majority of the people who make up our society are constitutionally unfit to face the task of abstinence. Those who would have fallen ill under milder sexual restrictions fall ill all the more readily and more severely before the demands of our cultural sexual morality of to-day; for we know no better safe-guard against the threat to normal sexual life offered by defective innate dispositions or disturbances of development than sexual satisfaction itself. The more a person is disposed to neurosis, the less can he tolerate abstinence; instincts which have been withdrawn from normal development, in the sense in which it has been described above, become at the same time all the more uninhibitable. But even those people who would have retained their health under the requirements of the second stage of civilization will now succumb to neurosis in great numbers. For the psychical value of sexual satisfaction increases with its frustration. The dammed-up libido is now put in a position to detect one or other of the weaker spots which are seldom absent in the structure of sexual life, and there to break through and obtain substitutive satisfaction of a neurotic kind in the form of pathological symptoms. Anyone who is able to penetrate the determinants of nervous illness will soon become convinced that its increase in our society arises from the intensification of sexual restrictions.

[1908d, 1956]

I ask any well-informed person to bear witness to the fact that I am not exaggerating but that I am describing a state of affairs of which equally bad instances can be observed over and over again. To the uninitiated it is hardly credible how seldom normal potency is to be found in a husband and how often a wife is frigid among married couples who live under the dominance of our civilized sexual morality, what a degree of renunciation, often on both sides, is entailed by marriage, and to what narrow limits married life - the happiness that is so ardently desired - is narrowed down. I have already explained that in these circumstances the most obvious outcome is nervous illness; but I must further point out the way in which a marriage of this kind continues to exercise its influence on the few children, or the only child born of it. At a first glance, it seems to be a case of transmission by inheritance; but closer inspection shows that it is really a question of the effect of powerful infantile impressions. A neurotic wife who is unsatisfied by her husband is, as a mother, over-tender and over-anxious towards her child, on to whom she transfers her need for love; and she awakens it to sexual precocity. The bad relations between its parents, moreover, excite its emotional life and cause it to feel love and hatred to an intense degree while it is still at a very tender age. Its strict upbringing, which tolerates no activity of the sexual life that has been aroused so early, lends support to the suppressing force and this conflict at such an age contains everything necessary for bringing about lifelong nervous illness.

[1908d, 1961]
I return now to my earlier assertion that, in judging the neuroses, their full importance is not as a rule taken into account. I do not mean by this the undervaluation of these states shown in their frivolous dismissal by relatives and in the boasting assurances by doctors that a few weeks of cold water treatment or a few months of rest and convalescence will cure the condition. These are merely the opinions of quite ignorant doctors and laymen and are mostly no more than words intended to give the sufferer a short-lived consolation. It is, on the contrary, a well-known fact that a chronic neurosis, even if it does not totally put an end to the subject's capacity for existence, represents a severe handicap in his life, of the same order, perhaps, as tuberculosis or a cardiac defect. The situation would even be tolerable if neurotic illness were to exclude from civilized activities only a number of individuals who were in any case of the weaker sort, and allowed the rest to play their part in it at the cost of troubles that were merely subjective. But, far from this being so, I must insist upon the view that neuroses, whatever their extent and wherever they occur, always succeed in frustrating the purposes of civilization, and in that way actually perform the work of the suppressed mental forces that are hostile to civilization. Thus, when society pays for obedience to its far-reaching regulations by an increase in nervous illness, it cannot claim to have purchased a gain at the price of sacrifices; it cannot claim a gain at all. Let us, for instance, consider the very common case of a woman who does not love her husband, because, owing to the conditions under which she entered marriage, she has no reason to love him, but who very much wants to love him, because that alone corresponds to the ideal of marriage to which she has been brought up. She will in that case suppress every impulse which would express the truth and contradict her endeavours to fulfil her ideal, and she will make special efforts to play the part of a loving, affectionate and attentive wife. The outcome of this self-suppression will be a neurotic illness; and this neurosis will in a short time have taken revenge on the unloved husband and have caused him just as much lack of satisfaction and worry as would have resulted from an acknowledgement of the true state of affairs. This example is completely typical of what a neurosis achieves. A similar failure to obtain compensation is to be seen after the suppression of impulses inimical to civilization which are not directly sexual. If a man, for example, has become over-kind as a result of a violent suppression of a constitutional inclination to harshness and cruelty, he often loses so much energy in doing this that he fails to carry out all that his compensatory impulses require, and he may, after all, do less good on the whole than he would have done without the suppression.

[1908d, 1962]

Let us add that a restriction of sexual activity in a community is quite generally accompanied by an increase of anxiety about life and of fear of death which interferes with the individual's capacity for enjoyment and does away with his readiness to face death for any purpose. A diminished inclination to beget children is the result, and the community or group of people in question is thus excluded from any share in the future. In view of this, we may well raise the question whether our 'civilized' sexual morality is worth the sacrifice which it imposes on us, especially if we are still so much enslaved to hedonism as to include among the aims of our cultural development a certain amount of satisfaction of individual happiness. It is certainly not a physician's business to come forward with proposals for reform; but it seemed to me that I might support the urgency of such proposals if I were to amplify Von Ehrenfels's description of the injurious effects of our 'civilized' sexual morality by pointing to the important bearing of that morality upon the spread of modern nervous illness.

[1908d, 1963]
Psycho-analytic research into the neuroses (the various forms of nervous illness with a mental causation) has endeavoured to trace their connection with instinctual life and the restrictions imposed on it by the claims of civilization, with the activities of the normal individual in phantasies and dreams, and with the creations of the popular mind in religion, myths and fairy tales. The psycho-analytic treatment of neurotic patients, based on this method of research, makes far higher demands on doctor and patient than the methods hitherto in common use, which operate through medicaments, diet, hydropathy and suggestion. But it brings the patients so much more relief and permanent strengthening in the face of life's problems, that there is no cause for surprise at the continual advances made by this therapeutic method in spite of violent opposition.

[1910b, 1995]

We must not omit to consider the third of the possible outcomes of the work of psycho-analysis. A certain portion of the repressed libidinal impulses has a claim to direct satisfaction and ought to find it in life. Our civilized standards make life too difficult for the majority of human organizations. Those standards consequently encourage the retreat from reality and the generating of neuroses, without achieving any surplus of cultural gain by this excess of sexual repression. We ought not to exalt ourselves so high as completely to neglect what was originally animal in our nature. Nor should we forget that the satisfaction of the individual's happiness cannot be erased from among the aims of our civilization. The plasticity of the components of sexuality, shown by their capacity for sublimation, may indeed offer a great temptation to strive for still greater cultural achievements by still further sublimation. But, just as we do not count on our machines converting more than a certain fraction of the heat consumed into useful mechanical work, we ought not to seek to alienate the whole amount of the energy of the sexual instinct from its proper ends. We cannot succeed in doing so; and if the restriction upon sexuality were to be carried too far it would inevitably bring with it all the evils of soil-exhaustion.

[1910a, 2239]

Now, however, I must once more damp your expectations. Society will not be in a hurry to grant us authority. It is bound to offer us resistance, for we adopt a critical attitude towards it; we point out to it that it itself plays a great part in causing neuroses. Just as we make an individual our enemy by uncovering what is repressed in him, so society cannot respond with sympathy to a relentless exposure of its injurious effects and deficiencies. Because we destroy illusions we are accused of endangering ideals. It might seem, therefore, as though the condition from which I expect such great advantages for our therapeutic prospects will never be fulfilled. And yet the situation is not so hopeless as one might think at the present time. Powerful though men's emotions and self-interest may be, yet intellect is a power too - a power which makes itself felt, not, it is true, immediately, but all the more certainly in the end. The harshest truths are heard and recognized at last, after the interests they have injured and the emotions they have roused have exhausted their fury. It has always been so, and the unwelcome truths which we psycho-analysts have to tell the world will have the same fate. Only it will not happen very quickly; we must be able to wait.

[1910d, 2311]
Secondly, we know that the sexual instinct is originally divided into a great number of components - or rather, it develops out of them - some of which cannot be taken up into the instinct in its later form, but have at an earlier stage to be suppressed or put to other uses. These are above all the coprophilic instinctual components, which have proved incompatible with our aesthetic standards of culture, probably since, as a result of our adopting an erect gait, we raised our organ of smell from the ground. The same is true of a large portion of the sadistic urges which are a part of erotic life. But all such developmental processes affect only the upper layers of the complex structure. The fundamental processes which produce erotic excitation remain unaltered. The excremental is all too intimately and inseparably bound up with the sexual; the position of the genitals - *inter unrinas et faeces* - remains the decisive and unchangeable factor. One might say here, varying a well-known saying of the great Napoleon: 'Anatomy is destiny.' The genitals themselves have not taken part in the development of the human body in the direction of beauty: they have remained animal, and thus love, too, has remained in essence just as animal as it ever was. The instincts of love are hard to educate; education of them achieves now too much, now too little. What civilization aims at making out of them seems unattainable except at the price of a sensible loss of pleasure; the persistence of the impulses that could not be made use of can be detected in sexual activity in the form of non-satisfaction.

The cultural development imposed on mankind is the factor which necessitates the restrictions and repressions of the sexual instinct, greater or lesser sacrifices being demanded according to the individual constitution. Development is hardly ever achieved smoothly, and disturbances may occur (whether on account of the individual constitution or of premature sexual incidents) leaving behind a disposition to future neuroses. Such dispositions may remain harmless if the adult's life proceeds satisfactorily and quietly; but they become pathogenic if the conditions of mature life forbid satisfaction of the libido or make too high demands on its suppression.

Thus with this type, to which, no doubt, the majority of human beings on the whole belong, the possibility of falling ill arises only when there is abstinence. And it may be judged from this what an important part in the causation of neuroses may be played by the limitation imposed by civilization on the field of accessible satisfactions. Frustration has a pathogenic effect because it damns up libido, and so submits the subject to a test as to how long he can tolerate this increase in psychical tension and as to what methods he will adopt for dealing with it. There are only two possibilities for remaining healthy when there is a persistent frustration of satisfaction in the real world. The first is by transforming the psychical tension into active energy which remains directed towards the external world and eventually extorts a real satisfaction of the libido from it. The second is by renouncing libidinal satisfaction, sublimating the dammed-up libido and turning it to the attainment of aims which are no longer erotic and which escape frustration. That these two possibilities are realized in men's lives proves that unhappiness does not coincide with neurosis and that frustration does not alone decide whether its victim remains healthy or falls ill. The immediate effect of frustration lies in its bringing into play the dispositional factors which have hitherto been inoperative.

Psycho-analysis has established an intimate connection between these psychical achievements of individuals on the one hand and societies on the other by postulating one and the same dynamic source for both of them. It starts out from the basic idea that the principal function of the mental mechanism is to relieve the individual from the tensions created in him by his needs. One part of this task can be achieved by extracting satisfaction from the external world; and for this purpose it is essential to have control over the real world. But the satisfaction of another part of these needs - among them certain affective impulses - is regularly frustrated by reality. This leads to the further task of finding some other means of dealing with the unsatisfied impulses. The whole course of the history of civilization is no more than an account of the various methods adopted by mankind for 'binding' their unsatisfied wishes, which, according to changing conditions (modified, moreover, by technological advances) have been met by reality sometimes with favour and sometimes with frustration.

[1913], 2822

For the rest, most of the problems of artistic creation and appreciation await further study, which will throw the light of analytic knowledge on them and assign them their place in the complex structure presented by the compensation for human wishes. Art is a conventionally accepted reality in which, thanks to artistic illusion, symbols and substitutes are able to provoke real emotions. Thus art constitutes a region half-way between a reality which frustrates wishes and the wish-fulfilling world of the imagination - a region in which, as it were, primitive man's strivings for omnipotence are still in full force.

[1913], 2823

On the other hand, psycho-analysis has fully demonstrated the part played by social conditions and requirements in the causation of neurosis. The forces which, operating from the ego, bring about the restriction and repression of instinct owe their origin essentially to compliance with the demands of civilization. A constitution and a set of childhood experiences which, in other cases, would inevitably lead to a neurosis will produce no such result where this compliance is absent or where these demands are not made by the social circle in which the particular individual is placed. The old assertion that the increase in nervous disorders is a product of civilization is at least a half-truth. Young people are brought into contact with the demands of civilization by upbringing and example; and if instinctual repression occurs independently of these two factors, it is a plausible hypothesis to suppose that a primaeval and prehistoric demand has at last become part of the organized and inherited endowment of mankind. A child who produces instinctual repressions spontaneously is thus merely repeating a part of the history of civilization. What is to-day an act of internal restraint was once an external one, imposed, perhaps, by the necessities of the moment; and, in the same way, what is now brought to bear upon every growing individual as an external demand of civilization may some day become an internal disposition to repression.

[1913], 2824

The meaning of psychical conflict can be adequately expressed in another way by saying that for an external frustration to become pathogenic an internal frustration must be added to it. In that case, of course, the external and internal frustration relate to different paths and objects. The external frustration removes one possibility of satisfaction and the internal frustration seeks to exclude another possibility, about which the conflict then breaks out. I prefer this way of representing the matter because it has a secret content. For it hints at the probability that the internal impediments arose from real external obstacles during the prehistoric periods of human development.

[1916-1917, 3411]
Think it over! You have learnt all that is essential about the determinants of falling ill as well as all the factors that come into effect after the patient has fallen ill. Where do these leave room for any therapeutic influence? In the first place there is hereditary disposition. We have not talked about it very often because it is emphatically stressed from other directions and we have nothing new to say about it. But do not suppose that we underestimate it; precisely as therapists we come to realize its power clearly enough. In any case we can do nothing to alter it; we too must take it as something given, which sets a limit to our efforts. Next there is the influence of early experiences in childhood, to which we are in the habit of giving prominence in analysis: they belong to the past and we cannot undo them. Then comes everything that we have summarized as ‘real frustration’ - the misfortunes of life from which arise deprivation of love, poverty, family quarrels, ill-judged choice of a partner in marriage, unfavourable social circumstances, and the strictness of the ethical standards to whose pressure the individual is subject. Here, to be sure, there would be handles enough for a very effective therapy, but it would have to be of the kind which Viennese folklore attributes to the Emperor Joseph - the benevolent interference of a powerful personage before whose will people bow and difficulties vanish. But who are we, that we should be able to adopt benevolence of this kind as an instrument of our therapy? Poor ourselves and socially powerless, and compelled to earn our livelihood from our medical activity, we are not even in a position to extend our efforts to people without means, as other doctors with other methods of treatment are after all able to do. Our therapy is too time-consuming and too laborious for that to be possible. Perhaps, however, you are clutching at one of the factors I have mentioned and believe that there you have found the point at which our influence can make its attack. If the ethical restrictions demanded by society play a part in the deprivation imposed on the patient, treatment can, after all, give him the courage, or perhaps a direct injunction, to disregard those barriers and achieve satisfaction and recovery while forgoing the fulfilment of an ideal that is exalted, but so often not adhered to, by society. The patient will thus become healthy by ‘living a full life’ sexually. This, it is true, casts a shadow on analytic treatment for not serving general morality. What it has given to the individual it will have taken from the community.
[1916-1917, 3475]

But you must not conclude from my eagerness in defending myself against the charge that neurotics are encouraged in analytic treatment to live a full life - you must not conclude from this that we influence them in favour of conventional virtue. That is at least as far from being the case. It is true that we are not reformers but merely observers; nevertheless, we cannot help observing with a critical eye and we have found it impossible to side with conventional sexual morality or to form a very high opinion of the manner in which society attempts the practical regulation of the problems of sexual life. We can present society with a blunt calculation that what is described as its morality calls for a bigger sacrifice than it is worth and that its proceedings are not based on honesty and do not display wisdom. We do not keep such criticisms from our patients’ ears, we accustom them to giving unprejudiced consideration to sexual matters no less than to any others; and if, having grown independent after the completion of their treatment, they decide on their own judgement in favour of some midway position between living a full life and absolute asceticism, we feel our conscience clear whatever their choice. We tell ourselves that anyone who has succeeded in educating himself to truth about himself is permanently defended against the danger of immorality, even though his standard of morality may differ in some respect from that which is customary in society. Moreover, we must guard against over-estimating the importance of the part played by the question of abstinence in influencing neuroses. Only in a minority of cases can the pathogenic situation of frustration and the subsequent damming-up of libido be brought to an end by the sort of sexual intercourse that can be procured without much trouble.
[1916-1917, 3477]
Such a display of unfairness and lack of logic cries out for an explanation. Its origin is not hard to find. Human civilization rests upon two pillars, of which one is the control of natural forces and the other the restriction of our instincts. The ruler's throne rests upon fettered slaves. Among the instinctual components which are thus brought into service, the sexual instincts, in the narrower sense of the word, are conspicuous for their strength and savagery. Woe, if they should be set loose! The throne would be overturned and the ruler trampled under foot. Society is aware of this - and will not allow the topic to be mentioned.

[1925e, 4127]

But why not? What harm could the discussion do? Psycho-analysis has never said a word in favour of unfettering instincts that would injure our community; on the contrary it has issued a warning and an exhortation to us to mend our ways. But society refuses to consent to the ventilation of the question, because it has a bad conscience in more than one respect. In the first place it has set up a high ideal of morality - morality being restriction of the instincts - and insists that all its members shall fulfil that ideal without troubling itself with the possibility that obedience may bear heavily upon the individual. Nor is it sufficiently wealthy or well-organized to be able to compensate the individual for the amount of his instinctual renunciation. It is consequently left to the individual to decide how he can obtain, for the sacrifice he has made, enough compensation to enable him to preserve his mental balance. On the whole, however, he is obliged to live psychologically beyond his means, while the unsatisfied claims of his instincts make him feel the demands of civilization as a constant pressure upon him. Thus society maintains a condition of cultural hypocrisy which is bound to be accompanied by a sense of insecurity and a necessity for guarding what is an undeniably precarious situation by forbidding criticism and discussion. This line of thought holds good for all the instinctual impulses, including, therefore, the egoistic ones. The question whether it applies to all possible forms of civilization, and not merely to those which have evolved hitherto, cannot be discussed here. As regards the sexual instincts in the narrower sense, there is the further point that in most people they are tamed insufficiently and in a manner which is psychologically wrong and are therefore readier than the rest to break loose.

[1925e, 4127]
By allowing common feeling to be our guide in deciding what features of human life are to be regarded as civilized, we have obtained a clear impression of the general picture of civilization; but it is true that so far we have discovered nothing that is not universally known. At the same time we have been careful not to fall in with the prejudice that civilization is synonymous with perfecting, that it is the road to perfection pre-ordained for men. But now a point of view presents itself which may lead in a different direction. The development of civilization appears to us as a peculiar process which mankind undergoes, and in which several things strike us as familiar. We may characterize this process with reference to the changes which it brings about in the familiar instinctual dispositions of human beings, to satisfy which is, after all, the economic task of our lives. A few of these instincts are used up in such a manner that something appears in their place which, in an individual, we describe as a character-trait. The most remarkable example of such a process is found in the anal erotism of young human beings. Their original interest in the excretory function, its organs and products, is changed in the course of their growth into a group of traits which are familiar to us as parsimony, a sense of order and cleanliness - qualities which, though valuable and welcome in themselves, may be intensified till they become markedly dominant and produce what is called the anal character. How this happens we do not know, but there is no doubt about the correctness of the finding.¹

Now we have seen that order and cleanliness are important requirements of civilization, although their vital necessity is not very apparent, any more than their suitability as sources of enjoyment. At this point we cannot fail to be struck by the similarity between the process of civilization and the libidinal development of the individual. Other instincts are induced to displace the conditions for their satisfaction, to lead them into other paths. In most cases this process coincides with that of the sublimation (of instinctual aims) with which we are familiar, but in some it can be differentiated from it. Sublimation of instinct is an especially conspicuous feature of cultural development; it is what makes it possible for higher psychical activities, scientific, artistic or ideological, to play such an important part in civilized life. If one were to yield to a first impression, one would say that sublimation is a vicissitude which has been forced upon the instincts entirely by civilization. But it would be wiser to reflect upon this a little longer. In the third place, finally, and this seems the most important of all, it is impossible to overlook the extent to which civilization is built up upon a renunciation of instinct, how much it presupposes precisely the non-satisfaction (by suppression, repression or some other means?) of powerful instincts. This 'cultural frustration' dominates the large field of social relationships between human beings. As we already know, it is the cause of the hostility against which all civilizations have to struggle. It will also make severe demands on our scientific work, and we shall have much to explain here. It is not easy to understand how it can become possible to deprive an instinct of satisfaction. Nor is doing so without danger. If the loss is not compensated for economically, one can be certain that serious disorders will ensue.

¹[1930a, 4494]

Psycho-analytic work has shown us that it is precisely these frustrations of sexual life which people known as neurotics cannot tolerate. The neurotic creates substitutive satisfactions for himself in his symptoms, and these either cause him suffering in themselves or become sources of suffering for him by raising difficulties in his relations with his environment and the society he belongs to. The latter fact is easy to understand; the former presents us with a new problem. But civilization demands other sacrifices besides that of sexual satisfaction.

[1930a, 4500]
We have treated the difficulty of cultural development as a general difficulty of development by tracing it to the inertia of the libido, to its disinclination to give up an old position for a new one. We are saying much the same thing when we derive the antithesis between civilization and sexuality from the circumstance that sexual love is a relationship between two individuals in which a third can only be superfluous or disturbing, whereas civilization depends on relationships between a considerable number of individuals. When a love-relationship is at its height there is no room left for any interest in the environment; a pair of lovers are sufficient to themselves, and do not even need the child they have in common to make them happy. In no other case does Eros so clearly betray the core of his being, his purpose of making one out of more than one; but when he has achieved this in the proverbial way through the love of two human beings, he refuses to go further.

[1930a, 4500]
REACTION-FORMATION AND SUBLIMATION

What is it that goes to the making of these constructions which are so important for the growth of a civilized and normal individual? They probably emerge at the cost of the infantile sexual impulses themselves. Thus the activity of those impulses does not cease even during this period of latency, though their energy is diverted, wholly or in great part, from their sexual use and directed to other ends. Historians of civilization appear to be at one in assuming that powerful components are acquired for every kind of cultural achievement by this diversion of sexual insti

tucl forces from sexual aims and their direction to new ones - a process which deserves the name of 'sublimation'. To this we would add, accordingly, that the same process plays a part in the development of the individual and we would place its beginning in the period of sexual latency of childhood.¹

[1905d, 1500]

Generally speaking, our civilization is built up on the suppression of instincts. Each individual has surrendered some part of his possessions - some part of the sense of omnipotence or of the aggressive or vindictive inclinations in his personality. From these contributions has grown civilization's common possession of material and ideal property. Besides the exigencies of life, no doubt it has been family feelings, derived from erotism, that have induced the separate individuals to make this renunciation. The renunciation has been a progressive one in the course of the evolution of civilization. The single steps in it were sanctioned by religion; the piece of instinctual satisfaction which each person had renounced was offered to the Deity as a sacrifice, and the communal property thus acquired was declared 'sacred'. The man who, in consequence of his unyielding constitution, cannot fall in with this suppression of instinct, becomes a 'criminal', an 'outlaw',¹ in the face of society - unless his social position or his exceptional capacities enable him to impose himself upon it as a great man, a 'hero'.

[1908d, 1951]

Further prospects are opened up when we take into consideration the fact that in man the sexual instinct does not originally serve the purposes of reproduction at all, but has as its aim the gaining of particular kinds of pleasure.¹ It manifests itself in this way in human infancy, during which it attains its aim of gaining pleasure not only from the genitals but from other parts of the body (the erotogenic zones), and can therefore disregard any objects other than these convenient ones. We call this stage the stage of auto-erotism, and the child's upbringing has, in our view, the task of restricting it, because to linger in it would make the sexual instinct uncontrollable and unserviceable later on. The development of the sexual instinct then proceeds from auto-erotism to object-love and from the autonomy of the erotogenic zones to their subordination under the primacy of the genitals, which are put at the service of reproduction. During this development a part of the sexual excitation which is provided by the subject's own body is inhibited as being unserviceable for the reproductive function and in favourable cases is brought to sublimation. The forces that can be employed for cultural activities are thus to a great extent obtained through the suppression of what are known as the perverse elements of sexual excitation.

[1908d, 1953]
In the first place (disregarding people whose sexual instinct is altogether excessive and uninhibitable) there are the different varieties _perverts_, in whom an infantile fixation to a preliminary sexual aim has prevented the primacy of the reproductive function from being established, and the _homosexuals_ or _inverts_, in whom, in a manner that is not yet quite understood, the sexual aim has been deflected away from the opposite sex. If the injurious effects of these two kinds of developmental disturbance are less than might be expected, this mitigation can be ascribed precisely to the complex way in which the sexual instinct is put together, which makes it possible for a person's sexual life to reach a serviceable final form even if one or more components of the instinct have been shut off from development. The constitution of people suffering from inversion - the homosexuals - is, indeed, often distinguished by their sexual instinct's possessing a special aptitude for cultural sublimation.

[1908d, 1953]

But even if the damage done by civilized sexual morality is admitted, it may be argued in reply to our third question that the cultural gain derived from such an extensive restriction of sexuality probably more than balances these sufferings, which, after all, only affect a minority in any severe form. I must confess that I am unable to balance gain against loss correctly on this point, but I could advance a great many more considerations on the side of the loss. Going back to the subject of abstinence, which I have already touched on, I must insist that it brings in its train other noxae besides those involved in the neuroses and that the importance of the neuroses has for the most part not been fully appreciated.

[1908d, 1958]

A second outcome of the work of psycho-analysis is that it then becomes possible for the unconscious instincts revealed by it to be employed for the useful purposes which they would have found earlier if development had not been interrupted. For the extirpation of the infantile wishful impulses is by no means the ideal aim of development. Owing to their repressions, neurotics have sacrificed many sources of mental energy whose contributions would have been of great value in the formation of their character and in their activity in life. We know of a far more expedient process of development, called 'sublimation', in which the energy of the infantile wishful impulses is not cut off but remains ready for use - the unserviceable aim of the various impulses being replaced by one that is higher, and perhaps no longer sexual. It happens to be precisely the components of the sexual instinct that are specially marked by a capacity of this kind for sublimation, for exchanging their sexual aim for another one which is comparatively remote and socially valuable. It is probable that we owe our highest cultural successes to the contributions of energy made in this way to our mental functions. Premature repression makes the sublimation of the repressed instinct impossible; when the repression is lifted, the path to sublimation becomes free once more.

[1910a, 2238]
Thus we may perhaps be forced to become reconciled to the idea that it is quite impossible to adjust the claims of the sexual instinct to the demands of civilization; that in consequence of its cultural development renunciation and suffering, as well as the danger of extinction in the remotest future, cannot be avoided by the human race. This gloomy prognosis rests, it is true, on the single conjecture that the non-satisfaction that goes with civilization is the necessary consequence of certain peculiarities which the sexual instinct has assumed under the pressure of culture. The very incapacity of the sexual instinct to yield complete satisfaction as soon as it submits to the first demands of civilization becomes the source, however, of the noblest cultural achievements which are brought into being by ever more extensive sublimation of its instinctual components. For what motive would men have for putting sexual instinctual forces to other uses if, by any distribution of those forces, they could obtain fully satisfying pleasure? They would never abandon that pleasure and they would never make any further progress. It seems, therefore, that the irreconcilable difference between the demands of the two instincts - the sexual and the egoistic - has made men capable of ever higher achievements, though subject, it is true, to a constant danger, to which, in the form of neurosis, the weaker are succumbing to-day.

If, then, as we have learnt, psychogenic disturbances of vision depend on certain ideas connected with seeing being cut off from consciousness, we must, on the psycho-analytic view, assume that these ideas have come into opposition to other, more powerful ones, for which we use the collective concept of the 'ego'- a compound which is made up variously at different times - and have for that reason come under repression. But what can be the origin of this opposition, which makes for repression, between the ego and various groups of ideas? You will no doubt notice that it was not possible to frame such a question before the advent of psycho-analysis, for nothing was known earlier of psychical conflict and repression. Our researches, however, have put us in a position to give us the desired answer. Our attention has been drawn to the importance of the instincts in ideational life. We have discovered that every instinct tries to make itself effective by activating ideas that are in keeping with its aims. These instincts are not always compatible with one another; their interests often come into conflict. Opposition between ideas is only an expression of struggles between the various instincts. From the point of view of our attempted explanation, a quite specially important part is played by the undeniable opposition between the instincts which subserve sexuality, the attainment of sexual pleasure, and those other instincts, which have as their aim the self-preservation of the individual - the ego-instincts. As the poet has said, all the organic instincts that operate in our mind may be classified as 'hunger' or 'love'. We have traced the 'sexual instinct' from its first manifestations in children to its final form, which is described as 'normal'. We have found that it is put together from numerous 'component instincts' which are attached to excitations of regions of the body; and we have come to see that these separate instincts have to pass through a complicated development before they can be brought effectively to serve the aims of reproduction. The light thrown by psychology on the evolution of our civilization has shown us that it originates mainly at the cost of the sexual component instincts, and that these must be suppressed, restricted, transformed and directed to higher aims, in order that the mental constructions of civilization may be established. We have been able to recognize as a valuable outcome of these researches something that our colleagues have not yet been willing to believe, namely that the human ailments known as 'neuroses' are derived from the many different ways in which these processes of transformation in the sexual component instincts may miscarry. The 'ego' feels threatened by the claims of the sexual instincts and fend them off by repressions; these, however, do not always have the desired result, but lead to the formation of dangerous substitutes for the repressed and to burdensome reactions on the part of the ego. From these two classes of phenomena taken together there emerge what we call the symptoms of neuroses.

[1912d, 2346]

[1910i, 2368]
After the stage of heterosexual object-choice has been reached, the homosexual tendencies are not, as might be supposed, done away with or brought to a stop; they are merely deflected from their sexual aim and applied to fresh uses. They now combine with portions of the ego-instincts and, as 'attached' components, help to constitute the social instincts, thus contributing an erotic factor to friendship and comradeship, to esprit de corps and to the love of mankind in general. How large a contribution is in fact derived from erotic sources (with the sexual aim inhibited) could scarcely be guessed from the normal social relations of mankind. But it is not irrelevant to note that it is precisely manifest homosexuals, and among them again precisely those that set themselves against an indulgence in sensual acts, who are distinguished by taking a particularly active share in the general interests of humanity - interests which have themselves sprung from a sublimation of erotic instincts.

The psycho-analytic explanation of the neuroses does not, however, call for such far-ranging considerations. The separate following-up of the sexual and ego-instincts has helped us to find the key to an understanding of the group of transference neuroses. We have been able to trace them back to the basic situation in which the sexual instincts have come into a dispute with the self-preservative instincts, or, to put it in biological (though less precise) terms, a situation in which one aspect of the ego, as an independent individual organism, comes into conflict with its other aspect, as a member of a succession of generations. A dissension of this kind may perhaps only occur in human beings, and on that account neurosis may, generally speaking, constitute their prerogative over the animals. The excessive development of their libido and - what is perhaps made possible precisely by that - their development of a richly articulated mental life seem to have created the determinants for the occurrence of such a conflict. It is at once obvious that these are also the determinants for the great advances that human beings have made beyond what they have in common with the animals; so that their susceptibility to neurosis would only be the reverse side of their other endowments. But these too are only speculations, which are diverting us from our immediate task.

It is an odd thing that the regular and essential part of this sexual activity was not overlooked. Or rather, it is by no means odd; for it was impossible to overlook it. Children's sexual impulses find their main expressions in self-gratification by friction of their own genitals, or, more precisely, of the male portion of them. The extraordinarily wide distribution of this form of childish 'naughtiness' was always known to adults, and it was regarded as a grave sin and severely punished. But please do not ask me how people could reconcile these observations of the immoral inclinations of children - for children do it, as they themselves say, because it gives them pleasure - with the theory of their innate purity and non-sensuality. You must get our opponents to solve this riddle. We have a more important problem before us. What attitude should we adopt towards the sexual activity of early childhood? We know the responsibility we are incurring if we suppress it; but we do not venture to let it take its course without restriction. Among races at a low level of civilization, and among the lower strata of civilized races, the sexuality of children seems to be given free rein. This probably provides a powerful protection against the subsequent development of neuroses in the individual. But does it not at the same time involve an extraordinary loss of the aptitude for cultural achievements? There is a good deal to suggest that here we are faced by a new Scylla and Charybdis.
It is advisable to draw a sharp distinction between the two types of onset of illness - a sharper distinction than observation as a rule permits. In the first type what is prominent is a change in the external world; in the second type the accent falls on an internal change. In the first type the subject falls ill from an experience; in the second type it is from a developmental process. In the first case he is faced by the task of renouncing satisfaction, and he falls ill from his incapacity for resistance; in the second case his task is to exchange one kind of satisfaction for another, and he breaks down from his inflexibility. In the second case the conflict, which is between the subject's effort to remain as he is and the effort to change himself in order to meet fresh purposes and fresh demands from reality, is present from the first. In the former case the conflict only arises after the dammed-up libido has chosen other, and incompatible, possibilities of satisfaction. The part played by the conflict and the previous fixation of the libido is incomparably more obvious in the second type than in the first, in which such unserviceable fixations may perhaps only emerge as a result of the external frustration.

A certain practical importance may readily be allowed to these types of onset. They are to be met with in their pure form, indeed, in individual cases; we should not have noticed the third and fourth types if they had not in some subjects constituted the sole precipitating causes of the illness. The first type keeps before our eyes the extraordinarily powerful influence of the external world, and the second the no less important influence - which opposes the former one - of the subject's peculiar individuality. Pathology could not do justice to the problem of the precipitating factors in the neuroses so long as it was merely concerned with deciding whether those affections were of an 'endogenous' or 'exogenous' nature. It was bound to meet every observation which pointed to the importance of abstinence (in the widest sense of the word) as a precipitating cause with the objection that other people tolerate the same experiences without falling ill. If, however, it sought to lay stress on the peculiar individuality of the subject as being the essential factor decisive between illness and health, it was obliged to put up with the proviso that people possessing such a peculiarity can remain healthy indefinitely, just so long as they are able to retain that peculiarity. Psycho-analysis has warned us that we must give up the unfruitful contrast between external and internal factors, between experience and constitution, and has taught us that we shall invariably find the cause of the onset of neurotic illness in a particular psychical situation which can be brought about in a variety of ways.

[1912c, 2561]
In further pursuing the discussion of this thesis, are we to consider the nature of the frustration or the peculiar character of those who are affected by it? It is extremely seldom, after all, that frustration is universal and absolute. In order to operate pathogenically it must no doubt affect the mode of satisfaction which alone the subject desires, of which alone he is capable. There are in general very many ways of tolerating deprivation of libidinal satisfaction without falling ill as a result. In the first place, we know people who are able to put up with a deprivation of this kind without being injured: they are not happy, they suffer from longing, but they do not fall ill. Next, we must bear in mind that the sexual instinctual impulses in particular are extraordinarily plastic, if I may so express it. One of them can take the place of another, one of them can take over another's intensity; if the satisfaction of one of them is frustrated by reality, the satisfaction of another can afford complete compensation. They are related to one another like a network of intercommunicating channels filled with a liquid; and this is so in spite of their being subject to the primacy of the genitals - a state of affairs that is not at all easily combined in a single picture. Further, the component instincts of sexuality, as well as the sexual current which is compounded from them, exhibit a large capacity for changing their object, for taking another in its place - and one, therefore, that is more easily attainable. This displaceability and readiness to accept a substitute must operate powerfully against the pathogenic effect of a frustration. Among these protective processes against falling ill owing to deprivation there is one which has gained special cultural significance. It consists in the sexual trend abandoning its aim of obtaining a component or a reproductive pleasure and taking on another which is related genetically to the abandoned one but is itself no longer sexual and must be described as social. We call this process 'sublimation', in accordance with the general estimate that places social aims higher than the sexual ones, which are at bottom self-interested. Sublimation is, incidentally, only a special case of the way in which sexual trends are attached to other, non-sexual ones. We shall have to discuss it again in another connection.

You may now have an impression that deprivation has been reduced to insignificance owing to all these methods of tolerating it. But no, it retains its pathogenic power. The counter-measures are on the whole insufficient. There is a limit to the amount of unsatisfied libido that human beings on the average can put up with. The plasticity or free mobility of the libido is by no means fully preserved in everyone, and sublimation is never able to deal with more than a certain fraction of libido, quite apart from the fact that many people are gifted with only a small amount of capacity to sublimate. The most important of these limitations is evidently that upon the mobility of the libido, since it makes a person's satisfaction depend on the attainment of only a very small number of aims and objects. You have only to recall that an imperfect development of the libido leaves behind it very fertile and perhaps, too, very numerous libidinal fixations to early phases of the organization and of the finding of objects, which are for the most part incapable of real satisfaction, and you will recognize in libidinal fixation the second powerful factor which combines with frustration as the cause of illness. You can declare, as a schematic abbreviation, that libidinal fixation represents the predisposing, internal factor in the aetiology of the neuroses, while frustration represents the accidental, external one.
You will no doubt have observed that in these last discussions I have introduced a fresh factor into the structure of the aetiological chain - namely the quantity, the magnitude, of the energies concerned. We have still to take this factor into account everywhere. A purely qualitative analysis of the aetiological determinants is not enough. Or, to put it another way, a merely *dynamic* view of these mental processes is insufficient; an *economic* line of approach is also needed. We must tell ourselves that the conflict between two trends does not break out till certain intensities of cathexis have been reached, even though the determinants for it have long been present so far as their subject-matter is concerned. In the same way, the pathogenic significance of the constitutional factors must be weighed according to how much *more* of one component instinct than of another is present in the inherited disposition. It may even be supposed that the disposition of all human beings is qualitatively alike and that they differ only owing to these quantitative conditions. The quantitative factor is no less decisive as regards capacity to resist neurotic illness. It is a matter of *what quota* of unemployed libido a person is able to hold in suspension and of *how large a fraction* of his libido he is able to divert from sexual to sublimated aims. The ultimate aim of mental activity, which may be described qualitatively as an endeavour to obtain pleasure and avoid unpleasure, emerges, looked at from the economic point of view, as the task of mastering the amounts of excitation (mass of stimuli) operating in the mental apparatus and of keeping down their accumulation which creates unpleasure.

[1916-1917, 3429]

If, then, there are children who come some way to meet this education in anxiety, and who go on to find dangers themselves that they have not been warned against, this is sufficiently explained by the fact that they have a greater amount of innate libidinal need in their constitution or have been prematurely spoiled by libidinal satisfaction. It is not to be wondered at if such children include, too, the later neurotics: as we know, what most facilitates the development of a neurosis is an incapacity to tolerate a considerable damming-up of libido over any great length of time. You will observe that here once more the constitutional factor comes into its rights - and these, indeed, we have never sought to dispute. We are only on our guard against those who in its favour neglect all other claims, and who introduce the constitutional factor at points at which the combined results of observation and analysis show that it does not belong or must take the last place.

[1916-1917, 3454]
Your second observation, too, raises a justifiable question, but it is aimed in the wrong direction. It is true that a withdrawal of the object-libido into the ego is not directly pathogenic; it takes place, indeed, as we know, every time before we go to sleep, only to be reversed when we wake up. The amoeba withdraws its protrusions only to send them out again at the first opportunity. But it is quite a different thing when a particular, very energetic process forces a withdrawal of libido from objects. Here the libido that has become narcissistic cannot find its way back to objects, and this interference with the libido's mobility certainly becomes pathogenic. It seems that an accumulation of narcissistic libido beyond a certain amount is not tolerated. We may even imagine that it was for that very reason that object-cathexes originally came about, that the ego was obliged to send out its libido so as not to fall ill as a result of its being dammed up. If it lay within our plan to go more deeply into dementia praecox, I would show you that the process which detaches the libido from objects and cuts off its return to them is closely related to the process of repression and is to be looked at as its counterpart. But you would, first and foremost, find yourselves on familiar ground when you learnt that the determinants of this process are almost identical - so far as we know at present - with those of repression. The conflict seems to be the same and to be carried on between the same forces. If the outcome is so different from, for instance, that in hysteria, the reason can only depend on a difference in innate disposition. The weak spot in the libidinal development of these patients lies in a different phase; the determining fixation, which, as you will recollect, permits the irruption that leads to the formation of symptoms, lies elsewhere, probably in the stage of primitive narcissism to which dementia praecox returns in its final outcome. It is very remarkable that in the case of all the narcissistic neuroses we have to assume fixation points for the libido going back to far earlier phases of development than in hysteria or obsessional neurosis. As you heard, however, the concepts which we arrived at during our study of the transference neuroses are adequate in helping us to find our way about in the narcissistic neuroses which are so much more severe in practice. The conformities go very far; at bottom the field of phenomena is the same. And you can imagine how small a prospect anyone has of explaining these disorders (which belong within the sphere of psychiatry) who is not forearmed for his task with an analytic knowledge of the transference neuroses.

[1916-1917, 3466]
Obsessional prohibitions involve just as extensive renunciations and restrictions in the lives of those who are subject to them as do taboo prohibitions; but some of them can be lifted if certain actions are performed. Thereafter, these actions must be performed: they become compulsive or obsessive acts, and there can be no doubt that they are in the nature of expiation, penance, defensive measures and purification. The commonest of these obsessive acts is washing in water ('washing mania'). Some taboo prohibitions can be replaced in just the same way; or rather their violation can be made good by a similar 'ceremonial'; and here again lustration with water is the preferred method.

If the violation of a taboo can be made good by atonement or expiation, which involve the renunciation of some possession or some freedom, this proves that obedience to the taboo injunction meant in itself the renunciation of something desirable. Emancipation from one renunciation is made up for by the imposition of another one elsewhere. This leads us to conclude that atonement is a more fundamental factor than purification in the ceremonies of taboo.

I shall not attempt to give a complete catalogue of the instances quoted by Frazer of restrictions imposed upon victorious manslayers. I will only remark upon a few more such cases in which their taboo character is particularly marked or in which the restrictions are accompanied by expiation, purification and other ceremonies.

However much the details and variations of the ceremonies of expiation and purification after the slaying of enemies might be of interest for deeper research into the subject, I shall break off at this point, since for our present purpose they have nothing more to tell us. I may perhaps suggest that the temporary or permanent isolation of professional executioners, which has persisted to the present day, may belong in this connection. The position of the public hangman in mediaeval society offers a good picture of the workings of taboo among savages.¹

In the accepted explanation of all these observances of appeasement, restriction, expiation and purification, two principles are combined: the extension of the taboo from the slain man on to everything that has come in contact with him, and the fear of the slain man's ghost. How these two factors are to be combined with each other to explain the ceremonies, whether they are to be regarded as of equal weight, whether one is primary and the other secondary, and if so which - none of these questions receives an answer, and indeed it would be hard to find one. We, on the other hand, can lay stress on the unity of our view, which derives all of these observances from emotional ambivalence towards the enemy.
The second danger in a development by stages of this sort lies in the fact that the portions which have proceeded further may also easily return retrogressively to one of these earlier stages - what we describe as a *regression*. The trend will find itself led into a regression of this kind if the exercise of its function - that is, the attainment of its aim of satisfaction - is met, in its later or more highly developed form, by powerful external obstacles. It is plausible to suppose that fixation and regression are not independent of each other. The stronger the fixations on its path of development, the more readily will the function evade external difficulties by regressing to the fixations - the more incapable, therefore, does the developed function turn out to be of resisting external obstacles in its course. Consider that, if a people which is in movement has left strong detachments behind at the stopping-places on its migration, it is likely that the more advanced parties will be inclined to retreat to these stopping-places if they have been defeated or have come up against a superior enemy. But they will also be in the greater danger of being defeated the more of their number they have left behind on their migration.

For the moment we will dwell a little longer on regression. After what you have learnt of the development of the libidinal function, you will be prepared to hear that there are regressions of two sorts: a return to the objects first cathected by the libido, which, as we know, are of an incestuous nature, and a return of the sexual organization as a whole to earlier stages. Both sorts are found in the transference neuroses and play a great part in their mechanism. In particular, a return to the first incestuous objects of the libido is a feature that is found in neurotics with positively fatiguing regularity. There is much more to be said about regressions of the libido itself when we take into account as well another group of neuroses, the narcissistic ones, which for the time being we do not intend to do. These disorders give us access to other developmental processes of the libidinal function which we have not yet mentioned, and show us correspondingly new sorts of regression as well. But above all I think I ought to warn you now not to confuse *regression* with *repression* and help you to form a clear idea of the relations between the two processes. Repression, as you will recall, is the process by which an act which is admissible to consciousness, one, therefore, which belongs to the system *Pcs.*, is made unconscious - is pushed back, therefore, into the system *Ucs.* And we equally speak of repression if the unconscious mental act is altogether forbidden access to the neighbouring preconscious system and is turned back at the threshold by the censorship. Thus the concept of repression involves no relation to sexuality: I must ask you to take special note of that. It indicates a purely psychological process, which we can characterize still better if we call it a 'topographical' one. By this we intend to say that it is concerned with the psychical regions which we have assumed to exist, or, if we drop this clumsy working hypothesis, with the construction of the mental apparatus out of distinct psychical systems.

[1916-1917, 3404]
The comparison we have proposed has drawn our attention for the first time to the fact that we have not hitherto been using the word 'regression' in its general sense but in a quite special one. If we give it its general sense - of a return from a higher to a lower stage of development - then repression too can be subsumed under the concept of regression, for it too can be described as a return to an earlier and deeper stage in the development of a psychical act. In the case of repression, however, this regressive movement does not concern us, since we also speak of repression, in the dynamic sense, when a psychical act is held back at the lower, unconscious, stage. The fact is that repression is a topographico-dynamic concept, while regression is a purely descriptive one. What we have hitherto spoken of as regression, however, and have related to fixation, has meant exclusively a return of the libido to earlier stopping places in its development - something, that is, entirely different in its nature from repression and entirely independent of it. Nor can we call regression of the libido a purely psychical process and we cannot tell where we should localize it in the mental apparatus. And though it is true that it exercises the most powerful influence on mental life, yet the most prominent factor in it is the organic one.

[1916-1917, 3406]

The transition from the pleasure principle to the reality principle is one of the most important steps forward in the ego's development. We know already that it is only late and unwillingly that the sexual instincts join in this piece of development, and we shall hear later the consequences for human beings of the fact that their sexuality is content with such a loose connection with external reality. And now in conclusion one last remark on this subject. If man's ego has its process of development like the libido, you will not be surprised to hear that there are also 'regressions of the ego', and you will be anxious to know too what part may be played in neurotic illnesses by this return of the ego to earlier phases of its development.

[1916-1917, 3416]

We already know that neurotic symptoms are the outcome of a conflict which arises over a new method of satisfying the libido. The two forces which have fallen out meet once again in the symptom and are reconciled, as it were, by the compromise of the symptom that has been constructed. It is for that reason, too, that the symptom is so resistant: it is supported from both sides. We also know that one of the two partners to the conflict is the unsatisfied libido which has been repulsed by reality and must now seek for other paths to its satisfaction. If reality remains relentless even though the libido is ready to take another object in place of the one that has been refused to it, then it will finally be compelled to take the path of regression and strive to find satisfaction either in one of the organizations which it has already outgrown or from one of the objects which it has earlier abandoned. The libido is lured into the path of regression by the fixation which it has left behind it at these points in its development.

[1916-1917, 3417]

The hereditary sexual constitution presents us with a great variety of dispositions, according as one component instinct or another, alone or in combination with others, is inherited in particular strength. The sexual constitution forms once again, together with the factor of infantile experience, a 'complemental series' exactly similar to the one we first came to know between disposition and the accidental experience of the adult. In both of them we find the same extreme cases and the same relations between the two factors concerned. And here the question suggests itself of whether the most striking kinds of libidinal regressions - those to earlier stages of the sexual organization - may not be predominantly determined by the hereditary constitutional factor. But it is best to postpone answering this question till we have been able to take a wider range of forms of neurotic illness into account.

[1916-1917, 3420]
The sexual function, as I found, is in existence from the very beginning of the individual's life, though at first it is attached to the other vital functions and does not become independent of them until later; it has to pass through a long and complicated process of development before it becomes what we are familiar with as the normal sexual life of the adult. It begins by manifesting itself in the activity of a whole number of component instincts. These are dependent upon erogenous zones in the body; some of them make their appearance in pairs of opposite impulses (such as sadism and masochism or the impulses to look and to be looked at); they operate independently of one another in a search for pleasure, and they find their object for the most part in the subject's own body. Thus at first the sexual function is non-centralized and predominantly auto-erotic. Later, syntheses begin to appear in it; a first stage of organization is reached under the dominance of the oral components, an anal-sadistic stage follows, and it is only after the third stage has at last been reached that the primacy of the genitals is established and that the sexual function begins to serve the ends of reproduction. In the course of this process of development a number of elements of the various component instincts turn out to be unserviceable for this last end and are therefore left on one side or turned to other uses, while others are diverted from their aims and carried over into the genital organization. I gave the name of libido to the energy of the sexual instincts and to that form of energy alone. I was next driven to suppose that the libido does not always pass through its prescribed course of development smoothly. As a result either of the excessive strength of certain of the components or of experiences involving premature satisfaction, fixations of the libido may occur at various points in the course of its development. If subsequently a repression takes place, the libido flows back to these points (a process described as regression), and it is from them that the energy breaks through in the form of a symptom. Later on it further became clear that the localization of the point of fixation is what determines the choice of neurosis, that is, the form in which the subsequent illness makes its appearance.

I am well aware that a number of cases exhibit a more complicated structure and that many other repressed instinctual impulses can enter into a phobia. But they are only tributary streams which have for the most part joined the main current of the neurosis at a later stage. The symptomatology of agoraphobia is complicated by the fact that the ego does not confine itself to making a renunciation. In order to rob the situation of danger it does more: it usually effects a temporal regression to infancy (in extreme cases, to a time when the subject was in his mother's womb and protected against the dangers which threaten him in the present). Such a regression now becomes a condition whose fulfilment exempts the ego from making its renunciation. For instance, an agoraphobic patient may be able to walk in the street provided he is accompanied, like a small child, by someone he knows and trusts; or, for the same reason, he may be able to go out alone provided he remains within a certain distance of his own house and does not go to places which are not familiar to him or where people do not know him. What these stipulations are will depend in each case on the infantile factors which dominate him through his neurosis. The phobia of being alone is unambiguous in its meaning, irrespective of any infantile regression: it is, ultimately, an endeavour to avoid the temptation to indulge in solitary masturbation. Infantile regression can, of course, only take place when the subject is no longer a child.
Now let us go back and turn to the id. It is not so easy to guess what occurs during repression in connection with the instinctual impulse that is being fought against. The main question which our interest raises is as to what happens to the energy, to the libidinal charge, of that excitation - how is it employed? You recollect that the earlier hypothesis was that it is precisely this that is transformed by repression into anxiety. We no longer feel able to say that. The modest reply will rather be that what happens to it is probably not always the same thing. There is probably an intimate correspondence which we ought to get to know about between what is occurring at the time in the ego and in the id in connection with the repressed impulse. For since we have decided that the pleasure-unpleasure principle, which is set in action by the signal of anxiety, plays a part in repression, we must alter our expectations. That principle exercises an entirely unrestricted dominance over what happens in the id. We can rely on its bringing about quite profound changes in the instinctual impulse in question. We are prepared to find that repression will have very various consequences, more or less far-reaching. In some cases the repressed instinctual impulse may retain its libidinal cathexis, and may persist in the id unchanged, although subject to constant pressure from the ego. In other cases what seems to happen is that it is totally destroyed, while its libido is permanently diverted along other paths. I expressed the view that this is what happens when the Oedipus complex is dealt with normally - in this desirable case, therefore, being not simply repressed but destroyed in the id. Clinical experience has further shown us that in many cases, instead of the customary result of repression, a degradation of the libido takes place - a regression of the libidinal organization to an earlier stage. This can, of course, only occur in the id, and if it occurs it will be under the influence of the same conflict which was introduced by the signal of anxiety. The most striking example of this kind is provided by the obsessional neurosis, in which libidinal regression and repression operate together.

[1933a, 4698]

Our attitude to the phases of the organization of the libido has in general shifted a little. Whereas earlier we chiefly emphasized the way in which each of them passed away before the next, our attention now is directed to the facts that show us how much of each earlier phase persists alongside of and behind the later configurations and obtains a permanent representation in the libidinal economy and character of the subject. Still more significant have studies become which have taught us how frequently under pathological conditions regressions to earlier phases occur and that particular regressions are characteristic of particular forms of illness. But I cannot go into that here, it forms part of the specialized psychology of the neuroses.

[1933a, 4705]
Two further reasons why dreams should be forgotten, which Benini quotes as having been brought forward by Bonatelli as additions to those mentioned by Strümpell, seem in fact to be already covered by the latter. They are (1) that the alteration in coenaesthesia between the sleeping and waking states is unfavourable to reciprocal reproduction between them; and (2) that the different arrangement of the ideational material in dreams makes them untranslatable, as it were, for waking consciousness.

[1900a, 555]

The deeper you penetrate into the pathogenesis of nervous illness, the more you will find revealed the connection between the neuroses and other productions of the human mind, including the most valuable. You will be taught that we humans, with the high standards of our civilization and under the pressure of our internal repressions, find reality unsatisfying quite generally, and for that reason entertain a life of phantasy in which we like to make up for the insufficiencies of reality by the production of wish-fulfilments. These phantasies include a great deal of the true constitutional essence of the subject's personality as well as of those of his impulses which are repressed where reality is concerned. The energetic and successful man is one who succeeds by his efforts in turning his wishful phantasies into reality. Where this fails, as a result of the resistances of the external world and of the subject's own weakness, he begins to turn away from reality and withdraws into his more satisfying world of phantasy, the content of which is transformed into symptoms should he fall ill. In certain favourable circumstances, it still remains possible for him to find another path leading from these phantasies to reality, instead of becoming permanently estranged from it by regressing to infancy. If a person who is at loggerheads with reality possesses an artistic gift (a thing that is still a psychological mystery to us), he can transform his phantasies into artistic creations instead of into symptoms. In this manner he can escape the doom of neurosis and by this roundabout path regain his contact with reality. (Cf. Rank, 1907.) If there is persistent rebellion against the real world and if this precious gift is absent or insufficient, it is almost inevitable that the libido, keeping to the sources of the phantasies, will follow the path of regression, and will revive infantile wishes and end in neurosis. To-day neurosis takes the place of the monasteries which used to be the refuge of all whom life had disappointed or who felt too weak to face it.

[1910a, 2235]
Leonardo emerges from the obscurity of his boyhood as an artist, a painter and a sculptor, owing to a specific talent which may have been reinforced by the precocious awakening in the first years of childhood of his scopophilic instinct. We should be most glad to give an account of the way in which artistic activity derives from the primal instincts of the mind if it were not just here that our capacities fail us. We must be content to emphasize the fact - which it is hardly any longer possible to doubt - that what an artist creates provides at the same time an outlet for his sexual desire; and in Leonardo's case we can point to the information which comes from Vasari, that heads of laughing women and beautiful boys - in other words, representations of his sexual objects - were notable among his first artistic endeavours. In the bloom of his youth Leonardo appears at first to have worked without inhibition. Just as he modelled himself on his father in the outward conduct of his life, so too he passed through a period of masculine creative power and artistic productiveness in Milan, where a kindly fate enabled him to find a father substitute in the duke Lodovico Moro. But soon we and confirmation of our experience that the almost total repression of a real sexual life does not provide the most favourable conditions for the exercise of sublimated sexual trends. The pattern imposed by sexual life made itself felt. His activity and his ability to form quick decisions began to fail; his tendency towards deliberation and delay was already noticeable as a disturbing element in the 'Last Supper', and by influencing his technique it had a decisive effect on the fate of that great painting. Slowly there occurred in him a process which can only be compared to the regressions in neurotics. The development that turned him into an artist at puberty was overtaken by the process which led him to be an investigator, and which had its determinants in early infancy. The second sublimation of his erotic instinct gave place to the original sublimation for which the way had been prepared on the occasion of the first repression. He became an investigator, at first still in the service of his art, but later independently of it and away from it. With the loss of his patron, the substitute for his father, and with the increasingly sombre colours which his life took on, this regressive shift assumed larger and larger proportions. He became 'impacientissimo al pennello',¹ as we are told by a correspondent of the Countess Isabella d'Este, who was extremely eager to possess a painting from his hand. His infantile past had gained control over him. But the research which now took the place of artistic creation seems to have contained some of the features which distinguish the activity of unconscious instincts - insatiability, unyielding rigidity and the lack of an ability to adapt to real circumstances.

At the summit of his life, when he was in his early fifties - a time when in women the sexual characters have already undergone involution and when in men the libido not infrequently makes a further energetic advance - a new transformation came over him. Still deeper layers of the contents of his mind became active once more; but this further regression was to the benefit of his art, which was in the process of becoming stunted. He met the woman who awakened his memory of his mother's happy smile of sensual rapture; and, influenced by this revived memory, he recovered the stimulus that guided him at the beginning of his artistic endeavours, at the time when he modelled the smiling women. He painted the Mona Lisa, the 'St. Anne with Two Others' and the series of mysterious pictures which are characterized by the enigmatic smile. With the help of the oldest of all his erotic impulses he enjoyed the triumph of once more conquering the inhibition in his art. This final development is obscured from our eyes in the shadows of approaching age. Before this his intellect had soared upwards to the highest realizations of a conception of the world that left his epoch far behind it.

¹[1910c, 2301]

²[1910c, 2302]
In my *Three Essays on the Theory of Sexuality* I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics *endeavour to protect themselves against any such sexualization of their social instinctual cathexes*, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) *schizophrenia*; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients’ dispositional fixations.

[1911c, 2431]

(3) The third phase, and the most important as regards pathological phenomena, is that of failure of repression, of *irruption*, of *return of the repressed*. This irruption takes its start from the point of fixation, and it implies a regression of the libidinal development to that point.

[1911c, 2435]
Our second problem - the problem of why transference appears in psycho-analysis as resistance - has been left for the moment untouched; and we must now approach it more closely. Let us picture the psychological situation during the treatment. An invariable and indispensable precondition of every onset of a psychoneurosis is the process to which Jung has given the appropriate name of 'introversion'.¹ That is to say: the portion of libido which is capable of becoming conscious and is directed towards reality is diminished, and the portion which is directed away from reality and is unconscious, and which, though it may still feed the subject's phantasies, nevertheless belongs to the unconscious, is proportionately increased. The libido (whether wholly or in part) has entered on a regressive course and has revived the subject's infantile imagos.² The analytic treatment now proceeds to follow it; it seeks to track down the libido, to make it accessible to consciousness and, in the end, serviceable for reality. Where the investigations of analysis come upon the libido withdrawn into its hiding-place, a struggle is bound to break out; all the forces which have caused the libido to regress will rise up as 'resistances' against the work of analysis, in order to conserve the new state of things. For if the libido's introversion or regression had not been justified by a particular relation between the subject and the external world - stated in the most general terms, by the frustration of satisfaction - and if it had not for the moment even become expedient, it could never have taken place at all. But the resistances from this source are not the only ones or indeed the most powerful. The libido at the disposal of the subject's personality had always been under the influence of the attraction of his unconscious complexes (or more correctly, of the portions of those complexes belonging to the unconscious), and it entered on a regressive course because the attraction of reality had diminished. In order to liberate it, this attraction of the unconscious has to be overcome; that is, the repression of the unconscious instincts and of their productions, which has meanwhile been set up in the subject, must be removed. This is responsible for by far the largest part of the resistance, which so often causes the illness to persist even after the turning away from reality has lost its temporary justification. The analysis has to struggle against the resistances from both these sources. The resistance accompanies the treatment step by step. Every single association, every act of the person under treatment must reckon with the resistance and represents a compromise between the forces that are striving towards recovery and the opposing ones which I have described.

² It would be convenient if we could say 'it has recathected his infantile complexes'. But this would be incorrect: the only justifiable way of putting it would be 'the unconscious portions of those complexes'. The topics dealt with in this paper are so extraordinarily involved that it is tempting to embark on a number of contiguous problems whose clarification would in point of fact be necessary before it would be possible to speak in unambiguous terms of the psychical processes that are to be described here. These problems include the drawing of a line of distinction between introversion and regression, the fitting of the theory of complexes into the libido theory, the relations of phantasying to the conscious and the unconscious as well as to reality - and others besides. I need not apologize for having resisted this temptation in the present paper.

[1912b, 2459]
Where these are present and sufficiently strongly developed, there is a risk of the libido becoming 'introverted'.¹ It turns away from reality, which, owing to the obstinate frustration, has lost its value for the subject, and turns towards the life of phantasy, in which it creates new wishful structures and revives the traces of earlier, forgotten ones. In consequence of the intimate connection between the activity of phantasy and material present in everyone which is infantile and repressed and has become unconscious, and thanks to the exceptional position enjoyed by the life of phantasy in regard to reality-testing,² the libido may thenceforward move on a backward course; it may follow the path of regression along infantile lines, and strive after aims that correspond with them. If these strivings, which are incompatible with the subject's present-day individuality, acquire enough intensity, a conflict must result between them and the other portion of his personality, which has maintained its relation to reality. This conflict is resolved by the formation of symptoms, and is followed by the onset of manifest illness. The fact that the whole process originated from frustration in the real world is reflected in the resulting event that the symptoms, in which the ground of reality is reached once more, represent substitutive satisfactions.

[1912c, 2560]

It is advisable to draw a sharp distinction between the two types of onset of illness - a sharper distinction than observation as a rule permits. In the first type what is prominent is a change in the external world; in the second type the accent falls on an internal change. In the first type the subject falls ill from an experience; in the second type it is from a developmental process. In the first case he is faced by the task of renouncing satisfaction, and he falls ill from his incapacity for resistance; in the second case his task is to exchange one kind of satisfaction for another, and he breaks down from his inflexibility. In the second case the conflict, which is between the subject's effort to remain as he is and the effort to change himself in order to meet fresh purposes and fresh demands from reality, is present from the first. In the former case the conflict only arises after the dammed-up libido has chosen other, and incompatible, possibilities of satisfaction. The part played by the conflict and the previous fixation of the libido is incomparably more obvious in the second type than in the first, in which such unserviceable fixations may perhaps only emerge as a result of the external frustration.

[1912c, 2561]
There has been little opportunity in the preceding pages for showing how new light can be thrown upon the facts of social psychology by the adoption of a psycho-analytic method of approach: for the horror of incest displayed by savages has long been recognized as such and stands in need of no further interpretation. All that I have been able to add to our understanding of it is to emphasize the fact that it is essentially an infan
tile feature and that it reveals a striking agreement with the mental life of neurotic patients. Psycho-analysis has taught us that a boy's earliest choice of objects for his love is incestuous and that those objects are forbidden ones - his mother and his sister. We have learnt, too, the manner in which, as he grows up, he liberates himself from this incestuous attraction. A neurotic, on the other hand, invariably exhibits some degree of psychical infantilism. He has either failed to get free from the psychosexual conditions that prevailed in his childhood or he has returned to them - two possibilities which may be summed up as developmental inhibition and regression. Thus incestuous fixations of libido continue to play (or begin once more to play) the principal part in his unconscious mental life. We have arrived at the point of regarding a child's relation to his parents, dominated as it is by incestuous longings, as the nuclear complex of neurosis. This revelation of the importance of incest in neurosis is naturally received with universal scepticism by adults and normal people. Similar expressions of disbelief, for instance, inevitably greet the writings of Otto Rank, which have brought more and more evidence to show the extent to which the interest of creative writers centres round the theme of incest and how the same theme, in countless variations and distortions, provides the subject-matter of poetry. We are driven to believe that this rejection is principally a product of the distaste which human beings feel for their early incestuous wishes, now over taken by repression. It is therefore of no small importance that we are able to show that these same incestuous wishes, which are later destined to become unconscious, are still regarded by savage peoples as immediate perils against which the most severe measures of defence must be enforced.

Another and far more surprising discovery has been that, in spite of all the later development that occurs in the adult, none of the infantile mental formations perish. All the wishes, instinctual impulses, modes of reaction and attitudes of childhood are still demonstrably present in maturity and in appropriate circumstances can emerge once more. They are not destroyed but merely overlaid - to use the spatial mode of description which psycho-analytic psychology has been obliged to adopt. Thus it is part of the nature of the mental past that, unlike the historic past, it is not absorbed by its derivatives; it persists (whether actually or only potentially) alongside what has proceeded from it. The proof of this assertion lies in the fact that the dreams of normal people revive their childhood characters every night and reduce their whole mental life to an infantile level. This same return to psychic infantilism ('regression') appears in the neuroses and psychoses, whose peculiarties may to a great extent be described as psychical archaisms. The strength in which the residues of infancy are still present in the mind shows us the amount of disposition to illness; that disposition may accordingly be regarded as an expression of an inhibition in development. The part of a person's psychical material which has remained infantile and has been repressed as being unserviceable constitutes the core of his unconscious. And we believe we can follow in our patients' life-histories the way in which this unconscious, held back as it is by the forces of repression, lies in wait for a chance to become active and makes use of its opportunities if the later and higher psychical structures fail to master the difficulties of real life.
We have recently received a piece of advice, purporting to represent one of the latest developments of psycho-analysis, to the effect that the current conflict and the exciting cause of illness are to be brought into the foreground in analysis. Now this is exactly what Breuer and I used to do at the beginning of our work with the cathartic method. We led the patient's attention directly to the traumatic scene in which the symptom had arisen, and we endeavoured to discover the mental conflict in that scene and to release the suppressed affect in it. In the course of this we discovered the mental process, characteristic of the neuroses, which I later named 'regression'. The patient's associations moved back from the scene which we were trying to elucidate to earlier experiences, and compelled the analysis, which was supposed to correct the present, to occupy itself with the past. This regression led constantly further backwards; at first it seemed regularly to bring us to puberty; later on, failures and points which still eluded explanation drew the analytic work still further back into years of childhood which had hitherto been inaccessible to any kind of exploration. This regressive direction became an important characteristic of analysis. It appeared that psycho-analysis could explain nothing belonging to the present without referring back to something past; indeed, that every pathogenic experience implied a previous experience which, though not in itself pathogenic, had yet endowed the later one with its pathogenic quality. The temptation to confine one's attention to the known present exciting cause was so strong, however, that even in later analyses I gave way to it. In the analysis of the patient I named 'Dora', carried out in 1899, I had knowledge of the scene which occasioned the outbreak of the current illness. I tried innumerable times to submit this experience to analysis, but even direct demands always failed to produce from her anything more than the same meagre and incomplete description of it. Not until a long détour, leading back over her earliest childhood, had been made, did a dream present itself which on analysis brought to her mind the hitherto forgotten details of this scene, so that a comprehension and a solution of the current conflict became possible.

This one example shows how very misleading is the advice referred to above, and what a degree of scientific regression is represented by the neglect of regression in analytic technique which is thus recommended to us.

Unconscious processes only become cognizable by us under the conditions of dreaming and of neurosis - that is to say, when processes of the higher, Pcs., system are set back to an earlier stage by being lowered (by regression). In themselves they cannot be cognized, indeed are even incapable of carrying on their existence; for the system Ucs. is at a very early moment overlaid by the Pcs. which has taken over access to consciousness and to motility. Discharge from the system Ucs. passes into somatic innervation that leads to development of affect; but even this path of discharge is, as we have seen, contested by the Pcs. By itself, the system Ucs. would not in normal conditions be able to bring about any expedient muscular acts, with the exception of those already organized as reflexes.

In investigating psychoneurotic states, we find ourselves led to emphasize in each of them what are known as temporal regressions, i.e. the amount of developmental recession peculiar to it. We distinguish two such regressions - one affecting the development of the ego and the other that of the libido. In the state of sleep, the latter is carried to the point of restoring primitive narcissism, while the former goes back to the stage of hallucinatory satisfaction of wishes.
We cannot dismiss the question of why, in what way and for what motive a person can arrive at such a remarkable attitude to life and one that is so inexpedient - assuming that this attitude is a general characteristic of neuroses and not a special peculiarity of these two patients. And in fact it is a general feature, of great practical importance, in every neurosis. Breuer's first hysterical patient was similarly fixated to the period when she was nursing her father in a serious illness. In spite of her recovery, in a certain respect she remained cut off from life; she remained healthy and efficient but avoided the normal course of a woman's life. In every one of our patients, analysis shows us that they have been carried back to some particular period of their past by the symptoms of their illness or their consequences. In the majority of cases, indeed, a very early phase of life is chosen for the purpose - a period of their childhood or even, laughable as this may sound, of their existence as an infant at the breast.

We are, I think, in agreement with the theories of general pathology in assuming that a development of this kind involves two dangers - first, of inhibition, and secondly, of regression. That is to say, in view of the general tendency of biological processes to variation, it is bound to be the case that not every preparatory phase will be passed through with equal success and completely superseded: portions of the function will be permanently held back at these early stages, and the total picture of development will be qualified by some amount of developmental inhibition.

It is important for your understanding of the neuroses that you should not leave this relation between fixation and regression out of sight. This will give you a firmer footing in facing the question of how the neuroses are caused - the question of the aetiology of the neuroses which we shall shortly have to meet.

For the moment we will dwell a little longer on regression. After what you have learnt of the development of the libidinal function, you will be prepared to hear that there are regressions of two sorts: a return to the objects first cathexed by the libido, which, as we know, are of an incestuous nature, and a return of the sexual organization as a whole to earlier stages. Both sorts are found in the transference neuroses and play a great part in their mechanism. In particular, a return to the first incestuous objects of the libido is a feature that is found in neurotics with positively fatiguing regularity. There is much more to be said about regressions of the libido itself when we take into account as well another group of neuroses, the narcissistic ones, which for the time being we do not intend to do. These disorders give us access to other developmental processes of the libidinal function which we have not yet mentioned, and show us correspondingly new sorts of regression as well. But above all I think I ought to warn you now not to confuse regression with repression and help you to form a clear idea of the relations between the two processes. Repression, as you will recall, is the process by which an act which is admissible to consciousness, one, therefore, which belongs to the system Pcs., is made unconscious - is pushed back, therefore, into the system Ucs. And we equally speak of repression if the unconscious mental act is altogether forbidden access to the neighbouring preconscious system and is turned back at the threshold by the censorship. Thus the concept of repression involves no relation to sexuality: I must ask you to take special note of that. It indicates a purely psychological process, which we can characterize still better if we call it a 'topographical' one. By this we intend to say that it is concerned with the psychical regions which we have assumed to exist, or, if we drop this clumsy working hypothesis, with the construction of the mental apparatus out of distinct psychical systems.
Discussions like this, Gentlemen, are bound to become somewhat arid. So let us turn to clinical material in order to find applications of it that will be a little more impressive. Hysteria and obsessional neuroses are, as you know, the two chief representatives of the group of transference neuroses. Now it is true that in hysteria there is a regression of the libido to the primary incestuous sexual objects and that this occurs quite regularly; but there is as good as no regression to an earlier stage of the sexual organization. To offset this, the chief part in the mechanism of hysteria is played by repression. If I might venture to complete what we already know for certain about this neurosis by making a construction, I might explain the position thus. The unification of the component instincts under the primacy of the genitals has been accomplished; but its results come up against the resistance of the preconscious system which is linked with consciousness. Thus the genital organization holds good for the unconscious, but not in the same way for the preconscious; and this rejection on the part of the preconscious brings about a picture which has certain resemblances to the state of things before genital primacy. But it is nevertheless something quite different.

The transition from the pleasure principle to the reality principle is one of the most important steps forward in the ego's development. We know already that it is only late and unwillingly that the sexual instincts join in this piece of development, and we shall hear later the consequences for human beings of the fact that their sexuality is content with such a loose connection with external reality. And now in conclusion one last remark on this subject. If man's ego has its process of development like the libido, you will not be surprised to hear that there are also 'regressions of the ego', and you will be anxious to know too what part may be played in neurotic illnesses by this return of the ego to earlier phases of its development.

We already know that neurotic symptoms are the outcome of a conflict which arises over a new method of satisfying the libido. The two forces which have fallen out meet once again in the symptom and are reconciled, as it were, by the compromise of the symptom that has been constructed. It is for that reason, too, that the symptom is so resistant: it is supported from both sides. We also know that one of the two partners to the conflict is the unsatisfied libido which has been repulsed by reality and must now seek for other paths to its satisfaction. If reality remains relentless even though the libido is ready to take another object in place of the one that has been refused to it, then it will finally be compelled to take the path of regression and strive to find satisfaction either in one of the organizations which it has already outgrown or from one of the objects which it has earlier abandoned. The libido is lured into the path of regression by the fixation which it has left behind it at these points in its development.
The path to perversion branches off sharply from that to neurosis. If these regressions rouse no objection from the ego, no neurosis will come about either; and the libido will arrive at some real, even though no longer normal, satisfaction. But if the ego, which has under its control not only consciousness but also the approaches to motor innervation and accordingly to the realization of mental desires, does not agree with these regressions, conflict will follow. The libido is, as it were, cut off and must try to escape in some direction where, in accordance with the requirements of the pleasure principle, it can find a discharge for its cathexis of energy. It must withdraw from the ego. An escape of this kind is offered it by the fixations on the path of its development which it has now entered on regressively - fixations from which the ego had protected itself in the past by repressions. By cathecting these repressed positions as it flows backward, the libido has withdrawn from the ego and its laws, and has at the same time renounced all the education it has acquired under the ego's influence. It was docile so long as satisfaction beckoned to it; but under the double pressure of external and internal frustration it becomes refractory, and recalls earlier and better times. Such is the libido's fundamentally unchangeable character. The ideas to which it now transfers its energy as a cathexis belong to the system of the unconscious and are subject to the processes which are possible there, particularly to condensation and displacement. In this way conditions are established which completely resemble those in dream-construction. The dream proper, which has been completed in the unconscious and is the fulfilment of an unconscious wishful phantasy, is brought up against a portion of (pre)conscious activity which exercises the office of censorship and which, when it has been indemnified, permits the formation of the manifest dream as a compromise. In the same way, what represents the libido in the unconscious has to reckon with the power of the preconscious ego. The opposition which had been raised against it in the ego pursues it as an 'anticathexis' and compels it to choose a form of expression which can at the same time become an expression of the opposition itself. Thus the symptom emerges as a many-times-distorted derivative of the unconscious libidinal wish-fulfilment, an ingeniously chosen piece of ambiguity with two meanings in complete mutual contradiction. In this last respect, however, there is a distinction between the construction of a dream and of a symptom. For in dream-formation the preconscious purpose is merely concerned to preserve sleep, to allow nothing that would disturb it to make its way into consciousness; it does not insist upon calling out sharply 'No! on the contrary!' to the unconscious wishful impulse. It can afford to be more tolerant because the situation of someone sleeping is less perilous. The state of sleep in itself bars any outlet into reality. [1916-1917, 3418]

Once again we shall not find it hard to reach a decision. The assertion that the libidinal cathexis (and therefore the pathogenic significance) of the infantile experiences has been largely intensified by the regression of the libido is undoubtedly correct, but it would lead to error if we were to regard it alone as decisive. Other considerations must be allowed weight as well. [1916-1917, 3421]
In the second place, we must reflect that it would be inconceivable for the libido to regress so regularly to the period of childhood unless there were something there to exercise an attraction on it. The fixation which we have supposed to be present at particular points in the course of development can only have a meaning if we regard it as consisting in the retention of a certain quota of libidinal energy. And finally I may point out to you that between the intensity and pathogenic importance of infantile and of later experiences a complemental relationship exists similar to the series we have already discussed. There are cases in which the whole weight of causation falls on the sexual experiences of childhood, cases in which those impressions exert a definitely traumatic effect and call for no other support than can be afforded them by an average sexual constitution and the fact of its incomplete development. Alongside of these cases there are others in which the whole accent lies on the later conflicts and the emphasis we find in the analysis laid on the impressions of childhood appears entirely as the work of regression. Thus we have extremes of 'developmental inhibition' and 'regression' and between them every degree of co-operation between the two factors.

[1916-1917, 3422]

Let us now go back to the symptoms. They create a substitute, then, for the frustrated satisfaction by means of a regression of the libido to earlier times, with which a return to earlier stages of object-choice or of the organization is inseparably bound up. We discovered some time ago that neurotics are anchored somewhere in their past; we know now that it is at a period of their past in which their libido did not lack satisfaction, in which they were happy. They search about in the history of their life till they find a period of that sort, even if they have to go back as far as the time when they were infants in arms - as they remember it or as they imagine it from later hints. In some way the symptom repeats this early infantile kind of satisfaction, distorted by the censorship arising from the conflict, turned as a rule to a feeling of suffering, and mingled with elements from the precipitating cause of the illness. The kind of satisfaction which the symptom brings has much that is strange about it.

[1916-1917, 3423]
The Non-Medical Applications and Correlations of Psycho-analysis. - Any estimate of psycho-analysis would be incomplete if it failed to make clear that, alone among the medical disciplines, it has the most extensive relations with the mental sciences, and that it is in a position to play a part of the same importance in the studies of religious and cultural history and in the sciences of mythology and literature as it is in psychiatry. This may seem strange when we reflect that originally its only object was the understanding and improvement of neurotic symptoms. But it is easy to indicate the starting-point of the bridge that leads over to the mental sciences. The analysis of dreams gave us an insight into the unconscious processes of the mind and showed us that the mechanisms which produce pathological symptoms are also operative in the normal mind. Thus psychoanalysis became a depth-psychology and capable as such of being applied to the mental sciences, and it was able to answer a good number of questions with which the academic psychology of consciousness was helpless to deal. At quite an early stage problems of human phylogenesis arose. It became clear that pathological function was often nothing more than a regression to an earlier stage in the development of normal function. C. G. Jung was the first to draw explicit attention to the striking similarity between the disordered phantasies of sufferers from dementia praecox and the myths of primitive peoples; while the present writer pointed out that the two wishes which combine to form the Oedipus complex coincide precisely with the two principal prohibitions imposed by totemism (not to kill the tribal ancestor and not to marry any woman belonging to one's own clan) and drew far-reaching conclusions from this fact. The significance of the Oedipus complex began to grow to gigantic proportions and it looked as though social order, morals, justice and religion had arisen together in the primaeval ages of mankind as reaction-formations against the Oedipus complex. Otto Rank threw a brilliant light upon mythology and the history of literature by the application of psycho-analytic views, as did Theodor Reik upon the history of morals and religions, while Dr. Pfister, of Zurich, aroused the interest of religious and secular teachers and demonstrated the importance of the psycho-analytic standpoint for education. Further discussion of these applications of psycho-analysis would be out of place here, and it is enough to say that the limits of their influence are not yet in sight.

In a far greater number of cases the neurosis is more autonomous and more independent of the interests of self-preservation and self-maintenance. In the conflict which creates the neurosis, what are at stake are either solely libidinal interests or libidinal interests in intimate connections with self-preservative ones. In all three instances the dynamics of the neurosis are the same. A dammed-up libido which cannot be satisfied in reality succeeds, with the help of a regression to old fixations, in finding discharge through the repressed unconscious. The sick man's ego, in so far as it can extract a 'gain from illness' out of this process, countenances the neurosis, although there can be no doubt of its injuriousness in its economic aspect.

Incidentally, the same objection arises in a specially marked manner when we are dealing with a neurosis in which the exciting cause (the 'traumatic scene') is known, and in which one can see how the person concerned turns away from the experience and consigns it to amnesia. Let me go back by way of example to a case analysed a great many years ago,¹ in which the patient, a young woman, was in love with her brother-in-law. Standing beside her sister's death-bed, she was horrified at having the thought: 'Now he is free and can marry me.' This scene was instantly forgotten, and thus the process of regression, which led to her hysterical pains, was set in motion. It is instructive precisely in this case, moreover, to learn along what path the neurosis attempted to solve the conflict. It took away from the value of the change that had occurred in reality, by repressing the instinctual demand which had emerged - that is, her love for her brother-in-law. The psychotic reaction would have been a disavowal of the fact of her sister's death.

¹[1923a, 3929]

²[1923d, 4027]

³[1924e, 4095]
A neurosis usually contents itself with avoiding the piece of reality in question and protecting itself against coming into contact with it. The sharp distinction between neurosis and psychosis, however, is weakened by the circumstance that in neurosis, too, there is no lack of attempts to replace a disagreeable reality by one which is more in keeping with the subject's wishes. This is made possible by the existence of a world of phantasy, of a domain which became separated from the real external world at the time of the introduction of the reality principle. This domain has since been kept free from the demands of the exigencies of life, like a kind of 'reservation'; it is not inaccessible to the ego, but is only loosely attached to it. It is from this world of phantasy that the neurosis draws the material for its new wishful constructions, and it usually finds that material along the path of regression to a more satisfying real past.

The idea of being devoured by the father is typical age-old childhood material. It has familiar parallels in mythology (e.g. the myth of Kronos) and in the animal kingdom. Yet in spite of this confirmation the idea is so strange to us that we can hardly credit its existence in a child. Nor do we know whether it really means what it seems to say, and we cannot understand how it can have become the subject of a phobia. Analytic observation supplies the requisite information. It shows that the idea of being devoured by the father gives expression, in a form that has undergone regressive degradation, to a passive, tender impulse to be loved by him in a genital-erotic sense. Further investigation of the case history leaves no doubt of the correctness of this explanation. The genital impulse, it is true, betrays no sign of its tender purpose when it is expressed in the language belonging to the superseded transitional phase between the oral and sadistic organizations of the libido. Is it, moreover, a question merely of the replacement of the representative by a regressive form of expression or is it a question of a genuine regressive degradation of the genitally-directed impulse in the id? It is not at all easy to make certain. The case history of the Russian 'Wolf Man' gives very definite support to the second, more serious, view; for, from the time of the decisive dream onward, the boy became naughty, tormenting and sadistic, and soon afterwards developed a regular obsessional neurosis. At any rate, we can see that repression is not the only means which the ego can employ for the purpose of defence against an unwelcome instinctual impulse. If it succeeds in making an instinct regress, it will actually have done it more injury than it could have by repressing it. Sometimes, indeed, after forcing an instinct to regress in this way, it goes on to repress it.

[1924e, 4097]

[1926d, 4265]
The case of the 'Wolf Man' and the somewhat less complicated one of 'Little Hans' raise a number of further considerations. But we have already made two unexpected discoveries. There can be no doubt that the instinctual impulse which was repressed in both phobias was a hostile one against the father. One might say that that impulse had been repressed by the process of being transformed into its opposite. Instead of aggressiveness on the part of the subject towards his father, there appeared aggressiveness (in the shape of revenge) on the part of his father towards the subject. Since this aggressiveness is in any case rooted in the sadistic phase of the libido, only a certain amount of degradation is needed to reduce it to the oral stage. This stage, while only hinted at in 'Little Hans's' fear of being bitten, was blatantly exhibited in the 'Wolf Man's' terror of being devoured. But, besides this, the analysis has demonstrated, beyond a shadow of doubt, the presence of another instinctual impulse of an opposite nature which had succumbed to repression. This was a tender, passive impulse directed towards the father, which had already reached the genital (phallic) level of libidinal organization. As regards the final outcome of the process of repression, this impulse seems, indeed, to have been the more important of the two; it underwent a more far-reaching regression and had a decisive influence upon the content of the phobia. In following up a single instinctual repression we have thus had to recognize a convergence of two such processes. The two instinctual impulses that have been overtaken by repression - sadistic aggressiveness towards the father and a tender passive attitude to him - form a pair of opposites. Furthermore, a full appreciation of 'Little Hans's' case shows that the formation of his phobia had had the effect of abolishing his affectionate object-cathexis of his mother as well, though the actual content of his phobia betrayed no sign of this. The process of repression had attacked almost all the components of his Oedipus complex - both his hostile and his tender impulses towards his father and his tender impulses towards his mother. In my Russian patient this state of affairs was much less obvious. [1926d, 4266]
These are unwelcome complications, considering that we only set out to study simple cases of symptom-formation due to repression, and with that intention selected the earliest and to all appearances, most transparent neuroses of childhood. Instead of a single repression we have found a collection of them and have become involved with regression into the bargain. Perhaps we have added to the confusion by treating the two cases of animal phobia at our disposal - 'Little Hans' and the 'Wolf Man' - as though they were cast in the same mould. As a matter of fact, certain differences between them stand out. It is only with regard to 'Little Hans' that we can say with certainty that what his phobia disposed of were the two main impulses of the Oedipus complex - his aggressiveness towards his father and his over-fondness for his mother. A tender feeling for his father was undoubtedly there too and played a part in repressing the opposite feeling; but we can prove neither that it was strong enough to draw repression upon itself nor that it disappeared afterwards. 'Hans' seems, in fact, to have been a normal boy with what is called a 'positive' Oedipus complex. It is possible that the factors which we do not find were actually at work in him, but we cannot demonstrate their existence. Even the most exhaustive analysis has gaps in its data and is insufficiently documented. In the case of the Russian the deficiency lies elsewhere. His attitude to female objects had been disturbed by an early seduction and his passive, feminine side was strongly developed. The analysis of his wolf-dream revealed very little intentional aggressiveness towards his father, but it brought forward unmistakable proof that what repression overtook was his passive tender attitude to his father. In his case, too, the other factors may have been operative as well; but they were not in evidence. How is it that, in spite of these differences in the two cases, almost amounting to an antithesis, the final outcome - a phobia - was approximately the same? The answer must be sought in another quarter. I think it will be found in the second fact which emerges from our brief comparative examination. It seems to me that in both cases we can detect what the motive force of the repression was and can substantiate our view of its nature from the line of development which the two children subsequently pursued. This motive force was the same in both of them. It was the fear of impending castration. 'Little Hans' gave up his aggressiveness towards his father from fear of being castrated. His fear that a horse would bite him can, without any forcing, be given the full sense of a fear that a horse would bite off his genitals, would castrate him. But it was from fear of being castrated, too, that the little Russian relinquished his wish to be loved by his father, for he thought that a relation of that sort presupposed a sacrifice of his genitals - of the organ which distinguished him from a female. As we see, both forms of the Oedipus complex, the normal, active form and the inverted one, came to grief through the castration complex. The Russian boy's anxiety-idea of being devoured by a wolf contained, it is true, no suggestion of castration, for the oral regression it had undergone had removed it too far from the phallic stage. But the analysis of his dream rendered further proof superfluous. It was a triumph of repression that the form in which his phobia was expressed should no longer have contained any allusion to castration.

[1926d, 4267]
In enforcing regression, the ego scores its first success in its defensive struggle against the demands of the libido. (In this connection it is of advantage to distinguish the more general notion of 'defence' from 'repression'. Repression is only one of the mechanisms which defence makes use of.) It is perhaps in obsessional cases more than in normal or hysterical ones that we can most clearly recognize that the motive force of defence is the castration complex and that what is being fended off are the trends of the Oedipus complex. We are at present dealing with the beginning of the latency period, a period which is characterized by the dissolution of the Oedipus complex, the creation or consolidation of the super-ego and the erection of ethical and aesthetic barriers in the ego. In obsessional neuroses these processes are carried further than is normal. In addition to the destruction of the Oedipus complex a regressive degradation of the libido takes place, the super-ego becomes exceptionally severe and unkind, and the ego, in obedience to the super-ego, produces strong reaction-formations in the shape of conscientiousness, pity and cleanliness. Implacable, though not always on that account successful, severity is shown in condemning the temptation to continue early infantile masturbation, which now attaches itself to regressive (sadistic-anal) ideas but which nevertheless represents the unsubjugated part of the phallic organization. There is an inherent contradiction about this state of affairs, in which, precisely in the interests of masculinity (that is to say, from fear of castration), every activity belonging to masculinity is stopped. But here, too, obsessional neurosis is only overdoing the normal method of getting rid of the Oedipus complex. We once more find here an illustration of the truth that every exaggeration contains the seed of its own undoing. For, under the guise of obsessional acts, the masturbation that has been suppressed approaches ever more closely to satisfaction.

[1926d, 4273]

I am well aware that a number of cases exhibit a more complicated structure and that many other repressed instinctual impulses can enter into a phobia. But they are only tributary streams which have for the most part joined the main current of the neurosis at a later stage. The symptomatology of agoraphobia is complicated by the fact that the ego does not confine itself to making a renunciation. In order to rob the situation of danger it does more: it usually effects a temporal regression to infancy (in extreme cases, to a time when the subject was in his mother's womb and protected against the dangers which threaten him in the present). Such a regression now becomes a condition whose fulfilment exempts the ego from making its renunciation. For instance, an agoraphobic patient may be able to walk in the street provided he is accompanied, like a small child, by someone he knows and trusts; or, for the same reason, he may be able to go out alone provided he remains within a certain distance of his own house and does not go to places which are not familiar to him or where people do not know him. What these stipulations are will depend in each case on the infantile factors which dominate him through his neurosis. The phobia of being alone is unambiguous in its meaning, irrespective of any infantile regression: it is, ultimately, an endeavour to avoid the temptation to indulge in solitary masturbation. Infantile regression can, of course, only take place when the subject is no longer a child.

[1926d, 4284]
Since the differentiation of the ego and the id, our interest in the problems of repression, too, was bound to receive a fresh impetus. Up till then we had been content to confine our interest to those aspects of repression which concerned the ego - the keeping away from consciousness and from motility, and the formation of substitutes (symptoms). With regard to the repressed instinctual impulses themselves, we assumed that they remained unaltered in the unconscious for an indefinite length of time. But now our interest is turned to the vicissitudes of the repressed and we begin to suspect that it is not self-evident, perhaps not even usual, that those impulses should remain unaltered and unalterable in this way. There is no doubt that the original impulses have been inhibited and deflected from their aim through repression. But has the portion of them in the unconscious maintained itself and been proof against the influences of life that tend to alter and depreciate them? In other words, do the old wishes, about whose former existence analysis tells us, still exist? The answer seems ready to hand and certain. It is that the old, repressed wishes must still be present in the unconscious since we still find their derivatives, the symptoms, in operation. But this answer is not sufficient. It does not enable us to decide between two possibilities: either that the old wish is now operating only through its derivatives, having transferred the whole of its cathetic energy to them, or that it is itself still in existence too. If its fate has been to exhaust itself in cathecting its derivatives, there is yet a third possibility. In the course of the neurosis it may have become re-animated by regression, anachronistic though it may now be. These are no idle speculations. There are many things about mental life, both normal and pathological, which seem to call for the raising of such questions. In my paper, 'The Dissolution of the Oedipus Complex' (1924), I had occasion to notice the difference between the mere repression and the real removal of an old wishful impulse.

A feebleness of the ego of this sort is to be found in all of us in childhood; and that is why the experiences of the earliest years of childhood are of such great importance for later life. Under the extraordinary burden of this period of childhood we have in a few years to cover the enormous developmental distance between stone-age primitive men and the participants in contemporary civilization, and, at the same time and in particular, we have to fend off the instinctual impulses of the early sexual period - under this burden, then, our ego takes refuge in repression and lays itself open to a childhood neurosis, the precipitate of which it carries with it into maturity as a disposition to a later nervous illness. Everything now depends on how the growing organism is treated by fate. If life becomes too hard, if the gulf between instinctual claims and the demands of reality becomes too great, the ego may fail in its efforts to reconcile the two, and the more readily, the more it is inhibited by the disposition carried over by it from infancy. The process of repression is then repeated, the instincts tear themselves away from the ego's domination, find their substitutive satisfactions along the paths of regression, and the poor ego has become helplessly neurotic.
Now let us go back and turn to the id. It is not so easy to guess what occurs during repression in connection with the instinctual impulse that is being fought against. The main question which our interest raises is as to what happens to the energy, to the libidinal charge, of that excitation - how is it employed? You recollect that the earlier hypothesis was that it is precisely this that is transformed by repression into anxiety. We no longer feel able to say that. The modest reply will rather be that what happens to it is probably not always the same thing. There is probably an intimate correspondence which we ought to get to know about between what is occurring at the time in the ego and in the id in connection with the repressed impulse. For since we have decided that the pleasure-unpleasure principle, which is set in action by the signal of anxiety, plays a part in repression, we must alter our expectations. That principle exercises an entirely unrestricted dominance over what happens in the id. We can rely on its bringing about quite profound changes in the instinctual impulse in question. We are prepared to find that repression will have very various consequences, more or less far-reaching. In some cases the repressed instinctual impulse may retain its libidinal cathexis, and may persist in the id unchanged, although subject to constant pressure from the ego. In other cases what seems to happen is that it is totally destroyed, while its libido is permanently diverted along other paths. I expressed the view that this is what happens when the Oedipus complex is dealt with normally - in this desirable case, therefore, being not simply repressed but destroyed in the id. Clinical experience has further shown us that in many cases, instead of the customary result of repression, a degradation of the libido takes place - a regression of the libidinal organization to an earlier stage. This can, of course, only occur in the id, and if it occurs it will be under the influence of the same conflict which was introduced by the signal of anxiety. The most striking example of this kind is provided by the obsessional neurosis, in which libidinal regression and repression operate together.

[1933a, 4698]

Our attitude to the phases of the organization of the libido has in general shifted a little. Whereas earlier we chiefly emphasized the way in which each of them passed away before the next, our attention now is directed to the facts that show us how much of each earlier phase persists alongside of and behind the later configurations and obtains a permanent representation in the libidinal economy and character of the subject. Still more significant have studies become which have taught us how frequently under pathological conditions regressions to earlier phases occur and that particular regressions are characteristic of particular forms of illness. But I cannot go into that here, it forms part of the specialized psychology of the neuroses.

[1933a, 4705]
It is further to be remarked that regression plays a no less important part in the theory of the formation of neurotic symptoms than it does in that of dreams. Three kinds of regression are thus to be distinguished: (a) *topographical* regression, in the sense of the schematic picture of the Ψ-systems which we have explained above; (b) *temporal* regression, in so far as what is in question is a harking back to older psychical structures; and (c) *formal* regression, where primitive methods of expression and representation take the place of the usual ones. All these three kinds of regression are, however, one at bottom and occur together as a rule; for what is older in time is more primitive in form and in psychical topography lies nearer to the perceptual end.

[1900a, 981]

Nor can we leave the subject of regression in dreams without setting down in words a notion by which we have already repeatedly been struck and which will recur with fresh intensity when we have entered more deeply into the study of the psycho-neuroses: namely that dreaming is on the whole an example of regression to the dreamer's earliest condition, a revival of his childhood, of the instinctual impulses which dominated it and of the methods of expression which were then available to him. Behind this childhood of the individual we are promised a picture of a phylogenetic childhood - a picture of the development of the human race, of which the individual's development is in fact an abbreviated recapitulation influenced by the chance circumstances of life. We can guess how much to the point is Nietzsche's assertion that in dreams 'some primaeval relic of humanity is at work which we can now scarcely reach any longer by a direct path'; and we may expect that the analysis of dreams will lead us to a knowledge of man's archaic heritage, of what is psychically innate in him. Dreams and neuroses seem to have preserved more mental antiquities than we could have imagined possible; so that psycho-analysis may claim a high place among the sciences which are concerned with the reconstruction of the earliest and most obscure periods of the beginnings of the human race.

[1900a, 981]
Those philosophers who have become aware that rational and highly complex thought-structures are possible without consciousness playing any part in them have found difficulty in assigning any function to consciousness; it has seemed to them that it can be no more than a superfluous reflected picture of the completed psychical process. We, on the other hand, are rescued from this embarrassment by the analogy between our Cs. system and the perceptual systems. We know that perception by our sense-organs has the result of directing a cathexis of attention to the paths along which the in-coming sensory excitation is spreading: the qualitative excitation of the $Pcpt.$ system acts as a regulator of the discharge of the mobile quantity in the psychical apparatus. We can attribute the same function to the overlying sense-organ of the Cs. system. By perceiving new qualities, it makes a new contribution to directing the mobile quantities of cathexis and distributing them in an expedient fashion. By the help of its perception of pleasure and unpleasure it influences the discharge of the cathexes within what is otherwise an unconscious apparatus operating by means of the displacement of quantities. It seems probable that in the first instance the unpleasure principle regulates the displacement of cathexes automatically. But it is quite possible that consciousness of these qualities may introduce in addition a second and more discriminating regulation, which is even able to oppose the former one, and which perfects the efficiency of the apparatus by enabling it, in contradiction to its original plan, to cathect and work over even what is associated with the release of unpleasure. We learn from the psychology of the neuroses that these processes of regulation carried out by the qualitative excitation of the sense organs play a great part in the functional activity of the apparatus. The automatic domination of the primary unpleasure principle and the consequent restriction imposed upon efficiency are interrupted by the processes of sensory regulation, which are themselves in turn automatic in action. We find that repression (which, though it served a useful purpose to begin with, leads ultimately to a damaging loss of inhibition and mental control) affects memories so much more easily than perceptions because the former can receive no extra cathexis from the excitation of the psychical sense-organs. It is true on the one hand that a thought which has to be warded off cannot become conscious, because it has undergone repression; but on the other hand it sometimes happens that a thought of this kind is only repressed because for other reasons it has been withdrawn from conscious perception. Here are some hints of which we take advantage in our therapeutic procedure in order to undo repressions which have already been effected.

[1900a, 1041]
The reproaches against her father for having made her ill, together with the self-reproach underlying them, the leucorrhoea, the playing with the reticule, the bed-wetting after her sixth year, the secret which she would not allow the doctors to tear from her - the circumstantial evidence of her having masturbated in childhood seems to me complete and without a flaw. In the present case I had begun to suspect the masturbation when she had told me of her cousin's gastric pains, and had then identified herself with her by complaining for days together of similar painful sensations. It is well known that gastric pains occur especially often in those who masturbate. According to a personal communication made to me by Wilhelm Fliess, it is precisely gastralgias of this character which can be interrupted by an application of cocaine to the 'gastric spot' discovered by him in the nose, and which can be cured by the cauterization of the same spot. In confirmation of my suspicion Dora gave me two facts from her conscious knowledge: she herself had frequently suffered from gastric pains, and she had good reasons for believing that her cousin was a masturbator. It is a very common thing for patients to recognize in other people a connection which, on account of their emotional resistances, they cannot perceive in themselves. And, indeed, Dora no longer denied my supposition, although she still remembered nothing. Even the date which she assigned to the bed-wetting, when she said that it lasted 'till a short time before the appearance of the nervous asthma', appears to me to be of clinical significance. Hysterical symptoms hardly ever appear so long as children are masturbating, but only afterwards, when a period of abstinence has set in;¹ they form a substitute for masturbatory satisfaction, the desire for which continues to persist in the unconscious until another and more normal kind of satisfaction appears - where that is still attainable. For upon whether it is still attainable or not depends the possibility of a hysteria being cured by marriage and normal sexual intercourse. But if the satisfaction afforded in marriage is again removed - as it may be owing to coitus interruptus, psychological estrangement, or other causes - then the libido flows back again into its old channel and manifests itself once more in hysterical symptoms.

In considering the question of abstinence, the distinction is not nearly strictly enough made between two forms of it - namely abstention from any sexual activity whatever and abstention from sexual intercourse with the opposite sex. Many people who boast of succeeding in being abstinent have only been able to do so with the help of masturbation and similar satisfactions which are linked with the auto-erotic sexual activities of early childhood. But precisely because of this connection such substitutive means of sexual satisfaction are by no means harmless; they predispose to the numerous varieties of neuroses and psychoses which are conditional on an involution of sexual life to its infantile forms. Masturbation, moreover, is far from meeting the ideal demands of civilized sexual morality, and consequently drives young people into the same conflicts with the ideals of education which they hoped to escape by abstinence. Furthermore, it vitiates the character through indulgence, and this in more than one way. In the first place, it teaches people to achieve important aims without taking trouble and by easy paths instead of through an energetic exertion of force - that is, it follows the principle that sexuality lays down the pattern of behaviour; secondly, in the phantasies that accompany satisfaction the sexual object is raised to a degree of excellence which is not easily found again in reality. A witty writer (Karl Kraus in the Vienna paper Die Fackel) once expressed this truth in reverse by cynically remarking: 'Copulation is no more than an unsatisfying substitute for masturbation.'
The flight from unsatisfactory reality into what, on account of the biological damage involved, we call illness (though it is never without an immediate yield of pleasure to the patient) takes place along the path of involution, of regression, of a return to earlier phases of sexual life, phases from which at one time satisfaction was not withheld. This regression appears to be a twofold one: a **temporal** one, in so far as the libido, the erotic needs, hark back to stages of development that are earlier in time, and a **formal** one, in that the original and primitive methods of psychical expression are employed in manifesting those needs. Both these kinds of regression, however, lead back to childhood and unite in bringing about an infantile condition of sexual life.

[1910a, 2234]

Leonardo emerges from the obscurity of his boyhood as an artist, a painter and a sculptor, owing to a specific talent which may have been reinforced by the precocious awakening in the first years of childhood of his scopophilic instinct. We should be most glad to give an account of the way in which artistic activity derives from the primal instincts of the mind if it were not just here that our capacities fail us. We must be content to emphasize the fact - which it is hardly any longer possible to doubt - that what an artist creates provides at the same time an outlet for his sexual desire; and in Leonardo's case we can point to the information which comes from Vasari, that heads of laughing women and beautiful boys - in other words, representations of his sexual objects - were notable among his first artistic endeavours. In the bloom of his youth Leonardo appears at first to have worked without inhibition. Just as he modelled himself on his father in the outward conduct of his life, so too he passed through a period of masculine creative power and artistic productiveness in Milan, where a kindly fate enabled him to find a father substitute in the duke Lodovico Moro. But soon we and confirmation of our experience that the almost total repression of a real sexual life does not provide the most favourable conditions for the exercise of sublimated sexual trends. The pattern imposed by sexual life made itself felt. His activity and his ability to form quick decisions began to fail; his tendency towards deliberation and delay was already noticeable as a disturbing element in the 'Last Supper', and by influencing his technique it had a decisive effect on the fate of that great painting. Slowly there occurred in him a process which can only be compared to the regressions in neurotics. The development that turned him into an artist at puberty was overtaken by the process which led him to be an investigator, and which had its determinants in early infancy. The second sublimation of his erotic instinct gave place to the original sublimation for which the way had been prepared on the occasion of the first repression. He became an investigator, at first still in the service of his art, but later independently of it and away from it. With the loss of his patron, the substitute for his father, and with the increasingly sombre colours which his life took on, this regressive shift assumed larger and larger proportions. He became 'impacientissimo al pennello',¹ as we are told by a correspondent of the Countess Isabella d'Este, who was extremely eager to possess a painting from his hand. His infantile past had gained control over him. But the research which now took the place of artistic creation seems to have contained some of the features which distinguish the activity of unconscious instincts - insatiability, unyielding rigidity and the lack of an ability to adapt to real circumstances.

[1910c, 2301]
At the summit of his life, when he was in his early fifties - a time when in women the sexual characters have already undergone involution and when in men the libido not infrequently makes a further energetic advance - a new transformation came over him. Still deeper layers of the contents of his mind became active once more: but this further regression was to the benefit of his art, which was in the process of becoming stunted. He met the woman who awakened his memory of his mother's happy smile of sensual rapture; and, influenced by this revived memory, he recovered the stimulus that guided him at the beginning of his artistic endeavours, at the time when he modelled the smiling women. He painted the Mona Lisa, the 'St. Anne with Two Others' and the series of mysterious pictures which are characterized by the enigmatic smile. With the help of the oldest of all his erotic impulses he enjoyed the triumph of once more conquering the inhibition in his art. This final development is obscured from our eyes in the shadows of approaching age. Before this his intellect had soared upwards to the highest realizations of a conception of the world that left his epoch far behind it.

In my *Three Essays on the Theory of Sexuality* I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics endeavour to protect themselves against any such sexualization of their social instinctual cathexes, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) schizophrenia; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.

In investigating psychoneurotic states, we find ourselves led to emphasize in each of them what are known as *temporal regressions*, i.e. the amount of developmental recession peculiar to it. We distinguish two such regressions - one affecting the development of the ego and the other that of the libido. In the state of sleep, the latter is carried to the point of restoring primitive narcissism, while the former goes back to the stage of hallucinatory satisfaction of wishes.

We call this kind of regression a *topographical* one, to distinguish it from the previously mentioned *temporal* or developmental regression. The two do not necessarily always coincide, but they do so in the particular example before us. The reversal of the course of the excitation from the *Pcs.* through the *Ucs.* to perception is at the same time a return to the early stage of hallucinatory wish-fulfilment.
We are, I think, in agreement with the theories of general pathology in assuming that a development of this kind involves two dangers - first, of inhibition, and secondly, of regression. That is to say, in view of the general tendency of biological processes to variation, it is bound to be the case that not every preparatory phase will be passed through with equal success and completely superseded: portions of the function will be permanently held back at these early stages, and the total picture of development will be qualified by some amount of developmental inhibition.

For the moment we will dwell a little longer on regression. After what you have learnt of the development of the libidinal function, you will be prepared to hear that there are regressions of two sorts: a return to the objects first cathexed by the libido, which, as we know, are of an incestuous nature, and a return of the sexual organization as a whole to earlier stages. Both sorts are found in the transference neuroses and play a great part in their mechanism. In particular, a return to the first incestuous objects of the libido is a feature that is found in neurotics with positively fatiguing regularity. There is much more to be said about regressions of the libido itself when we take into account as well another group of neuroses, the narcissistic ones, which for the time being we do not intend to do. These disorders give us access to other developmental processes of the libidinal function which we have not yet mentioned, and show us correspondingly new sorts of regression as well. But above all I think I ought to warn you now not to confuse regression with repression and help you to form a clear idea of the relations between the two processes. Repression, as you will recall, is the process by which an act which is admissible to consciousness, one, therefore, which belongs to the system Pcs., is made unconscious - is pushed back, therefore, into the system Ucs. And we equally speak of repression if the unconscious mental act is altogether forbidden access to the neighbouring preconscious system and is turned back at the threshold by the censorship. Thus the concept of repression involves no relation to sexuality: I must ask you to take special note of that. It indicates a purely psychological process, which we can characterize still better if we call it a 'topographical' one. By this we intend to say that it is concerned with the psychical regions which we have assumed to exist, or, if we drop this clumsy working hypothesis, with the construction of the mental apparatus out of distinct psychical systems.

The comparison we have proposed has drawn our attention for the first time to the fact that we have not hitherto been using the word 'regression' in its general sense but in a quite special one. If we give it its general sense - of a return from a higher to a lower stage of development - then repression too can be subsumed under the concept of regression, for it too can be described as a return to an earlier and deeper stage in the development of a psychical act. In the case of repression, however, this retrogressive movement does not concern us, since we also speak of repression, in the dynamic sense, when a psychical act is held back at the lower, unconscious, stage. The fact is that repression is a topographico-dynamic concept, while regression is a purely descriptive one. What we have hitherto spoken of as regression, however, and have related to fixation, has meant exclusively a return of the libido to earlier stopping places in its development - something, that is, entirely different in its nature from repression and entirely independent of it. Nor can we call regression of the libido a purely psychical process and we cannot tell where we should localize it in the mental apparatus. And though it is true that it exercises the most powerful influence on mental life, yet the most prominent factor in it is the organic one.
Of the two kinds of regression of the libido, that to an earlier phase of the sexual organization is by far the more striking. Since this is absent in hysteria, and since our whole view of the neuroses is still far too much under the influence of the study of hysteria, which was chronologically the first, the significance of libidinal regression also became clear to us far later than that of repression. We must be prepared to find that our views will be subjected to still further extensions and revaluations when we are able to take into consideration not only hysteria and obsessional neurosis but also the other, narcissistic neuroses.

In obsessional neurosis, on the contrary, it is the regression of the libido to the preliminary stage of the sadistic-anal organization that is the most striking fact and the one which is decisive for what is manifested in symptoms. The love-impulse is obliged, when this has happened, to disguise itself as a sadistic impulse. The obsessional idea 'I should like to kill you', when it has been freed from certain additions which are not a matter of chance but are indispensable, means at bottom nothing other than 'I should like to enjoy you in love'. If you consider further that there has been a simultaneous regression in regard to the object, so that these impulses apply only to those who are nearest and dearest to the patient, you can form some idea of the horror which these obsessions arouse in him and at the same time of the alien appearance which they present to his conscious perception. But repression, too, plays a great part in the mechanism of these neuroses, though in a cursory introduction like ours this is not easily demonstrated. A regression of the libido without repression would never produce a neurosis but would lead to a perversion. From this you can see that repression is the process which is most peculiar to neuroses and is most characteristic of them. Perhaps I may have an opportunity later of telling you what we know of the mechanism of the perversions, and you will see that in their case too things are not so simple as we should be glad to make them out.

We already know that neurotic symptoms are the outcome of a conflict which arises over a new method of satisfying the libido. The two forces which have fallen out meet once again in the symptom and are reconciled, as it were, by the compromise of the symptom that has been constructed. It is for that reason, too, that the symptom is so resistant: it is supported from both sides. We also know that one of the two partners to the conflict is the unsatisfied libido which has been repulsed by reality and must now seek for other paths to its satisfaction. If reality remains relentless even though the libido is ready to take another object in place of the one that has been refused to it, then it will finally be compelled to take the path of regression and strive to find satisfaction either in one of the organizations which it has already outgrown or from one of the objects which it has earlier abandoned. The libido is lured into the path of regression by the fixation which it has left behind it at these points in its development.

The hereditary sexual constitution presents us with a great variety of dispositions, according as one component instinct or another, alone or in combination with others, is inherited in particular strength. The sexual constitution forms once again, together with the factor of infantile experience, a 'complementary series' exactly similar to the one we first came to know between disposition and the accidental experience of the adult. In both of them we find the same extreme cases and the same relations between the two factors concerned. And here the question suggests itself of whether the most striking kinds of libidinal regressions - those to earlier stages of the sexual organization - may not be predominantly determined by the hereditary constitutional factor. But it is best to postpone answering this question till we have been able to take a wider range of forms of neurotic illness into account.
A neurosis usually contents itself with avoiding the piece of reality in question and protecting itself against coming into contact with it. The sharp distinction between neurosis and psychosis, however, is weakened by the circumstance that in neurosis, too, there is no lack of attempts to replace a disagreeable reality by one which is more in keeping with the subject's wishes. This is made possible by the existence of a world of phantasy, of a domain which became separated from the real external world at the time of the introduction of the reality principle. This domain has since been kept free from the demands of the exigencies of life, like a kind of reservation; it is not inaccessible to the ego, but is only loosely attached to it. It is from this world of phantasy that the neurosis draws the material for its new wishful constructions, and it usually finds that material along the path of regression to a more satisfying real past.

![image]

The idea of being devoured by the father is typical age-old childhood material. It has familiar parallels in mythology (e.g. the myth of Kronos) and in the animal kingdom. Yet in spite of this confirmation the idea is so strange to us that we can hardly credit its existence in a child. Nor do we know whether it really means what it seems to say, and we cannot understand how it can have become the subject of a phobia. Analytic observation supplies the requisite information. It shows that the idea of being devoured by the father gives expression, in a form that has undergone regressive degradation, to a passive, tender impulse to be loved by him in a genital-erotic sense. Further investigation of the case history leaves no doubt of the correctness of this explanation. The genital impulse, it is true, betrays no sign of its tender purpose when it is expressed in the language belonging to the superseded transitional phase between the oral and sadistic organizations of the libido. Is it, moreover, a question merely of the replacement of the representative by a regressive form of expression or is it a question of a genuine regressive degradation of the genitally-directed impulse in the id? It is not at all easy to make certain. The case history of the Russian 'Wolf Man' gives very definite support to the second, more serious, view; for, from the time of the decisive dream onward, the boy became naughty, tormenting and sadistic, and soon afterwards developed a regular obsessional neurosis. At any rate, we can see that repression is not the only means which the ego can employ for the purpose of defence against an unwelcome instinctual impulse. If it succeeds in making an instinct regress, it will actually have done it more injury than it could have by repressing it. Sometimes, indeed, after forcing an instinct to regress in this way, it goes on to repress it.

[1926d, 4265]
Now let us go back and turn to the id. It is not so easy to guess what occurs during repression in connection with the instinctual impulse that is being fought against. The main question which our interest raises is as to what happens to the energy, to the libidinal charge, of that excitation - how is it employed? You recollect that the earlier hypothesis was that it is precisely this that is transformed by repression into anxiety. We no longer feel able to say that. The modest reply will rather be that what happens to it is probably not always the same thing. There is probably an intimate correspondence which we ought to get to know about between what is occurring at the time in the ego and in the id in connection with the repressed impulse. For since we have decided that the pleasure-unpleasure principle, which is set in action by the signal of anxiety, plays a part in repression, we must alter our expectations. That principle exercises an entirely unrestricted dominance over what happens in the id. We can rely on its bringing about quite profound changes in the instinctual impulse in question. We are prepared to find that repression will have very various consequences, more or less far-reaching. In some cases the repressed instinctual impulse may retain its libidinal cathexis, and may persist in the id unchanged, although subject to constant pressure from the ego. In other cases what seems to happen is that it is totally destroyed, while its libido is permanently diverted along other paths. I expressed the view that this is what happens when the Oedipus complex is dealt with normally - in this desirable case, therefore, being not simply repressed but destroyed in the id. Clinical experience has further shown us that in many cases, instead of the customary result of repression, a degradation of the libido takes place - a regression of the libidinal organization to an earlier stage. This can, of course, only occur in the id, and if it occurs it will be under the influence of the same conflict which was introduced by the signal of anxiety. The most striking example of this kind is provided by the obsessional neurosis, in which libidinal regression and repression operate together.

[1933a, 4698]
The flight from unsatisfactory reality into what, on account of the biological damage involved, we call illness (though it is never without an immediate yield of pleasure to the patient) takes place along the path of involution, of regression, of a return to earlier phases of sexual life, phases from which at one time satisfaction was not withheld. This regression appears to be a twofold one: a temporal one, in so far as the libido, the erotic needs, hark back to stages of development that are earlier in time, and a formal one, in that the original and primitive methods of psychical expression are employed in manifesting those needs. Both these kinds of regression, however, lead back to childhood and unite in bringing about an infantile condition of sexual life.

In my Three Essays on the Theory of Sexuality I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of ‘fixation’, and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a ‘regression’): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of ‘frustration’; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics endeavour to protect themselves against any such sexualization of their social instinctual cathexes, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin’s dementia praecox or (as Bleuler has named it) schizophrenia; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients’ dispositional fixations.
For the moment we will dwell a little longer on regression. After what you have learnt of the development of the libidinal function, you will be prepared to hear that there are regressions of two sorts: a return to the objects first cathected by the libido, which, as we know, are of an incestuous nature, and a return of the sexual organization as a whole to earlier stages. Both sorts are found in the transference neuroses and play a great part in their mechanism. In particular, a return to the first incestuous objects of the libido is a feature that is found in neurotics with positively fatiguing regularity. There is much more to be said about regressions of the libido itself when we take into account as well another group of neuroses, the narcissistic ones, which for the time being we do not intend to do. These disorders give us access to other developmental processes of the libidinal function which we have not yet mentioned, and show us correspondingly new sorts of regression as well. But above all I think I ought to warn you now not to confuse regression with repression and help you to form a clear idea of the relations between the two processes. Repression, as you will recall, is the process by which an act which is admissible to consciousness, one, therefore, which belongs to the system \( Pcs \), is made unconscious - is pushed back, therefore, into the system \( Ucs \). And we equally speak of repression if the unconscious mental act is altogether forbidden access to the neighbouring preconscious system and is turned back at the threshold by the censorship. Thus the concept of repression involves no relation to sexuality: I must ask you to take special note of that. It indicates a purely psychological process, which we can characterize still better if we call it a 'topographical' one. By this we intend to say that it is concerned with the psychical regions which we have assumed to exist, or, if we drop this clumsy working hypothesis, with the construction of the mental apparatus out of distinct psychical systems.

The comparison we have proposed has drawn our attention for the first time to the fact that we have not hitherto been using the word 'regression' in its general sense but in a quite special one. If we give it its general sense - of a return from a higher to a lower stage of development - then repression too can be subsumed under the concept of regression, for it too can be described as a return to an earlier and deeper stage in the development of a psychical act. In the case of repression, however, this retrogressive movement does not concern us, since we also speak of repression, in the dynamic sense, when a psychical act is held back at the lower, unconscious, stage. The fact is that repression is a topographico-dynamic concept, while regression is a purely descriptive one. What we have hitherto spoken of as regression, however, and have related to fixation, has meant exclusively a return of the libido to earlier stopping places in its development - something, that is, entirely different in its nature from repression and entirely independent of it. Nor can we call regression of the libido a purely psychical process and we cannot tell where we should localize it in the mental apparatus. And though it is true that it exercises the most powerful influence on mental life, yet the most prominent factor in it is the organic one.

Of the two kinds of regression of the libido, that to an earlier phase of the sexual organization is by far the more striking. Since this is absent in hysteria, and since our whole view of the neuroses is still far too much under the influence of the study of hysteria, which was chronologically the first, the significance of libidinal regression also became clear to us far later than that of repression. We must be prepared to find that our views will be subjected to still further extensions and revaluations when we are able to take into consideration not only hysteria and obsessional neurosis but also the other, narcissistic neuroses.
In obsessional neurosis, on the contrary, it is the regression of the libido to the preliminary stage of the sadistic-anal organization that is the most striking fact and the one which is decisive for what is manifested in symptoms. The love-impulse is obliged, when this has happened, to disguise itself as a sadistic impulse. The obsessional idea 'I should like to kill you', when it has been freed from certain additions which are not a matter of chance but are indispensable, means at bottom nothing other than 'I should like to enjoy you in love'. If you consider further that there has been a simultaneous regression in regard to the object, so that these impulses apply only to those who are nearest and dearest to the patient, you can form some idea of the horror which these obsessions arouse in him and at the same time of the alien appearance which they present to his conscious perception. But repression, too, plays a great part in the mechanism of these neuroses, though in a cursory introduction like ours this is not easily demonstrated. A regression of the libido without repression would never produce a neurosis but would lead to a perversion. From this you can see that repression is the process which is most peculiar to neuroses and is most characteristic of them. Perhaps I may have an opportunity later of telling you what we know of the mechanism of the perversions, and you will see that in their case too things are not so simple as we should be glad to make them out.

We already know that neurotic symptoms are the outcome of a conflict which arises over a new method of satisfying the libido. The two forces which have fallen out meet once again in the symptom and are reconciled, as it were, by the compromise of the symptom that has been constructed. It is for that reason, too, that the symptom is so resistant: it is supported from both sides. We also know that one of the two partners to the conflict is the unsatisfied libido which has been repulsed by reality and must now seek for other paths to its satisfaction. If reality remains relentless even though the libido is ready to take another object in place of the one that has been refused to it, then it will finally be compelled to take the path of regression and strive to find satisfaction either in one of the organizations which it has already outgrown or from one of the objects which it has earlier abandoned. The libido is lured into the path of regression by the fixation which it has left behind it at these points in its development.

Once again we shall not find it hard to reach a decision. The assertion that the libidinal cathexis (and therefore the pathogenic significance) of the infantile experiences has been greatly intensified by the regression of the libido is undoubtedly correct, but it would lead to error if we were to regard it alone as decisive. Other considerations must be allowed weight as well.

In the second place, we must reflect that it would be inconceivable for the libido to regress so regularly to the period of childhood unless there were something there to exercise an attraction on it. The fixation which we have supposed to be present at particular points in the course of development can only have a meaning if we regard it as consisting in the retention of a certain quota of libidinal energy. And finally I may point out to you that between the intensity and pathogenic importance of infantile and of later experiences a complemental relationship exists similar to the series we have already discussed. There are cases in which the whole weight of causation falls on the sexual experiences of childhood, cases in which those impressions exert a definitely traumatic effect and call for no other support than can be afforded them by an average sexual constitution and the fact of its incomplete development. Alongside of these cases there are others in which the whole accent lies on the later conflicts and the emphasis we find in the analysis laid on the impressions of childhood appears entirely as the work of regression. Thus we have extremes of 'developmental inhibition' and 'regression' and between them every degree of co-operation between the two factors.
Let us now go back to the symptoms. They create a substitute, then, for the frustrated satisfaction by means of a regression of the libido to earlier times, with which a return to earlier stages of object-choice or of the organization is inseparably bound up. We discovered some time ago that neurotics are anchored somewhere in their past; we know now that it is at a period of their past in which their libido did not lack satisfaction, in which they were happy. They search about in the history of their life till they find a period of that sort, even if they have to go back as far as the time when they were infants in arms - as they remember it or as they imagine it from later hints. In some way the symptom repeats this early infantile kind of satisfaction, distorted by the censorship arising from the conflict, turned as a rule to a feeling of suffering, and mingled with elements from the precipitating cause of the illness. The kind of satisfaction which the symptom brings has much that is strange about it.

[1916-1917, 3423]

*The Theory of Repression.* - These theoretical considerations, taken together with the immediate impressions derived from analytic work, lead to a view of the neuroses which may be described in the roughest outline as follows. The neuroses are the expression of conflicts between the ego and such of the sexual impulses as seem to the ego incompatible with its integrity or with its ethical standards. Since these impulses are not *ego-syntonic*, the ego has *repressed* them: that is to say, it has withdrawn its interest from them and has shut them off from becoming conscious as well as from obtaining satisfaction by motor discharge. If in the course of analytic work one attempts to make these repressed impulses conscious, one becomes aware of the repressive forces in the form of *resistance*. But the achievement of repression fails particularly readily in the case of the sexual instincts. Their dammed-up libido finds other ways out from the unconscious: for it *regresses* to earlier phases of development and earlier attitudes towards objects, and, at weak points in the libidinal development where there are infantile fixations, it breaks through into consciousness and obtains discharge. What results is a *symptom* and consequently in its essence a substitutive sexual satisfaction. Nevertheless the symptom cannot entirely escape from the repressive forces of the ego and must therefore submit to modifications and displacements exactly as happens with dreams - by means of which its characteristic of being a sexual satisfaction becomes unrecognizable. Consequently symptoms are in the nature of compromises between the repressed sexual instincts and the repressing ego-instincts; they represent a wish-fulfilment for both partners to the conflict simultaneously, but one which is incomplete for each of them. This is quite strictly true of the symptoms of hysteria, while in the symptoms of obsessional neurosis there is often a stronger emphasis upon the side of the repressing function owing to the erection of reaction-formations, which are assurances against sexual satisfaction.

[1923a, 3923]
The sexual function, as I found, is in existence from the very beginning of the individual's life, though at first it is attached to the other vital functions and does not become independent of them until later; it has to pass through a long and complicated process of development before it becomes what we are familiar with as the normal sexual life of the adult. It begins by manifesting itself in the activity of a whole number of component instincts. These are dependent upon erotogenic zones in the body; some of them make their appearance in pairs of opposite impulses (such as sadism and masochism or the impulses to look and to be looked at); they operate independently of one another in a search for pleasure, and they find their object for the most part in the subject's own body. Thus at first the sexual function is non-centralized and predominantly auto-erotic. Later, syntheses begin to appear in it; a first stage of organization is reached under the dominance of the oral components, an anal-sadistic stage follows, and it is only after the third stage has at last been reached that the primacy of the genitals is established and that the sexual function begins to serve the ends of reproduction. In the course of this process of development a number of elements of the various component instincts turn out to be unserviceable for this last end and are therefore left on one side or turned to other uses, while others are diverted from their aims and carried over into the genital organization. I gave the name of libido to the energy of the sexual instincts and to that form of energy alone. I was next driven to suppose that the libido does not always pass through its prescribed course of development smoothly. As a result either of the excessive strength of certain of the components or of experiences involving premature satisfaction, fixations of the libido may occur at various points in the course of its development. If subsequently a repression takes place, the libido flows back to these points (a process described as regression), and it is from them that the energy breaks through in the form of a symptom. Later on it further became clear that the localization of the point of fixation is what determines the choice of neurosis, that is, the form in which the subsequent illness makes its appearance.

[1925d, 4211]
We shall be in even closer harmony with psycho-analytic research if we give a place of preference among the accidental factors to the experiences of early childhood. The single aetiological series then falls into two, which may be called the dispositional and the definitive. In the first the constitution and the accidental experiences of childhood interact in the same manner as do the disposition and later traumatic experiences in the second. All the factors that impair sexual development show their effects by bringing about a regression, a return to an earlier phase of development.

[1905d, 1550]

The flight from unsatisfactory reality into what, on account of the biological damage involved, we call illness (though it is never without an immediate yield of pleasure to the patient) takes place along the path of involution, of regression, of a return to earlier phases of sexual life, phases from which at one time satisfaction was not withheld. This regression appears to be a twofold one: a \textit{temporal} one, in so far as the libido, the erotic needs, hark back to stages of development that are earlier in time, and a \textit{formal} one, in that the original and primitive methods of psychical expression are employed in manifesting those needs. Both these kinds of regression, however, lead back to childhood and unite in bringing about an infantile condition of sexual life.

[1910a, 2234]

Leonardo emerges from the obscurity of his boyhood as an artist, a painter and a sculptor, owing to a specific talent which may have been reinforced by the precocious awakening in the first years of childhood of his scopophilic instinct. We should be most glad to give an account of the way in which artistic activity derives from the primal instincts of the mind if it were not just here that our capacities fail us. We must be content to emphasize the fact - which it is hardly any longer possible to doubt - that what an artist creates provides at the same time an outlet for his sexual desire; and in Leonardo's case we can point to the information which comes from Vasari, that heads of laughing women and beautiful boys - in other words, representations of his sexual objects - were notable among his first artistic endeavours. In the bloom of his youth Leonardo appears at first to have worked without inhibition. Just as he modelled himself on his father in the outward conduct of his life, so too he passed through a period of masculine creative power and artistic productiveness in Milan, where a kindly fate enabled him to find a father substitute in the duke Lodovico Moro. But soon we and confirmation of our experience that the almost total repression of a real sexual life does not provide the most favourable conditions for the exercise of sublimated sexual trends. The pattern imposed by sexual life made itself felt. His activity and his ability to form quick decisions began to fail; his tendency towards deliberation and delay was already noticeable as a disturbing element in the 'Last Supper', and by influencing his technique it had a decisive effect on the fate of that great painting. Slowly there occurred in him a process which can only be compared to the regressions in neurotics. The development that turned him into an artist at puberty was overtaken by the process which led him to be an investigator, and which had its determinants in early infancy. The second sublimation of his erotic instinct gave place to the original sublimation for which the way had been prepared on the occasion of the first repression. He became an investigator, at first still in the service of his art, but later independently of it and away from it. With the loss of his patron, the substitute for his father, and with the increasingly sombre colours which his life took on, this regressive shift assumed larger and larger proportions. He became \textit{'impacientissimo al pennello'},¹ as we are told by a correspondent of the Countess Isabella d'Este, who was extremely eager to possess a painting from his hand. His infantile past had gained control over him. But the research which now took the place of artistic creation seems to have contained some of the features which distinguish the activity of unconscious instincts - insatiability, unyielding rigidity and the lack of an ability to adapt to real circumstances.

[1910c, 2301]
For the moment we will dwell a little longer on regression. After what you have learnt of the development of the libidinal function, you will be prepared to hear that there are regressions of two sorts: a return to the objects first cathected by the libido, which, as we know, are of an incestuous nature, and a return of the sexual organization as a whole to earlier stages. Both sorts are found in the transference neuroses and play a great part in their mechanism. In particular, a return to the first incestuous objects of the libido is a feature that is found in neurotics with positively fatiguing regularity. There is much more to be said about regressions of the libido itself when we take into account as well another group of neuroses, the narcissistic ones, which for the time being we do not intend to do. These disorders give us access to other developmental processes of the libidinal function which we have not yet mentioned, and show us correspondingly new sorts of regression as well. But above all I think I ought to warn you now not to confuse regression with repression and help you to form a clear idea of the relations between the two processes. Repression, as you will recall, is the process by which an act which is admissible to consciousness, one, therefore, which belongs to the system $Pcs.$, is made unconscious - is pushed back, therefore, into the system $Ucs.$ And we equally speak of repression if the unconscious mental act is altogether forbidden access to the neighbouring preconscious system and is turned back at the threshold by the censorship. Thus the concept of repression involves no relation to sexuality: I must ask you to take special note of that. It indicates a purely psychological process, which we can characterize still better if we call it a 'topographical' one. By this we intend to say that it is concerned with the psychical regions which we have assumed to exist, or, if we drop this clumsy working hypothesis, with the construction of the mental apparatus out of distinct psychical systems.

Of the two kinds of regression of the libido, that to an earlier phase of the sexual organization is by far the more striking. Since this is absent in hysteria, and since our whole view of the neuroses is still far too much under the influence of the study of hysteria, which was chronologically the first, the significance of libidinal regression also became clear to us far later than that of repression. We must be prepared to find that our views will be subjected to still further extensions and revaluations when we are able to take into consideration not only hysteria and obsessional neurosis but also the other, narcissistic neuroses.

In obsessional neurosis, on the contrary, it is the regression of the libido to the preliminary stage of the sadistic-anal organization that is the most striking fact and the one which is decisive for what is manifested in symptoms. The love-impulse is obliged, when this has happened, to disguise itself as a sadistic impulse. The obsessional idea 'I should like to kill you', when it has been freed from certain additions which are not a matter of chance but are indispensable, means at bottom nothing other than 'I should like to enjoy you in love'. If you consider further that there has been a simultaneous regression in regard to the object, so that these impulses apply only to those who are nearest and dearest to the patient, you can form some idea of the horror which these obsessions arouse in him and at the same time of the alien appearance which they present to his conscious perception. But repression, too, plays a great part in the mechanism of these neuroses, though in a cursory introduction like ours this is not easily demonstrated. A regression of the libido without repression would never produce a neurosis but would lead to a perversion. From this you can see that repression is the process which is most peculiar to neuroses and is most characteristic of them. Perhaps I may have an opportunity later of telling you what we know of the mechanism of the perversions, and you will see that in their case too things are not so simple as we should be glad to make them out.
We already know that neurotic symptoms are the outcome of a conflict which arises over a new method of satisfying the libido. The two forces which have fallen out meet once again in the symptom and are reconciled, as it were, by the compromise of the symptom that has been constructed. It is for that reason, too, that the symptom is so resistant: it is supported from both sides. We also know that one of the two partners to the conflict is the unsatisfied libido which has been repulsed by reality and must now seek for other paths to its satisfaction. If reality remains relentless even though the libido is ready to take another object in place of the one that has been refused to it, then it will finally be compelled to take the path of regression and strive to find satisfaction either in one of the organizations which it has already outgrown or from one of the objects which it has earlier abandoned. The libido is lured into the path of regression by the fixation which it has left behind it at these points in its development.

[1916-1917, 3417]

The hereditary sexual constitution presents us with a great variety of dispositions, according as one component instinct or another, alone or in combination with others, is inherited in particular strength. The sexual constitution forms once again, together with the factor of infantile experience, a ‘complemental series’ exactly similar to the one we first came to know between disposition and the accidental experience of the adult. In both of them we find the same extreme cases and the same relations between the two factors concerned. And here the question suggests itself of whether the most striking kinds of libidinal regressions - those to earlier stages of the sexual organization - may not be predominantly determined by the hereditary constitutional factor. But it is best to postpone answering this question till we have been able to take a wider range of forms of neurotic illness into account.

[1916-1917, 3420]

Let us now go back to the symptoms. They create a substitute, then, for the frustrated satisfaction by means of a regression of the libido to earlier times, with which a return to earlier stages of object-choice or of the organization is inseparably bound up. We discovered some time ago that neurotics are anchored somewhere in their past; we know now that it is at a period of their past in which their libido did not lack satisfaction, in which they were happy. They search about in the history of their life till they find a period of that sort, even if they have to go back as far as the time when they were infants in arms - as they remember it or as they imagine it from later hints. In some way the symptom repeats this early infantile kind of satisfaction, distorted by the censorship arising from the conflict, turned as a rule to a feeling of suffering, and mingled with elements from the precipitating cause of the illness. The kind of satisfaction which the symptom brings has much that is strange about it.

[1916-1917, 3423]

One of the patient's pieces of information will make it easier for us to understand the alteration in his character which appeared during his parents' absence as a somewhat indirect consequence of his seduction. He said that he gave up masturbating very soon after his Nanya's refusal and threat. *His sexual life, therefore, which was beginning to come under the sway of the genital zone, gave way before an external obstacle, and was thrown back by its influence into an earlier phase of pregenital organization.* As a result of the suppression of his masturbation, the boy's sexual life took on a sadistic-anal character. He became irritable and a tormentor, and gratified himself in this way at the expense of animals and humans. His principal object was his beloved Nanya, and he knew how to torment her till she burst into tears. In this way he revenged himself on her for the refusal he had met with, and at the same time gratified his sexual lust in the form which corresponded to his present regressive phase. He began to be cruel to small animals, to catch flies and pull off their wings, to crush beetles underfoot; in his imagination he liked beating large animals (horses) as well. All of these, then, were active and sadistic proceedings; we shall discuss his anal impulses at this period in a later connection.

[1918b, 3516]
We now observe that at this point in our narrative we must make an alteration in our terminology. During the dream he had reached a new phase in his sexual organization. Up to then the sexual opposites had been for him *active* and *passive*. Since his seduction his sexual aim had been a passive one, of being touched on the genitals; it was then transformed, by regression to the earlier stage of the sadistic-anal organization, into the masochistic aim of being beaten or punished. It was a matter of indifference to him whether he reached this aim with a man or with a woman. He had travelled, without considering the difference of sex, from his Nanya to his father; he had longed to have his penis touched by his Nanya, and had tried to provoke a beating from his father. Here his genitals were left out of account; though the connection with them which had been concealed by the regression was still expressed in his phantasy of being beaten on the penis. The activation of the primal scene in the dream now brought him back to the genital organization. He discovered the vagina and the biological significance of masculine and feminine. He understood now that active was the same as masculine, while passive was the same as feminine. His passive sexual aim should now have been transformed into a feminine one, and have expressed itself as 'being copulated with by his father' instead of 'being beaten by him on the genitals or on the bottom'. This feminine aim, however, underwent repression and was obliged to let itself be replaced by fear of the wolf. 

[1918b, 3534]

The phantasy of the period of incestuous love had said: 'He (my father) loves only me, and not the other child, for he is beating it.' The sense of guilt can discover no punishment more severe than the reversal of this triumph: 'No, he does not love you, for he is beating you.' In this way the phantasy of the second phase, that of being beaten by her father, is a direct expression of the girl's sense of guilt, to which her love for her father has now succumbed. The phantasy, therefore, has become masochistic. So far as I know, this is always so; a sense of guilt is invariably the factor that transforms sadism into masochism. But this is certainly not the whole content of masochism. The sense of guilt cannot have won the field alone; a share must also fall to the love-impulse. We must remember that we are dealing with children in whom the sadistic component was able for constitutional reasons to develop prematurely and in isolation. We need not abandon this point of view. It is precisely such children who find it particularly easy to hark back to the pregenital, sadistic-anal organization of their sexual life. If the genital organization, when it has scarcely been effected, is met by repression, the result is not only that every psychical representation of the incestuous love becomes unconscious, or remains so, but there is another result as well: a regressive debasement of the genital organization itself to a lower level. 'My father loves me' was meant in a genital sense; owing to the regression it is turned into 'My father is beating me (I am being beaten by my father)'. This being beaten is now a convergence of the sense of guilt and sexual love. It *is not only the punishment for the forbidden genital relation, but also the regressive substitute for that relation*, and from this latter source it derives the libidinal excitation which is from this time forward attached to it, and which finds its outlet in masturbatory acts. Here for the first time we have the essence of masochism. 

[1919e, 3651]
Little light is thrown upon the genesis of masochism by our discussion of the beating-phantasy. To begin with, there seems to be a confirmation of the view that masochism is not the manifestation of a primary instinct, but originates from sadism which has been turned round upon the self - that is to say, by means of regression from an object to the ego.¹ Instincts with a passive aim must be taken for granted as existing, especially among women. But passivity is not the whole of masochism. The characteristic of displeasure belongs to it as well, - a bewildering accompaniment to the satisfaction of an instinct. The transformation of sadism into masochism appears to be due to the influence of the sense of guilt which takes part in the act of repression. Thus repression is operative here in three ways: it renders the consequences of the genital organization unconscious, it compels that organization itself to regress to the earlier sadistic-anal stage, and it transforms the sadism of this stage into masochism, which is passive and again in a certain sense narcissistic. The second of these three effects is made possible by the weakness of the genital organization, which must be presupposed in these cases. The third becomes necessary because the sense of guilt takes as much objection to sadism as to incestuous object-choice genitally conceived. Again, the analyses do not tell us the origin of the sense of guilt itself. It seems to be brought along by the new phase upon which the child is entering, and, if it afterwards persists, it seems to correspond to a scar-like formation which is similar to the sense of inferiority. According to our present orientation in the structure of the ego, which is as yet uncertain, we should assign it to the agency in the mind which sets itself up as a critical conscience over against the rest of the ego, which produces Silberer's functional phenomenon in dreams, and which cuts itself loose from the ego in delusions of being watched.

The Theory of Repression. - These theoretical considerations, taken together with the immediate impressions derived from analytic work, lead to a view of the neuroses which may be described in the roughest outline as follows. The neuroses are the expression of conflicts between the ego and such of the sexual impulses as seem to the ego incompatible with its integrity or with its ethical standards. Since these impulses are not ego-syntonic, the ego has repressed them: that is to say, it has withdrawn its interest from them and has shut them off from becoming conscious as well as from obtaining satisfaction by motor discharge. If in the course of analytic work one attempts to make these repressed impulses conscious, one becomes aware of the repressive forces in the form of resistance. But the achievement of repression fails particularly readily in the case of the sexual instincts. Their dammed-up libido finds other ways out from the unconscious: for it regresses to earlier phases of development and earlier attitudes towards objects, and, at weak points in the libidinal development where there are infantile fixations, it breaks through into consciousness and obtains discharge. What results is a symptom and consequently in its essence a substitutive sexual satisfaction. Nevertheless the symptom cannot entirely escape from the repressive forces of the ego and must therefore submit to modifications and displacements exactly as happens with dreams - by means of which its characteristic of being a sexual satisfaction becomes unrecognizable. Consequently symptoms are in the nature of compromises between the repressed sexual instincts and the repressing ego-instincts; they represent a wish-fulfilment for both partners to the conflict simultaneously, but one which is incomplete for each of them. This is quite strictly true of the symptoms of hysteria, while in the symptoms of obsessional neurosis there is often a stronger emphasis upon the side of the repressing function owing to the erection of reaction- formations, which are assurances against sexual satisfaction.
These are unwelcome complications, considering that we only set out to study simple cases of symptom-formation due to repression, and with that intention selected the earliest and to all appearances, most transparent neuroses of childhood. Instead of a single repression we have found a collection of them and have become involved with regression into the bargain. Perhaps we have added to the confusion by treating the two cases of animal phobia at our disposal - 'Little Hans' and the 'Wolf Man' - as though they were cast in the same mould. As a matter of fact, certain differences between them stand out. It is only with regard to 'Little Hans' that we can say with certainty that what his phobia disposed of were the two main impulses of the Oedipus complex - his aggressiveness towards his father and his over-fondness for his mother. A tender feeling for his father was undoubtedly there too and played a part in repressing the opposite feeling; but we can prove neither that it was strong enough to draw repression upon itself nor that it disappeared afterwards. 'Hans' seems, in fact, to have been a normal boy with what is called a 'positive' Oedipus complex. It is possible that the factors which we do not find were actually at work in him, but we cannot demonstrate their existence. Even the most exhaustive analysis has gaps in its data and is insufficiently documented. In the case of the Russian the deficiency lies elsewhere. His attitude to female objects had been disturbed by an early seduction and his passive, feminine side was strongly developed. The analysis of his wolf-dream revealed very little intentional aggressiveness towards his father, but it brought forward unmistakable proof that what repression overtook was his passive tender attitude to his father. In his case, too, the other factors may have been operative as well; but they were not in evidence. How is it that, in spite of these differences in the two cases, almost amounting to an antithesis, the final outcome - a phobia - was approximately the same? The answer must be sought in another quarter. I think it will be found in the second fact which emerges from our brief comparative examination. It seems to me that in both cases we can detect what the motive force of the repression was and can substantiate our view of its nature from the line of development which the two children subsequently pursued. This motive force was the same in both of them. It was the fear of impending castration. 'Little Hans' gave up his aggressiveness towards his father from fear of being castrated. His fear that a horse would bite him can, without any forcing, be given the full sense of a fear that a horse would bite off his genitals, would castrate him. But it was from fear of being castrated, too, that the little Russian relinquished his wish to be loved by his father, for he thought that a relation of that sort presupposed a sacrifice of his genitals - of the organ which distinguished him from a female. As we see, both forms of the Oedipus complex, the normal, active form and the inverted one, came to grief through the castration complex. The Russian boy's anxiety-idea of being devoured by a wolf contained, it is true, no suggestion of castration, for the oral regression it had undergone had removed it too far from the phallic stage. But the analysis of his dream rendered further proof superfluous. It was a triumph of repression that the form in which his phobia was expressed should no longer have contained any allusion to castration.

[1926d, 4267]
I am well aware that a number of cases exhibit a more complicated structure and that many other repressed instinctual impulses can enter into a phobia. But they are only tributary streams which have for the most part joined the main current of the neurosis at a later stage. The symptomatology of agoraphobia is complicated by the fact that the ego does not confine itself to making a renunciation. In order to rob the situation of danger it does more: it usually effects a temporal regression to infancy (in extreme cases, to a time when the subject was in his mother's womb and protected against the dangers which threaten him in the present). Such a regression now becomes a condition whose fulfilment exempts the ego from making its renunciation. For instance, an agoraphobic patient may be able to walk in the street provided he is accompanied, like a small child, by someone he knows and trusts; or, for the same reason, he may be able to go out alone provided he remains within a certain distance of his own house and does not go to places which are not familiar to him or where people do not know him. What these stipulations are will depend in each case on the infantile factors which dominate him through his neurosis. The phobia of being alone is unambiguous in its meaning, irrespective of any infantile regression: it is, ultimately, an endeavour to avoid the temptation to indulge in solitary masturbation. Infantile regression can, of course, only take place when the subject is no longer a child.

Now let us go back and turn to the id. It is not so easy to guess what occurs during repression in connection with the instinctual impulse that is being fought against. The main question which our interest raises is as to what happens to the energy, to the libidinal charge, of that excitation - how is it employed? You recollect that the earlier hypothesis was that it is precisely this that is transformed by repression into anxiety. We no longer feel able to say that. The modest reply will rather be that what happens to it is probably not always the same thing. There is probably an intimate correspondence which we ought to get to know about between what is occurring at the time in the ego and in the id in connection with the repressed impulse. For since we have decided that the pleasure-unpleasure principle, which is set in action by the signal of anxiety, plays a part in repression, we must alter our expectations. That principle exercises an entirely unrestricted dominance over what happens in the id. We can rely on its bringing about quite profound changes in the instinctual impulse in question. We are prepared to find that repression will have very various consequences, more or less far-reaching. In some cases the repressed instinctual impulse may retain its libidinal cathexis, and may persist in the id unchanged, although subject to constant pressure from the ego. In other cases what seems to happen is that it is totally destroyed, while its libido is permanently diverted along other paths. I expressed the view that this is what happens when the Oedipus complex is dealt with normally - in this desirable case, therefore, being not simply repressed but destroyed in the id. Clinical experience has further shown us that in many cases, instead of the customary result of repression, a degradation of the libido takes place - a regression of the libidinal organization to an earlier stage. This can, of course, only occur in the id, and if it occurs it will be under the influence of the same conflict which was introduced by the signal of anxiety. The most striking example of this kind is provided by the obsessional neurosis, in which libidinal regression and repression operate together.
The flight from unsatisfactory reality into what, on account of the biological damage involved, we call illness (though it is never without an immediate yield of pleasure to the patient) takes place along the path of involution, of regression, of a return to earlier phases of sexual life, phases from which at one time satisfaction was not withheld. This regression appears to be a twofold one: a temporal one, in so far as the libido, the erotic needs, hark back to stages of development that are earlier in time, and a formal one, in that the original and primitive methods of psychical expression are employed in manifesting those needs. Both these kinds of regression, however, lead back to childhood and unite in bringing about an infantile condition of sexual life.

[1910a, 2234]

The transition from the pleasure principle to the reality principle is one of the most important steps forward in the ego's development. We know already that it is only late and unwillingly that the sexual instincts join in this piece of development, and we shall hear later the consequences for human beings of the fact that their sexuality is content with such a loose connection with external reality. And now in conclusion one last remark on this subject. If man's ego has its process of development like the libido, you will not be surprised to hear that there are also 'regressions of the ego', and you will be anxious to know too what part may be played in neurotic illnesses by this return of the ego to earlier phases of its development.

[1916-1917, 3416]

I am well aware that a number of cases exhibit a more complicated structure and that many other repressed instinctual impulses can enter into a phobia. But they are only tributary streams which have for the most part joined the main current of the neurosis at a later stage. The symptomatology of agoraphobia is complicated by the fact that the ego does not confine itself to making a renunciation. In order to rob the situation of danger it does more: it usually effects a temporal regression to infancy (in extreme cases, to a time when the subject was in his mother's womb and protected against the dangers which threaten him in the present). Such a regression now becomes a condition whose fulfilment exempts the ego from making its renunciation. For instance, an agoraphobic patient may be able to walk in the street provided he is accompanied, like a small child, by someone he knows and trusts; or, for the same reason, he may be able to go out alone provided he remains within a certain distance of his own house and does not go to places which are not familiar to him or where people do not know him. What these stipulations are will depend in each case on the infantile factors which dominate him through his neurosis. The phobia of being alone is unambiguous in its meaning, irrespective of any infantile regression: it is, ultimately, an endeavour to avoid the temptation to indulge in solitary masturbation. Infantile regression can, of course, only take place when the subject is no longer a child.

[1926d, 4284]
In my *Three Essays on the Theory of Sexuality* I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics *endeavour to protect themselves against any such sexualization of their social instinctual cathexes*, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) *schizophrenia*; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations. [1911c, 2431]

The second danger in a development by stages of this sort lies in the fact that the portions which have proceeded further may also easily return retrogressively to one of these earlier stages - what we describe as a *regression*. The trend will find itself led into a regression of this kind if the exercise of its function - that is, the attainment of its aim of satisfaction - is met, in its later or more highly developed form, by powerful external obstacles. It is plausible to suppose that fixation and regression are not independent of each other. The stronger the fixations on its path of development, the more readily will the function evade external difficulties by regressing to the fixations - the more incapable, therefore, does the developed function turn out to be of resisting external obstacles in its course. Consider that, if a people which is in movement has left strong detachments behind at the stopping-places on its migration, it is likely that the more advanced parties will be inclined to retreat to these stopping-places if they have been defeated or have come up against a superior enemy. But they will also be in the greater danger of being defeated the more of their number they have left behind on their migration. [1916-1917, 3404]
The path to perversion branches off sharply from that to neurosis. If these regressions rouse no objection from the ego, no neurosis will come about either; and the libido will arrive at some real, even though no longer normal, satisfaction. But if the ego, which has under its control not only consciousness but also the approaches to motor innervation and accordingly to the realization of mental desires, does not agree with these regressions, conflict will follow. The libido is, as it were, cut off and must try to escape in some direction where, in accordance with the requirements of the pleasure principle, it can find a discharge for its cathexis of energy. It must withdraw from the ego. An escape of this kind is offered it by the fixations on the path of its development which it has now entered on regressively - fixations from which the ego had protected itself in the past by repressions. By cathecting these repressed positions as it flows backward, the libido has withdrawn from the ego and its laws, and has at the same time renounced all the education it has acquired under the ego's influence. It was docile so long as satisfaction beckoned to it; but under the double pressure of external and internal frustration it becomes refractory, and recalls earlier and better times. Such is the libido's fundamentally unchangeable character. The ideas to which it now transfers its energy as a cathexis belong to the system of the unconscious and are subject to the processes which are possible there, particularly to condensation and displacement. In this way conditions are established which completely resemble those in dream-construction. The dream proper, which has been completed in the unconscious and is the fulfilment of an unconscious wishful phantasy, is brought up against a portion of (pre)conscious activity which exercises the office of censorship and which, when it has been indemnified, permits the formation of the manifest dream as a compromise. In the same way, what represents the libido in the unconscious has to reckon with the power of the preconscious ego. The opposition which had been raised against it in the ego pursues it as an 'anticathexis' and compels it to choose a form of expression which can at the same time become an expression of the opposition itself. Thus the symptom emerges as a many-times-distorted derivative of the unconscious libidinal wish-fulfilment, an ingeniously chosen piece of ambiguity with two meanings in complete mutual contradiction. In this last respect, however, there is a distinction between the construction of a dream and of a symptom. For in dream-formation the preconscious purpose is merely concerned to preserve sleep, to allow nothing that would disturb it to make its way into consciousness; it does not insist upon calling out sharply 'No! on the contrary!' to the unconscious wishful impulse. It can afford to be more tolerant because the situation of someone sleeping is less perilous. The state of sleep in itself bars any outlet into reality.

Let us now go back to the symptoms. They create a substitute, then, for the frustrated satisfaction by means of a regression of the libido to earlier times, with which a return to earlier stages of object-choice or of the organization is inseparably bound up. We discovered some time ago that neurotics are anchored somewhere in their past; we know now that it is at a period of their past in which their libido did not lack satisfaction, in which they were happy. They search about in the history of their life till they find a period of that sort, even if they have to go back as far as the time when they were infants in arms - as they remember it or as they imagine it from later hints. In some way the symptom repeats this early infantile kind of satisfaction, distorted by the censorship arising from the conflict, turned as a rule to a feeling of suffering, and mingled with elements from the precipitating cause of the illness. The kind of satisfaction which the symptom brings has much that is strange about it.
The importance of the part played by phantasy in the formation of symptoms will be made clear to you by what I have to tell you. I have explained how in the case of frustration the libido cathects regressively the positions which it has given up but to which some quotas of it have remained adhering. I shall not withdraw this or correct it, but I have to insert a connecting link. How does the libido find its way to these points of fixation? All the objects and trends which the libido has given up have not yet been given up in every sense. They or their derivatives are still retained with a certain intensity in phantasies. Thus the libido need only withdraw on to phantasies in order to find the path open to every repressed fixation. These phantasies have enjoyed a certain amount of toleration: they have not come into conflict with the ego, however sharp the contrasts between them may have been, so long as a particular condition is observed.

This condition is of a quantitative nature and it is now upset by the backward flow of libido on to the phantasies. As a result of this surplus, the energetic cathexis of the phantasies is so much increased that they begin to raise claims, that they develop a pressure in the direction of becoming realized. But this makes a conflict between them and the ego inevitable. Whether they were previously preconscious or conscious, they are now subjected to repression from the direction of the ego and are at the mercy of attraction from the direction of the unconscious. From what are now unconscious phantasies the libido travels back to their origins in the unconscious - to its own points of fixation.

A perversion in childhood, as is well known, may become the basis for the construction of a perversion having a similar sense and persisting throughout life, one which consumes the subject's whole sexual life. On the other hand the perversion may be broken off and remain in the background of a normal sexual development, from which, however, it continues to withdraw a certain amount of energy. The first of these alternatives was already known before the days of analysis. Analytic investigation, however, of such fully-developed cases almost bridges the gulf between the two. For we find often enough with these perverts that they too made an attempt at developing normal sexual activity, usually at the age of puberty; but their attempt had not enough force in it and was abandoned in the face of the first obstacles which inevitably arise, where upon they fell back upon their infantile fixation once and for all.

In a far greater number of cases the neurosis is more autonomous and more independent of the interests of self-preservation and self-maintenance. In the conflict which creates the neurosis, what are at stake are either solely libidinal interests or libidinal interests in intimate connections with self-preservative ones. In all three instances the dynamics of the neurosis are the same. A dammed-up libido which cannot be satisfied in reality succeeds, with the help of a regression to old fixations, in finding discharge through the repressed unconscious. The sick man's ego, in so far as it can extract a 'gain from illness' out of this process, countenances the neurosis, although there can be no doubt of its injuriousness in its economic aspect.
The sexual life of children is of course different from that of adults. The sexual function, from its beginnings to the definitive form in which it is so familiar to us, undergoes a complicated process of development. It grows together from numerous component instincts with different aims and passes through several phases of organization till at last it comes into the service of reproduction. Not all the component instincts are equally serviceable for the final outcome; they must be diverted, remodelled and in part suppressed. Such a far-reaching course of development is not always passed through without a flaw; inhibitions in development take place, partial fixations at early stages of development. If obstacles arise later on to the exercise of the sexual function, the sexual urge - the libido, as we call it - is apt to hark back to these earlier points of fixation. The study of the sexuality of children and its transformations up to maturity has also given us the key to an understanding of what are known as the sexual perversions, which people used always to describe with all the requisite indications of disgust but whose origin they were never able to explain. The whole topic is of uncommon interest, but for the purposes of our conversation there is not much sense in telling you more about it. To find one's way about in it one of course needs anatomical and physiological knowledge, all of which is unfortunately not to be acquired in medical schools. But a familiarity with the history of civilization and with mythology is equally indispensable.

A feebleness of the ego of this sort is to be found in all of us in childhood; and that is why the experiences of the earliest years of childhood are of such great importance for later life. Under the extraordinary burden of this period of childhood we have in a few years to cover the enormous developmental distance between stone-age primitive men and the participants in contemporary civilization, and, at the same time and in particular, we have to fend off the instinctual impulses of the early sexual period - under this burden, then, our ego takes refuge in repression and lays itself open to a childhood neurosis, the precipitate of which it carries with it into maturity as a disposition to a later nervous illness. Everything now depends on how the growing organism is treated by fate. If life becomes too hard, if the gulf between instinctual claims and the demands of reality becomes too great, the ego may fail in its efforts to reconcile the two, and the more readily, the more it is inhibited by the disposition carried over by it from infancy. The process of repression is then repeated, the instincts tear themselves away from the ego's domination, find their substitutive satisfactions along the paths of regression, and the poor ego has become helplessly neurotic.

This process is not always performed faultlessly. Inhibitions in its development manifest themselves as the many sorts of disturbance in sexual life. When this is so, we find fixations of the libido to conditions in earlier phases, whose urge, which is independent of the normal sexual aim, is described as perversion. One such developmental inhibition, for instance, is homosexuality when it is manifest. Analysis shows that in every case a homosexual object-tie was present and in most cases persisted in a latent condition. The situation is complicated by the fact that as a rule the processes necessary for bringing about a normal outcome are not completely present or absent, but partially present, so that the final result remains dependent on these quantitative relations. In these circumstances the genital organization is, it is true, attained, but it lacks those portions of the libido which have not advanced with the rest and have remained fixated to pregenital objects and aims. This weakening shows itself in a tendency, if there is an absence of genital satisfaction or if there are difficulties in the real external world, for the libido to hark back to its earlier pregenital cathexes (regression).
Let us bring together what we have found out about the peculiar propensity of dreams to recast their ideational content into sensory images. We have not explained this feature of the dream-work, we have not traced it back to any known psychological laws; but we have rather picked it out as something that suggests unknown implications and we have characterized it with the word 'regressive.' We have put forward the view that in all probability this regression, wherever it may occur, is an effect of a resistance opposing the progress of a thought into consciousness along the normal path, and of a simultaneous attraction exercised upon the thought by the presence of memories possessing great sensory force.¹ In the case of dreams, regression may perhaps be further facilitated by the cessation of the progressive current - which streams in during the daytime from the sense organs; in other forms of regression, the absence of this accessory factor must be made up for by a greater intensity of the other motives for regression. Nor must we forget to observe that in these pathological cases of regression as well as in dreams the process of transference of energy must differ from what it is in regressions occurring in normal mental life, since in the former cases that process makes possible a complete hallucinatory cathexis of the perceptual systems. What we have described, in our analysis of the dream-work, as 'regard for representability' might be brought into connection with the selective attraction exercised by the visually recollected scenes touched upon by the dream-thoughts.

¹[1900a, 980]

For the moment we will dwell a little longer on regression. After what you have learnt of the development of the libidinal function, you will be prepared to hear that there are regressions of two sorts: a return to the objects first cathected by the libido, which, as we know, are of an incestuous nature, and a return of the sexual organization as a whole to earlier stages. Both sorts are found in the transference neuroses and play a great part in their mechanism. In particular, a return to the first incestuous objects of the libido is a feature that is found in neurotics with positively fatiguing regularity. There is much more to be said about regressions of the libido itself when we take into account as well another group of neuroses, the narcissistic ones, which for the time being we do not intend to do. These disorders give us access to other developmental processes of the libidinal function which we have not yet mentioned, and show us correspondingly new sorts of regression as well. But above all I think I ought to warn you now not to confuse regression with repression and help you to form a clear idea of the relations between the two processes. Repression, as you will recall, is the process by which an act which is admissible to consciousness, one, therefore, which belongs to the system $\text{Pcs.}$, is made unconscious - is pushed back, therefore, into the system $\text{Ucs.}$ And we equally speak of repression if the unconscious mental act is altogether forbidden access to the neighbouring preconscious system and is turned back at the threshold by the censorship. Thus the concept of repression involves no relation to sexuality: I must ask you to take special note of that. It indicates a purely psychological process, which we can characterize still better if we call it a 'topographical' one. By this we intend to say that it is concerned with the psychical regions which we have assumed to exist, or, if we drop this clumsy working hypothesis, with the construction of the mental apparatus out of distinct psychical systems.

[1916-1917, 3405]
The comparison we have proposed has drawn our attention for the first time to the fact that we have not hitherto been using the word 'regression' in its general sense but in a quite special one. If we give it its general sense - of a return from a higher to a lower stage of development - then repression too can be subsumed under the concept of regression, for it too can be described as a return to an earlier and deeper stage in the development of a psychical act. In the case of repression, however, this retrogressive movement does not concern us, since we also speak of regression, in the dynamic sense, when a psychical act is held back at the lower, unconscious, stage. The fact is that repression is a topographico-dynamic concept, while regression is a purely descriptive one. What we have hitherto spoken of as regression, however, and have related to fixation, has meant exclusively a return of the libido to earlier stopping places in its development - something, that is, entirely different in its nature from repression and entirely independent of it. Nor can we call regression of the libido a purely psychical process and we cannot tell where we should localize it in the mental apparatus. And though it is true that it exercises the most powerful influence on mental life, yet the most prominent factor in it is the organic one.

[1916-1917, 3406]

In obsessional neurosis, on the contrary, it is the regression of the libido to the preliminary stage of the sadistic-anal organization that is the most striking fact and the one which is decisive for what is manifested in symptoms. The love-impulse is obliged, when this has happened, to disguise itself as a sadistic impulse. The obsessional idea 'I should like to kill you', when it has been freed from certain additions which are not a matter of chance but are indispensable, means at bottom nothing other than 'I should like to enjoy you in love'. If you consider further that there has been a simultaneous regression in regard to the object, so that these impulses apply only to those who are nearest and dearest to the patient, you can form some idea of the horror which these obsessions arouse in him and at the same time of the alien appearance which they present to his conscious perception. But repression, too, plays a great part in the mechanism of these neuroses, though in a cursory introduction like ours this is not easily demonstrated. A regression of the libido without repression would never produce a neurosis but would lead to a perversion. From this you can see that repression is the process which is most peculiar to neuroses and is most characteristic of them. Perhaps I may have an opportunity later of telling you what we know of the mechanism of the perversions, and you will see that in their case too things are not so simple as we should be glad to make them out.

[1916-1917, 3407]
The path to perversion branches off sharply from that to neurosis. If these regressions rouse no objection from the ego, no neurosis will come about either; and the libido will arrive at some real, even though no longer normal, satisfaction. But if the ego, which has under its control not only consciousness but also the approaches to motor innervation and accordingly to the realization of mental desires, does not agree with these regressions, conflict will follow. The libido is, as it were, cut off and must try to escape in some direction where, in accordance with the requirements of the pleasure principle, it can find a discharge for its cathexis of energy. It must withdraw from the ego. An escape of this kind is offered it by the fixations on the path of its development which it has now entered on regressively - fixations from which the ego had protected itself in the past by repressions. By cathecting these repressed positions as it flows backward, the libido has withdrawn from the ego and its laws, and has at the same time renounced all the education it has acquired under the ego's influence. It was docile so long as satisfaction beckoned to it; but under the double pressure of external and internal frustration it becomes refractory, and recalls earlier and better times. Such is the libido's fundamentally unchangeable character. The ideas to which it now transfers its energy as a cathexis belong to the system of the unconscious and are subject to the processes which are possible there, particularly to condensation and displacement. In this way conditions are established which completely resemble those in dream-construction. The dream proper, which has been completed in the unconscious and is the fulfilment of an unconscious wishful phantasy, is brought up against a portion of (pre)conscious activity which exercises the office of censorship and which, when it has been indemnified, permits the formation of the manifest dream as a compromise. In the same way, what represents the libido in the unconscious has to reckon with the power of the preconscious ego. The opposition which had been raised against it in the ego pursues it as an 'anticathexis' and compels it to choose a form of expression which can at the same time become an expression of the opposition itself. Thus the symptom emerges as a many-times-distorted derivative of the unconscious libidinal wish-fulfilment, an ingeniously chosen piece of ambiguity with two meanings in complete mutual contradiction. In this last respect, however, there is a distinction between the construction of a dream and of a symptom. For in dream-formation the preconscious purpose is merely concerned to preserve sleep, to allow nothing that would disturb it to make its way into consciousness; it does not insist upon calling out sharply 'No! on the contrary!' to the unconscious wishful impulse. It can afford to be more tolerant because the situation of someone sleeping is less perilous. The state of sleep in itself bars any outlet into reality.

[1916-1917, 3418]
The phantasy of the period of incestuous love had said: 'He (my father) loves only me, and not the other child, for he is beating it.' The sense of guilt can discover no punishment more severe than the reversal of this triumph: 'No, he does not love you, for he is beating you.' In this way the phantasy of the second phase, that of being beaten by her father, is a direct expression of the girl's sense of guilt, to which her love for her father has now succumbed. The phantasy, therefore, has become masochistic. So far as I know, this is always so; a sense of guilt is invariably the factor that transforms sadism into masochism. But this is certainly not the whole content of masochism. The sense of guilt cannot have won the field alone; a share must also fall to the love-impulse. We must remember that we are dealing with children in whom the sadistic component was able for constitutional reasons to develop prematurely and in isolation. We need not abandon this point of view. It is precisely such children who find it particularly easy to hark back to the pregenital, sadistic-anal organization of their sexual life. If the genital organization, when it has scarcely been effected, is met by repression, the result is not only that every psychical representation of the incestuous love becomes unconscious, or remains so, but there is another result as well: a regressive debasement of the genital organization itself to a lower level. 'My father loves me' was meant in a genital sense; owing to the regression it is turned into 'My father is beating me (I am being beaten by my father). This being beaten is now a convergence of the sense of guilt and sexual love. It is not only the punishment for the forbidden genital relation, but also the regressive substitute for that relation, and from this latter source it derives the libidinal excitation which is from this time forward attached to it, and which finds its outlet in masturbatory acts. Here for the first time we have the essence of masochism.

The sexual function, as I found, is in existence from the very beginning of the individual's life, though at first it is attached to the other vital functions and does not become independent of them until later; it has to pass through a long and complicated process of development before it becomes what we are familiar with as the normal sexual life of the adult. It begins by manifesting itself in the activity of a whole number of component instincts. These are dependent upon erotogenic zones in the body; some of them make their appearance in pairs of opposite impulses (such as sadism and masochism or the impulses to look and to be looked at); they operate independently of one another in a search for pleasure, and they find their object for the most part in the subject's own body. Thus at first the sexual function is non-centralized and predominantly auto-erotic. Later, syntheses begin to appear in it; a first stage of organization is reached under the dominance of the oral components, an anal-sadistic stage follows, and it is only after the third stage has at last been reached that the primacy of the genitals is established and that the sexual function begins to serve the ends of reproduction. In the course of this process of development a number of elements of the various component instincts turn out to be unserviceable for this last end and are therefore left on one side or turned to other uses, while others are diverted from their aims and carried over into the genital organization. I gave the name of libido to the energy of the sexual instincts and to that form of energy alone. I was next driven to suppose that the libido does not always pass through its prescribed course of development smoothly. As a result either of the excessive strength of certain of the components or of experiences involving premature satisfaction, fixations of the libido may occur at various points in the course of its development. If subsequently a repression takes place, the libido flows back to these points (a process described as regression), and it is from them that the energy breaks through in the form of a symptom. Later on it further became clear that the localization of the point of fixation is what determines the choice of neurosis, that is, the form in which the subsequent illness makes its appearance.

[1919e, 3651]

[1925d, 4211]
The idea of being devoured by the father is typical age-old childhood material. It has familiar parallels in mythology (e.g. the myth of Kronos) and in the animal kingdom. Yet in spite of this confirmation the idea is so strange to us that we can hardly credit its existence in a child. Nor do we know whether it really means what it seems to say, and we cannot understand how it can have become the subject of a phobia. Analytic observation supplies the requisite information. It shows that the idea of being devoured by the father gives expression, in a form that has undergone regressive degradation, to a passive, tender impulse to be loved by him in a genital-erotic sense. Further investigation of the case history leaves no doubt of the correctness of this explanation. The genital impulse, it is true, betrays no sign of its tender purpose when it is expressed in the language belonging to the superseded transitional phase between the oral and sadistic organizations of the libido. Is it, moreover, a question merely of the replacement of the representative by a regressive form of expression or is it a question of a genuine regressive degradation of the genitally-directed impulse in the id? It is not at all easy to make certain. The case history of the Russian 'Wolf Man' gives very definite support to the second, more serious, view; for, from the time of the decisive dream onward, the boy became naughty, tormenting and sadistic, and soon afterwards developed a regular obsessional neurosis. At any rate, we can see that repression is not the only means which the ego can employ for the purpose of defence against an unwelcome instinctual impulse. If it succeeds in making an instinct regress, it will actually have done it more injury than it could have by repressing it. Sometimes, indeed, after forcing an instinct to regress in this way, it goes on to repress it.

[1926d, 4265]
Even a purely terminological innovation ought to justify its adoption; it ought to reflect some new point of view or some extension of knowledge. The revival of the concept of defence and the restriction of that of repression takes into account a fact which has long since been known but which has received added importance owing to some new discoveries. Our first observations of repression and of the formation of symptoms were made in connection with hysteria. We found that the perceptual content of exciting experiences and the ideational content of pathogenic structures of thought were forgotten and debarred from being reproduced in memory, and we therefore concluded that the keeping away from consciousness was a main characteristic of hysterical repression. Later on, when we came to study the obsessional neuroses, we found that in that illness pathogenic occurrences are not forgotten. They remain conscious but they are 'isolated' in some way that we cannot as yet grasp, so that much the same result is obtained as in hysterical amnesia. Nevertheless the difference is great enough to justify the belief that the process by which instinctual demands are set aside in obsessional neurosis cannot be the same as in hysteria. Further investigations have shown that in obsessional neurosis a regression of the instinctual impulses to an earlier libidinal stage is brought about through the opposition of the ego, and that this regression, although it does not make repression unnecessary, clearly works in the same sense as repression. We have seen, too, that in obsessional neurosis anticathexis, which is also presumably present in hysteria, plays a specially large part in protecting the ego by effecting a reactive alteration in it. Our attention has, moreover, been drawn to a process of 'isolation' (whose technique cannot as yet be elucidated) which finds direct symptomatic manifestation, and to a procedure, that may be called magical, of 'undoing' what has been done - a procedure about whose defensive purpose there can be no doubt, but which has no longer any resemblance to the process of 'repression'. These observations provide good enough grounds for re-introducing the old concept of defence, which can cover all these processes that have the same purpose - namely, the protection of the ego against instinctual demands - and for subsuming repression under it as a special case. The importance of this nomenclature is heightened if we consider the possibility that further investigations may show that there is an intimate connection between special forms of defence and particular illnesses, as, for instance, between repression and hysteria. In addition we may look forward to the possible discovery of yet another important correlation. It may well be that before its sharp cleavage into an ego and an id, and before the formation of a super-ego, the mental apparatus makes use of different methods of defence from those which it employs after it has reached these stages of organization.

[1926d, 4316]

A feebleness of the ego of this sort is to be found in all of us in childhood; and that is why the experiences of the earliest years of childhood are of such great importance for later life. Under the extraordinary burden of this period of childhood we have in a few years to cover the enormous developmental distance between stone-age primitive men and the participants in contemporary civilization, and, at the same time and in particular, we have to fend off the instinctual impulses of the early sexual period - under this burden, then, our ego takes refuge in repression and lays itself open to a childhood neurosis, the precipitate of which it carries with it into maturity as a disposition to a later nervous illness. Everything now depends on how the growing organism is treated by fate. If life becomes too hard, if the gulf between instinctual claims and the demands of reality becomes too great, the ego may fail in its efforts to reconcile the two, and the more readily, the more it is inhibited by the disposition carried over by it from infancy. The process of repression is then repeated, the instincts tear themselves away from the ego's domination, find their substitutive satisfactions along the paths of regression, and the poor ego has become helplessly neurotic.

[1926e, 4382]
Now let us go back and turn to the id. It is not so easy to guess what occurs during repression in connection with the instinctual impulse that is being fought against. The main question which our interest raises is as to what happens to the energy, to the libidinal charge, of that excitation - how is it employed? You recollect that the earlier hypothesis was that it is precisely this that is transformed by repression into anxiety. We no longer feel able to say that. The modest reply will rather be that what happens to it is probably not always the same thing. There is probably an intimate correspondence which we ought to get to know about between what is occurring at the time in the ego and in the id in connection with the repressed impulse. For since we have decided that the pleasure-unpleasure principle, which is set in action by the signal of anxiety, plays a part in repression, we must alter our expectations. That principle exercises an entirely unrestricted dominance over what happens in the id. We can rely on its bringing about quite profound changes in the instinctual impulse in question. We are prepared to find that repression will have very various consequences, more or less far-reaching. In some cases the repressed instinctual impulse may retain its libidinal cathexis, and may persist in the id unchanged, although subject to constant pressure from the ego. In other cases what seems to happen is that it is totally destroyed, while its libido is permanently diverted along other paths. I expressed the view that this is what happens when the Oedipus complex is dealt with normally - in this desirable case, therefore, being not simply repressed but destroyed in the id. Clinical experience has further shown us that in many cases, instead of the customary result of repression, a degradation of the libido takes place - a regression of the libidinal organization to an earlier stage. This can, of course, only occur in the id, and if it occurs it will be under the influence of the same conflict which was introduced by the signal of anxiety. The most striking example of this kind is provided by the obsessional neurosis, in which libidinal regression and repression operate together.

[1933a, 4698]
We shall be in even closer harmony with psycho-analytic research if we give a place of preference among the accidental factors to the experiences of early childhood. The single aetiological series then falls into two, which may be called the dispositional and the definitive. In the first the constitution and the accidental experiences of childhood interact in the same manner as do the disposition and later traumatic experiences in the second. All the factors that impair sexual development show their effects by bringing about a regression, a return to an earlier phase of development.

[1905d, 1550]

In my *Three Essays on the Theory of Sexuality* I have expressed the opinion that each stage in the development of psychosexuality affords a possibility of 'fixation', and thus of a dispositional point. People who have not freed themselves completely from the stage of narcissism - who, that is to say, have at that point a fixation which may operate as a disposition to a later illness - are exposed to the danger that some unusually intense wave of libido, finding no other outlet, may lead to a sexualization of their social instincts and so undo the sublimations which they had achieved in the course of their development. This result may be produced by anything that causes the libido to flow backwards (i.e. that causes a 'regression'): whether, on the one hand, the libido becomes collaterally reinforced owing to some disappointment over a woman, or is directly dammed up owing to a mishap in social relations with other men - both of these being instances of 'frustration'; or whether, on the other hand, there is a general intensification of the libido, so that it becomes too powerful to find an outlet along the channels which are already open to it, and consequently bursts through its banks at the weakest spot. Since our analyses show that paranoics endeavour to protect themselves against any such sexualization of their social instinctual cathexes, we are driven to suppose that the weak spot in their development is to be looked for somewhere between the stages of auto-erotism, narcissism and homosexuality, and that their disposition to illness (which may perhaps be susceptible of more precise definition) must be located in that region. A similar disposition would have to be assigned to patients suffering from Kraepelin's dementia praecox or (as Bleuler has named it) schizophrenia; and we shall hope later on to find clues which will enable us to trace back the differences between the two disorders (as regards both the form they take and the course they run) to corresponding differences in the patients' dispositional fixations.

[1911c, 2431]

(3) The third phase, and the most important as regards pathological phenomena, is that of failure of repression, of *irruption*, of *return of the repressed*. This irruption takes its start from the point of fixation, and it implies a regression of the libidinal development to that point.

[1911c, 2435]
A young man who has hitherto satisfied his libido by means of phantasies ending in masturbation, and who now seeks to replace a régime approximating to auto-erotism by the choice of a real object - or a girl who has given her whole affection to her father or brother and who must now, for the sake of a man who is courting her, allow her hitherto unconscious incestuous libidinal wishes to become conscious - or a married woman who would like to renounce her polygamous inclinations and phantasies of prostitution so as to become a faithful consort to her husband and a perfect mother to her child - all of these fall ill from the most laudable efforts, if the earlier fixations of their libido are powerful enough to resist a displacement; and this point will be decided, once again, by the factors of disposition, constitution and infantile experience. All of them, it might be said, meet with the fate of the little tree in the Grimms' fairy tale, which wished it had different leaves. From the hygienic point of view - which, to be sure, is not the only one to be taken into account - one could only wish for them that they had continued to be as undeveloped, as inferior and as useless as they were before they fell ill. The change which the patients strive after, but bring about only imperfectly or not at all, invariably has the value of a step forward from the point of view of real life. It is otherwise if we apply ethical standards: we see people falling ill just as often when they discard an ideal as when they seek to attain it.

[1912c, 2562]

The second danger in a development by stages of this sort lies in the fact that the portions which have proceeded further may also easily return retrogressively to one of these earlier stages - what we describe as a regression. The trend will find itself led into a regression of this kind if the exercise of its function - that is, the attainment of its aim of satisfaction - is met, in its later or more highly developed form, by powerful external obstacles. It is plausible to suppose that fixation and regression are not independent of each other. The stronger the fixations on its path of development, the more readily will the function evade external difficulties by regressing to the fixations - the more incapable, therefore, does the developed function turn out to be of resisting external obstacles in its course. Consider that, if a people which is in movement has left strong detachments behind at the stopping-places on its migration, it is likely that the more advanced parties will be inclined to retreat to these stopping-places if they have been defeated or have come up against a superior enemy. But they will also be in the greater danger of being defeated the more of their number they have left behind on their migration.

[1916-1917, 3404]

It is important for your understanding of the neuroses that you should not leave this relation between fixation and regression out of sight. This will give you a firmer footing in facing the question of how the neuroses are caused - the question of the aetiology of the neuroses which we shall shortly have to meet.

[1916-1917, 3405]
The comparison we have proposed has drawn our attention for the first time to the fact that we have not hitherto been using the word 'regression' in its general sense but in a quite special one. If we give it its general sense - of a return from a higher to a lower stage of development - then repression too can be subsumed under the concept of regression, for it too can be described as a return to an earlier and deeper stage in the development of a psychical act. In the case of repression, however, this retrogressive movement does not concern us, since we also speak of repression, in the dynamic sense, when a psychical act is held back at the lower, unconscious, stage. The fact is that repression is a topographico-dynamic concept, while regression is a purely descriptive one. What we have hitherto spoken of as regression, however, and have related to fixation, has meant exclusively a return of the libido to earlier stopping places in its development - something, that is, entirely different in its nature from repression and entirely independent of it. Nor can we call regression of the libido a purely psychical process and we cannot tell where we should localize it in the mental apparatus. And though it is true that it exercises the most powerful influence on mental life, yet the most prominent factor in it is the organic one.

We already know that neurotic symptoms are the outcome of a conflict which arises over a new method of satisfying the libido. The two forces which have fallen out meet once again in the symptom and are reconciled, as it were, by the compromise of the symptom that has been constructed. It is for that reason, too, that the symptom is so resistant: it is supported from both sides. We also know that one of the two partners to the conflict is the unsatisfied libido which has been repulsed by reality and must now seek for other paths to its satisfaction. If reality remains relentless even though the libido is ready to take another object in place of the one that has been refused to it, then it will finally be compelled to take the path of regression and strive to find satisfaction either in one of the organizations which it has already outgrown or from one of the objects which it has earlier abandoned. The libido is lured into the path of regression by the fixation which it has left behind it at these points in its development.
The path to perversion branches off sharply from that to neurosis. If these regressions rouse no objection from the ego, no neurosis will come about either; and the libido will arrive at some real, even though no longer normal, satisfaction. But if the ego, which has under its control not only consciousness but also the approaches to motor innervation and accordingly to the realization of mental desires, does not agree with these regressions, conflict will follow. The libido is, as it were, cut off and must try to escape in some direction where, in accordance with the requirements of the pleasure principle, it can find a discharge for its cathexis of energy. It must withdraw from the ego. An escape of this kind is offered it by the fixations on the path of its development which it has now entered on regressively - fixations from which the ego had protected itself in the past by repressions. By cathecting these repressed positions as it flows backward, the libido has withdrawn from the ego and its laws, and has at the same time renounced all the education it has acquired under the ego's influence. It was docile so long as satisfaction beckoned to it; but under the double pressure of external and internal frustration it becomes refractory, and recalls earlier and better times. Such is the libido's fundamentally unchangeable character. The ideas to which it now transfers its energy as a cathexis belong to the system of the unconscious and are subject to the processes which are possible there, particularly to condensation and displacement. In this way conditions are established which completely resemble those in dream-construction. The dream proper, which has been completed in the unconscious and is the fulfilment of an unconscious wishful phantasy, is brought up against a portion of (pre)conscious activity which exercises the office of censorship and which, when it has been indemnified, permits the formation of the manifest dream as a compromise. In the same way, what represents the libido in the unconscious has to reckon with the power of the preconscious ego. The opposition which had been raised against it in the ego pursues it as an 'anticathexis' and compels it to choose a form of expression which can at the same time become an expression of the opposition itself. Thus the symptom emerges as a many-times-distorted derivative of the unconscious libidinal wish-fulfilment, an ingeniously chosen piece of ambiguity with two meanings in complete mutual contradiction. In this last respect, however, there is a distinction between the construction of a dream and of a symptom. For in dream-formation the preconscious purpose is merely concerned to preserve sleep, to allow nothing that would disturb it to make its way into consciousness; it does not insist upon calling out sharply 'No! on the contrary!' to the unconscious wishful impulse. It can afford to be more tolerant because the situation of someone sleeping is less perilous. The state of sleep in itself bars any outlet into reality.

[1916-1917, 3418]

The importance of the part played by phantasy in the formation of symptoms will be made clear to you by what I have to tell you. I have explained how in the case of frustration the libido cathects regressively the positions which it has given up but to which some quotas of it have remained adhering. I shall not withdraw this or correct it, but I have to insert a connecting link. How does the libido find its way to these points of fixation? All the objects and trends which the libido has given up have not yet been given up in every sense. They or their derivatives are still retained with a certain intensity in phantasies. Thus the libido need only withdraw on to phantasies in order to find the path open to every repressed fixation. These phantasies have enjoyed a certain amount of toleration: they have not yet come into conflict with the ego, however sharp the contrasts between them may have been, so long as a particular condition is observed. This condition is of a quantitative nature and it is now upset by the backward flow of libido on to the phantasies. As a result of this surplus, the energetic cathexis of the phantasies is so much increased that they begin to raise claims, that they develop a pressure in the direction of becoming realized. But this makes a conflict between them and the ego inevitable. Whether they were previously preconscious or conscious, they are now subjected to repression from the direction of the ego and are at the mercy of attraction from the direction of the unconscious. From what are now unconscious phantasies the libido travels back to their origins in the unconscious - to its own points of fixation.

[1916-1917, 3428]
Your second observation, too, raises a justifiable question, but it is aimed in the wrong direction. It is true that a withdrawal of the object-libido into the ego is not directly pathogenic; it takes place, indeed, as we know, every time before we go to sleep, only to be reversed when we wake up. The amoeba withdraws its protrusions only to send them out again at the first opportunity. But it is quite a different thing when a particular, very energetic process forces a withdrawal of libido from objects. Here the libido that has become narcissistic cannot find its way back to objects, and this interference with the libido's mobility certainly becomes pathogenic. It seems that an accumulation of narcissistic libido beyond a certain amount is not tolerated. We may even imagine that it was for that very reason that object-cathexes originally came about, that the ego was obliged to send out its libido so as not to fall ill as a result of its being dammed up. If it lay within our plan to go more deeply into dementia praecox, I would show you that the process which detaches the libido from objects and cuts off its return to them is closely related to the process of repression and is to be looked at as its counterpart. But you would, first and foremost, find yourselves on familiar ground when you learnt that the determinants of this process are almost identical - so far as we know at present - with those of repression. The conflict seems to be the same and to be carried on between the same forces. If the outcome is so different from, for instance, that in hysteria, the reason can only depend on a difference in innate disposition. The weak spot in the libidinal development of these patients lies in a different phase; the determining fixation, which, as you will recollect, permits the irruption that leads to the formation of symptoms, lies elsewhere, probably in the stage of primitive narcissism to which dementia praecox returns in its final outcome. It is very remarkable that in the case of all the narcissistic neuroses we have to assume fixation points for the libido going back to far earlier phases of development than in hysteria or obsessional neurosis. As you heard, however, the concepts which we arrived at during our study of the transference neuroses are adequate in helping us to find our way about in the narcissistic neuroses which are so much more severe in practice. The conformities go very far; at bottom the field of phenomena is the same. And you can imagine how small a prospect anyone has of explaining these disorders (which belong within the sphere of psychiatry) who is not forearmed for his task with an analytic knowledge of the transference neuroses.

With this as a starting-point we go on to make our first important discovery. We learn that, when we try to understand neurotic disorders, by far the greater significance attaches to the sexual instincts; that in fact neuroses are the specific disorders, so to speak, of the sexual function; that in general whether or not a person develops a neurosis depends on the quantity of his libido, and on the possibility of satisfying it and of discharging it through satisfaction; that the form taken by the disease is determined by the way in which the individual passes through the course of development of his sexual function, or, as we put it, by the fixations his libido has undergone in the course of its development; and, further, that by a special, not very simple technique for influencing the mind we are able to throw light on the nature of some groups of neuroses and at the same time to do away with them. Our therapeutic efforts have their greatest success with a certain class of neuroses which proceed from a conflict between the ego-instincts and the sexual instincts. For in human beings it may happen that the demands of the sexual instincts, whose reach of course extends far beyond the individual, seem to the ego to constitute a danger which threatens its self-preservation or its self-esteem. The ego then assumes the defensive, denies the sexual instincts the satisfaction they desire and forces them into those by-paths of substitutive satisfaction which become manifest as nervous symptoms.
The Theory of Repression. - These theoretical considerations, taken together with the immediate impressions derived from analytic work, lead to a view of the neuroses which may be described in the roughest outline as follows. The neuroses are the expression of conflicts between the ego and such of the sexual impulses as seem to the ego incompatible with its integrity or with its ethical standards. Since these impulses are not ego-syntonic, the ego has repressed them: that is to say, it has withdrawn its interest from them and has shut them off from becoming conscious as well as from obtaining satisfaction by motor discharge. If in the course of analytic work one attempts to make these repressed impulses conscious, one becomes aware of the repressive forces in the form of resistance. But the achievement of repression fails particularly readily in the case of the sexual instincts. Their dammed-up libido finds other ways out of the unconscious: for it regresses to earlier phases of development and earlier attitudes towards objects, and, at weak points in the libido's development where there are infantile fixations, it breaks through into consciousness and obtains discharge. What results is a symptom and consequently in its essence a substitutive sexual satisfaction. Nevertheless the symptom cannot entirely escape from the repressive forces of the ego and must therefore submit to modifications and displacements exactly as happens with dreams - by means of which its characteristic of being a sexual satisfaction becomes unrecognizable. Consequently symptoms are in the nature of compromises between the repressed sexual instincts and the repressing ego-instincts; they represent a wish-fulfilment for both partners to the conflict simultaneously, but one which is incomplete for each of them. This is quite strictly true of the symptoms of hysteria, while in the symptoms of obsessional neurosis there is often a stronger emphasis upon the side of the repressing function owing to the erection of reaction-formations, which are assurances against sexual satisfaction.

In a far greater number of cases the neurosis is more autonomous and more independent of the interests of self-preservation and self-maintenance. In the conflict which creates the neurosis, what are at stake are either solely libidinal interests or libidinal interests in intimate connections with self-preservative ones. In all three instances the dynamics of the neurosis are the same. A dammed-up libido which cannot be satisfied in reality succeeds, with the help of a regression to old fixations, in finding discharge through the repressed unconscious. The sick man's ego, in so far as it can extract a 'gain from illness' out of this process, countenances the neurosis, although there can be no doubt of its injuriousness in its economic aspect.
The sexual function, as I found, is in existence from the very beginning of the individual's life, though at first it is attached to the other vital functions and does not become independent of them until later; it has to pass through a long and complicated process of development before it becomes what we are familiar with as the normal sexual life of the adult. It begins by manifesting itself in the activity of a whole number of component instincts. These are dependent upon erogenous zones in the body; some of them make their appearance in pairs of opposite impulses (such as sadism and masochism or the impulses to look and to be looked at); they operate independently of one another in a search for pleasure, and they find their object for the most part in the subject's own body. Thus at first the sexual function is non-centralized and predominantly auto-erotic. Later, syntheses begin to appear in it; a first stage of organization is reached under the dominance of the oral components, an anal-sadistic stage follows, and it is only after the third stage has at last been reached that the primacy of the genitals is established and that the sexual function begins to serve the ends of reproduction. In the course of this process of development a number of elements of the various component instincts turn out to be unserviceable for this last end and are therefore left on one side or turned to other uses, while others are diverted from their aims and carried over into the genital organization. I gave the name of libido to the energy of the sexual instincts and to that form of energy alone. I was next driven to suppose that the libido does not always pass through its prescribed course of development smoothly. As a result either of the excessive strength of certain of the components or of experiences involving premature satisfaction, fixations of the libido may occur at various points in the course of its development. If subsequently a repression takes place, the libido flows back to these points (a process described as regression), and it is from them that the energy breaks through in the form of a symptom. Later on it further became clear that the localization of the point of fixation is what determines the choice of neurosis, that is, the form in which the subsequent illness makes its appearance.

[1925d, 4211]

The sexual life of children is of course different from that of adults. The sexual function, from its beginnings to the definitive form in which it is so familiar to us, undergoes a complicated process of development. It grows together from numerous component instincts with different aims and passes through several phases of organization till at last it comes into the service of reproduction. Not all the component instincts are equally serviceable for the final outcome; they must be diverted, remodelled and in part suppressed. Such a far-reaching course of development is not always passed through without a flaw; inhibitions in development take place, partial fixations at early stages of development. If obstacles arise later on to the exercise of the sexual function, the sexual urge - the libido, as we call it - is apt to hark back to these earlier points of fixation. The study of the sexuality of children and its transformations up to maturity has also given us the key to an understanding of what are known as the sexual perversions, which people used always to describe with all the requisite indications of disgust but whose origin they were never able to explain. The whole topic is of uncommon interest, but for the purposes of our conversation there is not much sense in telling you more about it. To find one's way about in it one of course needs anatomical and physiological knowledge, all of which is unfortunately not to be acquired in medical schools. But a familiarity with the history of civilization and with mythology is equally indispensable.

[1926e, 4353]
For cultural reasons the most intense repression falls upon the sexual instincts; but it is precisely in connection with them that repression most easily miscarries, so that neurotic symptoms are found to be substitutive satisfactions of repressed sexuality. The belief that in man sexual life begins only at puberty is incorrect. On the contrary, signs of it can be detected from the beginning of extra-uterine existence; it reaches a first culminating point at or before the fifth year ('early period'), after which it is inhibited or interrupted ('latency period') until the age of puberty, which is the second climax of its development. This diphasic onset of sexual development seems to be distinctive of the genus Homo. All experiences during the first period of childhood are of the greatest importance to the individual, and in combination with his inherited sexual constitution form the dispositions for the subsequent development of character and disease. It is wrong to make sexuality coincide with 'genitality'. The sexual instincts pass through a complicated course of development, and it is only at the end of it that the 'primacy of the genital zones' is attained. Before this there are a number of 'pregenital' organizations of the libido - points at which it may become 'fixated' and to which, in the event of subsequent repression, it will return ('regression'). The infantile fixations of the libido are what determine the form of any later neurosis. Thus the neuroses are to be regarded as inhibitions in the development of the libido. There are no specific causes of nervous disorders; the question whether a conflict finds a healthy solution or leads to a neurotic inhibition of function depends upon quantitative considerations.

So far all this is trite repetition. And you must not suppose that the many things I have not mentioned this time no longer hold good. This repetition was necessary so that I might use it as the starting-point for a report on the advances in our knowledge. We can boast of having learnt much that is new, particularly about the early organizations of the libido, and of having obtained a clearer grasp of the significance of what is old; and I will give you at least a few examples to demonstrate this. Abraham showed in 1924 that two stages can be distinguished in the sadistic-anal phase. The earlier of these is dominated by the destructive trends of destroying and losing, the later one by trends friendly towards objects - those of keeping and possessing. It is in the middle of this phase, therefore, that consideration for the object makes its first appearance as a precursor of a later erotic cathexis. We are equally justified in making a similar subdivision in the first, oral phase. In the first sub-stage what is in question is only oral incorporation, there is no ambivalence at all in the relation to the object - the mother's breast. The second stage, characterized by the emergence of the biting activity, may be described as the 'oral-sadistic' one; it exhibits for the first time the phenomena of ambivalence, which become so much clearer afterwards, in the following sadistic-anal phase. The value of these new distinctions is to be seen especially if we look for the dispositional points in the development of the libido in the case of particular neuroses, such as obsessional neurosis or melancholia. You must here recall to mind what we have learnt about the connection between fixation of the libido, disposition and regression.

Our attitude to the phases of the organization of the libido has in general shifted a little. Whereas earlier we chiefly emphasized the way in which each of them passed away before the next, our attention now is directed to the facts that show us how much of each earlier phase persists alongside of and behind the later configurations and obtains a permanent representation in the libidinal economy and character of the subject. Still more significant have studies become which have taught us how frequently under pathological conditions regressions to earlier phases occur and that particular regressions are characteristic of particular forms of illness. But I cannot go into that here, it forms part of the specialized psychology of the neuroses.
This process is not always performed faultlessly. Inhibitions in its development manifest themselves as the many sorts of disturbance in sexual life. When this is so, we find fixations of the libido to conditions in earlier phases, whose urge, which is independent of the normal sexual aim, is described as *perversion*. One such developmental inhibition, for instance, is homosexuality when it is manifest. Analysis shows that in every case a homosexual object-tie was present and in most cases persisted in a *latent* condition. The situation is complicated by the fact that as a rule the processes necessary for bringing about a normal outcome are not completely present or absent, but *partially* present, so that the final result remains dependent on these *quantitative relations*. In these circumstances the genital organization is, it is true, attained, but it lacks those portions of the libido which have not advanced with the rest and have remained fixated to pregenital objects and aims. This weakening shows itself in a tendency, if there is an absence of genital satisfaction or if there are difficulties in the real external world, for the libido to hark back to its earlier pregenital cathexes (*regression*). [1940a [1938], 4966]
Once we have admitted the idea of a fusion of the two classes of instincts with each other, the possibility of a - more or less complete - 'defusion' of them forces itself upon us. The sadistic component of the sexual instinct would be a classical example of a serviceable instinctual fusion; and the sadism which has made itself independent as a perversion would be typical of a defusion, though not of one carried to extremes. From this point we obtain a view of a great domain of facts which has not before been considered in this light. We perceive that for purposes of discharge the instinct of destruction is habitually brought into the service of Eros; we suspect that the epileptic fit is a product and indication of an instinctual defusion; and we come to understand that instinctual defusion and the marked emergence of the death instinct call for particular consideration among the effects of some severe neuroses - for instance, the obsessional neuroses. Making a swift generalization, we might conjecture that the essence of a regression of libido (e. g. from the genital to the sadistic-anal phase) lies in a defusion of instincts, just as, conversely, the advance from the earlier phase to the definitive genital one would be conditioned by an accession of erotic components. The question also arises whether ordinary ambivalence, which is so often unusually strong in the constitutional disposition to neurosis, should not be regarded as the product of a defusion; ambivalence, however, is such a fundamental phenomenon that it more probably represents an instinctual fusion that has not been completed.

[1923b, 3975]

Let us again consider obsessional neurosis for a moment. The state of affairs is different here. The defusion of love into aggressiveness has not been effected by the work of the ego, but is the result of a regression which has come about in the id. But this process has extended beyond the id to the super-ego, which now increases its severity towards the innocent ego. It would seem, however, that in this case, no less than in that of melancholia, the ego, having gained control over the libido by means of identification, is punished for doing so by the super-ego through the instrumentality of the aggressiveness which was mixed with the libido.

[1923b, 3989]

As regards the metapsychological explanation of regression, I am inclined to find it in a 'defusion of instinct', in a detachment of the erotic components which, with the onset of the genital stage, had joined the destructive catexes belonging to the sadistic phase.

[1926d, 4273]
If the violation of a taboo can be made good by atonement or expiation, which involve the renunciation of some possession or some freedom, this proves that obedience to the taboo injunction meant in itself the renunciation of something desirable. Emancipation from one renunciation is made up for by the imposition of another one elsewhere. This leads us to conclude that atonement is a more fundamental factor than purification in the ceremonials of taboo.

[1912-1913, 2682]

I will now sum up the respects in which light has been thrown on the nature of taboo by comparing it with the obsessional prohibitions of neurotics. Taboo is a primaeval prohibition forcibly imposed (by some authority) from outside, and directed against the most powerful longings to which human beings are subject. The desire to violate it persists in their unconscious; those who obey the taboo have an ambivalent attitude to what the taboo prohibits. The magical power that is attributed to taboo is based on the capacity for arousing temptation; and it acts like a contagion because examples are contagious and because the prohibited desire in the unconscious shifts from one thing to another. The fact that the violation of a taboo can be atoned for by a renunciation shows that renunciation lies at the basis of obedience to taboo.

[1912-1913, 2682]

Another difficulty might actually be brought forward from psycho-analytic quarters. The earliest moral precepts and restrictions in primitive society have been explained by us as reactions to a deed which gave those who performed it the concept of 'crime'. They felt remorse for the deed and decided that it should never be repeated and that its performance should bring no advantage. This creative sense of guilt still persists among us. We find it operating in an asocial manner in neurotics, and producing new moral precepts and persistent restrictions, as an atonement for crimes that have been committed and as a precaution against the committing of new ones.¹ If, however, we inquire among these neurotics to discover what were the deeds which provoked these reactions, we shall be disappointed. We find no deeds, but only impulses and emotions, set upon evil ends but held back from their achievement. What lie behind the sense of guilt of neurotics are always psychical realities and never factual ones. What characterizes neurotics is that they prefer psychical to factual reality and react just as seriously to thoughts as normal people do to realities.

[1912-1913, 2798]

In another neurotic disorder, obsessional neurosis, the patients become the victims of distressing and apparently senseless ceremonials which take the form of the rhythmical repetition of the most trivial acts (such as washing or dressing) or of carrying out meaningless injunctions or of obeying mysterious prohibitions. It was nothing less than a triumph of psycho-analytic research when it succeeded in showing that all these obsessive acts, even the most insignificant and trivial of them, have a meaning, and that they are reflections, translated into indifferent terms, of conflicts in the patients' lives, of the struggle between temptations and moral restraints - reflections of the proscribed wish itself and of the punishment and atonement which that wish incurs. In another form of the same disorder the victim suffers from tormenting ideas (obsessions) which force themselves upon him and are accompanied by affects whose character and intensity are often only quite inadequately accounted for by the terms of the obsessive ideas themselves. Analytic investigation has shown in their case that the affects are entirely justified, since they correspond to self-reproaches which are based on something that is at least psychically real. But the ideas to which these affects are attached are not the original ones, but have found their way into their present position by a process of displacement - by being substituted for something that has been repressed. If these displacements can be reversed, the way is open to the discovery of the repressed ideas, and the relation between affect and idea is found to be perfectly appropriate.

[1913], 2810]
The second danger in a development by stages of this sort lies in the fact that the portions which have proceeded further may also easily return retrogressively to one of these earlier stages - what we describe as a regression. The trend will find itself led into a regression of this kind if the exercise of its function - that is, the attainment of its aim of satisfaction - is met, in its later or more highly developed form, by powerful external obstacles. It is plausible to suppose that fixation and regression are not independent of each other. The stronger the fixations on its path of development, the more readily will the function evade external difficulties by regressing to the fixations - the more incapable, therefore, does the developed function turn out to be of resisting external obstacles in its course. Consider that, if a people which is in movement has left strong detachments behind at the stopping-places on its migration, it is likely that the more advanced parties will be inclined to retreat to these stopping-places if they have been defeated or have come up against a superior enemy. But they will also be in the greater danger of being defeated the more of their number they have left behind on their migration.

[1916-1917, 3404]
The anxiety belonging to this emotional state, which underlies all phobias, is not derived from any memory; we may well wonder what the source of this powerful condition of the nervous system can be.

[1895c, 324]

A further question may be asked. Why, under such conditions of psychical insufficiency in mastering sexual excitation, does the nervous system find itself in the peculiar affective state of anxiety? An answer may be suggested as follows. The psyche finds itself in the affect of anxiety if it feels unable to deal by appropriate reaction with a task (a danger) approaching from the outside; it finds itself in the neurosis of anxiety if it notices that it is unable to even out the (sexual) excitation originating from within - that is to say, it behaves as though it were projecting that excitation outwards. The affect and its corresponding neurosis are firmly related to each other. The first is a reaction to an exogenous excitation, the second a reaction to the analogous endogenous one. The affect is a state which passes rapidly, the neurosis is a chronic one; because, while exogenous excitation operates with a single impact, the endogenous excitation operates as a constant force. In the neurosis, the nervous system is reacting against a source of excitation which is internal, whereas in the corresponding affect it is reacting against an analogous source of excitation which is external.

[1895b, 347]

'There is nothing new,' I shall be told, 'in the idea that some dreams are to be regarded as wish-fulfilments; the authorities noticed that fact long ago. Cf. Radestock (1879, 137 f.), Volkelt (1875, 110 f.), Purkinje (1846, 456), Tissié (1898, 70), Simon (1888, 42, on the hunger dreams of Baron Trenck while he was a prisoner), and a passage in Griesinger (1845, 89).¹ But to assert that there are no dreams other than wish-fulfilment dreams is only one more unjustifiable generalization, though fortunately one which it is easy to disprove. After all, plenty of dreams occur which contain the most distressing subject matter but never a sign of any wish-fulfilment. Eduard von Hartmann, the philosopher of pessimism, is probably furthest removed from the wish-fulfilment theory. In his Philosophie des Unbewussten (1890, 2, 344) he writes: "When it comes to dreams, we find all the annoyances of waking life carried over into the state of sleep; the only thing we do not find is what can to some extent reconcile an educated man to life - scientific and artistic enjoyment. . . ." But even less disgruntled observers have insisted that pain and unpleasure are more common in dreams than pleasure: for instance, Scholz (1893, 57), Volkelt (1875, 80), and others. Indeed two ladies, Florence Hallam and Sarah Weed (1896, 499), have actually given statistical expression, based on a study of their own dreams, to the preponderance of unpleasure in dreaming. They find that 57.2 per cent of dreams are "disagreeable" and only 28.6 percent positively "pleasant". And apart from these dreams, which carry over into sleep the various distressing emotions of life, there are anxiety-dreams, in which that most dreadful of all unpleasant feelings holds us in its grasp till we awaken. And the commonest victims of these anxiety-dreams are precisely children,² whose dreams you have described as undisguised wish-fulfilments.'

[1900a, 631]
Our discussion cannot be carried any further without examining the part played by the affects in these processes; but we can only do so imperfectly in the present connection. Let us assume, then, that the suppression of the Ucs. is necessary above all because, if the course of ideas in the Ucs. were left to itself, it would generate an affect which was originally of a pleasurable nature, but became unpleasurable after the process of 'repression' occurred. The purpose, and the result too, of suppression is to prevent this release of unpleasure. The suppression extends over the ideational content of the Ucs., since the release of unpleasure might start from that content. This presupposes a quite specific assumption as to the nature of the generation of affect. It is viewed as a motor or secretory function, the key to whose innervation lies in the ideas in the Ucs. Owing to the domination established by the Pcs. these ideas are, as it were, throttled, and inhibited from sending out impulses which would generate affect. If, therefore, the cathexis from the Pcs. ceases, the danger is that the unconscious excitations may release affect of a kind which (as a result of the repression which has already occurred) can only be experienced as unpleasure, as anxiety.

Hans's last words of comfort throw a light upon the situation and allow us to make some small corrections in his father's assertions. It is true that he was afraid of big animals because he was obliged to think of their big widdlers; but it cannot really be said that he was afraid of big widdlers themselves. Formerly the idea of them had been decidedly pleasurable to him, and he used to make every effort to get a glimpse of one. Since that time this enjoyment had been spoiled for him, owing to the general reversal of pleasure into unpleasure which had come over the whole of his sexual researches - in a way which has not yet been explained - and also owing to something which is clearer to us, namely, to certain experiences and reflections which had led to distressing conclusions. We may infer from his self-consolatory words ('my widdler will get bigger as I get bigger') that during his observations he had constantly been making comparisons, and that he had remained extremely dissatisfied with the size of his own widdler. Big animals reminded him of his defect, and were for that reason disagreeable to him. But since the whole train of thought was probably incapable of becoming clearly conscious, this distressing feeling, too, was transformed into anxiety, so that his present anxiety was erected both upon his former pleasure and his present unpleasure. When once a state of anxiety establishes itself, the anxiety swallows up all other feelings; with the progress of repression, and the more those ideas which are charged with affect and which have been conscious move down into the unconscious, all affects are capable of being changed into anxiety.

Lastly, I must warn you not to let yourselves be put out by the objection that the occurrence of anxiety-dreams contradicts our view of dreams as the fulfilments of wishes. Apart from the fact that these anxiety-dreams, like the rest, require interpretation before any judgement can be formed on them, it must be stated quite generally that the anxiety does not depend on the content of the dream in such a simple manner as one might imagine without having more knowledge and taking more account of the determinants of neurotic anxiety. Anxiety is one of the ego's reactions in repudiation of repressed wishes that have become powerful; and its occurrence in dreams as well is very easily explicable when the formation of the dream has been carried out with too much of an eye to the fulfilment of these repressed wishes.
I have no need to introduce anxiety itself to you. Every one of us has experienced that sensation, or, to speak more correctly, that affective state, at one time or other on our own account. But I think the question has never been seriously enough raised of why neurotics in particular suffer from anxiety so much more and so much more strongly than other people. Perhaps it has been regarded as something self-evident: the words ‘nervös’ and ‘ängstlich’ are commonly used interchangeably, as though they meant the same thing. But we have no right to do so: there are ‘ängstlich’ people who are otherwise not at all ‘nervös’ and, moreover, ‘nervös’ people who suffer from many symptoms, among which a tendency to ‘Angst’ is not included. [1916-1917, 3442]

However that may be, there is no question that the problem of anxiety is a nodal point at which the most various and important questions converge, a riddle whose solution would be found to throw a flood of light on our whole mental existence. I will not assert that I can give you this complete solution; but you will certainly expect psycho-analysis to approach this subject too in quite a different way from academic medicine. Interest there seems mainly to be centred on tracing the anatomical paths along which the state of anxiety is brought about. We are told that the medulla oblongata is stimulated, and the patient learns that he is suffering from a neurosis of the vagus nerve. The medulla oblongata is a very serious and lovely object. I remember quite clearly how much time and trouble I devoted to its study many years ago. To-day, however, I must remark that I know nothing that could be of less interest to me for the psychological understanding of anxiety than knowledge of the path of the nerves along which its excitations pass. [1916-1917, 3442]

It is possible at the start to work upon the subject of anxiety for quite a time without thinking at all of neurotic states. You will understand me at once when I describe this kind of anxiety as ‘realistic’ anxiety in contrast to ‘neurotic’ anxiety. Realistic anxiety strikes us as something very rational and intelligible. We may say of it that it is a reaction to the perception of an external danger - that is, of an injury which is expected and foreseen. It is connected with the flight reflex and it may be regarded as a manifestation of the self-preservative instinct. On what occasions anxiety appears - that is to say, in the face of what objects and in what situations - will of course depend to a large extent on the state of a person’s knowledge and on his sense of power vis-à-vis the external world. We can quite understand how a savage is afraid of a cannon and frightened by an eclipse of the sun, while a white man, who knows how to handle the instrument and can foretell the eclipse, remains without anxiety in these circumstances. On other occasions it is actually superior knowledge that promotes anxiety, because it makes an early recognition of the danger possible. Thus the savage will be terrified at a trail in the jungle that tells an uninformed person nothing, because it warns him of the proximity of a wild animal; and an experienced sailor will look with terror at a small cloud in the sky that seems trivial to a passenger, because it tells him of an approaching hurricane. [1916-1917, 3443]

On further consideration we must tell ourselves that our judgement that realistic anxiety is rational and expedient calls for drastic revision. For the only expedient behaviour when a danger threatens would be a cool estimate of one’s own strength in comparison with the magnitude of the threat and, on the basis of that, a decision as to whether flight or defence, or possibly even attack, offers the best prospect of a successful issue. But in this situation there is no place at all for anxiety; everything that happens would be achieved just as well and probably better if no anxiety were generated. And you can see, indeed, that if the anxiety is excessively great it proves in the highest degree inexpedient; it paralyses all action, including even flight. Usually the reaction to danger consists in a mixture of the affect of anxiety and defensive action. A terrified animal is afraid and flees; but the expedient part of this is the ‘flight’ and not the ‘being afraid’. [1916-1917, 3443]
Thus one feels tempted to assert that the generation of anxiety is never an expedient thing. It may perhaps help us to see more clearly if we dissect the situation of anxiety more carefully. The first thing about it is *preparedness* for the danger, which manifests itself in increased sensory attention and motor tension. This expectant preparedness can be unhesitatingly recognized as an advantage; indeed, its absence may be made responsible for serious consequences. From it there then proceeds on the one hand motor action - flight in the first instance and at a higher level active defence - and on the other hand what we feel as a state of anxiety. The more the generation of anxiety is limited to a mere abortive beginning - to a signal - the more will the preparedness for anxiety transform itself without disturbance into action and the more expedient will be the shape taken by the whole course of events. Accordingly, the *preparedness* for anxiety seems to me to be the expedient element in what we call anxiety, and the *generation* of anxiety the inexpedient one.

[1916-1917, 3444]

I shall avoid going more closely into the question of whether our linguistic usage means the same thing or something clearly different by ‘*Angst* [anxiety]’, ‘*Furcht* [fear]’ and ‘*Schreck* [fright]’. I will only say that I think ‘*Angst*’ relates to the state and disregards the object, while ‘*Furcht*’ draws attention precisely to the object. It seems that ‘*Schreck*’, on the other hand, does have a special sense; it lays emphasis, that is, on the effect produced by a danger which is not met by any preparedness for anxiety. We might say, therefore, that a person protects himself from fright by anxiety.

[1916-1917, 3444]

A certain ambiguity and indefiniteness in the use of the word ‘*Angst*’ will not have escaped you. By ‘anxiety’ we usually understand the subjective state into which we are put by perceiving the ‘generation of anxiety’ and we call this an affect. And what is an affect in the dynamic sense? It is in any case something highly composite. An affect includes in the first place particular motor innervations or discharges and secondly certain feelings; the latter are of two kinds - perceptions of the motor actions that have occurred and the direct feelings of pleasure and unpleasure which, as we say, give the affect its keynote. But I do not think that with this enumeration we have arrived at the essence of an affect. We seem to see deeper in the case of some affects and to recognize that the core which holds the combination we have described together is the repetition of some particular significant experience. This experience could only be a very early impression of a very general nature, placed in the prehistory not of the individual but of the species. To make myself more intelligible - an affective state would be constructed in the same way as a hysterical attack; and, like it, would be the precipitate of a reminiscence. A hysterical attack may thus be likened to a freshly constructed individual affect, and a normal affect to the expression of a general hysteria which has become a heritage.

[1916-1917, 3444]
Do not suppose that the things I have said to you here about affects are the recognized stock-in-trade of normal psychology. They are on the contrary views that have grown up on the soil of psycho-analysis and are native only to it. What you may gather about affects from psychology - the James-Lange theory, for example - is quite beyond understanding or discussion to us psycho-analysts. But we do not regard our knowledge about affects as very assured either; it is a first attempt at finding our bearings in this obscure region. I will proceed, however. We believe that in the case of the affect of anxiety we know what the early impression is which it repeats. We believe that it is in the act of birth that there comes about the combination of unpleasurable feelings, impulses of discharge and bodily sensations which has become the prototype of the effects of a mortal danger and has ever since been repeated by us as the state of anxiety. The immense increase of stimulation owing to the interruption of the renovation of the blood (internal respiration) was at the time the cause of the experience of anxiety; the first anxiety was thus a toxic one. The name 'Angst - 'augustiae', 'Enge'¹ - emphasizes the characteristic of restriction in breathing which was then present as a consequence of the real situation and is now almost invariably reinstated in the affect. We shall also recognize it as highly relevant that this first state of anxiety arose out of separation from the mother. It is, of course, our conviction that the disposition to repeat the first state of anxiety has been so thoroughly incorporated into the organism through a countless series of generations that a single individual cannot escape the affect of anxiety even if, like the legendary Macduff, he 'was from his mother's womb untimely ripped' and has therefore not himself experienced the act of birth. We cannot say what has become the prototype of the state of anxiety in the case of creatures other than mammals. And in the same way we do not know either what complex of feelings is in such creatures the equivalent to our anxiety.

[1916-1917, 3445]

If we now pass over to consider neurotic anxiety, what fresh forms and situations are manifested by anxiety? There is much to be described here. In the first place we find a general apprehensiveness, a kind of freely floating anxiety which is ready to attach itself to any idea that is in any way suitable, which influences judgement, selects what is to be expected, and lies in wait for any opportunity that will allow it to justify itself. We call this state 'expectant anxiety' or 'anxious expectation'. People who are tormented by this kind of anxiety always foresee the most frightful of all possibilities, interpret every chance event as a premonition of evil and exploit every uncertainty in a bad sense. A tendency to an expectation of evil of this sort is to be found as a character trait in many people whom one cannot otherwise regard as sick; one calls them over-anxious or pessimistic. A striking amount of expectant anxiety, however, forms a regular feature of a nervous disorder to which I have given the name of 'anxiety neurosis' and which I include among the 'actual' neuroses.

[1916-1917, 3446]
A second form of anxiety, in contrast to the ones I have just described, is bound psychically and attached particular objects or situations. This is the anxiety of the extremely multifarious and often very strange 'phobias'. Stanley Hall, the respected American psychologist, has recently taken the trouble to present us with a whole series of these phobias in all the magnificence of Greek names. This sounds like a list of the ten Plagues of Egypt, though their number goes far beyond ten. Listen to all the things that can become the object or content of a phobia: darkness, open air, open spaces, cats, spiders, caterpillars, snakes, mice, thunderstorms, sharp points, blood, enclosed spaces, crowds, solitude, crossing bridges, sea voyages and railway journeys, etc., etc. A first attempt at finding one's way about in this confusion suggests a division into three groups. Some of the dreaded objects and situations have something uncanny about them for normal people as well, some relation to danger; and such phobias, therefore, do not strike us as unintelligible, though their strength is greatly exaggerated. Thus most of us have a sense of repulsion if we meet with a snake. Snake phobia, we might say, is a universal human characteristic; and Darwin has described most impressively how he could not avoid feeling fear of a snake that struck at him, even though he knew that he was protected from it by a thick sheet of glass. We may refer to a second group the cases in which a relation to a danger is still present, though we are accustomed to minimize the danger and not to anticipate it. The majority of situation phobias belong to this group. We know that there is more chance of an accident when we are on a railway-journey than when we stay at home - the chance of a collision; we know, too, that a ship may go down, in which case there is a probability of being drowned; but we do not think about these dangers, and travel by rail and ship without anxiety. It cannot be disputed that we should fall into the river if the bridge collapsed at the moment we were crossing it; but that happens so exceedingly seldom that it does not arise as a danger. Solitude, too, has its dangers and in certain circumstances we avoid it; but there is no question of our not being able to tolerate it under any condition even for a moment. Much the same is true of crowds, of enclosed spaces, of thunderstorms and so on. What in general appears to us strange in these phobias of neurotics is not so much their content as their intensity. The anxiety of phobias is positively overwhelming. And sometimes we get an impression that what neurotics are afraid of are not at all the same things and situations which may in certain circumstances cause anxiety in us too and which they describe by the same names.

[1916-1917, 3446]

The two forms of anxiety that I have just described - the freely floating expectant anxiety and the sort which is bound to phobias - are independent of each other. One is not a higher stage, as it were, of the other; and they only appear simultaneously in exceptional cases and, so to speak, accidentally. The most powerful general apprehensiveness need not be expressed in phobias; people whose whole existence is restricted by agoraphobia may be entirely free from pessimistic expectant anxiety. Some phobias - for instance, agoraphobia and railway phobia - are demonstrably acquired at a fairly mature age, while others - such as fear of darkness, thunderstorms and animals - seem to have been present from the first. Those of the former kind have the significance of severe illnesses; the latter make their appearance rather as eccentricities or whims. If a person exhibits one of these latter, one may suspect as a rule that he will have other similar ones. I must add that we class all these phobias as anxiety hysteria; that is to say, we regard them as a disorder closely related to the familiar conversion hysteria.

[1916-1917, 3447]
The third of the forms of neurotic anxiety faces us with the puzzling fact that here the connection between anxiety and a threatening danger is completely lost to view. For instance, anxiety may appear in hysteria as an accompaniment to hysterical symptoms, or in some chance condition of excitement in which, it is true, we should expect some manifestation of affect but least of all one of anxiety; or it may make its appearance, divorced from any determinants and equally incomprehensible to us and to the patient, as an unrelated attack of anxiety. Here there is no sign whatever of any danger or of any cause that could be exaggerated into one. We next learn from these spontaneous attacks that the complex which we describe as a state of anxiety is capable of fragmentation. The total attack can be represented by a single, intensely developed symptom, by a tremor, a vertigo, by palpitation of the heart, or by dyspnoea; and the general feeling by which we recognize anxiety may be absent or have become indistinct. Yet these conditions, which we describe as 'anxiety-equivalents', have to be equated with anxiety in all clinical and aetiological respects. [1916-1917, 3448]

Two questions now arise. Can we relate neurotic anxiety, in which danger plays little or no part, to realistic anxiety, which is invariably a reaction to danger? And how are we to understand neurotic anxiety? We shall certainly be inclined in the first instance to hold fast to our expectation that where there is anxiety there must be something that one is afraid of. [1916-1917, 3448]

Of course, the sexual abstinence now so warmly recommended by doctors only has the same importance in generating anxiety states when the libido which is prevented from finding a satisfying discharge is correspondingly strong and has not been dealt with for the greater part by sublimation. Indeed, the decision on whether the outcome is to be illness or not always lies with quantitative factors. Even where what is in question is not illness but the form assumed by a person's character, it is easy to recognize that sexual restriction goes hand in hand with some kind of anxiousness and hesitancy, while intrepidity and impudent daring bring along with them a free indulgence of sexual needs. However much these relations are altered and complicated by a variety of cultural influences, it nevertheless remains true of the average of mankind that anxiety has a close connection with sexual limitation. [1916-1917, 3449]

We finally arrive at the connection we are in search of, if we take as our starting-point the opposition we have so often asserted between the ego and the libido. As we know, the generation of anxiety is the ego's reaction to danger and the signal for taking flight. If so, it seems plausible to suppose that in neurotic anxiety the ego is making a similar attempt at flight from the demand by its libido, that it is treating this internal danger as though it were an external one. This would therefore fulfil our expectation that where anxiety is shown there is something one is afraid of. But the analogy could be carried further. Just as the attempt at flight from an external danger is replaced by standing firm and the adoption of expedient measures of defence, so too the generation of neurotic anxiety gives place to the formation of symptoms, which results in the anxiety being bound. [1916-1917, 3452]

Let me sum up what we have learnt from our observations of the apprehensiveness of children. Infantile anxiety has very little to do with realistic anxiety, but, on the other hand, is closely related to the neurotic anxiety of adults. Like the latter, it is derived from unemployed libido and it replaces the missing love-object by an external object or by a situation. [1916-1917, 3454]
I have said that transformation into anxiety - it would be better to say discharge in the form of anxiety - is the immediate vicissitude of libido which is subjected to repression. I must add that that vicissitude is not the only or the definitive one. In the neuroses processes are in action which endeavour to bind this generating of anxiety and which even succeed in doing so in various ways. In phobias, for instance, two phases of the neurotic process can be clearly distinguished. The first is concerned with repression and the changing of libido into anxiety, which is then bound to an external danger. The second consists in the erection of all the precautions and guarantees by means of which any contact can be avoided with this danger, treated as it is like an external thing. Repression corresponds to an attempt at flight by the ego from libido which is felt as a danger. A phobia may be compared to an entrenchment against an external danger which now represents the dreaded libido. The weakness of the defensive system in phobias lies, of course, in the fact that the fortress which has been so greatly strengthened towards the outside remains assailable from within. A projection outwards of the danger of libido can never succeed thoroughly. For that reason, in other neuroses other systems of defence are in use against the possible generation of anxiety. That is a most interesting part of the psychology of the neuroses; but unluckily it would lead us too far and it presupposes a deeper specialized knowledge. I will only add one thing more. I have already spoken to you of the 'anticathexis' which is employed by the ego in the process of repression and which must be permanently maintained in order that the repression may have stability. This anticathexis has the task of carrying through the various forms of defence against the generating of anxiety after repression.

[1916-1917, 3456]

Let me once more, however, return for a moment to anxiety, to throw light on a last obscurity that we left there. I have said that there is something that does not tally with the relation (so thoroughly recognized apart from this) between anxiety and libido: the fact, namely, that realistic anxiety in face of a danger seems to be a manifestation of the self-preservative instinct - which, after all, can scarcely be disputed. How would it be, though, if what was responsible for the affect of anxiety was not the egoistic ego-instincts but the ego-libido? After all, the state of anxiety is in every instance inexpedient, and its inexpedience becomes obvious if it reaches a fairly high pitch. In such cases it interferes with action, whether flight or defence, which alone is expedient and alone serves the cause of self-preservation. If, therefore, we attribute the affective portion of realistic anxiety to ego-libido and the accompanying action to the self-preservation instinct, we shall have got rid of the theoretical difficulty. After all, you do not seriously believe that one runs away because one feels anxiety? No. One feels anxiety and one runs away for a common motive, which is roused by the perception of danger. People who have been through a great mortal danger tell us that they were not at all afraid but merely acted - for instance, that they aimed their rifle at the wild beast - and that is unquestionably what was most expedient.

[1916-1917, 3474]

It only became possible to extend the libido theory to the narcissistic neuroses after the concept of a 'narcissistic libido' had been put forward and applied - a concept, that is, of an amount of sexual energy attached to the ego itself and finding satisfaction in the ego just as satisfaction is usually found only in objects. This entirely legitimate development of the concept of sexuality promises to accomplish as much for the severer neuroses and for the psychoses as can be expected of a theory which is feeling its way forwards on an empirical basis. The traumatic neuroses of peace will also fit into the scheme as soon as a successful outcome has been reached of our investigations into the relations which undoubtedly exist between fright, anxiety and narcissistic libido.

[1919d, 3667]
At this point I will put forward two considerations which, I think, contain the gist of this short study. In the first place, if psycho-analytic theory is correct in maintaining that every affect belonging to an emotional impulse, whatever its kind, is transformed, if it is repressed, into anxiety, then among instances of frightening things there must be one class in which the frightening element can be shown to be something repressed which recurs. This class of frightening things would then constitute the uncanny; and it must be a matter of indifference whether what is uncanny was itself originally frightening or whether it carried some other affect. In the second place, if this is indeed the secret nature of the uncanny, we can understand why linguistic usage has extended *das Heimliche* into its opposite, *das Unheimliche* (p. 3680); for this uncanny is in reality nothing new or alien, but something which is familiar and old-established in the mind and which has become alienated from it only through the process of repression. This reference to the factor of repression enables us, furthermore, to understand Schelling's definition of the uncanny as something which ought to have remained hidden but has come to light.

[1919h, 3691]

Concerning the factors of silence, solitude and darkness, we can only say that they are actually elements in the production of the infantile anxiety from which the majority of human beings have never become quite free. This problem has been discussed from a psycho-analytic point of view elsewhere.

[1919h, 3700]

A condition has long been known and described which occurs after severe mechanical concussions, railway disasters and other accidents involving a risk to life; it has been given the name of 'traumatic neurosis'. The terrible war which has just ended gave rise to a great number of illnesses of this kind, but it at least put an end to the temptation to attribute the cause of the disorder to organic lesions of the nervous system brought about by mechanical force.¹ The symptomatic picture presented by traumatic neurosis approaches that of hysteria in the wealth of its similar motor symptoms, but surpasses it as a rule in its strongly marked signs of subjective ailment (in which it resembles hypochondria or melancholia) as well as in the evidence it gives of a far more comprehensive general enfeeblement and disturbance of the mental capacities. No complete explanation has yet been reached either of war neuroses or of the traumatic neuroses of peace. In the case of the war neuroses, the fact that the same symptoms sometimes came about without the intervention of any gross mechanical force seemed at once enlightening and bewildering. In the case of the ordinary traumatic neuroses two characteristics emerge prominently: first, that the chief weight in their causation seems to rest upon the factor of surprise, of fright; and secondly, that a wound or injury inflicted simultaneously works as a rule against the development of a neurosis. 'Fright', 'fear' and 'anxiety' are improperly used as synonymous expressions; they are in fact capable of clear distinction in their relation to danger. 'Anxiety' describes a particular state of expecting the danger or preparing for it, even though it may be an unknown one. 'Fear' requires a definite object of which to be afraid. 'Fright', however, is the name we give to the state a person gets into when he has run into danger without being prepared for it; it emphasizes the factor of surprise. I do not believe anxiety itself can produce a traumatic neurosis. There is something about anxiety that protects its subject against fright and so against fright-neuroses. We shall return to this point later.¹

[1920g, 3718]
From the other point of view, however, we see this same ego as a poor creature owing service to three masters and consequently menaced by three dangers: from the external world, from the libido of the id, and from the severity of the super-ego. Three kinds of anxiety correspond to these three dangers, since anxiety is the expression of a retreat from danger. As a frontier creature, the ego tries to mediate between the world and the id, to make the id pliable to the world and, by means of its muscular activity, to make the world fall in with the wishes of the id. In point of fact it behaves like the physician during an analytic treatment: it offers itself, with the attention it pays to the real world, as a libidinal object to the id, and aims at attaching the id's libido to itself. It is not only a helper to the id; it is also a submissive slave who courts his master's love. Whenever possible, it tries to remain on good terms with the id; it clothes the id's Ucs. commands with its Pcs. rationalizations; it pretends that the id is showing obedience to the admonitions of reality, even when in fact it is remaining obstinate and unyielding; it disguises the id's conflicts with reality and, if possible, its conflicts with the super-ego too. In its position midway between the id and reality, it only too often yields to the temptation to become sycophantic, opportunist and lying, like a politician who sees the truth but wants to keep his place in popular favour.

[1923b, 3990]

The ego is the actual seat of anxiety. Threatened by dangers from three directions, it develops the flight-reflex by withdrawing its own cathexis from the menacing perception or from the similarly regarded process in the id, and emitting it as anxiety. This primitive reaction is later replaced by the carrying-out of protective cathexes (the mechanism of the phobias). What it is that the ego fears from the external and from the libidinal danger cannot be specified; we know that the fear is of being overwhelmed or annihilated, but it cannot be grasped analytically. The ego is simply obeying the warning of the pleasure principle. On the other hand, we can tell what is hidden behind the ego's dread of the super-ego, the fear of conscience. The superior being, which turned into the ego ideal, once threatened castration, and this dread of castration is probably the nucleus round which the subsequent fear of conscience has gathered; it is this dread that persists as the fear of conscience.

[1923b, 3991]

The secondary defensive struggle against the symptom takes many shapes. It is fought out on different fields and makes use of a variety of methods. We shall not be able to say much about it until we have made an enquiry into the various different instances of symptom-formation. In doing this we shall have an opportunity of going into the problem of anxiety - a problem which has long been looming in the background. The wisest plan will be to start from the symptoms produced by the hysterical neurosis; for we are not as yet in a position to consider the conditions in which the symptoms of obsessional neurosis, paranoia and other neuroses are formed.

[1926d, 4260]

Anxiety, then, is in the first place something that is felt. We call it an affective state, although we are also ignorant of what an affect is. As a feeling, anxiety has a very marked character of unpleasure. But that is not the whole of its quality. Not every unpleasure can be called anxiety, for there are other feelings, such as tension, pain or mourning, which have the character of unpleasure. Thus anxiety must have other distinctive features besides this quality of unpleasure. Can we succeed in understanding the differences between these various unpleasurable affects?

[1926d, 4288]
We can at any rate note one or two things about the feeling of anxiety. Its unpleasurable character seems to have a note of its own - something not very obvious, whose presence is difficult to prove yet which is in all likelihood there. But besides having this special feature which is difficult to isolate, we notice that anxiety is accompanied by fairly definite physical sensations which can be referred to particular organs of the body. As we are not concerned here with the physiology of anxiety, we shall content ourselves with mentioning a few representatives of these sensations. The clearest and most frequent ones are those connected with the respiratory organs and with the heart. They provide evidence that motor innervations - that is, processes of discharge - play a part in the general phenomenon of anxiety.

Analysis of anxiety-states therefore reveals the existence of (1) a specific character of unpleasure, (2) acts of discharge and (3) perceptions of those acts. The two last points indicate at once a difference between states of anxiety and other similar states, like those of mourning and pain. The latter do not have any motor manifestation; or if they have, the manifestation is not an integral part of the whole state but is distinct from it as being a result of it or a reaction to it. Anxiety, then, is a special state of unpleasure with acts of discharge along particular paths. In accordance with our general views we should be inclined to think that anxiety is based upon an increase of excitation which on the one hand produces the character of unpleasure and on the other finds relief through the acts of discharge already mentioned. But a purely physiological account of this sort will scarcely satisfy us. We are tempted to assume the presence of a historical factor which binds the sensations of anxiety and its innervations firmly together. We assume, in other words, that an anxiety-state is the reproduction of some experience which contained the necessary conditions for such an increase of excitation and a discharge along particular paths, and that from this circumstance the unpleasure of anxiety receives its specific character. In man, birth provides a prototypic experience of this kind, and we are therefore inclined to regard anxiety-states as a reproduction of the trauma of birth.

This does not imply that anxiety occupies an exceptional position among the affective states. In my opinion the other affects are also reproductions of very early, perhaps even pre-individual, experiences of vital importance; and I should be inclined to regard them as universal, typical and innate hysterical attacks, as compared to the recently and individually acquired attacks which occur in hysterical neuroses and whose origin and significance as mnemonic symbols have been revealed by analysis. It would be very desirable, of course, to be able to demonstrate the truth of this view in a number of such affects - a thing which is still very far from being the case.

The view that anxiety goes back to the event of birth raises immediate objections which have to be met. It may be argued that anxiety is a reaction which, in all probability, is common to every organism, certainly every organism of a higher order, whereas birth is only experienced by the mammals; and it is doubtful whether in all of them, even, birth has the significance of a trauma. Therefore there can be anxiety without the prototype of birth. But this objection takes us beyond the barrier that divides psychology from biology. It may be that, precisely because anxiety has an indispensable biological function to fulfil as a reaction to a state of danger, it is differently contrived in different organisms. We do not know, besides, whether anxiety involves the same sensations and innervations in organisms far removed from man as it does in man himself. Thus there is no good argument here against the view that, in man, anxiety is modelled upon the process of birth.
If the structure and origin of anxiety are as described, the next question is: what is the function of anxiety and on what occasions is it reproduced? The answer seems to be obvious and convincing: anxiety arose originally as a reaction to a state of danger and it is reproduced whenever a state of that kind recurs.
[1926d, 4290]

This answer, however, raises further considerations. The innervations involved in the original state of anxiety probably had a meaning and purpose, in just the same way as the muscular movements which accompany a first hysterical attack. In order to understand a hysterical attack, all one has to do is to look for the situation in which the movements in question formed part of an appropriate and expedient action. Thus at birth it is probable that the innervation, in being directed to the respiratory organs, is preparing the way for the activity of the lungs, and, in accelerating the heartbeat, is helping to keep the blood free from toxic substances. Naturally, when the anxiety-state is reproduced later as an affect it will be lacking in any such expediency, just as are the repetitions of a hysterical attack. When the individual is placed in a new situation of danger it may well be quite inexpedient for him to respond with an anxiety-state (which is a reaction to an earlier danger) instead of initiating a reaction appropriate to the current danger. But his behaviour may become expedient once more if the danger-situation is recognized as it approaches and is signalled by an outbreak of anxiety. In that case he can at once get rid of his anxiety by having recourse to more suitable measures. Thus we see that there are two ways in which anxiety can emerge: in an inexpedient way, when a new situation of danger has occurred, or in an expedient way in order to give a signal and prevent such a situation from occurring.
[1926d, 4290]

This new view of things calls for an examination of another assertion of mine - namely, that the ego is the actual seat of anxiety. I think this proposition still holds good. There is no reason to assign any manifestation of anxiety to the super-ego; while the expression 'anxiety of the id' would stand in need of correction, though rather as to its form than its substance. Anxiety is an affective state and as such can, of course, only be felt by the ego. The id cannot have anxiety as the ego can; for it is not an organization and cannot make a judgement about situations of danger. On the other hand it very often happens that processes take place or begin to take place in the id which cause the ego to produce anxiety. Indeed, it is probable that the earliest repressions as well as most of the later ones are motivated by an ego-anxiety of this sort in regard to particular processes in the id. Here again we are rightly distinguishing between two cases: the case in which something occurs in the id which activates one of the danger-situations for the ego and induces the latter to give the anxiety-signal for inhibition to take place, and the case in which a situation analogous to the trauma of birth is established in the id and an automatic reaction of anxiety ensues. The two cases may be brought closer together if it is pointed out that the second case corresponds to the earliest and original danger-situation, while the first case corresponds to any one of the later determinants of anxiety that have been derived from it; or, as applied to the disorders which we in fact come across, that the second case is operative in the aetiology of the 'actual' neuroses, while the first remains typical for that of the psychoneuroses.
[1926d, 4295]
In describing the evolution of the various danger-situations from their prototype, the act of birth, I have had no intention of asserting that every later determinant of anxiety completely invalidates the preceding one. It is true that, as the development of the ego goes on, the earlier danger-situations tend to lose their force and to be set aside, so that we might say that each period of the individual’s life has its appropriate determinant of anxiety. Thus the danger of psychical helplessness is appropriate to the period of life when his ego is immature; the danger of loss of object, to early childhood when he is still dependent on others; the danger of castration, to the phallic phase; and the fear of his super-ego, to the latency period. Nevertheless, all these danger-situations and determinants of anxiety can persist side by side and cause the ego to react to them with anxiety at a period later than the appropriate one; or, again, several of them can come into operation at the same time. It is possible, moreover, that there is a fairly close relationship between the danger-situation that is operative and the form taken by the ensuing neurosis.¹

But this last point raises a fresh problem. Instead of the affect of anxiety let us take, for a moment, another affect - that of pain, for instance. It seems quite normal that at four years of age a girl should weep painfully if her doll is broken; or at six, if her governess reproves her; or at sixteen, if she is slighted by her young man; or at twenty-five, perhaps, if a child of her own dies. Each of these determinants of pain has its own time and each passes away when that time is over. Only the final and definitive determinants remain throughout life. We should think it strange if this same girl, after she had grown to be a wife and mother, were to cry over some worthless trinket that had been damaged. Yet that is how the neurotic behaves. Although all the agencies for mastering stimuli have long ago been developed within wide limits in his mental apparatus, and although he is sufficiently grown up to satisfy most of his needs for himself and has long ago learnt that castration is no longer practised as a punishment, he nevertheless behaves as though the old danger-situations still existed, and keeps hold of all the earlier determinants of anxiety.

[1926d, 4297]

[1926d, 4302]
Why this should be so calls for a rather long reply. First of all, we must sift the facts. In a great number of cases the old determinants of anxiety do really lapse, after having produced neurotic reactions. The phobias of very young children, fears of being alone or in the dark or with strangers - phobias which can almost be called normal - usually pass off later on; the child 'grows out of them', as we say about some other disturbances of childhood. Animal phobias, which are of such frequent occurrence, undergo the same fate and many conversion hysterias of early years find no continuation in later life. Ceremonial actions appear extremely often in the latency period, but only a very small percentage of them develop later into a full obsessional neurosis. In general, so far as we can tell from our observations of town children belonging to the white races and living according to fairly high cultural standards, the neuroses of childhood are in the nature of regular episodes in a child's development, although too little attention is still being paid to them. Signs of childhood neuroses can be detected in all adult neurotics without exception; but by no means all children who show those signs become neurotic in later life. It must be, therefore, that certain determinants of anxiety are relinquished and certain danger-situations lose their significance as the individual becomes more mature. Moreover, some of these danger-situations manage to survive into later times by modifying their determinants of anxiety so as to bring them up to date. Thus, for instance, a man may retain his fear of castration in the guise of a syphilidophobia, after he has come to know that it is no longer customary to castrate people for indulging their sexual lusts, but that, on the other hand, severe diseases may overtake anyone who thus gives way to his instincts. Other determinants of anxiety, such as fear of the super-ego, are destined not to disappear at all but to accompany people throughout their lives. In that case the neurotic will differ from the normal person in that his reactions to the dangers in question will be unduly strong. Finally, being grown-up affords no absolute protection against a return of the original traumatic anxiety-situation. Each individual has in all probability a limit beyond which his mental apparatus fails in its function of mastering the quantities of excitation which require to be disposed of.

[1926d, 4302]

These minor rectifications cannot in any way alter the fact which is here under discussion, that a great many people remain infantile in their behaviour in regard to danger and do not overcome determinants of anxiety which have grown out of date. To deny this would be to deny the existence of neurosis, for it is precisely such people whom we call neurotics. But how is this possible? Why are not all neuroses episodes in the development of the individual which come to a close when the next phase is reached? Whence comes the element of persistence in these reactions to danger? Why does the affect of anxiety alone seem to enjoy the advantage over all other affects of evoking reactions which are distinguished from the rest in being abnormal and which, through their inexpediency, run counter to the movement of life? In other words, we have once more come unawares upon the riddle which has so often confronted us: whence does neurosis come - what is its ultimate, its own peculiar raison d'être? After tens of years of psycho-analytic labours, we are as much in the dark about this problem as we were at the start. [1926d, 4303]
Anxiety is the reaction to danger. One cannot, after all, help suspecting that the reason why the affect of anxiety occupies a unique position in the economy of the mind has something to do with the essential nature of danger. Yet dangers are the common lot of humanity; they are the same for everyone. What we need and cannot lay our finger on is some factor which will explain why some people are able to subject the affect of anxiety, in spite of its peculiar quality, to the normal workings of the mind, or which decides who is doomed to come to grief over that task. Two attempts to find a factor of this kind have been made; and it is natural that such efforts should meet with a sympathetic reception, since they promise help to meet a tormenting need. The two attempts in question are mutually complementary; they approach the problem at opposite ends. The first was made by Alfred Adler more than ten years ago. His contention, reduced to its essence, was that the people who came to grief over the task set them by danger were those who were too greatly impeded by some organic inferiority. If it were true that *simp lex sigillum veri*, we should welcome such a solution as a deliverance. But on the contrary, our critical studies of the last ten years have effectively demonstrated the total inadequacy of such an explanation - an explanation, moreover, which sets aside the whole wealth of material that has been discovered by psycho-analysis. [1926d, 4304]

Rank's contention - which was originally my own -, that the affect of anxiety is a consequence of the event of birth and a repetition of the situation then experienced, obliged me to review the problem of anxiety once more. But I could make no headway with his idea that birth is a trauma, states of anxiety a reaction of discharge to it and all subsequent affects of anxiety an attempt to 'abreact' it more and more completely. I was obliged to go back from the anxiety reaction to the situation of danger that lay behind it. The introduction of this element opened up new aspects of the question. Birth was seen to be the prototype of all later situations of danger which overtook the individual under the new conditions arising from a changed mode of life and a growing mental development. On the other hand its own significance was reduced to this prototypic relationship to danger. The anxiety felt at birth became the prototype of an affective state which had to undergo the same vicissitudes as the other affects. Either the state of anxiety reproduced itself automatically in situations analogous to the original situation and was thus an inexpedient form of reaction instead of an expedient one as it had been in the first situation of danger; or the ego acquired power over this affect, reproduced it on its own initiative, and employed it as a warning of danger and as a means of setting the pleasure-unpleasure mechanism in motion. We thus gave the biological aspect of the anxiety affect its due importance by recognizing anxiety as the general reaction to situations of danger; while we endorsed the part played by the ego as the seat of anxiety by allocating to it the function of producing the anxiety affect according to its needs. Thus we attributed two modes of origin to anxiety in later life. One was involuntary, automatic and always justified on economic grounds, and arose whenever a danger situation analogous to birth had established itself. The other was produced by the ego as soon as a situation of this kind merely threatened to occur, in order to call for its avoidance. In the second case the ego subjects itself to anxiety as a sort of inoculation, submitting to a slight attack of the illness in order to escape its full strength. It vividly imagines the danger situation, as it were, with the unmistakable purpose of restricting that distressing experience to a mere indication, a signal. We have already seen in detail how the various situations of danger arise one after the other, retaining at the same time a genetic connection. [1926d, 4315]

We shall perhaps be able to proceed a little further in our understanding of anxiety when we turn to the problem of the relation between neurotic anxiety and realistic anxiety. [1926d, 4315]
The affect of anxiety exhibits one or two features the study of which promises to throw further light on the subject. Anxiety has an unmistakable relation to expectation: it is anxiety about something. It has a quality of indefiniteness and lack of object. In precise speech we use the word 'fear' rather than 'anxiety' if it has found an object. Moreover, in addition to its relation to danger, anxiety has a relation to neurosis which we have long been trying to elucidate. The question arises: why are not all reactions of anxiety neurotic - why do we accept so many of them as normal? And finally the problem of the difference between realistic anxiety and neurotic anxiety awaits a thorough examination.

[1926d, 4317]

To begin with the last problem. The advance we have made is that we have gone behind reactions of anxiety to situations of danger. If we do the same thing with realistic anxiety we shall have no difficulty in solving the question. Real danger is a danger that is known, and realistic anxiety is anxiety about a known danger of this sort. Neurotic anxiety is anxiety about an unknown danger. Neurotic danger is thus a danger that has still to be discovered. Analysis has shown that it is an instinctual danger. By bringing this danger which is not known to the ego into consciousness, the analyst makes neurotic anxiety no different from realistic anxiety, so that it can be dealt with in the same way.

[1926d, 4317]

There are two reactions to real danger. One is an affective reaction, an outbreak of anxiety. The other is a protective action. The same will presumably be true of instinctual danger. We know how the two reactions can co-operate in an expedient way, the one giving the signal for the other to appear. But we also know that they can behave in an inexpedient way: paralysis from anxiety may set in, and the one reaction spread at the cost of the other.

[1926d, 4317]

In some cases the characteristics of realistic anxiety and neurotic anxiety are mingled. The danger is known and real but the anxiety in regard to it is over-great, greater than seems proper to us. It is this surplus of anxiety which betrays the presence of a neurotic element. Such cases, however, introduce no new principle; for analysis shows that to the known real danger an unknown instinctual one is attached.

[1926d, 4317]

We can find out still more about this if, not content with tracing anxiety back to danger, we go on to enquire what the essence and meaning of a danger-situation is. Clearly, it consists in the subject's estimation of his own strength compared to the magnitude of the danger and in his admission of helplessness in the face of it - physical helplessness if the danger is real and psychical helplessness if it is instinctual. In doing this he will be guided by the actual experiences he has had. (Whether he is wrong in his estimation or not is immaterial for the outcome.) Let us call a situation of helplessness of this kind that has been actually experienced a traumatic situation. We shall then have good grounds for distinguishing a traumatic situation from a danger-situation.

[1926d, 4318]
The individual will have made an important advance in his capacity for self-preservation if he can foresee and expect a traumatic situation of this kind which entails helplessness, instead of simply waiting for it to happen. Let us call a situation which contains the determinant for such an expectation a danger-situation. It is in this situation that the signal of anxiety is given. The signal announces: 'I am expecting a situation of helplessness to set in', or: 'The present situation reminds me of one of the traumatic experiences I have had before. Therefore I will anticipate the trauma and behave as though it had already come, while there is yet time to turn it aside.' Anxiety is therefore on the one hand an expectation of a trauma, and on the other a repetition of it in a mitigated form. Thus the two features of anxiety which we have noted have a different origin. Its connection with expectation belongs to the danger-situation, whereas its indefiniteness and lack of object belong to the traumatic situation of helplessness - the situation which is anticipated in the danger-situation.

Taking this sequence, anxiety - danger - helplessness (trauma), we can now summarize what has been said. A danger-situation is a recognized, remembered, expected situation of helplessness. Anxiety is the original reaction to helplessness in the trauma and is reproduced later on in the danger-situation as a signal for help. The ego, which experienced the trauma passively, now repeats it actively in a weakened version, in the hope of being able itself to direct its course. It is certain that children behave in this fashion towards every distressing impression they receive, by reproducing it in their play. In thus changing from passivity to activity they attempt to master their experiences psychically. If this is what is meant by 'abreacting a trauma' we can no longer have anything to urge against the phrase. But what is of decisive importance is the first displacement of the anxiety-reaction from its origin in the situation of helplessness to an expectation of that situation - that is, to the danger-situation. After that come the later displacements, from the danger to the determinant of the danger - loss of the object and the modifications of that loss with which we are already acquainted.

So far we have had no occasion to regard realistic anxiety in any different light from neurotic anxiety. We know what the distinction is. A real danger is a danger which threatens a person from an external object, and a neurotic danger is one which threatens him from an instinctual demand. In so far as the instinctual demand is something real, his neurotic anxiety, too, can be admitted to have a realistic basis. We have seen that the reason why there seems to be a specially close connection between anxiety and neurosis is that the ego defends itself against an instinctual danger with the help of the anxiety reaction just as it does against an external real danger, but that this line of defensive activity eventuates in a neurosis owing to an imperfection of the mental apparatus. We have also come to the conclusion that an instinctual demand often only becomes an (internal) danger because its satisfaction would bring on an external danger - that is, because the internal danger represents an external one.

¹ It may quite often happen that although a danger-situation is correctly estimated in itself, a certain amount of instinctual anxiety is added to the realistic anxiety. In that case the instinctual demand before whose satisfaction the ego recoils is a masochistic one: the instinct of destruction directed against the subject himself. Perhaps an addition of this kind explains cases in which reactions of anxiety are exaggerated, inexpedient or paralysing. Phobias of heights (windows, towers, precipices and so on) may have some such origin. Their hidden feminine significance is closely connected with masochism.
So little is known about the psychology of emotional processes that the tentative remarks I am about to make on the subject may claim a very lenient judgement. The problem before us arises out of the conclusion we have reached that anxiety comes to be a reaction to the danger of a loss of an object. Now we already know one reaction to the loss of an object, and that is mourning. The question therefore is, when does that loss lead to anxiety and when to mourning? In discussing the subject of mourning on a previous occasion I found that there was one feature about it which remained quite unexplained. This was its peculiar painfulness.¹ And yet it seems self-evident that separation from an object should be painful. Thus the problem becomes more complicated: when does separation from an object produce anxiety, when does it produce mourning and when does it produce, it may be, only pain?

Our starting-point will again be the one situation which we believe we understand - the situation of the infant when it is presented with a stranger instead of its mother. It will exhibit the anxiety which we have attributed to the danger of loss of object. But its anxiety is undoubtedly more complicated than this and merits a more thorough discussion. That it does have anxiety there can be no doubt; but the expression of its face and its reaction of crying indicate that it is feeling pain as well. Certain things seem to be joined together in it which will later on be separated out. It cannot as yet distinguish between temporary absence and permanent loss. As soon as it loses sight of its mother it behaves as if it were never going to see her again; and repeated consoling experiences to the contrary are necessary before it learns that her disappearance is usually followed by her re-appearance. Its mother encourages this piece of knowledge which is so vital to it by playing the familiar game of hiding her face from it with her hands and then, to its joy, uncovering it again. In these circumstances it can, as it were, feel longing unaccompanied by despair.

In consequence of the infant's misunderstanding of the facts, the situation of missing its mother is not a danger-situation but a traumatic one. Or, to put it more correctly, it is a traumatic situation if the infant happens at the time to be feeling a need which its mother should be the one to satisfy. It turns into a danger-situation if this need is not present at the moment. Thus, the first determinant of anxiety, which the ego itself introduces, is loss of perception of the object (which is equated with loss of the object itself). There is as yet no question of loss of love. Later on, experience teaches the child that the object can be present but angry with it; and then loss of love from the object becomes a new and much more enduring danger and determinant of anxiety.

The traumatic situation of missing the mother differs in one important respect from the traumatic situation of birth. At birth no object existed and so no object could be missed. Anxiety was the only reaction that occurred. Since then repeated situations of satisfaction have created an object out of the mother; and this object, whenever the infant feels a need, receives an intense cathexis which might be described as a 'longing' one. It is to this new aspect of things that the reaction of pain is referable. Pain is thus the actual reaction to loss of object, while anxiety is the reaction to the danger which that loss entails and, by a further displacement, a reaction to the danger of the loss of object itself.
I devoted a lecture (the twenty-fifth) to anxiety in my previous series; and I must briefly recapitulate what I said in it. We described anxiety as an affective state - that is to say, a combination of certain feelings in the pleasure-unpleasure series with the corresponding innervations of discharge and a perception of them, but probably also the precipitate of a particular important event, incorporated by inheritance - something that may thus be likened to an individually acquired hysterical attack. The event which we look upon as having left behind it an affective trace of this sort is the process of birth, at the time of which the effects upon the heart's action and upon respiration characteristic of anxiety were expedient ones. The very first anxiety would thus have been a toxic one. We then started off from a distinction between realistic anxiety and neurotic anxiety, of which the former was a reaction, which seemed intelligible to us, to a danger - that is, to an expected injury from outside - while the latter was completely enigmatic, and appeared to be pointless.

[1933a, 4688]

In an analysis of realistic anxiety we brought it down to the state of increased sensory attention and motor tension which we describe as 'preparedness for anxiety'. It is out of this that the anxiety reaction develops. Here two outcomes are possible. Either the generation of anxiety - the repetition of the old traumatic experience - is limited to a signal, in which case the remainder of the reaction can adapt itself to the new situation of danger and can proceed to flight or defence; or the old situation can retain the upper hand and the total reaction may consist in no more than a generation of anxiety, in which case the affective state becomes paralysing and will be inexpedient for present purposes.

[1933a, 4689]

We then turned to neurotic anxiety and pointed out that we observe it under three conditions. We find it first as a freely floating, general apprehensiveness, ready to attach itself temporarily, in the form of what is known as 'expectant anxiety', to any possibility that may freshly arise - as happens, for instance, in a typical anxiety neurosis. Secondly, we find it firmly attached to certain ideas in the so-called 'phobias', in which it is still possible to recognize a relation to external danger but in which we must judge the fear exaggerated out of all proportion. Thirdly and lastly, we find anxiety in hysteria and other forms of severe neurosis, where it either accompanies symptoms or emerges independently as an attack or more persistent state, but always without any visible basis in an external danger. We then asked ourselves two questions: 'What are people afraid of in neurotic anxiety?' and 'How are we to bring it into relation with realistic anxiety felt in the face of external dangers?'

[1933a, 4689]

At the conclusion of my earlier lecture on anxiety I myself expressed the opinion that, although these various findings of our enquiry were not mutually contradictory, somehow they did not fit in with one another. Anxiety, it seems, in so far as it is an affective state, is the reproduction of an old event which brought a threat of danger; anxiety serves the purposes of self-preservation and is a signal of a new danger; it arises from libido that has in some way become unemployable and it also arises during the process of repression; it is replaced by the formation of a symptom, is, as it were, psychically bound - one has a feeling that something is missing here which would bring all these pieces together into a whole.

[1933a, 4691]
Fear of castration is not, of course, the only motive for repression: indeed, it finds no place in women, for though they have a castration complex they cannot have a fear of being castrated. Its place is taken in their sex by a fear of loss of love, which is evidently a later prolongation of the infant's anxiety if it finds its mother absent. You will realize how real a situation of danger is indicated by this anxiety. If a mother is absent or has withdrawn her love from her child, it is no longer sure of the satisfaction of its needs and is perhaps exposed to the most distressing feelings of tension. Do not reject the idea that these determinants of anxiety may at bottom repeat the situation of the original anxiety at birth, which, to be sure, also represented a separation from the mother. Indeed, if you follow a train of thought suggested by Ferenczi, you may add the fear of castration to this series, for a loss of the male organ results in an inability to unite once more with the mother (or a substitute for her) in the sexual act. I may mention to you incidentally that the very frequent phantasy of returning into the mother's womb is a substitute for this wish to copulate. There would be many interesting things and surprising connections to tell you at this point, but I cannot go outside the framework of an introduction to psychoanalysis. I will only draw your attention to the fact that here psychological researches trench upon the facts of biology.

[1933a, 4694]

And now, only one more remark on the problem of anxiety. Neurotic anxiety has changed in our hands into realistic anxiety, into fear of particular external situations of danger. But we cannot stop there, we must take another step - though it will be a step backward. We ask ourselves what it is that is actually dangerous and actually feared in a situation of danger of this kind. It is plainly not the injury to the subject as judged objectively, for this need be of no significance psychologically, but something brought about by it in the mind. Birth, for instance, our model for an anxiety state, can after all scarcely be regarded on its own account as an injury, although it may involve a danger of injuries. The essential thing about birth, as about every situation of danger, is that it calls up in mental experience a state of highly tense excitation, which is felt as unpleasure and which one is not able to master by discharging it. Let us call a state of this kind, before which the efforts of the pleasure principle break down, a 'traumatic' moment. Then, if we take in succession neurotic anxiety, realistic anxiety and the situation of danger, we arrive at this simple proposition: what is feared, what is the object of the anxiety, is invariably the emergence of a traumatic moment, which cannot be dealt with by the normal rules of the pleasure principle. We understand at once that our endowment with the pleasure principle does not guarantee us against objective injuries but only against a particular injury to our psychical economics. It is a long step from the pleasure principle to the self-preservation instinct; the intentions of the two of them are very far from coinciding from the start. But we see something else besides; perhaps it is the solution we are in search of. Namely, that in all this it is a question of relative quantities. It is only the magnitude of the sum of excitation that turns an impression into a traumatic moment, paralyses the function of the pleasure principle and gives the situation of danger its significance. And if that is how things are, if these puzzles can be solved so prosaically, why should it not be possible for similar traumatic moments to arise in mental life without reference to hypothetical situations of danger - traumatic moments, then, in which anxiety is not aroused as a signal but is generated anew for a fresh reason. Clinical experience declares decidedly that such is in fact the case. It is only the later repressions that exhibit the mechanism we have described, in which anxiety is awakened as a signal of an earlier situation of danger. The first and original repressions arise directly from traumatic moments, when the ego meets with an excessively great libidinal demand; they construct their anxiety afresh, although, it is true, on the model of birth. The same may apply to the generation of anxiety in anxiety neurosis owing to somatic damage to the sexual function. We shall no longer maintain that it is the libido itself that is turned into anxiety in such cases. But I can see no objection to there being a twofold origin of anxiety - one as a direct consequence of the traumatic moment and the other as a signal threatening a repetition of such a moment.

[1933a, 4700]
This state of affairs is what makes possible one group of anxiety-dreams - dream-structures unpropitious from the point of view of the wish-theory. A second group of them reveal a different mechanism; for anxiety in dreams may be psychoneurotic anxiety: it may originate from psychosexual excitations - in which case the anxiety corresponds to repressed libido. Where this is so, the anxiety, like the whole anxiety-dream, has the significance of a neurotic symptom, and we come near the limit at which the wish-fulfilling purpose of dreams breaks down. But there are some anxiety dreams in which the feeling of anxiety is determined somatically - where, for instance, there happens to be difficulty in breathing owing to disease of the lungs or heart - and in such cases the anxiety is exploited in order to assist the fulfilment in the form of dreams of energetically suppressed wishes which, if they had been dreamt about for psychical reasons, would have led to a similar release of anxiety. But there is no difficulty in reconciling these two apparently different groups. In both groups of dreams two psychical factors are involved: an inclination towards an affect and an ideational content; and these are intimately related to each other. If one of them is currently active, it calls up the other even in a dream; in the one case the somatically determined anxiety calls up the suppressed ideational content, and in the other the ideational content with its accompanying sexual excitation, having been set free from repression, calls up a release of anxiety. We can put it that in the first case a somatically determined affect is given a psychical interpretation; while in the other case, though the whole is psychically determined, the content which had been suppressed is easily replaced by a somatic interpretation appropriate to anxiety. The difficulties which all this offers to our understanding have little to do with dreams: they arise from the fact that we are here touching on the problem of the generation of anxiety and on the problem of repression.

[1900a, 715]

The theory of anxiety-dreams, as I have already repeatedly declared, forms part of the psychology of the neuroses. We have nothing more to do with it when once we have indicated its point of contact with the topic of the dream-process. There is only one thing more that I can do. Since I have asserted that neurotic anxiety arises from sexual sources, I can submit some anxiety-dreams to analysis in order to show the sexual material present in their dream-thoughts.

[1900a, 1010]

There is a second explanation, also unconcerned with sexuality, which has, however, a much more general scope than the first. It suggests that primitive man is prey to a perpetual lurking apprehensiveness, just as in the psycho-analytic theory of the neuroses we claim to be the case with people suffering from anxiety neurosis. This apprehensiveness will appear most strongly on all occasions which differ in any way from the usual, which involve something new or unexpected, something not understood or uncanny. This is also the origin of the ceremonial practices, widely adopted in later religions, which are connected with the beginning of every new undertaking, the start of every new period of time, the first-fruits of human, animal and plant life. The dangers which the anxious man believes to be threatening him never appear more vivid in his expectation than on the threshold of a dangerous situation, and then, too, is the only time when protecting himself against them is of any use. The first act of intercourse in marriage can certainly claim, on grounds of importance, to be preceded by such precautionary measures. These two attempts at explanation, based on horror of blood and on fear of first occurrences, do not contradict but rather reinforce each other. The first occasion of sexual intercourse is certainly a critical action, all the more so if it is to involve a flow of blood.

[1918a, 2353]
The ego ideal opens up an important avenue for the understanding of group psychology. In addition to its individual side, this ideal has a social side; it is also the common ideal of a family, a class or a nation. It binds not only a person's narcissistic libido, but also a considerable amount of his homosexual libido, which is in this way turned back into the ego. The want of satisfaction which arises from the non-fulfilment of this ideal liberates homosexual libido, and this is transformed into a sense of guilt (social anxiety). Originally this sense of guilt was a fear of punishment by the parents, or, more correctly, the fear of losing their love; later the parents are replaced by an indefinite number of fellow-men. The frequent causation of paranoia by an injury to the ego, by a frustration of satisfaction within the sphere of the ego ideal, is thus made more intelligible, as is the convergence of ideal-formation and sublimation in the ego ideal, as well as the involution of sublimations and the possible transformation of ideals in paraphrenic disorders.

LADIES AND GENTLEMEN, - What I said to you in my last lecture about the general neurotic state will no doubt have struck you as the most incomplete and inadequate of all my pronouncements. I know that is true, and nothing will have surprised you more, I expect, than that there was nothing in it about anxiety, of which most neurotics complain, which they themselves describe as their worst suffering and which does in fact attain enormous intensity in them and may result in their adopting the craziest measures. But there at least I had no intention of giving you short measure. On the contrary, it was my intention to attack the problem of anxiety in neurotics particularly keenly and to discuss it at length with you.

I have no need to introduce anxiety itself to you. Every one of us has experienced that sensation, or, to speak more correctly, that affective state, at one time or other on our own account. But I think the question has never been seriously enough raised of why neurotics in particular suffer from anxiety so much more and so much more strongly than other people. Perhaps it has been regarded as something self-evident: the words 'nervös' and 'ängstlich' are commonly used interchangeably, as though they meant the same thing. But we have no right to do so: there are 'ängstlich' people who are otherwise not at all 'nervös' and, moreover, 'nervös' people who suffer from many symptoms, among which a tendency to 'Angst' is not included.

If we now pass over to consider neurotic anxiety, what fresh forms and situations are manifested by anxiety? There is much to be described here. In the first place we find a general apprehensiveness, a kind of freely floating anxiety which is ready to attach itself to any idea that is in any way suitable, which influences judgement, selects what is to be expected, and lies in wait for any opportunity that will allow it to justify itself. We call this state 'expectant anxiety' or 'anxious expectation'. People who are tormented by this kind of anxiety always foresee the most frightful of all possibilities, interpret every chance event as a premonition of evil and exploit every uncertainty in a bad sense. A tendency to an expectation of evil of this sort is to be found as a character trait in many people whom one cannot otherwise regard as sick; one calls them over-anxious or pessimistic. A striking amount of expectant anxiety, however, forms a regular feature of a nervous disorder to which I have given the name of 'anxiety neurosis' and which I include among the 'actual' neuroses.
The third of the forms of neurotic anxiety faces us with the puzzling fact that here the connection between anxiety and a threatening danger is completely lost to view. For instance, anxiety may appear in hysteria as an accompaniment to hysterical symptoms, or in some chance condition of excitement in which, it is true, we should expect some manifestation of affect but least of all one of anxiety; or it may make its appearance, divorced from any determinants and equally incomprehensible to us and to the patient, as an unrelated attack of anxiety. Here there is no sign whatever of any danger or of any cause that could be exaggerated into one. We next learn from these spontaneous attacks that the complex which we describe as a state of anxiety is capable of fragmentation. The total attack can be represented by a single, intensely developed symptom, by a tremor, a vertigo, by palpitation of the heart, or by dyspnoea; and the general feeling by which we recognize anxiety may be absent or have become indistinct. Yet these conditions, which we describe as 'anxiety-equivalents', have to be equated with anxiety in all clinical and aetiological respects.

[1916-1917, 3448]

Two questions now arise. Can we relate neurotic anxiety, in which danger plays little or no part, to realistic anxiety, which is invariably a reaction to danger? And how are we to understand neurotic anxiety? We shall certainly be inclined in the first instance to hold fast to our expectation that where there is anxiety there must be something that one is afraid of.

[1916-1917, 3448]

Our observations on anxiety neurosis led us to conclude that the deflection of the libido from its normal employment, which causes the development of anxiety, takes place in the region of somatic processes. Analyses of hysteria and obsessional neurosis yield the additional conclusion that a similar deflection with the same outcome may also be the result of a refusal on the part of the psychical agencies. This much, therefore, we know about the origin of neurotic anxiety. It still sounds fairly indefinite; but for the moment I see no path that would lead us further. The second problem we set ourselves - of establishing a connection between neurotic anxiety, which is libido put to an abnormal employment, and realistic anxiety, which corresponds to a reaction to danger - seems even harder to solve. One might suppose that these were two quite disparate things; and yet we have no means of distinguishing in our feelings between realistic anxiety and neurotic anxiety.

[1916-1917, 3451]

We finally arrive at the connection we are in search of, if we take as our starting-point the opposition we have so often asserted between the ego and the libido. As we know, the generation of anxiety is the ego's reaction to danger and the signal for taking flight. If so, it seems plausible to suppose that in neurotic anxiety the ego is making a similar attempt at flight from the demand by its libido, that it is treating this internal danger as though it were an external one. This would therefore fulfil our expectation that where anxiety is shown there is something one is afraid of. But the analogy could be carried further. Just as the attempt at flight from an external danger is replaced by standing firm and the adoption of expedient measures of defence, so too the generation of neurotic anxiety gives place to the formation of symptoms, which results in the anxiety being bound.

[1916-1917, 3452]
In children the first phobias relating to situations are those of darkness and solitude. The former of these often persists throughout life; both are involved when a child feels the absence of some loved person who looks after it - its mother, that is to say. While I was in the next room, I heard a child who was afraid of the dark call out: 'Do speak to me, Auntie! I'm frightened!' 'Why, what good would that do? You can't see me.' To this the child replied: 'If someone speaks, it gets lighter.' Thus a longing felt in the dark is transformed into a fear of the dark. Far from its being the case that neurotic anxiety is only secondary and a special case of realistic anxiety, we see on the contrary that in a small child something that behaves like realistic anxiety shares its essential feature - origin from unemployed libido - with neurotic anxiety. Innately, children seem to have little true realistic anxiety. In all the situations which can later become determinants of phobias (on heights, on narrow bridges over water, on railway journeys, on ships) children exhibit no anxiety; and, to be sure, the greater their ignorance the less their anxiety. It would have been a very good thing if they had inherited more of such life-preserving instincts, for that would have greatly facilitated the task of watching over them to prevent their running into one danger after another. The fact is that children, to begin with, over-estimate their strength and behave fearlessly because they are ignorant of dangers. They will run along the brink of the water, climb on to the window-sill, play with sharp objects and with fire - in short, do everything that is bound to damage them and to worry those in charge of them. When in the end realistic anxiety is awakened in them, that is wholly the result of education; for they cannot be allowed to make the instructive experiences themselves.

Let me sum up what we have learnt from our observations of the apprehensiveness of children. Infantile anxiety has very little to do with realistic anxiety, but, on the other hand, is closely related to the neurotic anxiety of adults. Like the latter, it is derived from unemployed libido and it replaces the missing love-object by an external object or by a situation.

These considerations make it possible to regard the fear of death, like the fear of conscience, as a development of the fear of castration. The great significance which the sense of guilt has in the neuroses makes it conceivable that common neurotic anxiety is reinforced in severe cases by the generating of anxiety between the ego and the super-ego (fear of castration, of conscience, of death).

In a psychosis, the transforming of reality is carried out upon the psychical precipitates of former relations to it - that is, upon the memory-traces, ideas and judgements which have been previously derived from reality and by which reality was represented in the mind. But this relation was never a closed one; it was continually being enriched and altered by fresh perceptions. Thus the psychosis is also faced with the task of procuring for itself perceptions of a kind which shall correspond to the new reality; and this is most radically effected by means of hallucination. The fact that, in so many forms and cases of psychosis, the paramnesias, the delusions and the hallucinations that occur are of a most distressing character and are bound up with a generation of anxiety - this fact is without doubt a sign that the whole process of remodelling is carried through against forces which oppose it violently. We may construct the process on the model of a neurosis, with which we are more familiar. There we see that a reaction of anxiety sets in whenever the repressed instinct makes a thrust forward, and that the outcome of the conflict is only a compromise and does not provide complete satisfaction. Probably in a psychosis the rejected piece of reality constantly forces itself upon the mind, just as the repressed instinct does in a neurosis, and that is why in both cases the consequences too are the same. The elucidation of the various mechanisms which are designed, in the psychoses, to turn the subject away from reality and to reconstruct reality - this is a task for specialized psychiatric study which has not yet been taken in hand.
Anxiety is the reaction to danger. One cannot, after all, help suspecting that the reason why the affect of anxiety occupies a unique position in the economy of the mind has something to do with the essential nature of danger. Yet dangers are the common lot of humanity; they are the same for everyone. What we need and cannot lay our finger on is some factor which will explain why some people are able to subject the affect of anxiety, in spite of its peculiar quality, to the normal workings of the mind, or which decides who is doomed to come to grief over that task. Two attempts to find a factor of this kind have been made; and it is natural that such efforts should meet with a sympathetic reception, since they promise help to meet a tormenting need. The two attempts in question are mutually complementary; they approach the problem at opposite ends. The first was made by Alfred Adler more than ten years ago. His contention, reduced to its essence, was that the people who came to grief over the task set them by danger were those who were too greatly impeded by some organic inferiority. If it were true that simplex sigillum veri, we should welcome such a solution as a deliverance. But on the contrary, our critical studies of the last ten years have effectively demonstrated the total inadequacy of such an explanation - an explanation, moreover, which sets aside the whole wealth of material that has been discovered by psycho-analysis. [1926d, 4304]

To begin with the last problem. The advance we have made is that we have gone behind reactions of anxiety to situations of danger. If we do the same thing with realistic anxiety we shall have no difficulty in solving the question. Real danger is a danger that is known, and realistic anxiety is anxiety about a known danger of this sort. Neurotic anxiety is anxiety about an unknown danger. Neurotic danger is thus a danger that has still to be discovered. Analysis has shown that it is an instinctual danger. By bringing this danger which is not known to the ego into consciousness, the analyst makes neurotic anxiety no different from realistic anxiety, so that it can be dealt with in the same way. [1926d, 4317]

In some cases the characteristics of realistic anxiety and neurotic anxiety are mingled. The danger is known and real but the anxiety in regard to it is over-great, greater than seems proper to us. It is this surplus of anxiety which betrays the presence of a neurotic element. Such cases, however, introduce no new principle; for analysis shows that to the known real danger an unknown instinctual one is attached. [1926d, 4317]

So far we have had no occasion to regard realistic anxiety in any different light from neurotic anxiety. We know what the distinction is. A real danger is a danger which threatens a person from an external object, and a neurotic danger is one which threatens him from an instinctual demand. In so far as the instinctual demand is something real, his neurotic anxiety, too, can be admitted to have a realistic basis. We have seen that the reason why there seems to be a specially close connection between anxiety and neurosis is that the ego defends itself against an instinctual danger with the help of the anxiety reaction just as it does against an external real danger, but that this line of defensive activity eventuates in a neurosis owing to an imperfection of the mental apparatus. We have also come to the conclusion that an instinctual demand often only becomes an (internal) danger because its satisfaction would bring on an external danger - that is, because the internal danger represents an external one. [1926d, 4319]
We are warned by a proverb against serving two masters at the same time. The poor ego has things even worse: it serves three severe masters and does what it can to bring their claims and demands into harmony with one another. These claims are always divergent and often seem incompatible. No wonder that the ego so often fails in its task. Its three tyrannical masters are the external world, the super-ego and the id. When we follow the ego's efforts to satisfy them simultaneously - or rather, to obey them simultaneously - we cannot feel any regret at having personified this ego and having set it up as a separate organism. It feels hemmed in on three sides, threatened by three kinds of danger, to which, if it is hard pressed, it reacts by generating anxiety. Owing to its origin from the experiences of the perceptual system, it is earmarked for representing the demands of the external world, but it strives too to be a loyal servant of the id, to remain on good terms with it, to recommend itself to it as an object and to attract its libido to itself. In its attempts to mediate between the id and reality, it is often obliged to cloak the Ucs. commands of the id with its own Pcs. rationalizations, to conceal the id's conflicts with reality, to profess, with diplomatic disingenuousness, to be taking notice of reality even when the id has remained rigid and unyielding. On the other hand it is observed at every step it takes by the strict super-ego, which lays down definite standards for its conduct, without taking any account of its difficulties from the direction of the id and the external world, and which, if those standards are not obeyed, punishes it with tense feelings of inferiority and of guilt. Thus the ego, driven by the id, confined by the super-ego, repulsed by reality, struggles to master its economic task of bringing about harmony among the forces and influences working in and upon it; and we can understand how it is that so often we cannot suppress a cry: 'Life is not easy!' If the ego is obliged to admit its weakness it breaks out in anxiety - realistic anxiety regarding the external world, moral anxiety regarding the super-ego and neurotic anxiety regarding the strength of the passions in the id.

I devoted a lecture (the twenty-fifth) to anxiety in my previous series; and I must briefly recapitulate what I said in it. We described anxiety as an affective state - that is to say, a combination of certain feelings in the pleasure-unpleasure series with the corresponding innervations of discharge and a perception of them, but probably also the precipitate of a particular important event, incorporated by inheritance - something that may thus be likened to an individually acquired hysterical attack. The event which we look upon as having left behind it an affective trace of this sort is the process of birth, at the time of which the effects upon the heart's action and upon respiration characteristic of anxiety were expedient ones. The very first anxiety would thus have been a toxic one. We then started off from a distinction between realistic anxiety and neurotic anxiety, of which the former was a reaction, which seemed intelligible to us, to a danger - that is, to an expected injury from outside - while the latter was completely enigmatic, and appeared to be pointless.

We then turned to neurotic anxiety and pointed out that we observe it under three conditions. We find it first as a freely floating, general apprehensiveness, ready to attach itself temporarily, in the form of what is known as 'expectant anxiety', to any possibility that may freshly arise - as happens, for instance, in a typical anxiety neurosis. Secondly, we find it firmly attached to certain ideas in the so-called 'phobias', in which it is still possible to recognize a relation to external danger but in which we must judge the fear exaggerated out of all proportion. Thirdly and lastly, we find anxiety in hysteria and other forms of severe neurosis, where it either accompanies symptoms or emerges independently as an attack or more persistent state, but always without any visible basis in an external danger. We then asked ourselves two questions: 'What are people afraid of in neurotic anxiety?' and 'How are we to bring it into relation with realistic anxiety felt in the face of external dangers?'
Our investigations were far from remaining unsuccessful: we reached a few important conclusions. In regard to anxious expectation clinical experience revealed that it had a regular connection with the libidinal economics of sexual life. The commonest cause of anxiety neurosis is unconsummated excitation. Libidinal excitation is aroused but not satisfied, not employed; apprehensiveness then appears instead of this libido that has been diverted from its employment. I even thought I was justified in saying that this unsatisfied libido was directly changed into anxiety. This view found support in some quite regularly occurring phobias of small children. Many of these phobias are very puzzling to us, but others, such as the fear of being alone and the fear of strangers, can be explained with certainty. Loneliness as well as a strange face arouse the child's longing for his familiar mother; he is unable to control this libidinal excitation, he cannot hold it in suspense but changes it into anxiety. This infantile anxiety must therefore be regarded not as of the realistic but as of the neurotic kind. Infantile phobias and the expectation of anxiety in anxiety neurosis offer us two examples of one way in which neurotic anxiety originates: by a direct transformation of libido. We shall at once come to know of a second mechanism, but it will turn out not to be very different from the first.

In the course of these investigations our attention was drawn to a highly significant relation between the generation of anxiety and the formation of symptoms - namely, that these two represent and replace each other. For instance, an agoraphobic patient may start his illness with an attack of anxiety in the street. This would be repeated every time he went into the street again. He will now develop the symptom of agoraphobia; this may also be described as an inhibition, a restriction of the ego's functioning, and by means of it he spares himself anxiety attacks. We can witness the converse of this if we interfere in the formation of symptoms, as is possible, for instance, with obsessions. If we prevent a patient from carrying out a washing ceremonial, he falls into a state of anxiety which he finds hard to tolerate and from which he had evidently been protected by his symptom. And it seems, indeed, that the generation of anxiety is the earlier and the formation of symptoms the later of the two, as though the symptoms are created in order to avoid the outbreak of the anxiety state. This is confirmed too by the fact that the first neuroses of childhood are phobias - states in which we see so clearly how an initial generation of anxiety is replaced by the later formation of a symptom; we get an impression that it is from these interrelations that we shall best obtain access to an understanding of neurotic anxiety. And at the same time we have also succeeded in answering the question of what it is that a person is afraid of in neurotic anxiety and so in establishing the connection between neurotic and realistic anxiety. What he is afraid of is evidently his own libido. The difference between this situation and that of realistic anxiety lies in two points: that the danger is an internal instead of an external one and that it is not consciously recognized.

In phobias it is very easy to observe the way in which this internal danger is transformed into an external one - that is to say, how a neurotic anxiety is changed into an apparently realistic one. In order to simplify what is often a very complicated business, let us suppose that the agoraphobic patient is invariably afraid of feelings of temptation that are aroused in him by meeting people in the street. In his phobia he brings about a displacement and henceforward is afraid of an external situation. What he gains by this is obviously that he thinks he will be able to protect himself better in that way. One can save oneself from an external danger by flight; fleeing from an internal danger is a difficult enterprise.
Otto Rank, to whom psycho-analysis is indebted for many excellent contributions, also has the merit of having expressly emphasized the significance of the act of birth and of separation from the mother. Nevertheless we have all found it impossible to accept the extreme inferences which he has drawn from this factor as bearing on the theory of the neuroses and even on analytic therapy. The core of his theory - that the experience of anxiety at birth is the model of all later situations of danger - he found already there. If we dwell on these situations of danger for a moment, we can say that in fact a particular determinant of anxiety (that is, situation of danger) is allotted to every age of development as being appropriate to it. The danger of psychical helplessness fits the stage of the ego's early immaturity; the danger of loss of an object (or loss of love) fits the lack of self-sufficiency in the first years of childhood; the danger of being castrated fits the phallic phase; and finally fear of the super-ego, which assumes a special position, fits the period of latency. In the course of development the old determinants of anxiety should be dropped, since the situations of danger corresponding to them have lost their importance owing to the strengthening of the ego. But this only occurs most incompletely. Many people are unable to surmount the fear of loss of love; they never become sufficiently independent of other people's love and in this respect carry on their behaviour as infants. Fear of the super-ego should normally never cease, since, in the form of moral anxiety, it is indispensable in social relations, and only in the rarest cases can an individual become independent of human society. A few of the old situations of danger, too, succeed in surviving into later periods by making contemporary modifications in their determinants of anxiety. Thus, for instance, the danger of castration persists under the mark of syphilidophobia. It is true that as an adult one knows that castration is no longer customary as a punishment for the indulgence of sexual desires, but on the other hand one has learnt that instinctual liberty of that kind is threatened by serious diseases. There is no doubt that the people we describe as neurotics remain infantile in their attitude to danger and have not surmounted obsolete determinants of anxiety. We may take this as a factual contribution to the characterization of neurotics; it is not so easy to say why it should be so.

[1933a, 4695]
And now, only one more remark on the problem of anxiety. Neurotic anxiety has changed in our hands into realistic anxiety, into fear of particular external situations of danger. But we cannot stop there, we must take another step - though it will be a step backward. We ask ourselves what it is that is actually dangerous and actually feared in a situation of danger of this kind. It is plainly not the injury to the subject as judged objectively, for this need be of no significance psychologically, but something brought about by it in the mind. Birth, for instance, our model for an anxiety state, can after all scarcely be regarded on its own account as an injury, although it may involve a danger of injuries. The essential thing about birth, as about every situation of danger, is that it calls up in mental experience a state of highly tense excitation, which is felt as displeasure and which one is not able to master by discharging it. Let us call a state of this kind, before which the efforts of the pleasure principle break down, a 'traumatic' moment. Then, if we take in succession neurotic anxiety, realistic anxiety and the situation of danger, we arrive at this simple proposition: what is feared, what is the object of the anxiety, is invariably the emergence of a traumatic moment, which cannot be dealt with by the normal rules of the pleasure principle. We understand at once that our endowment with the pleasure principle does not guarantee us against objective injuries but only against a particular injury to our psychical economics. It is a long step from the pleasure principle to the self-preservative instinct; the intentions of the two of them are very far from coinciding from the start. But we see something else besides; perhaps it is the solution we are in search of. Namely, that in all this it is a question of relative quantities. It is only the magnitude of the sum of excitation that turns an impression into a traumatic moment, paralyses the function of the pleasure principle and gives the situation of danger its significance. And if that is how things are, if these puzzles can be solved so prosaically, why should it not be possible for similar traumatic moments to arise in mental life without reference to hypothetical situations of danger - traumatic moments, then, in which anxiety is not aroused as a signal but is generated anew for a fresh reason. Clinical experience declares decidedly that such is in fact the case. It is only the later repressions that exhibit the mechanism we have described, in which anxiety is awakened as a signal of an earlier situation of danger. The first and original repressions arise directly from traumatic moments, when the ego meets with an excessively great libidinal demand; they construct their anxiety afresh, although, it is true, on the model of birth. The same may apply to the generation of anxiety in anxiety neurosis owing to somatic damage to the sexual function. We shall no longer maintain that it is the libido itself that is turned into anxiety in such cases. But I can see no objection to there being a twofold origin of anxiety - one as a direct consequence of the traumatic moment and the other as a signal threatening a repetition of such a moment.

[1933a, 4700]
This view of delusions is not, I think, entirely new, but it nevertheless emphasizes a point of view which is not usually brought into the foreground. The essence of it is that there is not only method in madness, as the poet has already perceived, but also a fragment of historical truth; and it is plausible to suppose that the compulsive belief attaching to delusions derives its strength precisely from infantile sources of this kind. All that I can produce to-day in support of this theory are reminiscences, not fresh impressions. It would probably be worth while to make an attempt to study cases of the disorder in question on the basis of the hypotheses that have been here put forward and also to carry out their treatment on those same lines. The vain effort would be abandoned of convincing the patient of the error of his delusion and of its contradiction of reality; and, on the contrary, the recognition of its kernel of truth would afford common ground upon which the therapeutic work could develop. That work would consist in liberating the fragment of historical truth from its distortions and its attachments to the actual present day and in leading it back to the point in the past to which it belongs. The transposing of material from a forgotten past on to the present or on to an expectation of the future is indeed a habitual occurrence in neurotics no less than in psychotics. Often enough, when a neurotic is led by an anxiety-state to expect the occurrence of some terrible event, he is in fact merely under the influence of a repressed memory (which is seeking to enter consciousness but cannot become conscious) that something which was at that time terrifying did really happen. I believe that we should gain a great deal of valuable knowledge from work of this kind upon psychotics even if it led to no therapeutic success.

[1937d, 5058]
INFANTILE ANXIETY  Children themselves behave from an early age as though their dependence on the people looking after them were in the nature of sexual love. Anxiety in children is originally nothing other than an expression of the fact that they are feeling the loss of the person they love. It is for this reason that they are frightened of every stranger. They are afraid in the dark because in the dark they cannot see the person they love; and their fear is soothed if they can take hold of that person’s hand in the dark. To attribute to bogeys and blood-curdling stories told by nurses the responsibility for making children timid is to over-estimate their efficacy. The truth is merely that children who are inclined to be timid are affected by stories which would make no impression what ever upon others, and it is only children with a sexual instinct that is excessive or has developed prematurely or has become vociferous owing to too much petting who are inclined to be timid. In this respect a child, by turning his libido into anxiety when he cannot satisfy it, behaves like an adult. On the other hand an adult who has become neurotic owing to his libido being unsatisfied behaves in his anxiety like a child: he begins to be frightened when he is alone, that is to say when he is away from someone of whose love he had felt secure, and he seeks to assuage this fear by the most childish measures.¹

¹ For this explanation of the origin of infantile anxiety I have to thank a three-year-old boy whom I once heard calling out of a dark room: ‘Auntie, speak to me! I'm frightened because it's so dark.’ His aunt answered him: ‘What good would that do? You can't see me.’ ‘That doesn't matter,’ replied the child, ‘if anyone speaks, it gets light.’ Thus what he was afraid of was not the dark, but the absence of someone he loved; and he could feel sure of being soothed as soon as he had evidence of that person's presence.

[Added 1920:] One of the most important results of psycho-analytic research is this discovery that neurotic anxiety arises out of libido, that it is the product of a transformation of it, and that it is thus related to it in the same kind of way as vinegar is to wine. A further discussion of this problem will be found in my Introductory Lectures (1916-17), Lecture XXV, though even there it must be confessed, the question is not finally cleared up.

[1905d, 1537]

The difficulty in understanding now lies else here. The anxiety which signifies a flight of the ego from its libido is after all supposed to be derived from that libido itself. This is obscure and it reminds us not to forget that after all a person’s libido is fundamentally something of his and cannot be contrasted with him as something external. It is the topographical dynamics of the generation of anxiety which are still obscure to us - the question of what mental energies are produced in what process and from what mental systems they derive. This is once more a question which I cannot promise to answer: but there are two other tracks which we must not fail to follow and in doing so we shall once more be making use of direct observation and analytic enquiry as a help to our speculations. We will turn to the genesis of anxiety in children and to the source of the neurotic anxiety which is attached to phobias.

[1916-1917, 3452]

Apprehensiveness in children is something very usual, and it seems most difficult to distinguish whether it is neurotic or realistic anxiety. Indeed the value of making the distinction is put in question by the behaviour of children. For on the one hand we are not surprised if a child is frightened of all strangers, or of new situations and things; and we account for this reaction very easily as being due to his weakness and ignorance. Thus we attribute to children a strong inclination to realistic anxiety and we should regard it as quite an expedient arrangement if this apprehensiveness were an innate heritage in them. Children would merely be repeating in this the behaviour of prehistoric men and of modern primitive peoples who as a result of their ignorance and helplessness are afraid of every novelty and of many familiar things which no longer cause us any anxiety to-day. And it would fit in perfectly with our expectation if children’s phobias, in part at least, were the same as those which we may attribute to the primaeval periods of human development.

[1916-1917, 3452]
On the other hand we cannot overlook the fact that not all children are anxious to the same degree, and that precisely children who exhibit a special timidity towards objects and in situations of every kind turn out later to be neurotic. Thus the neurotic disposition betrays itself also by an outspoken tendency to realistic anxiety; apprehensiveness appears to be the primary thing and we reach the conclusion that the reason why children and, later, growing youths and girls are afraid of the height of their libido is because in fact they are afraid of everything. The genesis of anxiety from libido would in this way be denied; and if one examined into the determinants of realistic anxiety, consistency would lead one to the view that consciousness of one’s own weakness and helplessness - inferiority according to Adler's terminology, - if it can be prolonged from childhood into adult life, is the final basis of neuroses.

[1916-1917, 3453]

This sounds so simple and seductive that it has a claim on our attention. It is true that it would involve a displacement of the riddle of the neurotic state. The continued existence of the sense of inferiority - and thus, of what determine anxiety and the formation of symptoms - seems so well assured that what calls for an explanation is rather how, as an exception, what we know as health can come about. But what is revealed by a careful examination of apprehensiveness in children? At the very beginning, what children are afraid of is strange people; situations only become important because they include people, and impersonal things do not come into account at all until later. But a child is not afraid of these strangers because he attributes evil intentions to them and compares his weakness with their strength, and accordingly assesses them as dangers to his existence, safety and freedom from pain. A child who is mistrustful in this way and terrified of the aggressive instinct which dominates the world is a theoretical construction that has quite miscarried. A child is frightened of a strange face because he is adjusted to the sight of a familiar and beloved figure - ultimately of his mother. It is his disappointment and longing that are transformed into anxiety - his libido, in fact, which has become unemployable, which cannot at that time be held in suspense and is discharged as anxiety. And it can scarcely be a matter of chance, either, that in this situation which is the prototype of the anxiety of children there is a repetition of the determinant of the first state of anxiety during the act of birth - namely, separation from the mother.

[1916-1917, 3453]

In children the first phobias relating to situations are those of darkness and solitude. The former of these often persists throughout life; both are involved when a child feels the absence of some loved person who looks after it - its mother, that is to say. While I was in the next room, I heard a child who was afraid of the dark call out: 'Do speak to me, Auntie! I'm frightened!' 'Why, what good would that do? You can't see me.' To this the child replied: 'If someone speaks, it gets lighter.' Thus a longing felt in the dark is transformed into a fear of the dark. Far from its being the case that neurotic anxiety is only secondary and a special case of realistic anxiety, we see on the contrary that in a small child something that behaves like realistic anxiety shares its essential feature - origin from unemployed libido - with neurotic anxiety. Innately, children seem to have little true realistic anxiety. In all the situations which can later become determinants of phobias (on heights, on narrow bridges over water, on railway journeys, on ships) children exhibit no anxiety; and, to be sure, the greater their ignorance the less their anxiety. It would have been a very good thing if they had inherited more of such life-preserving instincts, for that would have greatly facilitated the task of watching over them to prevent their running into one danger after another. The fact is that children, to begin with, over-estimate their strength and behave fearlessly because they are ignorant of dangers. They will run along the brink of the water, climb on to the window-sill, play with sharp objects and with fire - in short, do everything that is bound to damage them and to worry those in charge of them. When in the end realistic anxiety is awakened in them, that is wholly the result of education; for they cannot be allowed to make the instructive experiences themselves.

[1916-1917, 3454]
If, then, there are children who come some way to meet this education in anxiety, and who go on to find dangers themselves that they have not been warned against, this is sufficiently explained by the fact that they have a greater amount of innate libidinal need in their constitution or have been prematurely spoiled by libidinal satisfaction. It is not to be wondered at if such children include, too, the later neurotics: as we know, what most facilitates the development of a neurosis is an incapacity to tolerate a considerable damming-up of libido over any great length of time. You will observe that here once more the constitutional factor comes into its rights - and these, indeed, we have never sought to dispute. We are only on our guard against those who in its favour neglect all other claims, and who introduce the constitutional factor at points at which the combined results of observation and analysis show that it does not belong or must take the last place.
[1916-1917, 3454]

Let me sum up what we have learnt from our observations of the apprehensiveness of children. Infantile anxiety has very little to do with realistic anxiety, but, on the other hand, is closely related to the neurotic anxiety of adults. Like the latter, it is derived from unemployed libido and it replaces the missing love-object by an external object or by a situation.
[1916-1917, 3454]

You will be glad to hear that the analysis of phobias has not much more that is new to teach us. For the same thing happens with them as with children's anxiety: unemployable libido is being constantly transformed into an apparently realistic anxiety and thus a tiny external danger is introduced to represent the claims of the libido. There is nothing to be wondered at in this agreement, for the infantile phobias are not only the prototype of the later ones which we class as 'anxiety hysteria' but are actually their precondition and the prelude to them. Every hysterical phobia goes back to an infantile anxiety and is a continuation of it, even if it has a different content and must thus be given another name. The difference between the two disorders lies in their mechanism. In order that libido shall be changed into anxiety, it no longer suffices in the case of adults for the libido to have become momentarily unemployable in the form of a longing. Adults have long since learnt how to hold such libido in suspense or to employ it in some other way. If, however, the libido belongs to a psychical impulse which has been subjected to repression, then circumstances are re-established similar to those in the case of a child in whom there is still no distinction between conscious and unconscious; and by mean of regression to the infantile phobia a passage is opened, as it were, through which the transformation of libido into anxiety can be comfortably accomplished.
[1916-1917, 3455]

Concerning the factors of silence, solitude and darkness, we can only say that they are actually elements in the production of the infantile anxiety from which the majority of human beings have never become quite free. This problem has been discussed from a psycho-analytic point of view elsewhere.
[1919h, 3700]
It is naturally no easy matter to trace the ontogenesis of the herd instinct. The fear which is shown by small children when they are left alone, and which Trotter claims as being already a manifestation of the instinct, nevertheless suggests more readily another interpretation. The fear relates to the child's mother, and later to other familiar people, and it is the expression of an unfulfilled desire, which the child does not yet know how to deal with in any way except by turning it into anxiety.¹ Nor is the child's fear when it is alone pacified by the sight of any haphazard 'member of the herd', but on the contrary it is brought into existence by the approach of a 'stranger' of this sort. Then for a long time nothing in the nature of herd instinct or group feeling is to be observed in children. Something like it first grows up, in a nursery containing many children, out of the children's relation to their parents, and it does so as a reaction to the initial envy with which the elder child receives the younger one. The elder child would certainly like to put his successor jealously aside, to keep it away from the parents, and to rob it of all its privileges; but in the face of the fact that this younger child (like all that come later) is loved by the parents as much as he himself is, and in consequence of the impossibility of his maintaining his hostile attitude without damaging himself, he is forced into identifying himself with the other children. So there grows up in the troop of children a communal or group feeling, which is then further developed at school. The first demand made by this reaction-formation is for justice, for equal treatment for all. We all know how loudly and implacably this claim is put forward at school. If one cannot be the favourite oneself, at all events nobody else shall be the favourite. This transformation - the replacing of jealousy by a group feeling in the nursery and classroom - might be considered improbable, if the same process could not later on be observed again in other circumstances. We have only to think of the troop of women and girls, all of them in love in an enthusiastically sentimental way, who crowd round a singer or pianist after his performance. It would certainly be easy for each of them to be jealous of the rest; but, in the face of their numbers and the consequent impossibility of their reaching the aim of their love, they renounce it, and, instead of pulling out one another's hair, they act as a united group, do homage to the hero of the occasion with their common actions, and would probably be glad to have a share of his flowing locks. Originally rivals, they have succeeded in identifying themselves with one another by means of a similar love for the same object. When, as is usual, an instinctual situation is capable of various outcomes, we shall not be surprised that the actual outcome is one which brings with it the possibility of a certain amount of satisfaction, whereas some other outcome, in itself more obvious, is passed over because the circumstances of life prevent its leading to any such satisfaction.

The fear of death in melancholia only admits of one explanation: that the ego gives itself up because it feels itself hated and persecuted by the super-ego, instead of loved. To the ego, therefore, living means the same as being loved - being loved by the super-ego, which here again appears as the representative of the id. The super-ego fulfils the same function of protecting and saving that was fulfilled in earlier days by the father and later by Providence or Destiny. But, when the ego finds itself in an excessive real danger which it believes itself unable to overcome by its own strength, it is bound to draw the same conclusion. It sees itself deserted by all protecting forces and lets itself die. Here, moreover, is once again the same situation as that which underlay the first great anxiety-state of birth and the infantile anxiety of longing - the anxiety due to separation from the protecting mother.

Only a few of the manifestations of anxiety in children are comprehensible to us, and we must confine our attention to them. They occur, for instance, when a child is alone, or in the dark, or when it finds itself with an unknown person instead of one to whom it is used - such as its mother. These three instances can be reduced to a single condition - namely, that of missing someone who is loved and longed for. But here, I think, we have the key to an understanding of anxiety and to a reconciliation of the contradictions that seem to beset it.
The child's mnemonic image of the person longed for is no doubt intensely cathected, probably in a hallucinatory way at first. But this has no effect; and now it seems as though the longing turns into anxiety. This anxiety has all the appearance of being an expression of the child's feeling at its wits' end, as though in its still very undeveloped state it did not know how better to cope with its cathexis of longing. Here anxiety appears as a reaction to the felt loss of the object; and we are at once reminded of the fact that castration anxiety, too, is a fear of being separated from a highly valued object, and that the earliest anxiety of all - the 'primal anxiety' of birth - is brought about on the occasion of a separation from the mother.

[1926d, 4292]

But a moment's reflection takes us beyond this question of loss of object. The reason why the infant in arms wants to perceive the presence of its mother is only because it already knows by experience that she satisfies all its needs without delay. The situation, then, which it regards as a 'danger' and against which it wants to be safeguarded is that of non-satisfaction, of a growing tension due to need, against which it is helpless. I think that if we adopt this view all the facts fall into place. The situation of non-satisfaction in which the amounts of stimulation rise to an unpleasurable height without its being possible for them to be mastered psychically or discharged must for the infant be analogous to the experience of being born - must be a repetition of the situation of danger. What both situations have in common is the economic disturbance caused by an accumulation of amounts of stimulation which require to be disposed of. It is this factor, then, which is the real essence of the 'danger'. In both cases the reaction of anxiety sets in. (This reaction is still an expedient one in the infant in arms, for the discharge, being directed into the respiratory and vocal muscular apparatus, now calls its mother to it, just as it activated the lungs of the new-born baby to get rid of the internal stimuli.) It is unnecessary to suppose that the child carries anything more with it from the time of its birth than this way of indicating the presence of danger.

[1926d, 4292]

When the infant has found out by experience that an external, perceptible object can put an end to the dangerous situation which is reminiscent of birth, the content of the danger it fears is displaced from the economic situation on to the condition which determined that situation, viz., the loss of object. It is the absence of the mother that is now the danger; and as soon as that danger arises the infant gives the signal of anxiety, before the dreaded economic situation has set in. This change constitutes a first great step forward in the provision made by the infant for its self-preservation, and at the same time represents a transition from the automatic and involuntary fresh appearance of anxiety to the intentional reproduction of anxiety as a signal of danger.

[1926d, 4293]

In these two aspects, as an automatic phenomenon and as a rescuing signal, anxiety is seen to be a product of the infant's mental helplessness which is a natural counterpart of its biological helplessness. The striking coincidence by which the anxiety of the new-born baby and the anxiety of the infant in arms are both conditioned by separation from the mother does not need to be explained on psychological lines. It can be accounted for simply enough biologically; for, just as the mother originally satisfied all the needs of the foetus through the apparatus of her own body, so now, after its birth, she continues to do so, though partly by other means. There is much more continuity between intra-uterine life and earliest infancy than the impressive caesura of the act of birth would have us believe. What happens is that the child's biological situation as a foetus is replaced for it by a psychical object-relation to its mother. But we must not forget that during its intra-uterine life the mother was not an object for the foetus, and that at that time there were no objects at all. It is obvious that in this scheme of things there is no place for the abreaction of the birth trauma. We cannot find that anxiety has any function other than that of being a signal for the avoidance of a danger situation.

[1926d, 4293]
In describing the evolution of the various danger-situations from their prototype, the act of birth, I have had no intention of asserting that every later determinant of anxiety completely invalidates the preceding one. It is true that, as the development of the ego goes on, the earlier danger-situations tend to lose their force and to be set aside, so that we might say that each period of the individual's life has its appropriate determinant of anxiety. Thus the danger of psychical helplessness is appropriate to the period of life when his ego is immature; the danger of loss of object, to early childhood when he is still dependent on others; the danger of castration, to the phallic phase; and the fear of his super-ego, to the latency period. Nevertheless, all these danger-situations and determinants of anxiety can persist side by side and cause the ego to react to them with anxiety at a period later than the appropriate one; or, again, several of them can come into operation at the same time. It is possible, moreover, that there is a fairly close relationship between the danger-situation that is operative and the form taken by the ensuing neurosis.¹

¹[1926d, 4297]

This study of the determinants of anxiety has, as it were, shown the defensive behaviour of the ego transfigured in a rational light. Each situation of danger corresponds to a particular period of life or a particular developmental phase of the mental apparatus and appears to be justifiable for it. In early infancy the individual is really not equipped to master psychically the large sums of excitation that reach him whether from without or from within. Again, at a certain period of life his most important interest really is that the people he is dependent on should not withdraw their loving care of him. Later on in his boyhood, when he feels that his father is a powerful rival in regard to his mother and becomes aware of his own aggressive inclinations towards him and of his sexual intentions towards his mother, he really is justified in being afraid of his father; and his fear of being punished by him can find expression through phylogenetic reinforcement in the fear of being castrated. Finally, as he enters into social relationships, it really is necessary for him to be afraid of his super-ego, to have a conscience; and the absence of that factor would give rise to severe conflicts, dangers and so on.

[1926d, 4301]
Why this should be so calls for a rather long reply. First of all, we must sift the facts. In a great number of cases the old determinants of anxiety do really lapse, after having produced neurotic reactions. The phobias of very young children, fears of being alone or in the dark or with strangers - phobias which can almost be called normal - usually pass off later on; the child 'grows out of them', as we say about some other disturbances of childhood. Animal phobias, which are of such frequent occurrence, undergo the same fate and many conversion hysterias of early years find no continuation in later life. Ceremonial actions appear extremely often in the latency period, but only a very small percentage of them develop later into a full obsessional neurosis. In general, so far as we can tell from our observations of town children belonging to the white races and living according to fairly high cultural standards, the neuroses of childhood are in the nature of regular episodes in a child's development, although too little attention is still being paid to them. Signs of childhood neuroses can be detected in all adult neurotics without exception; but by no means all children who show those signs become neurotic in later life. It must be, therefore, that certain determinants of anxiety are relinquished and certain danger-situations lose their significance as the individual becomes more mature. Moreover, some of these danger-situations manage to survive into later times by modifying their determinants of anxiety so as to bring them up to date. Thus, for instance, a man may retain his fear of castration in the guise of a syphilidophobia, after he has come to know that it is no longer customary to castrate people for indulging their sexual lusts, but that, on the other hand, severe diseases may overtake anyone who thus gives way to his instincts. Other determinants of anxiety, such as fear of the super-ego, are destined not to disappear at all but to accompany people throughout their lives. In that case the neurotic will differ from the normal person in that his reactions to the dangers in question will be unduly strong. Finally, being grown-up affords no absolute protection against a return of the original traumatic anxiety-situation. Each individual has in all probability a limit beyond which his mental apparatus fails in its function of mastering the quantities of excitation which require to be disposed of.

[1926d, 4302]
Otto Rank, to whom psycho-analysis is indebted for many excellent contributions, also has the merit of having expressly emphasized the significance of the act of birth and of separation from the mother. Nevertheless we have all found it impossible to accept the extreme inferences which he has drawn from this factor as bearing on the theory of the neuroses and even on analytic therapy. The core of his theory - that the experience of anxiety at birth is the model of all later situations of danger - he found already there. If we dwell on these situations of danger for a moment, we can say that in fact a particular determinant of anxiety (that is, situation of danger) is allotted to every age of development as being appropriate to it. The danger of psychical helplessness fits the stage of the ego's early immaturity; the danger of loss of an object (or loss of love) fits the lack of self-sufficiency in the first years of childhood; the danger of being castrated fits the phallic phase; and finally fear of the super-ego, which assumes a special position, fits the period of latency. In the course of development the old determinants of anxiety should be dropped, since the situations of danger corresponding to them have lost their importance owing to the strengthening of the ego. But this only occurs most incompletely. Many people are unable to surmount the fear of loss of love; they never become sufficiently independent of other people's love and in this respect carry on their behaviour as infants. Fear of the super-ego should normally never cease, since, in the form of moral anxiety, it is indispensable in social relations, and only in the rarest cases can an individual become independent of human society. A few of the old situations of danger, too, succeed in surviving into later periods by making contemporary modifications in their determinants of anxiety. Thus, for instance, the danger of castration persists under the mark of syphilidophobia. It is true that as an adult one knows that castration is no longer customary as a punishment for the indulgence of sexual desires, but on the other hand one has learnt that instinctual liberty of that kind is threatened by serious diseases. There is no doubt that the people we describe as neurotics remain infantile in their attitude to danger and have not surmounted obsolete determinants of anxiety. We may take this as a factual contribution to the characterization of neurotics; it is not so easy to say why it should be so.
[1933a, 4695]
During the hypnosis I asked her whether it would now be possible for her to take part in social life or whether she was still too much afraid. She said it was still disagreeable to have anyone standing behind her or just beside her. In this connection she told me of some more occasions on which she had been disagreeably surprised by someone suddenly appearing. Once, for instance, when she had been going for a walk with her daughters on the island of Rügen, two suspicious-looking individuals had come out from some bushes and insulted them. In Abbazia, while she was out for a walk one evening, a beggar had suddenly emerged from behind a rock and had knelt down in front of her. It seems that he was a harmless lunatic. Lastly, she told me of how her isolated country house had been broken into at night, which had very much alarmed her. It is easy to see, however, that the essential origin of this fear of people was the persecution to which she had been subjected after her husband's death.¹

¹ At the time I wrote this I was inclined to look for a psychical origin for all symptoms in cases of hysteria. I should now explain this sexually abstinent woman's tendency to anxiety as being due to neurosis (i.e. anxiety neurosis).

The anxiety from which Katharina suffered in her attacks was a hysterical one; that is, it was a reproduction of the anxiety which had appeared in connection with each of the sexual traumas. I shall not here comment on the fact which I have found regularly present in a very large number of cases - namely that a mere suspicion of sexual relations calls up the affect of anxiety in virginal individuals.¹

¹ To speak quite frankly, this is actually the criterion according to which we decide whether such feelings of mingled apprehension and longing are normal or not: we begin to call them 'pathological anxiety' from the moment at which they can no longer be relieved by the attainment of the object longed for.

There is another point in regard to which we must avoid giving way to this temptation. Hans admitted that every night before going to sleep he amused himself with playing with his penis. 'Ah!' the family doctor will be inclined to say, 'now we have it. The child masturbated: hence his pathological anxiety.' But gently. That the child was getting pleasure for himself by masturbating does not by any means explain his anxiety; on the contrary, it makes it more problematical than ever. States of anxiety are not produced by masturbation or by getting satisfaction in any shape. Moreover, we may presume that Hans, who was now four and three-quarters, had been indulging in this pleasure every evening for at least a year (see p. 2003). And we shall find that at this moment he was actually engaged in a struggle to break himself of the habit - a state of things which fits in much better with repression and the generation of anxiety.
Hans's last words of comfort throw a light upon the situation and allow us to make some small corrections in his father's assertions. It is true that he was afraid of big animals because he was obliged to think of their big widdlers; but it cannot really be said that he was afraid of big widdlers themselves. Formerly the idea of them had been decidedly pleasurable to him, and he used to make every effort to get a glimpse of one. Since that time this enjoyment had been spoiled for him, owing to the general reversal of pleasure into unpleasure which had come over the whole of his sexual researches - in a way which has not yet been explained - and also owing to something which is clearer to us, namely, to certain experiences and reflections which had led to distressing conclusions. We may infer from his self-consolatory words ('my widdler will get bigger as I get bigger') that during his observations he had constantly been making comparisons, and that he had remained extremely dissatisfied with the size of his own widdler. Big animals reminded him of his defect, and were for that reason disagreeable to him. But since the whole train of thought was probably incapable of becoming clearly conscious, this distressing feeling, too, was transformed into anxiety, so that his present anxiety was erected both upon his former pleasure and his present unpleasure. When once a state of anxiety establishes itself, the anxiety swallows up all other feelings; with the progress of repression, and the more those ideas which are charged with affect and which have been conscious move down into the unconscious, all affects are capable of being changed into anxiety.

[1909b, 2025]

We should be glad to be able to say something general about the vicissitudes of both; and having taken our bearings a little we shall in fact be able to do so. The general vicissitude which overtakes the idea that represents the instinct can hardly be anything else than that it should vanish from the conscious if it was previously conscious, or that it should be held back from consciousness if it was about to become conscious. The difference is not important; it amounts to much the same thing as the difference between my ordering an undesirable guest out of my drawing-room (or out of my front hall), and my refusing, after recognizing him, to let him cross my threshold at all.¹ The quantitative factor of the instinctual representative has three possible vicissitudes, as we can see from a cursory survey of the observations made by psycho-analysis: either the instinct is altogether suppressed, so that no trace of it is found, or it appears as an affect which is in some way or other qualitatively coloured, or it is changed into anxiety. The two latter possibilities set us the task of taking into account, as a further instinctual vicissitude, the transformation into affects, and especially into anxiety, of the psychical energies of instincts.

[1915d, 2983]
A condition has long been known and described which occurs after severe mechanical concussions, railway disasters and other accidents involving a risk to life; it has been given the name of 'traumatic neurosis'. The terrible war which has just ended gave rise to a great number of illnesses of this kind, but it at least put an end to the temptation to attribute the cause of the disorder to organic lesions of the nervous system brought about by mechanical force.¹ The symptomatic picture presented by traumatic neurosis approaches that of hysteria in the wealth of its similar motor symptoms, but surpasses it as a rule in its strongly marked signs of subjective ailment (in which it resembles hypochondria or melancholia) as well as in the evidence it gives of a far more comprehensive general enfeeblement and disturbance of the mental capacities. No complete explanation has yet been reached either of war neuroses or of the traumatic neuroses of peace. In the case of the war neuroses, the fact that the same symptoms sometimes came about without the intervention of any gross mechanical force seemed at once enlightening and bewildering. In the case of the ordinary traumatic neuroses two characteristics emerge prominently: first, that the chief weight in their causation seems to rest upon the factor of surprise, of fright; and secondly, that a wound or injury inflicted simultaneously works as a rule against the development of a neurosis. 'Fright', 'fear' and 'anxiety' are improperly used as synonymous expressions; they are in fact capable of clear distinction in their relation to danger. 'Anxiety' describes a particular state of expecting the danger or preparing for it, even though it may be an unknown one. 'Fear' requires a definite object of which to be afraid. 'Fright', however, is the name we give to the state a person gets into when he has run into danger without being prepared for it; it emphasizes the factor of surprise. I do not believe anxiety itself can produce a traumatic neurosis. There is something about anxiety that protects its subject against fright and so against fright-neuroses. We shall return to this point later.¹

[1920g, 3718]
INFANTILE ANXIETY  Children themselves behave from an early age as though their dependence on the people looking after them were in the nature of sexual love. Anxiety in children is originally nothing other than an expression of the fact that they are feeling the loss of the person they love. It is for this reason that they are frightened of every stranger. They are afraid in the dark because in the dark they cannot see the person they love; and their fear is soothed if they can take hold of that person's hand in the dark. To attribute to bogeys and blood-curdling stories told by nurses the responsibility for making children timid is to over-estimate their efficacy. The truth is merely that children who are inclined to be timid are affected by stories which would make no impression whatever upon others, and it is only children with a sexual instinct that is excessive or has developed prematurely or has become vociferous owing to too much petting who are inclined to be timid. In this respect a child, by turning his libido into anxiety when he cannot satisfy it, behaves like an adult. On the other hand an adult who has become neurotic owing to his libido being unsatisfied behaves in his anxiety like a child: he begins to be frightened when he is alone, that is to say when he is away from someone of whose love he had felt secure, and he seeks to assuage this fear by the most childish measures.¹

¹ For this explanation of the origin of infantile anxiety I have to thank a three-year-old boy whom I once heard calling out of a dark room: 'Auntie, speak to me! I'm frightened because it's so dark.' His aunt answered him: 'What good would that do? You can't see me.' 'That doesn't matter,' replied the child, 'if anyone speaks, it gets light.' Thus what he was afraid of was not the dark, but the absence of someone he loved; and he could feel sure of being soothed as soon as he had evidence of that person's presence.

[Added 1920:] One of the most important results of psycho-analytic research is this discovery that neurotic anxiety arises out of libido, that it is the product of a transformation of it, and that it is thus related to it in the same kind of way as vinegar is to wine. A further discussion of this problem will be found in my Introductory Lectures (1916-17), Lecture XXV, though even there it must be confessed, the question is not finally cleared up.

[1905d, 1537]

For Hanold's dream was an anxiety-dream. Its content was frightening, the dreamer felt anxiety while he slept and he was left with painful feelings afterwards. Now this is far from convenient for our attempt at an explanation; and we must once again borrow heavily from the theory of dream-interpretation. We are warned by that theory not to fall into the error of tracing the anxiety that may be felt in a dream to the content of the dream, and not to treat the content of the dream as though it were the content of an idea occurring in waking life. It points out to us how often we dream the most ghastly things without feeling a trace of anxiety. The true situation, we learn, is quite a different one, which cannot be easily guessed, but which can be proved with certainty. The anxiety in anxiety-dreams, like neurotic anxiety in general, corresponds to a sexual affect, a libidinal feeling, and arises out of libido by the process of repression.¹ When we interpret a dream, therefore, we must replace anxiety by sexual excitement. The anxiety that originates in this way has - not invariably, but frequently - a selective influence on the content of the dream and introduces into it ideational elements which seem, when the dream is looked at from a conscious and mistaken point of view, to be appropriate to the affect of anxiety. As I have said, this is not invariably so, for there are plenty of anxiety-dreams in which the content is not in the least frightening and where it is therefore impossible to give an explanation on conscious lines of the anxiety that is felt.

[1907a, 1856]
(a) It is not difficult to establish the fact that expectant anxiety or general apprehensiveness is closely dependent on certain happenings in sexual life, or, let us say, certain employments of the libido. The simplest and most instructive case of this sort occurs in people who expose themselves to what is known as unconsummated excitation - that is, people in whom violent sexual excitations meet with no sufficient discharge, cannot be brought to a satisfying conclusion - men for instance, while they are engaged to be married, and women whose husbands are insufficiently potent or, as a precaution, perform the sexual act in an incomplete or curtailed fashion. In such circumstances the libidinal excitation vanishes and anxiety appears in its place whether in the form of expectant anxiety or in attacks and anxiety-equivalents. Interruption of the sexual act as a precaution, if it is practised as a sexual régime, is such a regular cause of anxiety neurosis in men, but more particularly in women, that in medical practice it is advisable in such cases to begin by investigating this aetiology. It will then be found on countless occasions that the anxiety neurosis disappears when the sexual abuse is discontinued.

[1916-1917, 3448]

Of course, the sexual abstinence now so warmly recommended by doctors only has the same importance in generating anxiety states when the libido which is prevented from finding a satisfying discharge is correspondingly strong and has not been dealt with for the greater part by sublimation. Indeed, the decision on whether the outcome is to be illness or not always lies with quantitative factors. Even where what is in question is not illness but the form assumed by a person's character, it is easy to recognize that sexual restriction goes hand in hand with some kind of anxiousness and hesitancy, while intrepidity and impudent daring bring along with them a free indulgence of sexual needs. However much these relations are altered and complicated by a variety of cultural influences, it nevertheless remains true of the average of mankind that anxiety has a close connection with sexual limitation.

[1916-1917, 3449]

I have said that transformation into anxiety - it would be better to say discharge in the form of anxiety - is the immediate vicissitude of libido which is subjected to repression. I must add that that vicissitude is not the only or the definitive one. In the neuroses processes are in action which endeavour to bind this generating of anxiety and which even succeed in doing so in various ways. In phobias, for instance, two phases of the neurotic process can be clearly distinguished. The first is concerned with repression and the changing of libido into anxiety, which is then bound to an external danger. The second consists in the erection of all the precautions and guarantees by means of which any contact can be avoided with this danger, treated as it is like an external thing. Repression corresponds to an attempt at flight by the ego from libido which is felt as a danger. A phobia may be compared to an entrenchment against an external danger which now represents the dreaded libido. The weakness of the defensive system in phobias lies, of course, in the fact that the fortress which has been so greatly strengthened towards the outside remains assailable from within. A projection outwards of the danger of libido can never succeed thoroughly. For that reason, in other neuroses other systems of defence are in use against the possible generation of anxiety. That is a most interesting part of the psychology of the neuroses; but unluckily it would lead us too far and it presupposes a deeper specialized knowledge. I will only add one thing more. I have already spoken to you of the 'anticathexis' which is employed by the ego in the process of repression and which must be permanently maintained in order that the repression may have stability. This anticathexis has the task of carrying through the various forms of defence against the generating of anxiety after repression.

[1916-1917, 3456]
We thus find ourselves convinced that the problem of anxiety occupies a place in the question of the psychology of the neuroses which may rightly be described as central. We have received a strong impression of the way in which the generation of anxiety is linked to the vicissitudes of the libido and the system of the unconscious. There is only a single point that we have found disconnected - a gap in our views: the single, yet scarcely disputable, fact that realistic anxiety must be regarded as a manifestation of the ego's self-preservative instincts.

LADIES AND GENTLEMEN, - We have repeatedly (and only recently once again) had to deal with the distinction between the ego-instincts and the sexual instincts. In the first place, repression showed us that the two can come into opposition to each other, that the sexual instincts are then ostensibly subdued and are obliged to find satisfaction for themselves along regressive and roundabout paths, and that in doing so they are able to find compensation for their defeat in their indomitability. We next learnt that the two kinds of instincts are from the first differently related to Necessity the educator, so that their course of development is not the same and they do not enter into the same connection with the reality principle. Lastly, we seem to have found that the sexual instincts are linked by much closer bonds than the ego-instincts to the affective state of anxiety - a conclusion which seems incomplete in only one important respect. In order to establish it more firmly, therefore, I will bring forward the further noteworthy fact that if hunger and thirst (the two most elementary self-preservative instincts) are unsatisfied, the result is never their transformation into anxiety, whereas the changing of unsatisfied libido into anxiety is, as we have seen, among the best known and most frequently observed of phenomena.

Let me once more, however, return for a moment to anxiety, to throw light on a last obscurity that we left there. I have said that there is something that does not tally with the relation (so thoroughly recognized apart from this) between anxiety and libido: the fact, namely, that realistic anxiety in face of a danger seems to be a manifestation of the self-preservative instinct - which, after all, can scarcely be disputed. How would it be, though, if what was responsible for the affect of anxiety was not the egoistic ego-instincts but the ego-libido? After all, the state of anxiety is in every instance inexpedient, and its inexpediency becomes obvious if it reaches a fairly high pitch. In such cases it interferes with action, whether flight or defence, which alone is expedient and alone serves the cause of self-preservation. If, therefore, we attribute the affective portion of realistic anxiety to ego-libido and the accompanying action to the self-preservative instinct, we shall have got rid of the theoretical difficulty. After all, you do not seriously believe that one runs away because one feels anxiety? No. One feels anxiety and one runs away for a common motive, which is roused by the perception of danger. People who have been through a great mortal danger tell us that they were not at all afraid but merely acted - for instance, that they aimed their rifle at the wild beast - and that is unquestionably what was most expedient.

It only became possible to extend the libido theory to the narcissistic neuroses after the concept of a 'narcissistic libido' had been put forward and applied - a concept, that is, of an amount of sexual energy attached to the ego itself and finding satisfaction in the ego just as satisfaction is usually found only in objects. This entirely legitimate development of the concept of sexuality promises to accomplish as much for the severer neuroses and for the psychoses as can be expected of a theory which is feeling its way forwards on an empirical basis. The traumatic neuroses of peace will also fit into the scheme as soon as a successful outcome has been reached of our investigations into the relations which undoubtedly exist between fright, anxiety and narcissistic libido.
Our investigations were far from remaining unsuccessful: we reached a few important conclusions. In regard to anxious expectation clinical experience revealed that it had a regular connection with the libidinal economics of sexual life. The commonest cause of anxiety neurosis is unconsummated excitation. Libidinal excitation is aroused but not satisfied, not employed; apprehensiveness then appears instead of this libido that has been diverted from its employment. I even thought I was justified in saying that this unsatisfied libido was directly changed into anxiety. This view found support in some quite regularly occurring phobias of small children. Many of these phobias are very puzzling to us, but others, such as the fear of being alone and the fear of strangers, can be explained with certainty. Loneliness as well as a strange face arouse the child’s longing for his familiar mother; he is unable to control this libidinal excitation, he cannot hold it in suspense but changes it into anxiety. This infantile anxiety must therefore be regarded not as of the realistic but as of the neurotic kind. Infantile phobias and the expectation of anxiety in anxiety neurosis offer us two examples of one way in which neurotic anxiety originates: by a direct transformation of libido. We shall at once come to know of a second mechanism, but it will turn out not to be very different from the first.

[1933a, 4689]

At the conclusion of my earlier lecture on anxiety I myself expressed the opinion that, although these various findings of our enquiry were not mutually contradictory, somehow they did not fit in with one another. Anxiety, it seems, in so far as it is an affective state, is the reproduction of an old event which brought a threat of danger; anxiety serves the purposes of self-preservation and is a signal of a new danger; it arises from libido that has in some way become unemployable and it also arises during the process of repression; it is replaced by the formation of a symptom, is, as it were, psychically bound - one has a feeling that something is missing here which would bring all these pieces together into a whole.

[1933a, 4691]
The following theoretical discussion can only claim to have the value of a first, groping attempt; criticism of it ought not to affect an acceptance of the facts which have been brought forward above. Moreover, an assessment of this ‘theory of anxiety neurosis’ is made the more difficult from being only a fragment of a more comprehensive account of the neuroses. [1895b, 343]

A further point of departure is furnished by the observation, not so far mentioned, that in whole sets of cases anxiety neurosis is accompanied by a most noticeable decrease of sexual libido or psychical desire, so that on being told that their complaint results from 'insufficient satisfaction', patients regularly reply that that is impossible, for precisely now all sexual need has become extinguished in them. From all these indications - that we have to do with an accumulation of excitation; that the anxiety which probably corresponds to this accumulated excitation is of somatic origin, so that what is being accumulated is a somatic excitation; and, further, that this somatic excitation is of a sexual nature and that a decrease of psychical participation in the sexual processes goes along with it - all these indications, I say, incline us to expect that the mechanism of anxiety is to be looked for in a deflection of somatic excitation from the psychical sphere, and in a consequent abnormal employment of that excitation. [1895b, 343]

An attempt to arrive at a theory of anxiety neurosis leads to a formula to the effect that its mechanism lies in the deflection of somatic sexual excitation from the psychical field and a consequent abnormal employment of that excitation. Neurotic anxiety is transformed sexual libido. [1897b, 447]

Thus, in every case of neurosis there is a sexual aetiology; but in neurasthenia it is an aetiology of a present-day kind, whereas in the psychoneuroses the factors are of an infantile nature. This is the first great contrast in the aetiology of the neuroses. A second one emerges when we take account of a difference in the symptomatology of neurasthenia itself. Here, on the one hand, we find cases in which certain complaints characteristic of neurasthenia (intracranial pressure, proneness to fatigue, dyspepsia, constipation, spinal irritation, etc.) are prominent; in other cases these signs play a minor part and the clinical picture is composed of other symptoms, all of which exhibit a relation to the nuclear symptom, that of anxiety (free anxiousness, unrest, expectant anxiety, complete, rudimentary or supplementary anxiety attacks, locomotor vertigo, agoraphobia, insomnia, increased sensitivity to pain, and so on). I have left the name of neurasthenia to the first type, but have distinguished the second type as 'anxiety neurosis'; and I have given reasons for this separation in another place, where I have also taken account of the fact that as a rule both neuroses appear together. For the present purpose it is enough to emphasize that parallel to the difference in the symptoms of these two forms of illness there goes a difference in their aetiology. Neurasthenia can always be traced back to a condition of the nervous system such as is acquired by excessive masturbation or arises spontaneously from frequent emissions; anxiety neurosis regularly discloses sexual influences which have in common the factor of reservation or of incomplete satisfaction - such as coitus interruptus, abstinence together with a lively libido, so-called unconsummated excitation, and so on. In my short paper intended to introduce anxiety neurosis I put forward the formula that anxiety is always libido which has been deflected from its employment. [1897b, 460]
Since this intimate connection exists between anxiety in dreams and in neuroses, in discussing the former I must refer to the latter. In a short paper on anxiety-neurosis (Freud, 1895b), I argued some time ago that neurotic anxiety is derived from sexual life and corresponds to libido which has been diverted from its purpose and has found no employment. Since then this formula has met the test of time; and it enables us now to infer from it that anxiety-dreams are dreams with a sexual content, the libido belonging to which has been transformed into anxiety. There will be an opportunity later to support this assertion by the analysis of some neurotic patients’ dreams. In the course, too, of a further attempt to arrive at a theory of dreams, I shall have occasion to discuss once more the determinants of anxiety-dreams and their compatibility with the theory of wish-fulfilment.

[1900a, 654]

This state of affairs is what makes possible one group of anxiety-dreams - dream-structures unpropitious from the point of view of the wish-theory. A second group of them reveal a different mechanism; for anxiety in dreams may be psychoneurotic anxiety: it may originate from psychosexual excitations - in which case the anxiety corresponds to repressed libido. Where this is so, the anxiety, like the whole anxiety-dream, has the significance of a neurotic symptom, and we come near the limit at which the wish-fulfilling purpose of dreams breaks down. But there are some anxiety dreams in which the feeling of anxiety is determined somatically - where, for instance, there happens to be difficulty in breathing owing to disease of the lungs or heart - and in such cases the anxiety is exploited in order to assist the fulfilment in the form of dreams of energetically suppressed wishes which, if they had been dreamt about for psychical reasons, would have led to a similar release of anxiety. But there is no difficulty in reconciling these two apparently different groups. In both groups of dreams two psychical factors are involved: an inclination towards an affect and an ideational content; and these are intimately related to each other. If one of them is currently active, it calls up the other even in a dream; in the one case the somatically determined anxiety calls up the suppressed ideational content, and in the other the ideational content with its accompanying sexual excitation, having been set free from repression, calls up a release of anxiety. We can put it that in the first case a somatically determined affect is given a psychical interpretation; while in the other case, though the whole is psychically determined, the content which had been suppressed is easily replaced by a somatic interpretation appropriate to anxiety. The difficulties which all this offers to our understanding have little to do with dreams: they arise from the fact that we are here touching on the problem of the generation of anxiety and on the problem of repression.

[1900a, 715]

In other dreams, in which the 'not carrying out' of a movement occurs as a sensation and not simply as a situation, the sensation of the inhibition of a movement gives a more forcible expression to the same contradiction - it expresses a volition which is opposed by a counter-volition. Thus the sensation of the inhibition of a movement represents a conflict of will. We shall learn later that the motor paralysis accompanying sleep is precisely one of the fundamental determinants of the psychical process during dreaming. Now an impulse transmitted along the motor paths is nothing other than a volition, and the fact of our being so certain that we shall feel that impulse inhibited during sleep is what makes the whole process so admirably suited for representing an act of volition and a 'no' which opposes it. It is also easy to see, on my explanation of anxiety, why the sensation of an inhibition of will approximates so closely to anxiety and is so often linked with it in dreams. Anxiety is a libidinal impulse which has its origin in the unconscious and is inhibited by the preconscious.² When, therefore, the sensation of inhibition is linked with anxiety in a dream, it must be a question of an act of volition which was at one time capable of generating libido - that is, it must be a question of a sexual impulse.

[1900a, 806]
Our discussion cannot be carried any further without examining the part played by the affects in these processes; but we can only do so imperfectly in the present connection. Let us assume, then, that the suppression of the Ucs. is necessary above all because, if the course of ideas in the Ucs. were left to itself, it would generate an affect which was originally of a pleasurable nature, but became unpleasurable after the process of 'repression' occurred. The purpose, and the result too, of suppression is to prevent this release of unpleasure. The suppression extends over the ideational content of the Ucs., since the release of unpleasure might start from that content. This presupposes a quite specific assumption as to the nature of the generation of affect. It is viewed as a motor or secretory function, the key to whose innervation lies in the ideas in the Ucs. Owing to the domination established by the Pcs. these ideas are, as it were, throttled, and inhibited from sending out impulses which would generate affect. If, therefore, the cathexis from the Pcs. ceases, the danger is that the unconscious excitations may release affect of a kind which (as a result of the repression which has already occurred) can only be experienced as unpleasure, as anxiety.

[1900a, 1010]

The theory of anxiety-dreams, as I have already repeatedly declared, forms part of the psychology of the neuroses. We have nothing more to do with it when once we have indicated its point of contact with the topic of the dream-process. There is only one thing more that I can do. Since I have asserted that neurotic anxiety arises from sexual sources, I can submit some anxiety-dreams to analysis in order to show the sexual material present in their dream-thoughts.

[1900a, 1010]

There is really very little difficulty in inferring: (1) that the boy had masturbated when he was younger, that he had probably denied it, and that he had been threatened with severe punishment for his bad habit (cf. his admission: 'Je ne le ferais plus', and his denial: 'Albert n’a jamais fait ça'); (2) that with the onset of puberty the temptation to masturbate had revived with the tickling in his genitals; but (3) that a struggle for repression had broken out in him, which had suppressed his libido and transformed it into anxiety, and that the anxiety had taken over the punishments with which he had been threatened earlier.

[1900a, 1014]

INFANTILE ANXIETY   Children themselves behave from an early age as though their dependence on the people looking after them were in the nature of sexual love. Anxiety in children is originally nothing other than an expression of the fact that they are feeling the loss of the person they love. It is for this reason that they are frightened of every stranger. They are afraid in the dark because in the dark they cannot see the person they love; and their fear is soothed if they can take hold of that person's hand in the dark. To attribute to bogeys and blood-curdling stories told by nurses the responsibility for making children timid is to over-estimate their efficacy. The truth is merely that children who are inclined to be timid are affected by stories which would make no impression what ever upon others, and it is only children with a sexual instinct that is excessive or has developed prematurely or has become vociferous owing to too much petting who are inclined to be timid. In this respect a child, by turning his libido into anxiety when he cannot satisfy it, behaves like an adult. On the other hand an adult who has become neurotic owing to his libido being unsatisfied behaves in his anxiety like a child: he begins to be frightened when he is alone, that is to say when he is away from someone of whose love he had felt secure, and he seeks to assuage this fear by the most childish measures.¹

[1905d, 1537]
For this explanation of the origin of infantile anxiety I have to thank a three-year-old boy whom I once heard calling out of a dark room: 'Auntie, speak to me! I'm frightened because it's so dark.' His aunt answered him: 'What good would that do? You can't see me.' 'That doesn't matter,' replied the child, 'if anyone speaks, it gets light.' Thus what he was afraid of was not the dark, but the absence of someone he loved; and he could feel sure of being soothed as soon as he had evidence of that person's presence.

[Added 1920:] One of the most important results of psycho-analytic research is this discovery that neurotic anxiety arises out of libido, that it is the product of a transformation of it, and that it is thus related to it in the same kind of way as vinegar is to wine. A further discussion of this problem will be found in my Introductory Lectures (1916-17), Lecture XXV, though even there it must be confessed, the question is not finally cleared up.

For Hanold's dream was an anxiety-dream. Its content was frightening, the dreamer felt anxiety while he slept and he was left with painful feelings afterwards. Now this is far from convenient for our attempt at an explanation; and we must once again borrow heavily from the theory of dream-interpretation. We are warned by that theory not to fall into the error of tracing the anxiety that may be felt in a dream to the content of the dream, and not to treat the content of the dream as though it were the content of an idea occurring in waking life. It points out to us how often we dream the most ghastly things without feeling a trace of anxiety. The true situation, we learn, is quite a different one, which cannot be easily guessed, but which can be proved with certainty. The anxiety in anxiety-dreams, like neurotic anxiety in general, corresponds to a sexual affect, a libidinal feeling, and arises out of libido by the process of repression.¹ When we interpret a dream, therefore, we must replace anxiety by sexual excitement. The anxiety that originates in this way has - not invariably, but frequently - a selective influence on the content of the dream and introduces into it ideational elements which seem, when the dream is looked at from a conscious and mistaken point of view, to be appropriate to the affect of anxiety. As I have said, this is not invariably so, for there are plenty of anxiety-dreams in which the content is not in the least frightening and where it is therefore impossible to give an explanation on conscious lines of the anxiety that is felt.

I am aware that this explanation of anxiety in dreams sounds very strange and is not easy to credit; but I can only advise the reader to come to terms with it. Moreover it would be a very remarkable thing if Norbert Hanold's dream could be reconciled with this view of anxiety and could be explained in that way. On that basis, we should say that the dreamer's erotic longings were stirred up during the night and made a powerful effort to make conscious his memory of the girl he loved and so to tear him out of his delusion, but that those longings met with a fresh repudiation and were transformed into anxiety, which in its turn introduced into the content of the dream the terrifying pictures from the memories of his schooldays. In this manner the true unconscious content of the dream, his passionate longing for the Zoe he had once known, became transformed into its manifest content of the destruction of Pompeii and the loss of Gradiva.
Here, then, we have the beginning of Hans's anxiety as well as of his phobia. As we see, there is good reason for keeping the two separate. Moreover, the material seems to be amply sufficient for giving us our bearings; and no moment of time is so favourable for the understanding of a case as its initial stage, such as we have here, though unluckily that stage is as a rule neglected or passed over in silence. The disorder set in with thoughts that were at the same time fearful and tender, and then followed an anxiety dream on the subject of losing his mother and so not being able to coax with her any more. His affection for his mother must therefore have become enormously intensified. This was the fundamental phenomenon in his condition. In support of this, we may, recall his two attempts at seducing his mother, the first of which dated back to the summer, while the second (a simple commendation of his penis) occurred immediately before the outbreak of his street-anxiety. It was this increased affection for his mother which turned suddenly into anxiety - which, as we should say, succumbed to repression. We do not yet know from what quarter the impetus towards repression may have come. Perhaps it was merely the result of the intensity of the child's emotions, which had become greater than he could control; or perhaps other forces which we have not yet recognized were also at work. This we shall learn as we go on. Hans's anxiety, which thus corresponded to a repressed erotic longing, was, like every infantile anxiety, without an object to begin with: it was still anxiety and not yet fear. The child cannot tell what he is afraid of; and when Hans, on the first walk with the nursemaid, would not say what he was afraid of, it was simply that he himself did not yet know. He said all that he knew, which was that in the street he missed his mother, whom he could coax with, and that he did not want to be away from her. In saying this he quite straightforwardly confessed the primary meaning of his dislike of streets. [1909b, 2017]

His anxiety, then, corresponded to repressed longing. But it was not the same thing as the longing: the repression must be taken into account too. Longing can be completely transformed into satisfaction if it is presented with the object longed for. Therapy of that kind is no longer effective in dealing with anxiety. The anxiety remains even when the longing can be satisfied. It can no longer be completely retransformed into libido; there is something that keeps the libido back under repression.¹ This was shown to be so in the case of Hans on the occasion of his next walk, when his mother went with him. He was with his mother, and yet he still suffered from anxiety - that is to say, from an unsatisfied longing for her. It is true that the anxiety was less; for he did allow himself to be induced to go for the walk, whereas he had obliged the nursemaid to turn back. Nor is a street quite the right place for ‘coaxing’, or whatever else this young lover may have wanted. But his anxiety had stood the test; and the next thing for it to do was to find an object. It was on this walk that he first expressed a fear that a horse would bite him. Where did the material for this phobia come from? Probably from the complexes, as yet unknown to us, which had contributed to the repression and were keeping under repression his libidinal feelings towards his mother. That is an unsolved problem, and we shall now have to follow the development of the case in order to arrive at its solution. Hans's father has already given us certain clues, probably trustworthy ones, such as that Hans had always observed horses with interest on account of their large widdlers, that he had supposed that his mother must have a widdler like a horse, and so on. We might thus be led to think that the horse was merely a substitute for his mother. But if so, what would be the meaning of his being afraid in the evening that a horse would come into the room? A small boy’s foolish fears, it will be said. But a neurosis never says foolish things, any more than a dream. When we cannot understand something, we always fall back on abuse. An excellent way of making a task lighter. [1909b, 2019]
One day while Hans was in the street he was seized with an attack of anxiety. He could not yet say what it was he was afraid of; but at the very beginning of this anxiety-state he betrayed to his father his motive for being ill, the advantage he derived from it. He wanted to stay with his mother and to coax with her; his recollection that he had also been separated from her at the time of the baby's birth may also, as his father suggests, have contributed to his longing. It soon became evident that his anxiety was no longer reconvertible into longing; he was afraid even when his mother went with him. In the meantime indications appeared of what it was to which his libido (now changed into anxiety) had become attached. He gave expression to the quite specific fear that a white horse would bite him.

[1909b, 2099]

But the beginnings of this psychological situation go back further still. During the preceding summer Hans had had similar moods of mingled longing and apprehension, in which he had said similar things; and at that time they had secured him the advantage of being taken by his mother into her bed. We may assume that since then Hans had been in a state of intensified sexual excitement, the object of which was his mother. The intensity of this excitement was shown by his two attempts at seducing his mother (the second of which occurred just before the outbreak of his anxiety); and he found an incidental channel of discharge for it by masturbating every evening and in that way obtaining gratification. Whether the sudden change-over of this excitement into anxiety took place spontaneously, or as a result of his mother's rejection of his advances, or owing to the accidental revival of earlier impressions by the 'precipitating cause' of his illness (about which we shall hear presently) - this we cannot decide; and, indeed, it is a matter of indifference, for these three alternative possibilities cannot be regarded as mutually incompatible. The fact remains that his sexual excitement suddenly changed into anxiety.

[1909b, 2101]

Quite unexpectedly, and certainly without any prompting from his father, Hans now began to be occupied with the 'lumf' complex, and to show disgust at things that reminded him of evacuating his bowels. His father, who was reluctant to go with him along that line, pushed on with the analysis through thick and thin in the direction in which he wanted to go. He elicited from Hans the recollection of an event at Gmunden, the impression of which lay concealed behind that of the falling bus-horse. While they were playing at horses, Fritzl, the playmate of whom he was so fond, but at the same time, perhaps, his rival with his many girl friends, had hit his foot against a stone and had fallen down, and his foot had bled. Seeing the bus-horse fall had reminded him of this accident. It deserves to be noticed that Hans, who was at the moment concerned with other things, began by denying that Fritzl had fallen down (though this, was the event which formed the connection between the two scenes) and only admitted it at a later stage of the analysis. It is especially interesting, however, to observe the way in which the transformation of Hans's libido into anxiety was projected on to the principal object of his phobia, on to horses. Horses interested him the most of all the large animals; playing at horses was his favourite game with the other children. I had a suspicion - and this was confirmed by Hans's father when I asked him - that the first person who had served Hans as a horse must have been his father; and it was this that had enabled him to regard Fritzl as a substitute for his father when the accident happened at Gmunden. When repression had set in and brought a revulsion of feeling along with it, horses, which had till then been associated with so much pleasure, were necessarily turned into objects of fear.

[1909b, 2108]
It is hard to say what the influence was which, in the situation we have just sketched, led to the sudden change in Hans and to the transformation of his libidinal longing into anxiety - to say from what direction it was that repression set in. The question could probably only be decided by making a comparison between this analysis and a number of similar ones. Whether the scales were turned by the child's *intellectual* inability to solve the difficult problem of the begetting of children and to cope with the aggressive impulses that were liberated by his approaching its solution, or whether the effect was produced by a *somatic* incapacity, a constitutional intolerance of the masturbatory gratification in which he regularly indulged (whether, that is, the mere persistence of sexual excitement at such a high pitch of intensity was bound to bring about a revulsion) - this question must be left open until fresh experience can come to our assistance.

[1909b, 2115]

Nevertheless, the neurosis took its start directly from this chance event and preserved a trace of it in the circumstance of the horse being exalted into the object of his anxiety. In itself the impression of the accident which he happened to witness carried no ‘traumatic force’; it acquired its great effectiveness only from the fact that horses had formerly been of importance to him as objects of his predilection and interest, from the fact that he associated the event in his mind with an earlier event at Gmunden which had more claim to be regarded as traumatic, namely, with Fritzl's falling down while he was playing at horses, and lastly from the fact that there was an easy path of association from Fritzl to his father. Indeed, even these connections would probably not have been sufficient if it had not been that, thanks to the pliability and ambiguity of associative chains, the same event showed itself capable of stirring the second of the complexes that lurked in Hans's unconscious, the complex of his pregnant mother's confinement. From that moment the way was clear for the return of the repressed; and it returned in such a manner that *the pathogenic material was remodelled and transposed on to the horse-complex, while the accompanying affects were uniformly transformed into anxiety.*

[1909b, 2115]

In the second place, we cannot help being struck by the fact that a sense of guilt has about it much of the nature of anxiety: we could describe it without any misgivings as ‘dread of conscience’. But the anxiety points to unconscious sources. The psychology of the neuroses has taught us that, if wishful impulses are repressed, their libido is transformed into anxiety. And this reminds us that there is something unknown and unconscious in connection with the sense of guilt, namely the reasons for the act of repudiation. The character of anxiety that is inherent in the sense of guilt corresponds to this unknown factor.

[1912-1913, 2713]
The two cases are in fact not on all fours. In the first place, it may happen that an affective or emotional impulse is perceived but misconstrued. Owing to the repression of its proper representative it has been forced to become connected with another idea, and is now regarded by consciousness as the manifestation of that idea. If we restore the true connection, we call the original affective impulse an ‘unconscious’ one. Yet its affect was never unconscious; all that had happened was that its idea had undergone repression. In general, the use of the terms 'unconscious affect' and 'unconscious emotion' has reference to the vicissitudes undergone, in consequence of repression, by the quantitative factor in the instinctual impulse. We know that three such vicissitudes are possible:¹ either the affect remains, wholly or in part, as it is; or it is transformed into a qualitatively different quota of affect, above all into anxiety; or it is suppressed, i.e. it is prevented from developing at all. (These possibilities may perhaps be studied even more easily in the dream-work than in neuroses.) We know, too, that to suppress the development of affect is the true aim of repression and that its work is incomplete if this aim is not achieved. In every instance where repression has succeeded in inhibiting the development of affects, we term those affects (which we restore when we undo the work of repression) 'unconscious'. Thus it cannot be denied that the use of the terms in question is consistent; but in comparison with unconscious ideas there is the important difference that unconscious ideas continue to exist after repression as actual structures in the system Ucs., whereas all that corresponds in that system to unconscious affects is a potential beginning which is prevented from developing. Strictly speaking, then, and although no fault can be found with the linguistic usage, there are no unconscious affects as there are unconscious ideas. But there may very well be in the system Ucs. affective structures which, like others, become conscious. The whole difference arises from the fact that ideas are cathexes - basically of memory-traces - whilst affects and feelings correspond to processes of discharge, the final manifestations of which are perceived as feelings. In the present state of our knowledge of affects and feelings we cannot express this difference more clearly.

[1915e, 3001]

The importance of the system Cs. (Pcs.) as regards access to the release of affect and to action enables us also to understand the part played by substitutive ideas in determining the form taken by illness. It is possible for the development of affect to proceed directly from the system Ucs.; in that case the affect always has the character of anxiety, for which all 'repressed' affects are exchanged. Often, however, the instinctual impulse has to wait until it has found a substitutive idea in the system Cs. The development of affect can then proceed from this conscious substitute, and the nature of that substitute determines the qualitative character of the affect. We have asserted that in repression a severance takes place between the affect and the idea to which it belongs, and that each then undergoes its separate vicissitudes. Descriptively, this is incontrovertible; in actuality, however, the affect does not as a rule arise till the break-through to a new representation in the system Cs. has been successfully achieved.

[1915e, 3002]

In anxiety hysteria a first phase of the process is frequently overlooked, and may perhaps be in fact missed out; on careful observation, however, it can be clearly discerned. It consists in anxiety appearing without the subject knowing what he is afraid of. We must suppose that there was present in the Ucs. some love-impulse demanding to be transposed into the system Pcs.; but the cathexis directed to it from the latter system has drawn back from the impulse (as though in an attempt at flight) and the unconscious libidinal cathexis of the rejected idea has been discharged in the form of anxiety.

[1915e, 3005]
On the occasion of a repetition (if there should be one) of this process, a first step is taken in the direction of mastering the unwelcome development of anxiety. The cathexis that has taken flight attaches itself to a substitutive idea which, on the one hand, is connected by association with the rejected idea, and, on the other, has escaped repression by reason of its remoteness from that idea. This substitutive idea - a 'substitute by displacement' - permits the still uninhibitable development of anxiety to be rationalized. It now plays the part of an anticathexis for the system Cs. (Pcs.), by securing it against an emergence in the Cs. of the repressed idea. On the other hand it is, or acts as if it were, the point of departure for the release of the anxiety-affect, which has now really become quite uninhibitable. Clinical observation shows, for instance, that a child suffering from an animal phobia experiences anxiety under two kinds of conditions: in the first place, when his repressed love-impulse becomes intensified, and, in the second, when he perceives the animal he is afraid of. The substitutive idea acts in the one instance as a point at which there is a passage across from the system Ucs. to the system Cs., and, in the other instance, as a self-sufficing source for the release of anxiety. The extending dominance of the system Cs. usually manifests itself in the fact that the first of these two modes of excitation of the substitutive idea gives place more and more to the second. The child may perhaps end by behaving as though he had no predilection whatever towards his father but had become quite free from him, and as though his fear of the animal was a real fear - except that this fear of the animal, fed as such a fear is from an unconscious instinctual source, proves obdurate and exaggerated in the face of all influences brought to bear from the system Cs., and thereby betrays its derivation from the system Ucs. - In the second phase of anxiety hysteria, therefore, the anticathexis from the system Cs. has led to substitute-formation.

(a) It is not difficult to establish the fact that expectant anxiety or general apprehensiveness is closely dependent on certain happenings in sexual life, or, let us say, certain employments of the libido. The simplest and most instructive case of this sort occurs in people who expose themselves to what is known as unconsummated excitation - that is, people in whom violent sexual excitations meet with no sufficient discharge, cannot be brought to a satisfying conclusion - men for instance, while they are engaged to be married, and women whose husbands are insufficiently potent or, as a precaution, perform the sexual act in an incomplete or curtailed fashion. In such circumstances the libidinal excitation vanishes and anxiety appears in its place whether in the form of expectant anxiety or in attacks and anxiety-equivalents. Interruption of the sexual act as a precaution, if it is practised as a sexual régime, is such a regular cause of anxiety neurosis in men, but more particularly in women, that in medical practice it is advisable in such cases to begin by investigating this aetiology. It will then be found on countless occasions that the anxiety neurosis disappears when the sexual abuse is discontinued.

Of course, the sexual abstinence now so warmly recommended by doctors only has the same importance in generating anxiety states when the libido which is prevented from finding a satisfying discharge is correspondingly strong and has not been dealt with for the greater part by sublimation. Indeed, the decision on whether the outcome is to be illness or not always lies with quantitative factors. Even where what is in question is not illness but the form assumed by a person's character, it is easy to recognize that sexual restriction goes hand in hand with some kind of anxiousness and hesitancy, while intrepidity and impudent daring bring along with them a free indulgence of sexual needs. However much these relations are altered and complicated by a variety of cultural influences, it nevertheless remains true of the average of mankind that anxiety has a close connection with sexual limitation.
I am far from having told you of all the observations that speak in favour of the genetic relation I have asserted to exist between libido and anxiety. Among them, for instance, is the influence on anxiety disorders of certain phases of life to which, as in the case of puberty and the time of the menopause, a considerable increase in the production of libido may be attributed. In some states of excitement, too, it is possible to observe directly a mixture of libido and anxiety and the final replacement of libido by anxiety. The impression one gains from all these facts is twofold: first, that what is in question is an accumulation of libido which is kept away from its normal employment, and secondly, that here we are entirely in the sphere of somatic processes. How anxiety arises from libido is not at first discernible; we can only recognize that libido is absent and that anxiety is observed in its place.

Our observations on anxiety neurosis led us to conclude that the deflection of the libido from its normal employment, which causes the development of anxiety, takes place in the region of somatic processes. Analyses of hysteria and obsessional neurosis yield the additional conclusion that a similar deflection with the same outcome may also be the result of a refusal on the part of the psychical agencies. This much, therefore, we know about the origin of neurotic anxiety. It still sounds fairly indefinite; but for the moment I see no path that would lead us further. The second problem we set ourselves - of establishing a connection between neurotic anxiety, which is libido put to an abnormal employment, and realistic anxiety, which corresponds to a reaction to danger - seems even harder to solve. One might suppose that these were two quite disparate things; and yet we have no means of distinguishing in our feelings between realistic anxiety and neurotic anxiety.

In children the first phobias relating to situations are those of darkness and solitude. The former of these often persists throughout life; both are involved when a child feels the absence of some loved person who looks after it - its mother, that is to say. While I was in the next room, I heard a child who was afraid of the dark call out: 'Do speak to me, Auntie! I'm frightened!' 'Why, what good would that do? You can't see me.' To this the child replied: 'If someone speaks, it gets lighter.' Thus a longing felt in the dark is transformed into a fear of the dark. Far from its being the case that neurotic anxiety is only secondary and a special case of realistic anxiety, we see on the contrary that in a small child something that behaves like realistic anxiety shares its essential feature - origin from unemployed libido - with neurotic anxiety. Innately, children seem to have little true realistic anxiety. In all the situations which can later become determinants of phobias (on heights, on narrow bridges over water, on railway journeys, on ships) children exhibit no anxiety; and, to be sure, the greater their ignorance the less their anxiety. It would have been a very good thing if they had inherited more of such life-preserving instincts, for that would have greatly facilitated the task of watching over them to prevent their running into one danger after another. The fact is that children, to begin with, over-estimate their strength and behave fearlessly because they are ignorant of dangers. They will run along the brink of the water, climb on to the window-sill, play with sharp objects and with fire - in short, do everything that is bound to damage them and to worry those in charge of them. When in the end realistic anxiety is awakened in them, that is wholly the result of education; for they cannot be allowed to make the instructive experiences themselves.

Let me sum up what we have learnt from our observations of the apprehensiveness of children. Infantile anxiety has very little to do with realistic anxiety, but, on the other hand, is closely related to the neurotic anxiety of adults. Like the latter, it is derived from unemployed libido and it replaces the missing love-object by an external object or by a situation.
You will be glad to hear that the analysis of phobias has not much more that is new to teach us. For the same thing happens with them as with children's anxiety: unemployable libido is being constantly transformed into an apparently realistic anxiety and thus a tiny external danger is introduced to represent the claims of the libido. There is nothing to be wondered at in this agreement, for the infantile phobias are not only the prototype of the later ones which we class as 'anxiety hysteria' but are actually their precondition and the prelude to them. Every hysterical phobia goes back to an infantile anxiety and is a continuation of it, even if it has a different content and must thus be given another name. The difference between the two disorders lies in their mechanism. In order that libido shall be changed into anxiety, it no longer suffices in the case of adults for the libido to have become momentarily unemployable in the form of a longing. Adults have long since learnt how to hold such libido in suspense or to employ it in some other way. If, however, the libido belongs to a psychical impulse which has been subjected to repression, then circumstances are re-established similar to those in the case of a child in whom there is still no distinction between conscious and unconscious; and by mean of regression to the infantile phobia a passage is opened, as it were, through which the transformation of libido into anxiety can be comfortably accomplished.

[1916-1917, 3455]

I have said that transformation into anxiety - it would be better to say discharge in the form of anxiety - is the immediate vicissitude of libido which is subjected to repression. I must add that that vicissitude is not the only or the definitive one. In the neuroses processes are in action which endeavour to bind this generating of anxiety and which even succeed in doing so in various ways. In phobias, for instance, two phases of the neurotic process can be clearly distinguished. The first is concerned with repression and the changing of libido into anxiety, which is then bound to an external danger. The second consists in the erection of all the precautions and guarantees by means of which any contact can be avoided with this danger, treated as if it were something external. Repression corresponds to an attempt at flight by the ego from libido which is felt as a danger. A phobia may be compared to an entrenchment against an external danger which now represents the dreaded libido. The weakness of the defensive system in phobias lies, of course, in the fact that the fortress which has been so greatly strengthened towards the outside remains assailable from within. A projection outwards of the danger of libido can never succeed thoroughly. For that reason, in other neuroses other systems of defence are in use against the possible generation of anxiety. That is a most interesting part of the psychology of the neuroses; but unluckily it would lead us too far and it presupposes a deeper specialized knowledge. I will only add one thing more. I have already spoken to you of the 'anticathexis' which is employed by the ego in the process of repression and which must be permanently maintained in order that the repression may have stability. This anticathexis has the task of carrying through the various forms of defence against the generating of anxiety after repression.

[1916-1917, 3456]

We thus find ourselves convinced that the problem of anxiety occupies a place in the question of the psychology of the neuroses which may rightly be described as central. We have received a strong impression of the way in which the generation of anxiety is linked to the vicissitudes of the libido and the system of the unconscious. There is only a single point that we have found disconnected - a gap in our views: the single, yet scarcely disputable, fact that realistic anxiety must be regarded as a manifestation of the ego's self-preservative instincts.

[1916-1917, 3457]
LADIES AND GENTLEMEN, - We have repeatedly (and only recently once again) had to deal with
the distinction between the ego-instincts and the sexual instincts. In the first place, repression
showed us that the two can come into opposition to each other, that the sexual instincts are
then ostensibly subdued and are obliged to find satisfaction for themselves along regressive
and roundabout paths, and that in doing so they are able to find compensation for their defeat in
their indomitability. We next learnt that the two kinds of instincts are from the first differently
related to Necessity the educator, so that their course of development is not the same and they
do not enter into the same connection with the reality principle. Lastly, we seem to have found
that the sexual instincts are linked by much closer bonds than the ego-instincts to the affective
state of anxiety - a conclusion which seems incomplete in only one important respect. In order
to establish it more firmly, therefore, I will bring forward the further noteworthy fact that if hunger
and thirst (the two most elementary self-preservative instincts) are unsatisfied, the result is
never their transformation into anxiety, whereas the changing of unsatisfied libido into anxiety is,
as we have seen, among the best known and most frequently observed of phenomena.
[1916-1917, 3458]

The form of disease known as paranoia, chronic systematic insanity, occupies an unsettled
position in the attempts at classification made by present-day psychiatry. There is, however, no
doubt of its close affinity to dementia praecox. I once ventured to suggest that paranoia and
dementia praecox should be brought together under the common designation of 'paraphrenia'.
The forms of paranoia are described according to their content as megalomania, persecution
mania, erotomania, delusions of jealousy, and so on. We shall not expect anything much in the
way of an attempt at an explanation from psychiatry. Here is an example of one, though, it is
ture, one that is out of date and does not carry much weight - an attempt to derive one symptom
from another by means of an intellectual rationalization: it is suggested that the patient, who,
owing to a primary disposition, believes that he is being persecuted, infers from his persecution
that he must be someone of quite particular importance and so develops megalomania.
According to our analytic view the megalomania is the direct result of a magnification of the ego
due to the drawing in of the libidinal object-cathexes - a secondary narcissism which is a return
of the original early infantile one. We have, however, made a few observations of persecution
mania which have induced us to follow a particular track. The first thing that struck us was that
in the large majority of cases the persecutor was of the same sex as the persecuted patient.
This was still open to an innocent explanation; but in a few cases that were thoroughly studied it
was clear that the person of the same sex whom the patient loved most had, since his illness,
been turned into his persecutor. This made a further development possible: namely, the
replacement of the beloved person, along the line of familiar resemblances, by someone else -
for instance, a father by a schoolmaster or by some superior. Experiences of this kind in ever
increasing numbers led us to conclude that paranoia persecutoria is the form of the disease in
which a person is defending himself against a homosexual impulse which has become too
powerful. The change over from affection to hatred, which, it is well known, may become a
serious threat to the life of the loved and hated object, corresponds in such cases to the
transformation of libidinal impulses into anxiety which is a regular outcome of the process of
repression. Listen, for instance, to what is, once again, the most recent instance of my
observations in this connection.
[1916-1917, 3468]
But this explanation opens up fresh problems. Where does the energy come from which is employed for giving the signal of unpleasure? Here we may be assisted by the idea that a defence against an unwelcome internal process will be modelled upon the defence adopted against an external stimulus, that the ego wards off internal and external dangers alike along identical lines. In the case of external danger the organism has recourse to attempts at flight. The first thing it does is to withdraw cathexis from the perception of the dangerous object; later on it discovers that it is a better plan to perform muscular movements of such a sort as will render perception of the dangerous object impossible even in the absence of any refusal to perceive it - that it is a better plan, that is, to remove itself from the sphere of danger. Repression is an equivalent of this attempt at flight. The ego withdraws its (preconscious) cathexis from the instinctual representative that is to be repressed and uses that cathexis for the purpose of releasing unpleasure (anxiety). The problem of how anxiety arises in connection with repression may be no simple one; but we may legitimately hold firmly to the idea that the ego is the actual seat of anxiety and give up our earlier view that the cathectic energy of the repressed impulse is automatically turned into anxiety. If I expressed myself earlier in the latter sense, I was giving a phenomenological description and not a metapsychological account of what was occurring.

[1926d, 4253]

Here, then, is our unexpected finding: in both patients the motive force of the repression was fear of castration. The ideas contained in their anxiety - being bitten by a horse and being devoured by a wolf - were substitutes by distortion for the idea of being castrated by their father. This was the idea which had undergone repression. In the Russian boy the idea was an expression of a wish which was not able to subsist in the face of his masculine revolt; in 'Little Hans' it was the expression of a reaction in him which had turned his aggressiveness into its opposite. But the affect of anxiety, which was the essence of the phobia, came, not from the process of repression, not from the libidinal cathexes of the repressed impulses, but from the repressing agency itself. The anxiety belonging to the animal phobias was an untransformed fear of castration. It was therefore a realistic fear, a fear of a danger which was actually impending or was judged to be a real one. It was anxiety which produced repression and not, as I formerly believed, repression which produced anxiety.

[1926d, 4268]

It is no use denying the fact, though it is not pleasant to recall it, that I have on many occasions asserted that in repression the instinctual representative is distorted, displaced and so on, while the libido belonging to the instinctual impulse is transformed into anxiety. But now an examination of phobias, which should be best able to provide confirmatory evidence, fails to bear out my assertion; it seems, rather, to contradict it directly. The anxiety felt in animal phobias is the ego's fear of castration; while the anxiety felt in agoraphobia (a subject that has been less thoroughly studied) seems to be its fear of sexual temptation - a fear which, after all, must be connected in its origins with the fear of castration. As far as can be seen at present, the majority of phobias go back to an anxiety of this kind felt by the ego in regard to the demands of the libido. It is always the ego's attitude of anxiety which is the primary thing and which sets repression going. Anxiety never arises from repressed libido. If I had contented myself earlier with saying that after the occurrence of repression a certain amount of anxiety appeared in place of the manifestation of libido that was to be expected, I should have nothing to retract today. The description would be correct; and there does undoubtedly exist a correspondence of the kind asserted between the strength of the impulse that has to be repressed and the intensity of the resultant anxiety. But I must admit that I thought I was giving more than a mere description. I believed I had put my finger on a metapsychological process of direct transformation of libido into anxiety. I can now no longer maintain this view. And, indeed, I found it impossible at the time to explain how a transformation of that kind was carried out.

[1926d, 4268]
It may be asked how I arrived at this idea of transformation in the first instance. It was while I was studying the 'actual neuroses', at a time when analysis was still a very long way from distinguishing between processes in the ego and processes in the id. I found that outbreaks of anxiety and a general state of preparedness for anxiety were produced by certain sexual practices such as *coitus interruptus*, undischarged sexual excitation or enforced abstinence - that is, whenever sexual excitation was inhibited, arrested or deflected in its progress towards satisfaction. Since sexual excitation was an expression of libidinal instinctual impulses it did not seem too rash to assume that the libido was turned into anxiety through the agency of these disturbances. The observations which I made at the time still hold good. Moreover, it cannot be denied that the libido belonging to the id-processes is subjected to disturbance at the instigation of repression. It might still be true, therefore, that in repression anxiety is produced from the libidinal cathexis of the instinctual impulses. But how can we reconcile this conclusion with our other conclusion that the anxiety felt in phobias is an ego anxiety and arises in the ego, and that it does not proceed out of repression but, on the contrary, sets repression in motion? There seems to be a contradiction here which it is not at all a simple matter to solve. It will not be easy to reduce the two sources of anxiety to a single one. We might attempt to do so by supposing that, when coitus is disturbed or sexual excitation interrupted or abstinence enforced, the ego scents certain dangers to which it reacts with anxiety. But this takes us nowhere. On the other hand, our analysis of the phobias seems to admit of no correction. *Non liquet.*

This is as far as our investigations into the formation of symptoms take us. It is hardly worth while summing them up, for the results they have yielded are scanty and incomplete and tell us scarcely anything that we do not already know. It would be fruitless to turn our attention to symptom-formation in other disorders besides phobias, conversion hysteria and obsessional neurosis, for too little is known about them. But in reviewing those three neuroses together we are brought up against a very serious problem the consideration of which can no longer be put off. All three have as their outcome the destruction of the Oedipus complex; and in all three the motive force of the ego's opposition is, we believe, the fear of castration. Yet it is only in the phobias that this fear comes to the surface and is acknowledged. What has become of it in the other two neuroses? How has the ego spared itself this fear? The problem becomes accentuated when we recall the possibility, already referred to, that anxiety arises directly, by a kind of fermentation, from a libidinal cathexis whose processes have been disturbed. Furthermore, is it absolutely certain that fear of castration is the only motive force of repression (or defence)? If we think of neuroses in women we are bound to doubt it. For though we can with certainty establish in them the presence of a castration *complex*, we can hardly speak with propriety of castration *anxiety* where castration has already taken place.

At one time I attached some importance to the view that what was used as a discharge of anxiety was the cathexis which had been withdrawn in the process of repression. To-day this seems to me of scarcely any interest. The reason for this is that whereas I formerly believed that anxiety invariably arose automatically by an economic process, my present conception of anxiety as a signal given by the ego in order to affect the pleasure-unpleasure agency does away with the necessity of considering the economic factor. Of course there is nothing to be said against the idea that it is precisely the energy that has been liberated by being withdrawn through repression which is used by the ego to arouse the affect; but it is no longer of any importance which portion of energy is employed for this purpose.
We see, then, that it is not so much a question of taking back our earlier findings as of bringing them into line with more recent discoveries. It is still an undeniable fact that in sexual abstinence, in improper interference with the course of sexual excitation or if the latter is diverted from being worked over psychically, anxiety arises directly out of libido; in other words, that the ego is reduced to a state of helplessness in the face of an excessive tension due to need, as it was in the situation of birth, and that anxiety is then generated. Here once more, though the matter is of little importance, it is very possible that what finds discharge in the generating of anxiety is precisely the surplus of unutilized libido. As we know, a psychoneurosis is especially liable to develop on the basis of an 'actual' neurosis. This looks as though the ego were attempting to save itself from anxiety, which it has learned to keep in suspension for a while, and to bind it by the formation of symptoms. Analysis of the traumatic war neuroses - a term which, incidentally, covers a great variety of disorders - would probably have shown that a number of them possess some characteristics of the 'actual' neuroses.

(b) Anxiety from Transformation of Libido

The view of anxiety which I have put forward in these pages diverges somewhat from the one I have hitherto thought correct. Formerly I regarded anxiety as a general reaction of the ego under conditions of unpleasure. I always sought to justify its appearance on economic grounds and I assumed, on the strength of my investigations into the 'actual' neuroses, that libido (sexual excitation) which was rejected or not utilized by the ego found direct discharge in the form of anxiety. It cannot be denied that these various assertions did not go very well together, or at any rate did not necessarily follow from one another. Moreover, they gave the impression of there being a specially intimate connection between anxiety and libido and this did not accord with the general character of anxiety as a reaction to unpleasure.

The objection to this view arose from our coming to regard the ego as the sole seat of anxiety. It was one of the results of the attempt at a structural division of the mental apparatus which I made in The Ego and the Id. Whereas the old view made it natural to suppose that anxiety arose from the libido belonging to the repressed instinctual impulses, the new one, on the contrary, made the ego the source of anxiety. Thus it is a question of instinctual (id-) anxiety or ego-anxiety. Since the energy which the ego employs is desexualized, the new view also tended to weaken the close connection between anxiety and libido. I hope I have at least succeeded in making the contradiction plain and in giving a clear idea of the point in doubt.

Our investigations were far from remaining unsuccessful: we reached a few important conclusions. In regard to anxious expectation clinical experience revealed that it had a regular connection with the libidinal economics of sexual life. The commonest cause of anxiety neurosis is unconsummated excitation. Libidinal excitation is aroused but not satisfied, not employed; apprehensiveness then appears instead of this libido that has been diverted from its employment. I even thought I was justified in saying that this unsatisfied libido was directly changed into anxiety. This view found support in some quite regularly occurring phobias of small children. Many of these phobias are very puzzling to us, but others, such as the fear of being alone and the fear of strangers, can be explained with certainty. Loneliness as well as a strange face arouse the child's longing for his familiar mother; he is unable to control this libidinal excitation, he cannot hold it in suspense but changes it into anxiety. This infantile anxiety must therefore be regarded not as of the realistic but as of the neurotic kind. Infantile phobias and the expectation of anxiety in anxiety neurosis offer us two examples of one way in which neurotic anxiety originates: by a direct transformation of libido. We shall at once come to know of a second mechanism, but it will turn out not to be very different from the first.
The view here developed depicts the symptoms of anxiety neurosis as being in a sense surrogates of the omitted specific action following on sexual excitation. In further support of this view, I may point out that in normal copulation too the excitation expends itself, among other things, in accelerated breathing, palpitation, sweating, congestion, and so on. In the corresponding anxiety attacks of our neurosis we have before us the dyspnoea, palpitations, etc. of copulation in an isolated and exaggerated form.

[1895b, 347]

² [Footnote added 1909:] It was not for a long time that I learned to appreciate the importance of phantasies and unconscious thoughts about life in the womb. They contain an explanation of the remarkable dread that many people have of being buried alive; and they also afford the deepest unconscious basis for the belief in survival after death, which merely represents a projection into the future of this uncanny life before birth. Moreover, the act of birth is the first experience of anxiety, and thus the source and prototype of the affect of anxiety. [1900a, 856]

To these phantasies which have succeeded in dominating the man's love in real life, the urge to rescue the loved one seems to bear merely a loose and superficial relation, and one that is fully accounted for by conscious reasons. By her propensity to be fickle and unfaithful the loved one brings herself into dangerous situations, and thus it is understandable that the lover should be at pains to protect her from these dangers by watching over her virtue and counteracting her bad inclinations. However, the study of people's screen-memories, phantasies and nocturnal dreams shows that we have here a particularly felicitous 'rationalization' of an unconscious motive, a process which may be compared to a successful secondary revision of a dream. In actual fact the 'rescue-motif' has a meaning and history of its own, and is an independent derivative of the mother-complex, or more accurately, of the parental complex. When a child hears that he owes his life to his parents, or that his mother gave him life, his feelings of tenderness unite with impulses which strive at power and independence, and they generate the wish to return this gift to the parents and to repay them with one of equal value. It is as though the boy's defiance were to make him say: 'I want nothing from my father; I will give him back all I have cost him.' He then forms the phantasy of rescuing his father from danger and saving his life; in this way he puts his account square with him. This phantasy is commonly enough displaced on to the emperor, king or some other great man; after being thus distorted it becomes admissible to consciousness, and may even be made use of by creative writers. In its application to a boy's father it is the defiant meaning in the idea of rescuing which is by far the most important; where his mother is concerned it is usually its tender meaning. The mother gave the child life, and it is not easy to find a substitute, of equal value for this unique gift. With a slight change of meaning, such as is easily effected in the unconscious and is comparable to the way in which in consciousness concepts shade into one another, rescuing his mother takes on the significance of giving her a child or making a child for her - needless to say, one like himself. This is not too remote from the original sense of rescuing, and the change in meaning is not an arbitrary one. His mother gave him a life - his own life - and in exchange he gives her another life, that of a child which has the greatest resemblance to himself. The son shows his gratitude by wishing to have by his mother a son who is like himself: in other words, in the rescue-phantasy he is completely identifying himself with his father. All his instincts, those of tenderness, gratitude, lustfulness, defiance and independence, find satisfaction in the single wish to be his own father. Even the element of danger has not been lost in the change of meaning; for the act of birth itself is the danger from which he was saved by his mother's efforts. Birth is both the first of all dangers to life and the prototype of all the later ones that cause us to feel anxiety, and the experience of birth has probably left behind in us the expression of affect which we call anxiety. Macduff of the Scottish legend, who was not born of his mother but ripped from her womb, was for that reason unacquainted with anxiety. [1910h, 2333]
Do not suppose that the things I have said to you here about affects are the recognized stock-in-trade of normal psychology. They are on the contrary views that have grown up on the soil of psycho-analysis and are native only to it. What you may gather about affects from psychology - the James-Lange theory, for example - is quite beyond understanding or discussion to us psycho-analysts. But we do not regard our knowledge about affects as very assured either; it is a first attempt at finding our bearings in this obscure region. I will proceed, however. We believe that in the case of the affect of anxiety we know what the early impression is which it repeats. We believe that it is in the act of birth that there comes about the combination of unpleasurable feelings, impulses of discharge and bodily sensations which has become the prototype of the effects of a mortal danger and has ever since been repeated by us as the state of anxiety. The immense increase of stimulation owing to the interruption of the renovation of the blood (internal respiration) was at the time the cause of the experience of anxiety; the first anxiety was thus a toxic one. The name ‘Angst’ - ‘augustiae’, ‘Enge’¹ - emphasizes the characteristic of restriction in breathing which was then present as a consequence of the real situation and is now almost invariably reinstated in the affect. We shall also recognize it as highly relevant that this first state of anxiety arose out of separation from the mother. It is, of course, our conviction that the disposition to repeat the first state of anxiety has been so thoroughly incorporated into the organism through a countless series of generations that a single individual cannot escape the affect of anxiety even if, like the legendary Macduff, he ‘was from his mother's womb untimely ripped’ and has therefore not himself experienced the act of birth. We cannot say what has become the prototype of the state of anxiety in the case of creatures other than mammals. And in the same way we do not know either what complex of feelings is in such creatures the equivalent to our anxiety.

[1916-1917, 3445]

It may perhaps interest you to learn how anyone could have formed such an idea as that the act of birth is the source and prototype of the affect of anxiety. Speculation had a very small share in it; what I did, rather, was to borrow from the naïve popular mind. Long years ago, while I was sitting with a number of other young hospital doctors at our mid-day meal in an inn, a house physician from the midwifery department told us of a comic thing that had happened at the last examination for midwives. A candidate was asked what it meant if meconium (excreta) made its appearance at birth in the water coming away, and she promptly replied: 'it means the child's frightened.' She was laughed at and failed in the examination. But silently I took her side and began to suspect that this poor woman from the humbler classes had laid an unerring finger on an important correlation.

[1916-1917, 3445]
This sounds so simple and seductive that it has a claim on our attention. It is true that it would involve a displacement of the riddle of the neurotic state. The continued existence of the sense of inferiority - and thus, of what determine anxiety and the formation of symptoms - seems so well assured that what calls for an explanation is rather how, as an exception, what we know as health can come about. But what is revealed by a careful examination of apprehensiveness in children? At the very beginning, what children are afraid of is strange people; situations only become important because they include people, and impersonal things do not come into account at all until later. But a child is not afraid of these strangers because he attributes evil intentions to them and compares his weakness with their strength, and accordingly assesses them as dangers to his existence, safety and freedom from pain. A child who is mistrustful in this way and terrified of the aggressive instinct which dominates the world is a theoretical construction that has quite miscarried. A child is frightened of a strange face because he is adjusted to the sight of a familiar and beloved figure - ultimately of his mother. It is his disappointment and longing that are transformed into anxiety - his libido, in fact, which has become unemployable, which cannot at that time be held in suspense and is discharged as anxiety. And it can scarcely be a matter of chance, either, that in this situation which is the prototype of the anxiety of children there is a repetition of the determinant of the first state of anxiety during the act of birth - namely, separation from the mother.

[1916-1917, 3453]

This brings us to a further question: how is it possible, from an economic point of view, for a mere process of withdrawal and discharge, like the withdrawing of a preconscious ego-cathexis, to produce unpleasure or anxiety, seeing that, according to our assumptions, unpleasure and anxiety can only arise as a result of an increase in cathexis? The reply is that this causal sequence should not be explained from an economic point of view. Anxiety is not newly created in repression; it is reproduced as an affective state in accordance with an already existing mnemonic image. If we go further and enquire into the origin of that anxiety - and of affects in general - we shall be leaving the realm of pure psychology and entering the borderland of physiology. Affective states have become incorporated in the mind as precipitates of primaeval traumatic experiences, and when a similar situation occurs they are revived like mnemonic symbols. I do not think I have been wrong in likening them to the more recent and individually acquired hysterical attack and in regarding them as its normal prototypes. In man and the higher animals it would seem that the act of birth, as the individual's first experience of anxiety, has given the affect of anxiety certain characteristic forms of expression. But, while acknowledging this connection, we must not lay undue stress on it nor overlook the fact that biological necessity demands that a situation of danger should have an affective symbol, so that a symbol of this kind would have to be created in any case. Moreover, I do not think that we are justified in assuming that whenever there is an outbreak of anxiety something like a reproduction of the situation of birth goes on in the mind. It is not even certain whether hysterical attacks, though they were originally traumatic reproductions of this sort, retain that character permanently.

[1926d, 4254]
Analysis of anxiety-states therefore reveals the existence of (1) a specific character of unpleasure, (2) acts of discharge and (3) perceptions of those acts. The two last points indicate at once a difference between states of anxiety and other similar states, like those of mourning and pain. The latter do not have any motor manifestation; or if they have, the manifestation is not an integral part of the whole state but is distinct from it as being a result of it or a reaction to it. Anxiety, then, is a special state of unpleasure with acts of discharge along particular paths. In accordance with our general views we should be inclined to think that anxiety is based upon an increase of excitation which on the one hand produces the character of unpleasure and on the other finds relief through the acts of discharge already mentioned. But a purely physiological account of this sort will scarcely satisfy us. We are tempted to assume the presence of a historical factor which binds the sensations of anxiety and its innervations firmly together. We assume, in other words, that an anxiety-state is the reproduction of some experience which contained the necessary conditions for such an increase of excitation and a discharge along particular paths, and that from this circumstance the unpleasure of anxiety receives its specific character. In man, birth provides a prototypic experience of this kind, and we are therefore inclined to regard anxiety-states as a reproduction of the trauma of birth.

[1926d, 4289]

The view that anxiety goes back to the event of birth raises immediate objections which have to be met. It may be argued that anxiety is a reaction which, in all probability, is common to every organism, certainly every organism of a higher order, whereas birth is only experienced by the mammals; and it is doubtful whether in all of them, even, birth has the significance of a trauma. Therefore there can be anxiety without the prototype of birth. But this objection takes us beyond the barrier that divides psychology from biology. It may be that, precisely because anxiety has an indispensable biological function to fulfil as a reaction to a state of danger, it is differently contrived in different organisms. We do not know, besides, whether anxiety involves the same sensations and innervations in organisms far removed from man as it does in man himself. Thus there is no good argument here against the view that, in man, anxiety is modelled upon the process of birth.

[1926d, 4290]

This answer, however, raises further considerations. The innervations involved in the original state of anxiety probably had a meaning and purpose, in just the same way as the muscular movements which accompany a first hysterical attack. In order to understand a hysterical attack, all one has to do is to look for the situation in which the movements in question formed part of an appropriate and expedient action. Thus at birth it is probable that the innervation, in being directed to the respiratory organs, is preparing the way for the activity of the lungs, and, in accelerating the heartbeat, is helping to keep the blood free from toxic substances. Naturally, when the anxiety-state is reproduced later as an affect it will be lacking in any such expediency, just as are the repetitions of a hysterical attack. When the individual is placed in a new situation of danger it may well be quite inexpedient for him to respond with an anxiety-state (which is a reaction to an earlier danger) instead of initiating a reaction appropriate to the current danger. But his behaviour may become expedient once more if the danger-situation is recognized as it approaches and is signalled by an outbreak of anxiety. In that case he can at once get rid of his anxiety by having recourse to more suitable measures. Thus we see that there are two ways in which anxiety can emerge: in an inexpedient way, when a new situation of danger has occurred, or in an expedient way in order to give a signal and prevent such a situation from occurring.

[1926d, 4290]
But a moment's reflection takes us beyond this question of loss of object. The reason why the infant in arms wants to perceive the presence of its mother is only because it already knows by experience that she satisfies all its needs without delay. The situation, then, which it regards as a 'danger' and against which it wants to be safeguarded is that of non-satisfaction, of a growing tension due to need, against which it is helpless. I think that if we adopt this view all the facts fall into place. The situation of non-satisfaction in which the amounts of stimulation rise to an unpleasurable height without its being possible for them to be mastered psychically or discharged must for the infant be analogous to the experience of being born - must be a repetition of the situation of danger. What both situations have in common is the economic disturbance caused by an accumulation of amounts of stimulation which require to be disposed of. It is this factor, then, which is the real essence of the 'danger'. In both cases the reaction of anxiety sets in. (This reaction is still an expedient one in the infant in arms, for the discharge, being directed into the respiratory and vocal muscular apparatus, now calls its mother to it, just as it activated the lungs of the new-born baby to get rid of the internal stimuli.) It is unnecessary to suppose that the child carries anything more with it from the time of its birth than this way of indicating the presence of danger.

[1926d, 4292]

We see, then, that it is not so much a question of taking back our earlier findings as of bringing them into line with more recent discoveries. It is still an undeniable fact that in sexual abstinence, in improper interference with the course of sexual excitation or if the latter is diverted from being worked over psychically, anxiety arises directly out of libido; in other words, that the ego is reduced to a state of helplessness in the face of an excessive tension due to need, as it was in the situation of birth, and that anxiety is then generated. Here once more, though the matter is of little importance, it is very possible that what finds discharge in the generating of anxiety is precisely the surplus of unutilized libido. As we know, a psychoneurosis is especially liable to develop on the basis of an 'actual' neurosis. This looks as though the ego were attempting to save itself from anxiety, which it has learned to keep in suspension for a while, and to bind it by the formation of symptoms. Analysis of the traumatic war neuroses - a term which, incidentally, covers a great variety of disorders - would probably have shown that a number of them possess some characteristics of the 'actual' neuroses.

[1926d, 4296]

In describing the evolution of the various danger-situations from their prototype, the act of birth, I have had no intention of asserting that every later determinant of anxiety completely invalidates the preceding one. It is true that, as the development of the ego goes on, the earlier danger-situations tend to lose their force and to be set aside, so that we might say that each period of the individual's life has its appropriate determinant of anxiety. Thus the danger of psychical helplessness is appropriate to the period of life when his ego is immature; the danger of loss of object, to early childhood when he is still dependent on others; the danger of castration, to the phallic phase; and the fear of his super-ego, to the latency period. Nevertheless, all these danger-situations and determinants of anxiety can persist side by side and cause the ego to react to them with anxiety at a period later than the appropriate one; or, again, several of them can come into operation at the same time. It is possible, moreover, that there is a fairly close relationship between the danger-situation that is operative and the form taken by the ensuing neurosis.¹

[1926d, 4297]
Since we have traced back the generating of anxiety to a situation of danger, we shall prefer to say that symptoms are created in order to remove the ego from a situation of danger. If the symptoms are prevented from being formed, the danger does in fact materialize; that is, a situation analogous to birth is established in which the ego is helpless in the face of a constantly increasing instinctual demand - the earliest and original determinant of anxiety. Thus in our view the relation between anxiety and symptom is less close than was supposed, for we have inserted the factor of the danger-situation between them. We can also add that the generating of anxiety sets symptom formation going and is, indeed, a necessary prerequisite of it. For if the ego did not arouse the pleasure-unpleasure agency by generating anxiety, it would not obtain the power to arrest the process which is preparing in the id and which threatens danger. There is in all this an evident inclination to limit to a minimum the amount of anxiety generated and to employ it only as a signal; for to do otherwise would only result in feeling in another place the unpleasure which the instinctual process was threatening to produce, and that would not be a success from the standpoint of the pleasure principle, although it is one that occurs often enough in the neuroses.

[1926d, 4299]

The second attempt was made by Otto Rank in 1923 in his book, The Trauma of Birth. It would be unjust to put his attempt on the same level as Adler's except in this single point which concerns us here, for it remains on psycho-analytic ground and pursues a psycho-analytic line of thought, so that it may be accepted as a legitimate endeavour to solve the problems of analysis. In this matter of the relation of the individual to danger Rank moves away from the question of organic defect in the individual and concentrates on the variable degree of intensity of the danger. The process of birth is the first situation of danger, and the economic upheaval which it produces becomes the prototype of the reaction of anxiety. We have already traced the line of development which connects this first danger-situation and determinant of anxiety with all the later ones, and we have seen that they all retain a common quality in so far as they signify in a certain sense a separation from the mother - at first only in a biological sense, next as a direct loss of object and later as a loss of object incurred indirectly. The discovery of this extensive concatenation is an undoubted merit of Rank's construction. Now the trauma of birth overtakes each individual with a different degree of intensity, and the violence of his anxiety-reaction varies with the strength of the trauma; and it is the initial amount of anxiety generated in him which, according to Rank, decides whether he will ever learn to control it - whether he will become neurotic or normal.

[1926d, 4304]
Rank's contention - which was originally my own -, that the affect of anxiety is a consequence of the event of birth and a repetition of the situation then experienced, obliged me to review the problem of anxiety once more. But I could make no headway with his idea that birth is a trauma, states of anxiety a reaction of discharge to it and all subsequent affects of anxiety an attempt to 'abreact' it more and more completely. I was obliged to go back from the anxiety reaction to the situation of danger that lay behind it. The introduction of this element opened up new aspects of the question. Birth was seen to be the prototype of all later situations of danger which overtook the individual under the new conditions arising from a changed mode of life and a growing mental development. On the other hand its own significance was reduced to this prototypic relationship to danger. The anxiety felt at birth became the prototype of an affective state which had to undergo the same vicissitudes as the other affects. Either the state of anxiety reproduced itself automatically in situations analogous to the original situation and was thus an inexpedient form of reaction instead of an expedient one as it had been in the first situation of danger; or the ego acquired power over this affect, reproduced it on its own initiative, and employed it as a warning of danger and as a means of setting the pleasure-unpleasure mechanism in motion. We thus gave the biological aspect of the anxiety affect its due importance by recognizing anxiety as the general reaction to situations of danger; while we endorsed the part played by the ego as the seat of anxiety by allocating to it the function of producing the anxiety affect according to its needs. Thus we attributed two modes of origin to anxiety in later life. One was involuntary, automatic and always justified on economic grounds, and arose whenever a danger situation analogous to birth had established itself. The other was produced by the ego as soon as a situation of this kind merely threatened to occur, in order to call for its avoidance. In the second case the ego subjects itself to anxiety as a sort of inoculation, submitting to a slight attack of the illness in order to escape its full strength. It vividly imagines the danger situation, as it were, with the unmistakable purpose of restricting that distressing experience to a mere indication, a signal. We have already seen in detail how the various situations of danger arise one after the other, retaining at the same time a genetic connection.

I devoted a lecture (the twenty-fifth) to anxiety in my previous series; and I must briefly recapitulate what I said in it. We described anxiety as an affective state - that is to say, a combination of certain feelings in the pleasure-unpleasure series with the corresponding innervations of discharge and a perception of them, but probably also the precipitate of a particular important event, incorporated by inheritance - something that may thus be likened to an individually acquired hysterical attack. The event which we look upon as having left behind it an affective trace of this sort is the process of birth, at the time of which the effects upon the heart's action and upon respiration characteristic of anxiety were expedient ones. The very first anxiety would thus have been a toxic one. We then started off from a distinction between realistic anxiety and neurotic anxiety, of which the former was a reaction, which seemed intelligible to us, to a danger - that is, to an expected injury from outside - while the latter was completely enigmatic, and appeared to be pointless.
Fear of castration is not, of course, the only motive for repression: indeed, it finds no place in
women, for though they have a castration complex they cannot have a fear of being castrated.
Its place is taken in their sex by a fear of loss of love, which is evidently a later prolongation of
the infant's anxiety if it finds its mother absent. You will realize how real a situation of danger is
indicated by this anxiety. If a mother is absent or has withdrawn her love from her child, it is no
longer sure of the satisfaction of its needs and is perhaps exposed to the most distressing
feelings of tension. Do not reject the idea that these determinants of anxiety may at bottom
repeat the situation of the original anxiety at birth, which, to be sure, also represented a
separation from the mother. Indeed, if you follow a train of thought suggested by Ferenczi, you
may add the fear of castration to this series, for a loss of the male organ results in an inability to
unite once more with the mother (or a substitute for her) in the sexual act. I may mention to you
incidentally that the very frequent phantasy of returning into the mother's womb is a substitute
for this wish to copulate. There would be many interesting things and surprising connections to
tell you at this point, but I cannot go outside the framework of an introduction to psycho-
analysis. I will only draw your attention to the fact that here psychological researches trench
upon the facts of biology.
[1933a, 4694]

And now, only one more remark on the problem of anxiety. Neurotic anxiety has changed in
our hands into realistic anxiety, into fear of particular external situations of danger. But we
cannot stop there, we must take another step - though it will be a step backward. We ask
ourselves what it is that is actually dangerous and actually feared in a situation of danger of this
kind. It is plainly not the injury to the subject as judged objectively, for this need be of no
significance psychologically, but something brought about by it in the mind. Birth, for instance,
our model for an anxiety state, can after all scarcely be regarded on its own account as an
injury, although it may involve a danger of injuries. The essential thing about birth, as about
every situation of danger, is that it calls up in mental experience a state of highly tense
excitation, which is felt as unpleasure and which one is not able to master by discharging it. Let
us call a state of this kind, before which the efforts of the pleasure principle break down, a
'traumatic' moment. Then, if we take in succession neurotic anxiety, realistic anxiety and the
situation of danger, we arrive at this simple proposition: what is feared, what is the object of the
anxiety, is invariably the emergence of a traumatic moment, which cannot be dealt with by the
normal rules of the pleasure principle. We understand at once that our endowment with the
pleasure principle does not guarantee us against objective injuries but only against a particular
injury to our psychical economics. It is a long step from the pleasure principle to the self-
preservative instinct; the intentions of the two of them are very far from coinciding from the start.
But we see something else besides; perhaps it is the solution we are in search of. Namely, that
in all this it is a question of relative quantities. It is only the magnitude of the sum of excitation
that turns an impression into a traumatic moment, paralyses the function of the pleasure
principle and gives the situation of danger its significance. And if that is how things are, if these
puzzles can be solved so prosaically, why should it not be possible for similar traumatic
moments to arise in mental life without reference to hypothetical situations of danger - traumatic
moments, then, in which anxiety is not aroused as a signal but is generated anew for a fresh
reason. Clinical experience declares decidedly that such is in fact the case. It is only the later
repressions that exhibit the mechanism we have described, in which anxiety is awakened as a
signal of an earlier situation of danger. The first and original repressions arise directly from
traumatic moments, when the ego meets with an excessively great libidinal demand; they
construct their anxiety afresh, although, it is true, on the model of birth. The same may apply to
the generation of anxiety in anxiety neurosis owing to somatic damage to the sexual function.
We shall no longer maintain that it is the libido itself that is turned into anxiety in such cases. But
I can see no objection to there being a twofold origin of anxiety - one as a direct consequence of
the traumatic moment and the other as a signal threatening a repetition of such a moment.
[1933a, 4700]
The view here developed depicts the symptoms of anxiety neurosis as being in a sense surrogates of the omitted specific action following on sexual excitation. In further support of this view, I may point out that in normal copulation too the excitation expends itself, among other things, in accelerated breathing, palpitation, sweating, congestion, and so on. In the corresponding anxiety attacks of our neurosis we have before us the dyspnoea, palpitations, etc. of copulation in an isolated and exaggerated form.

I should like to be able to add some definite information as to when and under what particular influence Dora gave up masturbating; but owing to the incompleteness of the analysis I have only fragmentary material to present. We have heard that the bed-wetting lasted until shortly before she first fell ill with dyspnoea. Now the only light she was able to throw upon this first attack was that at the time of its occurrence her father was away from home for the first time since his health had improved. In this small recollection there must be a trace of an allusion to the aetiology of the dyspnoea. Dora's symptomatic acts and certain other signs gave me good reasons for supposing that the child, whose bedroom had been next door to her parents', had overheard her father in his wife's room at night and had heard him (for he was always short of breath) breathing hard while they had intercourse. Children, in such circumstances, divine something sexual in the uncanny sounds that reach their ears. Indeed, the movements expressive of sexual excitement lie within them ready to hand, as innate pieces of mechanism. I maintained years ago that the dyspnoea and palpitations that occur in hysteria and anxiety neurosis are only detached fragments of the act of copulation; and in many cases, as in Dora's, I have been able to trace back the symptom of dyspnoea or nervous asthma to the same exciting cause - to the patient's having overheard sexual intercourse taking place between adults. The sympathetic excitement which may be supposed to have occurred in Dora on such an occasion may very easily have made the child's sexuality veer round and have replaced her inclination to masturbation by an inclination to anxiety. A little while later, when her father was away and the child, devotedly in love with him, was wishing him back, she must have reproduced in the form of an attack of asthma the impression she had received. She had preserved in her memory the event which had occasioned the first onset of the symptom, and we can conjecture from it the nature of the train of thought, charged with anxiety, which had accompanied the attack. The first attack had come on after she had over-exerted herself on an expedition in the mountains, so that she had probably been really a little out of breath. To this was added the thought that her father was forbidden to climb mountains and was not allowed to over-exert himself, because he suffered from shortness of breath; then came the recollection of how much he had exerted himself with her mother that night, and the question whether it might not have done him harm; next came concern whether she might not have over-exerted herself in masturbating - an act which, like the other, led to a sexual orgasm accompanied by slight dyspnoea - and finally came a return of the dyspnoea in an intensified form as a symptom. Part of this material I was able to obtain directly from the analysis, but the rest required supplementing. But the way in which the occurrence of masturbation in Dora's case was verified has already shown us that material belonging to a single subject can only be collected piece by piece at various times and in different connections.¹

[1895b, 347]

[1905e, 1416]
Two questions now arise. Can we relate neurotic anxiety, in which danger plays little or no part, to realistic anxiety, which is invariably a reaction to danger? And how are we to understand neurotic anxiety? We shall certainly be inclined in the first instance to hold fast to our expectation that where there is anxiety there must be something that one is afraid of.

Our observations on anxiety neurosis led us to conclude that the deflection of the libido from its normal employment, which causes the development of anxiety, takes place in the region of somatic processes. Analyses of hysteria and obsessional neurosis yield the additional conclusion that a similar deflection with the same outcome may also be the result of a refusal on the part of the psychical agencies. This much, therefore, we know about the origin of neurotic anxiety. It still sounds fairly indefinite; but for the moment I see no path that would lead us further. The second problem we set ourselves - of establishing a connection between neurotic anxiety, which is libido put to an abnormal employment, and realistic anxiety, which corresponds to a reaction to danger - seems even harder to solve. One might suppose that these were two quite disparate things; and yet we have no means of distinguishing in our feelings between realistic anxiety and neurotic anxiety.

We finally arrive at the connection we are in search of, if we take as our starting-point the opposition we have so often asserted between the ego and the libido. As we know, the generation of anxiety is the ego's reaction to danger and the signal for taking flight. If so, it seems plausible to suppose that in neurotic anxiety the ego is making a similar attempt at flight from the demand by its libido, that it is treating this internal danger as though it were an external one. This would therefore fulfil our expectation that where anxiety is shown there is something one is afraid of. But the analogy could be carried further. Just as the attempt at flight from an external danger is replaced by standing firm and the adoption of expedient measures of defence, so too the generation of neurotic anxiety gives place to the formation of symptoms, which results in the anxiety being bound.

The difficulty in understanding now lies else here. The anxiety which signifies a flight of the ego from its libido is after all supposed to be derived from that libido itself. This is obscure and it reminds us not to forget that after all a person's libido is fundamentally something of his and cannot be contrasted with him as something external. It is the topographical dynamics of the generation of anxiety which are still obscure to us - the question of what mental energies are produced in what process and from what mental systems they derive. This is once more a question which I cannot promise to answer: but there are two other tracks which we must not fail to follow and in doing so we shall once more be making use of direct observation and analytic enquiry as a help to our speculations. We will turn to the genesis of anxiety in children and to the source of the neurotic anxiety which is attached to phobias.
On the other hand we cannot overlook the fact that not all children are anxious to the same degree, and that precisely children who exhibit a special timidity towards objects and in situations of every kind turn out later to be neurotic. Thus the neurotic disposition betrays itself also by an outspoken tendency to realistic anxiety; apprehensiveness appears to be the primary thing and we reach the conclusion that the reason why children and, later, growing youths and girls are afraid of the height of their libido is because in fact they are afraid of everything. The genesis of anxiety from libido would in this way be denied; and if one examined into the determinants of realistic anxiety, consistency would lead one to the view that consciousness of one's own weakness and helplessness - inferiority according to Adler's terminology, - if it can be prolonged from childhood into adult life, is the final basis of neuroses.

[1916-1917, 3453]

We thus find ourselves convinced that the problem of anxiety occupies a place in the question of the psychology of the neuroses which may rightly be described as central. We have received a strong impression of the way in which the generation of anxiety is linked to the vicissitudes of the libido and the system of the unconscious. There is only a single point that we have found disconnected - a gap in our views: the single, yet scarcely disputable, fact that realistic anxiety must be regarded as a manifestation of the ego's self-preservative instincts.

[1916-1917, 3457]

Let me once more, however, return for a moment to anxiety, to throw light on a last obscurity that we left there. I have said that there is something that does not tally with the relation (so thoroughly recognized apart from this) between anxiety and libido: the fact, namely, that realistic anxiety in face of a danger seems to be a manifestation of the self-preservative instinct - which, after all, can scarcely be disputed. How would it be, though, if what was responsible for the affect of anxiety was not the egoistic ego-instincts but the ego-libido? After all, the state of anxiety is in every instance inexpedient, and its inexpedience becomes obvious if it reaches a fairly high pitch. In such cases it interferes with action, whether flight or defence, which alone is expedient and alone serves the cause of self-preservation. If, therefore, we attribute the affective portion of realistic anxiety to ego-libido and the accompanying action to the self-preservative instinct, we shall have got rid of the theoretical difficulty. After all, you do not seriously believe that one runs away because one feels anxiety? No. One feels anxiety and one runs away for a common motive, which is roused by the perception of danger. People who have been through a great mortal danger tell us that they were not at all afraid but merely acted - for instance, that they aimed their rifle at the wild beast - and that is unquestionably what was most expedient.

[1916-1917, 3474]

Let us now consider the phobia. It came into existence on the level of the genital organization, and shows us the relatively simple mechanism of an anxiety-hysteria. The ego, by developing anxiety, was protecting itself against what it regarded as an overwhelming danger, namely, homosexual satisfaction. But the process of repression left behind it a trace which cannot be overlooked. The object to which the dangerous sexual aim had been attached had to have its place taken in consciousness by another one. What became conscious was fear not of the father but of the wolf. Nor did the process stop at the formation of a phobia with a single content. A considerable time afterwards the wolf was replaced by the lion. Simultaneously with sadistic impulses against small animals there was a phobia directed towards them, in their capacity of representatives of the boy's rivals, the possible small children. The origin of the butterfly phobia is of especial interest. It was like a repetition of the mechanism that produced the wolf phobia in the dream. Owing to a chance stimulus an old experience, the scene with Grusha, was activated; her threat of castration thus produced deferred effects, though at the time it was uttered it had made no impression.¹

[1918b, 3588]
It may truly be said that the anxiety that was concerned in the formation of these phobias was a fear of castration. This statement involves no contradiction of the view that the anxiety originated from the repression of homosexual libido. Both modes of expression refer to the same process: namely, the withdrawal of libido by the ego from the homosexual wishful impulse, the libido having then become converted into free anxiety and subsequently bound in phobias. The first method of statement merely mentions in addition the motive by which the ego was actuated.

[1918b, 3589]

A condition has long been known and described which occurs after severe mechanical concussions, railway disasters and other accidents involving a risk to life; it has been given the name of 'traumatic neurosis'. The terrible war which has just ended gave rise to a great number of illnesses of this kind, but it at least put an end to the temptation to attribute the cause of the disorder to organic lesions of the nervous system brought about by mechanical force.¹ The symptomatic picture presented by traumatic neurosis approaches that of hysteria in the wealth of its similar motor symptoms, but surpasses it as a rule in its strongly marked signs of subjective ailment (in which it resembles hypochondria or melancholia) as well as in the evidence it gives of a far more comprehensive general enfeeblement and disturbance of the mental capacities. No complete explanation has yet been reached either of war neuroses or of the traumatic neuroses of peace. In the case of the war neuroses, the fact that the same symptoms sometimes came about without the intervention of any gross mechanical force seemed at once enlightening and bewildering. In the case of the ordinary traumatic neuroses two characteristics emerge prominently: first, that the chief weight in their causation seems to rest upon the factor of surprise, of fright; and secondly, that a wound or injury inflicted simultaneously works as a rule against the development of a neurosis. 'Fear', 'fear' and 'anxiety' are improperly used as synonymous expressions; they are in fact capable of clear distinction in their relation to danger. 'Anxiety' describes a particular state of expecting the danger or preparing for it, even though it may be an unknown one. 'Fear' requires a definite object of which to be afraid. 'Anxiety', however, is the name we give to the state a person gets into when he has run into danger without being prepared for it; it emphasizes the factor of surprise. I do not believe anxiety itself can produce a traumatic neurosis. There is something about anxiety that protects its subject against fright and so against fright-neuroses. We shall return to this point later.¹

[1920g, 3718]

From the other point of view, however, we see this same ego as a poor creature owing service to three masters and consequently menaced by three dangers: from the external world, from the libido of the id, and from the severity of the super-ego. Three kinds of anxiety correspond to these three dangers, since anxiety is the expression of a retreat from danger. As a frontier creature, the ego tries to mediate between the world and the id, to make the id pliable to the world and, by means of its muscular activity, to make the world fall in with the wishes of the id. In point of fact it behaves like the physician during an analytic treatment: it offers itself, with the attention it pays to the real world, as a libidinal object to the id, and aims at attaching the id's libido to itself. It is not only a helper to the id; it is also a submissive slave who courts his master's love. Whenever possible, it tries to remain on good terms with the id; it clothes the id's commands with its rationalizations; it pretends that the id is showing obedience to the admonitions of reality, even when in fact it is remaining obstinate and unyielding; it disguises the id's conflicts with reality and, if possible, its conflicts with the super-ego too. In its position midway between the id and reality, it only too often yields to the temptation to become sycophantic, opportunist and lying, like a politician who sees the truth but wants to keep his place in popular favour.

[1923b, 3990]
The ego is the actual seat of anxiety. Threatened by dangers from three directions, it develops the flight-reflex by withdrawing its own cathexis from the menacing perception or from the similarly regarded process in the id, and emitting it as anxiety. This primitive reaction is later replaced by the carrying-out of protective cathexes (the mechanism of the phobias). What it is that the ego fears from the external and from the libidinal danger cannot be specified; we know that the fear is of being overwhelmed or annihilated, but it cannot be grasped analytically. The ego is simply obeying the warning of the pleasure principle. On the other hand, we can tell what is hidden behind the ego's dread of the super-ego, the fear of conscience. The superior being, which turned into the ego ideal, once threatened castration, and this dread of castration is probably the nucleus round which the subsequent fear of conscience has gathered; it is this dread that persists as the fear of conscience.

[1923b, 3991]

The high-sounding phrase, 'every fear is ultimately the fear of death', has hardly any meaning, and at any rate cannot be justified. It seems to me, on the contrary, perfectly correct to distinguish the fear of death from dread of an object (realistic anxiety) and from neurotic libidinal anxiety. It presents a difficult problem to psycho-analysis, for death is an abstract concept with a negative content for which no unconscious correlative can be found. It would seem that the mechanism of the fear of death can only be that the ego relinquishes its narcissistic libidinal cathexis in a very large measure - that is, that it gives up itself, just as it gives up some external object in other cases in which it feels anxiety. I believe that the fear of death is something that occurs between the ego and the super-ego.

[1923b, 3991]

In a psychosis, the transforming of reality is carried out upon the psychical precipitates of former relations to it - that is, upon the memory-traces, ideas and judgements which have been previously derived from reality and by which reality was represented in the mind. But this relation was never a closed one; it was continually being enriched and altered by fresh perceptions. Thus the psychosis is also faced with the task of procuring for itself perceptions of a kind which shall correspond to the new reality; and this is most radically effected by means of hallucination. The fact that, in so many forms and cases of psychosis, the paramnesias, the delusions and the hallucinations that occur are of a most distressing character and are bound up with a generation of anxiety - this fact is without doubt a sign that the whole process of remodelling is carried through against forces which oppose it violently. We may construct the process on the model of a neurosis, with which we are more familiar. There we see that a reaction of anxiety sets in whenever the repressed instinct makes a thrust forward, and that the outcome of the conflict is only a compromise and does not provide complete satisfaction. Probably in a psychosis the rejected piece of reality constantly forces itself upon the mind, just as the repressed instinct does in a neurosis, and that is why in both cases the consequences too are the same. The elucidation of the various mechanisms which are designed, in the psychoses, to turn the subject away from reality and to reconstruct reality - this is a task for specialized psychiatric study which has not yet been taken in hand.

[1924e, 4096]
Shortly before I wrote this study it seemed as though my life would soon be brought to an end by the recurrence of a malignant disease; but surgical skill saved me in 1923 and I was able to continue my life and my work, though no longer in freedom from pain. In the period of more than ten years that has passed since then, I have never ceased my analytic work nor my writing - as is proved by the completion of the twelfth volume of the German edition of my collected works. But I myself find that a significant change has come about. Threads which in the course of my development had become intertangled have now begun to separate; interests which I had acquired in the later part of my life have receded, while the older and original ones become prominent once more. It is true that in this last decade I have carried out some important pieces of analytic work, such as the revision of the problem of anxiety in my book *Inhibitions, Symptoms and Anxiety* (1926d) or the simple explanation of sexual 'fetishism' which I was able to make a year later (1927e). Nevertheless it would be true to say that, since I put forward my hypothesis of the existence of two classes of instinct (Eros and the death instinct) and since I proposed a division of the mental personality into an ego, a super-ego, and an id (1923b), I have made no further decisive contributions to psycho-analysis: what I have written on the subject since then has been either unessential or would soon have been supplied by someone else. This circumstance is connected with an alteration in myself, with what might be described as a phase of regressive development. My interest, after making a lifelong *détour* through the natural sciences, medicine and psychotherapy, returned to the cultural problems which had fascinated me long before, when I was a youth scarcely old enough for thinking. At the very climax of my psycho-analytic work, in 1912, I had already attempted in *Totem and Taboo* to make use of the newly discovered findings of analysis in order to investigate the origins of religion and morality. I now carried this work a stage further in two later essays, *The Future of an Illusion* (1927c) and *Civilization and its Discontents* (1930a). I perceived ever more clearly that the events of human history, the interactions between human nature, cultural development and the precipitates of primeval experiences (the most prominent example of which is religion) are no more than a reflection of the dynamic conflicts between the ego, the id and the super-ego, which psycho-analysis studies in the individual - are the very same processes repeated upon a wider stage. In *The Future of an Illusion* I expressed an essentially negative valuation of religion. Later, I found a formula which did better justice to it: while granting that its power lies in the truth which it contains, I showed that that truth was not a material but a historical truth.

It seems to me that the ego obtains this influence in virtue of its intimate connections with the perceptual system - connections which, as we know, constitute its essence and provide the basis of its differentiation from the id. The function of this system, which we have called *Pcpt.-Cs.*, is bound up with the phenomenon of consciousness. It receives excitations not only from outside but from within, and endeavours, by means of the sensations of pleasure and unpleasure which reach it from these quarters, to direct the course of mental events in accordance with the pleasure principle. We are very apt to think of the ego as powerless against the id; but when it is opposed to an instinctual process in the id it has only to give a 'signal of unpleasure' in order to attain its object with the aid of that almost omnipotent institution, the pleasure principle. To take this situation by itself for a moment, we can illustrate it by an example from another field. Let us imagine a country in which a certain small faction objects to a proposed measure the passage of which would have the support of the masses. This minority obtains command of the press and by its help manipulates the supreme arbiter, ‘public opinion’, and so succeeds in preventing the measure from being passed.
But this explanation opens up fresh problems. Where does the energy come from which is employed for giving the signal of unpleasure? Here we may be assisted by the idea that a defence against an unwelcome internal process will be modelled upon the defence adopted against an external stimulus, that the ego wards off internal and external dangers alike along identical lines. In the case of external danger the organism has recourse to attempts at flight. The first thing it does is to withdraw cathexis from the perception of the dangerous object; later on it discovers that it is a better plan to perform muscular movements of such a sort as will render perception of the dangerous object impossible even in the absence of any refusal to perceive it - that it is a better plan, that is, to remove itself from the sphere of danger.

Repression is an equivalent of this attempt at flight. The ego withdraws its (preconscious) cathexis from the instinctual representative that is to be repressed and uses that cathexis for the purpose of releasing unpleasure (anxiety). The problem of how anxiety arises in connection with repression may be no simple one; but we may legitimately hold firmly to the idea that the ego is the actual seat of anxiety and give up our earlier view that the cathetic energy of the repressed impulse is automatically turned into anxiety. If I expressed myself earlier in the latter sense, I was giving a phenomenological description and not a metapsychological account of what was occurring.

This brings us to a further question: how is it possible, from an economic point of view, for a mere process of withdrawal and discharge, like the withdrawing of a preconscious ego-cathexis, to produce unpleasure or anxiety, seeing that, according to our assumptions, unpleasure and anxiety can only arise as a result of an increase in cathexis? The reply is that this causal sequence should not be explained from an economic point of view. Anxiety is not newly created in repression; it is reproduced as an affective state in accordance with an already existing mnemonic image. If we go further and enquire into the origin of that anxiety - and of affects in general - we shall be leaving the realm of pure psychology and entering the borderland of physiology. Affective states have become incorporated in the mind as precipitates of primateal traumatic experiences, and when a similar situation occurs they are revived like mnemonic symbols. I do not think I have been wrong in likening them to the more recent and individually acquired hysterical attack and in regarding them as its normal prototypes. In man and the higher animals it would seem that the act of birth, as the individual's first experience of anxiety, has given the affect of anxiety certain characteristic forms of expression. But, while acknowledging this connection, we must not lay undue stress on it nor overlook the fact that biological necessity demands that a situation of danger should have an affective symbol, so that a symbol of this kind would have to be created in any case. Moreover, I do not think that we are justified in assuming that whenever there is an outbreak of anxiety something like a reproduction of the situation of birth goes on in the mind. It is not even certain whether hysterical attacks, though they were originally traumatic reproductions of this sort, retain that character permanently.

So long as we direct our attention to the ego's attempt at flight we shall get no nearer to the subject of symptom-formation. A symptom arises from an instinctual impulse which has been detrimentally affected by repression. If the ego, by making use of the signal of unpleasure, attains its object of completely suppressing the instinctual impulse, we learn nothing of how this has happened. We can only find out about it from those cases in which repression must be described as having to a greater or less extent failed. In this event the position, generally speaking, is that the instinctual impulse has found a substitute in spite of repression, but a substitute which is very much reduced, displaced and inhibited and which is no longer recognizable as a satisfaction. And when the substitutive impulse is carried out there is no sensation of pleasure; its carrying out has, instead, the quality of a compulsion.
The two lines of behaviour which the ego adopts towards the symptom are in fact directly opposed to each other. For the other line is less friendly in character, since it continues in the direction of repression. Nevertheless the ego, it appears, cannot be accused of inconsistency. Being of a peaceable disposition it would like to incorporate the symptom and make it part of itself. It is from the symptom itself that the trouble comes. For the symptom, being the true substitute for and derivative of the repressed impulse, carries on the role of the latter; it continually renews its demands for satisfaction and thus obliges the ego in its turn to give the signal of unpleasure and put itself in a posture of defence.

[1926d, 4260]

Here, then, is our unexpected finding: in both patients the motive force of the repression was fear of castration. The ideas contained in their anxiety—being bitten by a horse and being devoured by a wolf—were substitutes by distortion for the idea of being castrated by their father. This was the idea which had undergone repression. In the Russian boy the idea was an expression of a wish which was not able to subsist in the face of his masculine revolt; in 'Little Hans' it was the expression of a reaction in him which had turned his aggressiveness into its opposite. But the affect of anxiety, which was the essence of the phobia, came, not from the process of repression, not from the libidinal cathexes of the repressed impulses, but from the repressing agency itself. The anxiety belonging to the animal phobias was an untransformed fear of castration. It was therefore a realistic fear, a fear of a danger which was actually impending or was judged to be a real one. It was anxiety which produced repression and not, as I formerly believed, repression which produced anxiety.

[1926d, 4268]

It is no use denying the fact, though it is not pleasant to recall it, that I have on many occasions asserted that in repression the instinctual representative is distorted, displaced and so on, while the libido belonging to the instinctual impulse is transformed into anxiety. But now an examination of phobias, which should be best able to provide confirmatory evidence, fails to bear out my assertion; it seems, rather, to contradict it directly. The anxiety felt in animal phobias is the ego's fear of castration; while the anxiety felt in agoraphobia (a subject that has been less thoroughly studied) seems to be its fear of sexual temptation—a fear which, after all, must be connected in its origins with the fear of castration. As far as can be seen at present, the majority of phobias go back to an anxiety of this kind felt by the ego in regard to the demands of the libido. It is always the ego's attitude of anxiety which is the primary thing and which sets repression going. Anxiety never arises from repressed libido. If I had contented myself earlier with saying that after the occurrence of repression a certain amount of anxiety appeared in place of the manifestation of libido that was to be expected, I should have nothing to retract today. The description would be correct; and there does undoubtedly exist a correspondence of the kind asserted between the strength of the impulse that has to be repressed and the intensity of the resultant anxiety. But I must admit that I thought I was giving more than a mere description. I believed I had put my finger on a metapsychological process of direct transformation of libido into anxiety. I can now no longer maintain this view. And, indeed, I found it impossible at the time to explain how a transformation of that kind was carried out.

[1926d, 4268]
It may be asked how I arrived at this idea of transformation in the first instance. It was while I was studying the 'actual neuroses', at a time when analysis was still a very long way from distinguishing between processes in the ego and processes in the id. I found that outbreaks of anxiety and a general state of preparedness for anxiety were produced by certain sexual practices such as coitus interruptus, undischarged sexual excitation or enforced abstinence - that is, whenever sexual excitation was inhibited, arrested or deflected in its progress towards satisfaction. Since sexual excitation was an expression of libidinal instinctual impulses it did not seem too rash to assume that the libido was turned into anxiety through the agency of these disturbances. The observations which I made at the time still hold good. Moreover, it cannot be denied that the libido belonging to the id-processes is subjected to disturbance at the instigation of repression. It might still be true, therefore, that in repression anxiety is produced from the libidinal cathexis of the instinctual impulses. But how can we reconcile this conclusion with our other conclusion that the anxiety felt in phobias is an ego anxiety and arises in the ego, and that it does not proceed out of repression but, on the contrary, sets repression in motion? There seems to be a contradiction here which it is not at all a simple matter to solve. It will not be easy to reduce the two sources of anxiety to a single one. We might attempt to do so by supposing that, when coitus is disturbed or sexual excitation interrupted or abstinence enforced, the ego scents certain dangers to which it reacts with anxiety. But this takes us nowhere. On the other hand, our analysis of the phobias seems to admit of no correction. Non liquet.

[1926d, 4269]

This time we will not lose sight of the part played by anxiety. We have said that as soon as the ego recognizes the danger of castration it gives the signal of anxiety and inhibits through the pleasure-unpleasure agency (in a way which we cannot as yet understand) the impending cathetic process in the id. At the same time the phobia is formed. And now the castration anxiety is directed to a different object and expressed in a distorted form, so that the patient is afraid, not of being castrated by his father, but of being bitten by a horse or devoured by a wolf. This substitutive formation has two obvious advantages. In the first place it avoids a conflict due to ambivalence (for the father was a loved object, too), and in the second place it enables the ego to cease generating anxiety. For the anxiety belonging to a phobia is conditional; it only emerges when the object of it is perceived - and rightly so, since it is only then that the danger-situation is present. There is no need to be afraid of being castrated by a father who is not there. On the other hand one cannot get rid of a father; he can appear whenever he chooses. But if he is replaced by an animal, all one has to do is to avoid the sight of it - that is, its presence - in order to be free from danger and anxiety. 'Little Hans', therefore, imposed a restriction upon his ego. He produced the inhibition of not leaving the house, so as not to come across any horses. The young Russian had an even easier time of it, for it was hardly a privation for him not to look at a particular picture-book any more. If his naughty sister had not kept on showing him the book with the picture of the wolf standing upright in it, he would have been able to feel safe from his fear.

[1926d, 4282]

On a previous occasion I have stated that phobias have the character of a projection in that they replace an internal, instinctual danger by an external, perceptual one. The advantage of this is that the subject can protect himself against an external danger by fleeing from it and avoiding the perception of it, whereas it is useless to flee from dangers that arise from within. This statement of mine was not incorrect, but it did not go below the surface of things. For an instinctual demand is, after all, not dangerous in itself; it only becomes so inasmuch as it entails a real external danger, the danger of castration. Thus what happens in a phobia in the last resort is merely that one external danger is replaced by another. The view that in a phobia the ego is able to escape anxiety by means of avoidance or of inhibitory symptoms fits in very well with the theory that that anxiety is only an affective signal and that no alteration has taken place in the economic situation.

[1926d, 4283]
The anxiety felt in animal phobias is, therefore, an affective reaction on the part of the ego to danger; and the danger which is being signalled in this way is the danger of castration. This anxiety differs in no respect from the realistic anxiety which the ego normally feels in situations of danger, except that its content remains unconscious and only becomes conscious in the form of a distortion.
[1926d, 4283]

The conclusion we have come to, then, is this. Anxiety is a reaction to a situation of danger. It is obviated by the ego's doing something to avoid that situation or to withdraw from it. It might be said that symptoms are created so as to avoid the generating of anxiety. But this does not go deep enough. It would be truer to say that symptoms are created so as to avoid a danger-situation whose presence has been signalled by the generation of anxiety. In the cases that we have discussed, the danger concerned was the danger of castration or of something traceable back to castration.
[1926d, 4285]

If anxiety is a reaction of the ego to danger, we shall be tempted to regard the traumatic neuroses, which so often follow upon a narrow escape from death, as a direct result of a fear of death (or fear for life) and to dismiss from our minds the question of castration and the dependent relationships of the ego. Most of those who observed the traumatic neuroses that occurred during the last war took this line, and triumphantly announced that proof was now forthcoming that a threat to the instinct of self-preservation could by itself produce a neurosis without any admixture of sexual factors and without requiring any of the complicated hypotheses of psycho-analysis. It is in fact greatly to be regretted that not a single analysis of a traumatic neurosis of any value is extant. And it is to be regretted, not because such an analysis would contradict the aetiological importance of sexuality - for any such contradiction has long since been disposed of by the introduction of the concept of narcissism, which brings the libidinal cathexis of the ego into line with the cathexes of objects and emphasizes the libidinal character of the instinct of self-preservation - but because, in the absence of any analyses of this kind, we have lost a most precious opportunity of drawing decisive conclusions about the relations between anxiety and the formation of symptoms. In view of all that we know about the structure of the comparatively simple neuroses of everyday life, it would seem highly improbable that a neurosis could come into being merely because of the objective presence of danger, without any participation of the deeper levels of the mental apparatus. But the unconscious seems to contain nothing that could give any content to our concept of the annihilation of life. Castration can be pictured on the basis of the daily experience of the faeces being separated from the body or on the basis of losing the mother's breast at weaning. But nothing resembling death can ever have been experienced; or if it has, as in fainting, it has left no observable traces behind. I am therefore inclined to adhere to the view that the fear of death should be regarded as analogous to the fear of castration and that the situation to which the ego is reacting is one of being abandoned by the protecting super-ego - the powers of destiny - so that it has no longer any safeguard against all the dangers that surround it. In addition, it must be remembered that in the experiences which lead to a traumatic neurosis the protective shield against external stimuli is broken through and excessive amounts of excitation impinge upon the mental apparatus; so that we have here a second possibility - that anxiety is not only being signalled as an affect but is also being freshly created out of the economic conditions of the situation.
[1926d, 4286]
The statement I have just made, to the effect that the ego has been prepared to expect castration by having undergone constantly repeated object-losses, places the question of anxiety in a new light. We have hitherto regarded it as an affective signal of danger; but now, since the danger is so often one of castration, it appears to us as a reaction to a loss, a separation. Even though a number of considerations immediately arise which make against this view, we cannot but be struck by one very remarkable correlation. The first experience of anxiety which an individual goes through (in the case of human beings, at all events) is birth, and, objectively speaking, birth is a separation from the mother. It could be compared to a castration of the mother (by equating the child with a penis). Now it would be very satisfactory if anxiety, as a symbol of a separation, were to be repeated on every subsequent occasion on which a separation took place. But unfortunately we are prevented from making use of this correlation by the fact that birth is not experienced subjectively as a separation from the mother, since the foetus, being a completely narcissistic creature, is totally unaware of her existence as an object. Another adverse argument is that we know what the affective reactions to a separation are: they are pain and mourning, not anxiety. Incidentally, it may be remembered that in discussing the question of mourning we also failed to discover why it should be such a painful thing.

The view that anxiety goes back to the event of birth raises immediate objections which have to be met. It may be argued that anxiety is a reaction which, in all probability, is common to every organism, certainly every organism of a higher order, whereas birth is only experienced by the mammals; and it is doubtful whether in all of them, even, birth has the significance of a trauma. Therefore there can be anxiety without the prototype of birth. But this objection takes us beyond the barrier that divides psychology from biology. It may be that, precisely because anxiety has an indispensable biological function to fulfil as a reaction to a state of danger, it is differently contrived in different organisms. We do not know, besides, whether anxiety involves the same sensations and innervations in organisms far removed from man as it does in man himself. Thus there is no good argument here against the view that, in man, anxiety is modelled upon the process of birth.

If the structure and origin of anxiety are as described, the next question is: what is the function of anxiety and on what occasions is it reproduced? The answer seems to be obvious and convincing: anxiety arose originally as a reaction to a state of danger and it is reproduced whenever a state of that kind recurs.
This answer, however, raises further considerations. The innervations involved in the original state of anxiety probably had a meaning and purpose, in just the same way as the muscular movements which accompany a first hysterical attack. In order to understand a hysterical attack, all one has to do is to look for the situation in which the movements in question formed part of an appropriate and expedient action. Thus at birth it is probable that the innervation, in being directed to the respiratory organs, is preparing the way for the activity of the lungs, and, in accelerating the heartbeat, is helping to keep the blood free from toxic substances. Naturally, when the anxiety-state is reproduced later as an affect it will be lacking in any such expediency, just as are the repetitions of a hysterical attack. When the individual is placed in a new situation of danger it may well be quite inexpedient for him to respond with an anxiety-state (which is a reaction to an earlier danger) instead of initiating a reaction appropriate to the current danger. But his behaviour may become expedient once more if the danger-situation is recognized as it approaches and is signalled by an outbreak of anxiety. In that case he can at once get rid of his anxiety by having recourse to more suitable measures. Thus we see that there are two ways in which anxiety can emerge: in an inexpedient way, when a new situation of danger has occurred, or in an expedient way in order to give a signal and prevent such a situation from occurring.

[1926d, 4290]

When the infant has found out by experience that an external, perceptible object can put an end to the dangerous situation which is reminiscent of birth, the content of the danger it fears is displaced from the economic situation on to the condition which determined that situation, viz., the loss of object. It is the absence of the mother that is now the danger; and as soon as that danger arises the infant gives the signal of anxiety, before the dreaded economic situation has set in. This change constitutes a first great step forward in the provision made by the infant for its self-preservation, and at the same time represents a transition from the automatic and involuntary fresh appearance of anxiety to the intentional reproduction of anxiety as a signal of danger.

[1926d, 4293]

In these two aspects, as an automatic phenomenon and as a rescuing signal, anxiety is seen to be a product of the infant's mental helplessness which is a natural counterpart of its biological helplessness. The striking coincidence by which the anxiety of the new-born baby and the anxiety of the infant in arms are both conditioned by separation from the mother does not need to be explained on psychological lines. It can be accounted for simply enough biologically; for, just as the mother originally satisfied all the needs of the foetus through the apparatus of her own body, so now, after its birth, she continues to do so, though partly by other means. There is much more continuity between intra-uterine life and earliest infancy than the impressive caesura of the act of birth would have us believe. What happens is that the child's biological situation as a foetus is replaced for it by a psychical object-relation to its mother. But we must not forget that during its intra-uterine life the mother was not an object for the foetus, and that at that time there were no objects at all. It is obvious that in this scheme of things there is no place for the abreaction of the birth trauma. We cannot find that anxiety has any function other than that of being a signal for the avoidance of a danger situation.

[1926d, 4293]
The progress which the child makes in its development - its growing independence, the sharper division of its mental apparatus into several agencies, the advent of new needs - cannot fail to exert an influence upon the content of the danger situation. We have already traced the change of that content from loss of the mother as an object to castration. The next change is caused by the power of the super-ego. With the depersonalization of the parental agency from which castration was feared, the danger becomes less defined. Castration anxiety develops into moral anxiety - social anxiety - and it is not so easy now to know what the anxiety is about. The formula, 'separation and expulsion from the horde', only applies to that later portion of the super-ego which has been formed on the basis of social prototypes, not to the nucleus of the super-ego, which corresponds to the introjected parental agency. Putting it more generally, what the ego regards as the danger and responds to with an anxiety-signal is that the super-ego should be angry with it or punish it or cease to love it. The final transformation which the fear of the super-ego undergoes is, it seems to me, the fear of death (or fear for life) which is a fear of the super-ego projected on to the powers of destiny.

At one time I attached some importance to the view that what was used as a discharge of anxiety was the cathexis which had been withdrawn in the process of repression. To-day this seems to me of scarcely any interest. The reason for this is that whereas I formerly believed that anxiety invariably arose automatically by an economic process, my present conception of anxiety as a signal given by the ego in order to affect the pleasure-unpleasure agency does away with the necessity of considering the economic factor. Of course there is nothing to be said against the idea that it is precisely the energy that has been liberated by being withdrawn through repression which is used by the ego to arouse the affect; but it is no longer of any importance which portion of energy is employed for this purpose.

This new view of things calls for an examination of another assertion of mine - namely, that the ego is the actual seat of anxiety. I think this proposition still holds good. There is no reason to assign any manifestation of anxiety to the super-ego; while the expression 'anxiety of the id' would stand in need of correction, though rather as to its form than its substance. Anxiety is an affective state and as such can, of course, only be felt by the ego. The id cannot have anxiety as the ego can; for it is not an organization and cannot make a judgement about situations of danger. On the other hand it very often happens that processes take place or begin to take place in the id which cause the ego to produce anxiety. Indeed, it is probable that the earliest repressions as well as most of the later ones are motivated by an ego-anxiety of this sort in regard to particular processes in the id. Here again we are rightly distinguishing between two cases: the case in which something occurs in the id which activates one of the danger-situations for the ego and induces the latter to give the anxiety-signal for inhibition to take place, and the case in which a situation analogous to the trauma of birth is established in the id and an automatic reaction of anxiety ensues. The two cases may be brought closer together if it is pointed out that the second case corresponds to the earliest and original danger-situation, while the first case corresponds to any one of the later determinants of anxiety that have been derived from it; or, as applied to the disorders which we in fact come across, that the second case is operative in the aetiology of the 'actual' neuroses, while the first remains typical for that of the psychoneuroses.
In describing the evolution of the various danger-situations from their prototype, the act of birth, I have had no intention of asserting that every later determinant of anxiety completely invalidates the preceding one. It is true that, as the development of the ego goes on, the earlier danger-situations tend to lose their force and to be set aside, so that we might say that each period of the individual's life has its appropriate determinant of anxiety. Thus the danger of psychical helplessness is appropriate to the period of life when his ego is immature; the danger of loss of object, to early childhood when he is still dependent on others; the danger of castration, to the phallic phase; and the fear of his super-ego, to the latency period. Nevertheless, all these danger-situations and determinants of anxiety can persist side by side and cause the ego to react to them with anxiety at a period later than the appropriate one; or, again, several of them can come into operation at the same time. It is possible, moreover, that there is a fairly close relationship between the danger-situation that is operative and the form taken by the ensuing neurosis.¹

Since we have traced back the generating of anxiety to a situation of danger, we shall prefer to say that symptoms are created in order to remove the ego from a situation of danger. If the symptoms are prevented from being formed, the danger does in fact materialize; that is, a situation analogous to birth is established in which the ego is helpless in the face of a constantly increasing instinctual demand - the earliest and original determinant of anxiety. Thus in our view the relation between anxiety and symptom is less close than was supposed, for we have inserted the factor of the danger-situation between them. We can also add that the generating of anxiety sets symptom formation going and is, indeed, a necessary prerequisite of it. For if the ego did not arouse the pleasure-unpleasure agency by generating anxiety, it would not obtain the power to arrest the process which is preparing in the id and which threatens danger. There is in all this an evident inclination to limit to a minimum the amount of anxiety generated and to employ it only as a signal; for to do otherwise would only result in feeling in another place the unpleasure which the instinctual process was threatening to produce, and that would not be a success from the standpoint of the pleasure principle, although it is one that occurs often enough in the neuroses.

Symptom-formation, then, does in fact put an end to the danger-situation. It has two aspects: one, hidden from view, brings about the alteration in the id in virtue of which the ego is removed from danger; the other, presented openly, shows what has been created in place of the instinctual process that has been affected - namely, the substitutive formation.

These minor rectifications cannot in any way alter the fact which is here under discussion, that a great many people remain infantile in their behaviour in regard to danger and do not overcome determinants of anxiety which have grown out of date. To deny this would be to deny the existence of neurosis, for it is precisely such people whom we call neurotics. But how is this possible? Why are not all neuroses episodes in the development of the individual which come to a close when the next phase is reached? Whence comes the element of persistence in these reactions to danger? Why does the affect of anxiety alone seem to enjoy the advantage over all other affects of evoking reactions which are distinguished from the rest in being abnormal and which, through their inexpediency, run counter to the movement of life? In other words, we have once more come unawares upon the riddle which has so often confronted us: whence does neurosis come - what is its ultimate, its own peculiar raison d'être? After tens of years of psycho-analytic labours, we are as much in the dark about this problem as we were at the start.
Anxiety is the reaction to danger. One cannot, after all, help suspecting that the reason why the affect of anxiety occupies a unique position in the economy of the mind has something to do with the essential nature of danger. Yet dangers are the common lot of humanity; they are the same for everyone. What we need and cannot lay our finger on is some factor which will explain why some people are able to subject the affect of anxiety, in spite of its peculiar quality, to the normal workings of the mind, or which decides who is doomed to come to grief over that task. Two attempts to find a factor of this kind have been made; and it is natural that such efforts should meet with a sympathetic reception, since they promise help to meet a tormenting need. The two attempts in question are mutually complementary; they approach the problem at opposite ends. The first was made by Alfred Adler more than ten years ago. His contention, reduced to its essence, was that the people who came to grief over the task set them by danger were those who were too greatly impeded by some organic inferiority. If it were true that simplex sigillum veri, we should welcome such a solution as a deliverance. But on the contrary, our critical studies of the last ten years have effectively demonstrated the total inadequacy of such an explanation - an explanation, moreover, which sets aside the whole wealth of material that has been discovered by psycho-analysis.

(b) Anxiety from Transformation of Libido

The view of anxiety which I have put forward in these pages diverges somewhat from the one I have hitherto thought correct. Formerly I regarded anxiety as a general reaction of the ego under conditions of unpleasure. I always sought to justify its appearance on economic grounds and I assumed, on the strength of my investigations into the 'actual' neuroses, that libido (sexual excitation) which was rejected or not utilized by the ego found direct discharge in the form of anxiety. It cannot be denied that these various assertions did not go very well together, or at any rate did not necessarily follow from one another. Moreover, they gave the impression of there being a specially intimate connection between anxiety and libido and this did not accord with the general character of anxiety as a reaction to unpleasure.

The objection to this view arose from our coming to regard the ego as the sole seat of anxiety. It was one of the results of the attempt at a structural division of the mental apparatus which I made in The Ego and the Id. Whereas the old view made it natural to suppose that anxiety arose from the libido belonging to the repressed instinctual impulses, the new one, on the contrary, made the ego the source of anxiety. Thus it is a question of instinctual (id-) anxiety or ego-anxiety. Since the energy which the ego employs is desexualized, the new view also tended to weaken the close connection between anxiety and libido. I hope I have at least succeeded in making the contradiction plain and in giving a clear idea of the point in doubt.
Rank's contention - which was originally my own -, that the affect of anxiety is a consequence of the event of birth and a repetition of the situation then experienced, obliged me to review the problem of anxiety once more. But I could make no headway with his idea that birth is a trauma, states of anxiety a reaction of discharge to it and all subsequent affects of anxiety an attempt to 'abreact' it more and more completely. I was obliged to go back from the anxiety reaction to the situation of danger that lay behind it. The introduction of this element opened up new aspects of the question. Birth was seen to be the prototype of all later situations of danger which overtook the individual under the new conditions arising from a changed mode of life and a growing mental development. On the other hand its own significance was reduced to this prototypic relationship to danger. The anxiety felt at birth became the prototype of an affective state which had to undergo the same vicissitudes as the other affects. Either the state of anxiety reproduced itself automatically in situations analogous to the original situation and was thus an inexpedient form of reaction instead of an expedient one as it had been in the first situation of danger; or the ego acquired power over this affect, reproduced it on its own initiative, and employed it as a warning of danger and as a means of setting the pleasure-unpleasure mechanism in motion. We thus gave the biological aspect of the anxiety affect its due importance by recognizing anxiety as the general reaction to situations of danger; while we endorsed the part played by the ego as the seat of anxiety by allocating to it the function of producing the anxiety affect according to its needs. Thus we attributed two modes of origin to anxiety in later life. One was involuntary, automatic and always justified on economic grounds, and arose whenever a danger situation analogous to birth had established itself. The other was produced by the ego as soon as a situation of this kind merely threatened to occur, in order to call for its avoidance. In the second case the ego subjects itself to anxiety as a sort of inoculation, submitting to a slight attack of the illness in order to escape its full strength. It vividly imagines the danger situation, as it were, with the unmistakable purpose of restricting that distressing experience to a mere indication, a signal. We have already seen in detail how the various situations of danger arise one after the other, retaining at the same time a genetic connection.

[1926d, 4315]

To begin with the last problem. The advance we have made is that we have gone behind reactions of anxiety to situations of danger. If we do the same thing with realistic anxiety we shall have no difficulty in solving the question. Real danger is a danger that is known, and realistic anxiety is anxiety about a known danger of this sort. Neurotic anxiety is anxiety about an unknown danger. Neurotic danger is thus a danger that has still to be discovered. Analysis has shown that it is an instinctual danger. By bringing this danger which is not known to the ego into consciousness, the analyst makes neurotic anxiety no different from realistic anxiety, so that it can be dealt with in the same way.

[1926d, 4317]

There are two reactions to real danger. One is an affective reaction, an outbreak of anxiety. The other is a protective action. The same will presumably be true of instinctual danger. We know how the two reactions can co-operate in an expedient way, the one giving the signal for the other to appear. But we also know that they can behave in an inexpedient way: paralysis from anxiety may set in, and the one reaction spread at the cost of the other.

[1926d, 4317]
We can find out still more about this if, not content with tracing anxiety back to danger, we go on to enquire what the essence and meaning of a danger-situation is. Clearly, it consists in the subject's estimation of his own strength compared to the magnitude of the danger and in his admission of helplessness in the face of it - physical helplessness if the danger is real and psychical helplessness if it is instinctual. In doing this he will be guided by the actual experiences he has had. (Whether he is wrong in his estimation or not is immaterial for the outcome.) Let us call a situation of helplessness of this kind that has been actually experienced a traumatic situation. We shall then have good grounds for distinguishing a traumatic situation from a danger-situation.

The individual will have made an important advance in his capacity for self-preservation if he can foresee and expect a traumatic situation of this kind which entails helplessness, instead of simply waiting for it to happen. Let us call a situation which contains the determinant for such an expectation a danger-situation. It is in this situation that the signal of anxiety is given. The signal announces: 'I am expecting a situation of helplessness to set in', or: 'The present situation reminds me of one of the traumatic experiences I have had before. Therefore I will anticipate the trauma and behave as though it had already come, while there is yet time to turn it aside.' Anxiety is therefore on the one hand an expectation of a trauma, and on the other a repetition of it in a mitigated form. Thus the two features of anxiety which we have noted have a different origin. Its connection with expectation belongs to the danger-situation, whereas its indefiniteness and lack of object belong to the traumatic situation of helplessness - the situation which is anticipated in the danger-situation.

Taking this sequence, anxiety - danger - helplessness (trauma), we can now summarize what has been said. A danger-situation is a recognized, remembered, expected situation of helplessness. Anxiety is the original reaction to helplessness in the trauma and is reproduced later on in the danger-situation as a signal for help. The ego, which experienced the trauma passively, now repeats it actively in a weakened version, in the hope of being able itself to direct its course. It is certain that children behave in this fashion towards every distressing impression they receive, by reproducing it in their play. In thus changing from passivity to activity they attempt to master their experiences psychically. If this is what is meant by 'abreacting a trauma' we can no longer have anything to urge against the phrase. But what is of decisive importance is the first displacement of the anxiety-reaction from its origin in the situation of helplessness to an expectation of that situation - that is, to the danger-situation. After that come the later displacements, from the danger to the determinant of the danger - loss of the object and the modifications of that loss with which we are already acquainted.

So far we have had no occasion to regard realistic anxiety in any different light from neurotic anxiety. We know what the distinction is. A real danger is a danger which threatens a person from an external object, and a neurotic danger is one which threatens him from an instinctual demand. In so far as the instinctual demand is something real, his neurotic anxiety, too, can be admitted to have a realistic basis. We have seen that the reason why there seems to be a specially close connection between anxiety and neurosis is that the ego defends itself against an instinctual danger with the help of the anxiety reaction just as it does against an external real danger, but that this line of defensive activity eventuates in a neurosis owing to an imperfection of the mental apparatus. We have also come to the conclusion that an instinctual demand often only becomes an (internal) danger because its satisfaction would bring on an external danger - that is, because the internal danger represents an external one.
The traumatic situation of missing the mother differs in one important respect from the traumatic situation of birth. At birth no object existed and so no object could be missed. Anxiety was the only reaction that occurred. Since then repeated situations of satisfaction have created an object out of the mother; and this object, whenever the infant feels a need, receives an intense cathexis which might be described as a ‘longing’ one. It is to this new aspect of things that the reaction of pain is referable. Pain is thus the actual reaction to loss of object, while anxiety is the reaction to the danger which that loss entails and, by a further displacement, a reaction to the danger of the loss of object itself.

I must go back a little bit further. A small living organism is a truly miserable, powerless thing, is it not? compared with the immensely powerful external world, full as it is of destructive influences. A primitive organism, which has not developed any adequate ego-organization, is at the mercy of all these ‘traumas’. It lives by the ‘blind’ satisfaction of its instinctual wishes and often perishes in consequence. The differentiation of an ego is above all a step towards self-preservation. Nothing, it is true, can be learnt from being destroyed; but if one has luckily survived a trauma one takes notice of the approach of similar situations and signalizes the danger by an abbreviated repetition of the impressions one has experienced in connection with the trauma - by an affect of anxiety. This reaction to the perception of the danger now introduces an attempt at flight, which can have a life-saving effect till one has grown strong enough to meet the dangers of the external world in a more active fashion - even aggressively, perhaps.

We are warned by a proverb against serving two masters at the same time. The poor ego has things even worse: it serves three severe masters and does what it can to bring their claims and demands into harmony with one another. These claims are always divergent and often seem incompatible. No wonder that the ego so often fails in its task. Its three tyrannical masters are the external world, the super-ego and the id. When we follow the ego's efforts to satisfy them simultaneously - or rather, to obey them simultaneously - we cannot feel any regret at having personified this ego and having set it up as a separate organism. It feels hemmed in on three sides, threatened by three kinds of danger, to which, if it is hard pressed, it reacts by generating anxiety. Owing to its origin from the experiences of the perceptual system, it is earmarked for representing the demands of the external world, but it strives too to be a loyal servant of the id, to remain on good terms with it, to recommend itself to it as an object and to attract its libido to itself. In its attempts to mediate between the id and reality, it is often obliged to cloak the Ucs commands of the id with its own Pcs rationalizations, to conceal the id's conflicts with reality, to profess, with diplomatic disingenuousness, to be taking notice of reality even when the id has remained rigid and unyielding. On the other hand it is observed at every step it takes by the strict super-ego, which lays down definite standards for its conduct, without taking any account of its difficulties from the direction of the id and the external world, and which, if those standards are not obeyed, punishes it with tense feelings of inferiority and of guilt. Thus the ego, driven by the id, confined by the super-ego, repulsed by reality, struggles to master its economic task of bringing about harmony among the forces and influences working in and upon it; and we can understand how it is that so often we cannot suppress a cry: 'Life is not easy!' If the ego is obliged to admit its weakness it breaks out in anxiety - realistic anxiety regarding the external world, moral anxiety regarding the super-ego and neurotic anxiety regarding the strength of the passions in the id.
For we consider that what is responsible for the anxiety in hysteria and other neuroses is the process of repression. We believe it is possible to give a more complete account of this than before, if we separate what happens to the idea that has to be repressed from what happens to the quota of libido attaching to it. It is the idea which is subjected to repression and which may be distorted to the point of being unrecognizable; but its quota of affect is regularly transformed into anxiety - and this is so whatever the nature of the affect may be, whether it is aggressiveness or love. It makes no essential difference, then, for what reason a quota of libido has become unemployable: whether it is on account of the infantile weakness of the ego, as in children's phobias, or on account of somatic processes in sexual life, as in anxiety neurosis, or owing to repression, as in hysteria. Thus in reality the two mechanisms that bring about neurotic anxiety coincide.

[1933a, 4690]

At the conclusion of my earlier lecture on anxiety I myself expressed the opinion that, although these various findings of our enquiry were not mutually contradictory, somehow they did not fit in with one another. Anxiety, it seems, in so far as it is an affective state, is the reproduction of an old event which brought a threat of danger; anxiety serves the purposes of self-preservation and is a signal of a new danger; it arises from libido that has in some way become unemployable and it also arises during the process of repression; it is replaced by the formation of a symptom, is, as it were, psychically bound - one has a feeling that something is missing here which would bring all these pieces together into a whole.

[1933a, 4691]

Ladies and Gentlemen, the dissection of the mental personality into a super-ego, an ego and an id, which I put before you in my last lecture, has obliged us to take our bearings afresh in the problem of anxiety as well. With the thesis that the ego is the sole seat of anxiety - that the ego alone can produce and feel anxiety - we have established a new and stable position from which a number of things take on a new aspect. And indeed it is difficult to see what sense there would be in speaking of an 'anxiety of the id' or in attributing a capacity for apprehensiveness to the super-ego. On the other hand, we have welcomed a desirable element of correspondence in the fact that the three main species of anxiety, realistic, neurotic and moral, can be so easily connected with the ego's three dependent relations - to the external world, to the id and to the super-ego. Along with this new view, moreover, the function of anxiety as a signal announcing a situation of danger (a notion, incidentally, not unfamiliar to us) comes into prominence, the question of what the material is out of which anxiety is made loses interest, and the relations between realistic and neurotic anxiety have become surprisingly clarified and simplified. It is also to be remarked that we now understand the apparently complicated cases of the generation of anxiety better than those which were considered simple.

[1933a, 4692]
I hope you have not lost the thread of what I am saying and remember that we are investigating the relations between anxiety and repression. In the course of this we have learnt two new things: first, that anxiety makes repression and not, as we used to think, the other way round, and that the instinctual situation which is feared goes back ultimately to an external situation of danger. The next question will be: how do we now picture the process of a repression under the influence of anxiety? The answer will, I think, be as follows. The ego notices that the satisfaction of an emerging instinctual demand would conjure up one of the well-remembered situations of danger. This instinctual cathexis must therefore be somehow suppressed, stopped, made powerless. We know that the ego succeeds in this task if it is strong and has drawn the instinctual impulse concerned into its organization. But what happens in the case of repression is that the instinctual impulse still belongs to the id and that the ego feels weak. The ego thereupon helps itself by a technique which is at bottom identical with normal thinking. Thinking is an experimental action carried out with small amounts of energy, in the same way as a general shifts small figures about on a map before setting his large bodies of troops in motion. Thus the ego anticipates the satisfaction of the questionable instinctual impulse and permits it to bring about the reproduction of the unpleasurable feelings at the beginning of the feared situation of danger. With this the automatism of the pleasure-unpleasure principle is brought into operation and now carries out the repression of the dangerous instinctual impulse.

[1933a, 4696]

‘Stop a moment!’ you will exclaim; ‘we can't follow you any further there!’ You are quite right; I must add a little more before it can seem acceptable to you. First, I must admit that I have tried to translate into the language of our normal thinking what must in fact be a process that is neither conscious nor preconscious, taking place between quotas of energy in some unimaginable substratum. But that is not a strong objection, for it cannot be done in any other way. What is more important is that we should distinguish clearly what happens in the ego and what happens in the id when there is a repression. We have just said what the ego does: it makes use of an experimental cathexis and starts up the pleasure-unpleasure automatism by means of a signal of anxiety. After that, several reactions are possible or a combination of them in varying proportions. Either the anxiety attack is fully generated and the ego withdraws entirely from the objectionable excitation; or, in place of the experimental cathexis it opposes the excitation with an anticathexis, and this combines with the energy of the repressed impulse to form a symptom; or the anticathexis is taken up into the ego as a reaction-formation, as an intensification of certain of the ego’s dispositions, as a permanent alteration of it. The more the generation of anxiety can be restricted to a mere signal, so much the more does the ego expend on actions of defence which amount to the psychical binding of the repressed, and so much the closer, too, does the process approximate to a normal working-over of it, though no doubt without attaining to it.

[1933a, 4697]
Now let us go back and turn to the id. It is not so easy to guess what occurs during repression in connection with the instinctual impulse that is being fought against. The main question which our interest raises is as to what happens to the energy, to the libidinal charge, of that excitation - how is it employed? You recollect that the earlier hypothesis was that it is precisely this that is transformed by repression into anxiety. We no longer feel able to say that. The modest reply will rather be that what happens to it is probably not always the same thing. There is probably an intimate correspondence which we ought to get to know about between what is occurring at the time in the ego and in the id in connection with the repressed impulse. For since we have decided that the pleasure-unpleasure principle, which is set in action by the signal of anxiety, plays a part in repression, we must alter our expectations. That principle exercises an entirely unrestricted dominance over what happens in the id. We can rely on its bringing about quite profound changes in the instinctual impulse in question. We are prepared to find that repression will have very various consequences, more or less far-reaching. In some cases the repressed instinctual impulse may retain its libidinal cathexis, and may persist in the id unchanged, although subject to constant pressure from the ego. In other cases what seems to happen is that it is totally destroyed, while its libido is permanently diverted along other paths. I expressed the view that this is what happens when the Oedipus complex is dealt with normally - in this desirable case, therefore, being not simply repressed but destroyed in the id. Clinical experience has further shown us that in many cases, instead of the customary result of repression, a degradation of the libido takes place - a regression of the libidinal organization to an earlier stage. This can, of course, only occur in the id, and if it occurs it will be under the influence of the same conflict which was introduced by the signal of anxiety. The most striking example of this kind is provided by the obsessional neurosis, in which libidinal regression and repression operate together.
[1933a, 4698]

I fear, Ladies and Gentlemen, that you will find this exposition hard to follow, and you will guess that I have not stated it exhaustively. I am sorry to have had to rouse your displeasure. But I can set myself no other aim than to give you an impression of the nature of our findings and of the difficulties involved in working them out. The deeper we penetrate into the study of mental processes the more we recognize their abundance and complexity. A number of simple formulas which to begin with seemed to meet our needs have later turned out to be inadequate. We do not tire of altering and improving them. In my lecture on the theory of dreams I introduced you to a region in which for fifteen years there has scarcely been a new discovery. Here, where we are dealing with anxiety, you see everything in a state of flux and change. These novelties, moreover, have not yet been thoroughly worked through and perhaps this too adds to the difficulties of demonstrating them. But have patience! We shall soon be able to take leave of the subject of anxiety. I cannot promise that it will have been settled to our satisfaction, but it is to be hoped that we shall have made a little bit of progress. And in the meantime we have made all sorts of new discoveries. Now, for instance, our study of anxiety leads us to add a new feature to our description of the ego. We have said that the ego is weak in comparison with the id, that it is its loyal servant, eager to carry out its orders and to fulfil its demands. We have no intention of withdrawing this statement. But on the other hand this same ego is the better organized part of the id, with its face turned towards reality. We must not exaggerate the separation between the two of them too much, and we must not be surprised if the ego on its part can bring its influence to bear on the processes in the id. I believe the ego exercises this influence by putting into action the almost omnipotent pleasure-unpleasure principle by means of the signal of anxiety. On the other hand, it shows its weakness again immediately afterwards, for by the act of repression it renounces a portion of its organization and has to allow the repressed instinctual impulse to remain permanently withdrawn from its influence.
[1933a, 4699]
And now, only one more remark on the problem of anxiety. Neurotic anxiety has changed in our hands into realistic anxiety, into fear of particular external situations of danger. But we cannot stop there, we must take another step - though it will be a step backward. We ask ourselves what it is that is actually dangerous and actually feared in a situation of danger of this kind. It is plainly not the injury to the subject as judged objectively, for this need be of no significance psychologically, but something brought about by it in the mind. Birth, for instance, our model for an anxiety state, can after all scarcely be regarded on its own account as an injury, although it may involve a danger of injuries. The essential thing about birth, as about every situation of danger, is that it calls up in mental experience a state of highly tense excitation, which is felt as unpleasure and which one is not able to master by discharging it. Let us call a state of this kind, before which the efforts of the pleasure principle break down, a 'traumatic' moment. Then, if we take in succession neurotic anxiety, realistic anxiety and the situation of danger, we arrive at this simple proposition: what is feared, what is the object of the anxiety, is invariably the emergence of a traumatic moment, which cannot be dealt with by the normal rules of the pleasure principle. We understand at once that our endowment with the pleasure principle does not guarantee us against objective injuries but only against a particular injury to our psychical economics. It is a long step from the pleasure principle to the self-preservation instinct; the intentions of the two of them are very far from coinciding from the start. But we see something else besides; perhaps it is the solution we are in search of. Namely, that in all this it is a question of relative quantities. It is only the magnitude of the sum of excitation that turns an impression into a traumatic moment, paralyses the function of the pleasure principle and gives the situation of danger its significance. And if that is how things are, if these puzzles can be solved so prosaically, why should it not be possible for similar traumatic moments to arise in mental life without reference to hypothetical situations of danger - traumatic moments, then, in which anxiety is not aroused as a signal but is generated anew for a fresh reason. Clinical experience declares decidedly that such is in fact the case. It is only the later repressions that exhibit the mechanism we have described, in which anxiety is awakened as a signal of an earlier situation of danger. The first and original repressions arise directly from traumatic moments, when the ego meets with an excessively great libidinal demand; they construct their anxiety afresh, although, it is true, on the model of birth. The same may apply to the generation of anxiety in anxiety neurosis owing to somatic damage to the sexual function. We shall no longer maintain that it is the libido itself that is turned into anxiety in such cases. But I can see no objection to there being a twofold origin of anxiety - one as a direct consequence of the traumatic moment and the other as a signal threatening a repetition of such a moment. [1933a, 4700]
Here are the principal characteristics of the ego. In consequence of the pre-established connection between sense perception and muscular action, the ego has voluntary movement at its command. It has the task of self-preservation. As regards external events, it performs that task by becoming aware of stimuli, by storing up experiences about them (in the memory), by avoiding excessively strong stimuli (through flight), by dealing with moderate stimuli (through adaptation) and finally by learning to bring about expedient changes in the external world to its own advantage (through activity). As regards internal events, in relation to the id, it performs that task by gaining control over the demands of the instincts, by deciding whether they are to be allowed satisfaction, by postponing that satisfaction to times and circumstances favourable in the external world or by suppressing their excitations entirely. It is guided in its activity by consideration of the tensions produced by stimuli, whether these tensions are present in it or introduced into it. The raising of these tensions is in general felt as unpleasure and their lowering as pleasure. It is probable, however, that what is felt as pleasure or unpleasure is not the absolute height of this tension but something in the rhythm of the changes in them. The ego strives after pleasure and seeks to avoid unpleasure. An increase in unpleasure that is expected and foreseen is met by a signal of anxiety; the occasion of such an increase, whether it threatens from without or within, is known as a danger. From time to time the ego gives up its connection with the external world and withdraws into the state of sleep, in which it makes far-reaching changes in its organization. It is to be inferred from the state of sleep that this organization consists in a particular distribution of mental energy.

[1940a [1938], 4957]
The other agency of the mind, which we believe we know best and in which we recognize ourselves most easily - what is known as the ego - has been developed out of the id's cortical layer, which, through being adapted to the reception and exclusion of stimuli, is in direct contact with the external world (reality). Starting from conscious perception it has subjected to its influence ever larger regions and deeper strata of the id, and, in the persistence with which it maintains its dependence on the external world, it bears the indelible stamp of its origin (as it might be 'Made in Germany'). Its psychological function consists in raising the passage in the id to a higher dynamic level (perhaps by transforming freely mobile energy into bound energy, such as corresponds to the preconscious state); its constructive function consists in interpolating, between the demand made by an instinct and the action that satisfies it, the activity of thought which, after taking its bearings in the present and assessing earlier experiences, endeavours by means of experimental actions to calculate the consequences of the course of action proposed. In this way the ego comes to a decision on whether the attempt to obtain satisfaction is to be carried out or postponed or whether it may not be necessary for the demand by the instinct to be suppressed altogether as being dangerous. (Here we have the reality principle.) Just as the id is directed exclusively to obtaining pleasure, so the ego is governed by considerations of safety. The ego has set itself the task of self-preservation, which the id appears to neglect. It makes use of the sensations of anxiety as a signal to give a warning of dangers that threaten its integrity. Since memory traces can become conscious just as perceptions do, especially through their association with residues of speech, the possibility arises of a confusion which would lead to a mistaking of reality. The ego guards itself against this possibility by the institution of reality-testing, which is allowed to fall into abeyance in dreams on account of the conditions prevailing in the state of sleep. The ego, which seeks to maintain itself in an environment of overwhelming mechanical forces, is threatened by dangers which come in the first instance from external reality; but dangers do not threaten it from there alone. Its own id is a source of similar dangers, and that for two different reasons. In the first place, an excessive strength of instinct can damage the ego in a similar way to an excessive 'stimulus' from the external world. It is true that the former cannot destroy it; but it can destroy its characteristic dynamic organization and change the ego back into a portion of the id. In the second place, experience may have taught the ego that the satisfaction of some instinctual demand which is not in itself intolerable would involve dangers in the external world, so that an instinctual demand of that kind itself becomes a danger. Thus the ego is fighting on two fronts: it has to defend its existence against an external world which threatens it with annihilation as well as against an internal world that makes excessive demands. It adopts the same methods of defence against both, but its defence against the internal enemy is particularly inadequate. As a result of having originally been identical with this latter enemy and of having lived with it since on the most intimate terms, it has great difficulty in escaping from the internal dangers. They persist as threats, even if they can be temporarily held down.

[1940a [1938], 5005]
We finally arrive at the connection we are in search of, if we take as our starting-point the opposition we have so often asserted between the ego and the libido. As we know, the generation of anxiety is the ego’s reaction to danger and the signal for taking flight. If so, it seems plausible to suppose that in neurotic anxiety the ego is making a similar attempt at flight from the demand by its libido, that it is treating this internal danger as though it were an external one. This would therefore fulfil our expectation that where anxiety is shown there is something one is afraid of. But the analogy could be carried further. Just as the attempt at flight from an external danger is replaced by standing firm and the adoption of expedient measures of defence, so too the generation of neurotic anxiety gives place to the formation of symptoms, which results in the anxiety being bound.

[1916-1917, 3452]

The traumatic neuroses and war neuroses may proclaim too loudly the effects of mortal danger and may be silent or speak only in muted tones of the effects of frustration in love. But, on the other hand, the ordinary transference neuroses of peace-time set no aetiological store by the factor of mortal danger which, in the former class of neuroses, plays so mighty a part. It is even held that the peace-time neuroses are promoted by indulgence, good living and inactivity - which would afford an interesting contrast to the living-conditions under which the war neuroses develop. If they were to follow the example of their opponents, psycho-analysts, finding that their patients had fallen ill owing to frustration in love (owing to the claims of the libido being unsatisfied) would have to maintain that there can be no such things as danger-neuroses or that the disorders that appear after frightening experiences are not neuroses. They have, of course, no notion of maintaining any such thing. On the contrary, a convenient possibility occurs to them of bringing the two apparently divergent sets of facts together under a single hypothesis. In traumatic and war neuroses the human ego is defending itself from a danger which threatens it from without or which is embodied in a shape assumed by the ego itself. In the transference neuroses of peace the enemy from which the ego is defending itself is actually the libido, whose demands seem to it to be menacing. In both cases the ego is afraid of being damaged - in the latter case by the libido and in the former by external violence. It might, indeed, be said that in the case of the war neuroses, in contrast to the pure traumatic neuroses and in approximation to the transference neuroses, what is feared is nevertheless an internal enemy. The theoretical difficulties standing in the way of a unifying hypothesis of this kind do not seem insuperable: after all, we have a perfect right to describe repression, which lies at the basis of every neurosis, as a reaction to a trauma - as an elementary traumatic neurosis.

[1919d, 3668]
We have pointed out how the living vesicle is provided with a shield against stimuli from the external world; and we had previously shown that the cortical layer next to that shield must be differentiated as an organ for receiving stimuli from without. This sensitive cortex, however, which is later to become the system Cs, also receives excitations from within. The situation of the system between the outside and the inside and the difference between the conditions governing the reception of excitations in the two cases have a decisive effect on the functioning of the system and of the whole mental apparatus. Towards the outside it is shielded against stimuli, and the amounts of excitation impinging on it have only a reduced effect. Towards the inside there can be no such shield; the excitations in the deeper layers extend into the system directly and in undiminished amount, in so far as certain of their characteristics give rise to feelings in the pleasure-unpleasure series. The excitations coming from within are, however, in their intensity and in other, qualitative, respects - in their amplitude, perhaps - more commensurate with the system's method of working than the stimuli which stream in from the external world. This state of things produces two definite results. First, the feelings of pleasure and displeasure (which are an index to what is happening in the interior of the apparatus) predominate over all external stimuli. And secondly, a particular way is adopted of dealing with any internal excitations which produce too great an increase of displeasure: there is a tendency to treat them as though they were acting, not from the inside, but from the outside, so that it may be possible to bring the shield against stimuli into operation as a means of defence against them. This is the origin of projection, which is destined to play such a large part in the causation of pathological processes.

[1920g, 3732]

From the other point of view, however, we see this same ego as a poor creature owing service to three masters and consequently menaced by three dangers: from the external world, from the libido of the id, and from the severity of the super-ego. Three kinds of anxiety correspond to these three dangers, since anxiety is the expression of a retreat from danger. As a frontier creature, the ego tries to mediate between the world and the id, to make the id pliable to the world and, by means of its muscular activity, to make the world fall in with the wishes of the id. In point of fact it behaves like the physician during an analytic treatment: it offers itself, with the attention it pays to the real world, as a libidinal object to the id, and aims at attaching the id's libido to itself. It is not only a helper to the id; it is also a submissive slave who courts his master's love. Whenever possible, it tries to remain on good terms with the id; it clothes the id's Ucs. commands with its Pcs. rationalizations; it pretends that the id is showing obedience to the admonitions of reality, even when in fact it is remaining obstinate and unyielding; it disguises the id's conflicts with reality and, if possible, its conflicts with the super-ego too. In its position midway between the id and reality, it only too often yields to the temptation to become sycophantic, opportunist and lying, like a politician who sees the truth but wants to keep his place in popular favour.

[1923b, 3990]

The ego is the actual seat of anxiety. Threatened by dangers from three directions, it develops the flight-reflex by withdrawing its own cathexis from the menacing perception or from the similarly regarded process in the id, and emitting it as anxiety. This primitive reaction is later replaced by the carrying-out of protective cathexes (the mechanism of the phobias). What it is that the ego fears from the external and from the libidinal danger cannot be specified; we know that the fear is of being overwhelmed or annihilated, but it cannot be grasped analytically. The ego is simply obeying the warning of the pleasure principle. On the other hand, we can tell what is hidden behind the ego's dread of the super-ego, the fear of conscience. The superior being, which turned into the ego ideal, once threatened castration, and this dread of castration is probably the nucleus round which the subsequent fear of conscience has gathered; it is this dread that persists as the fear of conscience.

[1923b, 3991]
But this last point raises a fresh problem. Instead of the affect of anxiety let us take, for a moment, another affect - that of pain, for instance. It seems quite normal that at four years of age a girl should weep painfully if her doll is broken; or at six, if her governess reproves her; or at sixteen, if she is slighted by her young man; or at twenty-five, perhaps, if a child of her own dies. Each of these determinants of pain has its own time and each passes away when that time is over. Only the final and definitive determinants remain throughout life. We should think it strange if this same girl, after she had grown to be a wife and mother, were to cry over some worthless trinket that had been damaged. Yet that is how the neurotic behaves. Although all the agencies for mastering stimuli have long ago been developed within wide limits in his mental apparatus, and although he is sufficiently grown up to satisfy most of his needs for himself and has long ago learnt that castration is no longer practised as a punishment, he nevertheless behaves as though the old danger-situations still existed, and keeps hold of all the earlier determinants of anxiety.

[1926d, 4302]

Why this should be so calls for a rather long reply. First of all, we must sift the facts. In a great number of cases the old determinants of anxiety do really lapse, after having produced neurotic reactions. The phobias of very young children, fears of being alone or in the dark or with strangers - phobias which can almost be called normal - usually pass off later on; the child 'grows out of them', as we say about some other disturbances of childhood. Animal phobias, which are of such frequent occurrence, undergo the same fate and many conversion hysterias of early years find no continuation in later life. Ceremonial actions appear extremely often in the latency period, but only a very small percentage of them develop later into a full obsessional neurosis. In general, so far as we can tell from our observations of town children belonging to the white races and living according to fairly high cultural standards, the neuroses of childhood are in the nature of regular episodes in a child's development, although too little attention is still being paid to them. Signs of childhood neuroses can be detected in all adult neurotics without exception; but by no means all children who show those signs become neurotic in later life. It must be, therefore, that certain determinants of anxiety are relinquished and certain danger-situations lose their significance as the individual becomes more mature. Moreover, some of these danger-situations manage to survive into later times by modifying their determinants of anxiety so as to bring them up to date. Thus, for instance, a man may retain his fear of castration in the guise of a syphilidophobia, after he has come to know that it is no longer customary to castrate people for indulging their sexual lusts, but that, on the other hand, severe diseases may overtake anyone who thus gives way to his instincts. Other determinants of anxiety, such as fear of the super-ego, are destined not to disappear at all but to accompany people throughout their lives. In that case the neurotic will differ from the normal person in that his reactions to the dangers in question will be unduly strong. Finally, being grown-up affords no absolute protection against a return of the original traumatic anxiety-situation. Each individual has in all probability a limit beyond which his mental apparatus fails in its function of mastering the quantities of excitation which require to be disposed of.

[1926d, 4302]
The existence of the second, phylogenetic, factor, is based only upon inference. We have been led to assume its existence by a remarkable feature in the development of the libido. We have found that the sexual life of man, unlike that of most of the animals nearly related to him, does not make a steady advance from birth to maturity, but that, after an early efflorescence up till the fifth year, it undergoes a very decided interruption; and that it then starts on its course once more at puberty, taking up again the beginnings broken off in early childhood. This has led us to suppose that something momentous must have occurred in the vicissitudes of the human species which has left behind this interruption in the sexual development of the individual as a historical precipitate. This factor owes its pathogenic significance to the fact that the majority of the instinctual demands of this infantile sexuality are treated by the ego as dangers and fended off as such, so that the later sexual impulses of puberty, which in the natural course of things would be ego-syntonic, run the risk of succumbing to the attraction of their infantile prototypes and following them into repression. It is here that we come upon the most direct aetiology of the neuroses. It is a curious thing that early contact with the demands of sexuality should have a similar effect on the ego to that produced by premature contact with the external world. [1926d, 4309]

The third, psychological, factor resides in a defect of our mental apparatus which has to do precisely with its differentiation into an id and an ego, and which is therefore also attributable ultimately to the influence of the external world. In view of the dangers of reality, the ego is obliged to guard against certain instinctual impulses in the id and to treat them as dangers. But it cannot protect itself from internal instinctual dangers as effectively as it can from some piece of reality that is not part of itself. Intimately bound up with the id as it is, it can only fend off an instinctual danger by restricting its own organization and by acquiescing in the formation of symptoms in exchange for having impaired the instinct. If the rejected instinct reneges its attack, the ego is overtaken by all those difficulties which are known to us as neurotic ailments. [1926d, 4309]

So far we have had no occasion to regard realistic anxiety in any different light from neurotic anxiety. We know what the distinction is. A real danger is a danger which threatens a person from an external object, and a neurotic danger is one which threatens him from an instinctual demand. In so far as the instinctual demand is something real, his neurotic anxiety, too, can be admitted to have a realistic basis. We have seen that the reason why there seems to be a specially close connection between anxiety and neurosis is that the ego defends itself against an instinctual danger with the help of the anxiety reaction just as it does against an external real danger, but that this line of defensive activity eventuates in a neurosis owing to an imperfection of the mental apparatus. We have also come to the conclusion that an instinctual demand often only becomes an (internal) danger because its satisfaction would bring on an external danger - that is, because the internal danger represents an external one. [1926d, 4319]

On the other hand, the external (real) danger must also have managed to become internalized if it is to be significant for the ego. It must have been recognized as related to some situation of helplessness that has been experienced. Man seems not to have been endowed, or to have been endowed to only a very small degree, with an instinctive recognition of the dangers that threaten him from without. Small children are constantly doing things which endanger their lives, and that is precisely why they cannot afford to be without a protecting object. In relation to the traumatic situation, in which the subject is helpless, external and internal dangers, real dangers and instinctual demands converge. Whether the ego is suffering from a pain which will not stop or experiencing an accumulation of instinctual needs which cannot obtain satisfaction, the economic situation is the same, and the motor helplessness of the ego finds expression in psychical helplessness. [1926d, 4320]
We are warned by a proverb against serving two masters at the same time. The poor ego has things even worse: it serves three severe masters and does what it can to bring their claims and demands into harmony with one another. These claims are always divergent and often seem incompatible. No wonder that the ego so often fails in its task. Its three tyrannical masters are the external world, the super-ego and the id. When we follow the ego's efforts to satisfy them simultaneously - or rather, to obey them simultaneously - we cannot feel any regret at having personified this ego and having set it up as a separate organism. It feels hemmed in on three sides, threatened by three kinds of danger, to which, if it is hard pressed, it reacts by generating anxiety. Owing to its origin from the experiences of the perceptual system, it is earmarked for representing the demands of the external world, but it strives too to be a loyal servant of the id, to remain on good terms with it, to recommend itself to it as an object and to attract its libido to itself. In its attempts to mediate between the id and reality, it is often obliged to cloak the \( Ucs \)

commands of the id with its own \( Pcs \). rationalizations, to conceal the id's conflicts with reality, to profess, with diplomatic disingenuousness, to be taking notice of reality even when the id has remained rigid and unyielding. On the other hand it is observed at every step it takes by the strict super-ego, which lays down definite standards for its conduct, without taking any account of its difficulties from the direction of the id and the external world, and which, if those standards are not obeyed, punishes it with tense feelings of inferiority and of guilt. Thus the ego, driven by the id, confined by the super-ego, repulsed by reality, struggles to master its economic task of bringing about harmony among the forces and influences working in and upon it; and we can understand how it is that so often we cannot suppress a cry: 'Life is not easy!' If the ego is obliged to admit its weakness it breaks out in anxiety - realistic anxiety regarding the external world, moral anxiety regarding the super-ego and neurotic anxiety regarding the strength of the passions in the id.

[1933a, 4686]
And now, only one more remark on the problem of anxiety. Neurotic anxiety has changed in our hands into realistic anxiety, into fear of particular external situations of danger. But we cannot stop there, we must take another step - though it will be a step backward. We ask ourselves what it is that is actually dangerous and actually feared in a situation of danger of this kind. It is plainly not the injury to the subject as judged objectively, for this need be of no significance psychologically, but something brought about by it in the mind. Birth, for instance, our model for an anxiety state, can after all scarcely be regarded on its own account as an injury, although it may involve a danger of injuries. The essential thing about birth, as about every situation of danger, is that it calls up in mental experience a state of highly tense excitation, which is felt as unpleasure and which one is not able to master by discharging it. Let us call a state of this kind, before which the efforts of the pleasure principle break down, a 'traumatic' moment. Then, if we take in succession neurotic anxiety, realistic anxiety and the situation of danger, we arrive at this simple proposition: what is feared, what is the object of the anxiety, is invariably the emergence of a traumatic moment, which cannot be dealt with by the normal rules of the pleasure principle. We understand at once that our endowment with the pleasure principle does not guarantee us against objective injuries but only against a particular injury to our psychical economics. It is a long step from the pleasure principle to the self-preservation instinct; the intentions of the two of them are very far from coinciding from the start. But we see something else besides; perhaps it is the solution we are in search of. Namely, that in all this it is a question of relative quantities. It is only the magnitude of the sum of excitation that turns an impression into a traumatic moment, paralyses the function of the pleasure principle and gives the situation of danger its significance. And if that is how things are, if these puzzles can be solved so prosaically, why should it not be possible for similar traumatic moments to arise in mental life without reference to hypothetical situations of danger - traumatic moments, then, in which anxiety is not aroused as a signal but is generated anew for a fresh reason. Clinical experience declares decidedly that such is in fact the case. It is only the later repressions that exhibit the mechanism we have described, in which anxiety is awakened as a signal of an earlier situation of danger. The first and original repressions arise directly from traumatic moments, when the ego meets with an excessively great libidinal demand; they construct their anxiety afresh, although, it is true, on the model of birth. The same may apply to the generation of anxiety in anxiety neurosis owing to somatic damage to the sexual function. We shall no longer maintain that it is the libido itself that is turned into anxiety in such cases. But I can see no objection to there being a twofold origin of anxiety - one as a direct consequence of the traumatic moment and the other as a signal threatening a repetition of such a moment.

[1933a, 4700]
The other agency of the mind, which we believe we know best and in which we recognize ourselves most easily - what is known as the *ego* - has been developed out of the id's cortical layer, which, through being adapted to the reception and exclusion of stimuli, is in direct contact with the external world (*reality*). Starting from conscious perception it has subjected to its influence ever larger regions and deeper strata of the id, and, in the persistence with which it maintains its dependence on the external world, it bears the indelible stamp of its origin (as it might be 'Made in Germany'). Its psychological function consists in raising the passage in the id to a higher dynamic level (perhaps by transforming freely mobile energy into bound energy, such as corresponds to the preconscious state); its constructive function consists in interpolating, between the demand made by an instinct and the action that satisfies it, the activity of thought which, after taking its bearings in the present and assessing earlier experiences, endeavours by means of experimental actions to calculate the consequences of the course of action proposed. In this way the ego comes to a decision on whether the attempt to obtain satisfaction is to be carried out or postponed or whether it may not be necessary for the demand by the instinct to be suppressed altogether as being dangerous. (Here we have the *reality principle*.) Just as the id is directed exclusively to obtaining pleasure, so the ego is governed by considerations of safety. The ego has set itself the task of self-preservation, which the id appears to neglect. It makes use of the sensations of anxiety as a signal to give a warning of dangers that threaten its integrity. Since memory traces can become conscious just as perceptions do, especially through their association with residues of speech, the possibility arises of a confusion which would lead to a mistaking of reality. The ego guards itself against this possibility by the institution of *reality-testing*, which is allowed to fall into abeyance in dreams on account of the conditions prevailing in the state of sleep. The ego, which seeks to maintain itself in an environment of overwhelming mechanical forces, is threatened by dangers which come in the first instance from external reality; but dangers do not threaten it from there alone. Its own id is a source of similar dangers, and that for two different reasons. In the first place, an excessive strength of instinct can damage the ego in a similar way to an excessive 'stimulus' from the external world. It is true that the former cannot destroy it; but it can destroy its characteristic dynamic organization and change the ego back into a portion of the id. In the second place, experience may have taught the ego that the satisfaction of some instinctual demand which is not in itself intolerable would involve dangers in the external world, so that an instinctual demand of that kind itself becomes a danger. Thus the ego is fighting on two fronts: it has to defend its existence against an external world which threatens it with annihilation as well as against an internal world that makes excessive demands. It adopts the same methods of defence against both, but its defence against the internal enemy is particularly inadequate. As a result of having originally been identical with this latter enemy and of having lived with it since on the most intimate terms, it has great difficulty in escaping from the internal dangers. They persist as threats, even if they can be temporarily held down.

[1940a [1938], 5005]
We have heard how the weak and immature ego of the first period of childhood is permanently damaged by the stresses put upon it in its efforts to fend off the dangers that are peculiar to that period of life. Children are protected against the dangers that threaten them from the external world by the solicitude of their parents; they pay for this security by a fear of loss of love which would deliver them over helpless to the dangers of the external world. This factor exerts a decisive influence on the outcome of the conflict when a boy finds himself in the situation of the Oedipus complex, in which the threat to his narcissism by the danger of castration, reinforced from primaeval sources, takes possession of him. Driven by the combined operation of these two influences, the contemporary real danger and the remembered one with its phylogenetic basis, the child embarks on his attempts at defence - repressions - which are effective for the moment but nevertheless turn out to be psychologically inadequate when the later re-animation of sexual life brings a reinforcement to the instinctual demands which have been repudiated in the past. If this is so, it would have to be said from a biological standpoint that the ego comes to grief over the task of mastering the excitations of the early sexual period, at a time when its immaturity makes it incompetent to do so. It is in this lagging of ego development behind libidinal development that we see the essential precondition of neurosis; and we cannot escape the conclusion that neuroses could be avoided if the childish ego were spared this task - if, that is to say, the child's sexual life were allowed free play, as happens among many primitive peoples. It may be that the aetiology of neurotic illnesses is more complicated than we have here described it; if so, we have at least brought out one essential part of the aetiological complex. Nor should we forget the phylogenetic influences, which are represented in some way in the id in forms that we are not yet able to grasp, and which must certainly act upon the ego more powerfully in that early period than later. On the other hand, the realization dawns on us that such an early attempt at damming up the sexual instinct, so decided a partisanship by the young ego in favour of the external as opposed to the internal world, brought about by the prohibition of infantile sexuality, cannot be without its effect on the individual's later readiness for culture. The instinctual demands forced away from direct satisfaction are compelled to enter on new paths leading to substitutive satisfaction, and in the course of these détours they may become desexualized and their connection with their original instinctual aims may become looser. And at this point we may anticipate the thesis that many of the highly valued assets of our civilization were acquired at the cost of sexuality and by the restriction of sexual motive forces.

[1940a [1938], 5006]
A further question may be asked. Why, under such conditions of psychical insufficiency in mastering sexual excitation, does the nervous system find itself in the peculiar affective state of anxiety? An answer may be suggested as follows. The psyche finds itself in the affect of anxiety if it feels unable to deal by appropriate reaction with a task (a danger) approaching from the outside; it finds itself in the neurosis of anxiety if it notices that it is unable to even out the (sexual) excitation originating from within - that is to say, it behaves as though it were projecting that excitation outwards. The affect and its corresponding neurosis are firmly related to each other. The first is a reaction to an exogenous excitation, the second a reaction to the analogous endogenous one. The affect is a state which passes rapidly, the neurosis is a chronic one; because, while exogenous excitation operates with a single impact, the endogenous excitation operates as a constant force. In the neurosis, the nervous system is reacting against a source of excitation which is internal, whereas in the corresponding affect it is reacting against an analogous source of excitation which is external.

It is possible at the start to work upon the subject of anxiety for quite a time without thinking at all of neurotic states. You will understand me at once when I describe this kind of anxiety as 'realistic' anxiety in contrast to 'neurotic' anxiety. Realistic anxiety strikes us as something very rational and intelligible. We may say of it that it is a reaction to the perception of an external danger - that is, of an injury which is expected and foreseen. It is connected with the flight reflex and it may be regarded as a manifestation of the self-preservative instinct. On what occasions anxiety appears - that is to say, in the face of what objects and in what situations - will of course depend to a large extent on the state of a person's knowledge and on his sense of power vis-à-vis the external world. We can quite understand how a savage is afraid of a cannon and frightened by an eclipse of the sun, while a white man, who knows how to handle the instrument and can foretell the eclipse, remains without anxiety in these circumstances. On other occasions it is actually superior knowledge that promotes anxiety, because it makes an early recognition of the danger possible. Thus the savage will be terrified at a trail in the jungle that tells an uninformed person nothing, because it warns him of the proximity of a wild animal; and an experienced sailor will look with terror at a small cloud in the sky that seems trivial to a passenger, because it tells him of an approaching hurricane.
The traumatic neuroses and war neuroses may proclaim too loudly the effects of mortal danger and may be silent or speak only in muted tones of the effects of frustration in love. But, on the other hand, the ordinary transference neuroses of peace-time set no aetiological store by the factor of mortal danger which, in the former class of neuroses, plays so mighty a part. It is even held that the peace-time neuroses are promoted by indulgence, good living and inactivity - which would afford an interesting contrast to the living-conditions under which the war neuroses develop. If they were to follow the example of their opponents, psycho-analysts, finding that their patients had fallen ill owing to frustration in love (owing to the claims of the libido being unsatisfied) would have to maintain that there can be no such things as danger-neuroses or that the disorders that appear after frightening experiences are not neuroses. They have, of course, no notion of maintaining any such thing. On the contrary, a convenient possibility occurs to them of bringing the two apparently divergent sets of facts together under a single hypothesis. In traumatic and war neuroses the human ego is defending itself from a danger which threatens it from without or which is embodied in a shape assumed by the ego itself. In the transference neuroses of peace the enemy from which the ego is defending itself is actually the libido, whose demands seem to it to be menacing. In both cases the ego is afraid of being damaged - in the latter case by the libido and in the former by external violence. It might, indeed, be said that in the case of the war neuroses, in contrast to the pure traumatic neuroses and in approximation to the transference neuroses, what is feared is nevertheless an internal enemy. The theoretical difficulties standing in the way of a unifying hypothesis of this kind do not seem insuperable: after all, we have a perfect right to describe repression, which lies at the basis of every neurosis, as a reaction to a trauma - as an elementary traumatic neurosis.

We have pointed out how the living vesicle is provided with a shield against stimuli from the external world; and we had previously shown that the cortical layer next to that shield must be differentiated as an organ for receiving stimuli from without. This sensitive cortex, however, which is later to become the system $Cs$, also receives excitations from within. The situation of the system between the outside and the inside and the difference between the conditions governing the reception of excitations in the two cases have a decisive effect on the functioning of the system and of the whole mental apparatus. Towards the outside it is shielded against stimuli, and the amounts of excitation impinging on it have only a reduced effect. Towards the inside there can be no such shield; the excitations in the deeper layers extend into the system directly and in undiminished amount, in so far as certain of their characteristics give rise to feelings in the pleasure-unpleasure series. The excitations coming from within are, however, in their intensity and in other, qualitative, respects - in their amplitude, perhaps - more commensurate with the system's method of working than the stimuli which stream in from the external world. This state of things produces two definite results. First, the feelings of pleasure and unpleasure (which are an index to what is happening in the interior of the apparatus) predominate over all external stimuli. And secondly, a particular way is adopted of dealing with any internal excitations which produce too great an increase of unpleasure: there is a tendency to treat them as though they were acting, not from the inside, but from the outside, so that it may be possible to bring the shield against stimuli into operation as a means of defence against them. This is the origin of projection, which is destined to play such a large part in the causation of pathological processes.

[1919d, 3668]

[1920g, 3732]
The fact that the cortical layer which receives stimuli is without any protective shield against excitations from within must have as its result that these latter transmissions of stimulus have a preponderance in economic importance and often occasion economic disturbances comparable with traumatic neuroses. The most abundant sources of this internal excitation are what are described as the organism’s ‘instincts’ - the representatives of all the forces originating in the interior of the body and transmitted to the mental apparatus - at once the most important and the most obscure element of psychological research.

[1920g, 3737]

But this explanation opens up fresh problems. Where does the energy come from which is employed for giving the signal of unpleasure? Here we may be assisted by the idea that a defence against an unwelcome internal process will be modelled upon the defence adopted against an external stimulus, that the ego wards off internal and external dangers alike along identical lines. In the case of external danger the organism has recourse to attempts at flight. The first thing it does is to withdraw cathexis from the perception of the dangerous object; later on it discovers that it is a better plan to perform muscular movements of such a sort as will render perception of the dangerous object impossible even in the absence of any refusal to perceive it - that it is a better plan, that is, to remove itself from the sphere of danger. Repression is an equivalent of this attempt at flight. The ego withdraws its (preconscious) cathexis from the instinctual representative that is to be repressed and uses that cathexis for the purpose of releasing unpleasure (anxiety). The problem of how anxiety arises in connection with repression may be no simple one; but we may legitimately hold firmly to the idea that the ego is the actual seat of anxiety and give up our earlier view that the cathetic energy of the repressed impulse is automatically turned into anxiety. If I expressed myself earlier in the latter sense, I was giving a phenomenological description and not a metapsychological account of what was occurring.

[1926d, 4253]

This mention of the protective shield sounds a note which recalls to us the fact that repression occurs in two different situations - namely, when an undesirable instinctual impulse is aroused by some external perception, and when it arises internally without any such provocation. We shall return to this difference later. But the protective shield exists only in regard to external stimuli, not in regard to internal instinctual demands.

[1926d, 4255]

One objection to it is that loss of an object (or loss of love on the part of the object) and the threat of castration are just as much dangers coming from outside as, let us say, a ferocious animal would be; they are not instinctual dangers. Nevertheless, the two cases are not the same. A wolf would probably attack us irrespectively of our behaviour towards it; but the loved person would not cease to love us nor should we be threatened with castration if we did not entertain certain feelings and intentions within us. Thus such instinctual impulses are determinants of external dangers and so become dangerous in themselves; and we can now proceed against the external danger by taking measures against the internal ones. In phobias of animals the danger seems to be still felt entirely as an external one, just as it has undergone an external displacement in the symptom. In obsessional neuroses the danger is much more internalized. That portion of anxiety in regard to the super-ego which constitutes social anxiety still represents an internal substitute for an external danger, while the other portion - moral anxiety - is already completely endopsychic.

[1926d, 4300]
So far we have had no occasion to regard realistic anxiety in any different light from neurotic anxiety. We know what the distinction is. A real danger is a danger which threatens a person from an external object, and a neurotic danger is one which threatens him from an instinctual demand. In so far as the instinctual demand is something real, his neurotic anxiety, too, can be admitted to have a realistic basis. We have seen that the reason why there seems to be a specially close connection between anxiety and neurosis is that the ego defends itself against an instinctual danger with the help of the anxiety reaction just as it does against an external real danger, but that this line of defensive activity eventuates in a neurosis owing to an imperfection of the mental apparatus. We have also come to the conclusion that an instinctual demand often only becomes an (internal) danger because its satisfaction would bring on an external danger - that is, because the internal danger represents an external one.

On the other hand, the external (real) danger must also have managed to become internalized if it is to be significant for the ego. It must have been recognized as related to some situation of helplessness that has been experienced.¹ Man seems not to have been endowed, or to have been endowed to only a very small degree, with an instinctive recognition of the dangers that threaten him from without. Small children are constantly doing things which endanger their lives, and that is precisely why they cannot afford to be without a protecting object. In relation to the traumatic situation, in which the subject is helpless, external and internal dangers, real dangers and instinctual demands converge. Whether the ego is suffering from a pain which will not stop or experiencing an accumulation of instinctual needs which cannot obtain satisfaction, the economic situation is the same, and the motor helplessness of the ego finds expression in psychical helplessness.

[1926d, 4319]

[1926d, 4320]
Further reflection tells us that the adult's ego-feeling cannot have been the same from the beginning. It must have gone through a process of development, which cannot, of course, be demonstrated but which admits of being constructed with a fair degree of probability.¹ An infant at the breast does not as yet distinguish his ego from the external world as the source of the sensations flowing in upon him. He gradually learns to do so, in response to various promptings. He must be very strongly impressed by the fact that some sources of excitation, which he will later recognize as his own bodily organs, can provide him with sensations at any moment, whereas other sources evade him from time to time - among them what he desires most of all, his mother's breast - and only reappear as a result of his screaming for help. In this way there is for the first time set over against the ego an 'object', in the form of something which exists 'outside' and which is only forced to appear by a special action. A further incentive to a disengagement of the ego from the general mass of sensations - that is, to the recognition of an 'outside', an external world - is provided by the frequent, manifold and unavoidable sensations of pain and unpleasure the removal and avoidance of which is enjoined by the pleasure principle, in the exercise of its unrestricted domination. A tendency arises to separate from the ego everything that can become a source of such unpleasure, to throw it outside and to create a pure pleasure-ego which is confronted by a strange and threatening 'outside'. The boundaries of this primitive pleasure-ego cannot escape rectification through experience. Some of the things that one is unwilling to give up, because they give pleasure, are nevertheless not ego but object; and some sufferings that one seeks to expel turn out to be inseparable from the ego in virtue of their internal origin. One comes to learn a procedure by which, through a deliberate direction of one's sensory activities and through suitable muscular action, one can differentiate between what is internal - what belongs to the ego - and what is external - what emanates from the outer world. In this way one makes the first step towards the introduction of the reality principle which is to dominate future development. This differentiation, of course, serves the practical purpose of enabling one to defend oneself against sensations of unpleasure which one actually feels or with which one is threatened. In order to fend off certain unpleasurable excitations arising from within, the ego can use no other methods than those which it uses against unpleasure coming from without, and this is the starting-point of important pathological disturbances.
[1930a, 4467]

For we have recently been examining the way in which anxiety is generated in certain phobias which we class as anxiety hysteria, and have chosen cases in which we were dealing with the typical repression of wishful impulses arising from the Oedipus complex. We should have expected to find that it was a libidinal cathexis of the boy's mother as object which, as a result of repression, had been changed into anxiety and which now emerged, expressed in symptomatic terms, attached to a substitute for his father. I cannot present you with the detailed steps of an investigation such as this; it will be enough to say that the surprising result was the opposite of what we expected. It was not the repression that created the anxiety; the anxiety was there earlier; it was the anxiety that made the repression. But what sort of anxiety can it have been? Only anxiety in the face of a threatening external danger - that is to say, a realistic anxiety. It is true that the boy felt anxiety in the face of a demand by his libido - in this instance, anxiety at being in love with his mother; so the case was in fact one of neurotic anxiety. But this being in love only appeared to him as an internal danger, which he must avoid by renouncing that object, because it conjured up an external situation of danger. And in every case we examine we obtain the same result. It must be confessed that we were not prepared to find that internal instinctual danger would turn out to be a determinant and preparation for an external, real, situation of danger.
[1933a, 4692]
And now, only one more remark on the problem of anxiety. Neurotic anxiety has changed in our hands into realistic anxiety, into fear of particular external situations of danger. But we cannot stop there, we must take another step - though it will be a step backward. We ask ourselves what it is that is actually dangerous and actually feared in a situation of danger of this kind. It is plainly not the injury to the subject as judged objectively, for this need be of no significance psychologically, but something brought about by it in the mind. Birth, for instance, our model for an anxiety state, can after all scarcely be regarded on its own account as an injury, although it may involve a danger of injuries. The essential thing about birth, as about every situation of danger, is that it calls up in mental experience a state of highly tense excitation, which is felt as unpleasure and which one is not able to master by discharging it. Let us call a state of this kind, before which the efforts of the pleasure principle break down, a 'traumatic' moment. Then, if we take in succession neurotic anxiety, realistic anxiety and the situation of danger, we arrive at this simple proposition: what is feared, what is the object of the anxiety, is invariably the emergence of a traumatic moment, which cannot be dealt with by the normal rules of the pleasure principle. We understand at once that our endowment with the pleasure principle does not guarantee us against objective injuries but only against a particular injury to our psychical economics. It is a long step from the pleasure principle to the self-preservation instinct; the intentions of the two of them are very far from coinciding from the start. But we see something else besides; perhaps it is the solution we are in search of. Namely, that in all this it is a question of relative quantities. It is only the magnitude of the sum of excitation that turns an impression into a traumatic moment, paralyses the function of the pleasure principle and gives the situation of danger its significance. And if that is how things are, if these puzzles can be solved so prosaically, why should it not be possible for similar traumatic moments to arise in mental life without reference to hypothetical situations of danger - traumatic moments, then, in which anxiety is not aroused as a signal but is generated anew for a fresh reason. Clinical experience declares decidedly that such is in fact the case. It is only the later repressions that exhibit the mechanism we have described, in which anxiety is awakened as a signal of an earlier situation of danger. The first and original repressions arise directly from traumatic moments, when the ego meets with an excessively great libidinal demand; they construct their anxiety afresh, although, it is true, on the model of birth. The same may apply to the generation of anxiety in anxiety neurosis owing to somatic damage to the sexual function. We shall no longer maintain that it is the libido itself that is turned into anxiety in such cases. But I can see no objection to there being a twofold origin of anxiety - one as a direct consequence of the traumatic moment and the other as a signal threatening a repetition of such a moment.
The other agency of the mind, which we believe we know best and in which we recognize ourselves most easily - what is known as the ego - has been developed out of the id's cortical layer, which, through being adapted to the reception and exclusion of stimuli, is in direct contact with the external world (reality). Starting from conscious perception it has subjected to its influence ever larger regions and deeper strata of the id, and, in the persistence with which it maintains its dependence on the external world, it bears the indelible stamp of its origin (as it might be 'Made in Germany'). Its psychological function consists in raising the passage in the id to a higher dynamic level (perhaps by transforming freely mobile energy into bound energy, such as corresponds to the preconscious state); its constructive function consists in interpolating, between the demand made by an instinct and the action that satisfies it, the activity of thought which, after taking its bearings in the present and assessing earlier experiences, endeavours by means of experimental actions to calculate the consequences of the course of action proposed. In this way the ego comes to a decision on whether the attempt to obtain satisfaction is to be carried out or postponed or whether it may not be necessary for the demand by the instinct to be suppressed altogether as being dangerous. (Here we have the reality principle.) Just as the id is directed exclusively to obtaining pleasure, so the ego is governed by considerations of safety. The ego has set itself the task of self-preservation, which the id appears to neglect. It makes use of the sensations of anxiety as a signal to give a warning of dangers that threaten its integrity. Since memory traces can become conscious just as perceptions do, especially through their association with residues of speech, the possibility arises of a confusion which would lead to a mistaking of reality. The ego guards itself against this possibility by the institution of reality-testing, which is allowed to fall into abeyance in dreams on account of the conditions prevailing in the state of sleep. The ego, which seeks to maintain itself in an environment of overwhelming mechanical forces, is threatened by dangers which come in the first instance from external reality; but dangers do not threaten it from there alone. Its own id is a source of similar dangers, and that for two different reasons. In the first place, an excessive strength of instinct can damage the ego in a similar way to an excessive 'stimulus' from the external world. It is true that the former cannot destroy it; but it can destroy its characteristic dynamic organization and change the ego back into a portion of the id. In the second place, experience may have taught the ego that the satisfaction of some instinctual demand which is not in itself intolerable would involve dangers in the external world, so that an instinctual demand of that kind itself becomes a danger. Thus the ego is fighting on two fronts: it has to defend its existence against an external world which threatens it with annihilation as well as against an internal world that makes excessive demands. It adopts the same methods of defence against both, but its defence against the internal enemy is particularly inadequate. As a result of having originally been identical with this latter enemy and of having lived with it since on the most intimate terms, it has great difficulty in escaping from the internal dangers. They persist as threats, even if they can be temporarily held down.

[1940a [1938], 5005]
We have heard how the weak and immature ego of the first period of childhood is permanently damaged by the stresses put upon it in its efforts to fend off the dangers that are peculiar to that period of life. Children are protected against the dangers that threaten them from the external world by the solicitude of their parents; they pay for this security by a fear of loss of love which would deliver them over helpless to the dangers of the external world. This factor exerts a decisive influence on the outcome of the conflict when a boy finds himself in the situation of the Oedipus complex, in which the threat to his narcissism by the danger of castration, reinforced from primaeval sources, takes possession of him. Driven by the combined operation of these two influences, the contemporary real danger and the remembered one with its phylogenetic basis, the child embarks on his attempts at defence - repressions - which are effective for the moment but nevertheless turn out to be psychologically inadequate when the later re-animation of sexual life brings a reinforcement to the instinctual demands which have been repudiated in the past. If this is so, it would have to be said from a biological standpoint that the ego comes to grief over the task of mastering the excitations of the early sexual period, at a time when its immaturity makes it incompetent to do so. It is in this lagging of ego development behind libidinal development that we see the essential precondition of neurosis; and we cannot escape the conclusion that neuroses could be avoided if the childish ego were spared this task - if, that is to say, the child's sexual life were allowed free play, as happens among many primitive peoples. It may be that the aetiology of neurotic illnesses is more complicated than we have here described it; if so, we have at least brought out one essential part of the aetiological complex. Nor should we forget the phylogenetic influences, which are represented in some way in the id in forms that we are not yet able to grasp, and which must certainly act upon the ego more powerfully in that early period than later. On the other hand, the realization dawns on us that such an early attempt at damming up the sexual instinct, so decided a partisanship by the young ego in favour of the external as opposed to the internal world, brought about by the prohibition of infantile sexuality, cannot be without its effect on the individual's later readiness for culture. The instinctual demands forced away from direct satisfaction are compelled to enter on new paths leading to substitutive satisfaction, and in the course of these débouts they may become desexualized and their connection with their original instinctual aims may become looser. And at this point we may anticipate the thesis that many of the highly valued assets of our civilization were acquired at the cost of sexuality and by the restriction of sexual motive forces.

[1940a [1938], 5006]
We finally arrive at the connection we are in search of, if we take as our starting-point the opposition we have so often asserted between the ego and the libido. As we know, the generation of anxiety is the ego's reaction to danger and the signal for taking flight. If so, it seems plausible to suppose that in neurotic anxiety the ego is making a similar attempt at flight from the demand by its libido, that it is treating this internal danger as though it were an external one. This would therefore fulfil our expectation that where anxiety is shown there is something one is afraid of. But the analogy could be carried further. Just as the attempt at flight from an external danger is replaced by standing firm and the adoption of expedient measures of defence, so too the generation of neurotic anxiety gives place to the formation of symptoms, which results in the anxiety being bound.

In a psychosis, the transforming of reality is carried out upon the psychical precipitates of former relations to it - that is, upon the memory-traces, ideas and judgements which have been previously derived from reality and by which reality was represented in the mind. But this relation was never a closed one; it was continually being enriched and altered by fresh perceptions. Thus the psychosis is also faced with the task of procuring for itself perceptions of a kind which shall correspond to the new reality; and this is most radically effected by means of hallucination. The fact that, in so many forms and cases of psychosis, the paramnesias, the delusions and the hallucinations that occur are of a most distressing character and are bound up with a generation of anxiety - this fact is without doubt a sign that the whole process of remodelling is carried through against forces which oppose it violently. We may construct the process on the model of a neurosis, with which we are more familiar. There we see that a reaction of anxiety sets in whenever the repressed instinct makes a thrust forward, and that the outcome of the conflict is only a compromise and does not provide complete satisfaction. Probably in a psychosis the rejected piece of reality constantly forces itself upon the mind, just as the repressed instinct does in a neurosis, and that is why in both cases the consequences too are the same. The elucidation of the various mechanisms which are designed, in the psychoses, to turn the subject away from reality and to reconstruct reality - this is a task for specialized psychiatric study which has not yet been taken in hand.

To begin with the last problem. The advance we have made is that we have gone behind reactions of anxiety to situations of danger. If we do the same thing with realistic anxiety we shall have no difficulty in solving the question. Real danger is a danger that is known, and realistic anxiety is anxiety about a known danger of this sort. Neurotic anxiety is anxiety about an unknown danger. Neurotic danger is thus a danger that has still to be discovered. Analysis has shown that it is an instinctual danger. By bringing this danger which is not known to the ego into consciousness, the analyst makes neurotic anxiety no different from realistic anxiety, so that it can be dealt with in the same way.
We are warned by a proverb against serving two masters at the same time. The poor ego has things even worse: it serves three severe masters and does what it can to bring their claims and demands into harmony with one another. These claims are always divergent and often seem incompatible. No wonder that the ego so often fails in its task. Its three tyrannical masters are the external world, the super-ego and the id. When we follow the ego's efforts to satisfy them simultaneously - or rather, to obey them simultaneously - we cannot feel any regret at having personified this ego and having set it up as a separate organism. It feels hemmed in on three sides, threatened by three kinds of danger, to which, if it is hard pressed, it reacts by generating anxiety. Owing to its origin from the experiences of the perceptual system, it is earmarked for representing the demands of the external world, but it strives too to be a loyal servant of the id, to remain on good terms with it, to recommend itself to it as an object and to attract its libido to itself. In its attempts to mediate between the id and reality, it is often obliged to cloak the Ucs. commands of the id with its own Pcs. rationalizations, to conceal the id's conflicts with reality, to profess, with diplomatic disingenuousness, to be taking notice of reality even when the id has remained rigid and unyielding. On the other hand it is observed at every step it takes by the strict super-ego, which lays down definite standards for its conduct, without taking any account of its difficulties from the direction of the id and the external world, and which, if those standards are not obeyed, punishes it with tense feelings of inferiority and of guilt. Thus the ego, driven by the id, confined by the super-ego, repulsed by reality, struggles to master its economic task of bringing about harmony among the forces and influences working in and upon it; and we can understand how it is that so often we cannot suppress a cry: 'Life is not easy!' If the ego is obliged to admit its weakness it breaks out in anxiety - realistic anxiety regarding the external world, moral anxiety regarding the super-ego and neurotic anxiety regarding the strength of the passions in the id.

[1933a, 4686]

In the course of these investigations our attention was drawn to a highly significant relation between the generation of anxiety and the formation of symptoms - namely, that these two represent and replace each other. For instance, an agoraphobic patient may start his illness with an attack of anxiety in the street. This would be repeated every time he went into the street again. He will now develop the symptom of agoraphobia; this may also be described as an inhibition, a restriction of the ego's functioning, and by means of it he spares himself anxiety attacks. We can witness the converse of this if we interfere in the formation of symptoms, as is possible, for instance, with obsessions. If we prevent a patient from carrying out a washing ceremonial, he falls into a state of anxiety which he finds hard to tolerate and from which he had evidently been protected by his symptom. And it seems, indeed, that the generation of anxiety is the earlier and the formation of symptoms the later of the two, as though the symptoms are created in order to avoid the outbreak of the anxiety state. This is confirmed too by the fact that the first neuroses of childhood are phobias - states in which we see so clearly how an initial generation of anxiety is replaced by the later formation of a symptom; we get an impression that it is from these interrelations that we shall best obtain access to an understanding of neurotic anxiety. And at the same time we have also succeeded in answering the question of what it is that a person is afraid of in neurotic anxiety and so in establishing the connection between neurotic and realistic anxiety. What he is afraid of is evidently his own libido. The difference between this situation and that of realistic anxiety lies in two points: that the danger is an internal instead of an external one and that it is not consciously recognized.

[1933a, 4690]
In phobias it is very easy to observe the way in which this internal danger is transformed into an external one - that is to say, how a neurotic anxiety is changed into an apparently realistic one. In order to simplify what is often a very complicated business, let us suppose that the agoraphobic patient is invariably afraid of feelings of temptation that are aroused in him by meeting people in the street. In his phobia he brings about a displacement and henceforward is afraid of an external situation. What he gains by this is obviously that he thinks he will be able to protect himself better in that way. One can save oneself from an external danger by flight; fleeing from an internal danger is a difficult enterprise.

[1933a, 4691]
A further question may be asked. Why, under such conditions of psychical insufficiency in mastering sexual excitation, does the nervous system find itself in the peculiar affective state of anxiety? An answer may be suggested as follows. The psyche finds itself in the affect of anxiety if it feels unable to deal by appropriate reaction with a task (a danger) *approaching from the outside*; it finds itself in the *neurosis* of anxiety if it notices that it is unable to even out the (sexual) excitation originating *from within* - that is to say, *it behaves as though it were projecting that excitation outwards*. The affect and its corresponding neurosis are firmly related to each other. The first is a reaction to an exogenous excitation, the second a reaction to the analogous endogenous one. The affect is a state which passes rapidly, the neurosis is a chronic one; because, while exogenous excitation operates with a single impact, the endogenous excitation operates as a constant force. *In the neurosis, the nervous system is reacting against a source of excitation which is internal, whereas in the corresponding affect it is reacting against an analogous source of excitation which is external.*

But this explanation opens up fresh problems. Where does the energy come from which is employed for giving the signal of unpleasure? Here we may be assisted by the idea that a defence against an unwelcome *internal* process will be modelled upon the defence adopted against an *external* stimulus, that the ego wards off internal and external dangers alike along identical lines. In the case of external danger the organism has recourse to attempts at flight. The first thing it does is to withdraw cathexis from the perception of the dangerous object; later on it discovers that it is a better plan to perform muscular movements of such a sort as will render perception of the dangerous object impossible even in the absence of any refusal to perceive it - that it is a better plan, that is, to remove itself from the sphere of danger. Repression is an equivalent of this attempt at flight. The ego withdraws its (preconscious) cathexis from the instinctual representative that is to be repressed and uses that cathexis for the purpose of releasing unpleasure (anxiety). The problem of how anxiety arises in connection with repression may be no simple one; but we may legitimately hold firmly to the idea that the ego is the actual seat of anxiety and give up our earlier view that the cathectic energy of the repressed impulse is automatically turned into anxiety. If I expressed myself earlier in the latter sense, I was giving a phenomenological description and not a metapsychological account of what was occurring.

It would, however, be more correct to ascribe to the *defensive process* what we have just said about symptom-formation and to use the latter term as synonymous with substitute-formation. It will then be clear that the defensive process is analogous to the flight by means of which the ego removes itself from a danger that threatens it from outside. The defensive process is an attempt at flight from an instinctual danger. An examination of the weak points in this comparison will make things clearer.
One objection to it is that loss of an object (or loss of love on the part of the object) and the threat of castration are just as much dangers coming from outside as, let us say, a ferocious animal would be; they are not instinctual dangers. Nevertheless, the two cases are not the same. A wolf would probably attack us irrespectively of our behaviour towards it; but the loved person would not cease to love us nor should we be threatened with castration if we did not entertain certain feelings and intentions within us. Thus such instinctual impulses are determinants of external dangers and so become dangerous in themselves; and we can now proceed against the external danger by taking measures against the internal ones. In phobias of animals the danger seems to be still felt entirely as an external one, just as it has undergone an external displacement in the symptom. In obsessional neuroses the danger is much more internalized. That portion of anxiety in regard to the super-ego which constitutes social anxiety still represents an internal substitute for an external danger, while the other portion—moral anxiety—is already completely endopsychic.

Another objection is that in an attempt at flight from an impending external danger all that the subject is doing is to increase the distance between himself and what is threatening him. He is not preparing to defend himself against it or attempting to alter anything about it, as would be the case if he attacked the wolf with a stick or shot at it with a gun. But the defensive process seems to do something more than would correspond to an attempt at flight. It joins issue with the threatening instinctual process and somehow suppresses it or deflects it from its aims and thus renders it innocuous. This objection seems unimpeachable and must be given due weight. I think it is probable that there are some defensive processes which can truly be likened to an attempt at flight, while in others the ego takes a much more active line of self-protection and initiates vigorous counter-measures. But perhaps the whole analogy between defence and flight is invalidated by the fact that both the ego and the instinct in the id are parts of the same organization, not separate entities like the wolf and the child, so that any kind of behaviour on the part of the ego will result in an alteration in the instinctual process as well.
A further question may be asked. Why, under such conditions of psychical insufficiency in mastering sexual excitation, does the nervous system find itself in the peculiar affective state of anxiety? An answer may be suggested as follows. The psyche finds itself in the affect of anxiety if it feels unable to deal by appropriate reaction with a task (a danger) approaching from the outside; it finds itself in the neurosis of anxiety if it notices that it is unable to even out the (sexual) excitation originating from within - that is to say, it behaves as though it were projecting that excitation outwards. The affect and its corresponding neurosis are firmly related to each other. The first is a reaction to an exogenous excitation, the second a reaction to the analogous endogenous one. The affect is a state which passes rapidly, the neurosis is a chronic one; because, while exogenous excitation operates with a single impact, the endogenous excitation operates as a constant force. In the neurosis, the nervous system is reacting against a source of excitation which is internal, whereas in the corresponding affect it is reacting against an analogous source of excitation which is external.

[1895b, 347]

We have pointed out how the living vesicle is provided with a shield against stimuli from the external world; and we had previously shown that the cortical layer next to that shield must be differentiated as an organ for receiving stimuli from without. This sensitive cortex, however, which is later to become the system Cs., also receives excitations from within. The situation of the system between the outside and the inside and the difference between the conditions governing the reception of excitations in the two cases have a decisive effect on the functioning of the system and of the whole mental apparatus. Towards the outside it is shielded against stimuli, and the amounts of excitation impinging on it have only a reduced effect. Towards the inside there can be no such shield; the excitations in the deeper layers extend into the system directly and in undiminished amount, in so far as certain of their characteristics give rise to feelings in the pleasure-unpleasure series. The excitations coming from within are, however, in their intensity and in other, qualitative, respects - in their amplitude, perhaps - more commensurate with the system's method of working than the stimuli which stream in from the external world. This state of things produces two definite results. First, the feelings of pleasure and unpleasure (which are an index to what is happening in the interior of the apparatus) predominate over all external stimuli. And secondly, a particular way is adopted of dealing with any internal excitations which produce too great an increase of unpleasure: there is a tendency to treat them as though they were acting, not from the inside, but from the outside, so that it may be possible to bring the shield against stimuli into operation as a means of defence against them. This is the origin of projection, which is destined to play such a large part in the causation of pathological processes.

[1920g, 3732]

The fact that the cortical layer which receives stimuli is without any protective shield against excitations from within must have as its result that these latter transmissions of stimulus have a preponderance in economic importance and often occasion economic disturbances comparable with traumatic neuroses. The most abundant sources of this internal excitation are what are described as the organism's 'instincts' - the representatives of all the forces originating in the interior of the body and transmitted to the mental apparatus - at once the most important and the most obscure element of psychological research.

[1920g, 3737]

It would, however, be more correct to ascribe to the defensive process what we have just said about symptom-formation and to use the latter term as synonymous with substitute-formation. It will then be clear that the defensive process is analogous to the flight by means of which the ego removes itself from a danger that threatens it from outside. The defensive process is an attempt at flight from an instinctual danger. An examination of the weak points in this comparison will make things clearer.

[1926d, 4300]
The third, psychological, factor resides in a defect of our mental apparatus which has to do precisely with its differentiation into an id and an ego, and which is therefore also attributable ultimately to the influence of the external world. In view of the dangers of reality, the ego is obliged to guard against certain instinctual impulses in the id and to treat them as dangers. But it cannot protect itself from internal instinctual dangers as effectively as it can from some piece of reality that is not part of itself. Intimately bound up with the id as it is, it can only fend off an instinctual danger by restricting its own organization and by acquiescing in the formation of symptoms in exchange for having impaired the instinct. If the rejected instinct renews its attack, the ego is overtaken by all those difficulties which are known to us as neurotic ailments. [1926d, 4309]

On the other hand, the external (real) danger must also have managed to become internalized if it is to be significant for the ego. It must have been recognized as related to some situation of helplessness that has been experienced.¹ Man seems not to have been endowed, or to have been endowed to only a very small degree, with an instinctive recognition of the dangers that threaten him from without. Small children are constantly doing things which endanger their lives, and that is precisely why they cannot afford to be without a protecting object. In relation to the traumatic situation, in which the subject is helpless, external and internal dangers, real dangers and instinctual demands converge. Whether the ego is suffering from a pain which will not stop or experiencing an accumulation of instinctual needs which cannot obtain satisfaction, the economic situation is the same, and the motor helplessness of the ego finds expression in psychical helplessness. [1926d, 4320]
The other agency of the mind, which we believe we know best and in which we recognize ourselves most easily - what is known as the *ego* - has been developed out of the id's cortical layer, which, through being adapted to the reception and exclusion of stimuli, is in direct contact with the external world (*reality*). Starting from conscious perception it has subjected to its influence ever larger regions and deeper strata of the id, and, in the persistence with which it maintains its dependence on the external world, it bears the indelible stamp of its origin (as it might be 'Made in Germany'). Its psychological function consists in raising the passage in the id to a higher dynamic level (perhaps by transforming freely mobile energy into bound energy, such as corresponds to the preconscious state); its constructive function consists in interpolating, between the demand made by an instinct and the action that satisfies it, the activity of thought which, after taking its bearings in the present and assessing earlier experiences, endeavours by means of experimental actions to calculate the consequences of the course of action proposed. In this way the ego comes to a decision on whether the attempt to obtain satisfaction is to be carried out or postponed or whether it may not be necessary for the demand by the instinct to be suppressed altogether as being dangerous. (Here we have the *reality principle.*) Just as the id is directed exclusively to obtaining pleasure, so the ego is governed by considerations of safety. The ego has set itself the task of self-preservation, which the id appears to neglect. It makes use of the sensations of anxiety as a signal to give a warning of dangers that threaten its integrity. Since memory traces can become conscious just as perceptions do, especially through their association with residues of speech, the possibility arises of a confusion which would lead to a mistaking of reality. The ego guards itself against this possibility by the institution of *reality-testing*, which is allowed to fall into abeyance in dreams on account of the conditions prevailing in the state of sleep. The ego, which seeks to maintain itself in an environment of overwhelming mechanical forces, is threatened by dangers which come in the first instance from external reality; but dangers do not threaten it from there alone. Its own id is a source of similar dangers, and that for two different reasons. In the first place, an excessive strength of instinct can damage the ego in a similar way to an excessive 'stimulus' from the external world. It is true that the former cannot destroy it; but it can destroy its characteristic dynamic organization and change the ego back into a portion of the id. In the second place, experience may have taught the ego that the satisfaction of some instinctual demand which is not in itself intolerable would involve dangers in the external world, so that an instinctual demand of that kind itself becomes a danger. Thus the ego is fighting on two fronts: it has to defend its existence against an external world which threatens it with annihilation as well as against an internal world that makes excessive demands. It adopts the same methods of defence against both, but its defence against the internal enemy is particularly inadequate. As a result of having originally been identical with this latter enemy and of having lived with it since on the most intimate terms, it has great difficulty in escaping from the internal dangers. They persist as threats, even if they can be temporarily held down.

[1940a [1938], 5005]
If the analogy is not pursued too strictly, we may say that repression has the same relation to the other methods of defence as omission has to distortion of the text, and we may discover in the different forms of this falsification parallels to the variety of ways in which the ego is altered. An attempt may be made to raise the objection that the analogy goes wrong in an essential point, for the distortion of a text is the work of a tendentious censorship, no counterpart to which is to be found in the development of the ego. But this is not so; for a tendentious purpose of this kind is to a great extent represented by the compelling force of the pleasure principle. The psychical apparatus is intolerant of unpleasure; it has to fend it off at all costs, and if the perception of reality entails unpleasure, that perception - that is, the truth - must be sacrificed. Where external dangers are concerned, the individual can help himself for some time by flight and by avoiding the situation of danger, until he is strong enough later on to remove the threat by actively altering reality. But one cannot flee from oneself; flight is no help against internal dangers. And for that reason the defensive mechanisms of the ego are condemned to falsify one's internal perception and to give one only an imperfect and distorted picture of one's id. In its relations to the id, therefore, the ego is paralysed by its restrictions or blinded by its errors; and the result of this in the sphere of psychical events can only be compared to being out walking in a country one does not know and without having a good pair of legs.

[1937c, 5033]
Ladies and Gentlemen, the dissection of the mental personality into a super-ego, an ego and an id, which I put before you in my last lecture, has obliged us to take our bearings afresh in the problem of anxiety as well. With the thesis that the ego is the sole seat of anxiety - that the ego alone can produce and feel anxiety - we have established a new and stable position from which a number of things take on a new aspect. And indeed it is difficult to see what sense there would be in speaking of an 'anxiety of the id' or in attributing a capacity for apprehensiveness to the super-ego. On the other hand, we have welcomed a desirable element of correspondence in the fact that the three main species of anxiety, realistic, neurotic and moral, can be so easily connected with the ego's three dependent relations - to the external world, to the id and to the super-ego. Along with this new view, moreover, the function of anxiety as a signal announcing a situation of danger (a notion, incidentally, not unfamiliar to us) comes into prominence, the question of what the material is out of which anxiety is made loses interest, and the relations between realistic and neurotic anxiety have become surprisingly clarified and simplified. It is also to be remarked that we now understand the apparently complicated cases of the generation of anxiety better than those which were considered simple.

[1933a, 4692]
(10) It is not surprising that a person undergoing psycho-analytic treatment should often
dream of it and be led to give expression in his dreams to the many thoughts and expectations
to which the treatment gives rise. The imagery most frequently chosen to represent it is that of a
journey, usually by motor-car, as being a modern and complicated vehicle. The speed of the car
will then be used by the patient as an opportunity for giving vent to ironical comments. -If 'the
unconscious', as an element in the subject's waking thoughts, has to be represented in a
dream, it may be replaced very appropriately by subterranean regions. -These, where they
occur without any reference to analytic treatment, stand for the female body or the womb. -
'Down below' in dreams often relates to the genitals, 'up above', on the contrary, to the face,
mouth or breast. -Wild beasts are as a rule employed by the dream-work to represent
passionate impulses of which the dreamer is afraid, whether they are his own or those of other
people. (It then needs only a slight displacement for the wild beasts to come to represent the
people who are possessed by these passions. We have not far to go from here to cases in
which a dreaded father is represented by a beast of prey or a dog or wild horse - a form of
representation recalling totemism.) It might be said that the wild beasts are used to represent
the libido, a force dreaded by the ego and combated by means of repression. It often happens,
too, that the dreamer separates off his neurosis, his 'sick personality', from himself and depicts it
as an independent person.
[1900a, 865]

We finally arrive at the connection we are in search of, if we take as our starting-point the
opposition we have so often asserted between the ego and the libido. As we know, the
generation of anxiety is the ego's reaction to danger and the signal for taking flight. If so, it
seems plausible to suppose that in neurotic anxiety the ego is making a similar attempt at flight
from the demand by its libido, that it is treating this internal danger as though it were an external
one. This would therefore fulfil our expectation that where anxiety is shown there is something
one is afraid of. But the analogy could be carried further. Just as the attempt at flight from an
external danger is replaced by standing firm and the adoption of expedient measures of
defence, so too the generation of neurotic anxiety gives place to the formation of symptoms,
which results in the anxiety being bound.
[1916-1917, 3452]

LADIES AND GENTLEMEN, - We have repeatedly (and only recently once again) had to deal with
the distinction between the ego-instincts and the sexual instincts. In the first place, repression
showed us that the two can come into opposition to each other, that the sexual instincts are
then ostensibly subdued and are obliged to find satisfaction for themselves along regressive
and roundabout paths, and that in doing so they are able to find compensation for their defeat in
their indomitability. We next learnt that the two kinds of instincts are from the first differently
related to Necessity the educator, so that their course of development is not the same and they
do not enter into the same connection with the reality principle. Lastly, we seem to have found
that the sexual instincts are linked by much closer bonds than the ego-instincts to the affective
state of anxiety - a conclusion which seems incomplete in only one important respect. In order
to establish it more firmly, therefore, I will bring forward the further noteworthy fact that if hunger
and thirst (the two most elementary self-preservative instincts) are unsatisfied, the result is
never their transformation into anxiety, whereas the changing of unsatisfied libido into anxiety is,
as we have seen, among the best known and most frequently observed of phenomena.
[1916-1917, 3458]
The ego is the actual seat of anxiety. Threatened by dangers from three directions, it develops the flight-reflex by withdrawing its own cathexis from the menacing perception or from the similarly regarded process in the id, and emitting it as anxiety. This primitive reaction is later replaced by the carrying-out of protective cathexes (the mechanism of the phobias). What it is that the ego fears from the external and from the libidinal danger cannot be specified; we know that the fear is of being overwhelmed or annihilated, but it cannot be grasped analytically. The ego is simply obeying the warning of the pleasure principle. On the other hand, we can tell what is hidden behind the ego's dread of the super-ego, the fear of conscience. The superior being, which turned into the ego ideal, once threatened castration, and this dread of castration is probably the nucleus round which the subsequent fear of conscience has gathered; it is this dread that persists as the fear of conscience.

In a psychosis, the transforming of reality is carried out upon the psychical precipitates of former relations to it - that is, upon the memory-traces, ideas and judgements which have been previously derived from reality and by which reality was represented in the mind. But this relation was never a closed one; it was continually being enriched and altered by fresh perceptions. Thus the psychosis is also faced with the task of procuring for itself perceptions of a kind which shall correspond to the new reality; and this is most radically effected by means of hallucination. The fact that, in so many forms and cases of psychosis, the paramnesias, the delusions and the hallucinations that occur are of a most distressing character and are bound up with a generation of anxiety - this fact is without doubt a sign that the whole process of remodelling is carried through against forces which oppose it violently. We may construct the process on the model of a neurosis, with which we are more familiar. There we see that a reaction of anxiety sets in whenever the repressed instinct makes a thrust forward, and that the outcome of the conflict is only a compromise and does not provide complete satisfaction. Probably in a psychosis the rejected piece of reality constantly forces itself upon the mind, just as the repressed instinct does in a neurosis, and that is why in both cases the consequences too are the same. The elucidation of the various mechanisms which are designed, in the psychoses, to turn the subject away from reality and to reconstruct reality - this is a task for specialized psychiatric study which has not yet been taken in hand.

This new view of things calls for an examination of another assertion of mine - namely, that the ego is the actual seat of anxiety. I think this proposition still holds good. There is no reason to assign any manifestation of anxiety to the super-ego; while the expression 'anxiety of the id' would stand in need of correction, though rather as to its form than its substance. Anxiety is an affective state and as such can, of course, only be felt by the ego. The id cannot have anxiety as the ego can; for it is not an organization and cannot make a judgement about situations of danger. On the other hand it very often happens that processes take place or begin to take place in the id which cause the ego to produce anxiety. Indeed, it is probable that the earliest repressions as well as most of the later ones are motivated by an ego-anxiety of this sort in regard to particular processes in the id. Here again we are rightly distinguishing between two cases: the case in which something occurs in the id which activates one of the danger-situations for the ego and induces the latter to give the anxiety-signal for inhibition to take place, and the case in which a situation analogous to the trauma of birth is established in the id and an automatic reaction of anxiety ensues. The two cases may be brought closer together if it is pointed out that the second case corresponds to the earliest and original danger-situation, while the first case corresponds to any one of the later determinants of anxiety that have been derived from it; or, as applied to the disorders which we in fact come across, that the second case is operative in the aetiology of the 'actual' neuroses, while the first remains typical for that of the psychoneuroses.
It would, however, be more correct to ascribe to the defensive process what we have just said about symptom-formation and to use the latter term as synonymous with substitute-formation. It will then be clear that the defensive process is analogous to the flight by means of which the ego removes itself from a danger that threatens it from outside. The defensive process is an attempt at flight from an instinctual danger. An examination of the weak points in this comparison will make things clearer.

This study of the determinants of anxiety has, as it were, shown the defensive behaviour of the ego transfigured in a rational light. Each situation of danger corresponds to a particular period of life or a particular developmental phase of the mental apparatus and appears to be justifiable for it. In early infancy the individual is really not equipped to master psychically the large sums of excitement that reach him whether from without or from within. Again, at a certain period of life his most important interest really is that the people he is dependent on should not withdraw their loving care of him. Later on in his boyhood, when he feels that his father is a powerful rival in regard to his mother and becomes aware of his own aggressive inclinations towards him and of his sexual intentions towards his mother, he really is justified in being afraid of his father; and his fear of being punished by him can find expression through phylogenetic reinforcement in the fear of being castrated. Finally, as he enters into social relationships, it really is necessary for him to be afraid of his super-ego, to have a conscience; and the absence of that factor would give rise to severe conflicts, dangers and so on.

To begin with the last problem. The advance we have made is that we have gone behind reactions of anxiety to situations of danger. If we do the same thing with realistic anxiety we shall have no difficulty in solving the question. Real danger is a danger that is known, and realistic anxiety is anxiety about a known danger of this sort. Neurotic anxiety is anxiety about an unknown danger. Neurotic danger is thus a danger that has still to be discovered. Analysis has shown that it is an instinctual danger. By bringing this danger which is not known to the ego into consciousness, the analyst makes neurotic anxiety no different from realistic anxiety, so that it can be dealt with in the same way.

There are two reactions to real danger. One is an affective reaction, an outbreak of anxiety. The other is a protective action. The same will presumably be true of instinctual danger. We know how the two reactions can co-operate in an expedient way, the one giving the signal for the other to appear. But we also know that they can behave in an inexpedient way: paralysis from anxiety may set in, and the one reaction spread at the cost of the other.

We can find out still more about this if, not content with tracing anxiety back to danger, we go on to enquire what the essence and meaning of a danger-situation is. Clearly, it consists in the subject's estimation of his own strength compared to the magnitude of the danger and in his admission of helplessness in the face of it - physical helplessness if the danger is real and psychical helplessness if it is instinctual. In doing this he will be guided by the actual experiences he has had. (Whether he is wrong in his estimation or not is immaterial for the outcome.) Let us call a situation of helplessness of this kind that has been actually experienced a traumatic situation. We shall then have good grounds for distinguishing a traumatic situation from a danger-situation.
So far we have had no occasion to regard realistic anxiety in any different light from neurotic anxiety. We know what the distinction is. A real danger is a danger which threatens a person from an external object, and a neurotic danger is one which threatens him from an instinctual demand. In so far as the instinctual demand is something real, his neurotic anxiety, too, can be admitted to have a realistic basis. We have seen that the reason why there seems to be a specially close connection between anxiety and neurosis is that the ego defends itself against an instinctual danger with the help of the anxiety reaction just as it does against an external real danger, but that this line of defensive activity eventuates in a neurosis owing to an imperfection of the mental apparatus. We have also come to the conclusion that an instinctual demand often only becomes an (internal) danger because its satisfaction would bring on an external danger - that is, because the internal danger represents an external one.

[1926d, 4319]

On the other hand, the external (real) danger must also have managed to become internalized if it is to be significant for the ego. It must have been recognized as related to some situation of helplessness that has been experienced.¹ Man seems not to have been endowed, or to have been endowed to only a very small degree, with an instinctive recognition of the dangers that threaten him from without. Small children are constantly doing things which endanger their lives, and that is precisely why they cannot afford to be without a protecting object. In relation to the traumatic situation, in which the subject is helpless, external and internal dangers, real dangers and instinctual demands converge. Whether the ego is suffering from a pain which will not stop or experiencing an accumulation of instinctual needs which cannot obtain satisfaction, the economic situation is the same, and the motor helplessness of the ego finds expression in psychical helplessness.

[1926d, 4320]

¹ It may quite often happen that although a danger-situation is correctly estimated in itself, a certain amount of instinctual anxiety is added to the realistic anxiety. In that case the instinctual demand before whose satisfaction the ego recoils is a masochistic one: the instinct of destruction directed against the subject himself. Perhaps an addition of this kind explains cases in which reactions of anxiety are exaggerated, inexpedient or paralysing. Phobias of heights (windows, towers, precipices and so on) may have some such origin. Their hidden feminine significance is closely connected with masochism.

[1926d, 4320]
We are warned by a proverb against serving two masters at the same time. The poor ego has things even worse: it serves three severe masters and does what it can to bring their claims and demands into harmony with one another. These claims are always divergent and often seem incompatible. No wonder that the ego so often fails in its task. Its three tyrannical masters are the external world, the super-ego and the id. When we follow the ego's efforts to satisfy them simultaneously - or rather, to obey them simultaneously - we cannot feel any regret at having personified this ego and having set it up as a separate organism. It feels hemmed in on three sides, threatened by three kinds of danger, to which, if it is hard pressed, it reacts by generating anxiety. Owing to its origin from the experiences of the perceptual system, it is earmarked for representing the demands of the external world, but it strives too to be a loyal servant of the id, to remain on good terms with it, to recommend itself to it as an object and to attract its libido to itself. In its attempts to mediate between the id and reality, it is often obliged to cloak the Ucs. commands of the id with its own Pcs. rationalizations, to conceal the id's conflicts with reality, to profess, with diplomatic disingenuousness, to be taking notice of reality even when the id has remained rigid and unyielding. On the other hand it is observed at every step it takes by the strict super-ego, which lays down definite standards for its conduct, without taking any account of its difficulties from the direction of the id and the external world, and which, if those standards are not obeyed, punishes it with tense feelings of inferiority and of guilt. Thus the ego, driven by the id, confined by the super-ego, repulsed by reality, struggles to master its economic task of bringing about harmony among the forces and influences working in and upon it; and we can understand how it is that so often we cannot suppress a cry: 'Life is not easy!' If the ego is obliged to admit its weakness it breaks out in anxiety - realistic anxiety regarding the external world, moral anxiety regarding the super-ego and neurotic anxiety regarding the strength of the passions in the id.

In the course of these investigations our attention was drawn to a highly significant relation between the generation of anxiety and the formation of symptoms - namely, that these two represent and replace each other. For instance, an agoraphobic patient may start his illness with an attack of anxiety in the street. This would be repeated every time he went into the street again. He will now develop the symptom of agoraphobia; this may also be described as an inhibition, a restriction of the ego's functioning, and by means of it he spares himself anxiety attacks. We can witness the converse of this if we interfere in the formation of symptoms, as is possible, for instance, with obsessions. If we prevent a patient from carrying out a washing ceremonial, he falls into a state of anxiety which he finds hard to tolerate and from which he had evidently been protected by his symptom. And it seems, indeed, that the generation of anxiety is the earlier and the formation of symptoms the later of the two, as though the symptoms are created in order to avoid the outbreak of the anxiety state. This is confirmed too by the fact that the first neuroses of childhood are phobias - states in which we see so clearly how an initial generation of anxiety is replaced by the later formation of a symptom; we get an impression that it is from these interrelations that we shall best obtain access to an understanding of neurotic anxiety. And at the same time we have also succeeded in answering the question of what it is that a person is afraid of in neurotic anxiety and so in establishing the connection between neurotic and realistic anxiety. What he is afraid of is evidently his own libido. The difference between this situation and that of realistic anxiety lies in two points: that the danger is an internal instead of an external one and that it is not consciously recognized.

[1933a, 4686]
In phobias it is very easy to observe the way in which this internal danger is transformed into an external one - that is to say, how a neurotic anxiety is changed into an apparently realistic one. In order to simplify what is often a very complicated business, let us suppose that the agoraphobic patient is invariably afraid of feelings of temptation that are aroused in him by meeting people in the street. In his phobia he brings about a displacement and henceforward is afraid of an external situation. What he gains by this is obviously that he thinks he will be able to protect himself better in that way. One can save oneself from an external danger by flight; fleeing from an internal danger is a difficult enterprise.

[1933a, 4691]

Ladies and Gentlemen, the dissection of the mental personality into a super-ego, an ego and an id, which I put before you in my last lecture, has obliged us to take our bearings afresh in the problem of anxiety as well. With the thesis that the ego is the sole seat of anxiety - that the ego alone can produce and feel anxiety - we have established a new and stable position from which a number of things take on a new aspect. And indeed it is difficult to see what sense there would be in speaking of an 'anxiety of the id' or in attributing a capacity for apprehensiveness to the super-ego. On the other hand, we have welcomed a desirable element of correspondence in the fact that the three main species of anxiety, realistic, neurotic and moral, can be so easily connected with the ego's three dependent relations - to the external world, to the id and to the super-ego. Along with this new view, moreover, the function of anxiety as a signal announcing a situation of danger (a notion, incidentally, not unfamiliar to us) comes into prominence, the question of what the material is out of which anxiety is made loses interest, and the relations between realistic and neurotic anxiety have become surprisingly clarified and simplified. It is also to be remarked that we now understand the apparently complicated cases of the generation of anxiety better than those which were considered simple.

[1933a, 4692]

For we have recently been examining the way in which anxiety is generated in certain phobias which we class as anxiety hysteria, and have chosen cases in which we were dealing with the typical repression of wishful impulses arising from the Oedipus complex. We should have expected to find that it was a libidinal cathexis of the boy's mother as object which, as a result of repression, had been changed into anxiety and which now emerged, expressed in symptomatic terms, attached to a substitute for his father. I cannot present you with the detailed steps of an investigation such as this; it will be enough to say that the surprising result was the opposite of what we expected. It was not the repression that created the anxiety; the anxiety was there earlier; it was the anxiety that made the repression. But what sort of anxiety can it have been? Only anxiety in the face of a threatening external danger - that is to say, a realistic anxiety. It is true that the boy felt anxiety in the face of a demand by his libido - in this instance, anxiety at being in love with his mother; so the case was in fact one of neurotic anxiety. But this being in love only appeared to him as an internal danger, which he must avoid by renouncing that object, because it conjured up an external situation of danger. And in every case we examine we obtain the same result. It must be confessed that we were not prepared to find that internal instinctual danger would turn out to be a determinant and preparation for an external, real, situation of danger.

[1933a, 4692]
I hope you have not lost the thread of what I am saying and remember that we are investigating the relations between anxiety and repression. In the course of this we have learnt two new things: first, that anxiety makes repression and not, as we used to think, the other way round, and that the instinctual situation which is feared goes back ultimately to an external situation of danger. The next question will be: how do we now picture the process of a repression under the influence of anxiety? The answer will, I think, be as follows. The ego notices that the satisfaction of an emerging instinctual demand would conjure up one of the well-remembered situations of danger. This instinctual cathexis must therefore be somehow suppressed, stopped, made powerless. We know that the ego succeeds in this task if it is strong and has drawn the instinctual impulse concerned into its organization. But what happens in the case of repression is that the instinctual impulse still belongs to the id and that the ego feels weak. The ego thereupon helps itself by a technique which is at bottom identical with normal thinking. Thinking is an experimental action carried out with small amounts of energy, in the same way as a general shifts small figures about on a map before setting his large bodies of troops in motion. Thus the ego anticipates the satisfaction of the questionable instinctual impulse and permits it to bring about the reproduction of the unpleasurable feelings at the beginning of the feared situation of danger. With this the automatism of the pleasure-unpleasure principle is brought into operation and now carries out the repression of the dangerous instinctual impulse.

[1933a, 4696]
(a) It is not difficult to establish the fact that expectant anxiety or general apprehensiveness is closely dependent on certain happenings in sexual life, or, let us say, certain employments of the libido. The simplest and most instructive case of this sort occurs in people who expose themselves to what is known as unconsummated excitation - that is, people in whom violent sexual excitations meet with no sufficient discharge, cannot be brought to a satisfying conclusion - men for instance, while they are engaged to be married, and women whose husbands are insufficiently potent or, as a precaution, perform the sexual act in an incomplete or curtailed fashion. In such circumstances the libidinal excitation vanishes and anxiety appears in its place whether in the form of expectant anxiety or in attacks and anxiety-equivalents. Interruption of the sexual act as a precaution, if it is practised as a sexual régime, is such a regular cause of anxiety neurosis in men, but more particularly in women, that in medical practice it is advisable in such cases to begin by investigating this aetiology. It will then be found on countless occasions that the anxiety neurosis disappears when the sexual abuse is discontinued.

[1916-1917, 3448]

The ego is the actual seat of anxiety. Threatened by dangers from three directions, it develops the flight-reflex by withdrawing its own cathexis from the menacing perception or from the similarly regarded process in the id, and emitting it as anxiety. This primitive reaction is later replaced by the carrying-out of protective cathexes (the mechanism of the phobias). What it is that the ego fears from the external and from the libidinal danger cannot be specified; we know that the fear is of being overwhelmed or annihilated, but it cannot be grasped analytically. The ego is simply obeying the warning of the pleasure principle. On the other hand, we can tell what is hidden behind the ego's dread of the super-ego, the fear of conscience. The superior being, which turned into the ego ideal, once threatened castration, and this dread of castration is probably the nucleus round which the subsequent fear of conscience has gathered; it is this dread that persists as the fear of conscience.

[1923b, 3991]

These considerations make it possible to regard the fear of death, like the fear of conscience, as a development of the fear of castration. The great significance which the sense of guilt has in the neuroses makes it conceivable that common neurotic anxiety is reinforced in severe cases by the generating of anxiety between the ego and the super-ego (fear of castration, of conscience, of death).

[1923b, 3992]

We have attributed the function of conscience to the super-ego and we have recognized the consciousness of guilt as an expression of a tension between the ego and the super-ego. The ego reacts with feelings of anxiety (conscience anxiety) to the perception that it has not come up to the demands made by its ideal, the super-ego. What we want to know is how the super-ego has come to play this demanding role and why the ego, in the case of a difference with its ideal, should have to be afraid.

[1924c, 4079]
What we have learnt about anxiety in phobias is applicable to obsessional neuroses as well. In this respect it is not difficult for us to put obsessional neuroses on all fours with phobias. In the former, the mainspring of all later symptom-formation is clearly the ego's fear of its super-ego. The danger-situation from which the ego must get away is the hostility of the super-ego. There is no trace of projection here; the danger is completely internalized. But if we ask ourselves what it is that the ego fears from the super-ego, we cannot but think that the punishment threatened by the latter must be an extension of the punishment of castration. Just as the father has become depersonalized in the shape of the super-ego, so has the fear of castration at his hands become transformed into an undefined social or moral anxiety. But this anxiety is concealed. The ego escapes it by obediently carrying out the commands, precautions and penances that have been enjoined on it. If it is impeded in doing so, it is at once overtaken by an extremely distressing feeling of discomfort which may be regarded as an equivalent of anxiety and which the patients themselves liken to anxiety.

The progress which the child makes in its development - its growing independence, the sharper division of its mental apparatus into several agencies, the advent of new needs - cannot fail to exert an influence upon the content of the danger situation. We have already traced the change of that content from loss of the mother as an object to castration. The next change is caused by the power of the super-ego. With the depersonalization of the parental agency from which castration was feared, the danger becomes less defined. Castration anxiety develops into moral anxiety - social anxiety - and it is not so easy now to know what the anxiety is about. The formula, 'separation and expulsion from the horde', only applies to that later portion of the super-ego which has been formed on the basis of social prototypes, not to the nucleus of the super-ego, which corresponds to the introjected parental agency. Putting it more generally, what the ego regards as the danger and responds to with an anxiety-signal is that the super-ego should be angry with it or punish it or cease to love it. The final transformation which the fear of the super-ego undergoes is, it seems to me, the fear of death (or fear for life) which is a fear of the super-ego projected on to the powers of destiny.

In describing the evolution of the various danger-situations from their prototype, the act of birth, I have had no intention of asserting that every later determinant of anxiety completely invalidates the preceding one. It is true that, as the development of the ego goes on, the earlier danger-situations tend to lose their force and to be set aside, so that we might say that each period of the individual's life has its appropriate determinant of anxiety. Thus the danger of psychical helplessness is appropriate to the period of life when his ego is immature; the danger of loss of object, to early childhood when he is still dependent on others; the danger of castration, to the phallic phase; and the fear of his super-ego, to the latency period. Nevertheless, all these danger-situations and determinants of anxiety can persist side by side and cause the ego to react to them with anxiety at a period later than the appropriate one; or, again, several of them can come into operation at the same time. It is possible, moreover, that there is a fairly close relationship between the danger-situation that is operative and the form taken by the ensuing neurosis.¹

¹ [1926d, 4297]
When, in an earlier part of this discussion, we found that the danger of castration was of importance in more than one neurotic illness, we put ourselves on guard against overestimating that factor, since it could not be a decisive one for the female sex, who are undoubtedly more subject to neuroses than men. We now see that there is no danger of our regarding castration anxiety as the sole motive force of the defensive processes which lead to neurosis. I have shown elsewhere how little girls, in the course of their development, are led into making a tender object-cathexis by their castration complex. It is precisely in women that the danger situation of loss of object seems to have remained the most effective. All we need to do is to make a slight modification in our description of their determinant of anxiety, in the sense that it is no longer a matter of feeling the want of, or actually losing the object itself, but of losing the object's love. Since there is no doubt that hysteria has a strong affinity with femininity, just as obsessional neurosis has with masculinity, it appears probable that, as a determinant of anxiety, loss of love plays much the same part in hysteria as the threat of castration does in phobias and fear of the super-ego in obsessional neurosis.

One objection to it is that loss of an object (or loss of love on the part of the object) and the threat of castration are just as much dangers coming from outside as, let us say, a ferocious animal would be; they are not instinctual dangers. Nevertheless, the two cases are not the same. A wolf would probably attack us irrespectively of our behaviour towards it; but the loved person would not cease to love us nor should we be threatened with castration if we did not entertain certain feelings and intentions within us. Thus such instinctual impulses are determinants of external dangers and so become dangerous in themselves; and we can now proceed against the external danger by taking measures against the internal ones. In phobias of animals the danger seems to be still felt entirely as an external one, just as it has undergone an external displacement in the symptom. In obsessional neuroses the danger is much more internalized. That portion of anxiety in regard to the super-ego which constitutes social anxiety still represents an internal substitute for an external danger, while the other portion—moral anxiety—is already completely endopsychic.

This study of the determinants of anxiety has, as it were, shown the defensive behaviour of the ego transfigured in a rational light. Each situation of danger corresponds to a particular period of life or a particular developmental phase of the mental apparatus and appears to be justifiable for it. In early infancy the individual is really not equipped to master psychically the large sums of excitation that reach him whether from without or from within. Again, at a certain period of life his most important interest really is that the people he is dependent on should not withdraw their loving care of him. Later on in his boyhood, when he feels that his father is a powerful rival in regard to his mother and becomes aware of his own aggressive inclinations towards him and of his sexual intentions towards his mother, he really is justified in being afraid of his father; and his fear of being punished by him can find expression through phylogenetic reinforcement in the fear of being castrated. Finally, as he enters into social relationships, it really is necessary for him to be afraid of his super-ego, to have a conscience; and the absence of that factor would give rise to severe conflicts, dangers and so on.
Why this should be so calls for a rather long reply. First of all, we must sift the facts. In a great number of cases the old determinants of anxiety do really lapse, after having produced neurotic reactions. The phobias of very young children, fears of being alone or in the dark or with strangers - phobias which can almost be called normal - usually pass off later on; the child 'grows out of them', as we say about some other disturbances of childhood. Animal phobias, which are of such frequent occurrence, undergo the same fate and many conversion hysterias of early years find no continuation in later life. Ceremonial actions appear extremely often in the latency period, but only a very small percentage of them develop later into a full obsessional neurosis. In general, so far as we can tell from our observations of town children belonging to the white races and living according to fairly high cultural standards, the neuroses of childhood are in the nature of regular episodes in a child's development, although too little attention is still being paid to them. Signs of childhood neuroses can be detected in all adult neurotics without exception; but by no means all children who show those signs become neurotic in later life. It must be, therefore, that certain determinants of anxiety are relinquished and certain danger-situations lose their significance as the individual becomes more mature. Moreover, some of these danger-situations manage to survive into later times by modifying their determinants of anxiety so as to bring them up to date. Thus, for instance, a man may retain his fear of castration in the guise of a syphilidophobia, after he has come to know that it is no longer customary to castrate people for indulging their sexual lusts, but that, on the other hand, severe diseases may overtake anyone who thus gives way to his instincts. Other determinants of anxiety, such as fear of the super-ego, are destined not to disappear at all but to accompany people throughout their lives. In that case the neurotic will differ from the normal person in that his reactions to the dangers in question will be unduly strong. Finally, being grown-up affords no absolute protection against a return of the original traumatic anxiety-situation. Each individual has in all probability a limit beyond which his mental apparatus fails in its function of mastering the quantities of excitation which require to be disposed of.

[1926d, 4302]

This state of mind is called a 'bad conscience'; but actually it does not deserve this name, for at this stage the sense of guilt is clearly only a fear of loss of love, 'social' anxiety. In small children it can never be anything else, but in many adults, too, it has only changed to the extent that the place of the father or the two parents is taken by the larger human community. Consequently, such people habitually allow themselves to do any bad thing which promises them enjoyment, so long as they are sure that the authority will not know anything about it or cannot blame them for it; they are afraid only of being found out.¹ Present-day society has to reckon in general with this state of mind.

[1930a, 4515]
At this second stage of development, the conscience exhibits a peculiarity which was absent from the first stage and which is no longer easy to account for. For the more virtuous a man is, the more severe and distrustful is its behaviour, so that ultimately it is precisely those people who have carried saintliness furthest who reproach themselves with the worst sinfulness. This means that virtue forfeits some part of its promised reward; the docile and continent ego does not enjoy the trust of its mentor, and strives in vain, it would seem, to acquire it. The objection will at once be made that these difficulties are artificial ones, and it will be said that a stricter and more vigilant conscience is precisely the hallmark of a moral man. Moreover, when saints call themselves sinners, they are not so wrong, considering the temptations to instinctual satisfaction to which they are exposed in a specially high degree - since, as is well known, temptations are merely increased by constant frustration, whereas an occasional satisfaction of them causes them to diminish, at least for the time being. The field of ethics, which is so full of problems, presents us with another fact: namely that ill-luck - that is, external frustration - so greatly enhances the power of the conscience in the super-ego. As long as things go well with a man, his conscience is lenient and lets the ego do all sorts of things; but when misfortune befalls him, he searches his soul, acknowledges his sinfulness, heightens the demands of his conscience, imposes abstinences on himself and punishes himself with penances.¹ Whole peoples have behaved in this way, and still do. This, however, is easily explained by the original infantile stage of conscience, which, as we see, is not given up after the introjection into the super-ego, but persists alongside of it and behind it. Fate is regarded as a substitute for the parental agency. If a man is unfortunate it means that he is no longer loved by this highest power; and, threatened by such a loss of love, he once more bows to the parental representative in his super-ego - a representative whom, in his days of good fortune, he was ready to neglect. This becomes especially clear where Fate is looked upon in the strictly religious sense of being nothing else than an expression of the Divine Will. The people of Israel had believed themselves to be the favourite child of God, and when the great Father caused misfortune after misfortune to rain down upon this people of his, they were never shaken in their belief in his relationship to them or questioned his power or righteousness. Instead, they produced the prophets, who held up their sinfulness before them; and out of their sense of guilt they created the over-strict commandments of their priestly religion. It is remarkable how differently a primitive man behaves. If he has met with a misfortune, he does not throw the blame on himself but on his fetish, which has obviously not done its duty, and he gives it a thrashing instead of punishing himself.

[1930a, 4516]

Thus we know of two origins of the sense of guilt: one arising from fear of an authority, and the other, later on, arising from fear of the super-ego. The first insists upon a renunciation of instinctual satisfactions; the second, as well as doing this, presses for punishment, since the continuance of the forbidden wishes cannot be concealed from the super-ego. We have also learned how the severity of the super-ego - the demands of conscience - is to be understood. It is simply a continuation of the severity of the external authority, to which it has succeeded and which it has in part replaced. We now see in what relationship the renunciation of instinct stands to the sense of guilt. Originally, renunciation of instinct was the result of fear of an external authority: one renounced one's satisfactions in order not to lose its love. If one has carried out this renunciation, one is, as it were, quits with the authority and no sense of guilt should remain. But with fear of the super-ego the case is different. Here, instinctual renunciation is not enough, for the wish persists and cannot be concealed from the super-ego. Thus, in spite of the renunciation that has been made, a sense of guilt comes about. This constitutes a great economic disadvantage in the erection of a super-ego, or, as we may put it, in the formation of a conscience. Instinctual renunciation now no longer has a completely liberating effect; virtuous continence is no longer rewarded with the assurance of love. A threatened external unhappiness - loss of love and punishment on the part of the external authority - has been exchanged for a permanent internal unhappiness, for the tension of the sense of guilt.

[1930a, 4517]
These interrelations are so complicated and at the same time so important that, at the risk of repeating myself, I shall approach them from yet another angle. The chronological sequence, then, would be as follows. First comes renunciation of instinct owing to fear of aggression by the external authority. (This is, of course, what fear of the loss of love amounts to, for love is a protection against this punitive aggression.) After that comes the erection of an internal authority, and renunciation of instinct owing to fear of it - owing to fear of conscience. In this second situation bad intentions are equated with bad actions, and hence come a sense of guilt and a need for punishment. The aggressiveness of conscience keeps up the aggressiveness of the authority. So far things have no doubt been made clear; but where does this leave room for the reinforcing influence of misfortune (of renunciation imposed from without), and for the extraordinary severity of conscience in the best and most tractable people? We have already explained both these peculiarities of conscience, but we probably still have an impression that those explanations do not go to the bottom of the matter, and leave a residue still unexplained. And here at last an idea comes in which belongs entirely to psycho-analysis and which is foreign to people's ordinary way of thinking. This idea is of a sort which enables us to understand why the subject-matter was bound to seem so confused and obscure to us. For it tells us that conscience (or more correctly, the anxiety which later becomes conscience) is indeed the cause of instinctual renunciation to begin with, but that later the relationship is reversed. Every renunciation of instinct now becomes a dynamic source of conscience and every fresh renunciation increases the latter's severity and intolerance. If we could only bring it better into harmony with what we already know about the history of the origin of conscience, we should be tempted to defend the paradoxical statement that conscience is the result of instinctual renunciation, or that instinctual renunciation (imposed on us from without) creates conscience, which then demands further instinctual renunciation.

[1930a, 4518]
In the first place, I suspect that the reader has the impression that our discussions on the sense of guilt disrupt the framework of this essay: that they take up too much space, so that the rest of its subject-matter, with which they are not always closely connected, is pushed to one side. This may have spoilt the structure of my paper; but it corresponds faithfully to my intention to represent the sense of guilt as the most important problem in the development of civilization and to show that the price we pay for our advance in civilization is a loss of happiness through the heightening of the sense of guilt. Anything that still sounds strange about this statement, which is the final conclusion of our investigation, can probably be traced to the quite peculiar relationship - as yet completely unexplained - which the sense of guilt has to our consciousness. In the common case of remorse, which we regard as normal, this feeling makes itself clearly enough perceptible to consciousness. Indeed, we are accustomed to speak of a 'consciousness of guilt' instead of a 'sense of guilt'.

Our study of the neuroses, to which, after all we owe the most valuable pointers to an understanding of normal conditions, brings us up against some contradictions. In one of those affections, obsessional neurosis, the sense of guilt makes itself noisily heard in consciousness; it dominates the clinical picture and the patient's life as well, and it hardly allows anything else to appear alongside of it. But in most other cases and forms of neurosis it remains completely unconscious, without on that account producing any less important effects. Our patients do not believe us when we attribute an 'unconscious sense of guilt' to them. In order to make ourselves at all intelligible to them, we tell them of an unconscious need for punishment, in which the sense of guilt finds expression. But its connection with a particular form of neurosis must not be over-estimated. Even in obsessional neurosis there are types of patients who are not aware of their sense of guilt, or who only feel it as a tormenting uneasiness, a kind of anxiety, if they are prevented from carrying out certain actions. It ought to be possible eventually to understand these things; but as yet we cannot. Here perhaps we may be glad to have it pointed out that the sense of guilt is at bottom nothing else but a topographical variety of anxiety, in its later phases it coincides completely with fear of the super-ego. And the relations of anxiety to consciousness exhibit the same extraordinary variations. Anxiety is always present somewhere or other behind every symptom; but at one time it takes noisy possession of the whole of consciousness, while at another it conceals itself so completely that we are obliged to speak of unconscious anxiety or, if we want to have a clearer psychological conscience, since anxiety is in the first instance simply a feeling, of possibilities of anxiety. Consequently it is very conceivable that the sense of guilt produced by civilization is not perceived as such either, and remains to a large extent unconscious, or appears as a sort of malaise, a dissatisfaction, for which people seek other motivations.

Religions, at any rate, have never overlooked the part played in civilization by a sense of guilt. Furthermore - a point which I failed to appreciate elsewhere² - they claim to redeem mankind from this sense of guilt, which they call sin. From the manner in which, in Christianity, this redemption is achieved - by the sacrificial death of a single person, who in this manner takes upon himself a guilt that is common to everyone - we have been able to infer what the first occasion may have been on which this primal guilt, which was also the beginning of civilization, was acquired.³

[1930a, 4523]
Though it cannot be of great importance, it may not be superfluous to elucidate the meaning of a few words such as 'super-ego', 'conscience', 'sense of guilt', 'need for punishment' and 'remorse', which we have often, perhaps, used too loosely and interchangeably. They all relate to the same state of affairs, but denote different aspects of it. The super-ego is an agency which has been inferred by us, and conscience is a function which we ascribe, among other functions, to that agency. This function consists in keeping a watch over the actions and intentions of the ego and judging them, in exercising a censorship. The sense of guilt, the harshness of the super-ego, is thus the same thing as the severity of the conscience. It is the perception which the ego has of being watched over in this way, the assessment of the tension between its own strivings and the demands of the super-ego. The fear of this critical agency (a fear which is at the bottom of the whole relationship), the need for punishment, is an instinctual manifestation on the part of the ego, which has become masochistic under the influence of a sadistic super-ego; it is a portion, that is to say, of the instinct towards internal destruction present in the ego, employed for forming an erotic attachment to the super-ego. We ought not to speak of a conscience until a super-ego is demonstrably present. As to a sense of guilt, we must admit that it is in existence before the super-ego, and therefore before conscience, too. At that time it is the immediate expression of fear of the external authority, a recognition of the tension between the ego and that authority. It is the direct derivative of the conflict between the need for the authority's love and the urge towards instinctual satisfaction, whose inhibition produces the inclination to aggression. The superimposition of these two strata of the sense of guilt - one coming from fear of the external authority, the other from fear of the internal authority - has hampered our insight into the position of conscience in a number of ways. Remorse is a general term for the ego's reaction in a case of sense of guilt. It contains, in little altered form, the sensory material of the anxiety which is operating behind the sense of guilt; it is itself a punishment and can include the need for punishment. Thus remorse, too, can be older than conscience.

[1930a, 4524]
The analogy between the process of civilization and the path of individual development may be extended in an important respect. It can be asserted that the community, too, evolves a super-ego under whose influence cultural development proceeds. It would be a tempting task for anyone who has a knowledge of human civilizations to follow out this analogy in detail. I will confine myself to bringing forward a few striking points. The super-ego of an epoch of civilization has an origin similar to that of an individual. It is based on the impression left behind by the personalities of great leaders - men of overwhelming force of mind or men in whom one of the human impulsions has found its strongest and purest, and therefore often its most one-sided, expression. In many instances the analogy goes still further, in that during their lifetime these figures were - often enough, even if not always - mocked and maltreated by others and even despatched in a cruel fashion. In the same way, indeed, the primal father did not attain divinity until long after he had met his death by violence. The most arresting example of this fateful conjunction is to be seen in the figure of Jesus Christ - if, indeed, that figure is not a part of mythology, which called it into being from an obscure memory of that primal event. Another point of agreement between the cultural and the individual super-ego is that the former, just like the latter, sets up strict ideal demands, disobedience to which is visited with 'fear of conscience'. Here, indeed, we come across the remarkable circumstance that the mental processes concerned are actually more familiar to us and more accessible to consciousness as they are seen in the group than they can be in the individual man. In him, when tension arises, it is only the aggressiveness of the super-ego which, in the form of reproaches, makes itself noisily heard; its actual demands often remain unconscious in the background. If we bring them to conscious knowledge, we find that they coincide with the precepts of the prevailing cultural super-ego. At this point the two processes, that of the cultural development of the group and that of the cultural development of the individual, are, as it were, always interlocked. For that reason some of the manifestations and properties of the super-ego can be more easily detected in its behaviour in the cultural community than in the separate individual.

No doubt you will expect me to give you more than a mere illustration when I inform you that we have found out all kinds of things about the formation of the super-ego - that is to say, about the origin of conscience. Following a well-known pronouncement of Kant's which couples the conscience within us with the starry Heavens, a pious man might well be tempted to honour these two things as the masterpieces of creation. The stars are indeed magnificent, but as regards conscience God has done an uneven and careless piece of work, for a large majority of men have brought along with them only a modest amount of it or scarcely enough to be worth mentioning. We are far from overlooking the portion of psychological truth that is contained in the assertion that conscience is of divine origin; but the thesis needs interpretation. Even if conscience is something 'within us', yet it is not so from the first. In this it is a real contrast to sexual life, which is in fact there from the beginning of life and not only a later addition. But, as is well known, young children are amoral and possess no internal inhibitions against their impulses striving for pleasure. The part which is later taken on by the super-ego is played to begin with by an external power, by parental authority. Parental influence governs the child by offering proofs of love and by threatening punishments which are signs to the child of loss of love and are bound to be feared on their own account. This realistic anxiety is the precursor of the later moral anxiety. So long as it is dominant there is no need to talk of a super-ego and of a conscience. It is only subsequently that the secondary situation develops (which we are all too ready to regard as the normal one), where the external restraint is internalized and the super-ego takes the place of the parental agency and observes, directs and threatens the ego in exactly the same way as earlier the parents did with the child.
But let us return to the super-ego. We have allotted it the functions of self-observation, of conscience and of the ideal. It follows from what we have said about its origin that it presupposes an immensely important biological fact and a fateful psychological one: namely, the human child's long dependence on its parents and the Oedipus complex, both of which, again, are intimately interconnected. The super-ego is the representative for us of every moral restriction, the advocate of a striving towards perfection - it is, in short, as much as we have been able to grasp psychologically of what is described as the higher side of human life. Since it itself goes back to the influence of parents, educators and so on, we learn still more of its significance if we turn to those who are its sources. As a rule parents and authorities analogous to them follow the precepts of their own super-egos in educating children. Whatever understanding their ego may have come to with their super-ego, they are severe and exacting in educating children. They have forgotten the difficulties of their own childhood and they are glad to be able now to identify themselves fully with their own parents who in the past laid such severe restrictions upon them. Thus a child's super-ego is in fact constructed on the model not of its parents but of its parents' super-ego; the contents which fill it are the same and it becomes the vehicle of tradition and of all the time-resisting judgements of value which have propagated themselves in this manner from generation to generation. You may easily guess what important assistance taking the super-ego into account will give us in our understanding of the social behaviour of mankind - in the problem of delinquency, for instance - and perhaps even what practical hints on education. It seems likely that what are known as materialistic views of history sin in under-estimating this factor. They brush it aside with the remark that human 'ideologies' are nothing other than the product and superstructure of their contemporary economic conditions. That is true, but very probably not the whole truth. Mankind never lives entirely in the present. The past, the tradition of the race and of the people, lives on in the ideologies of the super-ego, and yields only slowly to the influences of the present and to new changes; and so long as it operates through the super-ego it plays a powerful part in human life, independently of economic conditions.

[1933a, 4676]

We are warned by a proverb against serving two masters at the same time. The poor ego has things even worse: it serves three severe masters and does what it can to bring their claims and demands into harmony with one another. These claims are always divergent and often seem incompatible. No wonder that the ego so often fails in its task. Its three tyrannical masters are the external world, the super-ego and the id. When we follow the ego's efforts to satisfy them simultaneously - or rather, to obey them simultaneously - we cannot feel any regret at having personified this ego and having set it up as a separate organism. It feels hemmed in on three sides, threatened by three kinds of danger, to which, if it is hard pressed, it reacts by generating anxiety. Owing to its origin from the experiences of the perceptual system, it is earmarked for representing the demands of the external world, but it strives too to be a loyal servant of the id, to remain on good terms with it, to recommend itself to it as an object and to attract its libido to itself. In its attempts to mediate between the id and reality, it is often obliged to cloak the Ucs. commands of the id with its own Pcs. rationalizations, to conceal the id's conflicts with reality, to profess, with diplomatic disingenuousness, to be taking notice of reality even when the id has remained rigid and unyielding. On the other hand it is observed at every step it takes by the strict super-ego, which lays down definite standards for its conduct, without taking any account of its difficulties from the direction of the id and the external world, and which, if those standards are not obeyed, punishes it with tense feelings of inferiority and of guilt. Thus the ego, driven by the id, confined by the super-ego, repulsed by reality, struggles to master its economic task of bringing about harmony among the forces and influences working in and upon it; and we can understand how it is that so often we cannot suppress a cry: 'Life is not easy!' If the ego is obliged to admit its weakness it breaks out in anxiety - realistic anxiety regarding the external world, moral anxiety regarding the super-ego and neurotic anxiety regarding the strength of the passions in the id.

[1933a, 4686]
Ladies and Gentlemen, the dissection of the mental personality into a super-ego, an ego and an id, which I put before you in my last lecture, has obliged us to take our bearings afresh in the problem of anxiety as well. With the thesis that the ego is the sole seat of anxiety - that the ego alone can produce and feel anxiety - we have established a new and stable position from which a number of things take on a new aspect. And indeed it is difficult to see what sense there would be in speaking of an 'anxiety of the id' or in attributing a capacity for apprehensiveness to the super-ego. On the other hand, we have welcomed a desirable element of correspondence in the fact that the three main species of anxiety, realistic, neurotic and moral, can be so easily connected with the ego's three dependent relations - to the external world, to the id and to the super-ego. Along with this new view, moreover, the function of anxiety as a signal announcing a situation of danger (a notion, incidentally, not unfamiliar to us) comes into prominence, the question of what the material is out of which anxiety is made loses interest, and the relations between realistic and neurotic anxiety have become surprisingly clarified and simplified. It is also to be remarked that we now understand the apparently complicated cases of the generation of anxiety better than those which were considered simple.

Otto Rank, to whom psycho-analysis is indebted for many excellent contributions, also has the merit of having expressly emphasized the significance of the act of birth and of separation from the mother. Nevertheless we have all found it impossible to accept the extreme inferences which he has drawn from this factor as bearing on the theory of the neuroses and even on analytic therapy. The core of his theory - that the experience of anxiety at birth is the model of all later situations of danger - he found already there. If we dwell on these situations of danger for a moment, we can say that in fact a particular determinant of anxiety (that is, situation of danger) is allotted to every age of development as being appropriate to it. The danger of psychical helplessness fits the stage of the ego's early immaturity; the danger of loss of an object (or loss of love) fits the lack of self-sufficiency in the first years of childhood; the danger of being castrated fits the phallic phase; and finally fear of the super-ego, which assumes a special position, fits the period of latency. In the course of development the old determinants of anxiety should be dropped, since the situations of danger corresponding to them have lost their importance owing to the strengthening of the ego. But this only occurs most incompletely. Many people are unable to surmount the fear of loss of love; they never become sufficiently independent of other people's love and in this respect carry on their behaviour as infants. Fear of the super-ego should normally never cease, since, in the form of moral anxiety, it is indispensable in social relations, and only in the rarest cases can an individual become independent of human society. A few of the old situations of danger, too, succeed in surviving into later periods by making contemporary modifications in their determinants of anxiety. Thus, for instance, the danger of castration persists under the mark of syphilidophobia. It is true that as an adult one knows that castration is no longer customary as a punishment for the indulgence of sexual desires, but on the other hand one has learnt that instinctual liberty of that kind is threatened by serious diseases. There is no doubt that the people we describe as neurotics remain infantile in their attitude to danger and have not surmounted obsolete determinants of anxiety. We may take this as a factual contribution to the characterization of neurotics; it is not so easy to say why it should be so.
So long as the ego works in full harmony with the super-ego it is not easy to distinguish between their manifestations; but tensions and estrangements between them make themselves very plainly visible. The torments caused by the reproaches of conscience correspond precisely to a child's fear of loss of love, a fear the place of which has been taken by the moral agency. On the other hand, if the ego has successfully resisted a temptation to do something which would be objectionable to the super-ego, it feels raised in its self-esteem and strengthened in its pride, as though it had made some precious acquisition. In this way the super-ego continues to play the part of an external world for the ego, although it has become a portion of the internal world. Throughout later life it represents the influence of a person's childhood, of the care and education given him by his parents and of his dependence on them - a childhood which is prolonged so greatly in human beings by a family life in common. And in all this it is not only the personal qualities of these parents that is making itself felt, but also everything that had a determining effect on them themselves, the tastes and standards of the social class in which they lived and the innate dispositions and traditions of the race from which they sprang. Those who have a liking for generalizations and sharp distinctions may say that the external world, in which the individual finds himself exposed after being detached from his parents, represents the power of the present; that his id, with its inherited trends, represents the organic past; and that the super-ego, which comes to join them later, represents more than anything the cultural past, which a child has, as it were, to repeat as an after-experience during the few years of his early life. It is unlikely that such generalizations can be universally correct. Some portion of the cultural acquisitions have undoubtedly left a precipitate behind them in the id; much of what is contributed by the super-ego will awaken an echo in the id; not a few of the child's new experiences will be intensified because they are repetitions of some primaeval phylogenetic experience.

[1940a [1938], 5011]
And the driving force of this repression? The circumstances of the case show that it can only have been his narcissistic genital libido which, in the form of concern for his male organ, was fighting against a satisfaction whose attainment seemed to involve the renunciation of that organ. And it was from his threatened narcissism that he derived the masculinity with which he defended himself against his passive attitude towards his father. [1918b, 3534]

The ego is the actual seat of anxiety. Threatened by dangers from three directions, it develops the flight-reflex by withdrawing its own cathexis from the menacing perception or from the similarly regarded process in the id, and emitting it as anxiety. This primitive reaction is later replaced by the carrying-out of protective cathexes (the mechanism of the phobias). What it is that the ego fears from the external and from the libidinal danger cannot be specified; we know that the fear is of being overwhelmed or annihilated, but it cannot be grasped analytically. The ego is simply obeying the warning of the pleasure principle. On the other hand, we can tell what is hidden behind the ego's dread of the super-ego, the fear of conscience. The superior being, which turned into the ego ideal, once threatened castration, and this dread of castration is probably the nucleus round which the subsequent fear of conscience has gathered; it is this dread that persists as the fear of conscience. [1923b, 3991]

These considerations make it possible to regard the fear of death, like the fear of conscience, as a development of the fear of castration. The great significance which the sense of guilt has in the neuroses makes it conceivable that common neurotic anxiety is reinforced in severe cases by the generating of anxiety between the ego and the super-ego (fear of castration, of conscience, of death). [1923b, 3992]

Here, then, is our unexpected finding: in both patients the motive force of the repression was fear of castration. The ideas contained in their anxiety - being bitten by a horse and being devoured by a wolf - were substitutes by distortion for the idea of being castrated by their father. This was the idea which had undergone repression. In the Russian boy the idea was an expression of a wish which was not able to subsist in the face of his masculine revolt; in 'Little Hans' it was the expression of a reaction in him which had turned his aggressiveness into its opposite. But the affect of anxiety, which was the essence of the phobia, came, not from the process of repression, not from the libidinal cathexes of the repressed impulses, but from the repressing agency itself. The anxiety belonging to the animal phobias was an untransformed fear of castration. It was therefore a realistic fear, a fear of a danger which was actually impending or was judged to be a real one. It was anxiety which produced repression and not, as I formerly believed, repression which produced anxiety. [1926d, 4268]
This is as far as our investigations into the formation of symptoms take us. It is hardly worth while summing them up, for the results they have yielded are scanty and incomplete and tell us scarcely anything that we do not already know. It would be fruitless to turn our attention to symptom-formation in other disorders besides phobias, conversion hysteria and obsessional neurosis, for too little is known about them. But in reviewing those three neuroses together we are brought up against a very serious problem the consideration of which can no longer be put off. All three have as their outcome the destruction of the Oedipus complex; and in all three the motive force of the ego's opposition is, we believe, the fear of castration. Yet it is only in the phobias that this fear comes to the surface and is acknowledged. What has become of it in the other two neuroses? How has the ego spared itself this fear? The problem becomes accentuated when we recall the possibility, already referred to, that anxiety arises directly, by a kind of fermentation, from a libidinal cathexis whose processes have been disturbed. Furthermore, is it absolutely certain that fear of castration is the only motive force of repression (or defence)? If we think of neuroses in women we are bound to doubt it. For though we can with certainty establish in them the presence of a castration complex, we can hardly speak with propriety of castration anxiety where castration has already taken place.

This time we will not lose sight of the part played by anxiety. We have said that as soon as the ego recognizes the danger of castration it gives the signal of anxiety and inhibits through the pleasure-unpleasure agency (in a way which we cannot as yet understand) the impending cathetic process in the id. At the same time the phobia is formed. And now the castration anxiety is directed to a different object and expressed in a distorted form, so that the patient is afraid, not of being castrated by his father, but of being bitten by a horse or devoured by a wolf. This substitutive formation has two obvious advantages. In the first place it avoids a conflict due to ambivalence (for the father was a loved object, too), and in the second place it enables the ego to cease generating anxiety. For the anxiety belonging to a phobia is conditional; it only emerges when the object of it is perceived - and rightly so, since it is only then that the danger-situation is present. There is no need to be afraid of being castrated by a father who is not there. On the other hand one cannot get rid of a father; he can appear whenever he chooses. But if he is replaced by an animal, all one has to do is to avoid the sight of it - that is, its presence - in order to be free from danger and anxiety. 'Little Hans', therefore, imposed a restriction upon his ego. He produced the inhibition of not leaving the house, so as not to come across any horses. The young Russian had an even easier time of it, for it was hardly a privation for him not to look at a particular picture-book any more. If his naughty sister had not kept on showing him the book with the picture of the wolf standing upright in it, he would have been able to feel safe from his fear.

The conclusion we have come to, then, is this. Anxiety is a reaction to a situation of danger. It is obviated by the ego's doing something to avoid that situation or to withdraw from it. It might be said that symptoms are created so as to avoid the generating of anxiety. But this does not go deep enough. It would be truer to say that symptoms are created so as to avoid a danger-situation whose presence has been signalled by the generation of anxiety. In the cases that we have discussed, the danger concerned was the danger of castration or of something traceable back to castration.
The statement I have just made, to the effect that the ego has been prepared to expect castration by having undergone constantly repeated object-losses, places the question of anxiety in a new light. We have hitherto regarded it as an affective signal of danger; but now, since the danger is so often one of castration, it appears to us as a reaction to a loss, a separation. Even though a number of considerations immediately arise which make against this view, we cannot but be struck by one very remarkable correlation. The first experience of anxiety which an individual goes through (in the case of human beings, at all events) is birth, and, objectively speaking, birth is a separation from the mother. It could be compared to a castration of the mother (by equating the child with a penis). Now it would be very satisfactory if anxiety, as a symbol of a separation, were to be repeated on every subsequent occasion on which a separation took place. But unfortunately we are prevented from making use of this correlation by the fact that birth is not experienced subjectively as a separation from the mother, since the foetus, being a completely narcissistic creature, is totally unaware of her existence as an object. Another adverse argument is that we know what the affective reactions to a separation are: they are pain and mourning, not anxiety. Incidentally, it may be remembered that in discussing the question of mourning we also failed to discover why it should be such a painful thing.

[1926d, 4287]

The child's mnemonic image of the person longed for is no doubt intensely cathexed, probably in a hallucinatory way at first. But this has no effect; and now it seems as though the longing turns into anxiety. This anxiety has all the appearance of being an expression of the child's feeling at its wits' end, as though in its still very undeveloped state it did not know how better to cope with its cathexis of longing. Here anxiety appears as a reaction to the felt loss of the object; and we are at once reminded of the fact that castration anxiety, too, is a fear of being separated from a highly valued object, and that the earliest anxiety of all - the 'primal anxiety' of birth - is brought about on the occasion of a separation from the mother.

[1926d, 4292]

The significance of the loss of object as a determinant of anxiety extends considerably further. For the next transformation of anxiety, viz. the castration anxiety belonging to the phallic phase, is also a fear of separation and is thus attached to the same determinant. In this case the danger is of being separated from one's genitals. Ferenczi has traced, quite correctly, I think, a clear line of connection between this fear and the fears contained in the earlier situations of danger. The high degree of narcissistic value which the penis possesses can appeal to the fact that that organ is a guarantee to its owner that he can be once more united to his mother - i.e. to a substitute for her - in the act of copulation. Being deprived of it amounts to a renewed separation from her, and this in its turn means being helplessly exposed to an unpleasurable tension due to instinctual need, as was the case at birth. But the need whose increase is feared is now a specific one belonging to the genital libido and is no longer an indeterminate one, as it was in the period of infancy. It may be added that for a man who is impotent (that is, who is inhibited by the threat of castration) the substitute for copulation is a phantasy of returning into his mother's womb. Following Ferenczi's line of thought, we might say that the man in question, having tried to bring about his return into his mother's womb by using his genital organ to represent him, is now replacing that organ regressively by his whole person.

[1926d, 4294]
The progress which the child makes in its development - its growing independence, the sharper division of its mental apparatus into several agencies, the advent of new needs - cannot fail to exert an influence upon the content of the danger situation. We have already traced the change of that content from loss of the mother as an object to castration. The next change is caused by the power of the super-ego. With the depersonalization of the parental agency from which castration was feared, the danger becomes less defined. Castration anxiety develops into moral anxiety - social anxiety - and it is not so easy now to know what the anxiety is about. The formula, 'separation and expulsion from the horde', only applies to that later portion of the super-ego which has been formed on the basis of social prototypes, not to the nucleus of the super-ego, which corresponds to the introjected parental agency. Putting it more generally, what the ego regards as the danger and responds to with an anxiety-signal is that the super-ego should be angry with it or punish it or cease to love it. The final transformation which the fear of the super-ego undergoes is, it seems to me, the fear of death (or fear for life) which is a fear of the super-ego projected on to the powers of destiny.

In describing the evolution of the various danger-situations from their prototype, the act of birth, I have had no intention of asserting that every later determinant of anxiety completely invalidates the preceding one. It is true that, as the development of the ego goes on, the earlier danger-situations tend to lose their force and to be set aside, so that we might say that each period of the individual's life has its appropriate determinant of anxiety. Thus the danger of psychical helplessness is appropriate to the period of life when his ego is immature; the danger of loss of object, to early childhood when he is still dependent on others; the danger of castration, to the phallic phase; and the fear of his super-ego, to the latency period. Nevertheless, all these danger-situations and determinants of anxiety can persist side by side and cause the ego to react to them with anxiety at a period later than the appropriate one; or, again, several of them can come into operation at the same time. It is possible, moreover, that there is a fairly close relationship between the danger-situation that is operative and the form taken by the ensuing neurosis.¹

When, in an earlier part of this discussion, we found that the danger of castration was of importance in more than one neurotic illness, we put ourselves on guard against overestimating that factor, since it could not be a decisive one for the female sex, who are undoubtedly more subject to neuroses than men. We now see that there is no danger of our regarding castration anxiety as the sole motive force of the defensive processes which lead to neurosis. I have shown elsewhere how little girls, in the course of their development, are led into making a tender object-cathexis by their castration complex. It is precisely in women that the danger situation of loss of object seems to have remained the most effective. All we need to do is to make a slight modification in our description of their determinant of anxiety, in the sense that it is no longer a matter of feeling the want of, or actually losing the object itself, but of losing the object's love. Since there is no doubt that hysteria has a strong affinity with femininity, just as obsessional neurosis has with masculinity, it appears probable that, as a determinant of anxiety, loss of love plays much the same part in hysteria as the threat of castration does in phobias and fear of the super-ego in obsessional neurosis.

[1926d, 4297]

[1926d, 4298]
One objection to it is that loss of an object (or loss of love on the part of the object) and the threat of castration are just as much dangers coming from outside as, let us say, a ferocious animal would be; they are not instinctual dangers. Nevertheless, the two cases are not the same. A wolf would probably attack us irrespectively of our behaviour towards it; but the loved person would not cease to love us nor should we be threatened with castration if we did not entertain certain feelings and intentions within us. Thus such instinctual impulses are determinants of external dangers and so become dangerous in themselves; and we can now proceed against the external danger by taking measures against the internal ones. In phobias of animals the danger seems to be still felt entirely as an external one, just as it has undergone an external displacement in the symptom. In obsessional neuroses the danger is much more internalized. That portion of anxiety in regard to the super-ego which constitutes social anxiety still represents an internal substitute for an external danger, while the other portion - moral anxiety - is already completely endopsychic.

This study of the determinants of anxiety has, as it were, shown the defensive behaviour of the ego transfigured in a rational light. Each situation of danger corresponds to a particular period of life or a particular developmental phase of the mental apparatus and appears to be justifiable for it. In early infancy the individual is really not equipped to master psychically the large sums of excitation that reach him whether from without or from within. Again, at a certain period of life his most important interest really is that the people he is dependent on should not withdraw their loving care of him. Later on in his boyhood, when he feels that his father is a powerful rival in regard to his mother and becomes aware of his own aggressive inclinations towards him and of his sexual intentions towards his mother, he really is justified in being afraid of his father; and his fear of being punished by him can find expression through phylogenetic reinforcement in the fear of being castrated. Finally, as he enters into social relationships, it really is necessary for him to be afraid of his super-ego, to have a conscience; and the absence of that factor would give rise to severe conflicts, dangers and so on.

But this last point raises a fresh problem. Instead of the affect of anxiety let us take, for a moment, another affect - that of pain, for instance. It seems quite normal that at four years of age a girl should weep painfully if her doll is broken; or at six, if her governess reproves her; or at sixteen, if she is slighted by her young man; or at twenty-five, perhaps, if a child of her own dies. Each of these determinants of pain has its own time and each passes away when that time is over. Only the final and definitive determinants remain throughout life. We should think it strange if this same girl, after she had grown to be a wife and mother, were to cry over some worthless trinket that had been damaged. Yet that is how the neurotic behaves. Although all the agencies for mastering stimuli have long ago been developed within wide limits in his mental apparatus, and although he is sufficiently grown up to satisfy most of his needs for himself and has long ago learnt that castration is no longer practised as a punishment, he nevertheless behaves as though the old danger-situations still existed, and keeps hold of all the earlier determinants of anxiety.
Why this should be so calls for a rather long reply. First of all, we must sift the facts. In a great number of cases the old determinants of anxiety do really lapse, after having produced neurotic reactions. The phobias of very young children, fears of being alone or in the dark or with strangers - phobias which can almost be called normal - usually pass off later on; the child 'grows out of them', as we say about some other disturbances of childhood. Animal phobias, which are of such frequent occurrence, undergo the same fate and many conversion hysteries of early years find no continuation in later life. Ceremonial actions appear extremely often in the latency period, but only a very small percentage of them develop later into a full obsessional neurosis. In general, so far as we can tell from our observations of town children belonging to the white races and living according to fairly high cultural standards, the neuroses of childhood are in the nature of regular episodes in a child's development, although too little attention is still being paid to them. Signs of childhood neuroses can be detected in all adult neurotics without exception; but by no means all children who show those signs become neurotic in later life. It must be, therefore, that certain determinants of anxiety are relinquished and certain dangersituations lose their significance as the individual becomes more mature. Moreover, some of these danger-situations manage to survive into later times by modifying their determinants of anxiety so as to bring them up to date. Thus, for instance, a man may retain his fear of castration in the guise of a syphilidophobia, after he has come to know that it is no longer customary to castrate people for indulging their sexual lusts, but that, on the other hand, severe diseases may overtake anyone who thus gives way to his instincts. Other determinants of anxiety, such as fear of the super-ego, are destined not to disappear at all but to accompany people throughout their lives. In that case the neurotic will differ from the normal person in that his reactions to the dangers in question will be unduly strong. Finally, being grown-up affords no absolute protection against a return of the original traumatic anxiety-situation. Each individual has in all probability a limit beyond which his mental apparatus fails in its function of mastering the quantities of excitation which require to be disposed of.

But we have not made any mention at all so far of what the real danger is that the child is afraid of as a result of being in love with his mother. The danger is the punishment of being castrated, of losing his genital organ. You will of course object that after all that is not a real danger. Our boys are not castrated because they are in love with their mothers during the phase of the Oedipus complex. But the matter cannot be dismissed so simply. Above all, it is not a question of whether castration is really carried out; what is decisive is that the danger is one that threatens from outside and that the child believes in it. He has some ground for this, for people threaten him often enough with cutting off his penis during the phallic phase, at the time of his early masturbation, and hints at that punishment must regularly find a phylogenetic reinforcement in him. It is our suspicion that during the human family's primaeval period castration used actually to be carried out by a jealous and cruel father upon growing boys, and that circumcision, which so frequently plays a part in puberty rites among primitive peoples, is a clearly recognizable relic of it. We are aware that here we are diverging widely from the general opinion; but we must hold fast to the view that fear of castration is one of the commonest and strongest motives for repression and thus for the formation of neuroses. The analysis of cases in which circumcision, though not, it is true, castration, has been carried out on boys as a cure or punishment for masturbation (a far from rare occurrence in Anglo-American society) has given our conviction a last degree of certainty. It is very tempting at this point to go more deeply into the castration complex, but I will stick to our subject.
Fear of castration is not, of course, the only motive for repression: indeed, it finds no place in women, for though they have a castration complex they cannot have a fear of being castrated. Its place is taken in their sex by a fear of loss of love, which is evidently a later prolongation of the infant's anxiety if it finds its mother absent. You will realize how real a situation of danger is indicated by this anxiety. If a mother is absent or has withdrawn her love from her child, it is no longer sure of the satisfaction of its needs and is perhaps exposed to the most distressing feelings of tension. Do not reject the idea that these determinants of anxiety may at bottom repeat the situation of the original anxiety at birth, which, to be sure, also represented a separation from the mother. Indeed, if you follow a train of thought suggested by Ferenczi, you may add the fear of castration to this series, for a loss of the male organ results in an inability to unite once more with the mother (or a substitute for her) in the sexual act. I may mention to you incidentally that the very frequent phantasy of returning into the mother's womb is a substitute for this wish to copulate. There would be many interesting things and surprising connections to tell you at this point, but I cannot go outside the framework of an introduction to psychoanalysis. I will only draw your attention to the fact that here psychological researches trench upon the facts of biology.

Otto Rank, to whom psycho-analysis is indebted for many excellent contributions, also has the merit of having expressly emphasized the significance of the act of birth and of separation from the mother. Nevertheless we have all found it impossible to accept the extreme inferences which he has drawn from this factor as bearing on the theory of the neuroses and even on analytic therapy. The core of his theory - that the experience of anxiety at birth is the model of all later situations of danger - he found already there. If we dwell on these situations of danger for a moment, we can say that in fact a particular determinant of anxiety (that is, situation of danger) is allotted to every age of development as being appropriate to it. The danger of psychical helplessness fits the stage of the ego's early immaturity; the danger of loss of an object (or loss of love) fits the lack of self-sufficiency in the first years of childhood; the danger of being castrated fits the phallic phase; and finally fear of the super-ego, which assumes a special position, fits the period of latency. In the course of development the old determinants of anxiety should be dropped, since the situations of danger corresponding to them have lost their importance owing to the strengthening of the ego. But this only occurs most incompletely. Many people are unable to surmount the fear of loss of love; they never become sufficiently independent of other people's love and in this respect carry on their behaviour as infants. Fear of the super-ego should normally never cease, since, in the form of moral anxiety, it is indispensable in social relations, and only in the rarest cases can an individual become independent of human society. A few of the old situations of danger, too, succeed in surviving into later periods by making contemporary modifications in their determinants of anxiety. Thus, for instance, the danger of castration persists under the mark of syphilidophobia. It is true that as an adult one knows that castration is no longer customary as a punishment for the indulgence of sexual desires, but on the other hand one has learnt that instinctual liberty of that kind is threatened by serious diseases. There is no doubt that the people we describe as neurtics remain infantile in their attitude to danger and have not surmounted obsolete determinants of anxiety. We may take this as a factual contribution to the characterization of neurtics; it is not so easy to say why it should be so.
It must be admitted that this historical survey has gaps in it and is uncertain at some points. But anyone who is inclined to pronounce our construction of primaeval history purely imaginary would be gravely under-estimating the wealth and evidential value of the material contained in it. Large portions of the past, which have been linked together here into a whole, are historically attested: totemism and the male confederacies, for instance. Other portions have survived in excellent replicas. Thus authorities have often been struck by the faithful way in which the sense and content of the old totem meal is repeated in the rite of the Christian Communion, in which the believer incorporates the blood and flesh of his god in symbolic form. Numerous relics of the forgotten primaeval age have survived in popular legends and fairy tales, and the analytic study of the mental life of children has provided an unexpected wealth of material for filling the gaps in our knowledge of the earliest times. As contributions to our understanding of the son’s relation to the father which is of such great importance, I need only bring forward animal phobias, the fear, which strikes us as so strange, of being eaten by the father, and the enormous intensity of the dread of being castrated. There is nothing wholly fabricated in our construction, nothing which could not be supported on solid foundations.

¹ We must not be misled by the term ‘masculine protest’ into supposing that what the man is repudiating is his passive attitude - what might be called the social aspect of femininity. Such a view is contradicted by an observation that is easily verifiable - namely that such men often display a masochistic attitude - a state that amounts to bondage - towards women. What they reject is not passivity in general, but passivity towards a male. In other words, the ‘masculine protest’ is in fact nothing else than castration anxiety.

[1939a, 4908]  

[1937c, 5046]
We see, then, that it is not so much a question of taking back our earlier findings as of bringing them into line with more recent discoveries. It is still an undeniable fact that in sexual abstinence, in improper interference with the course of sexual excitation or if the latter is diverted from being worked over psychically, anxiety arises directly out of libido; in other words, that the ego is reduced to a state of helplessness in the face of an excessive tension due to need, as it was in the situation of birth, and that anxiety is then generated. Here once more, though the matter is of little importance, it is very possible that what finds discharge in the generating of anxiety is precisely the surplus of unutilized libido. As we know, a psychoneurosis is especially liable to develop on the basis of an 'actual' neurosis. This looks as though the ego were attempting to save itself from anxiety, which it has learned to keep in suspension for a while, and to bind it by the formation of symptoms. Analysis of the traumatic war neuroses - a term which, incidentally, covers a great variety of disorders - would probably have shown that a number of them possess some characteristics of the 'actual' neuroses.
[1926d, 4296]
A further question may be asked. Why, under such conditions of psychical insufficiency in mastering sexual excitation, does the nervous system find itself in the peculiar affective state of anxiety? An answer may be suggested as follows. The psyche finds itself in the affect of anxiety if it feels unable to deal by appropriate reaction with a task (a danger) approaching from the outside; it finds itself in the neurosis of anxiety if it notices that it is unable to even out the (sexual) excitation originating from within - that is to say, it behaves as though it were projecting that excitation outwards. The affect and its corresponding neurosis are firmly related to each other. The first is a reaction to an exogenous excitation, the second a reaction to the analogous endogenous one. The affect is a state which passes rapidly, the neurosis is a chronic one; because, while exogenous excitation operates with a single impact, the endogenous excitation operates as a constant force. In the neurosis, the nervous system is reacting against a source of excitation which is internal, whereas in the corresponding affect it is reacting against an analogous source of excitation which is external.

[1895b, 347]
If the practising psycho-analyst asks himself on account of what disorder people most often come to him for help, he is bound to reply - disregarding the many forms of anxiety - that it is psychical impotence. This singular disturbance affects men of strongly libidinous natures, and manifests itself in a refusal by the executive organs of sexuality to carry out the sexual act, although before and after they may show themselves to be intact and capable of performing the act, and although a strong psychical inclination to carry it out is present. The first clue to understanding his condition is obtained by the sufferer himself on making the discovery that a failure of this kind only arises when the attempt is made with certain individuals; whereas with others there is never any question of such a failure. He now becomes aware that it is some feature of the sexual object which gives rise to the inhibition of his male potency, and sometimes he reports that he has a feeling of an obstacle inside him, the sensation of a counter-will which successfully interferes with his conscious intention. However, he is unable to guess what this internal obstacle is and what feature of the sexual object brings it into operation. If he has had repeated experience of a failure of this kind, he is likely, by the familiar process of 'erroneous connection', to decide that the recollection of the first occasion evoked the disturbing anxiety-idea and so caused the failure to be repeated each time; while he derives the first occasion itself from some 'accidental' impression.

(c) We make a third discovery when we come to patients suffering from obsessional actions, who seem in a remarkable way exempt from anxiety. If we try to hinder their carrying out of their obsessional action - their washing or their ceremonial - or if they themselves venture upon an attempt to give up one of their compulsions, they are forced by the most terrible anxiety to yield to the compulsion. We can see that the anxiety was screened by the obsessional action, and that the latter was only performed in order to avoid the anxiety. In an obsessional neurosis, therefore, anxiety which would otherwise inevitably set in is replaced by the formation of a symptom, and if we turn to hysteria we find a similar relation: the result of the process of repression is either a generating of anxiety pure and simple, or anxiety accompanied by the formation of a symptom, or a more complete formation of a symptom without anxiety. It would thus seem not to be wrong in an abstract sense to assert that in general symptoms are only formed to escape an otherwise unavoidable generating of anxiety. If we adopt this view, anxiety is placed, as it were, in the very centre of our interest in the problems of neurosis.

We thus find ourselves convinced that the problem of anxiety occupies a place in the question of the psychology of the neuroses which may rightly be described as central. We have received a strong impression of the way in which the generation of anxiety is linked to the vicissitudes of the libido and the system of the unconscious. There is only a single point that we have found disconnected - a gap in our views: the single, yet scarcely disputable, fact that realistic anxiety must be regarded as a manifestation of the ego's self-preservation instincts.

There seem to be two very widely held opinions on this subject. One is that anxiety is itself a symptom of neurosis. The other is that there is a much more intimate relation between the two. According to the second opinion, symptoms are only formed in order to avoid anxiety: they bind the psychical energy which would otherwise be discharged as anxiety. Thus anxiety would be the fundamental phenomenon and main problem of neurosis.
That this latter opinion is at least in part true is shown by some striking examples. If an agoraphobic patient who has been accompanied into the street is left alone there, he will produce an anxiety attack. Or if an obsessional neurotic is prevented from washing his hands after having touched something, he will become a prey to almost unbearable anxiety. It is plain, then, that the purpose and the result of the imposed condition of being accompanied in the street and the obsessional act of washing the hands were to obviate outbreaks of anxiety of this kind. In this sense every inhibition which the ego imposes on itself can be called a symptom.

These minor rectifications cannot in any way alter the fact which is here under discussion, that a great many people remain infantile in their behaviour in regard to danger and do not overcome determinants of anxiety which have grown out of date. To deny this would be to deny the existence of neurosis, for it is precisely such people whom we call neurotics. But how is this possible? Why are not all neuroses episodes in the development of the individual which come to a close when the next phase is reached? Whence comes the element of persistence in these reactions to danger? Why does the affect of anxiety alone seem to enjoy the advantage over all other affects of evoking reactions which are distinguished from the rest in being abnormal and which, through their inexpediency, run counter to the movement of life? In other words, we have once more come unawares upon the riddle which has so often confronted us: whence does neurosis come - what is its ultimate, its own peculiar raison d'être? After tens of years of psycho-analytic labours, we are as much in the dark about this problem as we were at the start.
In the first place, I suspect that the reader has the impression that our discussions on the sense of guilt disrupt the framework of this essay: that they take up too much space, so that the rest of its subject-matter, with which they are not always closely connected, is pushed to one side. This may have spoilt the structure of my paper; but it corresponds faithfully to my intention to represent the sense of guilt as the most important problem in the development of civilization and to show that the price we pay for our advance in civilization is a loss of happiness through the heightening of the sense of guilt.¹ Anything that still sounds strange about this statement, which is the final conclusion of our investigation, can probably be traced to the quite peculiar relationship - as yet completely unexplained - which the sense of guilt has to our consciousness. In the common case of remorse, which we regard as normal, this feeling makes itself clearly enough perceptible to consciousness. Indeed, we are accustomed to speak of a 'consciousness of guilt' instead of a 'sense of guilt'. Our study of the neuroses, to which, after all we owe the most valuable pointers to an understanding of normal conditions, brings us up against some contradictions. In one of those affections, obsessional neurosis, the sense of guilt makes itself noisily heard in consciousness; it dominates the clinical picture and the patient's life as well, and it hardly allows anything else to appear alongside of it. But in most other cases and forms of neurosis it remains completely unconscious, without on that account producing any less important effects. Our patients do not believe us when we attribute an 'unconscious sense of guilt' to them. In order to make ourselves at all intelligible to them, we tell them of an unconscious need for punishment, in which the sense of guilt finds expression. But its connection with a particular form of neurosis must not be over-estimated. Even in obsessional neurosis there are types of patients who are not aware of their sense of guilt, or who only feel it as a tormenting uneasiness, a kind of anxiety, if they are prevented from carrying out certain actions. It ought to be possible eventually to understand these things; but as yet we cannot. Here perhaps we may be glad to have pointed out that the sense of guilt is at bottom nothing else but a topographical variety of anxiety; in its later phases it coincides completely with fear of the super-ego. And the relations of anxiety to consciousness exhibit the same extraordinary variations. Anxiety is always present somewhere or other behind every symptom; but at one time it takes noisy possession of the whole of consciousness, while at another it conceals itself so completely that we are obliged to speak of unconscious anxiety or, if we want to have a clearer psychological conscience, since anxiety is in the first instance simply a feeling, of possibilities of anxiety. Consequently it is very conceivable that the sense of guilt produced by civilization is not perceived as such either, and remains to a large extent unconscious, or appears as a sort of malaise, a dissatisfaction, for which people seek other motivations. Religions, at any rate, have never overlooked the part played in civilization by a sense of guilt. Furthermore - a point which I failed to appreciate elsewhere² - they claim to redeem mankind from this sense of guilt, which they call sin. From the manner in which, in Christianity, this redemption is achieved - by the sacrificial death of a single person, who in this manner takes upon himself a guilt that is common to everyone - we have been able to infer what the first occasion may have been on which this primal guilt, which was also the beginning of civilization, was acquired.³

[1930a, 4523]
In spite of her euphoria at night, her psychical condition deteriorated steadily. Strong suicidal impulses appeared which made it seem inadvisable for her to continue living on the third floor. Against her will, therefore, she was transferred to a country house in the neighbourhood of Vienna (on June 7, 1881). I had never threatened her with this removal from her home, which she regarded with horror, but she herself had, without saying so, expected and dreaded it. This event made it clear once more how much the affect of anxiety dominated her psychical disorder. Just as after her father's death a calmer condition had set in, so now, when what she feared had actually taken place, she once more became calmer. Nevertheless, the move was immediately followed by three days and nights completely without sleep or nourishment, by numerous attempts at suicide (though, so long as she was in a garden, these were not dangerous), by smashing windows and so on, and by hallucinations unaccompanied by absences which she was able to distinguish easily from her other hallucinations. After this she grew quieter, let the nurse feed her and even took chloral at night.

In hypnosis she informed me that she still occasionally has frightening ideas, such as that something might happen to her children, that they might fall ill or lose their lives, or that her brother, who is now on his honeymoon, might have an accident, or his wife might die (because the marriages of all her brothers and sisters had been so short). I could not extract any other fears from her. I forbade her any need to be frightened when there was no reason for it. She promised to give it up 'because you ask me to'. I gave her further suggestions for her pains, her leg, etc.

Evening. - She gave a start as soon as I came in. 'I'm so glad you've come,' she said, 'I am so frightened.' At the same time she gave every indication of terror, together with stammering and tic. I first got her to tell me in her waking state what had happened. Crooking her fingers and stretching out her hands before her, she gave a vivid picture of her terror as she said: ‘An enormous mouse suddenly whisked across my hand in the garden and was gone in a flash; things kept on gliding back wards and forwards.’ (An illusion from the play of shadows?) ‘A whole lot of mice were sitting in the trees. - Don't you hear the horses stamping in the circus? - There's a man groaning in the next room; he must be in pain after his operation. - Can I be in Rügen? Did I have a stove there like that?’ She was confused by the multitude of thoughts crossing one another in her mind and by her efforts to sort out her actual surroundings from them. When I put questions to her about contemporary things, such as whether her daughters were here, she could make no answer.

[1895d, 28]
In the first place, I suspect that the reader has the impression that our discussions on the sense of guilt disrupt the framework of this essay: that they take up too much space, so that the rest of its subject-matter, with which they are not always closely connected, is pushed to one side. This may have spoilt the structure of my paper; but it corresponds faithfully to my intention to represent the sense of guilt as the most important problem in the development of civilization and to show that the price we pay for our advance in civilization is a loss of happiness through the heightening of the sense of guilt.¹ Anything that still sounds strange about this statement, which is the final conclusion of our investigation, can probably be traced to the quite peculiar relationship - as yet completely unexplained - which the sense of guilt has to our consciousness. In the common case of remorse, which we regard as normal, this feeling makes itself clearly enough perceptible to consciousness. Indeed, we are accustomed to speak of a 'consciousness of guilt' instead of a 'sense of guilt'. Our study of the neuroses, to which, after all we owe the most valuable pointers to an understanding of normal conditions, brings us up against some contradictions. In one of those affections, obsessional neurosis, the sense of guilt makes itself noisily heard in consciousness; it dominates the clinical picture and the patient's life as well, and it hardly allows anything else to appear alongside of it. But in most other cases and forms of neurosis it remains completely unconscious, without on that account producing any less important effects. Our patients do not believe us when we attribute an 'unconscious sense of guilt' to them. In order to make ourselves at all intelligible to them, we tell them of an unconscious need for punishment, in which the sense of guilt finds expression. But its connection with a particular form of neurosis must not be over-estimated. Even in obsessional neurosis there are types of patients who are not aware of their sense of guilt, or who only feel it as a tormenting uneasiness, a kind of anxiety, if they are prevented from carrying out certain actions. It ought to be possible eventually to understand these things; but as yet we cannot. And the relations of anxiety to consciousness exhibit the same extraordinary variations. Anxiety is always present somewhere or other behind every symptom; but at one time it takes noisy possession of the whole of consciousness, while at another it conceals itself so completely that we are obliged to speak of unconscious anxiety or, if we want to have a clearer psychological conscience, since anxiety is in the first instance simply a feeling, of possibilities of anxiety. Consequently it is very conceivable that the sense of guilt produced by civilization is not perceived as such either, and remains to a large extent unconscious, or appears as a sort of malaise, a dissatisfaction, for which people seek other motivations. Religions, at any rate, have never overlooked the part played in civilization by a sense of guilt. Furthermore - a point which I failed to appreciate elsewhere² - they claim to redeem mankind from this sense of guilt, which they call sin. From the manner in which, in Christianity, this redemption is achieved - by the sacrificial death of a single person, who in this manner takes upon himself a guilt that is common to everyone - we have been able to infer what the first occasion may have been on which this primal guilt, which was also the beginning of civilization, was acquired.³

[1930a, 4523]
May 15. - She had slept till 8.30 a.m. but had become restless towards morning, and received me with some slight signs of her tic, clacking and speech-inhibition. 'I'm frightened to death,' she said once more. In reply to a question she told me that the Pension in which her children were staying was on the fourth floor of a building and reached by a lift. She had insisted yesterday that the children should make use of the lift for coming down as well as going up, and was now reproaching herself about this, because the lift was not entirely to be trusted. The owner of the Pension had said so himself. Had I heard, she asked, the story of the Countess Sch. who had been killed in Rome in an accident of that kind? I happen to be acquainted with the Pension and I know that the lift is the private property of the owner of the Pension; it does not seem to me very likely that this man, who makes a special point of the lift in an advertisement, would himself have warned anyone against using it. It seemed to me that we had here one of the paramnesias that are brought about by anxiety. I told her my view and succeeded without any difficulty in getting her herself to laugh at the improbability of her fears. For that very reason I could not believe that this was the cause of her anxiety and determined to put the question to her hypnotic consciousness. During massage, which I resumed to-day after a few days' interval, she told me a loosely connected string of anecdotes, which may have been true - about a toad which was found in a cellar, an eccentric mother who looked after her idiot child in a strange fashion, a woman who was shut up in an asylum because she had melancholia - and which showed the kind of recollections that passed through her head when she was in a disquieted frame of mind. When she had got these stories out she became very cheerful. She described her life on her estate and her contacts with prominent men in German Russia and North Germany; and I really found it extremely hard to reconcile activities of this kind with the picture of such a severely neurotic woman.

[1895d, 64]

We are also now coming to the opinion that analytic technique must be modified in certain ways according to the nature of the disease and the dominant instinctual trends in the patient. We started out from the treatment of conversion hysteria; in anxiety hysteria (phobias) we must to some extent alter our procedure. For these patient cannot bring out the material necessary for resolving their phobia so long as they feel protected by obeying the condition which it lays down. One cannot, of course, succeed in getting them to give up their protective measures and work under the influence of anxiety from the beginning of the treatment. One must therefore help them by interpreting their unconscious to them until they can make up their minds to do without the protection of their phobia and expose themselves to a now greatly mitigated anxiety. Only after they have done so does the material become accessible, which, when it has been mastered, leads to a solution of the phobia. Other modifications of technique, which seem to me not yet ripe for discussion, will be required in the treatment of obsessional neurosis. In this connection very important questions arise, which have not hitherto been elucidated: how far the instincts which the patient is combating are to be allowed some satisfaction during the treatment, and what difference it makes whether these impulses are active (sadistic) or passive (masochistic) in their nature.

[1910d, 2310]
There is a second explanation, also unconcerned with sexuality, which has, however, a much more general scope than the first. It suggests that primitive man is prey to a perpetual lurking apprehensiveness, just as in the psycho-analytic theory of the neuroses we claim to be the case with people suffering from anxiety neurosis. This apprehensiveness will appear most strongly on all occasions which differ in any way from the usual, which involve something new or unexpected, something not understood or uncanny. This is also the origin of the ceremonial practices, widely adopted in later religions, which are connected with the beginning of every new undertaking, the start of every new period of time, the first-fruits of human, animal and plant life. The dangers which the anxious man believes to be threatening him never appear more vivid in his expectation than on the threshold of a dangerous situation, and then, too, is the only time when protecting himself against them is of any use. The first act of intercourse in marriage can certainly claim, on grounds of importance, to be preceded by such precautionary measures. These two attempts at explanation, based on horror of blood and on fear of first occurrences, do not contradict but rather reinforce each other. The first occasion of sexual intercourse is certainly a critical action, all the more so if it is to involve a flow of blood.
[1918a, 2353]

We finally arrive at the connection we are in search of, if we take as our starting-point the opposition we have so often asserted between the ego and the libido. As we know, the generation of anxiety is the ego's reaction to danger and the signal for taking flight. If so, it seems plausible to suppose that in neurotic anxiety the ego is making a similar attempt at flight from the demand by its libido, that it is treating this internal danger as though it were an external one. This would therefore fulfil our expectation that where anxiety is shown there is something one is afraid of. But the analogy could be carried further. Just as the attempt at flight from an external danger is replaced by standing firm and the adoption of expedient measures of defence, so too the generation of neurotic anxiety gives place to the formation of symptoms, which results in the anxiety being bound.
[1916-1917, 3452]

But this explanation opens up fresh problems. Where does the energy come from which is employed for giving the signal of unpleasure? Here we may be assisted by the idea that a defence against an unwelcome internal process will be modelled upon the defence adopted against an external stimulus, that the ego wards off internal and external dangers alike along identical lines. In the case of external danger the organism has recourse to attempts at flight. The first thing it does is to withdraw cathexis from the perception of the dangerous object; later on it discovers that it is a better plan to perform muscular movements of such a sort as will render perception of the dangerous object impossible even in the absence of any refusal to perceive it - that it is a better plan, that is, to remove itself from the sphere of danger. Repression is an equivalent of this attempt at flight. The ego withdraws its (preconscious) cathexis from the instinctual representative that is to be repressed and uses that cathexis for the purpose of releasing unpleasure (anxiety). The problem of how anxiety arises in connection with repression may be no simple one; but we may legitimately hold firmly to the idea that the ego is the actual seat of anxiety and give up our earlier view that the cathetic energy of the repressed impulse is automatically turned into anxiety. If I expressed myself earlier in the latter sense, I was giving a phenomenological description and not a metapsychological account of what was occurring.
[1926d, 4253]
Here, then, is our unexpected finding: in both patients the motive force of the repression was fear of castration. The ideas contained in their anxiety - being bitten by a horse and being devoured by a wolf - were substitutes by distortion for the idea of being castrated by their father. This was the idea which had undergone repression. In the Russian boy the idea was an expression of a wish which was not able to subsist in the face of his masculine revolt; in 'Little Hans' it was the expression of a reaction in him which had turned his aggressiveness into its opposite. But the affect of anxiety, which was the essence of the phobia, came, not from the process of repression, not from the libidinal cathexes of the repressed impulses, but from the repressing agency itself. The anxiety belonging to the animal phobias was an untransformed fear of castration. It was therefore a realistic fear, a fear of a danger which was actually impending or was judged to be a real one. It was anxiety which produced repression and not, as I formerly believed, repression which produced anxiety. [1926d, 4268]

It may be asked how I arrived at this idea of transformation in the first instance. It was while I was studying the 'actual neuroses', at a time when analysis was still a very long way from distinguishing between processes in the ego and processes in the id. I found that outbreaks of anxiety and a general state of preparedness for anxiety were produced by certain sexual practices such as coitus interruptus, undischarged sexual excitation or enforced abstinence - that is, whenever sexual excitation was inhibited, arrested or deflected in its progress towards satisfaction. Since sexual excitation was an expression of libidinal instinctual impulses it did not seem too rash to assume that the libido was turned into anxiety through the agency of these disturbances. The observations which I made at the time still hold good. Moreover, it cannot be denied that the libido belonging to the id-processes is subjected to disturbance at the instigation of repression. It might still be true, therefore, that in repression anxiety is produced from the libidinal cathexis of the instinctual impulses. But how can we reconcile this conclusion with our other conclusion that the anxiety felt in phobias is an ego anxiety and arises in the ego, and that it does not proceed out of repression but, on the contrary, sets repression in motion? There seems to be a contradiction here which it is not at all a simple matter to solve. It will not be easy to reduce the two sources of anxiety to a single one. We might attempt to do so by supposing that, when coitus is disturbed or sexual excitation interrupted or abstinence enforced, the ego scents certain dangers to which it reacts with anxiety. But this takes us nowhere. On the other hand, our analysis of the phobias seems to admit of no correction. Non liquet. [1926d, 4269]

We set out to study the formation of symptoms and the secondary struggle waged by the ego against symptoms. But in picking on the phobias for this purpose we have clearly made an unlucky choice. The anxiety which predominates in the picture of these disorders is now seen as a complication which obscures the situation. There are plenty of neuroses which exhibit no anxiety whatever. True conversion hysteria is one of these. Even in its most severe symptoms no admixture of anxiety is found. This fact alone ought to warn us against making too close a connection between anxiety and symptom-formation. The phobias are so closely akin to conversion hysteria in every other respect that I have felt justified in classing them alongside of it under the name of 'anxiety hysteria'. But no one has as yet been able to say what it is that determines whether any given case shall take the form of a conversion hysteria or a phobia - has been able, that is to say, to establish what determines the generating of anxiety in hysteria. [1926d, 4270]
This is as far as our investigations into the formation of symptoms take us. It is hardly worth while summing them up, for the results they have yielded are scanty and incomplete and tell us scarcely anything that we do not already know. It would be fruitless to turn our attention to symptom-formation in other disorders besides phobias, conversion hysteria and obsessional neurosis, for too little is known about them. But in reviewing those three neuroses together we are brought up against a very serious problem the consideration of which can no longer be put off. All three have as their outcome the destruction of the Oedipus complex; and in all three the motive force of the ego's opposition is, we believe, the fear of castration. Yet it is only in the phobias that this fear comes to the surface and is acknowledged. What has become of it in the other two neuroses? How has the ego spared itself this fear? The problem becomes accentuated when we recall the possibility, already referred to, that anxiety arises directly, by a kind of fermentation, from a libidinal cathexis whose processes have been disturbed. Furthermore, is it absolutely certain that fear of castration is the only motive force of repression (or defence)? If we think of neuroses in women we are bound to doubt it. For though we can with certainty establish in them the presence of a castration complex, we can hardly speak with propriety of castration anxiety where castration has already taken place.

This time we will not lose sight of the part played by anxiety. We have said that as soon as the ego recognizes the danger of castration it gives the signal of anxiety and inhibits through the pleasure-unpleasure agency (in a way which we cannot as yet understand) the impending cathetic process in the id. At the same time the phobia is formed. And now the castration anxiety is directed to a different object and expressed in a distorted form, so that the patient is afraid, not of being castrated by his father, but of being bitten by a horse or devoured by a wolf. This substitutive formation has two obvious advantages. In the first place it avoids a conflict due to ambivalence (for the father was a loved object, too), and in the second place it enables the ego to cease generating anxiety. For the anxiety belonging to a phobia is conditional; it only emerges when the object of it is perceived - and rightly so, since it is only then that the danger-situation is present. There is no need to be afraid of being castrated by a father who is not there. On the other hand one cannot get rid of a father; he can appear whenever he chooses. But if he is replaced by an animal, all one has to do is to avoid the sight of it - that is, its presence - in order to be free from danger and anxiety. 'Little Hans', therefore, imposed a restriction upon his ego. He produced the inhibition of not leaving the house, so as not to come across any horses. The young Russian had an even easier time of it, for it was hardly a privation for him not to look at a particular picture-book any more. If his naughty sister had not kept on showing him the book with the picture of the wolf standing upright in it, he would have been able to feel safe from his fear.

The conclusion we have come to, then, is this. Anxiety is a reaction to a situation of danger. It is obviated by the ego's doing something to avoid that situation or to withdraw from it. It might be said that symptoms are created so as to avoid the generating of anxiety. But this does not go deep enough. It would be truer to say that symptoms are created so as to avoid a danger-situation whose presence has been signalled by the generation of anxiety. In the cases that we have discussed, the danger concerned was the danger of castration or of something traceable back to castration.
We see, then, that it is not so much a question of taking back our earlier findings as of bringing them into line with more recent discoveries. It is still an undeniable fact that in sexual abstinence, in improper interference with the course of sexual excitation or if the latter is diverted from being worked over psychically, anxiety arises directly out of libido; in other words, that the ego is reduced to a state of helplessness in the face of an excessive tension due to need, as it was in the situation of birth, and that anxiety is then generated. Here once more, though the matter is of little importance, it is very possible that what finds discharge in the generating of anxiety is precisely the surplus of unutilized libido. As we know, a psychoneurosis is especially liable to develop on the basis of an 'actual' neurosis. This looks as though the ego were attempting to save itself from anxiety, which it has learned to keep in suspension for a while, and to bind it by the formation of symptoms. Analysis of the traumatic war neuroses - a term which, incidentally, covers a great variety of disorders - would probably have shown that a number of them possess some characteristics of the 'actual' neuroses.

In describing the evolution of the various danger-situations from their prototype, the act of birth, I have had no intention of asserting that every later determinant of anxiety completely invalidates the preceding one. It is true that, as the development of the ego goes on, the earlier danger-situations tend to lose their force and to be set aside, so that we might say that each period of the individual's life has its appropriate determinant of anxiety. Thus the danger of psychical helplessness is appropriate to the period of life when his ego is immature; the danger of loss of object, to early childhood when he is still dependent on others; the danger of castration, to the phallic phase; and the fear of his super-ego, to the latency period. Nevertheless, all these danger-situations and determinants of anxiety can persist side by side and cause the ego to react to them with anxiety at a period later than the appropriate one; or, again, several of them can come into operation at the same time. It is possible, moreover, that there is a fairly close relationship between the danger-situation that is operative and the form taken by the ensuing neurosis.

When, in an earlier part of this discussion, we found that the danger of castration was of importance in more than one neurotic illness, we put ourselves on guard against overestimating that factor, since it could not be a decisive one for the female sex, who are undoubtedly more subject to neuroses than men. We now see that there is no danger of our regarding castration anxiety as the sole motive force of the defensive processes which lead to neurosis. I have shown elsewhere how little girls, in the course of their development, are led into making a tender object-cathexis by their castration complex. It is precisely in women that the danger situation of loss of object seems to have remained the most effective. All we need to do is to make a slight modification in our description of their determinant of anxiety, in the sense that it is no longer a matter of feeling the want of, or actually losing the object itself, but of losing the object's love. Since there is no doubt that hysteria has a strong affinity with femininity, just as obsessional neurosis has with masculinity, it appears probable that, as a determinant of anxiety, loss of love plays much the same part in hysteria as the threat of castration does in phobias and fear of the super-ego in obsessional neurosis.

What is now left for us is to consider the relationship between the formation of symptoms and the generating of anxiety.
There seem to be two very widely held opinions on this subject. One is that anxiety is itself a symptom of neurosis. The other is that there is a much more intimate relation between the two. According to the second opinion, symptoms are only formed in order to avoid anxiety: they bind the psychical energy which would otherwise be discharged as anxiety. Thus anxiety would be the fundamental phenomenon and main problem of neurosis.

[1926d, 4299]

That this latter opinion is at least in part true is shown by some striking examples. If an agoraphobic patient who has been accompanied into the street is left alone there, he will produce an anxiety attack. Or if an obsessional neurotic is prevented from washing his hands after having touched something, he will become a prey to almost unbearable anxiety. It is plain, then, that the purpose and the result of the imposed condition of being accompanied in the street and the obsessional act of washing the hands were to obviate outbreaks of anxiety of this kind. In this sense every inhibition which the ego imposes on itself can be called a symptom.

[1926d, 4299]

Since we have traced back the generating of anxiety to a situation of danger, we shall prefer to say that symptoms are created in order to remove the ego from a situation of danger. If the symptoms are prevented from being formed, the danger does in fact materialize; that is, a situation analogous to birth is established in which the ego is helpless in the face of a constantly increasing instinctual demand - the earliest and original determinant of anxiety. Thus in our view the relation between anxiety and symptom is less close than was supposed, for we have inserted the factor of the danger-situation between them. We can also add that the generating of anxiety sets symptom formation going and is, indeed, a necessary prerequisite of it. For if the ego did not arouse the pleasure-unpleasure agency by generating anxiety, it would not obtain the power to arrest the process which is preparing in the id and which threatens danger. There is in all this an evident inclination to limit to a minimum the amount of anxiety generated and to employ it only as a signal; for to do otherwise would only result in feeling in another place the unpleasure which the instinctual process was threatening to produce, and that would not be a success from the standpoint of the pleasure principle, although it is one that occurs often enough in the neuroses.

[1926d, 4299]

Symptom-formation, then, does in fact put an end to the danger-situation. It has two aspects: one, hidden from view, brings about the alteration in the id in virtue of which the ego is removed from danger; the other, presented openly, shows what has been created in place of the instinctual process that has been affected - namely, the substitutive formation.

[1926d, 4300]

But this last point raises a fresh problem. Instead of the affect of anxiety let us take, for a moment, another affect - that of pain, for instance. It seems quite normal that at four years of age a girl should weep painfully if her doll is broken; or at six, if her governess reproves her; or at sixteen, if she is slighted by her young man; or at twenty-five, perhaps, if a child of her own dies. Each of these determinants of pain has its own time and each passes away when that time is over. Only the final and definitive determinants remain throughout life. We should think it strange if this same girl, after she had grown to be a wife and mother, were to cry over some worthless trinket that had been damaged. Yet that is how the neurotic behaves. Although all the agencies for mastering stimuli have long ago been developed within wide limits in his mental apparatus, and although he is sufficiently grown up to satisfy most of his needs for himself and has long ago learnt that castration is no longer practised as a punishment, he nevertheless behaves as though the old danger-situations still existed, and keeps hold of all the earlier determinants of anxiety.

[1926d, 4302]
These minor rectifications cannot in any way alter the fact which is here under discussion, that a great many people remain infantile in their behaviour in regard to danger and do not overcome determinants of anxiety which have grown out of date. To deny this would be to deny the existence of neurosis, for it is precisely such people whom we call neurotics. But how is this possible? Why are not all neuroses episodes in the development of the individual which come to a close when the next phase is reached? Whence comes the element of persistence in these reactions to danger? Why does the affect of anxiety alone seem to enjoy the advantage over all other affects of evoking reactions which are distinguished from the rest in being abnormal and which, through their inexpediency, run counter to the movement of life? In other words, we have once more come unawares upon the riddle which has so often confronted us: whence does neurosis come - what is its ultimate, its own peculiar raison d'être? After tens of years of psycho-analytic labours, we are as much in the dark about this problem as we were at the start.

The third, psychological, factor resides in a defect of our mental apparatus which has to do precisely with its differentiation into an id and an ego, and which is therefore also attributable ultimately to the influence of the external world. In view of the dangers of reality, the ego is obliged to guard against certain instinctual impulses in the id and to treat them as dangers. But it cannot protect itself from internal instinctual dangers as effectively as it can from some piece of reality that is not part of itself. Intimately bound up with the id as it is, it can only fend off an instinctual danger by restricting its own organization and by acquiescing in the formation of symptoms in exchange for having impaired the instinct. If the rejected instinct renews its attack, the ego is overtaken by all those difficulties which are known to us as neurotic ailments.

There are two reactions to real danger. One is an affective reaction, an outbreak of anxiety. The other is a protective action. The same will presumably be true of instinctual danger. We know how the two reactions can co-operate in an expedient way, the one giving the signal for the other to appear. But we also know that they can behave in an inexpedient way: paralysis from anxiety may set in, and the one reaction spread at the cost of the other.

In some cases the characteristics of realistic anxiety and neurotic anxiety are mingled. The danger is known and real but the anxiety in regard to it is over-great, greater than seems proper to us. It is this surplus of anxiety which betrays the presence of a neurotic element. Such cases, however, introduce no new principle; for analysis shows that to the known real danger an unknown instinctual one is attached.
We now observe that the store of religious ideas includes not only wish-fulfilments but important historical recollections. This concurrent influence of past and present must give religion a truly incomparable wealth of power. But perhaps with the help of an analogy yet another discovery may begin to dawn on us. Though it is not a good plan to transplant ideas far from the soil in which they grew up, yet here is a conformity which we cannot avoid pointing out. We know that a human child cannot successfully complete its development to the civilized stage without passing through a phase of neurosis sometimes of greater and sometimes of less distinctness. This is because so many instinctual demands which will later be unserviceable cannot be suppressed by the rational operation of the child's intellect but have to be tamed by acts of repression, behind which, as a rule, lies the motive of anxiety. Most of these infantile neuroses are overcome spontaneously in the course of growing up, and this is especially true of the obsessional neuroses of childhood. The remainder can be cleared up later still by psycho-analytic treatment. In just the same way, one might assume, humanity as a whole, in its development through the ages, fell into states analogous to the neuroses, and for the same reasons - namely because in the times of its ignorance and intellectual weakness the instinctual renunciations indispensable for man's communal existence had only been achieved by it by means of purely affective forces. The precipitates of these processes resembling repression which took place in prehistoric times still remained attached to civilization for long periods. Religion would thus be the universal obsessional neurosis of humanity; like the obsessional neuroses of children, it arose out of the Oedipus complex, out of the relation to the father. If this view is right, it is to be supposed that a turning-away from religion is bound to occur with the fatal inevitability of a process of growth, and that we find ourselves at this very juncture in the middle of that phase of development. Our behaviour should therefore be modelled on that of a sensible teacher who does not oppose an impending new development but seeks to ease its path and mitigate the violence of its irruption. Our analogy does not, to be sure, exhaust the essential nature of religion. If, on the one hand, religion brings with it obsessional restrictions, exactly as an individual obsessional neurosis does, on the other hand it comprises a system of wishful illusions together with a disavowal of reality, such as we find in an isolated form nowhere else but in amentia, in a state of blissful hallucinatory confusion. But these are only analogies, by the help of which we endeavour to understand a social phenomenon; the pathology of the individual does not supply us with a fully valid counterpart.

[1927c, 4452]

For we consider that what is responsible for the anxiety in hysteria and other neuroses is the process of repression. We believe it is possible to give a more complete account of this than before, if we separate what happens to the idea that has to be repressed from what happens to the quota of libido attaching to it. It is the idea which is subjected to repression and which may be distorted to the point of being unrecognizable; but its quota of affect is regularly transformed into anxiety - and this is so whatever the nature of the affect may be, whether it is aggressiveness or love. It makes no essential difference, then, for what reason a quota of libido has become unemployable: whether it is on account of the infantile weakness of the ego, as in children's phobias, or on account of somatic processes in sexual life, as in anxiety neurosis, or owing to repression, as in hysteria. Thus in reality the two mechanisms that bring about neurotic anxiety coincide.

[1933a, 4690]
In the course of these investigations our attention was drawn to a highly significant relation between the generation of anxiety and the formation of symptoms - namely, that these two represent and replace each other. For instance, an agoraphobic patient may start his illness with an attack of anxiety in the street. This would be repeated every time he went into the street again. He will now develop the symptom of agoraphobia; this may also be described as an inhibition, a restriction of the ego's functioning, and by means of it he spares himself anxiety attacks. We can witness the converse of this if we interfere in the formation of symptoms, as is possible, for instance, with obsessions. If we prevent a patient from carrying out a washing ceremonial, he falls into a state of anxiety which he finds hard to tolerate and from which he had evidently been protected by his symptom. And it seems, indeed, that the generation of anxiety is the earlier and the formation of symptoms the later of the two, as though the symptoms are created in order to avoid the outbreak of the anxiety state. This is confirmed too by the fact that the first neuroses of childhood are phobias - states in which we see so clearly how an initial generation of anxiety is replaced by the later formation of a symptom; we get an impression that it is from these interrelations that we shall best obtain access to an understanding of neurotic anxiety. And at the same time we have also succeeded in answering the question of what it is that a person is afraid of in neurotic anxiety and so in establishing the connection between neurotic and realistic anxiety. What he is afraid of is evidently his own libido. The difference between this situation and that of realistic anxiety lies in two points: that the danger is an internal instead of an external one and that it is not consciously recognized.

At the conclusion of my earlier lecture on anxiety I myself expressed the opinion that, although these various findings of our enquiry were not mutually contradictory, somehow they did not fit in with one another. Anxiety, it seems, in so far as it is an affective state, is the reproduction of an old event which brought a threat of danger; anxiety serves the purposes of self-preservation and is a signal of a new danger; it arises from libido that has in some way become unemployable and it also arises during the process of repression; it is replaced by the formation of a symptom, is, as it were, psychically bound - one has a feeling that something is missing here which would bring all these pieces together into a whole.

For we have recently been examining the way in which anxiety is generated in certain phobias which we class as anxiety hysteria, and have chosen cases in which we were dealing with the typical repression of wishful impulses arising from the Oedipus complex. We should have expected to find that it was a libidinal cathexis of the boy's mother as object which, as a result of repression, had been changed into anxiety and which now emerged, expressed in symptomatic terms, attached to a substitute for his father. I cannot present you with the detailed steps of an investigation such as this; it will be enough to say that the surprising result was the opposite of what we expected. It was not the repression that created the anxiety; the anxiety was there earlier; it was the anxiety that made the repression. But what sort of anxiety can it have been? Only anxiety in the face of a threatening external danger - that is to say, a realistic anxiety. It is true that the boy felt anxiety in the face of a demand by his libido - in this instance, anxiety at being in love with his mother; so the case was in fact one of neurotic anxiety. But this being in love only appeared to him as an internal danger, which he must avoid by renouncing that object, because it conjured up an external situation of danger. And in every case we examine we obtain the same result. It must be confessed that we were not prepared to find that internal instinctual danger would turn out to be a determinant and preparation for an external, real, situation of danger.
But we have not made any mention at all so far of what the real danger is that the child is afraid of as a result of being in love with his mother. The danger is the punishment of being castrated, of losing his genital organ. You will of course object that after all that is not a real danger. Our boys are not castrated because they are in love with their mothers during the phase of the Oedipus complex. But the matter cannot be dismissed so simply. Above all, it is not a question of whether castration is really carried out; what is decisive is that the danger is one that threatens from outside and that the child believes in it. He has some ground for this, for people threaten him often enough with cutting off his penis during the phallic phase, at the time of his early masturbation, and hints at that punishment must regularly find a phylogenetic reinforcement in him. It is our suspicion that during the human family's primaeval period castration used actually to be carried out by a jealous and cruel father upon growing boys, and that circumcision, which so frequently plays a part in puberty rites among primitive peoples, is a clearly recognizable relic of it. We are aware that here we are diverging widely from the general opinion; but we must hold fast to the view that fear of castration is one of the commonest and strongest motives for repression and thus for the formation of neuroses. The analysis of cases in which circumcision, though not, it is true, castration, has been carried out on boys as a cure or punishment for masturbation (a far from rare occurrence in Anglo-American society) has given our conviction a last degree of certainty. It is very tempting at this point to go more deeply into the castration complex, but I will stick to our subject.

[1933a, 4693]

Fear of castration is not, of course, the only motive for repression: indeed, it finds no place in women, for though they have a castration complex they cannot have a fear of being castrated. Its place is taken in their sex by a fear of loss of love, which is evidently a later prolongation of the infant's anxiety if it finds its mother absent. You will realize how real a situation of danger is indicated by this anxiety. If a mother is absent or has withdrawn her love from her child, it is no longer sure of the satisfaction of its needs and is perhaps exposed to the most distressing feelings of tension. Do not reject the idea that these determinants of anxiety may at bottom repeat the situation of the original anxiety at birth, which, to be sure, also represented a separation from the mother. Indeed, if you follow a train of thought suggested by Ferenczi, you may add the fear of castration to this series, for a loss of the male organ results in an inability to unite once more with the mother (or a substitute for her) in the sexual act. I may mention to you incidentally that the very frequent phantasy of returning into the mother's womb is a substitute for this wish to copulate. There would be many interesting things and surprising connections to tell you at this point, but I cannot go outside the framework of an introduction to psycho-analysis. I will only draw your attention to the fact that here psychological researches trench upon the facts of biology.

[1933a, 4694]
I hope you have not lost the thread of what I am saying and remember that we are investigating the relations between anxiety and repression. In the course of this we have learnt two new things: first, that anxiety makes repression and not, as we used to think, the other way round, and that the instinctual situation which is feared goes back ultimately to an external situation of danger. The next question will be: how do we now picture the process of a repression under the influence of anxiety? The answer will, I think, be as follows. The ego notices that the satisfaction of an emerging instinctual demand would conjure up one of the well-remembered situations of danger. This instinctual cathexis must therefore be somehow suppressed, stopped, made powerless. We know that the ego succeeds in this task if it is strong and has drawn the instinctual impulse concerned into its organization. But what happens in the case of repression is that the instinctual impulse still belongs to the id and that the ego feels weak. The ego thereupon helps itself by a technique which is at bottom identical with normal thinking. Thinking is an experimental action carried out with small amounts of energy, in the same way as a general shifts small figures about on a map before setting his large bodies of troops in motion. Thus the ego anticipates the satisfaction of the questionable instinctual impulse and permits it to bring about the reproduction of the unpleasurable feelings at the beginning of the feared situation of danger. With this the automatism of the pleasure-unpleasure principle is brought into operation and now carries out the repression of the dangerous instinctual impulse.

[1933a, 4696]

'Stop a moment!' you will exclaim; 'we can't follow you any further there!' You are quite right; I must add a little more before it can seem acceptable to you. First, I must admit that I have tried to translate into the language of our normal thinking what must in fact be a process that is neither conscious nor preconscious, taking place between quotas of energy in some unimaginable substratum. But that is not a strong objection, for it cannot be done in any other way. What is more important is that we should distinguish clearly what happens in the ego and what happens in the id when there is a repression. We have just said what the ego does: it makes use of an experimental cathexis and starts up the pleasure-unpleasure automatism by means of a signal of anxiety. After that, several reactions are possible or a combination of them in varying proportions. Either the anxiety attack is fully generated and the ego withdraws entirely from the objectionable excitation; or, in place of the experimental cathexis it opposes the excitation with an anticathexis, and this combines with the energy of the repressed impulse to form a symptom; or the anticathexis is taken up into the ego as a reaction-formation, as an intensification of certain of the ego's dispositions, as a permanent alteration of it. The more the generation of anxiety can be restricted to a mere signal, so much the more does the ego expend on actions of defence which amount to the psychical binding of the repressed, and so much the closer, too, does the process approximate to a normal working-over of it, though no doubt without attaining to it.

[1933a, 4697]
Now let us go back and turn to the id. It is not so easy to guess what occurs during repression in connection with the instinctual impulse that is being fought against. The main question which our interest raises is as to what happens to the energy, to the libidinal charge, of that excitation - how is it employed? You recollect that the earlier hypothesis was that it is precisely this that is transformed by repression into anxiety. We no longer feel able to say that. The modest reply will rather be that what happens to it is probably not always the same thing. There is probably an intimate correspondence which we ought to get to know about between what is occurring at the time in the ego and in the id in connection with the repressed impulse. For since we have decided that the pleasure-unpleasure principle, which is set in action by the signal of anxiety, plays a part in repression, we must alter our expectations. That principle exercises an entirely unrestricted dominance over what happens in the id. We can rely on its bringing about quite profound changes in the instinctual impulse in question. We are prepared to find that repression will have very various consequences, more or less far-reaching. In some cases the repressed instinctual impulse may retain its libidinal cathexis, and may persist in the id unchanged, although subject to constant pressure from the ego. In other cases what seems to happen is that it is totally destroyed, while its libido is permanently diverted along other paths. I expressed the view that this is what happens when the Oedipus complex is dealt with normally - in this desirable case, therefore, being not simply repressed but destroyed in the id. Clinical experience has further shown us that in many cases, instead of the customary result of repression, a degradation of the libido takes place - a regression of the libidinal organization to an earlier stage. This can, of course, only occur in the id, and if it occurs it will be under the influence of the same conflict which was introduced by the signal of anxiety. The most striking example of this kind is provided by the obsessional neurosis, in which libidinal regression and repression operate together.

[1933a, 4698]
And now, only one more remark on the problem of anxiety. Neurotic anxiety has changed in our hands into realistic anxiety, into fear of particular external situations of danger. But we cannot stop there, we must take another step - though it will be a step backward. We ask ourselves what it is that is actually dangerous and actually feared in a situation of danger of this kind. It is plainly not the injury to the subject as judged objectively, for this need be of no significance psychologically, but something brought about by it in the mind. Birth, for instance, our model for an anxiety state, can after all scarcely be regarded on its own account as an injury, although it may involve a danger of injuries. The essential thing about birth, as about every situation of danger, is that it calls up in mental experience a state of highly tense excitation, which is felt as unpleasure and which one is not able to master by discharging it. Let us call a state of this kind, before which the efforts of the pleasure principle break down, a 'traumatic' moment. Then, if we take in succession neurotic anxiety, realistic anxiety and the situation of danger, we arrive at this simple proposition: what is feared, what is the object of the anxiety, is invariably the emergence of a traumatic moment, which cannot be dealt with by the normal rules of the pleasure principle. We understand at once that our endowment with the pleasure principle does not guarantee us against objective injuries but only against a particular injury to our psychical economics. It is a long step from the pleasure principle to the self-preservation instinct; the intentions of the two of them are very far from coinciding from the start. But we see something else besides; perhaps it is the solution we are in search of. Namely, that in all this it is a question of relative quantities. It is only the magnitude of the sum of excitation that turns an impression into a traumatic moment, paralyses the function of the pleasure principle and gives the situation of danger its significance. And if that is how things are, if these puzzles can be solved so prosaically, why should it not be possible for similar traumatic moments to arise in mental life without reference to hypothetical situations of danger - traumatic moments, then, in which anxiety is not aroused as a signal but is generated anew for a fresh reason. Clinical experience declares decidedly that such is in fact the case. It is only the later repressions that exhibit the mechanism we have described, in which anxiety is awakened as a signal of an earlier situation of danger. The first and original repressions arise directly from traumatic moments, when the ego meets with an excessively great libidinal demand; they construct their anxiety afresh, although, it is true, on the model of birth. The same may apply to the generation of anxiety in anxiety neurosis owing to somatic damage to the sexual function. We shall no longer maintain that it is the libido itself that is turned into anxiety in such cases. But I can see no objection to there being a twofold origin of anxiety - one as a direct consequence of the traumatic moment and the other as a signal threatening a repetition of such a moment. [1933a, 4700]
Evening. - Though she appeared to be in high spirits, she greeted me with the exclamation: 'I'm frightened to death; oh, I can hardly tell you, I hate myself!' I learned at last that she had had a visit from Dr. Breuer and that on his appearance she had given a start of alarm. As he noticed it, she had assured him that it was 'only this once'. She felt so very sorry on my account that she should have had to betray this relic of her former nervousness. I have more than once had occasion to notice during these last few days how hard she is on herself, how liable she is to blame herself severely for the least signs of neglect if the towels for the massage are not in their usual place or if the newspaper for me to read when she is asleep is not instantly ready to hand. After the removal of the first and most superficial layer of tormenting recollections, her morally oversensitive personality, with its tendency to self-depreciation, has come into view. Both in her waking state and under hypnosis, I duly told her (what amounted to the old legal tag 'de minimis non curat lex') that there is a whole multitude of indifferent, small things lying between what is good and what is evil - things about which no one need reproach himself. She did not take in my lesson, I fancy, any more than would an ascetic mediaeval monk, who sees the finger of God or a temptation of the Devil in every trivial event of his life and who is incapable of picturing the world even for a brief moment or in its smallest corner as being without reference to himself.

I will now indicate which of the various elements put forward in this theory can be directly demonstrated and which have been filled in by me. What can be directly demonstrated, apart from the end-product of the process - the obsession - is in the first place the source of the affect which is now in a false connection. In all the cases I have analysed it was the subject's sexual life that had given rise to a distressing affect of precisely the same quality as that attaching to his obsession. Theoretically, it is not impossible that this affect should sometimes arise in other fields; I can only report that so far I have not come across any other origin. Moreover, it is easy to see that it is precisely sexual life which brings with it the most copious occasions for the emergence of incompatible ideas.

Anyone who believes in the occurrence of half-intentional self-injury - if I may use a clumsy expression - will be prepared also to assume that in addition to consciously intentional suicide there is such a thing as half-intentional self-destruction (self-destruction with an unconscious intention), capable of making skilful use of a threat to life and of disguising it as a chance mishap. There is no need to think such self-destruction rare. For the trend to self-destruction is present to a certain degree in very many more human beings than those in whom it is carried out; self-injuries are as a rule a compromise between this instinct and the forces that are still working against it, and even where suicide actually results, the inclination to suicide will have been present for a long time before in lesser strength or in the form of an unconscious and suppressed trend.

¹ [Footnote added 1915:] The problem of why the sense of guilt of neurotics is, as Bleuler recently recognized, regularly attached to the memory of some masturbatory activity, usually at puberty, still awaits an exhaustive analytic explanation. [Added 1920:] The most general and most important factor concerned must no doubt be that masturbation represents the executive agency of the whole of infantile sexuality and is, therefore, able to take over the sense of guilt attaching to it.
I should also like to point out that your test may possibly be subject to a complication which does not, by its very nature, arise in psycho-analysis. In your examination you may be led astray by a neurotic who, although he is innocent, reacts as if he were guilty, because a lurking sense of guilt that already exists in him seizures upon the accusation made in the particular instance. You must not regard this possibility as an idle fiction; you have only to think of life in the nursery, where such events can often enough be observed. It some times happens that a child who has been accused of a misdeed strongly denies the charge but at the same time weeps like a detected sinner. You may perhaps think that the child is lying when he asserts his innocence; but this is not necessarily so. It can be that he has in fact not committed the particular crime with which you have charged him but that he has committed one of which you know nothing and of which you are not accusing him. He therefore quite truthfully denies being guilty of the one misdeed, while at the same time betraying his sense of guilt on account of the other. In this respect - as in so many others - the adult neurotic behaves just like a child. Many people are like this, and it is still open to question whether your technique will succeed in distinguishing self-accusing individuals of this kind from those who are really guilty. Finally, one more point. You know that, according to the rules governing criminal proceedings, you may not subject the accused to any procedure which takes him by surprise. He will therefore have been made aware that in this experiment it is a matter for him of not betraying himself. It must then be asked whether one can expect the same reactions when the subject's attention is directed towards the complex as when it is directed away from it, and how far the intention to conceal something may affect modes of reaction in different people.

[1906c, 1897]

Analysis of obsessive actions has already given us some sort of an insight into their causes and into the chain of motives which bring them into effect. We may say that the sufferer from compulsions and prohibitions behaves as if he were dominated by a sense of guilt, of which, however, he knows nothing, so that we must call it an unconscious sense of guilt, in spite of the apparent contradiction in terms. This sense of guilt has its source in certain early mental events, but it is constantly being revived by renewed temptations which arise whenever there is a contemporary provocation. Moreover, it occasions a lurking sense of expectant anxiety, an expectation of misfortune, which is linked, through the idea of punishment, with the internal perception of the temptation. When the ceremonial is first being constructed, the patient is still conscious that he must do this or that lest some ill should befall, and as a rule the nature of the ill that is to be expected is still known to his consciousness. But what is already hidden from him is the connection - which is always demonstrable - between the occasion on which this expectant anxiety arises and the danger which it conjures up. Thus a ceremonial starts as an action for defence or insurance, a protective measure.

[1907b, 1906]
But Hans was not by any means a bad character; he was not even one of those children who at his age still give free play to the propensity towards cruelty and violence which is a constituent of human nature. On the contrary, he had an unusually kind-hearted and affectionate disposition; his father reported that the transformation of aggressive tendencies into feelings of pity took place in him at a very early age. Long before the phobia he had become uneasy when he saw the horses in a merry-go-round being beaten; and he was never unmoved if any one wept in his presence. At one stage in the analysis a piece of suppressed sadism made its appearance in a particular context:¹ but it was suppressed sadism, and we shall presently have to discover from the content what it stood for and what it was meant to replace. And Hans deeply loved the father against whom he cherished these death-wishes; and while his intellect demurred to such a contradiction,² he could not help demonstrating the fact of its existence, by hitting his father and immediately afterwards kissing the place he had hit. We ourselves, too, must guard against making a difficulty of such a contradiction. The emotional life of man is in general made up of pairs of contraries such as these.³ Indeed, if it were not so, repressions and neuroses would perhaps never come about. In the adult these pairs of contrary emotions do not as a rule become simultaneously conscious except at the climaxes of passionate love; at other times they usually go on suppressing each other until one of them succeeds in keeping the other altogether out of sight. But in children they can exist peaceably side by side for quite a considerable time.

[1909b, 2097]

When anyone has, like Leonardo, escaped being intimidated by his father during his earliest childhood, and has in his researches cast away the fetters of authority, it would be in the sharpest contradiction to our expectation if we found that he had remained a believer and had been unable to escape from dogmatic religion. Psycho-analysis has made us familiar with the intimate connection between the father-complex and belief in God; it has shown us that a personal God is, psychologically, nothing other than an exalted father, and it brings us evidence every day of how young people lose their religious beliefs as soon as their father's authority breaks down. Thus we recognize that the roots of the need for religion are in the parental complex; the almighty and just God, and kindly Nature, appear to us as grand sublimations of father and mother, or rather, as revivals and restorations of the young child's ideas of them. Biologically speaking, religiousness is to be traced to the small human child's long-drawn-out helplessness and need of help; and when at a later date he perceives how truly forlorn and weak he is when confronted with the great forces of life, he feels his condition as he did in childhood, and attempts to deny his own despondency by a regressive revival of the forces which protected his infancy. The protection against neurotic illness, which religion vouchsafes to those who believe in it, is easily explained: it removes their parental complex, on which the sense of guilt in individuals as well as in the whole human race depends, and disposes of it, while the unbeliever has to grapple with the problem on his own.

[1910c, 2294]
The strangest characteristic of unconscious (repressed) processes, to which no investigator can become accustomed without the exercise of great self-discipline, is due to their entire disregard of reality-testing; they equate reality of thought with external actuality, and wishes with their fulfilment - with the event - just as happens automatically under the dominance of the ancient pleasure principle. Hence also the difficulty of distinguishing unconscious phantasies from memories which have become unconscious. But one must never allow oneself to be misled into applying the standards of reality to repressed psychical structures, and on that account, perhaps, into undervaluing the importance of phantasies in the formation of symptoms on the ground that they are not actualities, or into tracing a neurotic sense of guilt back to some other source because there is no evidence that any actual crime has been committed. One is bound to employ the currency that is in use in the country one is exploring - in our case a neurotic currency. Suppose, for instance, that one is trying to solve a dream such as this. A man who had once nursed his father through a long and painful mortal illness, told me that in the months following his father's death he had repeatedly dreamt that his father was alive once more and that he was talking to him in his usual way. But he felt it exceedingly painful that his father had really died, only without knowing it. The only way of understanding this apparently nonsensical dream is by adding 'as the dreamer wished' or 'in consequence of his wish' after the words 'that his father had really died', and by further adding 'that he wished it' to the last words. The dream-thought then runs: it was a painful memory for him that he had been obliged to wish for his father's death (as a release) while he was still alive, and how terrible it would have been if his father had had any suspicion of it! What we have here is thus the familiar case of self-reproaches after the loss of someone loved, and in this instance the self-reproach went back to the infantile significance of death-wishes against the father.

In the second place, we cannot help being struck by the fact that a sense of guilt has about it much of the nature of anxiety: we could describe it without any misgivings as 'dread of conscience'. But the anxiety points to unconscious sources. The psychology of the neuroses has taught us that, if wishful impulses are repressed, their libido is transformed into anxiety. And this reminds us that there is something unknown and unconscious in connection with the sense of guilt, namely the reasons for the act of repudiation. The character of anxiety that is inherent in the sense of guilt corresponds to this unknown factor.

Another difficulty might actually be brought forward from psycho-analytic quarters. The earliest moral precepts and restrictions in primitive society have been explained by us as reactions to a deed which gave those who performed it the concept of 'crime'. They felt remorse for the deed and decided that it should never be repeated and that its performance should bring no advantage. This creative sense of guilt still persists among us. We find it operating in an asocial manner in neurotics, and producing new moral precepts and persistent restrictions, as an atonement for crimes that have been committed and as a precaution against the committing of new ones.¹ If, however, we inquire among these neurotics to discover what were the deeds which provoked these reactions, we shall be disappointed. We find no deeds, but only impulses and emotions, set upon evil ends but held back from their achievement. What lie behind the sense of guilt of neurotics are always psychical realities and never factual ones. What characterizes neurotics is that they prefer psychical to factual reality and react just as seriously to thoughts as normal people do to realities.
It is true that psycho-analysis has taken the individual mind as its subject, but in investigating the individual it could not avoid dealing with the emotional basis of the relation of the individual to society. It has found that the social feelings invariably contain an erotic element - an element which, if it is over-emphasized and then repressed, becomes one of the marks of a particular group of mental disorders. Psycho-analysis has recognized that in general the neuroses are asocial in their nature and that they always aim at driving the individual out of society and at replacing the safe monastic seclusion of earlier days by the isolation of illness. The intense feeling of guilt which dominates so many neuroses has been shown to be a social modification of neurotic anxiety.

I am quite prepared to be told again that I have misunderstood the substance and purpose of the Neo-Zurich theory; but I must protest in advance against any contradictions to my view of it that may be found in the publications of that school being laid at my door instead of theirs. I can find no other way of making the whole range of Jung's innovations intelligible to myself and of grasping all their implications. All the changes that Jung has proposed to make in psycho-analysis flow from his intention to eliminate what is objectionable in the family-complexes, so as not to find it again in religion and ethics. For sexual libido an abstract concept has been substituted, of which one may safely say that it remains mystifying and incomprehensible to wise men and fools alike. The Oedipus complex has a merely 'symbolic' meaning: the mother in it means the unattainable, which must be renounced in the interests of civilization; the father who is killed in the Oedipus myth is the 'inner' father, from whom one must set oneself free in order to become independent. Other parts of the material of sexual ideas will no doubt be subjected to similar re-interpretations in the course of time. In the place of a conflict between ego-dystonic erotic trends and the self-preservative ones a conflict appears between the 'life-task' and 'psychical inertia'; the neurotic's sense of guilt corresponds to his self-reproach for not properly fulfilling his 'life-task'. In this way a new religio-ethical system has been created, which, just like the Adlerian system, was bound to re-interpret, distort or jettison the factual findings of analysis. The truth is that these people have picked out a few cultural overtones from the symphony of life and have once more failed to hear the mighty and primordial melody of the instincts.

We should expect the answer to the question about unconscious feelings, emotions and affects to be just as easily given. It is surely of the essence of an emotion that we should be aware of it, i.e. that it should become known to consciousness. Thus the possibility of the attribute of unconsciousness would be completely excluded as far as emotions, feelings and affects are concerned. But in psycho-analytic practice we are accustomed to speak of unconscious love, hate, anger, etc., and find it impossible to avoid even the strange conjunction 'unconscious consciousness of guilt', or a paradoxical 'unconscious anxiety'. Is there more meaning in the use of these terms than there is in speaking of 'unconscious instincts'?  

Analytic work has no difficulty in showing us that it is forces of conscience which forbid the subject to gain the long hoped for advantage from the fortunate change in reality. It is a difficult task, however, to discover the essence and origin of these judging and punishing trends, which so often surprise us by their existence where we do not expect to find them. For the usual reasons I shall not discuss what we know or conjecture on the point in relation to cases of clinical observation, but in relation to figures which great writers have created from the wealth of their knowledge of the mind.
In the obscurity that reigns at present in the theory of the instincts, it would be unwise to reject any idea that promises to throw light on it. We started out from the great opposition between the life and death instincts. Now object-love itself presents us with a second example of a similar polarity - that between love (or other affection) and hate (or aggressiveness). If only we could succeed in relating these two polarities to each other and in deriving one from the other! From the very first we recognized the presence of a sadistic component in the sexual instinct.¹ As we know, it can make itself independent and can, in the form of a perversion, dominate an individual's entire sexual activity. It also emerges as a predominant component instinct in one of the 'pregenital organizations', as I have named them. But how can the sadistic instinct, whose aim it is to injure the object, be derived from Eros, the preserver of life? Is it not plausible to suppose that this sadism is in fact a death instinct which, under the influence of the narcissistic libido, has been forced away from the ego and has consequently only emerged in relation to the object? It now enters the service of the sexual function. During the oral stage of organization of the libido, the act of obtaining erotic mastery over an object coincides with that object's destruction; later, the sadistic instinct separates off, and finally, at the stage of genital primacy, it takes on, for the purposes of reproduction, the function of overpowering the sexual object to the extent necessary for carrying out the sexual act. It might indeed be said that the sadism which has been forced out of the ego has pointed the way for the libidinal components of the sexual instinct, and that these follow after it to the object. Wherever the original sadism has undergone no mitigation or intermixture, we find the familiar ambivalence of love and hate in erotic life.

¹920g, 3755

Here might be the starting-point for fresh investigations. Our consciousness communicates to us feelings from within not only of pleasure and unpleasure but also of a peculiar tension which in its turn can be either pleasurable or unpleasurable. Should the difference between these feelings enable us to distinguish between bound and unbound processes of energy? or is the feeling of tension to be related to the absolute magnitude, or perhaps to the level, of the cathexis, while the pleasure and unpleasure series indicates a change in magnitude of the cathexis within a given unit of time? Another striking fact is that the life instincts have so much more contact with our internal perception - emerging as breakers of the peace and constantly producing tensions whose release is felt as pleasure - while the death instincts seem to do their work unobtrusively. The pleasure principle seems actually to serve the death instincts. It is true that it keeps watch upon stimuli from without, which are regarded as dangers by both kinds of instincts; but it is more especially on guard against increases of stimulation from within, which would make the task of living more difficult. This in turn raises a host of other questions to which we can at present find no answer. We must be patient and await fresh methods and occasions of research. We must be ready, too, to abandon a path that we have followed for a time, if it seems to be leading to no good end. Only believers, who demand that science shall be a substitute for the catechism they have given up, will blame an investigator for developing or even transforming his views. We may take comfort, too, for the slow advances of our scientific knowledge in the words of the poet:

¹920g, 3762
I have lately developed a view of the instincts¹ which I shall here hold to and take as the basis of my further discussions. According to this view we have to distinguish two classes of instincts, one of which, the sexual instincts or Eros, is by far the more conspicuous and accessible to study. It comprises not merely the uninhibited sexual instinct proper and the instinctual impulses of an aim-inhibited or sublimated nature derived from it, but also the self-preservative instinct, which must be assigned to the ego and which at the beginning of our analytic work we had good reason for contrasting with the sexual object-instincts. The second class of instincts was not so easy to point to; in the end we came to recognize sadism as its representative. On the basis of theoretical considerations, supported by biology, we put forward the hypothesis of a death instinct, the task of which is to lead organic life back into the inanimate state; on the other hand, we supposed that Eros, by bringing about a more and more far-reaching combination of the particles into which living substance is dispersed, aims at complicating life and at the same time, of course, at preserving it. Acting in this way, both the instincts would be conservative in the strictest sense of the word, since both would be endeavouring to re-establish a state of things that was disturbed by the emergence of life. The emergence of life would thus be the cause of the continuance of life and also at the same time of the striving towards death; and life itself would be a conflict and compromise between these two trends. The problem of the origin of life would remain a cosmological one; and the problem of the goal and purpose of life would be answered dualistically.

[1923b, 3974]

It will be remembered that we have taken the view that the principle which governs all mental processes is a special case of Fechner's 'tendency towards stability',¹ and have accordingly attributed to the mental apparatus the purpose of reducing to nothing, or at least of keeping as low as possible, the sums of excitation which flow in upon it. Barbara Low has suggested the name of 'Nirvana principle' for this supposed tendency, and we have accepted the term. But we have unhesitatingly identified the pleasure-unpleasure principle with this Nirvana principle. Every unpleasure ought thus to coincide with a heightening, and every pleasure with a lowering, of mental tension due to stimulus; the Nirvana principle (and the pleasure principle which is supposedly identical with it) would be entirely in the service of the death instincts, whose aim is to conduct the restlessness of life into the stability of the inorganic state, and it would have the function of giving warnings against the demands of the life instincts - the libido - which try to disturb the intended course of life. But such a view cannot be correct. It seems that in the series of feelings of tension we have a direct sense of the increase and decrease of amounts of stimulus, and it cannot be doubted that there are pleasurable tensions and unpleasurable relaxations of tension. The state of sexual excitation is the most striking example of a pleasurable increase of stimulus of this sort, but it is certainly not the only one.

[1924c, 4071]
The inadequacy of this explanation is seen, however, in the fact that it throws no light on the regular and close connections of masochism with its counterpart in instinctual life, sadism. If we go back a little further, to our hypothesis of the two classes of instincts which we regard as operative in the living organism, we arrive at another derivation of masochism, which, however, is not in contradiction with the former one. In (multicellular) organisms the libido meets the instinct of death, or destruction, which is dominant in them and which seeks to disintegrate the cellular organism and to conduct each separate unicellular organism into a state of inorganic stability (relative though this may be). The libido has the task of making the destroying instinct innocuous, and it fulfills the task by diverting that instinct to a great extent outwards - soon with the help of a special organic system, the muscular apparatus - towards objects in the external world. The instinct is then called the destructive instinct, the instinct for mastery, or the will to power. A portion of the instinct is placed directly in the service of the sexual function, where it has an important part to play. This is sadism proper. Another portion does not share in this transposition outwards; it remains inside the organism and, with the help of the accompanying sexual excitation described above, becomes libidinally bound there. It is in this portion that we have to recognize the original, erotogenic masochism.

[1924c, 4075]

It is almost humiliating that, after working so long, we should still be having difficulty in understanding the most fundamental facts. But we have made up our minds to simplify nothing and to hide nothing. If we cannot see things clearly we will at least see clearly what the obscurities are. What is hampering us here is evidently some hitch in the development of our theory of the instincts. We began by tracing the organization of the libido through its successive stages - from the oral through the sadistic-anal to the genital - and in doing so placed all the components of the sexual instinct on the same footing. Later it appeared that sadism was the representative of another instinct, which was opposed to Eros. This new view, that the instincts fall into two groups, seems to explode the earlier construction of the successive stages of libidinal organization. But we do not have to break fresh ground in order to find a way out of the difficulty. The solution has been at hand for a long time and lies in the fact that what we are concerned with are scarcely ever pure instinctual impulses but mixtures in various proportions of the two groups of instincts. If this is so, there is no need to revise our view of the organizations of the libido. A sadistic cathexis of an object may also legitimately claim to be treated as a libidinal one; and an aggressive impulse against the father can just as well be subjected to repression as a tender impulse towards the mother. Nevertheless we shall bear in mind for future consideration the possibility that repression is a process which has a special relation to the genital organization of the libido and that the ego resorts to other methods of defence when it has to secure itself against the libido on other levels of organization. To continue: a case like 'Little Hans's' does not enable us to come to any clear conclusion. It is true that in him an aggressive impulse was disposed of by repression, but this happened after the genital organization had been reached.

[1926d, 4282]
From the first of these standpoints, the **dynamic** one, psycho-analysis derives all mental processes (apart from the reception of external stimuli) from the interplay of forces, which assist or inhibit one another, combine with one another, enter into compromises with one another, etc. All of these forces are originally in the nature of **instincts**; thus they have an organic origin. They are characterized by possessing an immense (somatic) store of power ("the compulsion to repeat"); and they are represented mentally as images or ideas with an affective charge. In psycho-analysis, no less than in other sciences, the theory of the instincts is an obscure subject. An empirical analysis leads to the formulation of two groups of instincts: the so-called 'ego-instincts', which are directed towards self-preservation, and the 'object-instincts', which are concerned with relations to an external object. The social instincts are not regarded as elementary or irreducible. Theoretical speculation leads to the suspicion that there are two fundamental instincts which lie concealed behind the manifest ego-instincts and object-instincts: namely (a) Eros, the instinct which strives for ever closer union, and (b) the instinct of destruction, which leads towards the dissolution of what is living. In psycho-analysis the manifestation of the force of Eros is given the name 'libido'.

[1926f, 4403]

For, whether a man is a homosexual or a necrophilic, a hysteric suffering from anxiety, an obsessional neurotic cut off from society, or a raving lunatic, the 'Individual Psychologist' of the Adlerian school will declare that the impelling motive of his condition is that he wishes to assert himself, to overcompensate for his inferiority, to remain 'on top', to pass from the feminine to the masculine line. In my young student days we used to hear something very much the same in the out-patients' department when a case of hysteria was introduced: hysterical patients, we were told, produce their symptoms to make themselves interesting, to draw attention to themselves. It is a remarkable thing how these ancient pieces of wisdom keep on cropping up. But even at that time this fragment of psychology did not seem to cover the riddle of hysteria. It left unexplained, for instance, why the patients used no other methods for attaining their purpose. There must, of course, be something correct in this theory of the 'Individual Psychologists': a small particle is taken for the whole. The self-preservative instinct will try to profit by every situation; the ego will seek to turn even illness to its advantage. In psycho-analysis this is known as the 'secondary gain from illness'. Though, indeed, when we think of the facts of masochism, of the unconscious need for punishment and of neurotic self-injury, which make plausible the hypothesis of there being instinctual impulses that run contrary to self-preservation, we even feel shaken in our belief in the general validity of the commonplace truth on which the theoretical structure of Individual Psychology is erected. But a theory such as this is bound to be very welcome to the great mass of the people, a theory which recognizes no complications, which introduces no new concepts that are hard to grasp, which knows nothing of the unconscious, which gets rid at a single blow of the universally oppressive problem of sexuality and which restricts itself to the discovery of the artifices by which people seek to make life easy. For the mass of the people themselves take things easily: they call for no more than a single reason by way of explanation, they do not thank science for its diffuseness, they want to have simple solutions and to know that problems are solved. When we consider how very far Individual Psychology goes in meeting these demands, we cannot suppress the recollection of a sentence in *Wallenstein*:

[1933a, 4743]

¹ The question arises whether the satisfaction of purely destructive instinctual impulses can be felt as pleasure, whether pure destructiveness without any libidinal admixture occurs. Satisfaction of the death instinct remaining in the ego seems not to produce feelings of pleasure, though masochism represents a fusion which is entirely analogous to sadism.

[1940a [1938], 4965]
This hypothesis throws no light whatever upon the manner in which the two classes of instincts are fused, blended, and alloyed with each other; but that this takes place regularly and very extensively is an assumption indispensable to our conception. It appears that, as a result of the combination of unicellular organisms into multicellular forms of life, the death instinct of the single cell can successfully be neutralized and the destructive impulses be diverted on to the external world through the instrumentality of a special organ. This special organ would seem to be the muscular apparatus; and the death instinct would thus seem to express itself - though probably only in part - as an instinct of destruction directed against the external world and other organisms.

[1923b, 3975]

The inadequacy of this explanation is seen, however, in the fact that it throws no light on the regular and close connections of masochism with its counterpart in instinctual life, sadism. If we go back a little further, to our hypothesis of the two classes of instincts which we regard as operative in the living organism, we arrive at another derivation of masochism, which, however, is not in contradiction with the former one. In (multicellular) organisms the libido meets the instinct of death, or destruction, which is dominant in them and which seeks to disintegrate the cellular organism and to conduct each separate unicellular organism into a state of inorganic stability (relative though this may be). The libido has the task of making the destroying instinct innocuous, and it fulfils the task by diverting that instinct to a great extent outwards - soon with the help of a special organic system, the muscular apparatus - towards objects in the external world. The instinct is then called the destructive instinct, the instinct for mastery, or the will to power. A portion of the instinct is placed directly in the service of the sexual function, where it has an important part to play. This is sadism proper. Another portion does not share in this transposition outwards; it remains inside the organism and, with the help of the accompanying sexual excitation described above, becomes libidinally bound there. It is in this portion that we have to recognize the original, erotogenic masochism.

[1924c, 4075]

The third form of masochism, moral masochism, is chiefly remarkable for having loosened its connection with what we recognize as sexuality. All other masochistic sufferings carry with them the condition that they shall emanate from the loved person and shall be endured at his command. This restriction has been dropped in moral masochism. The suffering itself is what matters; whether it is decreed by someone who is loved or by someone who is indifferent is of no importance. It may even be caused by impersonal powers or by circumstances; the true masochist always turns his cheek whenever he has a chance of receiving a blow. It is very tempting, in explaining this attitude, to leave the libido out of account and to confine oneself to assuming that in this case the destructive instinct has been turned inwards again and is now raging against the self; yet there must be some meaning in the fact that linguistic usage has not given up the connection between this norm of behaviour and erotism and calls these self-injurers masochists too.

[1924c, 4077]
It is almost humiliating that, after working so long, we should still be having difficulty in understanding the most fundamental facts. But we have made up our minds to simplify nothing and to hide nothing. If we cannot see things clearly we will at least see clearly what the obscurities are. What is hampering us here is evidently some hitch in the development of our theory of the instincts. We began by tracing the organization of the libido through its successive stages - from the oral through the sadistic-anal to the genital - and in doing so placed all the components of the sexual instinct on the same footing. Later it appeared that sadism was the representative of another instinct, which was opposed to Eros. This new view, that the instincts fall into two groups, seems to explode the earlier construction of the successive stages of libidinal organization. But we do not have to break fresh ground in order to find a way out of the difficulty. The solution has been at hand for a long time and lies in the fact that what we are concerned with are scarcely ever pure instinctual impulses but mixtures in various proportions of the two groups of instincts. If this is so, there is no need to revise our view of the organizations of the libido. A sadistic cathexis of an object may also legitimately claim to be treated as a libidinal one; and an aggressive impulse against the father can just as well be subjected to repression as a tender impulse towards the mother. Nevertheless we shall bear in mind for future consideration the possibility that repression is a process which has a special relation to the genital organization of the libido and that the ego resorts to other methods of defence when it has to secure itself against the libido on other levels of organization. To continue: a case like 'Little Hans's' does not enable us to come to any clear conclusion. It is true that in him an aggressive impulse was disposed of by repression, but this happened after the genital organization had been reached.

² The view expressed above is supported by the following considerations. Man is an animal organism with (like others) an unmistakably bisexual disposition. The individual corresponds to a fusion of two symmetrical halves, of which, according to some investigators, one is purely male and the other female. It is equally possible that each half was originally hermaphrodite. Sex is a biological fact which, although it is of extraordinary importance in mental life, is hard to grasp psychologically. We are accustomed to say that every human being displays both male and female instinctual impulses, needs and attributes; but though anatomy, it is true, can point out the characteristic of maleness and femaleness, psychology cannot. For psychology the contrast between the sexes fades away into one between activity and passivity, in which we far too readily identify activity with maleness and passivity with femaleness, a view which is by no means universally confirmed in the animal kingdom. The theory of bisexuality is still surrounded by many obscurities and we cannot but feel it as a serious impediment in psycho-analysis that it has not yet found any link with the theory of the instincts. However this may be, if we assume it as a fact that each individual seeks to satisfy both male and female wishes in his sexual life, we are prepared for the possibility that those demands are not fulfilled by the same object, and that they interfere with each other unless they can be kept apart and each impulse guided into a particular channel that is suited to it. Another difficulty arises from the circumstance that there is so often associated with the erotic relationship, over and above its own sadistic components, a quota of plain inclination to aggression. The love-object will not always view these complications with the degree of understanding and tolerance shown by the peasant woman who complained that her husband did not love her any more, since he had not beaten her for a week.
Every analyst will admit that even to-day this view has not the sound of a long-discarded error. Nevertheless, alterations in it became essential, as our enquiries advanced from the repressed to the repressing forces, from the object-instincts to the ego. The decisive step forward was the introduction of the concept of narcissism - that is to say, the discovery that the ego itself is cathected with libido, that the ego, indeed, is the libido's original home, and remains to some extent its headquarters. This narcissistic libido turns towards objects, and thus becomes object-libido; and it can change back into narcissistic libido once more. The concept of narcissism made it possible to obtain an analytic understanding of the traumatic neuroses and of many of the affections bordering on the psychoses, as well as of the latter themselves. It was not necessary to give up our interpretation of the transference neuroses as attempts made by the ego to defend itself against sexuality; but the concept of libido was endangered. Since the ego-instincts, too, were libidinal, it seemed for a time inevitable that we should make libido coincide with instinctual energy in general, as C. G. Jung had already advocated earlier. Nevertheless, there still remained in me a kind of conviction, for which I was not as yet able to find reasons, that the instincts could not all be of the same kind. My next step was taken in Beyond the Pleasure Principle (1920g), when the compulsion to repeat and the conservative character of instinctual life first attracted my attention. Starting from speculations on the beginning of life and from biological parallels, I drew the conclusion that, besides the instinct to preserve living substance and to join it into ever larger units,¹ there must exist another, contrary instinct seeking to dissolve those units and to bring them back to their primaeval, inorganic state. That is to say, as well as Eros there was an instinct of death. The phenomena of life could be explained from the concurrent or mutually opposing action of these two instincts. It was not easy, however, to demonstrate the activities of this supposed death instinct. The manifestations of Eros were conspicuous and noisy enough. It might be assumed that the death instinct operated silently within the organism towards its dissolution, but that, of course, was no proof. A more fruitful idea was that a portion of the instinct is diverted towards the external world and comes to light as an instinct of aggressiveness and destructiveness. In this way the instinct itself could be pressed into the service of Eros, in that the organism was destroying some other thing, whether animate or inanimate, instead of destroying its own self. Conversely, any restriction of this aggressiveness directed outwards would be bound to increase the self-destruction, which is in any case proceeding. At the same time one can suspect from this example that the two kinds of instinct seldom - perhaps never - appear in isolation from each other, but are alloyed with each other in varying and very different proportions and so become unrecognizable to our judgement. In sadism, long since known to us as a component instinct of sexuality, we should have before us a particularly strong alloy of this kind between trends of love and the destructive instinct; while its counterpart, masochism, would be a union between destructiveness directed inwards and sexuality - a union which makes what is otherwise an imperceptible trend into a conspicuous and tangible one.

¹ Our present point of view can be roughly expressed in the statement that libido has a share in every instinctual manifestation, but that not everything in that manifestation is libido.

[1930a, 4509]
This is, I think, the place at which to put forward for serious consideration a view which I have earlier recommended for provisional acceptance. In the most recent analytic literature a predilection is shown for the idea that any kind of frustration, any thwarted instinctual satisfaction, results, or may result, in a heightening of the sense of guilt.¹ A great theoretical simplification will, I think, be achieved if we regard this as applying only to the aggressive instincts, and little will be found to contradict this assumption. For how are we to account, on dynamic and economic grounds, for an increase in the sense of guilt appearing in place of an unfulfilled erotic demand? This only seems possible in a round-about way - if we suppose, that is, that the prevention of an erotic satisfaction calls up a piece of aggressiveness against the person who has interfered with the satisfaction, and that this aggressiveness has itself to be suppressed in turn. But if this is so, it is after all only the aggressiveness which is transformed into a sense of guilt, by being suppressed and made over to the super-ego. I am convinced that many processes will admit of a simpler and clearer exposition if the findings of psycho-analysis with regard to the derivation of the sense of guilt are restricted to the aggressive instincts.

Examination of the clinical material gives us no unequivocal answer here, because, as our hypothesis tells us, the two classes of instinct hardly ever appear in a pure form, isolated from each other; but an investigation of extreme cases would probably point in the direction I anticipate.

[1930a, 4526]

It is our opinion, then, that in sadism and in masochism we have before us two excellent examples of a mixture of the two classes of instinct, of Eros and aggressiveness; and we proceed to the hypothesis that this relation is a model one - that every instinctual impulse that we can examine consists of similar fusions or alloys of the two classes of instinct. These fusions, of course, would be in the most varied ratios. Thus the erotic instincts would introduce the multiplicity of their sexual aims into the fusion, while the others would only admit of mitigations or gradations in their monotonous trend. This hypothesis opens a prospect to us of investigations which may some day be of great importance for the understanding of pathological processes. For fusions may also come apart, and we may expect that functioning will be most gravely affected by defusions of such a kind. But these conceptions are still too new; no one has yet tried to apply them in our work.

[1933a, 4708]
And here, at an unexpected point, we have emerged from the psychical underworld into the open market-place. I cannot lead you any further, but before I take leave of you for to-day I must detain you with one more train of thought. It has become our habit to say that our civilization has been built up at the cost of sexual trends which, being inhibited by society, are partly, it is true, repressed but have partly been made usable for other aims. We have admitted, too, that, in spite of all our pride in our cultural attainments, it is not easy for us to fulfill the requirements of this civilization or to feel comfortable in it, because the instinctual restrictions imposed on us constitute a heavy psychical burden. Well, what we have come to see about the sexual instincts, applies equally and perhaps still more to the other ones, the aggressive instincts. It is they above all that make human communal life difficult and threaten its survival. Restriction of the individual's aggressiveness is the first and perhaps the severest sacrifice which society requires of him. We have learnt the ingenious way in which the taming of this unruly thing has been achieved. The institution of the super-ego which takes over the dangerous aggressive impulses, introduces a garrison, as it were, into regions that are inclined to rebellion. But on the other hand, if we look at it purely psychologically, we must recognize that the ego does not feel happy in being thus sacrificed to the needs of society, in having to submit to the destructive trends of aggressiveness which it would have been glad to employ itself against others. It is like a prolongation in the mental sphere of the dilemma of 'eat or be eaten' which dominates the organic animate world. Luckily the aggressive instincts are never alone but always alloyed with the erotic ones. These latter have much to mitigate and much to avert under the conditions of the civilization which mankind has created.

[1933a, 4714]

An abundant source of a child's hostility to its mother is provided by its multifarious sexual wishes, which alter according to the phase of the libido and which cannot for the most part be satisfied. The strongest of these frustrations occur at the phallic period, if the mother forbids pleasurable activity with the genitals - often with severe threats and every sign of displeasure - activity to which, after all, she herself had introduced the child. One would think these were reasons enough to account for a girl's turning away from her mother. One would judge, if so, that the estrangement follows inevitably from the nature of children's sexuality, from the immoderate character of their demand for love and the impossibility of fulfilling their sexual wishes. It might be thought indeed that this first love-relation of the child's is doomed to dissolution for the very reason that it is the first, for these early object-cathexes are regularly ambivalent to a high degree. A powerful tendency to aggressiveness is always present beside a powerful love, and the more passionately a child loves its object the more sensitive does it become to disappointments and frustrations from that object; and in the end the love must succumb to the accumulated hostility. Or the idea that there is an original ambivalence such as this in erotic cathexes may be rejected, and it may be pointed out that it is the special nature of the mother-child relation that leads, with equal inevitability, to the destruction of the child's love; for even the mildest upbringing cannot avoid using compulsion and introducing restrictions, and any such intervention in the child's liberty must provoke as a reaction an inclination to rebelliousness and aggressiveness. A discussion of these possibilities might, I think, be most interesting; but an objection suddenly emerges which forces our interest in another direction. All these factors - the slights, the disappointments in love, the jealousy, the seduction followed by prohibition - are, after all, also in operation in the relation of a boy to his mother and are yet unable to alienate him from the maternal object. Unless we can find something that is specific for girls and is not present or not in the same way present in boys, we shall not have explained the termination of the attachment of girls to their mother.

[1933a, 4726]
According to our hypothesis human instincts are of only two kinds: those which seek to preserve and unite - which we call 'erotic', exactly in the sense in which Plato uses the word 'Eros' in his *Symposium*, or 'sexual', with a deliberate extension of the popular conception of 'sexuality' - and those which seek to destroy and kill and which we group together as the aggressive or destructive instinct. As you see, this is in fact no more than a theoretical clarification of the universally familiar opposition between Love and Hate which may perhaps have some fundamental relation to the polarity of attraction and repulsion that plays a part in your own field of knowledge. But we must not be too hasty in introducing ethical judgements of good and evil. Neither of these instincts is any less essential than the other; the phenomena of life arise from the concurrent or mutually opposing action of both. Now it seems as though an instinct of the one sort can scarcely ever operate in isolation; it is always accompanied - or, as we say, alloyed - with a certain quota from the other side, which modifies its aim or is, in some cases, what enables it to achieve that aim. Thus, for instance, the instinct of self-preservation is certainly of an erotic kind, but it must nevertheless have aggressiveness at its disposal if it is to fulfil its purpose. So, too, the instinct of love, when it is directed towards an object, stands in need of some contribution from the instinct for mastery if it is in any way to obtain possession of that object. The difficulty of isolating the two classes of instinct in their actual manifestations is indeed what has so long prevented us from recognizing them.

[1933b, 4798]

If you will follow me a little further, you will see that human actions are subject to another complication of a different kind. It is very rarely that an action is the work of a single instinctual impulse (which must in itself be compounded of Eros and destructiveness). In order to make an action possible there must be as a rule a combination of such compounded motives. This was perceived long ago by a specialist in your own subject, a Professor G. C. Lichtenberg who taught physics at Göttingen during our classical age - though perhaps he was even more remarkable as a psychologist than as a physicist. He invented a Compass of Motives, for he wrote: 'The motives that lead us to do anything might be arranged like the thirty-two winds and might be given names in a similar way: for instance, "bread-bread-fame" or "fame-fame-bread".' So that when human beings are incited to war they may have a whole number of motives for assenting - some noble and some base, some which are openly declared and others which are never mentioned. There is no need to enumerate them all. A lust for aggression and destruction is certainly among them: the countless cruelties in history and in our everyday lives vouch for its existence and its strength. The satisfaction of these destructive impulses is of course facilitated by their admixture with others of an erotic and idealistic kind. When we read of the atrocities of the past, it sometimes seems as though the idealistic motives served only as an excuse for the destructive appetites; and sometimes - in the case, for instance, of the cruelties of the Inquisition - it seems as though the idealistic motives had pushed themselves forward in consciousness, while the destructive ones lent them an unconscious reinforcement. Both may be true.

[1933b, 4799]
As regards the other point - the specific instinctual factor - we come upon an interesting discrepancy between theory and experience. Theoretically there is no objection to supposing that any sort of instinctual demand might occasion the same repressions and their consequences; but our observation shows us invariably, so far as we can judge, that the excitations that play this pathogenic part arise from the component instincts of sexual life. The symptoms of neuroses are, it might be said, without exception either a substitutive satisfaction of some sexual urge or measures to prevent such a satisfaction; and as a rule they are compromises between the two, of the kind that come about in accordance with the laws operating between contraries in the unconscious. The gap in our theory cannot at present be filled; our decision is made more difficult by the fact that most of the urges of sexual life are not of a purely erotic nature but have arisen from alloys of the erotic instinct with portions of the destructive instinct. But it cannot be doubted that the instincts which manifest themselves physiologically as sexuality play a prominent, unexpectedly large part in the causation of the neuroses - whether it is an exclusive one remains to be decided. It must also be borne in mind that in the course of cultural development no other function has been so energetically and extensively repudiated as precisely the sexual one. Theory must rest satisfied with a few hints that betray a deeper connection: the fact that the first period of childhood, during which the ego begins to be differentiated from the id, is also the period of the early sexual efflorescence which is brought to an end by the period of latency; that it can hardly be a matter of chance that this momentous early period subsequently falls a victim to infantile amnesia; and lastly, that biological changes in sexual life (such as the function's diphasic onset which we have already mentioned, the disappearance of the periodic character of sexual excitation and the transformation in the relation between female menstruation and male excitation) - that these innovations in sexuality must have been of high importance in the evolution of animals into man. It is left for the science of the future to bring these still isolated data together into a new understanding. It is not in psychology but in biology that there is a gap here. We shall not be wrong, perhaps, in saying that the weak point in the ego's organization seems to lie in its attitude to the sexual function, as though the biological antithesis between self-preservation and the preservation of the species had found a psychological expression at that point.

[1940a [1938], 4994]
Similarly, the term masochism comprises any passive attitude towards sexual life and the sexual object, the extreme instance of which appears to be that in which satisfaction is conditional upon suffering physical or mental pain at the hands of the sexual object. Masochism, in the form of a perversion, seems to be further removed from the normal sexual aim than its counterpart; it may be doubted at first whether it can ever occur as a primary phenomenon or whether, on the contrary, it may not invariably arise from a transformation of sadism.¹ It can often be shown that masochism is nothing more than an extension of sadism turned round upon the subject's own self, which thus, to begin with, takes the place of the sexual object. Clinical analysis of extreme cases of masochistic perversions show that a great number of factors (such as the castration complex and the sense of guilt) have combined to exaggerate and fixate the original passive sexual attitude.

[1905d, 1484]

(c) An especially prominent part is played as factors in the formation of symptoms in psychoneuroses by the component instincts, which emerge for the most part as pairs of opposites and which we have met with as introducing new sexual aims - the scopophilic instinct and exhibitionism and the active and passive forms of the instinct for cruelty. The contribution made by the last of these is essential to the understanding of the fact that symptoms involve suffering, and it almost invariably dominates a part of the patient's social behaviour. It is also through the medium of this connection between libido and cruelty that the transformation of love into hate takes place, the transformation of affectionate into hostile impulses, which is characteristic of a great number of cases of neurosis, and indeed, it would seem, of paranoia in general.

[1905d, 1491]

I should also like to point out that your test may possibly be subject to a complication which does not, by its very nature, arise in psycho-analysis. In your examination you may be led astray by a neurotic who, although he is innocent, reacts as if he were guilty, because a lurking sense of guilt that already exists in him seizes upon the accusation made in the particular instance. You must not regard this possibility as an idle fiction; you have only to think of life in the nursery, where such events can often enough be observed. It sometimes happens that a child who has been accused of a misdeed strongly denies the charge but at the same time weeps like a detected sinner. You may perhaps think that the child is lying when he asserts his innocence; but this is not necessarily so. It can be that he has in fact not committed the particular crime with which you have charged him but that he has committed one of which you know nothing and of which you are not accusing him. He therefore quite truthfully denies being guilty of the one misdeed, while at the same time betraying his sense of guilt on account of the other. In this respect - as in so many others - the adult neurotic behaves just like a child. Many people are like this, and it is still open to question whether your technique will succeed in distinguishing self-accusing individuals of this kind from those who are really guilty. Finally, one more point. You know that, according to the rules governing criminal proceedings, you may not subject the accused to any procedure which takes him by surprise. He will therefore have been made aware that in this experiment it is a matter for him of not betraying himself. It must then be asked whether one can expect the same reactions when the subject's attention is directed towards the complex as when it is directed away from it, and how far the intention to conceal something may affect modes of reaction in different people.

[1906c, 1897]
Analysis of obsessive actions has already given us some sort of an insight into their causes and into the chain of motives which bring them into effect. We may say that the sufferer from compulsions and prohibitions behaves as if he were dominated by a sense of guilt, of which, however, he knows nothing, so that we must call it an unconscious sense of guilt, in spite of the apparent contradiction in terms. This sense of guilt has its source in certain early mental events, but it is constantly being revived by renewed temptations which arise whenever there is a contemporary provocation. Moreover, it occasions a lurking sense of expectant anxiety, an expectation of misfortune, which is linked, through the idea of punishment, with the internal perception of the temptation. When the ceremonial is first being constructed, the patient is still conscious that he must do this or that lest some ill should befall, and as a rule the nature of the ill that is to be expected is still known to his consciousness. But what is already hidden from him is the connection - which is always demonstrable - between the occasion on which this expectant anxiety arises and the danger which it conjures up. Thus a ceremonial starts as an action for defence or insurance, a protective measure.

At the next session, which was the seventh, he took up the same subject once more. He could not believe, he said, that he had ever entertained such a wish against his father. He remembered a story of Sudermann's, he went on, that had made a deep impression upon him. In this story there was a woman who, as she sat by her sister's sick-bed, felt a wish that her sister should die so that she herself might marry her husband. The woman thereupon committed suicide, thinking she was not fit to live after being guilty of such baseness. He could understand this, he said, and it would be only right if his thoughts were the death of him, for he deserved nothing less.¹ - I remarked that it was well known to us that patients derived a certain satisfaction from their sufferings, so that in reality they all resisted their own recovery to some extent. He must never lose sight of the fact that a treatment like ours proceeded to the accompaniment of a constant resistance; I should be repeatedly reminding him of this fact.

When anyone has, like Leonardo, escaped being intimidated by his father during his earliest childhood, and has in his researches cast away the fetters of authority, it would be in the sharpest contradiction to our expectation if we found that he had remained a believer and had been unable to escape from dogmatic religion. Psycho-analysis has made us familiar with the intimate connection between the father-complex and belief in God; it has shown us that a personal God is, psychologically, nothing other than an exalted father, and it brings us evidence every day of how young people lose their religious beliefs as soon as their father's authority breaks down. Thus we recognize that the roots of the need for religion are in the parental complex; the almighty and just God, and kindly Nature, appear to us as grand sublimations of father and mother, or rather, as revivals and restorations of the young child's ideas of them. Biologically speaking, religiousness is to be traced to the small human child's long-drawn-out helplessness and need of help; and when at a later date he perceives how truly forlorn and weak he is when confronted with the great forces of life, he feels his condition as he did in childhood, and attempts to deny his own despondency by a regressive revival of the forces which protected his infancy. The protection against neurotic illness, which religion vouchsafes to those who believe in it, is easily explained: it removes their parental complex, on which the sense of guilt in individuals as well as in the whole human race depends, and disposes of it, while the unbeliever has to grapple with the problem on his own.
It is true that psycho-analysis has taken the individual mind as its subject, but in investigating the individual it could not avoid dealing with the emotional basis of the relation of the individual to society. It has found that the social feelings invariably contain an erotic element - an element which, if it is over-emphasized and then repressed, becomes one of the marks of a particular group of mental disorders. Psycho-analysis has recognized that in general the neuroses are asocial in their nature and that they always aim at driving the individual out of society and at replacing the safe monastic seclusion of earlier days by the isolation of illness. The intense feeling of guilt which dominates so many neuroses has been shown to be a social modification of neurotic anxiety.

[1913], 2824

When I speak of disillusionment, everyone will know at once what I mean. One need not be a sentimentalist; one may perceive the biological and psychological necessity for suffering in the economy of human life, and yet condemn war both in its means and ends and long for the cessation of all wars. We have told ourselves, no doubt, that wars can never cease so long as nations live under such widely differing conditions, so long as the value of individual life is so variously assessed among them, and so long as the animosities which divide them represent such powerful motive forces in the mind. We were prepared to find that wars between the primitive and the civilized peoples, between the races who are divided by the colour of their skin - wars, even, against and among the nationalities of Europe whose civilization is little developed or has been lost - would occupy mankind for some time to come. But we permitted ourselves to have other hopes. We had expected the great world-dominating nations of white race upon whom the leadership of the human species has fallen, who were known to have world-wide interests as their concern, to whose creative powers were due not only our technical advances towards the control of nature but the artistic and scientific standards of civilization - we had expected these peoples to succeed in discovering another way of settling misunderstandings and conflicts of interest. Within each of these nations high norms of moral conduct were laid down for the individual, to which his manner of life was bound to conform if he desired to take part in a civilized community. These ordinances, often too stringent, demanded a great deal of him - much self-restraint, much renunciation of instinctual satisfaction. He was above all forbidden to make use of the immense advantages to be gained by the practice of lying and deception in the competition with his fellow-men. The civilized states regarded these moral standards as the basis of their existence. They took serious steps if anyone ventured to tamper with them, and often declared it improper even to subject them to examination by a critical intelligence. It was to be assumed, therefore, that the state itself would respect them, and would not think of undertaking anything against them which would contradict the basis of its own existence. Observation showed, to be sure, that embedded in these civilized states there were remnants of certain other peoples, which were universally unpopular and had therefore been only reluctantly, and even so not fully, admitted to participation in the common work of civilization, for which they had shown themselves suitable enough. But the great nations themselves, it might have been supposed, would have acquired so much comprehension of what they had in common, and so much tolerance for their differences, that 'foreigner' and 'enemy' could no longer be merged, as they still were in classical antiquity, into a single concept.

[1915b, 3068]

So much the more surprising, and indeed bewildering, must it appear when as a doctor one makes the discovery that people occasionally fall ill precisely when a deeply-rooted and long-cherished wish has come to fulfilment. It seems then as though they were not able to tolerate their happiness; for there can be no question that there is a causal connection between their success and their falling ill.

[1916d, 3104]
Analytic work has no difficulty in showing us that it is forces of conscience which forbid the subject to gain the long hoped for advantage from the fortunate change in reality. It is a difficult task, however, to discover the essence and origin of these judging and punishing trends, which so often surprise us by their existence where we do not expect to find them. For the usual reasons I shall not discuss what we know or conjecture on the point in relation to cases of clinical observation, but in relation to figures which great writers have created from the wealth of their knowledge of the mind.

[1916d, 3106]

After this long digression into literature, let us return to clinical experience - but only to establish in a few words the complete agreement between them. Psycho-analytic work teaches that the forces of conscience which induce illness in consequence of success, instead of, as normally, in consequence of frustration, are closely connected with the Oedipus complex, the relation to father and mother - as perhaps, indeed, is our sense of guilt in general.

[1916d, 3117]

But scientific work is not satisfied with the establishment of a curious fact. There are two further questions to answer: what is the origin of this obscure sense of guilt before the deed, and is it probable that this kind of causation plays any considerable part in human crime?

[1916d, 3118]

An examination of the first question held out the promise of bringing us information about the source of mankind's sense of guilt in general. The invariable outcome of analytic work was to show that this obscure sense of guilt derived from the Oedipus complex and was a reaction to the two great criminal intentions of killing the father and having sexual relations with the mother. In comparison with these two, the crimes committed in order to fix the sense of guilt to something came as a relief to the sufferers. We must remember in this connection that parricide and incest with the mother are the two great human crimes, the only ones which, as such, are pursued and abhorred in primitive communities. And we must remember, too, how close other investigations have brought us to the hypothesis that the conscience of mankind, which now appears as an inherited mental force, was acquired in connection with the Oedipus complex.

[1916d, 3118]

If, in the third place, you will recall our idea that the dreamer fighting against his own wishes is to be compared with a summation of two separate, though in some way intimately connected, people, you will understand another possibility. For there is a possibility that the fulfilment of a wish may bring about something very far from pleasant - namely, a punishment. Here we can once more use the fairy tale of the three wishes as an illustration. The fried sausages on a plate were the direct fulfilment of the wish of the first person, the woman, The sausages on her nose were the fulfilment of the wish of the second person, the man, but were at the same time a punishment for the woman's foolish wish. (We shall discover in neuroses the motive for the third wish, the last remaining one in the fairy tale.) There are many such punitive trends in the mental life of human beings; they are very powerful, and we may hold them responsible for some of the distressing dreams. Perhaps you will now say that this leaves very little over of the famous wish-fulfilment. But if you look more closely you will admit that you are wrong. Compared with the multiplicity (which I shall mention later) of the things that dreams might be and according to many authorities actually are, our solution - wish-fulfilment, anxiety-fulfilment, punishment-fulfilment - is a very restricted one. We may add that the anxiety is the direct opposite of the wish, that opposites are especially close to one another in associations and that in the unconscious they coalesce; and further, that the punishment is also the fulfilment of a wish - of the wish of the other, censoring person.

[1916-1917, 3307]
It will have been easy to guess from my account that the patient was a Russian. I parted from him, regarding him as cured, a few weeks before the unexpected outbreak of the Great War; and I did not see him again until the shifting chances of the war had given the Central European Powers access to South Russia. He then came to Vienna and reported that immediately after the end of the treatment he had been seized with a longing to tear himself free from my influence. After a few months' work, a piece of the transference which had not hitherto been overcome was successfully dealt with. Since then the patient has felt normal and has behaved unexceptionably, in spite of the war having robbed him of his home, his possessions, and all his family relationships. It may be that his very misery, by gratifying his sense of guilt, contributed to the consolidation of his recovery.

[1918b, 3596]

As far as I can see, the danger threatens from two directions in especial. On the one hand, when the illness has been broken down by the analysis, the patient makes the most assiduous efforts to create for himself in place of his symptoms new substitutive satisfactions, which now lack the feature of suffering. He makes use of the enormous capacity for displacement possessed by the now partly liberated libido, in order to cathect with libido and promote to the position of substitutive satisfactions the most diverse kinds of activities, preferences and habits, not excluding some that have been his already. He continually finds new distractions of this kind, into which the energy necessary to carrying on the treatment escapes, and he knows how to keep them secret for a time. It is the analyst's task to detect these divergent paths and to require him every time to abandon them, however harmless the activity which leads to satisfaction may be in itself. The half-recovered patient may also enter on less harmless paths - as when, for instance, if he is a man, he seeks prematurely to attach himself to a woman. It may be observed, incidentally, that unhappy marriage and physical infirmity are the two things that most often supersede a neurosis. They satisfy in particular the sense of guilt (need for punishment) which makes many patients cling so fast to their neuroses. By a foolish choice in marriage they punish themselves; they regard a long organic illness as a punishment by fate and thereafter often cease to keep up their neurosis.

[1919a, 3632]

In the obscurity that reigns at present in the theory of the instincts, it would be unwise to reject any idea that promises to throw light on it. We started out from the great opposition between the life and death instincts. Now object-love itself presents us with a second example of a similar polarity - that between love (or other affection) and hate (or aggressiveness). If only we could succeed in relating these two polarities to each other and in deriving one from the other! From the very first we recognized the presence of a sadistic component in the sexual instinct.¹ As we know, it can make itself independent and can, in the form of a perversion, dominate an individual's entire sexual activity. It also emerges as a predominant component instinct in one of the 'pregenital organizations', as I have named them. But how can the sadistic instinct, whose aim it is to injure the object, be derived from Eros, the preserver of life? Is it not plausible to suppose that this sadism is in fact a death instinct which, under the influence of the narcissistic libido, has been forced away from the ego and has consequently only emerged in relation to the object? It now enters the service of the sexual function. During the oral stage of organization of the libido, the act of obtaining erotic mastery over an object coincides with that object's destruction; later, the sadistic instinct separates off, and finally, at the stage of genital primacy, it takes on, for the purposes of reproduction, the function of overpowering the sexual object to the extent necessary for carrying out the sexual act. It might indeed be said that the sadism which has been forced out of the ego has pointed the way for the libidinal components of the sexual instinct, and that these follow after it to the object. Wherever the original sadism has undergone no mitigation or intermixture, we find the familiar ambivalence of love and hate in erotic life.

[1920g, 3755]
If such an assumption as this is permissible, then we have met the demand that we should produce an example of a death instinct - though, it is true, a displaced one. But this way of looking at things is very far from being easy to grasp and creates a positively mystical impression. It looks suspiciously as though we were trying to find a way out of a highly embarrassing situation at any price. We may recall, however, that there is nothing new in an assumption of this kind. We put one forward on an earlier occasion, before there was any question of an embarrassing situation. Clinical observations led us at that time to the view that masochism, the component instinct which is complementary to sadism, must be regarded as sadism that has been turned round upon the subject's own ego.² But there is no difference in principle between an instinct turning from an object to the ego and its turning from the ego to an object - which is the new point now under discussion. Masochism, the turning round of the instinct upon the subject's own ego, would in that case be a return to an earlier phase of the instinct's history, a regression. The account that was formerly given of masochism requires emendation as being too sweeping in one respect: there might be such a thing as primary masochism - a possibility which I had contested at that time.³

The dangerous death instincts are dealt with in the individual in various ways: in part they are rendered harmless by being fused with erotic components, in part they are diverted towards the external world in the form of aggression, while to a large extent they undoubtedly continue their internal work unhindered. How is it then that in melancholia the super-ego can become a kind of gathering-place for the death instincts? [1923b, 3988]

From the point of view of instinctual control, of morality, it may be said of the id that it is totally non-moral, of the ego that it strives to be moral, and of the super-ego that it can be super-moral and then become as cruel as only the id can be. It is remarkable that the more a man checks his aggressiveness towards the exterior the more severe - that is aggressive - he becomes in his ego ideal. The ordinary view sees the situation the other way round: the standard set up by the ego ideal seems to be the motive for the suppression of aggressiveness. The fact remains, however, as we have stated it: the more a man controls his aggressiveness, the more intense becomes his ideal's inclination to aggressiveness against his ego. It is like a displacement, a turning round upon his own ego. But even ordinary normal morality has a harshly restraining, cruelly prohibiting quality. It is from this, indeed, that the conception arises of a higher being who deals out punishment inexorably. [1923b, 3988]

I cannot go further in my consideration of these questions without introducing a fresh hypothesis. The super-ego arises, as we know, from an identification with the father taken as a model. Every such identification is in the nature of a desexualization or even of a sublimation. It now seems as though when a transformation of this kind takes place, an instinctual defusion occurs at the same time. After sublimation the erotic component no longer has the power to bind the whole of the destructiveness that was combined with it, and this is released in the form of an inclination to aggression and destruction. This defusion would be the source of the general character of harshness and cruelty exhibited by the ideal - its dictatorial 'Thou shalt'. [1923b, 3988]
But since the ego's work of sublimation results in a defusion of the instincts and a liberation of the aggressive instincts in the super-ego, its struggle against the libido exposes it to the danger of maltreatment and death. In suffering under the attacks of the super-ego or perhaps even succumbing to them, the ego is meeting with a fate like that of the protista which are destroyed by the products of decomposition that they themselves have created. From the economic point of view the morality that functions in the super-ego seems to be a similar product of decomposition.

[1923b, 3990]

To return to masochism. Masochism comes under our observation in three forms: as a condition imposed on sexual excitation, as an expression of the feminine nature, and as a norm of behaviour. We may, accordingly, distinguish an erotogenic, a feminine and a moral masochism. The first, the erotogenic, masochism - pleasure in pain - lies at the bottom of the other two forms as well. Its basis must be sought along biological and constitutional lines and it remains incomprehensible unless one decides to make certain assumptions about matters that are extremely obscure. The third, and in some respects the most important, form assumed by masochism has only recently been recognized by psycho-analysis as a sense of guilt which is mostly unconscious; but it can already be completely explained and fitted into the rest of our knowledge. Feminine masochism, on the other hand, is the one that is most accessible to our observation and least problematical, and it can be surveyed in all its relations. We will begin our discussion with it.

[1924c, 4073]

The inadequacy of this explanation is seen, however, in the fact that it throws no light on the regular and close connections of masochism with its counterpart in instinctual life, sadism. If we go back a little further, to our hypothesis of the two classes of instincts which we regard as operative in the living organism, we arrive at another derivation of masochism, which, however, is not in contradiction with the former one. In (multicellular) organisms the libido meets the instinct of death, or destruction, which is dominant in them and which seeks to disintegrate the cellular organism and to conduct each separate unicellular organism into a state of inorganic stability (relative though this may be). The libido has the task of making the destroying instinct innocuous, and it fulfils the task by diverting that instinct to a great extent outwards - soon with the help of a special organic system, the muscular apparatus - towards objects in the external world. The instinct is then called the destructive instinct, the instinct for mastery, or the will to power. A portion of the instinct is placed directly in the service of the sexual function, where it has an important part to play. This is sadism proper. Another portion does not share in this transposition outwards; it remains inside the organism and, with the help of the accompanying sexual excitation described above, becomes libidinally bound there. It is in this portion that we have to recognize the original, erotogenic masochism.

[1924c, 4075]

If one is prepared to overlook a little inexactitude, it may be said that the death instinct which is operative in the organism - primal sadism - is identical with masochism. After the main portion of it has been transposed outwards on to objects, there remains inside, as a residuum of it, the erotogenic masochism proper, which on the one hand has become a component of the libido and, on the other, still has the self as its object. This masochism would thus be evidence of, and a remainder from, the phase of development in which the coalescence, which is so important for life, between the death instinct and Eros took place. We shall not be surprised to hear that in certain circumstances the sadism, or instinct of destruction, which has been directed outwards, projected, can be once more introjected, turned inwards, and in this way regress to its earlier situation. If this happens, a secondary masochism is produced, which is added to the original masochism.

[1924c, 4076]
The third form of masochism, moral masochism, is chiefly remarkable for having loosened its connection with what we recognize as sexuality. All other masochistic sufferings carry with them the condition that they shall emanate from the loved person and shall be endured at his command. This restriction has been dropped in moral masochism. The suffering itself is what matters; whether it is decreed by someone who is loved or by someone who is indifferent is of no importance. It may even be caused by impersonal powers or by circumstances; the true masochist always turns his cheek whenever he has a chance of receiving a blow. It is very tempting, in explaining this attitude, to leave the libido out of account and to confine oneself to assuming that in this case the destructive instinct has been turned inwards again and is now raging against the self; yet there must be some meaning in the fact that linguistic usage has not given up the connection between this norm of behaviour and erotism and calls these self-injurers masochists too.

[1924c, 4077]

Let us keep to a habit of our technique and consider first the extreme and unmistakably pathological form of this masochism. I have described elsewhere¹ how in analytic treatment we come across patients to whom, owing to their behaviour towards its therapeutic influence, we are obliged to ascribe an 'unconscious' sense of guilt. I pointed out the sign by which such people can be recognized (a 'negative therapeutic reaction') and I did not conceal the fact that the strength of such an impulse constitutes one of the most serious resistances and the greatest danger to the success of our medical or educative aims. The satisfaction of this unconscious sense of guilt is perhaps the most powerful bastion in the subject's (usually composite) gain from illness - in the sum of forces which struggle against his recovery and refuse to surrender his state of illness. The suffering entailed by neuroses is precisely the factor that makes them valuable to the masochistic trend. It is instructive, too, to find, contrary to all theory and expectation, that a neurosis which has defied every therapeutic effort may vanish if the subject becomes involved in the misery of an unhappy marriage, or loses all his money, or develops a dangerous organic disease. In such instances one form of suffering has been replaced by another; and we see that all that mattered was that it should be possible to maintain a certain amount of suffering.

[1924c, 4078]

Patients do not easily believe us when we tell them about the unconscious sense of guilt. They know only too well by what torments - the pangs of conscience - a conscious sense of guilt, a consciousness of guilt, expresses itself, and they therefore cannot admit that they could harbour exactly analogous impulses in themselves without being in the least aware of them. We may, I think, to some extent meet their objection if we give up the term 'unconscious sense of guilt', which is in any case psychologically incorrect, and speak instead of a 'need for punishment', which covers the observed state of affairs just as aptly. We cannot, however, restrain ourselves from judging and localizing this unconscious sense of guilt in the same way as we do the conscious kind.

[1924c, 4078]
The turning back of sadism against the self regularly occurs where a cultural suppression of the instincts holds back a large part of the subject's destructive instinctual components from being exercised in life. We may suppose that this portion of the destructive instinct which has retreated appears in the ego as an intensification of masochism. The phenomena of conscience, however, lead us to infer that the destructiveness which returns from the external world is also taken up by the super-ego, without any such transformation, and increases its sadism against the ego. The sadism of the super-ego and the masochism of the ego supplement each other and unite to produce the same effects. It is only in this way, I think, that we can understand how the suppression of an instinct can - frequently or quite generally - result in a sense of guilt and how a person's conscience becomes more severe and more sensitive the more he refrains from aggression against others. One might expect that if a man knows that he is in the habit of avoiding the commission of acts of aggression that are undesirable from a cultural standpoint he will for that reason have a good conscience and will watch over his ego less suspiciously. The situation is usually presented as though ethical requirements were the primary thing and the renunciation of instinct followed from them. This leaves the origin of the ethical sense unexplained. Actually, it seems to be the other way about. The first instinctual renunciation is enforced by external powers, and it is only this which creates the ethical sense, which expresses itself in conscience and demands a further renunciation of instinct.

[1924c, 4082]

Thus moral masochism becomes a classical piece of evidence for the existence of fusion of instinct. Its danger lies in the fact that it originates from the death instinct and corresponds to the part of that instinct which has escaped being turned outwards as an instinct of destruction. But since, on the other hand, it has the significance of an erotic component, even the subject's destruction of himself cannot take place without libidinal satisfaction.

[1924c, 4082]

Theodor Reik and G. Róheim, the ethnologist, have taken up the line of thought which I developed in Totem and Taboo and, in a series of important works, have extended it, deepened it, or corrected it. I myself have since returned to it more than once, in the course of my investigations into the 'unconscious sense of guilt' (which also plays such an important part among the motives of neurotic suffering) and in my attempts at forming a closer connection between social psychology and the psychology of the individual.' I have moreover made use of the idea of an archaic heritage from the 'primal horde' epoch of mankind's development in explaining susceptibility to hypnosis.

[1925d, 4241]
When I described the relation between the ego and the id to you, I suppressed an important part of the theory of the mental apparatus. For we have been obliged to assume that within the ego itself a particular agency has become differentiated, which we name the super-ego. This super-ego occupies a special position between the ego and the id. It belongs to the ego and shares its high degree of psychological organization; but it has a particularly intimate connection with the id. It is in fact a precipitate of the first object-cathexes of the id and is the heir to the Oedipus complex after its demise. This super-ego can confront the ego and treat it like an object; and it often treats it very harshly. It is as important for the ego to remain on good terms with the super-ego as with the id. Estrangements between the ego and the super-ego are of great significance in mental life. You will already have guessed that the super-ego is the vehicle of the phenomenon that we call conscience. Mental health very much depends on the super-ego's being normally developed - that is, on its having become sufficiently impersonal. And that is precisely what it is not in neurotics, whose Oedipus complex has not passed through the correct process of transformation. Their super-ego still confronts their ego as a strict father confronts a child; and their morality operates in a primitive fashion in that the ego gets itself punished by the super-ego. Illness is employed as an instrument for this 'self-punishment', and neurotics have to behave as though they were governed by a sense of guilt which, in order to be satisfied, needs to be punished by illness.
[1926e, 4365]
Every analyst will admit that even to-day this view has not the sound of a long-discarded error. Nevertheless, alterations in it became essential, as our enquiries advanced from the repressed to the repressing forces, from the object-instincts to the ego. The decisive step forward was the introduction of the concept of narcissism - that is to say, the discovery that the ego itself is cathected with libido, that the ego, indeed, is the libido's original home, and remains to some extent its headquarters. This narcissistic libido turns towards objects, and thus becomes object-libido; and it can change back into narcissistic libido once more. The concept of narcissism made it possible to obtain an analytic understanding of the traumatic neuroses and of many of the affections bordering on the psychoses, as well as of the latter themselves. It was not necessary to give up our interpretation of the transference neuroses as attempts made by the ego to defend itself against sexuality; but the concept of libido was endangered. Since the ego-instincts, too, were libidinal, it seemed for a time inevitable that we should make libido coincide with instinctual energy in general, as C. G. Jung had already advocated earlier. Nevertheless, there still remained in me a kind of conviction, for which I was not as yet able to find reasons, that the instincts could not all be of the same kind. My next step was taken in Beyond the Pleasure Principle (1920g), when the compulsion to repeat and the conservative character of instinctual life first attracted my attention. Starting from speculations on the beginning of life and from biological parallels, I drew the conclusion that, besides the instinct to preserve living substance and to join it into ever larger units,¹ there must exist another, contrary instinct seeking to dissolve those units and to bring them back to their primaeval, inorganic state. That is to say, as well as Eros there was an instinct of death. The phenomena of life could be explained from the concurrent or mutually opposing action of these two instincts. It was not easy, however, to demonstrate the activities of this supposed death instinct. The manifestations of Eros were conspicuous and noisy enough. It might be assumed that the death instinct operated silently within the organism towards its dissolution, but that, of course, was no proof. A more fruitful idea was that a portion of the instinct is diverted towards the external world and comes to light as an instinct of aggressiveness and destructiveness. In this way the instinct itself could be pressed into the service of Eros, in that the organism was destroying some other thing, whether animate or inanimate, instead of destroying its own self. Conversely, any restriction of this aggressiveness directed outwards would be bound to increase the self-destruction, which is in any case proceeding. At the same time one can suspect from this example that the two kinds of instinct seldom - perhaps never - appear in isolation from each other, but are alloyed with each other in varying and very different proportions and so become unrecognizable to our judgement. In sadism, long since known to us as a component instinct of sexuality, we should have before us a particularly strong alloy of this kind between trends of love and the destructive instinct; while its counterpart, masochism, would be a union between destructiveness directed inwards and sexuality - a union which makes what is otherwise an imperceptible trend into a conspicuous and tangible one.

[1930a, 4509]
Another question concerns us more nearly. What means does civilization employ in order to inhibit the aggressiveness which opposes it, to make it harmless, to get rid of it, perhaps? We have already become acquainted with a few of these methods, but not yet with the one that appears to be the most important. This we can study in the history of the development of the individual. What happens in him to render his desire for aggression innocuous? Something very remarkable, which we should never have guessed and which is nevertheless quite obvious. His aggressiveness is introjected, internalized; it is, in point of fact, sent back to where it came from - that is, it is directed towards his own ego. There it is taken over by a portion of the ego, which sets itself over against the rest of the ego as super-ego, and which now, in the form of 'conscience', is ready to put into action against the ego the same harsh aggressiveness that the ego would have liked to satisfy upon other, extraneous individuals. The tension between the harsh super-ego and the ego that is subjected to it, is called by us the sense of guilt; it expresses itself as a need for punishment. Civilization, therefore, obtains mastery over the individual's dangerous desire for aggression by weakening and disarming it and by setting up an agency within him to watch over it, like a garrison in a conquered city.

[1930a, 4513]

As to the origin of the sense of guilt, the analyst has different views from other psychologists; but even he does not find it easy to give an account of it. To begin with, if we ask how a person comes to have a sense of guilt, we arrive at an answer which cannot be disputed: a person feels guilty (devout people would say 'sinful') when he has done something which he knows to be 'bad'. But then we notice how little this answer tells us. Perhaps, after some hesitation, we shall add that even when a person has not actually done the bad thing but has only recognized in himself an intention to do it, he may regard himself as guilty; and the question then arises of why the intention is regarded as equal to the deed. Both cases, however, presuppose that one had already recognized that what is bad is reprehensible, is something that must not be carried out. How is this judgement arrived at? We may reject the existence of an original, as it were natural, capacity to distinguish good from bad. What is bad is often not at all what is injurious or dangerous to the ego; on the contrary, it may be something which is desirable and enjoyable to the ego. Here, therefore, there is an extraneous influence at work, and it is this that decides what is to be called good or bad. Since a person's own feelings would not have led him along this path, he must have had a motive for submitting to this extraneous influence. Such a motive is easily discovered in his helplessness and his dependence on other people, and it can best be designated as fear of loss of love. If he loses the love of another person upon whom he is dependent, he also ceases to be protected from a variety of dangers. Above all, he is exposed to the danger that this stronger person will show his superiority in the form of punishment. At the beginning, therefore, what is bad is whatever causes one to be threatened with loss of love. For fear of that loss, one must avoid it. This, too, is the reason why it makes little difference whether one has already done the bad thing or only intends to do it. In either case the danger only sets in if and when the authority discovers it, and in either case the authority would behave in the same way.

[1930a, 4514]
At this second stage of development, the conscience exhibits a peculiarity which was absent from the first stage and which is no longer easy to account for. For the more virtuous a man is, the more severe and distrustful is its behaviour, so that ultimately it is precisely those people who have carried saintliness furthest who reproach themselves with the worst sinfulness. This means that virtue forfeits some part of its promised reward; the docile and continent ego does not enjoy the trust of its mentor, and strives in vain, it would seem, to acquire it. The objection will at once be made that these difficulties are artificial ones, and it will be said that a stricter and more vigilant conscience is precisely the hallmark of a moral man. Moreover, when saints call themselves sinners, they are not so wrong, considering the temptations to instinctual satisfaction to which they are exposed in a specially high degree - since, as is well known, temptations are merely increased by constant frustration, whereas an occasional satisfaction of them causes them to diminish, at least for the time being. The field of ethics, which is so full of problems, presents us with another fact: namely that ill-luck - that is, external frustration - so greatly enhances the power of the conscience in the super-ego. As long as things to well with a man, his conscience is lenient and lets the ego do all sorts of things; but when misfortune befalls him, he searches his soul, acknowledges his sinfulness, heightens the demands of his conscience, imposes abstinences on himself and punishes himself with penances.¹ Whole peoples have behaved in this way, and still do. This, however, is easily explained by the original infantile stage of conscience, which, as we see, is not given up after the introjection into the super-ego, but persists alongside of it and behind it. Fate is regarded as a substitute for the parental agency. If a man is unfortunate it means that he is no longer loved by this highest power; and, threatened by such a loss of love, he once more bows to the parental representative in his super-ego - a representative whom, in his days of good fortune, he was ready to neglect. This becomes especially clear where Fate is looked upon in the strictly religious sense of being nothing else than an expression of the Divine Will. The people of Israel had believed themselves to be the favourite child of God, and when the great Father caused misfortune after misfortune to rain down upon this people of his, they were never shaken in their belief in his relationship to them or questioned his power or righteousness. Instead, they produced the prophets, who held up their sinfulness before them; and out of their sense of guilt they created the over-strict commandments of their priestly religion. It is remarkable how differently a primitive man behaves. If he has met with a misfortune, he does not throw the blame on himself but on his fetish, which has obviously not done its duty, and he gives it a thrashing instead of punishing himself.

¹[1930a, 4516]
These interrelations are so complicated and at the same time so important that, at the risk of repeating myself, I shall approach them from yet another angle. The chronological sequence, then, would be as follows. First comes renunciation of instinct owing to fear of aggression by the external authority. (This is, of course, what fear of the loss of love amounts to, for love is a protection against this punitive aggression.) After that comes the erection of an internal authority, and renunciation of instinct owing to fear of it - owing to fear of conscience. In this second situation bad intentions are equated with bad actions, and hence come a sense of guilt and a need for punishment. The aggressiveness of conscience keeps up the aggressiveness of the authority. So far things have no doubt been made clear; but where does this leave room for the reinforcing influence of misfortune (of renunciation imposed from without), and for the extraordinary severity of conscience in the best and most tractable people? We have already explained both these peculiarities of conscience, but we probably still have an impression that those explanations do not go to the bottom of the matter, and leave a residue still unexplained. And here at last an idea comes in which belongs entirely to psycho-analysis and which is foreign to people's ordinary way of thinking. This idea is of a sort which enables us to understand why the subject-matter was bound to seem so confused and obscure to us. For it tells us that conscience (or more correctly, the anxiety which later becomes conscience) is indeed the cause of instinctual renunciation to begin with, but that later the relationship is reversed. Every renunciation of instinct now becomes a dynamic source of conscience and every fresh renunciation increases the latter's severity and intolerance. If we could only bring it better into harmony with what we already know about the history of the origin of conscience, we should be tempted to defend the paradoxical statement that conscience is the result of instinctual renunciation, or that instinctual renunciation (imposed on us from without) creates conscience, which then demands further instinctual renunciation.

[1930a, 4518]

The contradiction between this statement and what we have previously said about the genesis of conscience is in point of fact not so very great, and we see a way of further reducing it. In order to make our exposition easier, let us take as our example the aggressive instinct, and let us assume that the renunciation in question is always a renunciation of aggression. (This, of course, is only to be taken as a temporary assumption.) The effect of instinctual renunciation on the conscience then is that every piece of aggression whose satisfaction the subject gives up is taken over by the super-ego and increases the latter's aggressiveness (against the ego). This does not harmonize well with the view that the original aggressiveness of conscience is a continuance of the severity of the external authority and therefore has nothing to do with renunciation. But the discrepancy is removed if we postulate a different derivation for this first instalment of the super-ego's aggressivity. A considerable amount of aggressiveness must be developed in the child against the authority which prevents him from having his first, but none the less his most important, satisfactions, whatever the kind of instinctual deprivation that is demanded of him may be; but he is obliged to renounce the satisfaction of this revengeful aggressiveness. He finds his way out of this economically difficult situation with the help of familiar mechanisms. By means of identification he takes the unattackable authority into himself. The authority now turns into his super-ego and enters into possession of all the aggressiveness which a child would have liked to exercise against it. The child's ego has to content itself with the unhappy role of the authority - the father - who has been thus degraded. Here, as so often, the situation is reversed: 'If I were the father and you were the child, I should treat you badly.' The relationship between the super-ego and the ego is a return, distorted by a wish, of the real relationships between the ego, as yet undivided, and an external object. That is typical, too. But the essential difference is that the original severity of the super-ego does not - or does not so much - represent the severity which one has experienced from it, or which one attributes to it; it represents rather one's own aggressiveness towards it. If this is correct, we may assert truly that in the beginning conscience arises through the suppression of an aggressive impulse, and that it is subsequently reinforced by fresh suppressions of the same kind.

[1930a, 4519]
The two main types of pathogenic methods of upbringing - over-strictness and spoiling - have been accurately assessed by Franz Alexander in his book *The Psychoanalysis of the Total Personality* (1927) in connection with Aichhorn's study of delinquency. The 'unduly lenient and indulgent father' is the cause of children's forming an over-severe super-ego, because, under the impression of the love that they receive, they have no other outlet for their aggressiveness but turning it inwards. In delinquent children, who have been brought up without love, the tension between ego and super-ego is lacking, and the whole of their aggressiveness can be directed outwards. Apart from a constitutional factor which may be supposed to be present, it can be said, therefore, that a severe conscience arises from the joint operation of two factors: the frustration of instinct, which unleashes aggressiveness, and the experience of being loved, which turns the aggressiveness inwards and hands it over to the super-ego.

But if the human sense of guilt goes back to the killing of the primal father, that was after all a case of 'remorse'. Are we to assume that a conscience and a sense of guilt were not, as we have presupposed, in existence before the deed? If not, where, in this case, did the remorse come from? There is no doubt that this case should explain the secret of the sense of guilt to us and put an end to our difficulties. And I believe it does. This remorse was the result of the primordial ambivalence of feeling towards the father. His sons hated him, but they loved him, too. After their hatred had been satisfied by their act of aggression, their love came to the fore in their remorse for the deed. It set up the super-ego by identification with the father; it gave that agency the father's power, as though as a punishment for the deed of aggression they had carried out against him, and it created the restrictions which were intended to prevent a repetition of the deed. And since the inclination to aggressiveness against the father was repeated in the following generations, the sense of guilt, too, persisted, and it was reinforced once more by every piece of aggressiveness that was suppressed and carried over to the super-ego. Now, I think, we can at last grasp two things perfectly clearly: the part played by love in the origin of conscience and the fatal inevitability of the sense of guilt. Whether one has killed one's father or has abstained from doing so is not really the decisive thing. One is bound to feel guilty in either case, for the sense of guilt is an expression of the conflict due to ambivalence, of the eternal struggle between Eros and the instinct of destruction or death. This conflict is set going as soon as men are faced with the task of living together. So long as the community assumes no other form than that of the family, the conflict is bound to express itself in the Oedipus complex, to establish the conscience and to create the first sense of guilt. When an attempt is made to widen the community, the same conflict is continued in forms which are dependent on the past; and it is strengthened and results in a further intensification of the sense of guilt. Since civilization obeys an internal erotic impulsion which causes human beings to unite in a closely-knit group, it can only achieve this aim through an ever-increasing reinforcement of the sense of guilt. What began in relation to the father is completed in relation to the group. If civilization is a necessary course of development from the family to humanity as a whole, then - as a result of the inborn conflict arising from ambivalence, of the eternal struggle between the trends of love and death - there is inextricably bound up with it an increase of the sense of guilt, which will perhaps reach heights that the individual finds hard to tolerate. One is reminded of the great poet's moving arraignment of the 'Heavenly Powers':-

[1930a, 4522]
In the first place, I suspect that the reader has the impression that our discussions on the sense of guilt disrupt the framework of this essay: that they take up too much space, so that the rest of its subject-matter, with which they are not always closely connected, is pushed to one side. This may have spoilt the structure of my paper; but it corresponds faithfully to my intention to represent the sense of guilt as the most important problem in the development of civilization and to show that the price we pay for our advance in civilization is a loss of happiness through the heightening of the sense of guilt.¹ Anything that still sounds strange about this statement, which is the final conclusion of our investigation, can probably be traced to the quite peculiar relationship - as yet completely unexplained - which the sense of guilt has to our consciousness. In the common case of remorse, which we regard as normal, this feeling makes itself clearly enough perceptible to consciousness. Indeed, we are accustomed to speak of a 'consciousness of guilt' instead of a 'sense of guilt'. Our study of the neuroses, to which, after all we owe the most valuable pointers to an understanding of normal conditions, brings us up against some contradictions. In one of those affections, obsessional neurosis, the sense of guilt makes itself noisily heard in consciousness; it dominates the clinical picture and the patient's life as well, and it hardly allows anything else to appear alongside of it. But in most other cases and forms of neurosis it remains completely unconscious, without on that account producing any less important effects. Our patients do not believe us when we attribute an 'unconscious sense of guilt' to them. In order to make ourselves at all intelligible to them, we tell them of an unconscious need for punishment, in which the sense of guilt finds expression. But its connection with a particular form of neurosis must not be over-estimated. Even in obsessional neurosis there are types of patients who are not aware of their sense of guilt, or who only feel it as a tormenting uneasiness, a kind of anxiety, if they are prevented from carrying out certain actions. It ought to be possible eventually to understand these things; but as yet we cannot.

Here perhaps we may be glad to have it pointed out that the sense of guilt is at bottom nothing else but a topographical variety of anxiety; in its later phases it coincides completely with fear of the super-ego. And the relations of anxiety to consciousness exhibit the same extraordinary variations. Anxiety is always present somewhere or other behind every symptom; but at one time it takes noisy possession of the whole of consciousness, while at another it conceals itself so completely that we are obliged to speak of unconscious anxiety or, if we want to have a clearer psychological conscience, since anxiety is in the first instance simply a feeling, of possibilities of anxiety. Consequently it is very conceivable that the sense of guilt produced by civilization is not perceived as such either, and remains to a large extent unconscious, or appears as a sort of malaise, a dissatisfaction, for which people seek other motivations. Religions, at any rate, have never overlooked the part played in civilization by a sense of guilt. Furthermore - a point which I failed to appreciate elsewhere² - they claim to redeem mankind from this sense of guilt, which they call sin. From the manner in which, in Christianity, this redemption is achieved - by the sacrificial death of a single person, who in this manner takes upon himself a guilt that is common to everyone - we have been able to infer what the first occasion may have been on which this primal guilt, which was also the beginning of civilization, was acquired.³

[1930a, 4523]
Though it cannot be of great importance, it may not be superfluous to elucidate the meaning of a few words such as 'super-ego', 'conscience', 'sense of guilt', 'need for punishment' and 'remorse', which we have often, perhaps, used too loosely and interchangeably. They all relate to the same state of affairs, but denote different aspects of it. The super-ego is an agency which has been inferred by us, and conscience is a function which we ascribe, among other functions, to that agency. This function consists in keeping a watch over the actions and intentions of the ego and judging them, in exercising a censorship. The sense of guilt, the harshness of the super-ego, is thus the same thing as the severity of the conscience. It is the perception which the ego has of being watched over in this way, the assessment of the tension between its own strivings and the demands of the super-ego. The fear of this critical agency (a fear which is at the bottom of the whole relationship), the need for punishment, is an instinctual manifestation on the part of the ego, which has become masochistic under the influence of a sadistic super-ego; it is a portion, that is to say, of the instinct towards internal destruction present in the ego, employed for forming an erotic attachment to the super-ego. We ought not to speak of a conscience until a super-ego is demonstrably present. As to a sense of guilt, we must admit that it is in existence before the super-ego, and therefore before conscience, too. At that time it is the immediate expression of fear of the external authority, a recognition of the tension between the ego and that authority. It is the direct derivative of the conflict between the need for the authority's love and the urge towards instinctual satisfaction, whose inhibition produces the inclination to aggression. The superimposition of these two strata of the sense of guilt - one coming from fear of the external authority, the other from fear of the internal authority - has hampered our insight into the position of conscience in a number of ways. Remorse is a general term for the ego's reaction in a case of sense of guilt. It contains, in little altered form, the sensory material of the anxiety which is operating behind the sense of guilt; it is itself a punishment and can include the need for punishment. Thus remorse, too, can be older than conscience.

[1930a, 4524]

The second contradiction concerned the aggressive energy with which we suppose the super-ego to be endowed. According to one view, that energy merely carries on the punitive energy of the external authority and keeps it alive in the mind; while, according to another view, it consists, on the contrary, of one's own aggressive energy which has not been used and which one now directs against that inhibiting authority. The first view seemed to fit in better with the history, and the second with the theory, of the sense of guilt. Closer reflection has resolved this apparently irreconcilable contradiction almost too completely; what remained as the essential and common factor was that in each case we were dealing with an aggressiveness which had been displaced inwards. Clinical observation, moreover, allows us in fact to distinguish two sources for the aggressiveness which we attribute to the super-ego; one or the other of them exercises the stronger effect in any given case, but as a general rule they operate in unison.

[1930a, 4526]
This is, I think, the place at which to put forward for serious consideration a view which I have earlier recommended for provisional acceptance. In the most recent analytic literature a predilection is shown for the idea that any kind of frustration, any thwarted instinctual satisfaction, results, or may result, in a heightening of the sense of guilt.¹ A great theoretical simplification will, I think, be achieved if we regard this as applying only to the aggressive instincts, and little will be found to contradict this assumption. For how are we to account, on dynamic and economic grounds, for an increase in the sense of guilt appearing in place of an unfulfilled erotic demand? This only seems possible in a round-about way - if we suppose, that is, that the prevention of an erotic satisfaction calls up a piece of aggressiveness against the person who has interfered with the satisfaction, and that this aggressiveness has itself to be suppressed in turn. But if this is so, it is after all only the aggressiveness which is transformed into a sense of guilt, by being suppressed and made over to the super-ego. I am convinced that many processes will admit of a simpler and clearer exposition if the findings of psycho-analysis with regard to the derivation of the sense of guilt are restricted to the aggressive instincts. Examination of the clinical material gives us no unequivocal answer here, because, as our hypothesis tells us, the two classes of instinct hardly ever appear in a pure form, isolated from each other; but an investigation of extreme cases would probably point in the direction I anticipate.

[1930a, 4526]

Let us go back to the special problem presented to us by masochism. If for a moment we leave its erotic components on one side, it affords us a guarantee of the existence of a trend that has self-destruction as its aim. If it is true of the destructive instinct as well that the ego - but what we have in mind here is rather the id, the whole person - originally includes all the instinctual impulses, we are led to the view that masochism is older than sadism, and that sadism is the destructive instinct directed outwards, thus acquiring the characteristic of aggressiveness. A certain amount of the original destructive instinct may still remain in the interior. It seems that we can only perceive it under two conditions: if it is combined with erotic instincts into masochism or if - with a greater or lesser erotic addition - it is directed against the external world as aggressiveness. And now we are struck by the significance of the possibility that the aggressiveness may not be able to find satisfaction in the external world because it comes up against real obstacles. If this happens, it will perhaps retreat and increase the amount of self-destructiveness holding sway in the interior. We shall hear how this is in fact what occurs and how important a process this is. Impeded aggressiveness seems to involve a grave injury. It really seems as though it is necessary for us to destroy some other thing or person in order not to destroy ourselves, in order to guard against the impulsion to self-destruction. A sad disclosure indeed for the moralist!

[1933a, 4709]
You may perhaps shrug your shoulders and say: 'That isn't natural science, it's Schopenhauer's philosophy!' But, Ladies and Gentlemen, why should not a bold thinker have guessed something that is afterwards confirmed by sober and painstaking detailed research? Moreover, there is nothing that has not been said already, and similar things had been said by many people before Schopenhauer. Furthermore, what we are saying is not even genuine Schopenhauer. We are not asserting that death is the only aim of life; we are not overlooking the fact that there is life as well as death. We recognize two basic instincts and give each of them its own aim. How the two of them are mingled in the process of living, how the death instinct is made to serve the purposes of Eros, especially by being turned outwards as aggressiveness - these are tasks which are left to future investigation. We have not gone beyond the point at which this prospect lies open before us. The question, too, of whether the conservative character may not belong to all instincts without exception, whether the erotic instincts as well may not be seeking to bring back an earlier state of things when they strive to bring about a synthesis of living things into greater unities - this question, too, we must leave unanswered.

[1933a, 4711]

There is, as we think, no doubt about the origin of this unconscious need for punishment. It behaves like a piece of conscience, like a prolongation of our conscience into the unconscious; and it must have the same origin as conscience and correspond, therefore, to a piece of aggressiveness that has been internalized and taken over by the super-ego. If only the words went together better, we should be justified for all practical purposes in calling it an 'unconscious sense of guilt'. Theoretically we are in fact in doubt whether we should suppose that all the aggressiveness that has returned from the external world is bound by the super-ego and accordingly turned against the ego, or that a part of it is carrying on its mute and uncanny activity as a free destructive instinct in the ego and the id. A distribution of the latter kind is the more probable; but we know nothing more about it. There is no doubt that, when the super-ego was first instituted, in equipping that agency use was made of the piece of the child's aggressiveness towards his parents for which he was unable to effect a discharge outwards on account of his erotic fixation as well as of external difficulties; and for that reason the severity of the super-ego need not simply correspond to the strictness of the upbringing. It is very possible that, when there are later occasions for suppressing aggressiveness, the instinct may take the same path that was opened to it at that decisive point of time.

[1933a, 4713]
And here, at an unexpected point, we have emerged from the psychical underworld into the open market-place. I cannot lead you any further, but before I take leave of you for to-day I must detain you with one more train of thought. It has become our habit to say that our civilization has been built up at the cost of sexual trends which, being inhibited by society, are partly, it is true, repressed but have partly been made usable for other aims. We have admitted, too, that, in spite of all our pride in our cultural attainments, it is not easy for us to fulfil the requirements of this civilization or to feel comfortable in it, because the instinctual restrictions imposed on us constitute a heavy psychical burden. Well, what we have come to see about the sexual instincts, applies equally and perhaps still more to the other ones, the aggressive instincts. It is they above all that make human communal life difficult and threaten its survival. Restriction of the individual's aggressiveness is the first and perhaps the severest sacrifice which society requires of him. We have learnt the ingenious way in which the taming of this unruly thing has been achieved. The institution of the super-ego which takes over the dangerous aggressive impulses, introduces a garrison, as it were, into regions that are inclined to rebellion. But on the other hand, if we look at it purely psychologically, we must recognize that the ego does not feel happy in being thus sacrificed to the needs of society, in having to submit to the destructive trends of aggressiveness which it would have been glad to employ itself against others. It is like a prolongation in the mental sphere of the dilemma of 'eat or be eaten' which dominates the organic animate world. Luckily the aggressive instincts are never alone but always alloyed with the erotic ones. These latter have much to mitigate and much to avert under the conditions of the civilization which mankind has created.

[1933a, 4714]

For, whether a man is a homosexual or a necrophilic, a hysterical suffering from anxiety, an obsessional neurotic cut off from society, or a raving lunatic, the 'Individual Psychologist' of the Adlerian school will declare that the impelling motive of his condition is that he wishes to assert himself, to overcompensate for his inferiority, to remain 'on top', to pass from the feminine to the masculine line. In my young student days we used to hear something very much the same in the out-patients' department when a case of hysteria was introduced: hysterical patients, we were told, produce their symptoms to make themselves interesting, to draw attention to themselves. It is a remarkable thing how these ancient pieces of wisdom keep on cropping up. But even at that time this fragment of psychology did not seem to cover the riddle of hysteria. It left unexplained, for instance, why the patients used no other methods for attaining their purpose. There must, of course, be something correct in this theory of the 'Individual Psychologists': a small particle is taken for the whole. The self-preservative instinct will try to profit by every situation; the ego will seek to turn even illness to its advantage. In psycho-analysis this is known as the 'secondary gain from illness'. Though, indeed, when we think of the facts of masochism, of the unconscious need for punishment and of neurotic self-injury, which make plausible the hypothesis of there being instinctual impulses that run contrary to self-preservation, we even feel shaken in our belief in the general validity of the commonplace truth on which the theoretical structure of Individual Psychology is erected. But a theory such as this is bound to be very welcome to the great mass of the people, a theory which recognizes no complications, which introduces no new concepts that are hard to grasp, which knows nothing of the unconscious, which gets rid at a single blow of the universally oppressive problem of sexuality and which restricts itself to the discovery of the artifices by which people seek to make life easy. For the mass of the people themselves take things easily: they call for no more than a single reason by way of explanation, they do not thank science for its diffuseness, they want to have simple solutions and to know that problems are solved. When we consider how very far Individual Psychology goes in meeting these demands, we cannot suppress the recollection of a sentence in Wallenstein:

[1933a, 4743]
Transformation into the opposite is most radically present in a third feature of the legend, in the punishment of the Bringer of Fire. Prometheus was chained to a rock, and every day a vulture fed on his liver. In the fire-legends of other peoples, too, a bird plays a part, and it must have something to do with the matter; but for the moment I shall not attempt an interpretation. On the other hand, we feel on firm ground when it comes to explaining why the liver was selected as the location of the punishment. In ancient times the liver was regarded as the seat of all passions and desires; hence a punishment like that of Prometheus was the right one for a criminal driven by instinct, who had committed an offence at the prompting of evil desires. But the exact opposite is true of the Bringer of Fire: he had renounced an instinct and had shown how beneficent, and at the same time how indispensable, such a renunciation was for the purposes of civilization. And why should the legend treat a deed that was thus a benefit to civilization as a crime deserving punishment? Well, if, through all its distortions, it barely allows us to get a glimpse of the fact that the acquisition of control over fire presupposes an instinctual renunciation, at least it makes no secret of the resentment which the culture-hero could not fail to arouse in men driven by their instincts. And this is in accordance with what we know and expect. We know that a demand for a renunciation of instinct, and the enforcement of that demand, call out hostility and aggressiveness, which is only transformed into a sense of guilt in a later phase of psychical development.

[1932a, 4783]

I fear I may be abusing your interest, which is after all concerned with the prevention of war and not with our theories. Nevertheless I should like to linger for a moment over our destructive instinct, whose popularity is by no means equal to its importance. As a result of a little speculation, we have come to suppose that this instinct is at work in every living creature and is striving to bring it to ruin and to reduce life to its original condition of inanimate matter. Thus it quite seriously deserves to be called a death instinct, while the erotic instincts represent the effort to live. The death instinct turns into the destructive instinct when, with the help of special organs, it is directed outwards, on to objects. The organism preserves its own life, so to say, by destroying an extraneous one. Some portion of the death instinct, however, remains operative within the organism, and we have sought to trace quite a number of normal and pathological phenomena to this internalization of the destructive instinct. We have even been guilty of the heresy of attributing the origin of conscience to this diversion inwards of aggressiveness. You will notice that it is by no means a trivial matter if this process is carried too far: it is positively unhealthy. On the other hand if these forces are turned to destruction in the external world, the organism will be relieved and the effect must be beneficial. This would serve as a biological justification for all the ugly and dangerous impulses against which we are struggling. It must be admitted that they stand nearer to Nature than does our resistance to them for which an explanation also needs to be found. It may perhaps seem to you as though our theories are a kind of mythology and, in the present case, not even an agreeable one. But does not every science come in the end to a kind of mythology like this? Cannot the same be said to-day of your own Physics?

[1933b, 4800]
When we have established the existence of a phenomenon, the next question is of course as to its cause. Incredulity of this kind is obviously an attempt to repudiate a piece of reality; but there is something strange about it. We should not be in the least astonished if an attempt of this kind were aimed at a piece of reality that threatened to bring unpleasure: the mechanism of our mind is, so to speak, planned to work along just such lines. But why should such incredulity arise in something which, on the contrary, promises to bring a high degree of pleasure? Truly paradoxical behaviour! But I recollect that on a previous occasion I dealt with the similar case of the people who, as I put it, are 'wrecked by success'. As a rule people fall ill as a result of frustration, of the non-fulfilment of some vital necessity or desire. But with these people the opposite is the case; they fall ill, or even go entirely to pieces, because an overwhelmingly powerful wish of theirs has been fulfilled. But the contrast between the two situations is not so great as it seems at first. What happens in the paradoxical case is merely that the place of the external frustration is taken by an internal one. The sufferer does not permit himself happiness: the internal frustration commands him to cling to the external one. But why? Because - so runs the answer in a number of cases - one cannot expect Fate to grant one anything so good. In fact, another instance of 'too good to be true', the expression of a pessimism of which a large portion seems to find a home in many of us. In another set of cases, just as in those who are wrecked by success, we find a sense of guilt or inferiority, which can be translated: 'I'm not worthy of such happiness, I don't deserve it.' But these two motives are essentially the same, for one is only a projection of the other. For, as has long been known, the Fate which we expect to treat us so badly is a materialization of our conscience, of the severe super-ego within us, itself a residue of the punitive agency of our childhood.

[1936a, 4826]

So long as that instinct operates internally, as a death instinct, it remains silent; it only comes to our notice when it is diverted outwards as an instinct of destruction. It seems to be essential for the preservation of the individual that this diversion should occur; the muscular apparatus serves this purpose. When the super-ego is established, considerable amounts of the aggressive instinct are fixated in the interior of the ego and operate there self-destructively. This is one of the dangers to health by which human beings are faced on their path to cultural development. Holding back aggressiveness is in general unhealthy and leads to illness (to mortification). A person in a fit of rage will often demonstrate how the transition from aggressiveness that has been prevented to self-destructiveness is brought about by diverting the aggressiveness against himself: he tears his hair or beats his face with his fists, though he would evidently have preferred to apply this treatment to someone else. Some portion of self-destructiveness remains within, whatever the circumstances; till at last it succeeds in killing the individual, not, perhaps, until his libido has been used up or fixated in a disadvantageous way. Thus it may in general be suspected that the individual dies of his internal conflicts but that the species dies of its unsuccessful struggle against the external world if the latter changes in a fashion which cannot be adequately dealt with by the adaptations which the species has acquired.

[1940a [1938], 4961]
The further our work proceeds and the more deeply our insight penetrates into the mental life of neurotics, the more clearly two new factors force themselves on our notice, which demand the closest attention as sources of resistance. Both of them are completely unknown to the patient, neither of them could be taken into account when our pact was made; nor do they arise from the patient's ego. They may both be embraced under the single name of 'need to be ill or to suffer', but they have different origins though in other respects they are of a kindred nature. The first of these two factors is the sense of guilt or consciousness of guilt, as it is called, though the patient does not feel it and is not aware of it. It is evidently the portion of the resistance contributed by a super-ego that has become particularly severe and cruel. The patient must not become well but must remain ill, for he deserves no better. This resistance does not actually interfere with our intellectual work, but it makes it inoperative; indeed, it often allows us to remove one form of neurotic suffering, but is ready at once to replace it by another, or perhaps by some somatic illness. The sense of guilt also explains the cure or improvement of severe neuroses which we occasionally observe after real misfortunes: all that matters is that the patient should be miserable - in what way is of no consequence. The uncomplaining resignation with which such people often put up with their hard fate is most remarkable, but also revealing. In warding off this resistance we are obliged to restrict ourselves to making it conscious and attempting to bring about the slow demolition of the hostile super-ego.

[1940a [1938], 4989]

In yet another group of cases the distinguishing characteristics of the ego, which are to be held responsible as sources of resistance against analytic treatment and as impediments to therapeutic success, may spring from different and deeper roots. Here we are dealing with the ultimate things which psychological research can learn about: the behaviour of the two primal instincts, their distribution, mingling and defusion - things which we cannot think of as being confined to a single province of the mental apparatus, the id, the ego or the super-ego. No stronger impression arises from the resistances during the work of analysis than of there being a force which is defending itself by every possible means against recovery and which is absolutely resolved to hold on to illness and suffering. One portion of this force has been recognized by us, undoubtedly with justice, as the sense of guilt and need for punishment, and has been localized by us in the ego's relation to the super-ego. But this is only the portion of it which is, as it were, psychically bound by the super-ego and thus becomes recognizable; other quotas of the same force, whether bound or free, may be at work in other, unspecified places. If we take into consideration the total picture made up of the phenomena of masochism immanent in so many people, the negative therapeutic reaction and the sense of guilt found in so many neurotics, we shall no longer be able to adhere to the belief that mental events are exclusively governed by the desire for pleasure. These phenomena are unmistakable indications of the presence of a power in mental life which we call the instinct of aggression or of destruction according to its aims, and which we trace back to the original death instinct of living matter. It is not a question of an antithesis between an optimistic and a pessimistic theory of life. Only by the concurrent or mutually opposing action of the two primal instincts - Eros and the death instinct -, never by one or the other alone, can we explain the rich multiplicity of the phenomena of life.

[1937c, 5037]
When anyone has, like Leonardo, escaped being intimidated by his father during his earliest childhood, and has in his researches cast away the fetters of authority, it would be in the sharpest contradiction to our expectation if we found that he had remained a believer and had been unable to escape from dogmatic religion. Psycho-analysis has made us familiar with the intimate connection between the father-complex and belief in God; it has shown us that a personal God is, psychologically, nothing other than an exalted father, and it brings us evidence every day of how young people lose their religious beliefs as soon as their father's authority breaks down. Thus we recognize that the roots of the need for religion are in the parental complex; the almighty and just God, and kindly Nature, appear to us as grand sublimations of father and mother, or rather, as revivals and restorations of the young child's ideas of them. Biologically speaking, religiousness is to be traced to the small human child's long-drawn-out helplessness and need of help; and when at a later date he perceives how truly forlorn and weak he is when confronted with the great forces of life, he feels his condition as he did in childhood, and attempts to deny his own despondency by a regressive revival of the forces which protected his infancy. The protection against neurotic illness, which religion vouchsafes to those who believe in it, is easily explained: it removes their parental complex, on which the sense of guilt in individuals as well as in the whole human race depends, and disposes of it, while the unbeliever has to grapple with the problem on his own.

[1910c, 2294]

It is true that psycho-analysis has taken the individual mind as its subject, but in investigating the individual it could not avoid dealing with the emotional basis of the relation of the individual to society. It has found that the social feelings invariably contain an erotic element - an element which, if it is over-emphasized and then repressed, becomes one of the marks of a particular group of mental disorders. Psycho-analysis has recognized that in general the neuroses are asocial in their nature and that they always aim at driving the individual out of society and at replacing the safe monastic seclusion of earlier days by the isolation of illness. The intense feeling of guilt which dominates so many neuroses has been shown to be a social modification of neurotic anxiety.

[1913j, 2824]

There can be no doubt that the Oedipus complex may be looked upon as one of the most important sources of the sense of guilt by which neurotics are so often tormented. But more than this: in a study of the beginnings of human religion and morality which I published in 1913 under the title of *Totem and Taboo* I put forward a suggestion that mankind as a whole may have acquired its sense of guilt, the ultimate source of religion and morality, at the beginning of its history, in connection with the Oedipus complex. I should be very glad to tell you more about this, but I had better leave it on one side. Once one has begun on that topic it is hard to break off; and we must go back to individual psychology.

[1916-1917, 3399]

It will have been easy to guess from my account that the patient was a Russian. I parted from him, regarding him as cured, a few weeks before the unexpected outbreak of the Great War; and I did not see him again until the shifting chances of the war had given the Central European Powers access to South Russia. He then came to Vienna and reported that immediately after the end of the treatment he had been seized with a longing to tear himself free from my influence. After a few months' work, a piece of the transference which had not hitherto been overcome was successfully dealt with. Since then the patient has felt normal and has behaved unexceptionably, in spite of the war having robbed him of his home, his possessions, and all his family relationships. It may be that his very misery, by gratifying his sense of guilt, contributed to the consolidation of his recovery.

[1918b, 3596]
As far as I can see, the danger threatens from two directions in especial. On the one hand, when the illness has been broken down by the analysis, the patient makes the most assiduous efforts to create for himself in place of his symptoms new substitutive satisfactions, which now lack the feature of suffering. He makes use of the enormous capacity for displacement possessed by the now partly liberated libido, in order to cathcet with libido and promote to the position of substitutive satisfactions the most diverse kinds of activities, preferences and habits, not excluding some that have been his already. He continually finds new distractions of this kind, into which the energy necessary to carrying on the treatment escapes, and he knows how to keep them secret for a time. It is the analyst's task to detect these divergent paths and to require him every time to abandon them, however harmless the activity which leads to satisfaction may be in itself. The half-recovered patient may also enter on less harmless paths - as when, for instance, if he is a man, he seeks prematurely to attach himself to a woman. It may be observed, incidentally, that unhappy marriage and physical infirmity are the two things that most often supersede a neurosis. They satisfy in particular the sense of guilt (need for punishment) which makes many patients cling so fast to their neuroses. By a foolish choice in marriage they punish themselves; they regard a long organic illness as a punishment by fate and thereafter often cease to keep up their neurosis.

We may note too in passing that the analysis of the infantile perversion dealt with here is also of help in solving an old riddle - one which, it is true, has always troubled those who have not accepted psycho-analysis more than analysts themselves. Yet quite recently even Bleuler regarded it as a remarkable and inexplicable fact that neurotics make masturbation the central point of their sense of guilt. We have long assumed that this sense of guilt relates to the masturbation of early childhood and not to that of puberty, and that in the main it is to be connected not with the act of masturbation but with the phantasy which, although unconscious, lies at its root - that is to say, with the Oedipus complex.

There is another phenomenon, however, which is far stranger. In our analyses we discover that there are people in whom the faculties of self-criticism and conscience - mental activities, that is, that rank as extremely high ones - are unconscious and unconsciously produce effects of the greatest importance; the example of resistance remaining unconscious during analysis is therefore by no means unique. But this new discovery, which compels us, in spite of our better critical judgement, to speak of an 'unconscious sense of guilt', bewilders us far more than the other and sets us fresh problems, especially when we gradually come to see that in a great number of neuroses an unconscious sense of guilt of this kind plays a decisive economic part and puts the most powerful obstacles in the way of recovery. If we come back once more to our scale of values, we shall have to say that not only what is lowest but also what is highest in the ego can be unconscious. It is as if we were thus supplied with a proof of what we have just asserted of the conscious ego: that it is first and foremost a body-ego.

There are certain people who behave in a quite peculiar fashion during the work of analysis. When one speaks hopefully to them or expresses satisfaction with the progress of the treatment, they show signs of discontent and their condition invariably becomes worse. One begins by regarding this as defiance and as an attempt to prove their superiority to the physician, but later one comes to take a deeper and juster view. One becomes convinced, not only that such people cannot endure any praise or appreciation, but that they react inversely to the progress of the treatment. Every partial solution that ought to result, and in other people does result, in an improvement or a temporary suspension of symptoms produces in them for the time being an exacerbation of their illness; they get worse during the treatment instead of getting better. They exhibit what is known as a 'negative therapeutic reaction'.

[1919a, 3632]

[1923b, 3961]

[1923b, 3983]
There is no doubt that there is something in these people that sets itself against their recovery, and its approach is dreaded as though it were a danger. We are accustomed to say that the need for illness has got the upper hand in them over the desire for recovery. If we analyse this resistance in the usual way then, even after allowance has been made for an attitude of defiance towards the physician and for fixation to the various forms of gain from illness, the greater part of it is still left over; and this reveals itself as the most powerful of all obstacles to recovery, more powerful than the familiar ones of narcissistic inaccessibility, a negative attitude towards the physician and clinging to the gain from illness.

In the end we come to see that we are dealing with what may be called a 'moral' factor, a sense of guilt, which is finding its satisfaction in the illness and refuses to give up the punishment of suffering. We shall be right in regarding this disheartening explanation as final. But as far as the patient is concerned this sense of guilt is dumb; it does not tell him he is guilty; he does not feel guilty, he feels ill. This sense of guilt expresses itself only as a resistance to recovery which it is extremely difficult to overcome. It is also particularly difficult to convince the patient that this motive lies behind his continuing to be ill; he holds fast to the more obvious explanation that treatment by analysis is not the right remedy for his case.¹

The description we have given applies to the most extreme instances of this state of affairs, but in a lesser measure this factor has to be reckoned with in very many cases, perhaps in all comparatively severe cases of neurosis. In fact it may be precisely this element in the situation, the attitude of the ego ideal, that determines the severity of a neurotic illness. We shall not hesitate, therefore, to discuss rather more fully the way in which the sense of guilt expresses itself under different conditions.

¹ The battle with the obstacle of an unconscious sense of guilt is not made easy for the analyst. Nothing can be done against it directly, and nothing indirectly but the slow procedure of unmasking its unconscious repressed roots, and of thus gradually changing it into a conscious sense of guilt. One has a special opportunity for influencing it when this Ucs. sense of guilt is a "borrowed" one - when it is the product of an identification with some other person who was once the object of an erotic cathexis. A sense of guilt that has been adopted in this way is often the sole remaining trace of the abandoned love-relation and not at all easy to recognize as such. (The likeness between this process and what happens in melancholia is unmistakable.) If one can unmask this former object-cathexis behind the Ucs. sense of guilt, the therapeutic success is often brilliant, but otherwise the outcome of one's efforts is by no means certain. It depends principally on the intensity of the sense of guilt; there is often no counteracting force of a similar order of strength which the treatment can oppose to it. Perhaps it may depend, too, on whether the personality of the analyst allows of the patient's putting him in the place of his ego ideal, and this involves a temptation for the analyst to play the part of prophet, saviour and redeemer to the patient. Since the rules of analysis are diametrically opposed to the physician's making use of his personality in any such manner, it must be honestly confessed that here we have another limitation to the effectiveness of analysis; after all, analysis does not set out to make pathological reactions impossible, but to give the patient's ego freedom to decide one way or the other.

An interpretation of the normal, conscious sense of guilt (conscience) presents no difficulties; it is based on the tension between the ego and the ego ideal and is the expression of a condemnation of the ego by its critical agency. The feelings of inferiority so well known in neurotics are presumably not far removed from it. In two very familiar maladies the sense of guilt is over-strongly conscious; in them the ego ideal displays particular severity and often rages against the ego in a cruel fashion. The attitude of the ego ideal in these two conditions, obsessional neurosis and melancholia, presents, alongside of this similarity, differences that are no less significant.
It is certainly not clear why the sense of guilt reaches such an extraordinary strength in these two neurotic disorders; but the main problem presented in this state of affairs lies in another direction. We shall postpone discussion of it until we have dealt with the other cases in which the sense of guilt remains unconscious.

It is essentially in hysteria and in states of a hysterical type that this is found. Here the mechanism by which the sense of guilt remains unconscious is easy to discover. The hysterical ego fends off a distressing perception with which the criticisms of its super-ego threaten it, in the same way in which it is in the habit of fending off an unendurable object-cathexis - by an act of repression. It is the ego, therefore, that is responsible for the sense of guilt remaining unconscious. We know that as a rule the ego carries out repressions in the service and at the behest of its super-ego; but this is a case in which it has turned the same weapon against its harsh taskmaster. In obsessional neurosis, as we know, the phenomena of reaction-formation predominate; but here the ego succeeds only in keeping at a distance the material to which the sense of guilt refers.

These considerations make it possible to regard the fear of death, like the fear of conscience, as a development of the fear of castration. The great significance which the sense of guilt has in the neuroses makes it conceivable that common neurotic anxiety is reinforced in severe cases by the generating of anxiety between the ego and the super-ego (fear of castration, of conscience, of death).

Let us keep to a habit of our technique and consider first the extreme and unmistakably pathological form of this masochism. I have described elsewhere how in analytic treatment we come across patients to whom, owing to their behaviour towards its therapeutic influence, we are obliged to ascribe an 'unconscious' sense of guilt. I pointed out the sign by which such people can be recognized (a 'negative therapeutic reaction') and I did not conceal the fact that the strength of such an impulse constitutes one of the most serious resistances and the greatest danger to the success of our medical or educative aims. The satisfaction of this unconscious sense of guilt is perhaps the most powerful bastion in the subject's (usually composite) gain from illness - in the sum of forces which struggle against his recovery and refuse to surrender his state of illness. The suffering entailed by neuroses is precisely the factor that makes them valuable to the masochistic trend. It is instructive, too, to find, contrary to all theory and expectation, that a neurosis which has defied every therapeutic effort may vanish if the subject becomes involved in the misery of an unhappy marriage, or loses all his money, or develops a dangerous organic disease. In such instances one form of suffering has been replaced by another; and we see that all that mattered was that it should be possible to maintain a certain amount of suffering.

Patients do not easily believe us when we tell them about the unconscious sense of guilt. They know only too well by what torments - the pangs of conscience - a conscious sense of guilt, a consciousness of guilt, expresses itself, and they therefore cannot admit that they could harbour exactly analogous impulses in themselves without being in the least aware of them. We may, I think, to some extent meet their objection if we give up the term 'unconscious sense of guilt', which is in any case psychologically incorrect, and speak instead of a 'need for punishment', which covers the observed state of affairs just as aptly. We cannot, however, restrain ourselves from judging and localizing this unconscious sense of guilt in the same way as we do the conscious kind.
After these preliminaries we can return to our consideration of moral masochism. We have said that, by their behaviour during treatment and in life, the individuals in question give an impression of being morally inhibited to an excessive degree, of being under the domination of an especially sensitive conscience, although they are not conscious of any of this ultra-morality. On closer inspection, we can see the difference there is between an unconscious extension of morality of this kind and moral masochism. In the former, the accent falls on the heightened sadism of the super-ego to which the ego submits; in the latter, it falls on the ego's own masochism which seeks punishment, whether from the super-ego or from the parental powers outside. We may be forgiven for having confused the two to begin with; for in both cases it is a question of a relationship between the ego and the super-ego (or powers that are equivalent to it), and in both cases what is involved is a need which is satisfied by punishment and suffering. It can hardly be an insignificant detail, then, that the sadism of the super-ego becomes for the most part glaringly conscious, whereas the masochistic trend of the ego remains as a rule concealed from the subject and has to be inferred from his behaviour.

Theodor Reik and G. Róheim, the ethnologist, have taken up the line of thought which I developed in *Totem and Taboo* and, in a series of important works, have extended it, deepened it, or corrected it. I myself have since returned to it more than once, in the course of my investigations into the 'unconscious sense of guilt' (which also plays such an important part among the motives of neurotic suffering) and in my attempts at forming a closer connection between social psychology and the psychology of the individual.¹ I have moreover made use of the idea of an archaic heritage from the 'primal horde' epoch of mankind's development in explaining susceptibility to hypnosis.

There are clearly also inhibitions which serve the purpose of self-punishment. This is often the case in inhibitions of professional activities. The ego is not allowed to carry on those activities, because they would bring success and gain, and these are things which the severe super-ego has forbidden. So the ego gives them up too, in order to avoid coming into conflict with the super-ego.

It must not be supposed that these emendations provide us with a complete survey of all the kinds of resistance that are met with in analysis. Further investigation of the subject shows that the analyst has to combat no less than five kinds of resistance, emanating from three directions - the ego, the id and the super-ego. The ego is the source of three of these, each differing in its dynamic nature. The first of these three ego-resistances is the *repression* resistance, which we have already discussed above and about which there is least new to be added. Next there is the *transference* resistance, which is of the same nature but which has different and much clearer effects in analysis, since it succeeds in establishing a relation to the analytic situation or the analyst himself and thus re-animating a repression which should only have been recollected. The third resistance, though also an ego-resistance, is of quite a different nature. It proceeds from the *gain from illness* and is based upon an assimilation of the symptom into the ego. It represents an unwillingness to renounce any satisfaction or relief that has been obtained. The fourth variety, arising from the *id*, is the resistance which, as we have just seen, necessitates 'working-through'. The fifth, coming from the *super-ego* and the last to be discovered, is also the most obscure though not always the least powerful one. It seems to originate from the sense of guilt or the need for punishment; and it opposes every move towards success, including, therefore, the patient's own recovery through analysis.
When I described the relation between the ego and the id to you, I suppressed an important part of the theory of the mental apparatus. For we have been obliged to assume that within the ego itself a particular agency has become differentiated, which we name the super-ego. This super-ego occupies a special position between the ego and the id. It belongs to the ego and shares its high degree of psychological organization; but it has a particularly intimate connection with the id. It is in fact a precipitate of the first object-cathexes of the id and is the heir to the Oedipus complex after its demise. This super-ego can confront the ego and treat it like an object; and it often treats it very harshly. It is as important for the ego to remain on good terms with the super-ego as with the id. Estrangements between the ego and the super-ego are of great significance in mental life. You will already have guessed that the super-ego is the vehicle of the phenomenon that we call conscience. Mental health very much depends on the super-ego's being normally developed - that is, on its having become sufficiently impersonal. And that is precisely what it is not in neurotics, whose Oedipus complex has not passed through the correct process of transformation. Their super-ego still confronts their ego as a strict father confronts a child; and their morality operates in a primitive fashion in that the ego gets itself punished by the super-ego. Illness is employed as an instrument for this 'self-punishment', and neurotics have to behave as though they were governed by a sense of guilt which, in order to be satisfied, needs to be punished by illness.
[1926e, 4365]
In the first place, I suspect that the reader has the impression that our discussions on the sense of guilt disrupt the framework of this essay: that they take up too much space, so that the rest of its subject-matter, with which they are not always closely connected, is pushed to one side. This may have spoilt the structure of my paper; but it corresponds faithfully to my intention to represent the sense of guilt as the most important problem in the development of civilization and to show that the price we pay for our advance in civilization is a loss of happiness through the heightening of the sense of guilt.\footnote{ Anything that still sounds strange about this statement, which is the final conclusion of our investigation, can probably be traced to the quite peculiar relationship - as yet completely unexplained - which the sense of guilt has to our consciousness. In the common case of remorse, which we regard as normal, this feeling makes itself clearly enough perceptible to consciousness. Indeed, we are accustomed to speak of a 'consciousness of guilt' instead of a 'sense of guilt'. Our study of the neuroses, to which, after all we owe the most valuable pointers to an understanding of normal conditions, brings us up against some contradictions. In one of those affections, obsessional neurosis, the sense of guilt makes itself noisily heard in consciousness; it dominates the clinical picture and the patient's life as well, and it hardly allows anything else to appear alongside of it. But in most other cases and forms of neurosis it remains completely unconscious, without on that account producing any less important effects. Our patients do not believe us when we attribute an 'unconscious sense of guilt' to them. In order to make ourselves at all intelligible to them, we tell them of an unconscious need for punishment, in which the sense of guilt finds expression. But its connection with a particular form of neurosis must not be over-estimated. Even in obsessional neurosis there are types of patients who are not aware of their sense of guilt, or who only feel it as a tormenting uneasiness, a kind of anxiety, if they are prevented from carrying out certain actions. It ought to be possible eventually to understand these things; but as yet we cannot. Here perhaps we may be glad to have it pointed out that the sense of guilt is at bottom nothing else but a topographical variety of anxiety; in its later phases it coincides completely with \textit{fear of the super-ego}. And the relations of anxiety to consciousness exhibit the same extraordinary variations. Anxiety is always present somewhere or other behind every symptom; but at one time it takes noisy possession of the whole of consciousness, while at another it conceals itself so completely that we are obliged to speak of unconscious anxiety or, if we want to have a clearer psychological conscience, since anxiety is in the first instance simply a feeling, of possibilities of anxiety. Consequently it is very conceivable that the sense of guilt produced by civilization is not perceived as such either, and remains to a large extent unconscious, or appears as a sort of \textit{malaise}, a dissatisfaction, for which people seek other motivations. Religions, at any rate, have never overlooked the part played in civilization by a sense of guilt. Furthermore - a point which I failed to appreciate elsewhere\footnote{ Furthermore - a point which I failed to appreciate elsewhere - they claim to redeem mankind from this sense of guilt, which they call sin. From the manner in which, in Christianity, this redemption is achieved - by the sacrificial death of a single person, who in this manner takes upon himself a guilt that is common to everyone - we have been able to infer what the first occasion may have been on which this primal guilt, which was also the beginning of civilization, was acquired.} - they claim to redeem mankind from this sense of guilt, which they call sin. From the manner in which, in Christianity, this redemption is achieved - by the sacrificial death of a single person, who in this manner takes upon himself a guilt that is common to everyone - we have been able to infer what the first occasion may have been on which this primal guilt, which was also the beginning of civilization, was acquired.\footnote{ Furthermore - a point which I failed to appreciate elsewhere - they claim to redeem mankind from this sense of guilt, which they call sin. [1930a, 4523]

I am tempted to extract a first advantage from this more restricted view of the case by applying it to the process of repression. As we have learned, neurotic symptoms are, in their essence, substitutive satisfactions for unfulfilled sexual wishes. In the course of our analytic work we have discovered to our surprise that perhaps every neurosis conceals a quota of unconscious sense of guilt, which in its turn fortifies the symptoms by making use of them as a punishment. It now seems plausible to formulate the following proposition. When an instinctual trend undergoes repression, its libidinal elements are turned into symptoms, and its aggressive components into a sense of guilt. Even if this proposition is only an average approximation to the truth, it is worthy of our interest.

[1930a, 4527]
The publication of Dostoevsky's posthumous papers and of his wife's diaries has thrown a glaring light on one episode in his life, namely the period in Germany when he was obsessed with a mania for gambling (cf. Fülöp-Miller and Eckstein, 1925), which no one could regard as anything but an unmistakable fit of pathological passion. There was no lack of rationalizations for this remarkable and unworthy behaviour. As often happens with neurotics, Dostoevsky's sense of guilt had taken a tangible shape as a burden of debt, and he was able to take refuge behind the pretext that he was trying by his winnings at the tables to make it possible for him to return to Russia without being arrested by his creditors. But this was no more than a pretext and Dostoevsky was acute enough to recognize the fact and honest enough to admit it. He knew that the chief thing was gambling for its own sake - *le jeu pour le jeu*.¹ All the details of his impulsively irrational conduct show this and something more besides. He never rested until he had lost everything. For him gambling was a method of self-punishment as well. Time after time he gave his young wife his promise or his word of honour not to play any more or not to play any more on that particular day; and, as she says, he almost always broke it. When his losses had reduced himself and her to the direst need, he derived a second pathological satisfaction from that. He could then scold and humiliate himself before her, invite her to despise him and to feel sorry that she had married such an old sinner; and when he had thus unburdened his conscience, the whole business would begin again next day. His young wife accustomed herself to this cycle, for she had noticed that the one thing which offered any real hope of salvation - his literary production - never went better than when they had lost everything and pawned their last possessions. Naturally she did not understand the connection. When his sense of guilt was satisfied by the punishments he had inflicted on himself, the inhibition upon his work became less severe and he allowed himself to take a few steps along the road to success.²

There is, as we think, no doubt about the origin of this unconscious need for punishment. It behaves like a piece of conscience, like a prolongation of our conscience into the unconscious; and it must have the same origin as conscience and correspond, therefore, to a piece of aggressiveness that has been internalized and taken over by the super-ego. If only the words went together better, we should be justified for all practical purposes in calling it an 'unconscious sense of guilt'. Theoretically we are in fact in doubt whether we should suppose that all the aggressiveness that has returned from the external world is bound by the super-ego and accordingly turned against the ego, or that a part of it is carrying on its mute and uncanny activity as a free destructive instinct in the ego and the id. A distribution of the latter kind is the more probable; but we know nothing more about it. There is no doubt that, when the super-ego was first instituted, in equipping that agency use was made of the piece of the child's aggressiveness towards his parents for which he was unable to effect a discharge outwards on account of his erotic fixation as well as of external difficulties; and for that reason the severity of the super-ego need not simply correspond to the strictness of the upbringing. It is very possible that, when there are later occasions for suppressing aggressiveness, the instinct may take the same path that was opened to it at that decisive point of time.

¹ [1928b, 4566]
² [1933a, 4713]
People in whom this unconscious sense of guilt is excessively strong betray themselves in analytic treatment by the negative therapeutic reaction which is so disagreeable from the prognostic point of view. When one has given them the solution of a symptom, which should normally be followed by at least its temporary disappearance, what they produce instead is a momentary exacerbation of the symptom and of the illness. It is often enough to praise them for their behaviour in the treatment or to say a few hopeful words about the progress of the analysis in order to bring about an unmistakable worsening of their condition. A non-analyst would say that the 'will to recovery' was absent. If you follow the analytic way of thinking, you will see in this behaviour a manifestation of the unconscious sense of guilt, for which being ill, with its sufferings and impediments, is just what is wanted. The problems which the unconscious sense of guilt has opened up, its connections with morality, education, crime and delinquency, are at present the preferred field of work for psycho-analysts.
[1933a, 4714]

The further our work proceeds and the more deeply our insight penetrates into the mental life of neurotics, the more clearly two new factors force themselves on our notice, which demand the closest attention as sources of resistance. Both of them are completely unknown to the patient, neither of them could be taken into account when our pact was made; nor do they arise from the patient's ego. They may both be embraced under the single name of 'need to be ill or to suffer', but they have different origins though in other respects they are of a kindred nature. The first of these two factors is the sense of guilt or consciousness of guilt, as it is called, though the patient does not feel it and is not aware of it. It is evidently the portion of the resistance contributed by a super-ego that has become particularly severe and cruel. The patient must not become well but must remain ill, for he deserves no better. This resistance does not actually interfere with our intellectual work, but it makes it inoperative; indeed, it often allows us to remove one form of neurotic suffering, but is ready at once to replace it by another, or perhaps by some somatic illness. The sense of guilt also explains the cure or improvement of severe neuroses which we occasionally observe after real misfortunes: all that matters is that the patient should be miserable - in what way is of no consequence. The uncomplaining resignation with which such people often put up with their hard fate is most remarkable, but also revealing. In warding off this resistance we are obliged to restrict ourselves to making it conscious and attempting to bring about the slow demolition of the hostile super-ego.
[1940a [1938], 4989]
Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. On the patient's side a few rational factors work in our favour, such as the need for recovery which has its motive in his sufferings, and the intellectual interest that we may awaken in him in the theories and revelations of psychoanalysis; but of far greater force is the positive transference with which he meets us. Fighting against us, on the other hand, are the negative transference, the ego's resistance due to repression (that is, its unpleasure at having to lay itself open to the hard work imposed on it), the sense of guilt arising from its relation to the super-ego and the need to be ill due to deep-going changes in the economics of his instincts. The share taken by the last two factors decides whether the case is to be regarded as slight or severe. Apart from these, a few other factors may be discerned as having a favourable or unfavourable bearing. A certain psychical inertia, a sluggishness of the libido, which is unwilling to abandon its fixations cannot be welcome to us; the patient's capacity for sublimating his instincts plays a large part and so does his capacity for rising above the crude life of the instincts; so, too, does the relative power of his intellectual functions.

[1940a [1938], 4990]
In yet another group of cases the distinguishing characteristics of the ego, which are to be held responsible as sources of resistance against analytic treatment and as impediments to therapeutic success, may spring from different and deeper roots. Here we are dealing with the ultimate things which psychological research can learn about: the behaviour of the two primal instincts, their distribution, mingling and defusion - things which we cannot think of as being confined to a single province of the mental apparatus, the id, the ego or the super-ego. No stronger impression arises from the resistances during the work of analysis than of there being a force which is defending itself by every possible means against recovery and which is absolutely resolved to hold on to illness and suffering. One portion of this force has been recognized by us, undoubtedly with justice, as the sense of guilt and need for punishment, and has been localized by us in the ego's relation to the super-ego. But this is only the portion of it which is, as it were, psychically bound by the super-ego and thus becomes recognizable; other quotas of the same force, whether bound or free, may be at work in other, unspecified places. If we take into consideration the total picture made up of the phenomena of masochism immanent in so many people, the negative therapeutic reaction and the sense of guilt found in so many neurotics, we shall no longer be able to adhere to the belief that mental events are exclusively governed by the desire for pleasure. These phenomena are unmistakable indications of the presence of a power in mental life which we call the instinct of aggression or of destruction according to its aims, and which we trace back to the original death instinct of living matter. It is not a question of an antithesis between an optimistic and a pessimistic theory of life. Only by the concurrent or mutually opposing action of the two primal instincts - Eros and the death instinct -, never by one or the other alone, can we explain the rich multiplicity of the phenomena of life. [1937c, 5037]
Oh, that is not so hard to understand. Think of the war neurotics, who do not have to serve, precisely because they are ill. In civil life illness can be used as a screen to gloss over incompetence in one's profession or in competition with other people; while in the family it can serve as a means for sacrificing the other members and extorting proofs of their love or for imposing one's will upon them. All of this lies fairly near the surface; we sum it up in the term 'gain from illness'. It is curious, however, that the patient - that is, his ego - nevertheless knows nothing of the whole concatenation of these motives and the actions which they involve. One combats the influence of these trends by compelling the ego to take cognizance of them. But there are other motives, that lie still deeper, for holding on to being ill, which are not so easily dealt with. But these cannot be understood without a fresh journey into psychological theory. [1926e, 4364]

It is less easy to demonstrate the existence of another resistance, our means of combating which are specially inadequate. There are some neurotics in whom, to judge by all their reactions, the instinct of self-preservation has actually been reversed. They seem to aim at nothing other than self-injury and self-destruction. It is possible too that the people who in fact do in the end commit suicide belong to this group. It is to be assumed that in such people far-reaching defusions of instinct have taken place, as a result of which there has been a liberation of excessive quantities of the destructive instinct directed inwards. Patients of this kind are not able to tolerate recovery through our treatment and fight against it with all their strength. But we must confess that this is a case which we have not yet succeeded in completely explaining. [1940a [1938], 4989]
Let us once more glance over the situation which we have reached in our attempt at bringing help to the patient's neurotic ego. That ego is no longer able to fulfil the task set it by the external world (including human society). Not all of its experiences are at its disposal, a large proportion of its store of memories have escaped it. Its activity is inhibited by strict prohibitions from the super-ego, its energy is consumed in vain attempts at fending off the demands of the id. Beyond this, as a result of continuous irruptions by the id, its organization is impaired, it is no longer capable of any proper synthesis, it is torn by mutually opposed urges, by unsettled conflicts and by unsolved doubts. To start with, we get the patient's thus weakened ego to take part in the purely intellectual work of interpretation, which aims at provisionally filling the gaps in his mental assets, and to transfer to us the authority of his super-ego; we encourage it to take up the struggle over each individual demand made by the id and to conquer the resistances which arise in connection with it. At the same time we restore order in the ego by detecting the material and urges which have forced their way in from the unconscious, and expose them to criticism by tracing them back to their origin. We serve the patient in various functions, as an authority and a substitute for his parents, as a teacher and educator; and we have done the best for him if, as analysts, we raise the mental processes in his ego to a normal level, transform what has become unconscious and repressed into preconscious material and thus return it once more to the possession of his ego. If we take into consideration the total picture made up of the phenomena of masochism immanent in so many people, the negative therapeutic reaction and the sense of guilt found in so many neurotics, we shall no longer be able to adhere to the belief that mental events are exclusively governed by the desire for pleasure. These phenomena are unmistakable indications of the presence of a power in mental life which we call the instinct of aggression or of destruction according to its aims, and which we trace back to the original death instinct of living matter. It is not a question of an antithesis between an optimistic and a pessimistic theory of life. Only by the concurrent or mutually opposing action of the two primal instincts - Eros and the death instinct -, never by one or the other alone, can we explain the rich multiplicity of the phenomena of life.

[1937c, 5037]
Here then my material leaves me in the lurch, as might be expected, and I have to fall back on conjectures and inferences. It is well known that in the severer cases of psychoneurosis instances of self-injury are occasionally found as symptoms and that in such cases suicide can never be ruled out as a possible outcome of the psychical conflict. I have now learnt and can prove from convincing examples that many apparently accidental injuries that happen to such patients are really instances of self-injury. What happens is that an impulse to self-punishment, which is constantly on the watch and which normally finds expression in self-reproach or contributes to the formation of a symptom, takes ingenious advantage of an external situation that chance happens to offer, or lends assistance to that situation until the desired injurious effect is brought about. Such occurrences are by no means uncommon in cases even of moderate severity, and they betray the part which the unconscious intention plays by a number of special features - e. g. by the striking composure that the patients retain in what is supposed to be an accident.³

³ In the present state of our civilization self-injury which does not have total self-destruction as its aim has no other choice whatever than to hide itself behind something accidental or to manifest itself by imitating the onset of a spontaneous illness. Formerly self-injury was a customary sign of mourning; at other periods it could express trends towards piety and renunciation of the world.

Instead of a number of cases I will give a detailed report of only a single example from my medical experience. A young married woman broke her leg below the knee in a carriage accident, so that she was bed-ridden for weeks; what was striking was the absence of any expressions of pain and the calmness with which she bore her misfortune. This accident introduced a long and severe neurotic illness of which she was finally cured by psycho-analysis. In treating her I learnt of the circumstances surrounding the accident and of certain events that had preceded it. The young woman was staying with her very jealous husband on the estate of a married sister, in company with her numerous other sisters and brothers with their husbands and wives. One evening in this intimate circle she showed off one of her accomplishments; she gave an accurate performance of the can-can, which was received with hearty applause by her relatives but with scanty satisfaction by her husband, who afterwards whispered to her: 'Carrying on like a tart again!' The remark struck home - we will not enquire whether it was only on account of the dancing display. She spent a restless night. Next morning she felt a desire to go for a drive. She selected the horses herself, refusing one pair and asking for another. Her youngest sister wanted her baby and its nurse to go in the carriage with her; my patient vigorously opposed this. During the drive she showed signs of nerves; she warned the coachman that the horses were growing skittish, and when the restless animals were really causing a moment's difficulty she jumped out in a fright and broke her leg, while the others who stayed in the carriage were unharmed. Although after learning these details we can hardly remain in doubt that this accident was really contrived, we cannot fail to admire the skill which forced chance to mete out a punishment that fitted the crime so well. For it had now been made impossible for her to dance the can-can for quite a long time.
Anyone who believes in the occurrence of half-intentional self-injury - if I may use a clumsy expression - will be prepared also to assume that in addition to consciously intentional suicide there is such a thing as half-intentional self-destruction (self-destruction with an unconscious intention), capable of making skilful use of a threat to life and of disguising it as a chance mishap. There is no need to think such self-destruction rare. For the trend to self-destruction is present to a certain degree in very many more human beings than those in whom it is carried out; self-injuries are as a rule a compromise between this instinct and the forces that are still working against it, and even where suicide actually results, the inclination to suicide will have been present for a long time before in lesser strength or in the form of an unconscious and suppressed trend.

[1901b, 1260]

Even a conscious intention of committing suicide chooses its time, means and opportunity; and it is quite in keeping with this that an unconscious intention should wait for a precipitating occasion which can take over a part of the causation and, by engaging the subject's defensive forces, can liberate the intention from their pressure.¹ The views I am putting forward here are far from being idle ones. I have learned of more than one apparently chance mishap (on horseback or in a carriage) the details of which justify a suspicion that suicide was unconsciously allowed to come about. For example, an officer, riding in a race with some fellow-officers, fell from his horse and was so severely injured that he died some days later. His behaviour on regaining consciousness was striking in some ways; and his previous behaviour had been even more remarkable. He had been deeply depressed by the death of his beloved mother, had had fits of sobbing in the company of his fellow officers, and to his trusted friends had spoken of being weary of life. He had wanted to leave the service to take part in a war in Africa which had not interested him previously;² formerly a dashing rider, he now avoided riding whenever possible. Finally, before the race, from which he could not withdraw, he expressed gloomy forebodings; with the view that we hold in these matters, it will not remain a surprise to us that these forebodings turned out to be justified. I shall be told that it is not to be wondered at if a person in such a state of nervous depression cannot manage a horse as well as on normal days. I quite agree; but the mechanism of the motor inhibition produced by this state of 'nerves' should, I think, be looked for in the intention of self-destruction that I am insisting on.

[1901b, 1261]

² It is evident that conditions on a field of battle are such as to come to the help of a conscious intention to commit suicide which nevertheless shuns the direct way. Compare the words of the Swedish captain concerning the death of Max Piccolomini in Wallensteins Tod: 'They say he wanted to die.'

[1901b, 1261]

S. Ferenczi of Budapest has handed over to me for publication the analysis of an ostensibly accidental injury by shooting, which he explains as an unconscious attempt at suicide. I can only declare my agreement with his view of the matter:

[1901b, 1262]
Gentlemen, - I have an impression that, in spite of all the valuable material that has been brought before us in this discussion, we have not reached a decision on the problem that interests us. We were anxious above all to know how it becomes possible for the extraordinarily powerful life instinct to be overcome: whether this can only come about with the help of a disappointed libido or whether the ego can renounce its self-preservation for its own egoistic motives. It may be that we have failed to answer this psychological question because we have no adequate means of approaching it. We can, I think, only take as our starting-point the condition of melancholia, which is so familiar to us clinically, and a comparison between it and the affect of mourning. The affective processes in melancholia, however, and the vicissitudes undergone by the libido in that condition, are totally unknown to us. Nor have we arrived at a psycho-analytic understanding of the chronic affect of mourning. Let us suspend our judgement till experience has solved this problem.

¹ We find that impulses to suicide in a neurotic turn out regularly to be self-punishments for wishes for someone else's death.
[1910g, 2381]

In mourning we found that the inhibition and loss of interest are fully accounted for by the work of mourning in which the ego is absorbed. In melancholia, the unknown loss will result in a similar internal work and will therefore be responsible for the melancholic inhibition. The difference is that the inhibition of the melancholic seems puzzling to us because we cannot see what it is that is absorbing him so entirely. The melancholic displays something else besides which is lacking in mourning - an extraordinary diminution in his self-regard, an impoverishment of his ego on a grand scale. In mourning it is the world which has become poor and empty; in melancholia it is the ego itself. The patient represents his ego to us as worthless, incapable of any achievement and morally despicable; he reproaches himself, vilifies himself and expects to be cast out and punished. He abases himself before everyone and commiserates with his own relatives for being connected with anyone so unworthy. He is not of the opinion that a change has taken place in him, but extends his self-criticism back over the past; he declares that he was never any better. This picture of a delusion of (mainly moral) inferiority is completed by sleeplessness and refusal to take nourishment, and - what is psychologically very remarkable - by an overcoming of the instinct which compels every living thing to cling to life.
[1917e, 3043]

¹ That the various methods of suicide can represent sexual wish-fulfilments has long been known to all analysts. (To poison oneself = to become pregnant; to drown - to bear a child; to throw oneself from a height = to be delivered of a child.)
[1920a, 3851]

The question which we put off answering runs as follows: How is it that the super-ego manifests itself essentially as a sense of guilt (or rather, as criticism - for the sense of guilt is the perception in the ego answering to this criticism) and moreover develops such extraordinary harshness and severity towards the ego? If we turn to melancholia first, we find that the excessively strong super-ego which has obtained a hold upon consciousness rages against the ego with merciless violence, as if it had taken possession of the whole of the sadism available in the person concerned. Following our view of sadism, we should say that the destructive component had entrenched itself in the super-ego and turned against the ego. What is now holding sway in the super-ego is, as it were, a pure culture of the death instinct, and in fact it often enough succeeds in driving the ego into death, if the latter does not fend off its tyrant in time by the change round into mania.
[1923b, 3987]
The reproaches of conscience in certain forms of obsessional neurosis are as distressing and tormenting, but here the situation is less perspicuous. It is noteworthy that the obsessional neurotic, in contrast to the melancholic, never in fact takes the step of self-destruction; it is as though he were immune against the danger of suicide, and he is far better protected from it than the hysteric. We can see that what guarantees the safety of the ego is the fact that the object has been retained. In obsessional neurosis it has become possible, through a regression to the pregenital organization, for the love-impulses to transform themselves into impulses of aggression against the object. Here again the instinct of destruction has been set free and it seeks to destroy the object, or at least it appears to have that intention. These purposes have not been adopted by the ego and it struggles against them with reaction-formations and precautionary measures; they remain in the id. The super-ego, however, behaves as if the ego were responsible for them and shows at the same time by the seriousness with which it chastises these destructive intentions that they are no mere semblance evoked by regression but an actual substitution of hate for love. Helpless in both directions, the ego defends itself vainly, alike against the instigations of the murderous id and against the reproaches of the punishing conscience. It succeeds in holding in check at least the most brutal actions of both sides; the first outcome is interminable self-torment, and eventually there follows a systematic torturing of the object, in so far as it is within reach.
[1923b, 3987]

The third form of masochism, moral masochism, is chiefly remarkable for having loosened its connection with what we recognize as sexuality. All other masochistic sufferings carry with them the condition that they shall emanate from the loved person and shall be endured at his command. This restriction has been dropped in moral masochism. The suffering itself is what matters; whether it is decreed by someone who is loved or by someone who is indifferent is of no importance. It may even be caused by impersonal powers or by circumstances; the true masochist always turns his cheek whenever he has a chance of receiving a blow. It is very tempting, in explaining this attitude, to leave the libido out of account and to confine oneself to assuming that in this case the destructive instinct has been turned inwards again and is now raging against the self; yet there must be some meaning in the fact that linguistic usage has not given up the connection between this norm of behaviour and erotism and calls these self-injurers masochists too.
[1924c, 4077]

¹ It may quite often happen that although a danger-situation is correctly estimated in itself, a certain amount of instinctual anxiety is added to the realistic anxiety. In that case the instinctual demand before whose satisfaction the ego recoils is a masochistic one: the instinct of destruction directed against the subject himself. Perhaps an addition of this kind explains cases in which reactions of anxiety are exaggerated, inexpedient or paralysing. Phobias of heights (windows, towers, precipices and so on) may have some such origin. Their hidden feminine significance is closely connected with masochism.
[1926d, 4320]
For, whether a man is a homosexual or a necrophilic, a hysterical suffering from anxiety, an obsessional neurotic cut off from society, or a raving lunatic, the 'Individual Psychologist' of the Adlerian school will declare that the impelling motive of his condition is that he wishes to assert himself, to overcompensate for his inferiority, to remain 'on top', to pass from the feminine to the masculine line. In my young student days we used to hear something very much the same in the out-patients' department when a case of hysteria was introduced: hysterical patients, we were told, produce their symptoms to make themselves interesting, to draw attention to themselves. It is a remarkable thing how these ancient pieces of wisdom keep on cropping up. But even at that time this fragment of psychology did not seem to cover the riddle of hysteria. It left unexplained, for instance, why the patients used no other methods for attaining their purpose. There must, of course, be something correct in this theory of the 'Individual Psychologists': a small particle is taken for the whole. The self-preservative instinct will try to profit by every situation; the ego will seek to turn even illness to its advantage. In psycho-analysis this is known as the 'secondary gain from illness'. Though, indeed, when we think of the facts of masochism, of the unconscious need for punishment and of neurotic self-injury, which make plausible the hypothesis of there being instinctual impulses that run contrary to self-preservation, we even feel shaken in our belief in the general validity of the commonplace truth on which the theoretical structure of Individual Psychology is erected. But a theory such as this is bound to be very welcome to the great mass of the people, a theory which recognizes no complications, which introduces no new concepts that are hard to grasp, which knows nothing of the unconscious, which gets rid at a single blow of the universally oppressive problem of sexuality and which restricts itself to the discovery of the artifices by which people seek to make life easy. For the mass of the people themselves take things easily: they call for no more than a single reason by way of explanation, they do not thank science for its diffuseness, they want to have simple solutions and to know that problems are solved. When we consider how very far Individual Psychology goes in meeting these demands, we cannot suppress the recollection of a sentence in Wallenstein:

[1933a, 4743]

It is less easy to demonstrate the existence of another resistance, our means of combating which are specially inadequate. There are some neurotics in whom, to judge by all their reactions, the instinct of self-preservation has actually been reversed. They seem to aim at nothing other than self-injury and self-destruction. It is possible too that the people who in fact do in the end commit suicide belong to this group. It is to be assumed that in such people far-reaching defusions of instinct have taken place, as a result of which there has been a liberation of excessive quantities of the destructive instinct directed inwards. Patients of this kind are not able to tolerate recovery through our treatment and fight against it with all their strength. But we must confess that this is a case which we have not yet succeeded in completely explaining. [1940a [1938], 4989]
In none of my women patients, to take an example, have I failed to come upon this dream of the death of a brother or sister, which tallies with an increase in hostility. I have only found a single exception; and it was easy to interpret this as a confirmation of the rule. On one occasion during an analytic session I was explaining this subject to a lady, since in view of her symptom its discussion seemed to me relevant. To my astonishment she replied that she had never had such a dream. Another dream, however, occurred to her, which ostensibly had no connection with the topic - a dream which she had first dreamt when she was four years old and at that time the youngest of the family, and which she had dreamt repeatedly since: A whole crowd of children - all her brothers, sisters and cousins of both sexes - were romping in a field. Suddenly they all grew wings, flew away and disappeared. She had no idea what this dream meant; but it is not hard to recognize that in its original form it had been a dream of the death of all her brothers and sisters, and had been only slightly influenced by the censorship. I may venture to suggest the following analysis. On the occasion of the death of one of this crowd of children (in this instance the children of two brothers had been brought up together as a single family) the dreamer, not yet four years old at the time, must have asked some wise grown-up person what became of children when they were dead. The reply must have been: 'They grow wings and turn into little angels.' In the dream which followed upon this piece of information all the dreamer's brothers and sisters had wings like angels and - which is the main point - flew away. Our little baby-killer was left alone, strange to say: the only survivor of the whole crowd! We can hardly be wrong in supposing that the fact of the children romping in field before flying away points to butterflies. It is as though the child was led by the same chain of thought as the peoples of antiquity to picture the soul as having a butterfly's wings.
[1900a, 732]
I do not propose at this point to discuss how it is that in such circumstances as these a recent occasion for the generation of an affect can hark back to an infantile situation and be replaced by that situation as far as the production of affect is concerned. This question forms part of the psychology of unconscious thinking, and would find its proper place in a psychological elucidation of the neuroses. For the purposes of dream-interpretation let us assume that a childhood memory arose, or was constructed in phantasy, with some such content as the following. The two children had a dispute about some object. (What the object was may be left an open question, though the memory or pseudo-memory had a quite specific one in view.) Each of them claimed to have got there before the other and therefore to have a better right to it. They came to blows and might prevail over right. On the evidence of the dream, I may myself have been aware that I was in the wrong ('I myself noticed the mistake'). However, this time I was the stronger and remained in possession of the field. The vanquished party hurried to his grandfather - my father - and complained about me, and I defended myself in the words which I know from my father's account: 'I hit him 'cos he hit me.' This memory, or more probably phantasy, which came into my mind while I was analysing the dream - without further evidence I myself could not tell how - constituted an intermediate element in the dream-thoughts, which gathered up the emotions raging in them as a well collects the water that flows into it. From this point the dream-thoughts proceeded along some such lines as these: 'It serves you right if you had to make way for me. Why did you try to push me out of the way? I don't need you, I can easily find someone else to play with', and so on. These thoughts now entered upon the paths which led to their representation in the dream. There had been a time when I had had to reproach my friend Josef for an attitude of this same kind: 'Ôte-toi que je m'y mette!' He had followed in my footsteps as demonstrator in Brücke's laboratory, but promotion there was slow and tedious. Neither of Brücke's two assistants was inclined to budge from his place, and youth was impatient. My friend, who knew that he could not expect to live long, and whom no bonds of intimacy attached to his immediate superior, sometimes gave loud expression to his impatience, and, since this superior was seriously ill, P.'s wish to have him out of the way might have an uglier meaning than the mere hope for the man's promotion. Not unnaturally, a few years earlier, I myself had nourished a still livelier wish to fill a vacancy. Wherever there is rank and promotion the way lies open for wishes that call for suppression. Shakespeare's Prince Hal could not, even at his father's sick-bed, resist the temptation of trying on the crown. But, as was to be expected, the dream punished my friend, and not me, for this callous wish.²

[1900a, 924]

'As he was ambitious, I slew him.' As he could not wait for the removal of another man, he was himself removed. These had been my thoughts immediately after I attended the unveiling at the University of the memorial - not to him but to the other man. Thus a part of the satisfaction I felt in the dream was to be interpreted: 'A just punishment! It serves you right!' [1900a, 924]
I know that the subject would merit the most exhaustive treatment; but I shall here do no more than give the analysis of a single case of 'déjà vu' where the feeling was characterized by especial intensity and persistence. A lady who is now thirty-seven claimed to have a most distinct memory of having at the age of twelve and a half paid her first visit to some school friends in the country. When she entered the garden, she had an immediate feeling of having been there before. This feeling was repeated when she went into the reception rooms, so that she felt she knew in advance what room would be the next one, what view there would be from it, and so on. But the possibility that this feeling of familiarity could have owed its origin to an earlier visit to the house and garden, perhaps one in her earliest childhood, was absolutely ruled out and was disproved as a result of her questioning her parents. The lady who reported this was not in search of any psychological explanation, but saw the occurrence of this feeling as a prophetic indication of the significance for her emotional life which these same school friends later acquired. However, a consideration of the circumstances in which the phenomenon occurred in her shows us the way to another view of the matter. At the time when she paid the visit she knew that these girls had an only brother, who was seriously ill. During the visit she actually set eyes on him, though he looked very ill and she said to herself that he would die soon. Now, her own only brother had been dangerously ill with diphtheria a few months earlier; during his illness she had spent several weeks away from her parents' house, staying with a relative. She believed that her brother had been with her on this visit to the country; she even thought it had been his first considerable journey after his illness; but her memory was remarkably uncertain on these points while of all the other details, and in particular of the dress she was wearing that day, she had an ultra-clear picture. Anyone who is well-informed will find no difficulty in concluding from these hints that the expectation that her brother would die had at that time played an important part in the girl's thoughts and either had never become conscious or, after the favourable termination of the illness, had succumbed to energetic repression. If things had turned out otherwise, she would have had to wear a different dress - mourning. She found an analogous situation in the home of her friends, whose only brother was in danger of dying soon, as in fact he did shortly after. She ought to have remembered consciously that she herself had lived through this situation a few months before: instead of remembering it - which was prevented by repression - she transferred her feeling of remembering something to her surroundings, the garden and the house, and fell a victim to the 'fausse reconnaissance' of having seen all this exactly the same once before. From the fact that repression occurred we may conclude that her former expectation of her brother's death had not been far removed from a wishful phantasy. She would then have been the only child. In her later neurosis she suffered most severely from a fear of losing her parents, behind which, as usual, analysis was able to reveal the unconscious wish with the same content.

[1901b, 1336]
But Hans was not by any means a bad character; he was not even one of those children who at his age still give free play to the propensity towards cruelty and violence which is a constituent of human nature. On the contrary, he had an unusually kind-hearted and affectionate disposition; his father reported that the transformation of aggressive tendencies into feelings of pity took place in him at a very early age. Long before the phobia he had become uneasy when he saw the horses in a merry-go-round being beaten; and he was never unmoved if any one wept in his presence. At one stage in the analysis a piece of suppressed sadism made its appearance in a particular context:¹ but it was suppressed sadism, and we shall presently have to discover from the content what it stood for and what it was meant to replace. And Hans deeply loved the father against whom he cherished these death-wishes; and while his intellect demurred to such a contradiction,² he could not help demonstrating the fact of its existence, by hitting his father and immediately afterwards kissing the place he had hit. We ourselves, too, must guard against making a difficulty of such a contradiction. The emotional life of man is in general made up of pairs of contraries such as these.³ Indeed, if it were not so, repressions and neuroses would perhaps never come about. In the adult these pairs of contrary emotions do not as a rule become simultaneously conscious except at the climaxes of passionate love; at other times they usually go on suppressing each other until one of them succeeds in keeping the other altogether out of sight. But in children they can exist peaceably side by side for quite a considerable time.

[1909b, 2097]

The most important influence upon the course of Hans's psychosexual development was the birth of a baby sister when he was three and a half years old. That event accentuated his relations to his parents and gave him some insoluble problems to think about; and later, as he watched the way in which the infant was looked after, the memory-traces of his own earliest experiences of pleasure were revived in him. This influence, too, is a typical one: in an unexpectedly large number of life-histories, normal as well as pathological, we find ourselves obliged to take as our starting-point an outburst of sexual pleasure and sexual curiosity connected, like this one, with the birth of the next child. Hans's behaviour towards the new arrival was just what I have described in The Interpretation of Dreams. In his fever a few days later he betrayed how little he liked the addition to the family. Affection for his sister might come later,¹ but his first attitude was hostility. From that time forward fear that yet another baby might arrive found a place among his conscious thoughts. In the neurosis, his hostility, already suppressed, was represented by a special fear - a fear of the bath. In the analysis he gave undisguised expression to his death-wish against his sister, and was not content with allusions which required supplementing by his father. His inner conscience did not consider this wish so wicked as the analogous one against his father; but it is clear that in his unconscious he treated both persons in the same way, because they both took his mummy away from him, and interfered with his being alone with her.

[1909b, 2098]
He admitted that all of this sounded quite plausible, but he was naturally not in the very least convinced by it.¹ He would venture to ask, he said, how it was that an idea of this kind could have remissions, how it could appear for a moment when he was twelve years old, and again when he was twenty, and then once more two years later, this time for good. He could not believe that his hostility had been extinguished in the intervals, and yet during them there had been no sign of self-reproaches. - To this I replied that whenever any one asked a question like that, he was already prepared with an answer; he needed only to be encouraged to go on talking. - He then proceeded, somewhat disconnectedly as it seemed, to say that he had been his father's best friend, and that his father had been his. Except on a few subjects, upon which fathers and sons usually hold aloof from one another - (What could he mean by that?) -, there had been a greater intimacy between them than there was between him and his best friend. As regards the lady for whose sake he had sacrificed his father in that idea of his, it was true that he had loved her very much, but he had never felt really sensual wishes towards her, such as he had constantly had in his childhood. Altogether, in his childhood his sensual impulses had been much stronger than during his puberty. - At this I told him I thought he had now produced the answer we were waiting for, and had at the same time discovered the third great characteristic of the unconscious. The source from which his hostility to his father derived its indestructibility was evidently something in the nature of sensual desires, and in that connection he must have felt his father as in some way or other an interference. A conflict of this kind, I added, between sensuality and childish love was entirely typical. The remissions he had spoken of had occurred because the premature explosion of his sensual feelings had had as its immediate consequence a considerable diminution of their violence. It was not until he was once more seized with intense erotic desires that his hostility reappeared again owing to the revival of the old situation. I then got him to agree that I had not led him on to the subject either of childhood or of sex, but that he had raised them both of his own free will. - He then went on to ask why he had not simply come to a decision, at the time he was in love with the lady, that his father's interference with that love could not for a moment weigh against his love of his father. - I replied that it was scarcely possible to destroy a person in absentia. Such a decision would only have been possible if the wish that he took objection to had made its first appearance on that occasion; whereas, as a matter of fact, it was a long-repressed wish, towards which he could not behave otherwise than he had formerly done, and which was consequently immune from destruction. This wish (to get rid of his father as being an interference) must have originated at a time when circumstances had been very different - at a time, perhaps, when he had not loved his father more than the person whom he desired sensually, or when he was incapable of making a clear decision. It must have been in his very early childhood, therefore, before he had reached the age of six, and before the date at which his memory became continuous; and things must have remained in the same state ever since. - With this piece of construction our discussion was broken off for the time being.

[1909d, 2145]

At the next session, which was the seventh, he took up the same subject once more. He could not believe, he said, that he had ever entertained such a wish against his father. He remembered a story of Sudermann's, he went on, that had made a deep impression upon him. In this story there was a woman who, as she sat by her sister's sick-bed, felt a wish that her sister should die so that she herself might marry her husband. The woman thereupon committed suicide, thinking she was not fit to live after being guilty of such baseness. He could understand this, he said, and it would be only right if his thoughts were the death of him, for he deserved nothing less.¹ - I remarked that it was well known to us that patients derived a certain satisfaction from their sufferings, so that in reality they all resisted their own recovery to some extent. He must never lose sight of the fact that a treatment like ours proceeded to the accompaniment of a constant resistance; I should be repeatedly reminding him of this fact.

[1909d, 2146]
He then went on to say that he would like to speak of a criminal act, whose author he did not recognize as himself, though he quite clearly recollected committing it. He quoted a saying of Nietzsche's:² "I did this," says my Memory. "I cannot have done this," says my Pride and remains inexorable. In the end - Memory yields. 'Well,' he continued, 'my memory has not yielded on this point.' - 'That is because you derive pleasure from your self-reproaches as a means of self-punishment.' - 'My younger brother - I am really very fond of him now, and he is causing me a great deal of worry just at present, for he wants to make what I consider a preposterous match; I have thought before now of going and killing the person concerned so as to prevent his marrying her - well, my younger brother and I used to fight a lot when we were children. We were very fond of each other at the same time, and were inseparable; but I was plainly filled with jealousy, as he was the stronger and better-looking of the two and consequently the favourite.' - 'Yes. You have already given me a description of a scene of jealousy in connection with Fräulein Lina.' - 'Very well then, on some such occasion (it was certainly before I was eight years old, for I was not going to school yet, which I began to do when I was eight) - on some such occasion, this is what I did. We both had toy guns of the usual make. I loaded mine with the ram rod and told him that if he looked up the barrel he would see something. Then, while he was looking in, I pulled the trigger. He was hit on the forehead and not hurt; but I had meant to hurt him very much indeed. Afterwards I was quite beside myself, and threw myself on the ground and asked myself however I could have done such a thing. But I did do it.' - I took the opportunity of urging my case. If he had preserved the recollection of an action so foreign to him as this, he could not, I maintained, deny the possibility of something similar, which he had now forgotten entirely, having happened at a still earlier age in relation to his father. - He then told me he was aware of having felt other vindictive impulses, this time towards the lady he admired so much, of whose character he painted a glowing picture. It might be true, he said, that she could not love easily; but she was reserving her whole self for the one man to whom she would some day belong. She did not love him. When he had become certain of that, a conscious phantasy had taken shape in his mind of how he should grow very rich and marry some one else, and should then take her to call on the lady in order to hurt her feelings. But at that point the phantasy had broken down, for he had been obliged to own to himself that the other woman, his wife, was completely indifferent to him; then his thoughts had become confused, till finally it had been clearly borne in upon him that this other woman would have to die. In this phantasy, just as in his attempt upon his brother, he recognized the quality of cowardice which was so particularly horrible to him.³ - In the further course of our conversation I pointed out to him that he ought logically to consider himself as in no way responsible for any of these traits in his character; for all of these reprehensible impulses originated from his infancy, and were only derivatives of his infantile character surviving in his unconscious; and he must know that moral responsibility could not be applied to children. It was only by a process of development, I added, that a man, with his moral responsibility, grew up out of the sum of his infantile predispositions.⁴ He expressed a doubt, however, whether all his evil impulses had originated from that source. But I promised to prove it to him in the course of the treatment.

[1909d, 2146]
By all accounts our patient's father was a most excellent man. Before his marriage he had been a non-commissioned officer, and, as relics of that period of his life, he had retained a straightforward soldierly manner and a *penchant* for using downright language. Apart from those virtues which are celebrated upon every tombstone, he was distinguished by a hearty sense of humour and a kindly tolerance towards his fellow-men. That he could be hasty and violent was certainly not inconsistent with his other qualities, but was rather a necessary complement to them; but it occasionally brought down the most severe castigations upon the children, while they were young and naughty. When they grew up, however, he differed from other fathers in not attempting to exalt himself into a sacrosanct authority, but in sharing with them a knowledge of the little failures and misfortunes of his life with good-natured candour. His son was certainly not exaggerating when he declared that they had lived together like the best of friends, except upon a single point (p. 2145). And it must no doubt have been in connection with that very point that thoughts about his father's death had occupied his mind when he was a small boy with unusual and undue intensity (p. 2133), and that those thoughts made their appearance in the wording of the obsessional ideas of his childhood; and it can only have been in that same connection that he was able to wish for his father's death, in order that a certain little girl's sympathy might be aroused and that she might behave more kindly towards him (p. 2144). [1909d, 2158]

There can be no question that there was something in the sphere of sexuality that stood between the father and son, and that the father had come into some sort of opposition to the son's prematurely developed erotic life. Several years after his father's death, the first time he experienced the pleasurable sensations of copulation, an idea sprang into his mind: 'This is glorious! One might murder one's father for this!' This was at once an echo and an elucidation of the obsessional ideas of his childhood. Moreover, his father, shortly before his death, had directly opposed what later became our patient's dominating passion. He had noticed that his son was always in the lady's company, and had advised him to keep away from her, saying that it was imprudent of him and that he would only make a fool of himself. [1909d, 2158]

The ego, freed from all ethical bonds, also finds itself at one with all the demands of sexual desire, even those which have long been condemned by our aesthetic upbringing and those which contradict all the requirements of moral restraint. The desire for pleasure - the 'libido', as we call it - chooses its objects without inhibition, and by preference, indeed, the forbidden ones: not only other men's wives, but above all incestuous objects, objects sanctified by the common agreement of mankind, a man's mother and sister, a woman's father and brother. (The dream of our fifty-year-old lady, too, was incestuous; her libido was unmistakably directed to her son.) Lusts which we think of as remote from human nature show themselves strong enough to provoke dreams. Hatred, too, rages without restraint. Wishes for revenge and death directed against those who are nearest and dearest in waking life, against the dreamer's parents, brothers and sisters, husband or wife, and his own children are nothing unusual. These censored wishes appear to rise up out of a positive Hell; after they have been interpreted when we are awake, no censorship of them seems to us too severe. [1916-1917, 3237]
When other children appear on the scene the Oedipus complex is enlarged into a family complex. This, with fresh support from the egoistic sense of injury, gives grounds for receiving the new brothers or sisters with repugnance and for unhesitatingly getting rid of them by a wish. It is even true that as a rule children are far readier to give verbal expression to these feelings of hate than to those arising from the parental complex. If a wish of this kind is fulfilled and the undesired addition to the family is removed again shortly afterwards by death, we can discover from a later analysis what an important experience this death has been to the child, even though it need not have remained fixed in his memory. A child who has been put into second place by the birth of a brother or sister, and who is now for the first time almost isolated from his mother, does not easily forgive her this loss of place; feelings which in an adult would be described as greatly embittered arise in him and are often the basis of a permanent estrangement. We have already mentioned that the child's sexual researches, with all their consequences, usually follow from this vital experience of his. As these brothers and sisters grow up, the boy's attitude to them undergoes very significant transformations. He may take his sister as a love-object by way of substitute for his faithless mother. Where there are several brothers, all of them courting a younger sister, situations of hostile rivalry, which are so important for later life, arise already in the nursery. A little girl may find in her elder brother a substitute for her father who no longer takes an affectionate interest in her as he did in her earliest years. Or she may take a younger sister as a substitute for the baby she has vainly wished for from her father.

[1916-1917, 3400]
We are led into quite another realm of explanation by the analysis of the attempt at suicide, which I must regard as seriously intended, and which, incidentally, considerably improved her position both with her parents and with the lady she loved. She went for a walk with her one day in a part of the town and at an hour at which she was not unlikely to meet her father on his way from his office. So it turned out. Her father passed them in the street and cast a furious look at her and her companion, about whom he had by that time come to know. A few moments later she flung herself into the railway cutting. The explanation she gave of the immediate reasons determining her decision sounded quite plausible. She had confessed to the lady that the man who had given them such an irate glance was her father, and that he had absolutely forbidden their friendship. The lady became incensed at this and ordered the girl to leave her then and there, and never again to wait for her or to address her - the affair must now come to an end. In her despair at having thus lost her loved one for ever, she wanted to put an end to herself. The analysis, however, was able to disclose another and deeper interpretation behind the one she gave, which was confirmed by the evidence of her own dreams. The attempted suicide was, as might have been expected, determined by two other motives besides the one she gave: it was the fulfilment of a punishment (self-punishment), and the fulfilment of a wish. As the latter it meant the attainment of the very wish which, when frustrated, had driven her into homosexuality - namely, the wish to have a child by her father, for now she 'fell' through her father's fault.¹ The fact that at that moment the lady had spoken in just the same terms as her father, and had uttered the same prohibition, forms the connecting link between this deep interpretation and the superficial one of which the girl herself was conscious. From the point of view of self-punishment the girl's action shows us that she had developed in her unconscious strong death-wishes against one or other of her parents - perhaps against her father, out of revenge for impeding her love, but more probably against her mother too, when she was pregnant with the little brother. For analysis has explained the enigma of suicide in the following way: probably no one finds the mental energy required to kill himself unless, in the first place, in doing so he is at the same time killing an object with whom he has identified himself, and, in the second place, is turning against himself a death-wish which had been directed against someone else. Nor need the regular discovery of these unconscious death-wishes in those who have attempted suicide surprise us (any more than it ought to make us think that it confirms our deductions), since the unconscious of all human beings is full enough of such death-wishes, even against those they love.² Since the girl identified herself with her mother, who should have died at the birth of the child denied to herself, this punishment-fulfilment itself was once again a wish-fulfilment. Finally, the discovery that several quite different motives, all of great strength, must have co-operated to make such a deed possible is only in accordance with what we should expect.

[1920a, 3851]

The dead brother, however, was not only our correspondent's imaginary child; he also represented a rival whom she had regarded with hatred from the time of his birth. By far the greater number of all telepathic intimations relate to death or the possibility of death; when patients under analysis keep telling us of the frequency and infallibility of their gloomy forebodings, we can with equal regularity show them that they are fostering particularly strong death-wishes in their unconscious against their nearest relations and have long been thus suppressing them. The patient whose history I related in 1909¹ was an example to the point; he was called a 'carrion crow' by his relations. But when this kindly and highly intelligent man - who has since himself perished in the war - began to make progress towards recovery, he himself gave me considerable assistance in clearing up his own psychological conjuring tricks. In the same way, the account given in our first correspondent's letter, of how he and his three brothers had received the news of their youngest brother's death as a thing they had long been inwardly aware of, appears to need no other explanation. The elder brothers would all have been equally convinced of the superfluousness of the youngest arrival.
[1922a, 3896]
Here is one instance. It is well known that at all periods there have been, as there still are, people who can take as their sexual objects members of their own sex as well as of the opposite one, without the one trend interfering with the other. We call such people bisexuals, and we accept their existence without feeling much surprise about it. We have come to learn, however, that every human being is bisexual in this sense and that his libido is distributed, either in a manifest or a latent fashion, over objects of both sexes. But we are struck by the following point. Whereas in the first class of people the two trends have got on together without clashing, in the second and more numerous class they are in a state of irreconcilable conflict. A man's heterosexuality will not put up with any homosexuality, and vice versa. If the former is the stronger it succeeds in keeping the latter latent and forcing it away from satisfaction in reality. On the other hand, there is no greater danger for a man's heterosexual function than its being disturbed by his latent homosexuality. We might attempt to explain this by saying that each individual only has a certain quota of libido at his disposal, for which the two rival trends have to struggle. But it is not clear why the rivals do not always divide up the available quota of libido between them according to their relative strength, since they are able to do so in a number of cases. We are forced to the conclusion that the tendency to a conflict is something special, something which is newly added to the situation, irrespective of the quantity of libido. An independently-emerging tendency to conflict of this sort can scarcely be attributed to anything but the intervention of an element of free aggressiveness.

If we recognize the case we are discussing as an expression of the destructive or aggressive instinct, the question at once arises whether this view should not be extended to other instances of conflict, and, indeed, whether all that we know about psychical conflict should not be revised from this new angle. After all, we assume that in the course of man's development from a primitive state to a civilized one his aggressiveness undergoes a very considerable degree of internalization or turning inwards; if so, his internal conflicts would certainly be the proper equivalent for the external struggles which have then ceased. I am well aware that the dualistic theory according to which an instinct of death or of destruction or aggression claims equal rights as a partner with Eros as manifested in the libido, has found little sympathy and has not really been accepted even among psycho-analysts. This made me all the more pleased when not long ago I came upon this theory of mine in the writings of one of the great thinkers of ancient Greece. I am very ready to give up the prestige of originality for the sake of such a confirmation, especially as I can never be certain, in view of the wide extent of my reading in early years, whether what I took for a new creation might not be an effect of cryptomnesia.
The view expressed above is supported by the following considerations. Man is an animal organism with (like others) an unmistakably bisexual disposition. The individual corresponds to a fusion of two symmetrical halves, of which, according to some investigators, one is purely male and the other female. It is equally possible that each half was originally hermaphrodite. Sex is a biological fact which, although it is of extraordinary importance in mental life, is hard to grasp psychologically. We are accustomed to say that every human being displays both male and female instinctual impulses, needs and attributes; but though anatomy, it is true, can point out the characteristic of maleness and femaleness, psychology cannot. For psychology the contrast between the sexes fades away into one between activity and passivity, in which we far too readily identify activity with maleness and passivity with femaleness, a view which is by no means universally confirmed in the animal kingdom. The theory of bisexuality is still surrounded by many obscurities and we cannot but feel it as a serious impediment in psycho-analysis that it has not yet found any link with the theory of the instincts. However this may be, if we assume it as a fact that each individual seeks to satisfy both male and female wishes in his sexual life, we are prepared for the possibility that those demands are not fulfilled by the same object, and that they interfere with each other unless they can be kept apart and each impulse guided into a particular channel that is suited to it. Another difficulty arises from the circumstance that there is so often associated with the erotic relationship, over and above its own sadistic components, a quota of plain inclination to aggression. The love-object will not always view these complications with the degree of understanding and tolerance shown by the peasant woman who complained that her husband did not love her any more, since he had not beaten her for a week.

Here is one instance. It is well known that at all periods there have been, as there still are, people who can take as their sexual objects members of their own sex as well as of the opposite one, without the one trend interfering with the other. We call such people bisexuals, and we accept their existence without feeling much surprise about it. We have come to learn, however, that every human being is bisexual in this sense and that his libido is distributed, either in a manifest or a latent fashion, over objects of both sexes. But we are struck by the following point. Whereas in the first class of people the two trends have got on together without clashing, in the second and more numerous class they are in a state of irreconcilable conflict. A man's heterosexuality will not put up with any homosexuality, and vice versa. If the former is the stronger it succeeds in keeping the latter latent and forcing it away from satisfaction in reality. On the other hand, there is no greater danger for a man's heterosexual function than its being disturbed by his latent homosexuality. We might attempt to explain this by saying that each individual only has a certain quota of libido at his disposal, for which the two rival trends have to struggle. But it is not clear why the rivals do not always divide up the available quota of libido between them according to their relative strength, since they are able to do so in a number of cases. We are forced to the conclusion that the tendency to a conflict is something special, something which is newly added to the situation, irrespective of the quantity of libido. An independently-emerging tendency to conflict of this sort can scarcely be attributed to anything but the intervention of an element of free aggressiveness.
I am tempted to extract a first advantage from this more restricted view of the case by applying it to the process of repression. As we have learned, neurotic symptoms are, in their essence, substitutive satisfactions for unfulfilled sexual wishes. In the course of our analytic work we have discovered to our surprise that perhaps every neurosis conceals a quota of unconscious sense of guilt, which in its turn fortifies the symptoms by making use of them as a punishment. It now seems plausible to formulate the following proposition. When an instinctual trend undergoes repression, its libidinal elements are turned into symptoms, and its aggressive components into a sense of guilt. Even if this proposition is only an average approximation to the truth, it is worthy of our interest.

[1930a, 4527]
In the second place, we cannot help being struck by the fact that a sense of guilt has about it much of the nature of anxiety: we could describe it without any misgivings as 'dread of conscience'. But the anxiety points to unconscious sources. The psychology of the neuroses has taught us that, if wishful impulses are repressed, their libido is transformed into anxiety. And this reminds us that there is something unknown and unconscious in connection with the sense of guilt, namely the reasons for the act of repudiation. The character of anxiety that is inherent in the sense of guilt corresponds to this unknown factor.
[1912-1913, 2713]

It is true that psycho-analysis has taken the individual mind as its subject, but in investigating the individual it could not avoid dealing with the emotional basis of the relation of the individual to society. It has found that the social feelings invariably contain an erotic element - an element which, if it is over-emphasized and then repressed, becomes one of the marks of a particular group of mental disorders. Psycho-analysis has recognized that in general the neuroses are asocial in their nature and that they always aim at driving the individual out of society and at replacing the safe monastic seclusion of earlier days by the isolation of illness. The intense feeling of guilt which dominates so many neuroses has been shown to be a social modification of neurotic anxiety.
[1913], 2824]
Her other reproach against her father was that his ill-health was only a pretext and that he exploited it for his own purposes. This reproach, too, concealed a whole section of her own secret history. One day she complained of a professedly new symptom, which consisted of piercing gastric pains. 'Whom are you copying now?' I asked her, and found I had hit the mark. The day before she had visited her cousins, the daughters of the aunt who had died. The younger one had become engaged, and this had given occasion to the elder one for falling ill with gastric pains, and she was to be sent off to Semmering. Dora thought it was all just envy on the part of the elder sister; she always got ill when she wanted something, and what she wanted now was to be away from home so as not to have to look on at her sister's happiness.¹ But Dora's own gastric pains proclaimed the fact that she identified herself with her cousin, who, according to her, was a malingerer. Her grounds for this identification were either that she too envied the luckier girl her love, or that she saw her own story reflected in that of the elder sister, who had recently had a love-affair which had ended unhappily.² But she had also learned from observing Frau K. what useful things illnesses could become. Herr K. spent part of the year in travelling. Whenever he came back, he used to find his wife in bad health, although, as Dora knew, she had been quite well only the day before. Dora realized that the presence of the husband had the effect of making his wife ill, and that she was glad to be ill so as to be able to escape the conjugal duties which she so much detested. At this point in the discussion Dora suddenly brought in an allusion to her own alternations between poor and bad health during the first years of her girlhood at B--; and I was thus driven to suspect that her states of health were to be regarded as depending upon something else, in the same way as Frau K.'s. (It is a rule of psycho-analytic technique that an internal connection which is still undisclosed will announce its presence by means of a contiguity - a temporal proximity of associations; just as in writing, if 'a' and 'b' are put side by side, it means that the syllable 'ab' is to be formed out of them.) Dora had had a very large number of attacks of coughing accompanied by loss of voice. Could it be that the presence or absence of the man she loved had had an influence upon the appearance and disappearance of the symptoms of her illness? If this were so, it must be possible to discover some coincidence or other which would betray the fact. I asked her what the average length of these attacks had been. 'From three to six weeks, perhaps.' How long had Herr K.'s absences lasted? 'Three to six weeks, too,' she was obliged to admit. Her illness was therefore a demonstration of her love for K., just as his wife's was a demonstration of her dislike. It was only necessary to suppose that her behaviour had been the opposite of Frau K.'s and that she had been ill when he was absent and well when he had come back. And this really seemed to have been so, at least during the first period of the attacks. Later on it no doubt became necessary to obscure the coincidence between her attacks of illness and the absence of the man she secretly loved, lest its regularity should betray her secret. The length of the attacks would then remain as a trace of their original significance.

[1905e, 1376]
I now return to the reproach of malingering which Dora brought against her father. It soon became evident that this reproach corresponded to self-reproaches not only concerning her earlier states of ill-health but also concerning the present time. At such points the physician is usually faced by the task of guessing and filling in what the analysis offers him in the shape only of hints and allusions. I was obliged to point out to the patient that her present ill-health was just as much actuated by motives and was just as tendentious as had been Frau K.'s illness, which she had understood so well. There could be no doubt, I said, that she had an aim in view which she hoped to gain by her illness. That aim could be none other than to detach her father from Frau K. She had been unable to achieve this by prayers or arguments; perhaps she hoped to succeed by frightening her father (there was her farewell letter), or by awakening his pity (there were her fainting-fits), or if all this was in vain, at least she would be taking her revenge on him. She knew very well, I went on, how much he was attached to her, and that tears used to come into his eyes whenever he was asked after his daughter's health. I felt quite convinced that she would recover at once if only her father were to tell her that he had sacrificed Frau K, for the sake of her health. But, I added, I hoped he would not let himself be persuaded to do this, for then she would have learned what a powerful weapon she had in her hands, and she would certainly not fail on every future occasion to make use once more of her liability to ill health. Yet if her father refused to give way to her, I was quite sure she would not let herself be deprived of her illness so easily.

I will pass over the details which showed how entirely correct all of this was, and I will instead add a few general remarks upon the part played in hysteria by the motives of illness. A motive for being ill is sharply to be distinguished as a concept from a potentiality for illness - from the material out of which symptoms are formed. The motives have no share in the formation of symptoms, and indeed are not present at the beginning of the illness. They only appear secondarily to it; but it is not until they have appeared that the disease is fully constituted.¹ Their presence can be reckoned upon in every case in which there is real suffering and which is of fairly long standing. A symptom comes into the patient's mental life at first as an unwelcome guest; it has everything against it; and that is why it may vanish so easily, apparently of its own accord, under the influence of time. To begin with there is no use to which it can be put in the domestic economy of the mind; but very often it succeeds in finding one secondarily. Some psychical current or other finds it convenient to make use of it, and in that way the symptom manages to obtain a secondary function and remains, as it were, anchored fast in the patient's mental life. And so it happens that any one who tries to make him well is to his astonishment brought up against a powerful resistance, which teaches him that the patient's intention of getting rid of his complaint is not so entirely and completely serious as it seemed.² Let us imagine a workman, a bricklayer, let us say, who has fallen off a house and been crippled, and now earns his livelihood by begging at the street-corner. Let us then suppose that a miracle-worker comes along and promises him to make his crooked leg straight and capable of walking. It would be unwise, I think, to look forward to seeing an expression of peculiar bliss upon the man's features. No doubt at the time of the accident he felt he was extremely unlucky, when he realized that he would never be able to do any more work and would have to starve or live upon charity. But since then the very thing which in the first instance threw him out of employment has become his source of income: he lives by his disablement. If that is taken from him he may become totally helpless. He has in the meantime forgotten his trade and lost his habits of industry; he has grown accustomed to idleness, and perhaps to drink as well.
The motives for being ill often begin to be active even in childhood. A little girl in her greed for love does not enjoy having to share the affection of her parents with her brothers and sisters; and she notices that the whole of their affection is lavished on her once more whenever she arouses their anxiety by falling ill. She has now discovered a means of enticing out her parents’ love, and will make use of that means as soon as she has the necessary psychical material at her disposal for producing an illness. When such a child has grown up to be a woman she may find all the demands she used to make in her childhood countered owing to her marriage with an inconsiderate husband, who may subjugate her will, mercilessly exploit her capacity for work, and lavish neither his affection nor his money upon her. In that case ill-health will be her one weapon for maintaining her position. It will procure her the care she longs for; it will force her husband to make pecuniary sacrifices for her and to show her consideration, as he would never have done while she was well; and it will compel him to treat her with solicitude if she recovers, for otherwise a relapse will threaten. Her state of ill-health will have every appearance of being objective and involuntary - the very doctor who treats her will bear witness to the fact; and for that reason she will no need to feel any conscious self-reproaches at making such successful use of a means which she had found effective in her years of childhood.

And yet illnesses of this kind are the result of intention for the purposes they serve. They are as a rule levelled at a particular person, and consequently vanish with that person’s departure. The crudest and most commonplace views on the character of hysterical disorder - such as are to be heard from uneducated relatives or nurses - are in a certain sense right. It is true that the paralysed and bedridden woman would spring to her feet if a fire were to break out in her room, and that the spoiled wife would forget all her sufferings if her child were to fall dangerously ill or if some catastrophe were to threaten the family circumstances. People who speak of the patients in this way are right except upon a single point: they overlook the psychological distinction between what is conscious and what is unconscious. This may be permissible where children are concerned, but with adults it is no longer possible. That is why all these asseverations that it is ‘only a question of willing’ and all the encouragements and abuse that are addressed to the patient are of no avail. An attempt must first be made by the roundabout methods of analysis to convince the patient herself of the existence in her of an intention to be ill.
It is in combating the motives of illness that the weak point in every kind of therapeutic
treatment of hysteria lies. This in quite generally true, and it applies equally to psycho-analysis.
Destiny has an easier time of it in this respect: it need not concern itself either with the patient's
constitution or with his pathogenic material; it has only to take away a motive for being ill, and
the patient is temporarily or perhaps even permanently freed from his illness. How many fewer
miraculous cures and spontaneous disappearances of symptoms should we physicians have to
register in cases of hysteria, if we were more often given a sight of the human interests which
the patient keeps hidden from us! In one case, some stated period of time has elapsed; in a
second, consideration for some other person has ceased to operate; in a third, the situation has
been fundamentally changed by some external event - and the whole disorder which up till then
had shown the greatest obstinacy, vanishes at a single blow, apparently of its own accord, but
really because it has been deprived of its most powerful motive, one of the uses to which it has
been put in the patient's life.
[1905e, 1382]

Motives that support the patient in being ill are probably to be found in all fully developed
cases. But there are some in which the motives are purely internal - such as desire for self-
punishment, that is, penitence and remorse. It will be found much easier to solve the therapeutic
problem in such cases than in those in which the illness is related to the attainment of some
external aim. In Dora's case that aim was clearly to touch her father's heart and to detach him
from Frau K.
[1905e, 1383]

Nor is the case of whose history and treatment I have published a fragment in these pages
well calculated to put the value of psycho-analytic therapy in its true light. Not only the briefness
of the treatment (which hardly lasted three months) but another factor inherent in the nature of
the case prevented results being brought about such as are attainable in other instances, where
the improvement will be admitted by the patient and his relatives and will approximate more or
less closely to a complete recovery. Satisfactory results of this kind are reached when the
symptoms are maintained solely by the internal conflict between the impulses concerned with
sexuality. In such cases the patient's condition will be seen improving in proportion as he is
helped towards a solution of his mental problems by the translation of pathogenic into normal
material. The course of events is very different when the symptoms have become enlisted in the
service of external motives, as had happened with Dora during the two preceding years. It is
surprising, and might easily be misleading, to find that the patient's condition shows no
noticeable alteration even though considerable progress has been made with the work of
analysis. But in reality things are not as bad as they seem. It is true that the symptoms do not
disappear while the work is proceeding; but they disappear a little while later, when the relations
between patient and physician have been dissolved. The postponement of recovery or
improvement is really only caused by the physician's own person.
[1905e, 1449]

Now that the flood-waters of war have subsided, it is satisfactory to be able to record the fact
that interest in psycho-analytic research remains unimpaired in the world at large. But the
different parts of the theory have not all had the same history. The purely psychological theses
and findings of psycho-analysis on the unconscious, repression, conflict as a cause of illness,
the advantage accruing from illness, the mechanisms of the formation of symptoms, etc., have
come to enjoy increasing recognition and have won notice even from those who are in general
opposed to our views. That part of the theory, however, which lies on the frontiers of biology
and the foundations of which are contained in this little work is still faced with undiminished
contradiction. It has even led some who for a time took a very active interest in psycho-analysis
to abandon it and to adopt fresh views which were intended to restrict once more the part
played by the factor of sexuality in normal and pathological mental life.
[1905d, 1462]
And there is another, still more important consideration. In describing the very remarkable results of suggestion, people are only too ready to forget that here, as in all mental operations, relative size and strength must be taken into account. If we put a healthy person into deep hypnosis and then tell him to take a bite out of a potato under the impression that it is a pear, or if we tell him that he is meeting one of his acquaintances and must greet him as such, he is likely to prove completely tractable, because the hypnotized subject has no serious reason for resisting the suggestion. But in the case of other instructions - if, for instance, we ask a naturally modest girl to uncover herself or if we ask an honest man to steal some valuable object - we may already find the subject putting up a resistance, which may even go to the length of his refusing to obey the suggestion. This teaches us that even in the best hypnosis suggestion does not exercise unlimited power but only power of a definite strength. The hypnotic subject will make small sacrifices, but, just as though he were awake, he hesitates before making great ones. If, then, we are dealing with a patient, and urge him by suggestion to give up his illness, we perceive that this means a great sacrifice to him and not a small one. Here the power of suggestion is contending against the force which created the symptom, and maintains them, and experience shows that that force is of quite a different order of strength from hypnotic influences. The same patient who is perfectly tractable in putting himself into any dream-situation one may suggest to him (if it is not actually objectionable) may remain completely recalcitrant towards a suggestion which denies the reality of, let us say, an imaginary paralysis. There is the further fact, moreover, that precisely neurotic patients are for the most part bad hypnotic subjects, so that the struggle against the powerful forces by which the illness is rooted in the patient's mind has to be waged not by a complete hypnotic influence but only by a fragment of it.

[1890a, 1602]

The onset of hysterical attacks follows laws that are easily understandable. Since the repressed complex consists of a libidinal cathexis and an ideational content (the phantasy), the attack can be evoked (1) associatively, when the content of the complex (if sufficiently cathected) is touched on by something connected with it in conscious life; (2) organically, when, for internal somatic reasons and as a result of psychical influences from outside, the libidinal cathexis rises above a certain degree; (3) in the service of the primary purpose - as an expression of a 'flight into illness', when reality becomes distressing or frightening - that is, as a consolation; (4) in the service of the secondary purposes, with which the illness allies itself, as soon as, by producing an attack, the patient can achieve an aim that is useful to him. In the last case the attack is directed at particular individuals; it can be put off till they are present, and it gives an impression of being consciously simulated.

[1909a, 1983]

Investigation of the childhood history of hysterical patients shows that the hysterical attack is designed to take the place of an auto-erotic satisfaction previously practised and since given up. In a great number of cases this satisfaction (masturbation by contact or by pressure of the thighs, or, again, by movements of the tongue, and so on) recurs during the attack itself, while the subject's consciousness is deflected. Moreover, the onset of an attack that is due to an increase of libido and is in the service of the primary purpose - as a consolation - exactly repeats the conditions under which, at the earlier time, the patient had intentionally sought this auto-erotic satisfaction. The anamnesis of the patient shows the following stages: (a) auto-erotic satisfaction, without ideational content; (b) the same satisfaction, connected with a phantasy which leads to the act of satisfaction; (c) renunciation of the act, with retention of the phantasy; (d) repression of the phantasy, which then comes into effect as a hysterical attack, either in an unchanged form, or in a modified one and adapted to new environmental impressions. Furthermore, (e) the phantasy may even reinstate the act of satisfaction belonging to it which had ostensibly been given up. This is a typical cycle of infantile sexual activity: repression, failure of repression, and return of the repressed.

[1909a, 1983]
One day while Hans was in the street he was seized with an attack of anxiety. He could not yet say what it was he was afraid of; but at the very beginning of this anxiety-state he betrayed to his father his motive for being ill, the advantage he derived from it. He wanted to stay with his mother and to coax with her; his recollection that he had also been separated from her at the time of the baby's birth may also, as his father suggests, have contributed to his longing. It soon became evident that his anxiety was no longer reconvertible into longing; he was afraid even when his mother went with him. In the meantime indications appeared of what it was to which his libido (now changed into anxiety) had become attached. He gave expression to the quite specific fear that a white horse would bite him.

This allows us, therefore, to make a radical distinction. We shall probably come to understand the case more deeply if we turn to those other components which do fulfill the two conditions that have just been mentioned. These other components were tendencies in Hans which had already been suppressed and which, so far as we can tell, had never been able to find uninhibited expression: hostile and jealous feelings towards his father, and sadistic impulses (premonitions, as it were, of copulation) towards his mother. These early suppressions may perhaps have gone to form the predisposition for his subsequent illness. These aggressive propensities of Hans's found no outlet, and as soon as there came a time of privation and of intensified sexual excitement, they tried to break their way out with reinforced strength. It was then that the battle which we call his 'phobia' burst out. During the course of it a part of the repressed ideas, in a distorted form and transposed on to another complex, forced their way into consciousness as the content of the phobia. But it was a decidedly paltry success. Victory lay with the forces of repression; and they made use of the opportunity to extend their domain over components other than those that had rebelled. This last circumstance, however, does not in the least alter the fact that the essence of Hans's illness was entirely dependent upon the nature of the instinctual components that had to be repulsed. The content of his phobia was such as to impose a very great measure of restriction upon his freedom of movement, and that was its purpose. It was therefore a powerful reaction against the obscure impulses to movement which were especially directed against his mother. For Hans horses had always typified pleasure in movement ('I'm a young horse', he had said as he jumped about); but since this pleasure in movement included the impulse to copulate, the neurosis imposed a restriction on it and exalted the horse into an emblem of terror. Thus it would seem as though all that the repressed instincts got from the neurosis was the honour of providing pretexts for the appearance of the anxiety in consciousness. But however clear may have been the victory in Hans's phobia of the forces that were opposed to sexuality, nevertheless, since such an illness is in its very nature a compromise, this cannot have been all that the repressed instincts obtained. After all, Hans's phobia of horses was an obstacle to his going into the street, and could serve as a means of allowing him to stay at home with his beloved mother. In this way, therefore, his affection for his mother triumphantly achieved its aim. In consequence of his phobia, the lover clung to the object of his love - though, to be sure, steps had been taken to make him innocuous. The true character of a neurotic disorder is exhibited in this twofold result.

[1909b, 2117]
For this reason it not uncommonly happens that obsessional neurotics, who are troubled with self-reproaches but have connected their affects with the wrong causes, will also tell the physician the true causes, without any suspicion that their self-reproaches have simply become detached from them. In relating such an incident they will sometimes add with astonishment or even with an air of pride: 'But I think nothing of that.' This happened in the first case of obsessional neurosis which gave me an insight many years ago into the nature of the malady. The patient, who was a government official, was troubled by innumerable scruples. He was the man whose compulsive act in connection with the branch in the park at Schönbrunn I have already described. I was struck by the fact that the florin notes with which he paid his consultation fees were invariably clean and smooth. (This was before we had a silver coinage in Austria.) I once remarked to him that one could always tell a government official by the brand-new florins that he drew from the State treasury, and he then informed me that his florins were by no means new, but that he had them ironed out at home. It was a matter of conscience with him, he explained, not to hand any one dirty paper florins; for they harboured all sorts of dangerous bacteria and might do some harm to the recipient. At that time I already had a vague suspicion of the connection between neuroses and sexual life, so on another occasion I ventured to ask the patient how he stood in regard to that matter. 'Oh, that's quite all right,' he answered airily, 'I'm not at all badly off in that respect. I play the part of a dear old uncle in a number of respectable families, and now and then I make use of my position to invite some young girl to go out with me for a day's excursion in the country. Then I arrange that we shall miss the train home and be obliged to spend the night out of town. I always engage two rooms - I do things most handsomely; but when the girl has gone to bed I go in to her and masturbate her with my fingers.' - 'But aren't you afraid of doing her some harm, fiddling about in her genitals with your dirty hand?' - At this he flared up: 'Harm? Why, what harm should it do her? It hasn't done a single one of them any harm yet, and they've all of them enjoyed it. Some of them are married now, and it hasn't done them any harm at all.' - He took my remonstrance in very bad part, and never appeared again. But I could only account for the contrast between his fastidiousness with the paper florins and his unscrupulousness in abusing the girls entrusted to him by supposing that the self-reproachful affect had become displaced. The aim of this displacement was obvious enough: if his self-reproaches had been allowed to remain where they belonged he would have had to abandon a form of sexual gratification to which he was probably impelled by some powerful infantile determinants. The displacement therefore ensured his deriving a considerable advantage from his illness.

[1909d, 2155]

The proof that this view was correct lies in the fact that the chief result of his illness was an obstinate incapacity for work, which allowed him to postpone the completion of his education for years. But the results of such an illness are never unintentional; what appears to be the consequence of the illness is in reality the cause or motive of falling ill.

[1909d, 2157]
Another mental need, which is also shared by obsessional neurotics and which is in some respects related to the one just mentioned, is the need for uncertainty in their life, or for doubt. An enquiry into this characteristic leads deep into the investigation of instinct. The creation of uncertainty is one of the methods employed by the neurosis for drawing the patient away from reality and isolating him from the world - which is among the objects of every psychoneurotic disorder. Again, it is only too obvious what efforts are made by the patients themselves in order to be able to avoid certainty and remain in doubt. Some of them, indeed, give a vivid expression to this tendency in a dislike of clocks and watches (for these at least make the time of day certain), and in the unconscious artifices which they employ in order to render these doubt removing instruments innocuous. Our present patient had developed a peculiar talent for avoiding a knowledge of any facts which would have helped him in deciding his conflict. Thus he was in ignorance upon those matters relating to his lady which were the most relevant to the question of his marriage: he was ostensibly unable to say who had operated upon her and whether the operation had been unilateral or bilateral. He had to be forced into remembering what he had forgotten and into finding out what he had overlooked.

If we wish to obtain a grasp of the psychical forces whose interplay built up this neurosis, we must turn back to what we have learnt from the patient on the subject of the precipitating causes of his falling ill as a grown-up man and as a child. He fell ill when he was in his twenties on being faced with a temptation to marry another woman instead of the one whom he had loved so long; and he avoided a decision of this conflict by postponing all the necessary preliminary actions. The means for doing this was given him by his neurosis. His hesitation between the lady he loved and the other girl can be reduced to a conflict between his father's influence and his love for his lady, or, in other words, to a conflicting choice between his father and his sexual object, such as had already subsisted (judging from his recollections and obsessional ideas) in his remote childhood. All through his life, moreover, he was unmistakably victim to a conflict between love and hatred, in regard both to his lady and to his father. His phantasies of revenge and such obsessional phenomena as his obsession for understanding and his exploit with the stone in the road bore witness to his divided feelings; and they were to a certain degree comprehensible and normal, for the lady by her original refusal and subsequently by her coolness had given him some excuse for hostility. But his relations with his father were dominated by a similar division of feeling, as we have seen from our translation of his obsessional thoughts; and his father, too, must have given him an excuse for hostility in his childhood, as indeed we have been able to establish almost beyond question. His attitude towards the lady - a compound of tenderness and hostility - came to a great extent within the scope of his conscious knowledge; at most he deceived himself over the degree and violence of his negative feelings. But his hostility towards his father, on the contrary, though he had once been acutely conscious of it, had long since vanished from his ken, and it was only in the teeth of the most violent resistance that it could be brought back into his consciousness. We may regard the repression of his infantile hatred of his father as the event which brought his whole subsequent career under the dominion of the neurosis.
LADIES AND GENTLEMEN, - With the discovery of infantile sexuality and the tracing back of neurotic symptoms to erotic instinctual components we have arrived at some unexpected formulas concerning the nature and purposes of neurotic illnesses. We see that human beings fall ill when, as a result of external obstacles or of an internal lack of adaptation, the satisfaction of their erotic needs in reality frustrated. We see that they then take flight into illness in order that by its help they may find a satisfaction to take the place of what has been frustrated. We recognize that the pathological symptoms constitute a portion of the subject's sexual activity or even the whole of his sexual life, and we find that the withdrawal from reality is the main purpose of the illness but also the main damage caused by it. We suspect that our patients' resistance to recovery is no simple one, but compounded of several motives. Not only does the patient's ego rebel against giving up the repressions by means of which it has risen above its original disposition, but the sexual instincts are unwilling to renounce their substitutive satisfaction so long as it is uncertain whether reality will offer them anything better.

[1910a, 2234]

The flight from unsatisfactory reality into what, on account of the biological damage involved, we call illness (though it is never without an immediate yield of pleasure to the patient) takes place along the path of involution, of regression, of a return to earlier phases of sexual life, phases from which at one time satisfaction was not withheld. This regression appears to be a twofold one: a temporal one, in so far as the libido, the erotic needs, hark back to stages of development that are earlier in time, and a formal one, in that the original and primitive methods of psychical expression are employed in manifesting those needs. Both these kinds of regression, however, lead back to childhood and unite in bringing about an infantile condition of sexual life.

[1910a, 2234]

In place of a single sick person let us put society - suffering as a whole from neuroses, though composed of sick and healthy members; and in place of individual acceptance in the one case let us put general recognition in the other. A little reflection will then show you that this substitution cannot in any way alter the outcome. The success which the treatment can have with the individual must occur equally with the community. Sick people will not be able to let their various neuroses become known - their anxious over-tenderness which is meant to conceal their hatred, their agoraphobia which tells of disappointed ambition, their obsessive actions which represent self-reproaches for evil intentions and precautions against them - if all their relatives and every stranger from whom they wish to conceal their mental processes know the general meaning of such symptoms, and if they themselves know that in the manifestations of their illness they are producing nothing that other people cannot instantly interpret. The effect, however, will not be limited to the concealment of the symptoms which, incidentally, it is often impossible to carry out; for this necessity for concealment destroys the use of being ill. Disclosure of the secret will have attacked, at its most sensitive point, the 'aetiological equation' from which neuroses arise - it will have made the gain from the illness illusory; and consequently the final outcome of the changed situation brought about by the physician's indiscretion can only be that the production of the illness will be brought to a stop.

[1910d, 2312]

If this hope seems Utopian to you, you may remember that neurotic phenomena have actually been dispelled already by this means, although only in quite isolated instances. Think how common hallucinations of the Virgin Mary used to be among peasant girls in former times. So long as such a phenomenon brought a flock of believers and might lead to a chapel being built on the sacred spot, the visionary state of these girls was inaccessible to influence. To-day even our clergy have changed their attitude to such things; they allow police and doctors to examine the visionary, and now the Virgin makes only very rare appearances.

[1910d, 2313]
Let us return to our more serious case. A certain number of people, faced in their lives by conflicts which they have found too difficult to solve, have taken flight into neurosis and in this way won an unmistakable, although in the long run too costly, gain from illness. What will these people have to do if their flight into illness is barred by the indiscreet revelations of psycho-analysis? They will have to be honest, confess to the instincts that are at work in them, face the conflict, fight for what they want, or go without it; and the tolerance of society, which is bound to ensue as a result of psycho-analytic enlightenment, will help them in their task.

Let us remember, however, that our attitude to life ought not to be that of a fanatic for hygiene or therapy. We must admit that the ideal prevention of neurotic illnesses which we have in mind would not be of advantage to every individual. A good number of those who now take flight into illness would not, under the conditions we have assumed, support the conflict but would rapidly succumb or would cause a mischief greater than their own neurotic illness. Neuroses have in fact their biological function as a protective contrivance and they have their social justification: the 'gain from illness' they provide is not always a purely subjective one. Is there one of you who has not at some time looked into the causation of a neurosis and had to allow that it was the mildest possible outcome of the situation? And should such heavy sacrifices be made in order to eradicate the neuroses in particular, when the world is full of other unavoidable misery?

Are we, then, to abandon our efforts to explain the hidden meaning of neurosis as being in the last resort dangerous to the individual and harmful to the workings of society? Are we to give up drawing the practical conclusion from a piece of scientific insight? No; I think that in spite of this our duty lies in the other direction. The gain from illness provided by the neuroses is nevertheless on the whole and in the end detrimental to individuals as well as to society. The unhappiness that our work of enlightenment may cause will after all only affect some individuals. The change-over to a more realistic and creditable attitude on the part of society will not be bought too dearly by these sacrifices. But above all, all the energies which are to-day consumed in the production of neurotic symptoms serving the purposes of a world of phantasy isolated from reality, will, even if they cannot at once be put to uses in life, help to strengthen the clamour for the changes in our civilization through which alone we can look for the well-being of future generations.

One may be very far from the ascetic view of money as a curse and yet regret that analytic therapy is almost inaccessible to poor people, both for external and internal reasons. Little can be done to remedy this. Perhaps there is truth in the widespread belief that those who are forced by necessity to a life of hard toil are less easily overtaken by neurosis. But on the other hand experience shows without a doubt that when once a poor man has produced a neurosis it is only with difficulty that he lets it be taken from him. It renders him too good a service in the struggle for existence; the secondary gain from illness which it brings him is much too important. He now claims by right of his neurosis the pity which the world has refused to his material distress, and he can now absolve himself from the obligation of combating his poverty by working. Anyone therefore who tries to deal with the neurosis of a poor person by psychotherapy usually discovers that what is here required of him is a practical therapy of a very different kind - the kind which, according to our local tradition, used to be dispensed by the Emperor Joseph II. Naturally, one does occasionally come across deserving people who are helpless from no fault of their own, in whom unpaid treatment does not meet with any of the obstacles that I have mentioned and in whom it leads to excellent results.
It is now time for us to take a survey of the play of forces which is set in motion by the treatment. The primary motive force in the therapy is the patient's suffering and the wish to be cured that arises from it. The strength of this motive force is subtracted from by various factors - which are not discovered till the analysis is in progress - above all, by what we have called the 'secondary gain from illness'; but it must be maintained till the end of the treatment. Every improvement effects a diminution of it. By itself, however, this motive force is not sufficient to get rid of the illness. Two things are lacking in it for this: it does not know what paths to follow to reach this end; and it does not possess the necessary quota of energy with which to oppose the resistances. The analytic treatment helps to remedy both these deficiencies. It supplies the amounts of energy that are needed for overcoming the resistances by making mobile the energies which lie ready for the transference; and, by giving the patient information at the right time, it shows him the paths along which he should direct those energies. Often enough the transference is able to remove the symptoms of the disease by itself, but only for a while - only for as long as it itself lasts. In this case the treatment is a treatment by suggestion, and not a psycho-analysis at all. It only deserves the latter name if the intensity of the transference has been utilized for the overcoming of resistances. Only then has being ill become impossible, even when the transference has once more been dissolved, which is its destined end. 
[1913c, 2494]

Psycho-analysis recognized early that every neurotic symptom owes its possibility of existence to a compromise. Every symptom must therefore in some way comply with the demands of the ego which manipulates the repression; it must offer some advantage, it must admit of some useful application, or it would meet with the same fate as the original instinctual impulse itself which has been fended off. The term 'gain from illness' has taken this into account; one is even justified in differentiating the 'primary' gain to the ego, which must be operative at the time of the generation of the symptom, from a 'secondary' part, which supervenes in attachment to other purposes of the ego, if the symptom is to persist. It has also long been known that the withdrawal of this gain from illness, or its disappearance in consequence of some change in real external circumstances, constitutes one of the mechanisms of a cure of the symptom. In the Adlerian doctrine the main emphasis falls on these easily verifiable and clearly intelligible connections, while the fact is altogether overlooked that on countless occasions the ego is merely making a virtue of necessity in submitting, because of its usefulness, to the very disagreeable symptom which is forced upon it - for instance, in accepting anxiety as a means to security. The ego is here playing the ludicrous part of the clown in a circus who by his gestures tries to convince the audience that every change in the circus ring is being carried out under his orders. But only the youngest of the spectators are deceived by him.
[1914d, 2916]

The same effect was produced on the life of our second patient, the young girl, by an erotic attachment to her father which had started during the years before her puberty. The conclusion she herself drew was that she could not marry as long as she was so ill. We, however, may suspect that she had become so ill in order not to have to marry and in order to remain with her father.
[1916-1917, 3351]
We cannot dismiss the question of why, in what way and for what motive a person can arrive at such a remarkable attitude to life and one that is so inexpedient - assuming that this attitude is a general characteristic of neuroses and not a special peculiarity of these two patients. And in fact it is a general feature, of great practical importance, in every neurosis. Breuer's first hysterical patient was similarly fixated to the period when she was nursing her father in a serious illness. In spite of her recovery, in a certain respect she remained cut off from life; she remained healthy and efficient but avoided the normal course of a woman's life. In every one of our patients, analysis shows us that they have been carried back to some particular period of their past by the symptoms of their illness or their consequences. In the majority of cases, indeed, a very early phase of life is chosen for the purpose - a period of their childhood or even, laughable as this may sound, of their existence as an infant at the breast.

The ego takes a similar interest, however, in the development and maintenance of the neurosis in every other case. I have already shown that symptoms are supported by the ego, too, because they have a side with which they offer satisfaction to the repressing purpose of the ego. Moreover, settling the conflict by constructing a symptom is the most convenient way out and the one most agreeable to the pleasure principle: it unquestionably spares the ego a large amount of internal work which is felt as distressing. Indeed there are cases in which even the physician must admit that for a conflict to end in neurosis is the most harmless and socially tolerable solution. You must not be surprised to hear that even the physician may occasionally take the side of the illness he is combating. It is not his business to restrict himself in every situation in life to being a fanatic in favour of health. He knows that there is not only neurotic misery in the world but real, irremovable suffering as well, that necessity may even require a person to sacrifice his health; and he learns that a sacrifice of this kind made by a single person can prevent immeasurable unhappiness for many others. If we may say, then, that whenever a neurotic is faced by a conflict he takes flight into illness, yet we must allow that in some cases that flight is fully justified, and a physician who has recognized how the situation lies will silently and solicitously withdraw.

But let us disregard these exceptional cases and proceed with our discussion. In average circumstances we recognize that by escaping into a neurosis the ego obtains a certain internal 'gain from illness'. In some circumstances of life this is further accompanied by an appreciable external advantage bearing a greater or less real value. Consider the commonest example of this sort. A woman who is roughly treated and ruthlessly exploited by her husband will fairly regularly find a way out in neurosis, if her constitution makes it possible, if she is too cowardly or too moral to console herself secretly with another man, if she is not strong enough to separate from her husband in the face of every external deterrent, if she has no prospect of supporting herself or obtaining a better husband and if in addition she is still attached to this brutal husband by her sexual feelings. Her illness now becomes a weapon in her battle with her dominating husband - a weapon which she can use for her defence and misuse for her revenge. To complain of her illness is allowable, though to lament her marriage was probably not. She finds a helper in her doctor, she forces her usually inconsiderate husband to look after her, to spend money on her, to allow her at times to be away from home and so free from her married oppression. When an external or accidental gain from illness like this is really considerable and no real substitute for it is available, you must not reckon very high the chances of influencing the neurosis by your treatment.
You will now protest that what I have told you about the gain from illness argues entirely in favour of the view I have rejected - that the ego itself wills and creates the neurosis. Not too fast, Gentlemen! It may perhaps mean nothing more than that the ego puts up with the neurosis, which it cannot, after all, prevent, and that it makes the best of it, if anything can be made of it at all. That is only one side of the business, the pleasant side, it is true. So far as the neurosis has advantages the ego no doubt accepts it; but it does not only have advantages. As a rule it soon turns out that the ego has made a bad bargain by letting itself in for the neurosis. It has paid too dearly for an alleviation of the conflict, and the sufferings attached to the symptoms are perhaps an equivalent substitute for the torments of the conflict, but they probably involve an increase in unpleasure. The ego would like to free itself from this unpleasure of the symptoms without giving up the gain from illness, and this is just what it cannot achieve. This shows, then, that it was not so entirely active as it thought it was; and we shall bear this well in mind.

In your contact as doctors with neurotics, Gentlemen, you will soon give up expecting that the ones who raise the most lamentations and complaints about their illness will be the most eager to co-operate and will offer you the least resistance. It is rather the opposite. But of course you will easily realize that everything that contributes to the gain from illness will intensify the resistance due to repression and will increase the therapeutic difficulties. But to the portion of gain from illness which is, so to say, born with the illness we have to add another portion which arises later. When a psychical organization like an illness has lasted for some time, it behaves eventually like an independent organism; it manifests something like a self-preservative instinct; it establishes a kind of modus vivendi between itself and other parts of the mind, even with those which are at bottom hostile to it; and there can scarcely fail to be occasions when it proves once again useful and expedient and acquires, as it were, a secondary function which strengthens its stability afresh. Instead of an example from pathology, let us take a glaring instance from daily life. A capable working-man, who earns his living, is crippled by an accident in the course of his occupation. The injured man can no longer work, but eventually he obtains a small disablement pension, and he learns how to exploit his mutilation by begging. His new, though worsened, means of livelihood is based precisely on the very thing that deprived him of his former means of livelihood. If you could put an end to his injury you would make him, to begin with, without means of subsistence; the question would arise of whether he was still capable of taking up his earlier work again. What corresponds in the case of neuroses to a secondary exploitation like this of an illness may be described as the secondary gain from illness in contrast to the primary one.

In general, however, I should like to recommend that, while not under-estimating the practical importance of the gain from illness, you should not let yourselves be impressed by it theoretically. After all, apart from the exceptions recognized earlier, it always calls to mind the examples of 'animal intelligence' illustrated by Oberländer in Fliegende Blätter. An Arab was riding his camel along a narrow path cut in the steep face of a mountain. At a turn in the path he suddenly found himself face to face with a lion, which prepared to make a spring. He saw no way out: on one side a perpendicular cliff and on the other a precipice; retreat and flight were impossible. He gave himself up for lost. But the animal thought otherwise. He took one leap with his rider into the abyss - and the lion was left in the lurch. The help provided by a neurosis has as a rule no better success with the patient. This may be because dealing with a conflict by forming symptoms is after all an automatic process which cannot prove adequate to meeting the demands of life, and in which the subject has abandoned the use of his best and highest powers. If there were a choice, it would be preferable to go down in an honourable struggle with fate.
Instead of reporting a number of cases, I will tell you the story of a single one, in which, from considerations of medical discretion, I was condemned to play a long-suffering part. I undertook the analytic treatment - it was many years ago - of a girl who had for some time been unable, owing to anxiety, to go out in the street or to stay at home by herself. The patient slowly brought out an admission that her imagination had been seized by chance observations of the affectionate relations between her mother and a well-to-do friend of the family. But she was so clumsy - or so subtle - that she gave her mother a hint of what was being talked about in the analytic sessions. She brought this about by changing her behaviour towards her mother, by insisting on being protected by no one but her mother from her anxiety at being alone and by barring the door to her in her anxiety if she tried to leave the house. Her mother had herself been very neurotic in the past, but had been cured years before in a hydropathic establishment. Or rather, she had there made the acquaintance of the man with whom she was able to enter into a relation that was in every way satisfying to her. The girl's passionate demands took her aback, and she suddenly understood the meaning of her daughter's anxiety: the girl had made herself ill in order to keep her mother prisoner and to rob her of the freedom of movement that her relations with her lover required. The mother quickly made up her mind and brought the obnoxious treatment to an end. The girl was taken to a sanatorium for nervous diseases and was demonstrated for many years as 'a poor victim of psycho-analysis'. All this time, too, I was pursued by the calumny of responsibility for the unhappy end of the treatment. I kept silence, for I thought I was bound by the duty of medical discretion. Long afterwards I learnt from one of my colleagues, who visited the sanatorium and had seen the agoraphobic girl there, that the liaison between her mother and the well-to-do friend of the family was common knowledge in the city and that it was probably connived at by the husband and father. Thus it was to this 'secret' that the treatment had been sacrificed.

[1916-1917, 3499]

The patient with whom I am here concerned remained for a long time unassailably entrenched behind an attitude of 'obliging apathy'. He listened, understood, and remained unapproachable. His unimpeachable intelligence was, as it were, cut off from the instinctual forces which governed his behaviour in the few relations of life that remained to him. It required a long education to induce him to take an independent share in the work; and when as a result of this exertion he began for the first time to feel relief, he immediately gave up working in order to avoid any further changes, and in order to remain comfortably in the situation which had been thus established. His shrinking from a self-sufficient existence was so great as to outweigh all the vexations of his illness. Only one way was to be found of overcoming it. I was obliged to wait until his attachment to myself had become strong enough to counter-balance this shrinking, and then played off this one factor against the other. I determined - but not until trustworthy signs had led me to judge that the right moment had come - that the treatment must be brought to an end at a particular fixed date, no matter how far it had advanced. I was resolved to keep to the date; and eventually the patient came to see that I was in earnest. Under the inexorable pressure of this fixed limit his resistance and his fixation to the illness gave way, and now in a disproportionately short time the analysis produced all the material which made it possible to clear up his inhibitions and remove his symptoms. All the information, too, which enabled me to understand his infantile neurosis is derived from this last period of the work, during which resistance temporarily disappeared and the patient gave an impression of lucidity which is usually attainable only in hypnosis.

[1918b, 3507]
We shall then be faced by the task of adapting our technique to the new conditions. I have no doubt that the validity of our psychological assumptions will make its impression on the uneducated too, but we shall need to look for the simplest and most easily intelligible ways of expressing our theoretical doctrines. We shall probably discover that the poor are even less ready to part with their neuroses than the rich, because the hard life that awaits them if they recover offers them no attraction, and illness gives them one more claim to social help. Often, perhaps, we may only be able to achieve anything by combining mental assistance with some material support, in the manner of the Emperor Joseph. It is very probable, too, that the large-scale application of our therapy will compel us to alloy the pure gold of analysis freely with the copper of direct suggestion; and hypnotic influence, too, might find a place in it again, as it has in the treatment of war neuroses. But, whatever form this psychotherapy for the people may take, whatever the elements out of which it is compounded, its most effective and most important ingredients will assuredly remain those borrowed from strict and untendentious psycho-analysis.

But this episode, though it is now closed, was not without an important influence on the spread of psycho-analysis. Medical men who had hitherto held back from any approach to psycho-analytic theories were brought into closer contact with them when, in the course of their duties as army doctors, they were obliged to deal with war neuroses. The reader will be able to gather from Ferenczi's paper with what hesitations and under what disguises these closer contacts were made. Some of the factors which psycho-analysis had recognized and described long before as being at work in peace-time neuroses - the psychogenic origin of the symptoms, the importance of unconscious instinctual impulses, the part played in dealing with mental conflicts by the primary gain from being ill ('the flight into illness') - were observed to be present equally in the war neuroses and were accepted almost universally. Simmel's studies show, too, what successes could be achieved by treating war neurotics by the method of catharsis, which, as we know, was the first step towards the psycho-analytic technique.

Moreover, the successes of treatment by a strong electric current, which were brilliant to begin with, turned out afterwards not to be lasting. A patient who, having been restored to health by it, was sent back to the Front, could repeat the business afresh and have a relapse, by means of which he at least gained time and escaped the danger which was at the moment the immediate one. If he was once more under fire his fear of the electric current receded, just as during the treatment his fear of active service had faded. In the course of the war years, too, a rapidly increasing fatigue in the popular spirit made itself felt more and more, and a growing dislike of fighting, so that the treatment I have described began to fail in its effects. In these circumstances some of the army doctors gave way to the inclination, characteristic of Germans, to carry through their intentions regardless of all else - which should never have happened. The strength of the current, as well as the severity of the rest of the treatment, were increased to an unbearable point in order to deprive war neurotics of the advantage they gained from their illness. The fact has never been contradicted that in German hospitals there were deaths at that time during treatment and suicides as a result of it. I am quite unable to say, however, whether the Vienna Clinics, too, passed through this phase of therapy.
There is no doubt that there is something in these people that sets itself against their recovery, and its approach is dreaded as though it were a danger. We are accustomed to say that the need for illness has got the upper hand in them over the desire for recovery. If we analyse this resistance in the usual way then, even after allowance has been made for an attitude of defiance towards the physician and for fixation to the various forms of gain from illness, the greater part of it is still left over; and this reveals itself as the most powerful of all obstacles to recovery, more powerful than the familiar ones of narcissistic inaccessibility, a negative attitude towards the physician and clinging to the gain from illness.

On the other hand, the diary written in Vienna, which he gave to the clerics on his second visit to Mariazell, bears the stamp of veracity. It undoubtedly affords us a deep insight into the motivation - or let us rather say, the exploitation - of the neurosis.

To superficial observation Haizmann's neurosis appears to be a masquerade which overlays a part of the serious, if commonplace, struggle for existence. This is not always the case, but it is not infrequently so. Analysts often discover how unprofitable it is to treat a business man who 'though otherwise in good health, has for some time shown signs of a neurosis'. The business catastrophe with which he feels himself threatened throws up the neurosis as a by-product; and this gives him the advantage of being able to conceal his worries about his real life behind his symptoms. But apart from this the neurosis serves no useful purpose whatever, since it uses up forces which would have been more profitably employed in dealing rationally with the dangerous situation.

In a far greater number of cases the neurosis is more autonomous and more independent of the interests of self-preservation and self-maintenance. In the conflict which creates the neurosis, what are at stake are either solely libidinal interests or libidinal interests in intimate connections with self-preservative ones. In all three instances the dynamics of the neurosis are the same. A dammed-up libido which cannot be satisfied in reality succeeds, with the help of a regression to old fixations, in finding discharge through the repressed unconscious. The sick man's ego, in so far as it can extract a 'gain from illness' out of this process, countenances the neurosis, although there can be no doubt of its injuriousness in its economic aspect.

Let us keep to a habit of our technique and consider first the extreme and unmistakably pathological form of this masochism. I have described elsewhere¹ how in analytic treatment we come across patients to whom, owing to their behaviour towards its therapeutic influence, we are obliged to ascribe an 'unconscious' sense of guilt. I pointed out the sign by which such people can be recognized (a 'negative therapeutic reaction') and I did not conceal the fact that the strength of such an impulse constitutes one of the most serious resistances and the greatest danger to the success of our medical or educative aims. The satisfaction of this unconscious sense of guilt is perhaps the most powerful bastion in the subject's (usually composite) gain from illness - in the sum of forces which struggle against his recovery and refuse to surrender his state of illness. The suffering entailed by neuroses is precisely the factor that makes them valuable to the masochistic trend. It is instructive, too, to find, contrary to all theory and expectation, that a neurosis which has defied every therapeutic effort may vanish if the subject becomes involved in the misery of an unhappy marriage, or loses all his money, or develops a dangerous organic disease. In such instances one form of suffering has been replaced by another; and we see that all that mattered was that it should be possible to maintain a certain amount of suffering.
But this does not at all agree with the observation which all of us can make that every neurosis disturbs the patient's relation to reality in some way, that it serves him as a means of withdrawing from reality, and that, in its severe forms, it actually signifies a flight from real life. This contradiction seems a serious one; but it is easily resolved, and the explanation of it will in fact help us to understand neuroses.

[1924e, 4094]

The World War, which broke up so many other organizations, could do nothing against our 'International'. The first meeting after the war took place in 1920, at The Hague, on neutral ground. It was moving to see how hospitably the Dutch welcomed the starving and impoverished subjects of the Central European states; and I believe this was the first occasion in a ruined world on which Englishmen and Germans sat at the same table for the friendly discussion of scientific interests. Both in Germany and in the countries of Western Europe the war had actually stimulated interest in psycho-analysis. The observation of war neuroses had at last opened the eyes of the medical profession to the importance of psychogenesis in neurotic disturbances, and some of our psychological conceptions, such as the 'gain from illness' and the 'flight into illness', quickly became popular. The last Congress before the German collapse, which was held at Budapest in 1918, was attended by official representatives of the allied governments of the Central European powers, and they agreed to the establishment of psycho-analytic Centres for the treatment of war neuroses. But this point was never reached. Similarly too the comprehensive plans made by one of our leading members, Dr. Anton von Freund, for establishing in Budapest a centre for analytic study and treatment came to grief as a result of the political upheavals that followed soon afterwards and of the premature death of their irreplaceable author. At a later date some of his ideas were put into execution by Max Eitingon, who in 1920 founded a psycho-analytical clinic in Berlin. During the brief period of Bolshevik rule in Hungary, Ferenczi was still able to carry on a successful course of instruction as the official representative of psycho-analysis at the University of Budapest. After the war our opponents were pleased to announce that events had produced a conclusive argument against the validity of the theses of analysis. The war neuroses, they said, had proved that sexual factors were unnecessary to the aetiology of neurotic disorders. But their triumph was frivolous and premature. For on the one hand no one had been able to carry out a thorough analysis of a case of war neurosis, so that in fact nothing whatever was known for certain as to their motivation and no conclusions could be drawn from this uncertainty; while on the other hand psycho-analysis had long before arrived at the concept of narcissism and of narcissistic neuroses, in which the subject's libido is attached to his own ego instead of to an object. Though on other occasions, therefore, the charge was brought against psycho-analysis of having made an unjustifiable extension of the concept of sexuality, yet, when it became convenient for controversial ends, this crime was forgotten and we were once more held down to the narrowest meaning of the word.

[1925d, 4229]
In this secondary defensive struggle the ego presents two faces with contradictory expressions. The one line of behaviour it adopts springs from the fact that its very nature obliges it to make what must be regarded as an attempt at restoration or reconciliation. The ego is an organization. It is based on the maintenance of free intercourse and of the possibility of reciprocal influence between all its parts. Its desexualized energy still shows traces of its origin in its impulsion to bind together and unify, and this necessity to synthesize grows stronger in proportion as the strength of the ego increases. It is therefore only natural that the ego should try to prevent symptoms from remaining isolated and alien by using every possible method to bind them to itself in one way or another, and to incorporate them into its organization by means of those bonds. As we know, a tendency of this kind is already operative in the very act of forming a symptom. A classical instance of this are those hysterical symptoms which have been shown to be a compromise between the need for satisfaction and the need for punishment. Such symptoms participate in the ego from the very beginning, since they fulfil a requirement of the super-ego, while on the other hand they represent positions occupied by the repressed and points at which an irruption has been made by it into the ego-organization. They are a kind of frontier-station with a mixed garrison. (Whether all primary hysterical symptoms are constructed on these lines would be worth enquiring into very carefully.) The ego now proceeds to behave as though it recognized that the symptom had come to stay and that the only thing to do was to accept the situation in good part and draw as much advantage from it as possible. It makes an adaptation to the symptom - to this piece of the internal world which is alien to it - just as it normally does to the real external world. It can always find plenty of opportunities for doing so. The presence of a symptom may entail a certain impairment of capacity, and this can be exploited to appease some demand on the part of the super-ego or to refuse some claim from the external world. In this way the symptom gradually comes to be the representative of important interests; it is found to be useful in asserting the position of the self and becomes more and more closely merged with the ego and more and more indispensable to it. It is only very rarely that the physical process of 'healing' round a foreign body follows such a course as this. There is a danger, too, of exaggerating the importance of a secondary adaptation of this kind to a symptom, and of saying that the ego has created the symptom merely in order to enjoy its advantages. It would be equally true to say that a man who had lost his leg in the war had got it shot away so that he might thenceforward live on his pension without having to do any more work.

[1926d, 4259]

In obsessional neurosis and paranoia the forms which the symptoms assume become very valuable to the ego because they obtain for it, not certain advantages, but a narcissistic satisfaction which it would otherwise be without. The systems which the obsessional neurotic constructs flatter his self-love by making him feel that he is better than other people because he is specially cleanly or specially conscientious. The delusional constructions of the paranoic offer to his acute perceptive and imaginative powers a field of activity which he could not easily find elsewhere.

[1926d, 4260]

All of this results in what is familiar to us as the '(secondary) gain from illness' which follows a neurosis. This gain comes to the assistance of the ego in its endeavour to incorporate the symptom and increases the symptom's fixation. When the analyst tries subsequently to help the ego in its struggle against the symptom, he finds that these conciliatory bonds between ego and symptom operate on the side of the resistances and that they are not easy to loosen.

[1926d, 4260]
It must not be supposed that these emendations provide us with a complete survey of all the kinds of resistance that are met with in analysis. Further investigation of the subject shows that the analyst has to combat no less than five kinds of resistance, emanating from three directions: the ego, the id and the super-ego. The ego is the source of three of these, each differing in its dynamic nature. The first of these three ego-resistances is the repression resistance, which we have already discussed above and about which there is least new to be added. Next there is the transference resistance, which is of the same nature but which has different and much clearer effects in analysis, since it succeeds in establishing a relation to the analytic situation or the analyst himself and thus re-animating a repression which should only have been recollected. The third resistance, though also an ego-resistance, is of quite a different nature. It proceeds from the gain from illness and is based upon an assimilation of the symptom into the ego. It represents an unwillingness to renounce any satisfaction or relief that has been obtained. The fourth variety, arising from the id, is the resistance which, as we have just seen, necessitates ‘working-through’. The fifth, coming from the super-ego and the last to be discovered, is also the most obscure though not always the least powerful one. It seems to originate from the sense of guilt or the need for punishment; and it opposes every move towards success, including, therefore, the patient's own recovery through analysis.

[1926d, 4313]

The derivatives of what is repressed have broken into his ego and established themselves there; and the ego has as little control over trends from that source as it has over what is actually repressed, and as a rule it knows nothing about them. These patients, indeed, are of a peculiar nature and raise difficulties with which we are not accustomed to reckon. All our social institutions are framed for people with a united and normal ego, which one can classify as good or bad, which either fulfils its function or is altogether eliminated by an overpowering influence. Hence the juridical alternative: responsible or irresponsible. None of these distinctions apply to neurotics. It must be admitted that there is difficulty in adapting social demands to their psychological condition. This was experienced on a large scale during the last war. Were the neurotics who evaded service malingerers or not? They were both. If they were treated as malingerers and if their illness was made highly uncomfortable, they recovered; if after being ostensibly restored they were sent back into service, they promptly took flight once more into illness. Nothing could be done with them. And the same is true of neurotics in civil life. They complain of their illness but exploit it with all their strength; and if someone tries to take it away from them they defend it like the proverbial lioness with her young. Yet there would be no sense in reproaching them for this contradiction.

[1926e, 4363]

Oh, that is not so hard to understand. Think of the war neurotics, who do not have to serve, precisely because they are ill. In civil life illness can be used as a screen to gloss over incompetence in one's profession or in competition with other people; while in the family it can serve as a means for sacrificing the other members and extorting proofs of their love or for imposing one's will upon them. All of this lies fairly near the surface; we sum it up in the term 'gain from illness'. It is curious, however, that the patient - that is, his ego - nevertheless knows nothing of the whole concatenation of these motives and the actions which they involve. One combats the influence of these trends by compelling the ego to take cognizance of them. But there are other motives, that lie still deeper, for holding on to being ill, which are not so easily dealt with. But these cannot be understood without a fresh journey into psychological theory.

[1926e, 4364]
Yes, we are only beginning to appreciate the significance of all these important circumstances. That is why my description was bound to turn out so obscure. But now I can proceed. We describe all the forces that oppose the work of recovery as the patient's 'resistances'. The gain from illness is one such resistance. The 'unconscious sense of guilt' represents the super-ego's resistance; it is the most powerful factor, and the one most dreaded by us. We meet with still other resistances during the treatment. If the ego during the early period has set up a repression out of fear, then the fear still persists and manifests itself as a resistance if the ego approaches the repressed material. And finally, as you can imagine, there are likely to be difficulties if an instinctual process which has been going along a particular path for whole decades is suddenly expected to take a new path that has just been made open for it. That might be called the id's resistance. The struggle against all these resistances is our main work during an analytic treatment; the task of making interpretations is nothing compared to it. But as a result of this struggle and of the overcoming of the resistances, the patient's ego is so much altered and strengthened that we can look forward calmly to his future behaviour when the treatment is over. On the other hand, you can understand now why we need such long treatments. The length of the path of development and the wealth of the material are not the decisive factors. It is more a question of whether the path is clear. An army can be held up for weeks on a stretch of country which in peace time an express train crosses in a couple of hours - if the army has to overcome the enemy's resistance there. Such battles call for time in mental life too. I am unfortunately obliged to tell you that every effort to hasten analytic treatment appreciably has hitherto failed. The best way of shortening it seems to be to carry it out according to the rules.

For, whether a man is a homosexual or a necrophilic, a hysterical suffering from anxiety, an obsessional neurotic cut off from society, or a raving lunatic, the 'Individual Psychologist' of the Adlerian school will declare that the impelling motive of his condition is that he wishes to assert himself, to overcompensate for his inferiority, to remain 'on top', to pass from the feminine to the masculine line. In my young student days we used to hear something very much the same in the out-patients' department when a case of hysteria was introduced: hysterical patients, we were told, produce their symptoms to make themselves interesting, to draw attention to themselves. It is a remarkable thing how these ancient pieces of wisdom keep on cropping up. But even at that time this fragment of psychology did not seem to cover the riddle of hysteria. It left unexplained, for instance, why the patients used no other methods for attaining their purpose. There must, of course, be something correct in this theory of the 'Individual Psychologists': a small particle is taken for the whole. The self-preservative instinct will try to profit by every situation; the ego will seek to turn even illness to its advantage. In psychoanalysis this is known as the 'secondary gain from illness'. Though, indeed, when we think of the facts of masochism, of the unconscious need for punishment and of neurotic self-injury, which make plausible the hypothesis of there being instinctual impulses that run contrary to self-preservation, we even feel shaken in our belief in the general validity of the commonplace truth on which the theoretical structure of Individual Psychology is erected. But a theory such as this is bound to be very welcome to the great mass of the people, a theory which recognizes no complications, which introduces no new concepts that are hard to grasp, which knows nothing of the unconscious, which gets rid at a single blow of the universally oppressive problem of sexuality and which restricts itself to the discovery of the artifices by which people seek to make life easy. For the mass of the people themselves take things easily: they call for no more than a single reason by way of explanation, they do not thank science for its diffuseness, they want to have simple solutions and to know that problems are solved. When we consider how very far Individual Psychology goes in meeting these demands, we cannot suppress the recollection of a sentence in Wallenstein:

[1933a, 4743]
Let us now consider the manner in which our therapy operates. It falls in with one of the dearest human wishes - the wish to be able to do something over again. Someone has experienced a psychical trauma without reacting to it sufficiently. We get him to experience it a second time, but under hypnosis; and we now compel him to complete his reaction to it. He can then get rid of the idea's affect, which was so to say 'strangulated', and when this is done the operation of the idea is brought to an end. Thus we cure - not hysteria but some of its individual symptoms - by causing an unaccomplished reaction to be completed.

[1893a, 298]

² If anyone is curious to know, I may add that the dream concealed a phantasy of my behaving in an improper and sexually provocative manner, and of the patient putting up a defence against my conduct. If this interpretation seems incredible, I need only point to the numerous instances in which doctors have charges of the same kind brought against them by hysterical women. But in such cases the phantasy emerges into consciousness undisguised and in the form of a delusion, instead of being distorted and appearing only as a dream. - [Added 1909:] This dream occurred at the beginning of the patient's psycho-analytic treatment. It was not until later that I learnt that she had been repeating in it the initial trauma from which her neurosis had arisen. I have since then come across the same behaviour in other patients; having been exposed to a sexual assault in their childhood, they seek, as it were, to bring about a repetition of it in their dreams.

[1900a, 671]

I have already discussed a dream which taught us that the wishes which are represented in dreams as fulfilled are not always present-day wishes. They may also be wishes of the past which have been abandoned, overlaid and repressed, and to which we have to attribute some sort of continued existence only because of their re-emergence in a dream. They are not dead in our sense of the word but only like the shades in the Odyssey, which awoke to some sort of life as soon as they had tasted blood. In the dream of the dead child in the 'case' (p. 154) what was involved was a wish which had been an immediate one fifteen years earlier and was frankly admitted as having existed at that time. I may add - and this may not be without its bearing upon the theory of dreams - that even behind this wish there lay a memory from the dreamer's earliest childhood. When she was a small child - the exact date could not be fixed with certainty - she had heard that her mother had fallen into a deep depression during the pregnancy of which she had been the fruit and had passionately wished that the child she was bearing might die. When the dreamer herself was grown-up and pregnant, she merely followed her mother's example.

[1900a, 728]
If a furious raging against one's own integrity and one's own life can be hidden in this way behind apparently accidental clumsiness and motor inefficiency, it is not a very large step to find it possible to transfer the same view to mistakes that seriously endanger the lives and health of other people. What evidence I have to show that this view is a valid one is drawn from my experience with neurotics, and thus does not wholly meet the demands of the situation. I will give an account of a case in which something that was not strictly a faulty action but that rather deserves the name of a symptomatic or chance action gave me the clue which subsequently made it possible to resolve the patient's conflict. I once undertook the task of bringing an improvement to the marriage of a very intelligent man, whose disagreements with his fondly attached young wife could undoubtedly be shown to have a real basis, but could not, as he himself admitted, be completely accounted for in that way. He was continually occupied with the thought of a divorce, which he then dismissed once more because of his warm love for his two small children. In spite of this he constantly returned to his intention and made no attempt to find a way of making the situation tolerable to himself. Such inability to deal with a conflict is taken by me as proof that unconscious and repressed motives have lent a hand in strengthening the conscious ones which are struggling against each other, and I undertake in such cases to end the conflict by psychical analysis. One day the man told me of a small incident which had frightened him extremely. He was romping with his elder child, who was by far his favourite; he was swinging him high in the air and down again, and once he swung him so high while he was standing at a particular spot that the top of the child's head almost struck the heavy gas chandelier that was hanging there. Almost, but not quite - or perhaps just! No harm came to the child, but it was made giddy with fright. The father stood horrified with the child in his arms, and the mother had a hysterical attack. The peculiar adroitness of this imprudent movement and the violence of the parents' reaction prompted me to look for a symptomatic act in this accident - one which aimed at expressing an evil intention directed against the beloved child. I was able to remove the contradiction between this and the father's contemporary affection for his child by shifting the impulse to injure it back to the time when this child had been the only one and had been so small that its father had not yet had any reason to take an affectionate interest in it. It was then easy for me to suppose that, as he was getting little satisfaction from his wife, he may at that time have had a thought or formed a decision of this kind: 'If this little creature that means nothing at all to me dies, I shall be free and able to get a divorce.' A wish for the death of the creature that he now loved so dearly must therefore have persisted unconsciously. From this point it was easy to find the path by which this wish had become unconsciously fixated. A powerful determinant was in fact provided by a memory from the patient's childhood: namely that the death of a small brother, for which his mother blamed his father's negligence, had led to violent quarrels between the parents and threats of a divorce. The subsequent course of my patient's marriage, as well as my therapeutic success, confirmed my conjecture.

[1901b, 1266]
'May you not have thought that he wanted to get divorced from his wife so as to marry you? And that now he no longer wants to because he has no one to replace her? It is true that two years ago you were very young. But you told me yourself that your mother was engaged at seventeen and then waited two years for her husband. A daughter usually takes her mother's love-story as her model. So you too wanted to wait for him, and you took it that he was only waiting till you were grown up enough to be his wife.¹ I imagine that this was a perfectly serious plan for the future in your eyes. You have not even got the right to assert that it was out of the question for Herr K. to have had any such intention; you have told me enough about him that points directly towards his having such an intention.² Nor does his behaviour at L-- contradict this view. After all, you did not let him finish his speech and do not know what he meant to say to you. Incidentally, the scheme would by no means have been so impracticable. Your father's relations with Frau K.- and it was probably only for this reason that you lent them your support for so long - made it certain that her consent to a divorce could be obtained; and you can get anything you like out of your father. Indeed, if your temptation at L-- had had a different upshot, this would have been the only possible solution for all the parties concerned. And I think that is why you regretted the actual event so deeply and emended it in the phantasy which made its appearance in the shape of the appendicitis. So it must have been a bitter piece of disillusionment for you when the effect of your charges against Herr K. was not that he renewed his proposals but that he replied instead with denials and slanders. You will agree that nothing makes you so angry as having it thought that you merely fancied the scene by the lake. I know now - and this is what you do not want to be reminded of - that you did fancy that Herr K.'s proposals were serious, and that he would not leave off until you had married him.' [1905e, 1443]

PERTINACITY OF EARLY IMPRESSIONS The importance of all early sexual manifestations is increased by a psychical factor of unknown origin, which at the moment, it must be admitted, can only be brought forward as a provisional psychological concept. I have in mind the fact that, in order to account for the situation, it is necessary to assume that these early impressions of sexual life are characterized by an increased pertinacity or susceptibility to fixation in persons who are later to become neurotics or perverts. For the same premature sexual manifestations, when they occur in other persons, fail to make so deep an impression; they do not tend in a compulsive manner towards repetition nor do they lay down the path to be taken by the sexual instinct for a whole lifetime. Part of the explanation of this pertinacity of early impressions may perhaps lie in another psychical factor which we must not overlook in the causation of the neuroses, namely the preponderance attaching in mental life to memory-traces in comparison with recent impressions. This factor is clearly dependent on intellectual education and increases in proportion to the degree of individual culture. The savage has been described in contrast as 'das unglückselige Kind des Augenblickes' ['The hapless child of the moment.'].¹ In consequence of the inverse relation holding between civilization and the free development of sexuality, of which the consequences can be followed far into the structure of our existences, the course taken by the sexual life of a child is just as unimportant for later life where the cultural or social level is relatively low as it is important where that level is relatively high. [1905d, 1552]
The second case, in which the comic depends entirely on 'empathy', includes the most numerous possibilities - the comic of situation, of exaggeration (caricature), of mimicry, of degradation and of unmasking. This is the case in which the introduction of the infantile point of view proves most useful. For the comic of situation is mostly based on embarrassments, in which we rediscover the child's helplessness. The worst of the embarrassments, the interference by the peremptory demands of natural needs with other functions, corresponds to the child's incomplete control over his bodily functions. Where the comic of situation operates by means of repetitions, it is based on the child's peculiar pleasure in constant repetition (of questions or of being told stories) which make him a nuisance to the adult. Exaggeration, which still gives pleasure to adults in so far as it can find justification with their critical faculty, is connected with the child's peculiar lack of a sense of proportion, his ignorance of all quantitative relations, which he comes to know later than qualitative ones. The use of moderation and restraint, even in the case of permitted impulses, is a late fruit of education and is acquired by the mutual inhibition of mental activities brought together in a combination. Where such combinations are weakened, as in the unconscious of dreams or in the mono-ideism of psychoneuroses, the child's lack of moderation re-emerges.

(d) Over a period of time she used to repeat an especially noticeable and senseless obsessive action. She would run out of her room into another room in the middle of which there was a table. She would straighten the tablecloth on it in a particular manner and ring for the housemaid. The latter had to come up to the table, and the patient would then dismiss her on some indifferent errand. In the attempts to explain this compulsion, it occurred to her that at one place on the tablecloth there was a stain, and that she always arranged the cloth in such a way that the housemaid was bound to see the stain. The whole scene proved to be a reproduction of an experience in her married life which had later on given her thoughts a problem to solve. On the wedding-night her husband had met with a not unusual mishap. He found himself impotent, and 'many times in the course of the night he came hurrying from his room into hers' to try once more whether he could succeed. In the morning he said he would feel ashamed in front of the hotel housemaid who made the beds, and he took a bottle of red ink and poured its contents over the sheet; but he did it so clumsily that the red stain came in a place that was very unsuitable for his purpose. With her obsessive action, therefore, she was representing the wedding-night. 'Bed and board' between them make up marriage.

Investigation of the childhood history of hysterical patients shows that the hysterical attack is designed to take the place of an auto-erotic satisfaction previously practised and since given up. In a great number of cases this satisfaction (masturbation by contact or by pressure of the thighs, or, again, by movements of the tongue, and so on) recurs during the attack itself, while the subject's consciousness is deflected. Moreover, the onset of an attack that is due to an increase of libido and is in the service of the primary purpose - as a consolation - exactly repeats the conditions under which, at the earlier time, the patient had intentionally sought this auto-erotic satisfaction. The anamnesis of the patient shows the following stages: (a) auto-erotic satisfaction, without ideational content; (b) the same satisfaction, connected with a phantasy which leads to the act of satisfaction; (c) renunciation of the act, with retention of the phantasy; (d) repression of the phantasy, which then comes into effect as a hysterical attack, either in an unchanged form, or in a modified one and adapted to new environmental impressions. Furthermore, (e) the phantasy may even reinstate the act of satisfaction belonging to it which had ostensibly been given up. This is a typical cycle of infantile sexual activity: repression, failure of repression, and return of the repressed.
It must be understood that each individual, through the combined operation of his innate disposition and the influences brought to bear on him during his early years, has acquired a specific method of his own in his conduct of his erotic life - that is, in the preconditions to falling in love which he lays down, in the instincts he satisfies and the aims he sets himself in the course of it.¹ This produces what might be described as a stereotype plate (or several such), which is constantly repeated - constantly reprinted afresh - in the course of the person's life, so far as external circumstances and the nature of the love objects accessible to him permit, and which is certainly not entirely insusceptible to change in the face of recent experiences. Now, our observations have shown that only a portion of these impulses which determine the course of erotic life have passed through the full process of psychical development. That portion is directed towards reality, is at the disposal of the conscious personality, and forms a part of it. Another portion of the libidinal impulses has been held up in the course of development; it has been kept away from the conscious personality and from reality, and has either been prevented from further expansion except in phantasy or has remained wholly in the unconscious so that it is unknown to the personality's consciousness. If someone's need for love is not entirely satisfied by reality, he is bound to approach every new person whom he meets with libidinal anticipatory ideas; and it is highly probable that both portions of his libido, the portion that is capable of becoming conscious as well as the unconscious one, have a share in forming that attitude.
[1912b, 2457]

Nevertheless, it emerges from this discussion that there is no need to assume the existence of a special imitative instinct in order to provide a motive for play. Finally, a reminder may be added that the artistic play and artistic imitation carried out by adults, which, unlike children's, are aimed at an audience, do not spare the spectators (for instance, in tragedy) the most painful experiences and can yet be felt by them as highly enjoyable. This is convincing proof that, even under the dominance of the pleasure principle, there are ways and means enough of making what is in itself unpleasurable into a subject to be recollected and worked over in the mind. The consideration of these cases and situations, which have a yield of pleasure as their final outcome, should be undertaken by some system of aesthetics with an economic approach to its subject-matter. They are of no use for our purposes, since they presuppose the existence and dominance of the pleasure principle; they give no evidence of the operation of tendencies beyond the pleasure principle, that is, of tendencies more primitive than it and independent of it.
[1920g, 3722]
But it became ever clearer that the aim which had been set up - the aim that what was unconscious should become conscious - is not completely attainable by that method. The patient cannot remember the whole of what is repressed in him, and what he cannot remember may be precisely the essential part of it. Thus he acquires no sense of conviction of the correctness of the construction that has been communicated to him. He is obliged to repeat the repressed material as a contemporary experience instead of, as the physician would prefer to see, remembering it as something belonging to the past.¹ These reproductions, which emerge with such unwished-for exactitude, always have as their subject some portion of infantile sexual life - of the Oedipus complex, that is, and its derivatives; and they are invariably acted out in the sphere of the transference, of the patient's relation to the physician. When things have reached this stage, it may be said that the earlier neurosis has now been replaced by a fresh, 'transference neurosis'. It has been the physician's endeavour to keep this transference neurosis within the narrowest limits: to force as much as possible into the channel of memory and to allow as little as possible to emerge as repetition. The ratio between what is remembered and what is reproduced varies from case to case. The physician cannot as a rule spare his patient this phase of the treatment. He must get him to re-experience some portion of his forgotten life, but must see to it, on the other hand, that the patient retains some degree of aloofness, which will enable him, in spite of everything, to recognize that what appears to be reality is in fact only a reflection of a forgotten past. If this can be successfully achieved, the patient's sense of conviction is won, together with the therapeutic success that is dependent on it.

[1920g, 3723]

In order to make it easier to understand this 'compulsion to repeat', which emerges during the psycho-analytic treatment of neurotics, we must above all get rid of the mistaken notion that what we are dealing with in our struggle against resistances is resistance on the part of the unconscious. The unconscious - that is to say, the 'repressed' - offers no resistance whatever to the efforts of the treatment. Indeed, it itself has no other endeavour than to break through the pressure weighing down on it and force its way either to consciousness or to a discharge through some real action. Resistance during treatment arises from the same higher strata and systems of the mind which originally carried out repression. But the fact that, as we know from experience, the motives of the resistances, and indeed the resistances themselves, are unconscious at first during the treatment, is a hint to us that we should correct a shortcoming in our terminology. We shall avoid a lack of clarity if we make our contrast not between the conscious and the unconscious but between the coherent ego and the repressed. It is certain that much of the ego is itself unconscious, and notably what we may describe as its nucleus; only a small part of it is covered by the term 'preconscious'. Having replaced a purely descriptive terminology by one which is systematic or dynamic, we can say that the patient's resistance arises from his ego, and we then at once perceive that the compulsion to repeat must be ascribed to the unconscious repressed. It seems probable that the compulsion can only express itself after the work of treatment has gone half-way to meet it and has loosened the repression.¹

[1920g, 3724]
There is no doubt that the resistance of the conscious and unconscious ego operates under the sway of the pleasure principle: it seeks to avoid the unpleasure which would be produced by the liberation of the repressed. Our efforts, on the other hand, are directed towards procuring the toleration of that unpleasure by an appeal to the reality principle. But how is the compulsion to repeat - the manifestation of the power of the repressed - related to the pleasure principle? It is clear that the greater part of what is re-experienced under the compulsion to repeat must cause the ego unpleasure, since it brings to light activities of repressed instinctual impulses. That, however, is unpleasure of a kind we have already considered and does not contradict the pleasure principle: unpleasure for one system and simultaneously satisfaction for the other. But we come now to a new and remarkable fact, namely that the compulsion to repeat also recalls from the past experiences which include no possibility of pleasure, and which can never, even long ago, have brought satisfaction even to instinctual impulses which have since been repressed.

[1920g, 3725]

Patients repeat all of these unwanted situations and painful emotions in the transference and revive them with the greatest ingenuity. They seek to bring about the interruption of the treatment while it is still incomplete; they contrive once more to feel themselves scorned, to oblige the physician to speak severely to them and treat them coldly; they discover appropriate objects for their jealousy; instead of the passionately desired baby of their childhood, they produce a plan or a promise of some grand present - which turns out as a rule to be no less unreal. None of these things can have produced pleasure in the past, and it might be supposed that they would cause less unpleasure to-day if they emerged as memories or dreams instead of taking the form of fresh experiences. They are of course the activities of instincts intended to lead to satisfaction; but no lesson has been learnt from the old experience of these activities having led instead only to unpleasure. In spite of that, they are repeated, under pressure of a compulsion.

[1920g, 3725]
What psycho-analysis reveals in the transference phenomena of neurotics can also be observed in the lives of some normal people. The impression they give is of being pursued by a malignant fate or possessed by some 'daemonic' power; but psycho-analysis has always taken the view that their fate is for the most part arranged by themselves and determined by early infantile influences. The compulsion which is here in evidence differs in no way from the compulsion to repeat which we have found in neurotics, even though the people we are now considering have never shown any signs of dealing with a neurotic conflict by producing symptoms. Thus we have come across people all of whose human relationships have the same outcome: such as the benefactor who is abandoned in anger after a time by each of his protégés, however much they may otherwise differ from one another, and who thus seems doomed to taste all the bitterness of ingratitude; or the man whose friendships all end in betrayal by his friend; or the man who time after time in the course of his life raises someone else into a position of great private or public authority and then, after a certain interval, himself upsets that authority and replaces him by a new one; or, again, the lover each of whose love affairs with a woman passes through the same phases and reaches the same conclusion. This 'perpetual recurrence of the same thing' causes us no astonishment when it relates to active behaviour on the part of the person concerned and when we can discern in him an essential character-trait which always remains the same and which is compelled to find expression in a repetition of the same experiences. We are much more impressed by cases where the subject appears to have a passive experience, over which he has no influence, but in which he meets with a repetition of the same fatality. There is the case, for instance, of the woman who married three successive husbands each of whom fell ill soon afterwards and had to be nursed by her on their death-beds.' The most moving poetic picture of a fate such as this is given by Tasso in his romantic epic Gerusalemme Liberata. Its hero, Tancred, unwittingly kills his beloved Clorinda in a duel while she is disguised in the armour of an enemy knight. After her burial he makes his way into a strange magic forest which strikes the Crusaders’ army with terror. He slashes with his sword at a tall tree; but blood streams from the cut and the voice of Clorinda, whose soul is imprisoned in the tree, is heard complaining that he has wounded his beloved once again.

If we take into account observations such as these, based upon behaviour in the transference and upon the life-histories of men and women, we shall find courage to assume that there really does exist in the mind a compulsion to repeat which overrides the pleasure principle. Now too we shall be inclined to relate to this compulsion the dreams which occur in traumatic neuroses and the impulse which leads children to play.

But it is to be noted that only in rare instances can we observe the pure effects of the compulsion to repeat, unsupported by other motives. In the case of children's play we have already laid stress on the other ways in which the emergence of the compulsion may be interpreted; the compulsion to repeat and instincntual satisfaction which is immediately pleasurable seem to converge here into an intimate partnership. The phenomena of transference are obviously exploited by the resistance which the ego maintains in its pertinacious insistence upon repression; the compulsion to repeat, which the treatment tries to bring into its service is, as it were, drawn over by the ego to its side (clinging as the ego does to the pleasure principle). A great deal of what might be described as the compulsion of destiny seems intelligible on a rational basis; so that we are under no necessity to call in a new and mysterious motive force to explain it.
The manifestations of a compulsion to repeat (which we have described as occurring in the early activities of infantile mental life as well as among the events of psycho-analytic treatment) exhibit to a high degree an instinctual character and, when they act in opposition to the pleasure principle, give the appearance of some 'daemonic' force at work. In the case of children's play we seemed to see that children repeat unpleasurable experiences for the additional reason that they can master a powerful impression far more thoroughly by being active than they could by merely experiencing it passively. Each fresh repetition seems to strengthen the mastery they are in search of. Nor can children have their pleasurable experiences repeated often enough, and they are inexorable in their insistence that the repetition shall be an identical one. This character trait disappears later on. If a joke is heard for a second time it produces almost no effect; a theatrical production never creates so great an impression the second time as the first; indeed, it is hardly possible to persuade an adult who has very much enjoyed reading a book to re-read it immediately. Novelty is always the condition of enjoyment. But children will never tire of asking an adult to repeat a game that he has shown them or played with them, till he is too exhausted to go on. And if a child has been told a nice story, he will insist on hearing it over and over again rather than a new one; and he will remorselessly stipulate that the repetition shall be an identical one and will correct any alterations of which the narrator may be guilty - though they may actually have been made in the hope of gaining fresh approval. None of this contradicts the pleasure principle; repetition, the re-experiencing of something identical, is clearly in itself a source of pleasure. In the case of a person in analysis, on the contrary, the compulsion to repeat the events of his childhood in the transference evidently disregards the pleasure principle in every way. The patient behaves in a purely infantile fashion and thus shows us that the repressed memory-traces of his primaeval experiences are not present in him in a bound state and are indeed in a sense incapable of obeying the secondary process. It is to this fact of not being bound, moreover, that they owe their capacity for forming, in conjunction with the residues of the previous day, a wishful phantasy that emerges in a dream. This same compulsion to repeat frequently meets us as an obstacle to our treatment when at the end of an analysis we try to induce the patient to detach himself completely from his physician. It may be presumed, too, that when people unfamiliar with analysis feel an obscure fear - a dread of rousing something that, so they feel, is better left sleeping - what they are afraid of at bottom is the emergence of this compulsion with its hint of possession by some 'daemonic' power.

In Beyond the Pleasure Principle (1920g) I have dealt with the economic problem of how what are in every respect distressing experiences of the early infantile sexual period can succeed in forcing their way through to some kind of reproduction. I was obliged to ascribe to them an extraordinarily strong upward drive in the shape of the 'compulsion to repeat' - a force able to overcome the repression which, in obedience to the pleasure principle, weighs down upon them - though not until 'the work of treatment has gone half-way to meet it and has loosened the repression'. Here we may add that it is the positive transference that gives this assistance to the compulsion to repeat. Thus an alliance has been made between the treatment and the compulsion to repeat, an alliance which is directed in the first instance against the pleasure principle but of which the ultimate purpose is the establishment of the dominion of the reality principle. As I have shown in the passage to which I am referring, it happens only too often that the compulsion to repeat throws over its obligations under this alliance and is not content with the return of the repressed merely in the form of dream-pictures.
In the works of my later years (Beyond the Pleasure Principle, Group Psychology and the Analysis of the Ego, and The Ego and the Id), I have given free rein to the inclination, which I kept down for so long, to speculation, and I have also contemplated a new solution of the problem of the instincts. I have combined the instincts for self-preservation and for the preservation of the species under the concept of Eros and have contrasted with it an instinct of death or destruction which works in silence. Instinct in general is regarded as a kind of elasticity of living things, an impulsion towards the restoration of a situation which once existed but was brought to an end by some external disturbance. This essentially conservative character of instincts is exemplified by the phenomena of the compulsion to repeat. The picture which life presents to us is the result of the concurrent and mutually opposing action of Eros and the death instinct.

[1925d, 4232]

Psycho-analysis leads to less simple and satisfactory conclusions. What I have to say in this connection has long been familiar and I have nothing new to add. If the ego succeeds in protecting itself from a dangerous instinctual impulse, through, for instance, the process of repression, it has certainly inhibited and damaged the particular part of the id concerned; but it has at the same time given it some independence and has renounced some of its own sovereignty. This is inevitable from the nature of repression, which is, fundamentally, an attempt at flight. The repressed is now, as it were, an outlaw; it is excluded from the great organization of the ego and is subject only to the laws which govern the realm of the unconscious. If, now, the danger-situation changes so that the ego has no reason for fending off a new instinctual impulse analogous to the repressed one, the consequence of the restriction of the ego which has taken place will become manifest. The new impulse will run its course under an automatic influence - or, as I should prefer to say, under the influence of the compulsion to repeat. It will follow the same path as the earlier, repressed impulse, as though the danger-situation that had been overcome still existed. The fixating factor in repression, then, is the unconscious id's compulsion to repeat - a compulsion which in normal circumstances is only done away with by the freely mobile function of the ego. The ego may occasionally manage to break down the barriers of repression which it has itself put up and to recover its influence over the instinctual impulse and direct the course of the new impulse in accordance with the changed danger-situation. But in point of fact the ego very seldom succeeds in doing this: it cannot undo its repressions. It is possible that the way the struggle will go depends upon quantitative relations. In some cases one has the impression that the outcome is an enforced one: the regressive attraction exerted by the repressed impulse and the strength of the repression are so great that the new impulse has no choice but to obey the compulsion to repeat. In other cases we perceive a contribution from another play of forces: the attraction exerted by the repressed prototype is reinforced by a repulsion coming from the direction of difficulties in real life which stand in the way of any different course that might be taken by the new instinctual impulse.

[1926d, 4307]
We showed on an earlier occasion that the resistance that has to be overcome in analysis proceeds from the ego, which clings to its anticathexes. It is hard for the ego to direct its attention to perceptions and ideas which it has up till now made a rule of avoiding, or to acknowledge as belonging to itself impulses that are the complete opposite of those which it knows as its own. Our fight against resistance in analysis is based upon this view of the facts. If the resistance is itself unconscious, as so often happens owing to its connection with the repressed material, we make it conscious. If it is conscious, or when it has become conscious, we bring forward logical arguments against it; we promise the ego rewards and advantages if it will give up its resistance. There can be no doubt or mistake about the existence of this resistance on the part of the ego. But we have to ask ourselves whether it covers the whole state of affairs in analysis. For we find that even after the ego has decided to relinquish its resistances it still has difficulty in undoing the repressions; and we have called the period of strenuous effort which follows after its praiseworthy decision, the phase of 'working-through'.

The dynamic factor which makes a working-through of this kind necessary and comprehensible is not far to seek. It must be that after the ego's resistance has been removed the power of the compulsion to repeat - the attraction exerted by the unconscious prototype upon the repressed instinctual process - has still to be overcome. There is nothing to be said against describing this factor as the resistance of the unconscious. There is no need to be discouraged by these emendations. They are to be welcomed if they add something to our knowledge, and they are no disgrace to us so long as they enrich rather than invalidate our earlier views - by limiting some statement, perhaps, that was too general or by enlarging some idea that was too narrowly formulated.

From the first of these standpoints, the dynamic one, psycho-analysis derives all mental processes (apart from the reception of external stimuli) from the interplay of forces, which assist or inhibit one another, combine with one another, enter into compromises with one another, etc. All of these forces are originally in the nature of instincts; thus they have an organic origin. They are characterized by possessing an immense (somatic) store of power ('the compulsion to repeat'); and they are represented mentally as images or ideas with an affective charge. In psycho-analysis, no less than in other sciences, the theory of the instincts is an obscure subject. An empirical analysis leads to the formulation of two groups of instincts: the so-called 'ego-instincts', which are directed towards self-preservation, and the 'object-instincts', which are concerned with relations to an external object. The social instincts are not regarded as elementary or irreducible. Theoretical speculation leads to the suspicion that there are two fundamental instincts which lie concealed behind the manifest ego-instincts and object-instincts: namely (a) Eros, the instinct which strives for ever closer union, and (b) the instinct of destruction, which leads towards the dissolution of what is living. In psycho-analysis the manifestation of the force of Eros is given the name 'libido'.

[1926d, 4312][1926f, 4403]
Every analyst will admit that even to-day this view has not the sound of a long-discarded error. Nevertheless, alterations in it became essential, as our enquiries advanced from the repressed to the repressing forces, from the object-instincts to the ego. The decisive step forward was the introduction of the concept of narcissism - that is to say, the discovery that the ego itself is cathexed with libido, that the ego, indeed, is the libido's original home, and remains to some extent its headquarters. This narcissistic libido turns towards objects, and thus becomes object-libido; and it can change back into narcissistic libido once more. The concept of narcissism made it possible to obtain an analytic understanding of the traumatic neuroses and of many of the affections bordering on the psychoses, as well as of the latter themselves. It was not necessary to give up our interpretation of the transference neuroses as attempts made by the ego to defend itself against sexuality; but the concept of libido was endangered. Since the ego-instincts, too, were libidinal, it seemed for a time inevitable that we should make libido coincide with instinctual energy in general, as C. G. Jung had already advocated earlier. Nevertheless, there still remained in me a kind of conviction, for which I was not as yet able to find reasons, that the instincts could not all be of the same kind. My next step was taken in Beyond the Pleasure Principle (1920g), when the compulsion to repeat and the conservative character of instinctual life first attracted my attention. Starting from speculations on the beginning of life and from biological parallels, I drew the conclusion that, besides the instinct to preserve living substance and to join it into ever larger units,¹ there must exist another, contrary instinct seeking to dissolve those units and to bring them back to their primaeval, inorganic state. That is to say, as well as Eros there was an instinct of death. The phenomena of life could be explained from the concurrent or mutually opposing action of these two instincts. It was not easy, however, to demonstrate the activities of this supposed death instinct. The manifestations of Eros were conspicuous and noisy enough. It might be assumed that the death instinct operated silently within the organism towards its dissolution, but that, of course, was no proof. A more fruitful idea was that a portion of the instinct is diverted towards the external world and comes to light as an instinct of aggressiveness and destructiveness. In this way the instinct itself could be pressed into the service of Eros, in that the organism was destroying some other thing, whether animate or inanimate, instead of destroying its own self. Conversely, any restriction of this aggressiveness directed outwards would be bound to increase the self-destruction, which is in any case proceeding. At the same time one can suspect from this example that the two kinds of instinct seldom - perhaps never - appear in isolation from each other, but are alloyed with each other in varying and very different proportions and so become unrecognizable to our judgement. In sadism, long since known to us as a component instinct of sexuality, we should have before us a particularly strong alloy of this kind between trends of love and the destructive instinct; while its counterpart, masochism, would be a union between destructiveness directed inwards and sexuality - a union which makes what is otherwise an imperceptible trend into a conspicuous and tangible one.

[1930a, 4509]
But the moralist will console himself for a long time to come with the improbability of our speculations. A queer instinct indeed, directed to the destruction of its own organic home! Poets, it is true, talk of such things; but poets are irresponsible people and enjoy the privilege of poetic licence. Incidentally, such ideas are not foreign even to physiology: consider the notion, for instance, of the mucous membrane of the stomach digesting itself. It must be admitted, however, that our self-destructive instinct calls for support on a wider basis. One cannot, after all, venture on a hypothesis of such a wide range merely because a few poor fools have linked their sexual satisfaction to a peculiar condition. A more profound study of the instincts will, I believe, give us what we need. The instincts rule not only mental but also vegetative life, and these organic instincts exhibit a characteristic which deserves our deepest interest. (We shall not be able to judge until later whether it is a general characteristic of instincts.) For they reveal an effort to restore an earlier state of things. We may suppose that from the moment at which a state of things that has once been attained is upset, an instinct arises to create it afresh and brings about phenomena which we can describe as a 'compulsion to repeat'. Thus the whole of embryology is an example of the compulsion to repeat. A power of regenerating lost organs extends far up into the animal kingdom, and the instinct for recovery to which, alongside of therapeutic assistance, our cures are due must be the residue of this capacity which is so enormously developed in the lower animals. The spawning migrations of fishes, the migratory flights of birds, and possibly all that we describe as manifestations of instinct in animals, take place under the orders of the compulsion to repeat, which expresses the conservative nature of the instincts. Nor have we far to look in the mental field for its manifestations. We have been struck by the fact that the forgotten and repressed experiences of childhood are reproduced during the work of analysis in dreams and reactions, particularly in those occurring in the transference, although their revival runs counter to the interest of the pleasure principle; and we have explained this by supposing that in these cases a compulsion to repeat is overcoming even the pleasure principle. Outside analysis, too, something similar can be observed. There are people in whose lives the same reactions are perpetually being repeated uncorrected, to their own detriment, or others who seem to be pursued by a relentless fate, though closer investigation teaches us that they are unwittingly bringing this fate on themselves. In such cases we attribute a 'daemonic' character to the compulsion to repeat.

[1933a, 4710]

(2) Two points must be stressed in regard to the common characteristics or peculiarities of neurotic phenomena: (a) The effects of traumas are of two kinds, positive and negative. The former are attempts to bring the trauma into operation once again - that is, to remember the forgotten experience or, better still, to make it real, to experience a repetition of it anew, or, even if it was only an early emotional relationship, to revive it in an analogous relationship with someone else. We summarize these efforts under the name of 'fixations' to the trauma and as a 'compulsion to repeat'. They may be taken up into what passes as a normal ego and, as permanent trends in it, may lend it unalterable character-traits, although, or rather precisely because, their true basis and historical origin are forgotten. Thus a man who has spent his childhood in an excessive and to-day forgotten attachment to his mother, may spend his whole life looking for a wife on whom he can make himself dependent and by whom he can arrange to be nourished and supported. A girl who was made the object of a sexual seduction in her early childhood may direct her later sexual life so as constantly to provoke similar attacks. It may easily be guessed that from such discoveries about the problem of neurosis we can penetrate to an understanding of the formation of character in general.

[1939a, 4901]
A few years later at a Scientific Congress I met a prominent physician from Frau Emmy's part of the country. I asked him if he was acquainted with the lady and knew anything of her condition. Yes, he said, he knew her, and had himself given her hypnotic treatment. She had gone through the same performance with him - and with many other doctors - as she had with me. Her condition had become very bad; she had rewarded his hypnotic treatment of her by making a remarkable recovery, but had then suddenly quarrelled with him, left him, and once more set her illness going to its full extent. It was a genuine instance of the 'compulsion to repeat'.

¹ The appearance in dreams of things of great size and in great quantities and amounts, and of exaggeration generally, may be another childish characteristic. Children have no more ardent wish than to be big and grown-up and to get as much of things as grown-up people do. They are hard to satisfy, know no such word as 'enough' and insist insatiably on a repetition of things which they have enjoyed or whose taste they liked. It is only the civilizing influence of education that teaches them moderation and how to be content or resigned. Everyone knows that neurotics are equally inclined to be extravagant and immoderate.

'[1900a, 745]

'May you not have thought that he wanted to get divorced from his wife so as to marry you? And that now he no longer wants to because he has no one to replace her? It is true that two years ago you were very young. But you told me yourself that your mother was engaged at seventeen and then waited two years for her husband. A daughter usually takes her mother's love-story as her model. So you too wanted to wait for him, and you took it that he was only waiting till you were grown up enough to be his wife.¹ I imagine that this was a perfectly serious plan for the future in your eyes. You have not even got the right to assert that it was out of the question for Herr K. to have had any such intention; you have told me enough about him that points directly towards his having such an intention.² Nor does his behaviour at L-- contradict this view. After all, you did not let him finish his speech and do not know what he meant to say to you. Incidentally, the scheme would by no means have been so impracticable. Your father's relations with Frau K.- and it was probably only for this reason that you lent them your support for so long - made it certain that her consent to a divorce could be obtained; and you can get anything you like out of your father. Indeed, if your temptation at L-- had had a different upshot, this would have been the only possible solution for all the parties concerned. And I think that is why you regretted the actual event so deeply and emended it in the phantasy which made its appearance in the shape of the appendicitis. So it must have been a bitter piece of disillusionment for you when the effect of your charges against Herr K. was not that he renewed his proposals but that he replied instead with denials and slanders. You will agree that nothing makes you so angry as having it thought that you merely fancied the scene by the lake. I know now - and this is what you do not want to be reminded of - that you did fancy that Herr K.'s proposals were serious, and that he would not leave off until you had married him.'

[1905e, 1443]

The different theories of children's play have only recently been summarized and discussed from the psycho-analytic point of view by Pfeifer (1919), to whose paper I would refer my readers. These theories attempt to discover the motives which lead children to play, but they fail to bring into the foreground the economic motive, the consideration of the yield of pleasure involved. Without wishing to include the whole field covered by these phenomena, I have been able, through a chance opportunity which presented itself, to throw some light upon the first game played by a little boy of one and a half and invented by himself. It was more than a mere fleeting observation, for I lived under the same roof as the child and his parents for some weeks, and it was some time before I discovered the meaning of the puzzling activity which he constantly repeated.

[1920g, 3720]
The interpretation of the game then became obvious. It was related to the child's great cultural achievement - the instinctual renunciation (that is, the renunciation of instinctual satisfaction) which he had made in allowing his mother to go away without protesting. He compensated himself for this, as it were, by himself staging the disappearance and return of the objects within his reach. It is of course a matter of indifference from the point of view of judging the effective nature of the game whether the child invented it himself or took it over on some outside suggestion. Our interest is directed to another point. The child cannot possibly have felt his mother's departure as something agreeable or even indifferent. How then does his repetition of this distressing experience as a game fit in with the pleasure principle? It may perhaps be said in reply that her departure had to be enacted as a necessary preliminary to her joyful return, and that it was in the latter that lay the true purpose of the game. But against this must be counted the observed fact that the first act, that of departure, was staged as a game in itself and far more frequently than the episode in its entirety, with its pleasurable ending.

[1920g, 3721]

No certain decision can be reached from the analysis of a single case like this. On an unprejudiced view one gets an impression that the child turned his experience into a game from another motive. At the outset he was in a passive situation - he was overpowered by the experience; but, by repeating it, unpleasurable though it was, as a game, he took on an active part. These efforts might be put down to an instinct for mastery that was acting independently of whether the memory was in itself pleasurable or not. But still another interpretation may be attempted. Throwing away the object so that it was 'gone' might satisfy an impulse of the child's, which was suppressed in his actual life, to revenge himself on his mother for going away from him. In that case it would have a defiant meaning: 'All right, then, go away! I don't need you. I'm sending you away myself.' A year later, the same boy whom I had observed at his first game used to take a toy, if he was angry with it, and throw it on the floor, exclaiming: 'Go to the fwon!' He had heard at that time that his absent father was 'at the front', and was far from regretting his absence; on the contrary he made it quite clear that he had no desire to be disturbed in his sole possession of his mother.¹ We know of other children who liked to express similar hostile impulses by throwing away objects instead of persons.² We are therefore left in doubt as to whether the impulse to work over in the mind some overpowering experience so as to make oneself master of it can find expression as a primary event, and independently of the pleasure principle. For, in the case we have been discussing, the child may, after all, only have been able to repeat his unpleasant experience in play because the repetition carried along with it a yield of pleasure of another sort but none the less a direct one.

[1920g, 3721]

Nor shall we be helped in our hesitation between these two views by further considering children's play. It is clear that in their play children repeat everything that has made a great impression on them in real life, and that in doing so they abreact the strength of the impression and, as one might put it, make themselves master of the situation. But on the other hand it is obvious that all their play is influenced by a wish that dominates them the whole time - the wish to be grown-up and to be able to do what grown-up people do. It can also be observed that the unpleasurable nature of an experience does not always unsuit it for play. If the doctor looks down a child's throat or carries out some small operation on him, we may be quite sure that these frightening experiences will be the subject of the next game; but we must not in that connection overlook the fact that there is a yield of pleasure from another source. As the child passes over from the passivity of the experience to the activity of the game, he hands on the disagreeable experience to one of his playmates and in this way revenges himself on a substitute.

[1920g, 3722]
Nevertheless, it emerges from this discussion that there is no need to assume the existence of a special imitative instinct in order to provide a motive for play. Finally, a reminder may be added that the artistic play and artistic imitation carried out by adults, which, unlike children's, are aimed at an audience, do not spare the spectators (for instance, in tragedy) the most painful experiences and can yet be felt by them as highly enjoyable. This is convincing proof that, even under the dominance of the pleasure principle, there are ways and means enough of making what is in itself unpleasurable into a subject to be recollected and worked over in the mind. The consideration of these cases and situations, which have a yield of pleasure as their final outcome, should be undertaken by some system of aesthetics with an economic approach to its subject-matter. They are of no use for our purposes, since they presuppose the existence and dominance of the pleasure principle; they give no evidence of the operation of tendencies beyond the pleasure principle, that is, of tendencies more primitive than it and independent of it. [1920g, 3722]

If we take into account observations such as these, based upon behaviour in the transference and upon the life-histories of men and women, we shall find courage to assume that there really does exist in the mind a compulsion to repeat which overrides the pleasure principle. Now too we shall be inclined to relate to this compulsion the dreams which occur in traumatic neuroses and the impulse which leads children to play. [1920g, 3726]

But it is to be noted that only in rare instances can we observe the pure effects of the compulsion to repeat, unsupported by other motives. In the case of children's play we have already laid stress on the other ways in which the emergence of the compulsion may be interpreted; the compulsion to repeat and instinctual satisfaction which is immediately pleasurable seem to converge here into an intimate partnership. The phenomena of transference are obviously exploited by the resistance which the ego maintains in its pertinacious insistence upon repression; the compulsion to repeat, which the treatment tries to bring into its service is, as it were, drawn over by the ego to its side (clinging as the ego does to the pleasure principle). A great deal of what might be described as the compulsion of destiny seems intelligible on a rational basis; so that we are under no necessity to call in a new and mysterious motive force to explain it. [1920g, 3727]
The manifestations of a compulsion to repeat (which we have described as occurring in the early activities of infantile mental life as well as among the events of psycho-analytic treatment) exhibit to a high degree an instinctual character and, when they act in opposition to the pleasure principle, give the appearance of some 'daemonic' force at work. In the case of children's play we seemed to see that children repeat unpleasurable experiences for the additional reason that they can master a powerful impression far more thoroughly by being active than they could by merely experiencing it passively. Each fresh repetition seems to strengthen the mastery they are in search of. Nor can children have their pleasurable experiences repeated often enough, and they are inexorable in their insistence that the repetition shall be an identical one. This character trait disappears later on. If a joke is heard for a second time it produces almost no effect; a theatrical production never creates so great an impression the second time as the first; indeed, it is hardly possible to persuade an adult who has very much enjoyed reading a book to re-read it immediately. Novelty is always the condition of enjoyment. But children will never tire of asking an adult to repeat a game that he has shown them or played with them, till he is too exhausted to go on. And if a child has been told a nice story, he will insist on hearing it over and over again rather than a new one; and he will remorselessly stipulate that the repetition shall be an identical one and will correct any alterations of which the narrator may be guilty - though they may actually have been made in the hope of gaining fresh approval. None of this contradicts the pleasure principle; repetition, the re-experiencing of something identical, is clearly in itself a source of pleasure. In the case of a person in analysis, on the contrary, the compulsion to repeat the events of his childhood in the transference evidently disregards the pleasure principle in every way. The patient behaves in a purely infantile fashion and thus shows us that the repressed memory-traces of his pramaeval experiences are not present in him in a bound state and are indeed in a sense incapable of obeying the secondary process. It is to this fact of not being bound, moreover, that they owe their capacity for forming, in conjunction with the residues of the previous day, a wishful phantasy that emerges in a dream. This same compulsion to repeat frequently meets us as an obstacle to our treatment when at the end of an analysis we try to induce the patient to detach himself completely from his physician. It may be presumed, too, that when people unfamiliar with analysis feel an obscure fear - a dread of rousing something that, so they feel, is better left sleeping - what they are afraid of at bottom is the emergence of this compulsion with its hint of possession by some 'daemonic' power.

[1920g, 3738]
It was not I but Dr. Breuer who received news of her about seven months later. Her health had continued good for several months but had then broken down again as a result of a fresh psychical shock. Her elder daughter, during their first stay in Vienna, had already followed her mother in developing neck-cramps and mild hysterical states; but in particular, she had suffered from pains in walking owing to a retroverted uterus. On my advice she had gone for treatment to Dr. N., one of our most distinguished gynaecologists, who had put her uterus right by massage, and she had remained free from trouble for several months. Her trouble recurred, however, while they were at home, and her mother called in a gynaecologist from the neighbouring University town. He prescribed a combined local and general treatment for the girl, which, however, brought on a severe nervous illness (she was seventeen at the time). It is probable that this was already an indication of her pathological disposition which was to manifest itself a year later in a character-change. Her mother, who had handed the girl over to the doctors with her usual mixture of docility and mistrust, was overcome by the most violent self-reproaches after the unfortunate outcome of the treatment. A train of thought which I have not investigated brought her to the conclusion that Dr. N. and I were together responsible for the girl's illness because we had made light of her serious condition. By an act of will as it were, she undid the effects of my treatment and promptly, relapsed into the states from which I had freed her. A distinguished physician in her neighbourhood, to whom she went for advice, and Dr. Breuer, who was in correspondence with her, succeeded in convincing her of the innocence of the two targets of her accusations; but even after this was cleared up, the aversion to me which she formed at the time was left over as a hysterical residue, and she declared that it was impossible for her to take up her treatment with me again. On the advice of the same medical authority she turned for help to a Sanatorium in North Germany. At Breuer's desire I explained to the physician in charge the modifications of hypnotic therapy which I had found effective in her case.

[1895d, 71]

I saw Frau von N. again in the spring of the following year at her estate near D---. At this time her elder daughter, whose name she had called out during her 'storms in the head', entered on a phase of abnormal development. She exhibited unbridled ambitions which were out of all proportion to the poverty of her gifts, and she became disobedient and even violent towards her mother. I still enjoyed her mother's confidence and was sent for to give my opinion on the girl's condition. I formed an unfavourable impression of the psychological change that had occurred in the girl, and in arriving at a prognosis I had also to take into account the fact that all her step-brothers and sisters (the children of Herr von N. by his first marriage) had succumbed to paranoia. In her mother's family, too, there was no lack of a neuropathic heredity, although none of her more immediate relatives had developed a chronic psychosis. I communicated to Frau von N. without any reservation the opinion for which she had asked and she received it calmly and with understanding. She had grown stout, and looked in flourishing health. She had felt relatively very well during the nine months that had passed since the end of her last treatment. She had only been disturbed by slight neck-cramps and other minor ailments. During the several days which I spent in her house I came for the first time to realize the whole extent of her duties, occupations and intellectual interests. I also met the family doctor, who had not many complaints to make about the lady; so she had to some degree come to terms with the profession.

[1895d, 77]
(3) Where a period of hysterical production, an acute hysterical paroxysm, has been overcome and all that is left over are hysterical symptoms in the shape of residual phenomena, the cathartic method suffices for every indication and brings about complete and permanent successes. A favourable therapeutic constellation of this kind is not seldom to be found precisely in the region of sexual life, owing to the wide oscillations in the intensity of sexual needs and the complications of the conditions necessary in order to bring about a sexual trauma. Here the cathartic method does all that can be asked of it, for the physician cannot set himself the task of altering a constitution such as the hysterical one. He must content himself with getting rid of the troubles to which such a constitution is inclined and which may arise from it with the conjunction of external circumstances. He will feel satisfied if the patient regains her working capacity. Moreover, he is not without consolation for the future when he considers the possibility of a relapse. He is aware of the principal feature in the aetiology of the neuroses - that their genesis is as a rule overdetermined, that several factors must come together to produce this result; and he may hope that this convergence will not be repeated at once, even though a few individual aetiological factors remain operative.

[1895d, 232]

It seems to be the expression of a special inherited mental disposition. At any rate, 'similar heredity' is often enough found in obsessional cases, and in hysteria. Thus the patient in Case 2 told me that his father had suffered from similar symptoms. He once introduced me to a first cousin who had obsessions and a tic convulsif, and to his sister’s daughter, aged eleven, who already gave evidence of obsessions (probably of remorse).

[1895c, 322]

"In some cases of anxiety neurosis no aetiology at all is to be discovered. It is worth noting that in such cases there is seldom any difficulty in establishing evidence of a grave hereditary taint.

[1895f, 362]

"But where there are grounds for regarding the neurosis as an acquired one, careful enquiry directed to that end reveals that a set of noxae and influences from sexual life . . ." Löwenfeld quotes this passage and adds the following gloss: 'From this it appears that Freud always regards a neurosis as “acquired” whenever incidental causes are to be found for it.'

[1895f, 362]

If this meaning follows naturally from my text, then the latter gives a very distorted expression to my thoughts. Let me point out that in the preceding pages I have shown myself far stricter than Löwenfeld in my evaluation of incidental causes. If I were myself to elucidate the meaning of the passage I wrote I should add, after the subordinate clause ‘But where there are grounds for regarding the neurosis as an acquired one . . .’, the words ‘because evidence (referred to in the previous sentence) of a hereditary taint is not forthcoming . . .’ What this means is that I hold the case to be an acquired one, since no heredity is to be discovered in it. In doing so I am behaving like everyone else, perhaps with the slight difference that others may declare the case to be determined by heredity even when there is no heredity, so that they overlook the whole category of acquired neuroses. But this difference runs in my favour. I admit, however, that I am myself to blame for this misunderstanding, on account of the way in which I expressed myself in the first sentence: ‘no aetiology at all is to be discovered’. I shall certainly be taken to task from other directions as well and be told that I have created useless trouble for myself by searching for the specific causes of neuroses. Some will say that the true aetiology of anxiety neurosis, as of neuroses in general, is known: it is heredity. And two real causes cannot exist side by side. I have not, they will say, denied the aetiological role of heredity, but if so, all other aetiologies are merely incidental causes and equal to one an other in value or want of value.

[1895f, 362]
If we accept the idea of an aetiological equation of several terms which must be satisfied if the effect is to take place, then we may characterize as the precipitating or releasing cause the one which makes its appearance last in the equation, so that it immediately precedes the emergence of the effect. It is this chronological factor alone which constitutes the essential nature of a precipitating cause. Any of the other causes, too, can in a particular case play the role of precipitating cause; and this role can change within the same aetiological combination.

If I consider this aetiological formula for anxiety neurosis in detail, I am able to add the following remarks. Whether a special personal constitution (which need not be produced by heredity) is absolutely necessary for the production of an anxiety neurosis, or whether any normal person can be made to have an anxiety neurosis by some given quantitative increase of the specific factor - this I am not able to decide with certainty; but I incline strongly to the latter view. -Heredity disposition is the most important precondition for anxiety neurosis; but it is not an indispensable one, since it is absent in a class of borderline cases. -The presence of the specific sexual factor can, in the majority of cases, be demonstrated with certainty. In one series of cases (congenital ones) this factor is not separated from the precondition of heredity, but is fulfilled with the help of it. That is to say, in some patients this peculiarity of the vita sexualis - psychical inadequacy in mastering somatic sexual tension - is innate in the form of a stigma whereas ordinarily it is via that peculiarity that they acquire the neurosis. In another class of borderline cases the specific cause is contained in a contributory one. This is when the psychical inadequacy which I have just mentioned is brought about by exhaustion and such causes. All these cases fall into classes which melt into one another and do not form separate categories. In all of them, moreover, we find that the sexual tension undergoes the same vicissitudes; and for most of them the distinction between precondition, specific and auxiliary cause holds good, in conformity with the solution of the aetiological equation which I have given above.

When I consult my experience on this point, I cannot find that there is any antithetic relation as regards anxiety neurosis between hereditary disposition and the specific sexual factor. On the contrary, the two aetiological factors support and supplement each other. The sexual factor is usually only operative in those who have an innate hereditary taint as well; heredity alone is usually not able to produce an anxiety neurosis, but waits for the occurrence of a sufficient amount of the specific sexual noxa. The discovery of the hereditary element does not, therefore, exempt us from searching for a specific factor. On its discovery, incidentally, all our therapeutic interest as well depends. For what can we do therapeutically about heredity as an aetiological element? It has always been there in the patient and will continue to be there until the end of his life. Taken by itself, it cannot help us to understand the episodic onset of a neurosis or the cessation of a neurosis as a result of treatment. It is nothing but a precondition of the neurosis - an inexpRESSibly important precondition, it is true, but nevertheless one which has been over-estimated, to the detriment of therapy and theoretical comprehension. To be convinced by the contrasting state of affairs, one has only to think of the cases of nervous diseases that run in families (such as chorea chronica, Thomsen's disease, and so on), in which heredity unites in itself all the aetiological preconditions.

(2) What dimensions the neurosis attains depends in the first instance on the amount of the hereditary taint. Heredity acts like a multiplier introduced into an electric circuit, which increases the deviation of the needle many times over.
In the pathogenesis of the major neuroses, then, heredity fulfills the role of a precondition, powerful in every case and even indispensable in most cases. It could not do without the collaboration of the specific causes; but the importance of hereditary disposition is proved by the fact that the same specific causes acting on a healthy individual produce no manifest pathological effect, whereas in a predisposed person their action causes the neurosis to come to light, whose development will be proportionate in intensity and extent to the degree of the hereditary precondition.

[1896a, 371]

There is yet another thing to be noted in the relations between the hereditary precondition and the specific causes of neuroses. Experience shows - what one might have guessed in advance - that in these questions of aetiology one should not neglect the relative quantities, so to speak, of the aetiological influences. But one could not have guessed the following fact, which seems to arise from my observations: namely that heredity and the specific causes can replace each other as regards quantity, that the same pathological effect will be produced by the coincidence of a very serious specific aetiology with a moderate disposition or of a severely loaded nervous heredity with a slight specific influence. And we shall simply be meeting not unexpected extreme instances in this series if we come upon cases of neurosis in which we shall look in vain for an appreciable degree of hereditary disposition, provided that what is lacking is made up for by a powerful specific influence.

[1896a, 371]

I will say finally that the pathogenesis of neurasthenia and anxiety neurosis can easily do without the co-operation of a hereditary disposition. That is the outcome of daily observation. But if heredity is present, the development of the neurosis will be affected by its powerful influence.

[1896a, 375]

What can the other factors be which the 'specific aetiology' of hysteria still needs in order actually to produce the neurosis? That, Gentlemen, is a theme in itself, which I do not propose to enter upon. To-day I need only indicate the point of contact at which the two parts of the topic - the specific and the auxiliary aetiology - fit into one another. No doubt a considerable quantity of factors will have to be taken into account. There will be the subject's inherited and personal constitution, the inherent importance of the infantile sexual experiences, and, above all, their number: a brief relationship with a strange boy, who afterwards becomes indifferent, will leave a less powerful effect on a girl than intimate sexual relations of several years' standing with her own brother. In the aetiology of the neuroses quantitative preconditions are as important as qualitative ones: there are threshold-values which have to be crossed before the illness can become manifest. Moreover, I do not myself regard this aetiological series as complete; nor does it solve the riddle of why hysteria is not more common among the lower classes. (You will remember, by the way, what a surprisingly large incidence of hysteria was reported by Charcot among working-class men). I may also remind you that a few years ago I myself pointed out a factor, hitherto little considered, to which I attribute the leading role in provoking hysteria after puberty. I then put forward the view that the outbreak of hysteria may almost invariably be traced to a psychical conflict arising through an incompatible idea setting in action a defence on the part of the ego and calling up a demand for repression. What the circumstances are in which a defensive endeavour of this kind has the pathological effect of actually thrusting the memory which is distressing to the ego into the unconscious and of creating a hysterical symptom in its place I was not able to say at that time. But to-day I can repair the omission. The defence achieves its purpose of thrusting the incompatible idea out of consciousness if there are infantile sexual scenes present in the (hitherto normal) subject in the form of unconscious memories, and if the idea that is to be repressed can be brought into logical or associative connection with an infantile experience of that kind.

[1896c, 424]
Finding fault with one’s wife, a friendship which has turned into its opposite, a doctor’s error in
diagnosis, a rebuff by some one with similar interests, borrowing someone else’s ideas - it can
hardly be accidental that a collection of instances of forgetting, gathered at random, should
require me to enter into such distressing subjects in explaining them. On the contrary, I suspect
that everyone who is willing to enquire into the motives behind his lapses of memory will be able
to record a similar sample list of objectionable subjects. The tendency to forget what is
disagreeable seems to me to be a quite universal one; the capacity to do so is doubtless
developed with different degrees of strength in different people. It is probable that many instances
of disowning which we encounter in our medical work are to be traced to forgetting.¹ It is true that
our view of such forgetting limits the distinction between the two forms of behaviour to purely
psychological factors and allows us to see in both modes of reaction the expression of the same
motive. Of all the numerous examples of the disavowal of unpleasant memories which I have
observed on the part of relatives of patients, one remains in my recollection as especially
singular. A mother was giving me information about the childhood of her neurotic son, now in his
puberty, in the course of which she said that, like his brothers and sisters, he had been a bed-
wetter till late on - a fact which is certainly of some significance in the case history of a neurotic
patient. A few weeks later, when she was wanting to find out about the progress of the treatment,
I had occasion to draw her attention to the signs of a constitutional disposition to illness on the
young man’s part, and in doing so I referred to the bed-wetting which she had brought out in the
anamnesis. To my astonishment she contested this fact in regard both to him and to the other
children, and asked me how I could know it. Finally I told her that she herself had informed me a
short time before. She must therefore have forgotten it.²

¹ I do not, it is true, adopt the position that heredity is the only aetiological factor in hysteria. But, on the
other hand - and I say this with particular reference to some of my earlier publications, e.g. ‘Heredity and the
Aetiology of the Neuroses’ (1896n), in which I combated that view - I do not wish to give an impression of
underestimating the importance of heredity in the aetiology of hysteria or of asserting that it can be
dispensed with. In the case of the present patient the information I have given about her father and his
brother and sister indicates a sufficiently heavy taint; and, indeed, if the view is taken that pathological
conditions such as her mother’s must also imply a hereditary predisposition, the patient’s heredity may be
regarded as a convergent one. To my mind, however, there is another factor which is of more significance in
the girl’s hereditary or, properly speaking, constitutional predisposition. I have mentioned that her father had
contracted syphilis before his marriage. Now a strikingly high percentage of the patients whom I have
treated psycho-analytically come of fathers who have suffered from tabes or general paralysis. In
consequence of the novelty of my therapeutic method, I see only the severest cases, which have already
been under treatment for years without any success. In accordance with the Erb-Fournier theory, tabes or
general paralysis in the male parent may be regarded as evidence of an earlier luetic infection; and indeed I
was able to obtain direct confirmation of such an infection in a number of cases. In the most recent
discussion on the offspring of syphilitic parents (Thirteenth International Medical Congress, held in Paris,
August 2nd to 9th, 1900: papers by Finger, Tarnowsky, Jullien, etc.), I find no mention of the conclusion to
which I have been driven by my experience as a neuro-pathologist - namely, that syphilis in the male parent
is a very relevant factor in the aetiology of the neuropathic constitution of children.

² [1905e, 1359]
As regards the second kind of emotional reaction, which is not directed against me this time, but against my patient - supposing that my view of her is correct - and which regards the perverse nature of her phantasies as horrible, I should like to say emphatically that a medical man has no business to indulge in such passionate condemnation. I may also remark in passing that it seems to me superfluous for a physician who is writing upon the aberrations of the sexual instincts to seize every opportunity of inserting into the text expressions of his personal repugnance at such revolting things. We are faced by a fact; and it is to be hoped that we shall grow accustomed to it, when we have put our own tastes on one side. We must learn to speak without indignation of what we call the sexual perversions - instances in which the sexual function has extended its limits in respect either to the part of the body concerned or to the sexual object chosen. The uncertainty in regard to the boundaries of what is to be called normal sexual life, when we take different races and different epochs into account, should in itself be enough to cool the zealot's ardour. We surely ought not to forget that the perversion which is the most repellent to us, the sensual love of a man for a man, was not only tolerated by a people so far our superiors in cultivation as were the Greeks, but was actually entrusted by them with important social functions. The sexual life of each one of us extends to a slight degree - now in this direction, now in that - beyond the narrow lines imposed as the standard of normality. The perversions are neither bestial nor degenerate in the emotional sense of the word. They are a development of germs all of which are contained in the undifferentiated sexual disposition of the child, and which, by being suppressed or by being diverted to higher, asexual aims - by being 'sublimated' - are destined to provide the energy for a great number of our cultural achievements. When, therefore, any one has become a gross and manifest pervert, it would be more correct to say that he has remained one, for he exhibits a certain stage of inhibited development. All psychoneurotics are persons with strongly marked perverse tendencies, which have been repressed in the course of their development and have become unconscious. Consequently their unconscious phantasies show precisely the same content as the documentarily recorded actions of perverts - even though they have not read Krafft-Ebing's *Psychopathia Sexualis*, to which simple-minded people attribute such a large share of the responsibility for the production of perverse tendencies. Psychoneuroses are, so to speak, the negative of perversions. In neurotics their sexual constitution, under which the effects of heredity are included, operates in combination with any accidental influences in their life which may disturb the development of normal sexuality. A stream of water which meets with an obstacle in the river-bed is dammed up and flows back into old channels which had formerly seemed fated to run dry. The motive forces leading to the formation of hysterical symptoms draw their strength not only from repressed normal sexuality but also from unconscious perverse activities.¹

[1905e, 1387]
Her father, then, had fallen ill through leading a loose life, and she assumed that he had handed on his bad health to her by heredity. I was careful not to tell her that, as I have already mentioned, I too was of opinion that the offspring of luetics were very specially predisposed to severe neuropsychoses. The line of thought in which she brought this accusation against her father was continued in her unconscious material. For several days on end she identified herself with her mother by means of slight symptoms and peculiarities of manner, which gave her an opportunity for some really remarkable achievements in the direction of intolerable behaviour. She then allowed it to transpire that she was thinking of a stay she had made at Franzensbad, which she had visited with her mother - I forget in what year. Her mother was suffering from abdominal pains and from a discharge (a catarrh) which necessitated a cure at Franzensbad. It was Dora's view - and here again she was probably right - that this illness was due to her father, who had thus handed on his venereal disease to her mother. It was quite natural that in drawing this conclusion she should, like the majority of laymen, have confused gonorrhoea and syphilis, as well as what is contagious and what is hereditary. The persistence with which she held to this identification with her mother almost forced me to ask her whether she too was suffering from a venereal disease; and I then learnt that she was afflicted with a catarrh (leucorrhoea) whose beginning, she said, she could not remember.

Any one who has learnt to appreciate the delicacy of the fabric of structures such as dreams will not be surprised to find that Dora's wish that her father might take the place of the man who was her tempter called up in her memory not merely a casual collection of material from her childhood, but precisely such material as was most intimately bound up with the suppression of her temptation. For if Dora felt unable to yield to her love for the man, if in the end she repressed that love instead of surrendering to it, there was no factor upon which her decision depended more directly than upon her premature sexual enjoyment and its consequence - her bed-wetting, her catarrh, and her disgust. An early history of this kind can afford a basis for two kinds of behaviour in response to the demands of love in maturity - which of the two will depend upon the summation of constitutional determinants in the subject. He will either exhibit an abandonment to sexuality which is entirely without resistances and borders upon perversity; or there will be a reaction - he will repudiate sexuality, and will at the same time fall ill of a neurosis. In the case of our present patient, her constitution and the high level of her intellectual and moral upbringing decided in favour of the latter course.

The fact that this book is based upon the psycho-analytic observations which led to its composition is shown, however, not only in the choice of the topics dealt with, but also in their arrangement. Throughout the entire work the various factors are placed in a particular order of precedence: preference is given to the accidental factors while disposition is left in the background, and more weight is attached to ontogenesis than to phylogenesis. For it is the accidental factors that play the principal part in analysis: they are almost entirely subject to its influence. The dispositional ones only come to light after them, as something stirred into activity by experience: adequate consideration of them would lead far beyond the sphere of psychoanalysis.

The relation between ontogenesis and phylogenesis is a similar one. Ontogenesis may be regarded as a recapitulation of phylogenesis, in so far as the latter has not been modified by more recent experience. The phylogenetic disposition can be seen at work behind the ontogenetic process. But disposition is ultimately the precipitate of earlier experience of the species to which the more recent experience of the individual, as the sum of the accidental factors, is super-added.
EXPLANATION OF INVERSION  The nature of inversion is explained neither by the hypothesis that it is innate nor by the alternative hypothesis that it is acquired. In the former case we must ask in what respect it is innate, unless we are to accept the crude explanation that everyone is born with his sexual instinct attached to a particular sexual object. In the latter case it may be questioned whether the various accidental influences would be sufficient to explain the acquisition of inversion without the co-operation of something in the subject himself. As we have already shown, the existence of this last factor is not to be denied.

The preceding discussion may perhaps have placed the sexuality of psychoneurotics in a false light. It may have given the impression that, owing to their disposition, psychoneurotics approximate closely to perverts in their sexual behaviour and are proportionately remote from normal people. It may indeed very well be that the constitutional disposition of these patients (apart from their exaggerated degree of sexual repression and the excessive intensity of their sexual instinct) includes an unusual tendency to perversion, using that word in its widest sense. Nevertheless, investigation of comparatively slight cases shows that this last assumption is not absolutely necessary, or at least that in forming a judgement on these pathological developments there is a factor to be considered which weighs in the other direction. Most psychoneurotics only fall ill after the age of puberty as a result of the demands made upon them by normal sexual life. (It is most particularly against the latter that repression is directed.) Or else illnesses of this kind set in later, when the libido fails to obtain satisfaction along normal lines. In both these cases the libido behaves like a stream whose main bed has become blocked. It proceeds to fill up collateral channels which may hitherto have been empty. Thus, in the same way, what appears to be the strong tendency (though, it is true, a negative one) of psychoneurotics to perversion may be collaterally determined, and must, in any case, be collaterally intensified. The fact is that we must put sexual repression as an internal factor alongside such external factors as limitation of freedom, inaccessibility of a normal sexual object, the dangers of the normal sexual act, etc., which bring about perversions in persons who might perhaps otherwise have remained normal.

In this respect different cases of neurosis may behave differently: in one case the preponderating factor may be the innate strength of the tendency to perversion, in another it may be the collateral increase of that tendency owing to the libido being forced away from a normal sexual aim and sexual object. It would be wrong to represent as opposition what is in fact a co-operative relation. Neurosis will always produce its greatest effects when constitution and experience work together in the same direction. Where the constitution is a marked one it will perhaps not require the support of actual experiences; while a great shock in real life will perhaps bring about a neurosis even in an average constitution. (Incidentally, this view of the relative aetiological importance of what is innate and what is accidentally experienced applies equally in other fields.)

If we prefer to suppose, nevertheless, that a particularly strongly developed tendency to perversion is among the characteristics of psychoneurotic constitutions, we have before us the prospect of being able to distinguish a number of such constitutions according to the innate preponderance of one or the other of the erotogenic zones or of one or the other of the component instincts. The question whether a special relation holds between the perverse disposition and the particular form of illness adopted, has, like so much else in this field, not yet been investigated.
THE SEXUAL OBJECT DURING EARLY INFANCY

But even after sexual activity has become detached from the taking of nourishment, an important part of this first and most significant of all sexual relations is left over, which helps to prepare for the choice of an object and thus to restore the happiness that has been lost. All through the period of latency children learn to feel for other people who help them in their helplessness and satisfy their needs a love which is on the model of, and a continuation of, their relation as sucklings to their nursing mother. There may perhaps be an inclination to dispute the possibility of identifying a child's affection and esteem for those who look after him with sexual love. I think, however, that a closer psychological examination may make it possible to establish this identity beyond any doubt. A child's intercourse with anyone responsible for his care affords him an unending source of sexual excitation and satisfaction from his erotogenic zones. This is especially so since the person in charge of him, who, after all, is as a rule his mother, herself regards him with feelings that are derived from her own sexual life: she strokes him, kisses him, rocks him and quite clearly treats him as a substitute for a complete sexual object.¹ A mother would probably be horrified if she were made aware that all her marks of affection were rousing her child's sexual instinct and preparing for its later intensity. She regards what she does as asexual, 'pure' love, since, after all, she carefully avoids applying more excitations to the child's genitals than are unavoidable in nursery care. As we know, however, the sexual instinct is not aroused only by direct excitation of the genital zone. What we call affection will unfailingly show its effects one day on the genital zones as well. Moreover, if the mother understood more of the high importance of the part played by instincts in mental life as a whole - in all its ethical and psychical achievements - she would spare herself any self-reproaches even after her enlightenment. She is only fulfilling her task in teaching the child to love. After all, he is meant to grow up into a strong and capable person with vigorous sexual needs and to accomplish during his life all the things that human beings are urged to do by their instincts. It is true that an excess of parental affection does harm by causing precocious sexual maturity and also because, by spoiling the child, it makes him incapable in later life of temporarily doing without love or of being content with a smaller amount of it. One of the clearest indications that a child will later become neurotic is to be seen in an insatiable demand for his parents' affection. And on the other hand neuropathic parents, who are inclined as a rule to display excessive affection, are precisely those who are most likely by their caresses to arouse the child's disposition to neurotic illness. Incidentally, this example shows that there are ways more direct than inheritance by which neurotic parents can hand their disorder on to their children.

[1905d, 1536]
The time has arrived for me to attempt to summarize what I have said. We started out from the aberrations of the sexual instinct in respect of its object and of its aim and we were faced by the question of whether these arise from an innate disposition or are acquired as a result of experiences in life. We arrived at an answer to this question from an understanding, derived from psycho-analytic investigation, of the workings of the sexual instinct in psychoneurotics, a numerous class of people and one not far removed from the healthy. We found that in them tendencies to every kind of perversion can be shown to exist as unconscious forces and betray their presence as factors leading to the formation of symptoms. It was thus possible to say that neurosis is, as it were, the negative of perversion. In view of what was now seen to be the wide dissemination of tendencies to perversion we were driven to the conclusion that a disposition to perversions is an original and universal disposition of the human sexual instinct and that normal sexual behaviour is developed out of it as a result of organic changes and psychical inhibitions occurring in the course of maturation; we hoped to be able to show the presence of this original disposition in childhood. Among the forces restricting the direction taken by the sexual instinct we laid emphasis upon shame, disgust, pity and the structures of morality and authority erected by society. We were thus led to regard any established aberration from normal sexuality as an instance of developmental inhibition and infantilism. Though it was necessary to place in the foreground the importance of the variations in the original disposition, a co-operative and not an opposing relation was to be assumed as existing between them and the influences of actual life. It appeared, on the other hand, that since the original disposition is necessarily a complex one, the sexual instinct itself must be something put together from various factors, and that in the perversions it falls apart, as it were, into its components. The perversions were thus seen to be on the one hand inhibitions, and on the other hand dissociations, of normal development. Both these aspects were brought together in the supposition that the sexual instinct of adults arises from a combination of a number of impulses of childhood into a unity, an impulsion with a single aim.

[1905d, 1542]

CONSTITUTION AND HEREDITY First and foremost we must name the innate variety of sexual constitutions, upon which it is probable that the principal weight falls, but which can clearly only be inferred from their later manifestations and even then not always with great certainty. We picture this variety as a preponderance of one or another of the many sources of sexual excitation, and it is our view that a difference in disposition of this kind is always bound to find expression in the final result, even though that result may not overstep the limits of what is normal. No doubt it is conceivable that there may also be variations in the original disposition of a kind which must necessarily, and without the concurrence of any other factors, lead to the development of an abnormal sexual life. These might be described as “degenerative” and be regarded as an expression of inherited degeneracy. In this connection I have a remarkable fact to record. In more than half of the severe cases of hysteria, obsessional neurosis, etc., which I have treated psychotherapeutically, I have been able to prove with certainty that the patient’s father suffered from syphilis before marriage, whether there was evidence of tabes or general paralysis, or whether the anamnesis indicated in some other way the presence of syphilitic disease. I should like to make it perfectly plain that the children who later became neurotic bore no physical signs of hereditary syphilis, so that it was their abnormal sexual constitution that was to be regarded as the last echo of their syphilitic heritage. Though I am far from wishing to assert that descent from syphilitic parents is an invariable or indispensable aetiological condition of a neuropathic constitution, I am nevertheless of opinion that the coincidence which I have observed is neither accidental nor unimportant.

[1905d, 1546]
The hereditary conditions in the case of positive perverts are less well known, for they know how to avoid investigation. Yet there are good reasons to suppose that what is true of the neuroses applies also to the perversions. For it is no rare thing to find perversions and psychoneuroses occurring in the same family, and distributed between the two sexes in such a way that the male members of the family, or one of them, are positive perverts, while the females, true to the tendency of their sex to repression, are negative perverts, that is, hysterics. This is good evidence of the essential connections which we have shown to exist between the two disorders.

[1905d, 1546]

FURTHER MODIFICATION On the other hand, it is not possible to adopt the view that the form to be taken by sexual life is unambiguously decided, once and for all, with the inception of the different components of the sexual constitution. On the contrary, the determining process continues, and further possibilities arise according to the vicissitudes of the tributary streams of sexuality springing from their separate sources. This further modification is clearly what brings the decisive outcome, and constitutions which might be described as the same can lead to three different final results: -

[1905d, 1547]

If the relation between all the different dispositions - a relation which we will assume to be abnormal - persists and grows stronger at maturity, the result can only be a perverse sexual life. The analysis of abnormal constitutional dispositions of this kind has not yet been properly taken in hand. But we already know cases which can easily be explained on such a basis as this. Writers on the subject, for instance, have asserted that the necessary precondition of a whole number of perverse fixations lies in an innate weakness of the sexual instinct. In this form the view seems to me untenable. It makes sense, however, if what is meant is a constitutional weakness of one particular factor in the sexual instinct, namely the genital zone - a zone which takes over the function of combining the separate sexual activities for the purposes of reproduction. For if the genital zone is weak, this combination, which is required to take place at puberty, is bound to fail, and the strongest of the other components of sexuality will continue its activity as a perversion.¹

[1905d, 1547]

ACCIDENTAL EXPERIENCES No other influences on the course of sexual development can compare in importance with releases of sexuality, waves of repression and sublimations - the two latter being processes of which the inner causes are quite unknown to us. It might be possible to include repressions and sublimations as a part of the constitutional disposition, by regarding them as manifestations of it in life; and anyone who does so is justified in asserting that the final shape taken by sexual life is principally the outcome of the innate constitution. No one with perception will, however, dispute that an interplay of factors such as this also leaves room for the modifying effects of accidental events experienced in childhood and later. It is not easy to estimate the relative efficacy of the constitutional and accidental factors. In theory one is always inclined to overestimate the former; therapeutic practice emphasizes the importance of the latter. It should, however, of no account be forgotten that the relation between the two is a co-operative and not a mutually exclusive one. The constitutional factor must await experiences before it can make itself felt; the accidental factor must have a constitutional basis in order to come into operation. To cover the majority of cases we can picture what has been described as a 'complemental series', in which the diminishing intensity of one factor is balanced by the increasing intensity of the other; there is, however, no reason to deny the existence of extreme cases at the two ends of the series.

[1905d, 1550]
We shall be in even closer harmony with psycho-analytic research if we give a place of preference among the accidental factors to the experiences of early childhood. The single aetiological series then falls into two, which may be called the dispositional and the definitive. In the first the constitution and the accidental experiences of childhood interact in the same manner as do the disposition and later traumatic experiences in the second. All the factors that impair sexual development show their effects by bringing about a regression, a return to an earlier phase of development.

Various qualifications are required of anyone who is to be beneficially affected by psycho-analysis. To begin with, he must be capable of a psychically normal condition; during periods of confusion or melancholic depression nothing can be accomplished even in cases of hysteria. Furthermore, a certain measure of natural intelligence and ethical development are to be required of him; if the physician has to deal with a worthless character, he soon loses the interest which makes it possible for him to enter profoundly into the patient's mental life. Deep-rooted malformations of character, traits of an actually degenerate constitution, show themselves during treatment as sources of a resistance that can scarcely be overcome. In this respect the constitution of the patient sets a general limit to the curative effect of psychotherapy. If the patient's age is in the neighbourhood of the fifties the conditions for psycho-analysis become unfavourable. The mass of psychical material is then no longer manageable; the time required for recovery is too long; and the ability to undo psychical processes begins to grow weaker.

(1) One should look beyond the patient's illness and form an estimate of his whole personality; those patients who do not possess a reasonable degree of education and a fairly reliable character should be refused. It must not be forgotten that there are healthy people as well as unhealthy ones who are good for nothing in life, and that there is a temptation to ascribe to their illness everything that incapacitates them, if they show any sign of neurosis. In my opinion a neurosis is by no means a stamp of degeneracy, though it may often enough be found in one person along with the signs of degeneracy. Now analytic psychotherapy is not a process suited to the treatment of neuropathic degeneracy; on the contrary, degeneracy is a barrier to its effectiveness. Nor is the method applicable to people who are not driven to seek treatment by their own sufferings, but who submit to it only because they are forced to by the authority of relatives. The qualification which is the determining factor of fitness for psycho-analytic treatment - that is, whether the patient is educable - must be discussed further from another standpoint.
There is, however, another angle from which you may seek to understand the psycho-analytic method. The uncovering and translating of the unconscious occurs in the face of a continuous resistance on the part of the patient. The process of bringing this unconscious material to light is associated with displeasure, and because of this the patient rejects it again and again. It is for you then to interpose in this conflict in the patient's mental life. If you succeed in persuading him to accept, by virtue of a better understanding, something that up to now, in consequence of this automatic regulation by displeasure, he has rejected (repressed), you will have accomplished something towards his education. For it is education even to induce someone who dislikes getting up early to do so all the same. Psycho-analytic treatment may in general be conceived of as such a re-education in overcoming internal resistances. Re-education of this kind is, however, in no respect more necessary to nervous patients than in regard to the mental element in their sexual life. For nowhere else have civilization and education done so much harm as in this field, and this is the point, as experience will show you, at which to look for those aetiologies of the neuroses that are amenable to influence; for the other aetiological factor, the constitutional component, consists of something fixed and unalterable. And from this it follows that one important qualification is required of the physician in this work: not only must his own character be irreproachable - 'As to morals, that goes without saying', as the hero of Vischer's novel Auch Einer was in the habit of declaring - but he must also have overcome in his own mind that mixture of prurience and prudery with which, unfortunately, so many people habitually consider sexual problems.

[1905a, 1571]

After I had made this correction, 'infantile sexual traumas' were in a sense replaced by the 'infantilism of sexuality'. A second modification of the original theory lay not far off. Along with the supposed frequency of seduction in childhood, I ceased also to lay exaggerated stress on the accidental influencing of sexuality on to which I had sought to thrust the main responsibility for the causation of the illness, though I had not on that account denied the constitutional and hereditary factors. I had even hoped to solve the problem of choice of neurosis (the decision to which form of psychoneurosis the patient is to fall a victim) by reference to the details of the sexual experiences of childhood. I believed at that time - though with reservations - that a passive attitude in these scenes produced a predisposition to hysteria and, on the other hand, an active one a predisposition to obsessional neurosis. Later on I was obliged to abandon this view entirely, even though some facts demand that in some way or other the supposed correlation between passivity and hysteria and between activity and obsessional neurosis shall be maintained. Accidental influences derived from experience having thus receded into the background, the factors of constitution and heredity necessarily gained the upper hand once more; but there was this difference between my views and those prevailing in other quarters, that on my theory the 'sexual constitution' took the place of a 'general neuropathic disposition'. In my recently published Three Essays on the Theory of Sexuality (1905d) I have tried to give a picture of the variegated nature of this sexual constitution as well as of the composite character of the sexual instinct in general and its derivation from contributory sources from different parts of the organism.

[1906a, 1579]
I think it is worth emphasizing the fact that, whatever modifications my views on the aetiology of the psychoneuroses have passed through, there are two positions which I have never repudiated or abandoned - the importance of sexuality and of infantilism. Apart from this, accidental influences have been replaced by constitutional factors and 'defence' in the purely psychological sense has been replaced by organic 'sexual repression'. The question may, however, be raised of where convincing evidence is to be found in favour of the alleged aetiological importance of sexual factors in the psychoneuroses, in view of the fact that the onset of these illnesses may be observed in response to the most commonplace emotions or even to somatic precipitating causes, and since I have had to abandon a specific aetiology depending on the particular form of the childhood experiences concerned. To such a question I would reply that the psycho-analytic examination of neurotics is the source from which this disputed conviction of mine is derived. If we make use of that irreplaceable method of research, we discover that the patient's symptoms constitute his sexual activity (whether wholly or in part), which arises from the sources of the normal or perverse component instincts of sexuality. Not only is a large part of the symptomatology of hysteria derived directly from expressions of sexual excitement, not only do a number of erotogenic zones attain the significance of genitals during neuroses owing to an intensification of infantile characteristics, but the most complicated symptoms are themselves revealed as representing, by means of 'conversion', phantasies which have a sexual situation as their subject-matter. Anyone who knows how to interpret the language of hysteria will recognize that the neurosis is concerned only with the patient's repressed sexuality. The sexual function must, however, be understood in its true extent, as it is laid down by disposition in infancy. Wherever some commonplace emotion must be included among the determinants of the onset of the illness, analysis invariably shows that it is the sexual component of the traumatic experience - a component that is never lacking which has produced the pathogenic result.

Accordingly, the aetiology of the neuroses comprises everything which can act in a detrimental manner upon the processes serving the sexual function. In the forefront, then, are to be ranked the noxae which affect the sexual function itself - in so far as these are regarded as injurious by the sexual constitution, varying as it does with different degrees of culture and education. In the next place comes every other kind of noxa and trauma which, by causing general damage to the organism, may lead secondarily to injury to its sexual processes. It should not, however, be forgotten that the aetiological problem in the case of the neuroses is at least as complicated as the causative factors of any other illness. A single pathogenic influence is scarcely ever sufficient; in the large majority of cases a number of aetiological factors are required, which support one another and must therefore not be regarded as being in mutual opposition. For this reason a state of neurotic illness cannot be sharply differentiated from health. The onset of the illness is the product of a summation and the necessary total of aetiological determinants can be completed from any direction. To look for the aetiology of the neuroses exclusively in heredity or in the constitution would be just as one-sided as to attribute that aetiology solely to the accidental influences brought to bear upon sexuality in the course of the subject's life - whereas better insight shows that the essence of these illnesses lies solely in a disturbance of the organism’s sexual processes.
Furthermore, since our hero was a person capable of developing a delusion on the basis of such a strange preference, a strict psychiatrist would at once stamp him as a *dégénééré* and would investigate the heredity which had remorselessly driven him to this fate. But here the author does not follow the psychiatrist, and with good reason. He wishes to bring the hero closer to us so as to make 'empathy' easier; the diagnosis of *dégénééré*, whether it is right or wrong, at once puts the young archaeologist at a distance from us, for we readers are the normal people and the standard of humanity. Nor is the author greatly concerned with the hereditary and constitutional preconditions of the state, but on the other hand he plunges deep into the personal mental make-up which can give rise to such a delusion.

[1907a, 1844]

And here we must give what will perhaps be an unexpected answer. In fact the situation is quite the reverse: it is science that cannot hold its own before the achievement of the author. Science allows a gulf to yawn between the hereditary and constitutional preconditions of a delusion and its creations, which seem to emerge ready-made - a gulf which we find that our author has filled. Science does not as yet suspect the importance of repression, it does not recognize that in order to explain the world of psychopathological phenomena the unconscious is absolutely essential, it does not look for the basis of delusions in a psychical conflict, and it does not regard their symptoms as compromises. Does our author stand alone, then, in the face of united science? No, that is not the case (if, that is, I may count my own works as part of science), since for a number of years - and, until recently, more or less alone¹ - I myself have supported all the views that I have here extracted from Jensen's *Gradiva* and stated in technical terms. I indicated, in most detail in connection with the states known as hysteria and obsessions, that the individual determinant of these psychical disorders is the suppression of a part of instinctual life and the repression of the ideas by which the suppressed instinct is represented, and soon afterwards I repeated the same views in relation to some forms of delusion.² The question whether the instincts concerned in this causation are always components of the sexual instinct or may be of another kind as well is a problem which may be regarded as a matter of indifference in the particular case of the analysis of *Gradiva*; for in the instance chosen by our author what was at issue was quite certainly nothing other than the suppression of erotic feelings. The validity of the hypotheses of psychical conflict and of the formation of symptoms by means of compromises between the two mental currents struggling against each other has been demonstrated by me in the case of patients observed and medically treated in real life, just as I have been able to in the imaginary case of Norbert Hanold.³ Even before me, Pierre Janet, a pupil of the great Charcot, and Josef Breuer, in collaboration with me, had traced back the products of neurotic, and especially of hysterical, illness to the power of unconscious thoughts.⁴

[1907a, 1851]

Careful clinical observation allows us to distinguish two groups of nervous disorders: the *neuroses* proper and the *psychoneuroses*. In the former the disturbances (the symptoms), whether they show their effects in somatic or mental functioning, appear to be of a toxic nature. They behave exactly like the phenomena accompanying an excess or a deprivation of certain nerve poisons. These neuroses - which are commonly grouped together as 'neurasthenia'⁵ - can be induced by certain injurious influences in sexual life, without any hereditary taint being necessarily present; indeed, the form taken by the disease corresponds to the nature of these noxae, so that often enough the particular sexual etiology can at once be deduced from the clinical picture. There is a total absence, on the other hand, of any such regular correspondence between the form of a nervous illness and the other injurious influences of civilization which are blamed by the authorities. We may, therefore, regard the sexual factor as the essential one in the causation of the neuroses proper.

[1908d, 1950]
With the psychoneuroses, the influence of heredity is more marked and the causation less transparent. A peculiar method of investigation known as psycho-analysis has, however, enabled us to recognize that the symptoms of these disorders (hysteria, obsessional neurosis, etc.) are psychogenic and depend upon the operation of unconscious (repressed) ideational complexes. This same method has also taught us what those unconscious complexes are and has shown that, quite generally speaking, they have a sexual content. They spring from the sexual needs of people who are unsatisfied and represent for them a kind of substitutive satisfaction. We must therefore view all factors which impair sexual life, suppress its activity or distort its aims as being pathogenic factors in the psychoneuroses as well.

[1908d, 1951]

The sexual instinct - or, more correctly, the sexual instincts, for analytic investigation teaches us that the sexual instinct is made up of many separate constituents or component instincts - is probably more strongly developed in man than in most of the higher animals; it is certainly more constant, since it has almost entirely overcome the periodicity to which it is tied in animals. It places extraordinarily large amounts of force at the disposal of civilized activity, and it does this in virtue of its especially marked characteristic of being able to displace its aim without materially diminishing in intensity. This capacity to exchange its originally sexual aim for another one, which is no longer sexual but which is psychically related to the first aim, is called the capacity for sublimation. In contrast to this displaceability, in which its value for civilization lies, the sexual instinct may also exhibit a particularly obstinate fixation which renders it unserviceable and which sometimes causes it to degenerate into what are described as abnormalities. The original strength of the sexual instinct probably varies in each individual; certainly the proportion of it which is suitable for sublimation varies. It seems to us that it is the innate constitution of each individual which decides in the first instance how large a part of his sexual instinct it will be possible to sublimate and make use of. In addition to this, the effects of experience and the intellectual influences upon his mental apparatus succeed in bringing about the sublimation of a further portion of it. To extend this process of displacement indefinitely is, however, certainly not possible, any more than is the case with the transformation of heat into mechanical energy in our machines. A certain amount of direct sexual satisfaction seems to be indispensable for most organizations, and a deficiency in this amount, which varies from individual to individual, is visited by phenomena which, on account of their detrimental effects on functioning and their subjective quality of unpleasure, must be regarded as an illness.

[1908d, 1952]

If we take the second of these stages as an average, we must point out that a number of people are, on account of their organization, not equal to meeting its demands. In whole classes of individuals the development of the sexual instinct, as we have described it above, from auto-eroticism to object-love with its aim of uniting the genitals, has not been carried out correctly and sufficiently fully. As a result of these disturbances of development two kinds of harmful deviation from normal sexuality - that is, sexuality which is serviceable to civilization - come about; and the relation between these two is almost that of positive and negative.¹

[1908d, 1953]
Where the sexual instinct is fairly intense, but perverse, there are two possible outcomes. The first, which we shall not discuss further, is that the person affected remains a pervert and has to put up with the consequences of his deviation from the standard of civilization. The second is far more interesting. It is that, under the influence of education and social demands, a suppression of the perverse instincts is indeed achieved, but it is a kind of suppression which is really no suppression at all. It can better be described as a suppression that has failed. The inhibited sexual instincts are, it is true, no longer expressed as such - and this constitutes the success of the process - but they find expression in other ways, which are quite as injurious to the subject and make him quite as useless for society as satisfaction of the suppressed instincts in an unmodified form would have done. This constitutes the failure of the process, which in the long run more than counterbalances its success. The substitutive phenomena which emerge in consequence of the suppression of the instinct amount to what we call nervous illness, or, more precisely, the psychoneuroses.¹ Neurotics are the class of people who, since they possess a recalcitrant organization, only succeed, under the influence of cultural requirements, in achieving a suppression of their instincts which is apparent and which becomes increasingly unsuccessful. They therefore only carry on their collaboration with cultural activities by a great expenditure of force and at the cost of an internal impoverishment, or are obliged at times to interrupt it and fall ill. I have described the neuroses as the ‘negative’ of the perversions because in the neuroses the perverse impulses, after being repressed, manifest themselves from the unconscious part of the mind - because the neuroses contain the same tendencies, though in a state of ‘repression’, as do the positive perversions.

[1908d, 1954]

It is one of the obvious social injustices that the standard of civilization should demand from everyone the same conduct of sexual life - conduct which can be followed without any difficulty by some people, thanks to their organization, but which imposes the heaviest psychical sacrifices on others; though, indeed, the injustice is as a rule wiped out by disobedience to the injunctions of morality.

[1908d, 1955]

I do not think much of the objection that neurotics are a special class of people, marked by an innate disposition that is ‘degenerate’, from whose childhood life we must not be allowed to infer anything about the childhood of other people. Neurotics are people much like others. They cannot be sharply differentiated from normal people, and in their childhood they are not always easily distinguishable from those who remain healthy in later life. It is one of the most valuable results of our psycho-analytic investigations to have discovered that the neuroses of such people have no special mental content that is peculiar to them, but that, as Jung has expressed it, they fall ill of the same complexes against which we healthy people struggle as well. The only difference is that healthy people know how to overcome those complexes without any gross damage demonstrable in practical life, whereas in nervous cases the suppression of the complexes succeeds only at the price of costly substitutive formations - that is to say, from a practical point of view it is a failure. In childhood neurotic and normal people naturally approximate to each other much more closely than they do in later life, so that I cannot regard it as a methodological error to make use of the communications of neurotics about their childhood for drawing conclusions by analogy about normal childhood life. But since those who later become neurotics very often have in their inborn constitution an especially strong sexual instinct and a tendency to precocity and to a premature expression of that instinct, they make it possible for us to recognize a great deal of infantile activity more sharply and clearly than our capacity for observation (which is in any case a blunted one) would enable us to do in other children. But we shall of course only be able to assess the true value of these communications made by neurotic adults when, following Havelock Ellis’s example, we shall have thought it worth while to collect the childhood memories of healthy adults as well.

[1908c, 1967]
A sexual constitution like that of little Hans does not appear to carry with it a predisposition to the development either of perversions or of their negative (we will limit ourselves to a consideration of hysteria). As far as my experience goes (and there is still a real need for speaking with caution on this point) the innate constitution of hysterics - that this is also true of perverts is almost self-evident - is marked by the genital zone being relatively less prominent than the other erogenous zones. But we must expressly except from this rule one particular 'aberration' of sexual life. In those who later become homosexuals we meet with the same predominance in infancy of the genital zone (and especially of the penis) as in normal persons.¹ Indeed it is the high esteem felt by the homosexual for the male organ which decides his fate. In his childhood he chooses women as his sexual object, so long as he assumes that they too possess what in his eyes is an indispensable part of the body; when he becomes convinced that women have deceived him in this particular, they cease to be acceptable to him as a sexual object. He cannot forgo a penis in any one who is to attract him to sexual intercourse; and if circumstances are favourable he will fix his libido upon the 'woman with a penis', a youth of feminine appearance. Homosexuals, then, are persons who, owing to the erogenous importance of their own genitals, cannot do without a similar feature in their sexual object. In the course of their development from auto-eroticism to object-love, they have remained at a point of fixation between the two.

[1909b, 2093]

Anxiety-hysterias are the most common of all psychoneurotic disorders. But, above all, they are those which make their appearance earliest in life; they are par excellence the neuroses of childhood. When a mother uses such phrases as that her child's 'nerves' are in a bad state, we can be certain that in nine cases out of ten the child is suffering from some kind of anxiety or from many kinds at once. Unfortunately the finer mechanism of these highly significant disorders has not yet been sufficiently studied. It has not yet been established whether anxiety-hystera is determined, in contradistinction to conversion-hystera and other neuroses, solely by constitutional factors or solely by accidental experiences, or by what combination of the two.¹ It seems to me that of all neurotic disorders it is the least dependent upon a special constitutional predisposition and that it is consequently the most easily acquired at any time of life.

[1909b, 2100]

¹ [Footnote added 1923:] The question which is raised here has not been pursued further. But there is no reason to suppose that anxiety-hystera is an exception to the rule that both predisposition and experience must co-operate in the aetiology of a neurosis. Rank's view of the effects of the trauma of birth seems to throw special light upon the predisposition to anxiety-hystera which is so strong in childhood.

[1909b, 2100]

I shall now proceed to what I hope will be a brief discussion of how far little Hans's phobia offers any contribution of general importance to our views upon the life and upbringing of children. But before doing so I must return to the objection which has so long been held over, and according to which Hans was a neurotic, a 'degenerate' with a bad heredity, and not a normal child, knowledge about whom could be applied to other children. I have for some time been thinking with pain of the way in which the adherents of 'the normal person' will fall upon poor little Hans as soon as they are told that he can in fact be shown to have had a hereditary taint. His beautiful mother fell ill with a neurosis as a result of a conflict during her girlhood. I was able to be of assistance to her at the time, and this had in fact been the beginning of my connection with Hans's parents. It is only with the greatest diffidence that I venture to bring forward one or two considerations in his favour.

[1909b, 2119]
In the first place Hans was not what one would understand, strictly speaking, by a degenerate child, condemned by his heredity to be a neurotic. On the contrary, he was well formed physically, and was a cheerful, amiable, active-minded young fellow who might give pleasure to more people than his own father. There can be no question, of course, as to his sexual precocity; but on that point there is very little material upon which a fair comparison can be based. I gather, for instance, from a piece of collective research conducted in America, that it is by no means such a rare thing to find object-choice and feelings of love in boys at a similarly early age; and the same may be learnt from studying the records of the childhood of men who have later come to be recognized as 'great'. I should therefore be inclined to believe that sexual precocity is a correlate, which is seldom absent, of intellectual precocity, and that it is therefore to be met with in gifted children more often than might be expected. [1909b, 2119]

Furthermore, let me say in Hans's favour (and I frankly admit my partisan attitude) that he is not the only child who has been overtaken by a phobia at some time or other in his childhood. Troubles of that kind are well known to be quite extraordinarily frequent, even in children the strictness of whose upbringing has left nothing to be desired. In later life these children either become neurotic or remain healthy. Their phobias are shouted down in the nursery because they are inaccessible to treatment and are decidedly inconvenient. In the course of months or years they diminish, and the child seems to recover; but no one can tell what psychological changes are necessitated by such a recovery, or what alterations in character are involved in it. When, however, an adult neurotic patient comes to us for psycho-analytic treatment (and let us assume that his illness has only become manifest after he has reached maturity), we find regularly that his neurosis has as its point of departure an infantile anxiety such as we have been discussing, and is in fact a continuation of it; so that, as it were, a continuous and undisturbed thread of psychical activity, taking its start from the conflicts of his childhood, has been spun through his life - irrespective of whether the first symptom of those conflicts has persisted or has retreated under the pressure of circumstances. I think, therefore, that Hans's illness may perhaps have been no more serious than that of many other children who are not branded as 'degenerates'; but since he was brought up without being intimidated, and with as much consideration and as little coercion as possible, his anxiety dared to show itself more boldly. With him there was no place for such motives as a bad conscience or a fear of punishment, which with other children must no doubt contribute to making the anxiety less. It seems to me that we concentrate too much upon symptoms and concern ourselves too little with their causes. In bringing up children we aim only at being left in peace and having no difficulties, in short, at training up a model child, and we pay very little attention to whether such a course of development is for the child's good as well. I can therefore quite imagine that it may have been to Hans's advantage to have produced this phobia. For it directed his parents' attention to the unavoidable difficulties by which a child is confronted when in the course of his cultural training he is called upon to overcome the innate instinctual components of his mind; and his trouble brought his father to his assistance. It may be that Hans now enjoys an advantage over other children, in that he no longer carries within him that seed in the shape of repressed complexes which must always be of some significance for a child's later life, and which undoubtedly brings with it a certain degree of deformity of character if not a predisposition to a subsequent neurosis. I am inclined to think that this is so, but I do not know if many others will share my opinion; nor do I know whether experience will prove me right. [1909b, 2120]
To this unimpeachable body of evidence we shall be able to add fresh material, if we turn to the history of the masturbatory side of our patient's sexual activities. There is a conflict between the opinions of doctors and patients on this subject which has not hitherto been properly appreciated. The patients are unanimous in their belief that masturbation, by which they mean masturbation during puberty, is the root and origin of all their troubles. The doctors are, upon the whole, unable to decide what line to take; but, influenced by the knowledge that not only neurotics but most normal people pass through a period of masturbation during their puberty, the majority of them are inclined to dismiss the patients' assertions as gross exaggerations. In my opinion the patients are once again nearer to a correct view than the doctors; for the patients have some glimmering notion of the truth, while the doctors are in danger of overlooking an essential point. The thesis propounded by the patients certainly does not correspond to the facts in the sense in which they themselves construe it, namely, that masturbation during puberty (which may almost be described as a typical occurrence) is responsible for all neurotic disturbances. Their thesis requires interpretation. The masturbation of puberty is in fact no more than a revival of the masturbation of infancy, a subject which has hitherto invariably been neglected. Infantile masturbation reaches a kind of climax, as a rule, between the ages of three and four or five; and it is the clearest expression of a child's sexual constitution, in which the aetiology of subsequent neuroses must be sought. In this disguised way, therefore, the patients are putting the blame for their illnesses upon their infantile sexuality; and they are perfectly right in doing so. On the other hand, the problem of masturbation becomes insoluble if we attempt to treat it as a clinical unit, and forget that it can represent the discharge of every variety of sexual component and of every sort of phantasy to which such components can give rise. The injurious effects of masturbation are only in a very small degree autonomous - that is to say, determined by its own nature. They are in substance merely part and parcel of the pathogenic significance of the subject's sexual life as a whole. The fact that so many people can tolerate masturbation - that is, a certain amount of it - without injury merely shows that their sexual constitution and the course of development of their sexual life have been such as to allow them to exercise the sexual function within the limits of what is culturally permissible; whereas other people, because their sexual constitution has been less favourable or their development has been disturbed, fall ill as a result of their sexuality - they cannot, that is, achieve the necessary suppression or sublimation of their sexual components without having recourse to inhibitions or substitutes.¹

If we consider a number of analyses of obsessional neurotics we shall find it impossible to escape the impression that a relation between love and hatred such as we have found in our present patient is among the most frequent, the most marked, and probably, therefore, the most important characteristics of obsessional neurosis. But however tempting it may be to bring the problem of the 'choice of neurosis' into connection with instinctual life, there are reasons enough for avoiding such a course. For we must remember that in every neurosis we come upon the same suppressed instincts behind the symptoms. After all, hatred, kept suppressed in the unconscious by love, plays a great part in the pathogenesis of hysteria and paranoia. We know too little of the nature of love to be able to arrive at any definite conclusion here; and, in particular, the relation between the negative factor¹ in love and the sadistic components of the libido remains completely obscure. What follows is therefore to be regarded as no more than a provisional explanation. We may suppose, then, that in the cases of unconscious hatred with which we are concerned the sadistic components of love have, from constitutional causes, been exceptionally strongly developed, and have consequently undergone a premature and all too thorough suppression, and that the neurotic phenomena we have observed arise on the one hand from conscious feelings of affection which have become exaggerated as a reaction, and on the other hand from sadism persisting in the unconscious in the form of hatred.

[1909d, 2159]
You must forgive me if I have not succeeded in giving you a more clearly intelligible account of these basic positions adopted by the method of treatment that is now described as 'psycho-analysis'. The difficulties have not lain only in the novelty of the subject. The nature of the incompatible wishes which, in spite of repression, succeed in making their existence in the unconscious perceptible, and the subjective and constitutional determinants which must be present in anyone before a failure of repression can occur and a substitute or symptom be formed - on all this I shall have more light to throw in some of my later observations.

We must expressly insist that we have never reckoned Leonardo as a neurotic or a 'nerve case', as the awkward phrase goes. Anyone who protests at our so much as daring to examine him in the light of discoveries gained in the field of pathology is still clinging to prejudices which we have to-day rightly abandoned. We no longer think that health and illness, normal and neurotic people, are to be sharply distinguished from each other, and that neurotic traits must necessarily be taken as proofs of a general inferiority. To-day we know that neurotic symptoms are structures which are substitutes for certain achievements of repression that we have to carry out in the course of our development from a child to a civilized human being. We know too that we all produce such substitutive structures, and that it is only their number, intensity and distribution which justify us in using the practical concept of illness and in inferring the presence of constitutional inferiority. From the slight indications we have about Leonardo's personality we should be inclined to place him close to the type of neurotic that we describe as 'obsessional'; and we may compare his researches to the 'obsessive brooding' of neurotics, and his inhibitions to what are known as their 'abulias'.
